THE PARIS EXHIBITION.

Since 1851, when the doors of Paxton's fairy palace in Hyde Park were thrown open to cosmopolitan myriads, International Exhibitions have been held with sufficient frequency to deprive them of at least the charm of novelty. Nevertheless several of the successors of Great Britain's first "World's Fair" have proved to be no mean rivals, if indeed it must not be confessed that in some respects they have completely overshadowed it. Among them, the Exposition Universelle, which Republican France has called into existence on the Champ de Mars, where not long since Imperial troops were manœuvred, has, in spite of many shortcomings, already taken high rank. Never before, perhaps, has there been gathered together a more marvellous collection of the gifts of nature, and of the products of the skill of artists, scientists, and manufacturers, now working separately, or now uniting their efforts to the perfection of one object, and the man must be singularly constituted who could walk through the miles of courts now open to the inspection of the sightseer and the student without finding much to interest and instruct him.

Although there will be many temptations to digression, any report on this exhibition appearing in these columns must necessarily be restricted to matters in some degree connected with pharmacy or the sciences and industries with which it is most closely allied. Even when limited by these bounds the subjects to be noticed are so multitudinous that the necessities of space and time will require the exercise of brevity and method in their description. Still it is not intended to make these papers mere catalogues of exhibitors' names; the principal object will be to place before the readers such points in connection with the exhibits and their history as appear to be most useful as well as novel and interesting.

It will not be out of place, however, to remark here that the small amount of assistance afforded towards properly performing such a task by the conditions under which exhibits are usually presented to the visitor has been on the present occasion diminished by the general unreadiness that has hitherto been such an unsatisfactory characteristic of the Paris Exposition of 1878. The bald manner in which both crude and manufactured articles are often set out in cases or bottles, secure from examination by finger, tongue or nose, and very often without a word of explanation as to their source or to peculiarities in the method of their production, always renders a good descriptive catalogue a welcome guide as well as an indispensable help in examining them. But when four or five weeks had elapsed since the official opening of the building in the Champ de Mars many of the cases even of the French exhibitors were still unoccupied, whole sections were not yet numbered or labelled, some were still in the hands of the carpenters, while of the Official Catalogue, only four volumes out of eight had appeared. As to a Descriptive Catalogue, although it had been talked about, and though Austria, Algeria, and Victoria promptly contributed their portions, its completion, whilst the exhibition exists to be examined with its aid, appears problematical. The question naturally arises whether exhibitors might not remedy such a defect and at the same time greatly increase the interest of the public in their exhibits by largely amplifying the descriptions accompanying them, and it is only fair to say that the question is decided in the affirmative by a few notable exceptions to the general rule. In the following papers some of these exceptions will be mentioned, and the information afforded will be made use of. This will further be supplemented by information that has been furnished by many exhibitors at home and abroad in reply to a special application, and to these gentlemen the reporters desire especially to express their thanks for the courtesy thus shown.

As the order in which it will be necessary to deal with the several subjects comprised in the following report will give but little clue to the general arrangements and classification adopted in the exhibition, it will be as well to preface it by a few details descriptive of the building and in explanation of the system of classification.

The best bird's-eye view of the exhibition is obtained immediately after passing through the Trocadero Palace entrance. This building stands on the high ground bearing the name and situated near the banks of the Seine at the western end of Paris. Between it and the river, which must be crossed over the Pont de Jena to reach the main buildings, are scattered several outlying structures. On the left are to be seen the white walls of the Algerian building, and by the side of it another building specially devoted to the exhibits of the Administration des Forêts, both of which contain much that is interesting. On the right hand is a group of smaller but not less pretentious structures, where a visitor—if rich in faith—may fancy he is purchasing in oriental bazaars articles that have been manufactured in Tunis, Morocco, Persia, or some other eastern country. Beyond the Seine the eye falls upon the principal façade of the great Champ de Mars building, bearing a dome at each extremity and one in the centre. This building may be described briefly as an enormous parallelogram, the

sides of which are formed of two series of long iron and glass arcades such as have now become associated in the public mind with exhibitions and might, though perhaps somewhat irreverently, be compared with the better class of goods sheds of factories or railway stations; these are connected at each end by a shorter arcade running transversely. The series of arcades on the right hand is devoted to exhibits from foreign countries; that on the left hand is occupied entirely by French exhibitors, the French colonies being represented at the further end. Starting from under the middle dome is a third arcade devoted to the fine arts, but interrupted so as to form a central space in which stands a tasteful edifice containing models of the public buildings and engineering works, as well as the art and other treasures of the "Ville de Paris." In the open space on one side of this central arcade is built the picturesque "street of nations," which is intended to illustrate the domestic architecture characteristic of various countries.

The classification adopted is the division of the whole of the exhibits into nine groups, and these are again subdivided into ninety classes. Group I., "Works of Art," however interesting, cannot be descanted upon here. In Group II., "Education and Instruction: Apparatus and Processes of the Liberal Arts," are to be found apparatus used in teaching chemistry and illustrations of the diagrams, apparatus, and specimens used in the French medical and pharmaceutical schools. This will be perhaps the best opportunity of mentioning that in France there are four medical faculties,—at Paris, Nancy, Lille, and Lyons,—each of which has its chair of medical chemistry and pharmacy. Of pharmaceutical schools of the first rank, under the control of the state, there are three: one at Paris, endowed with nine professional chairs; and two others at Montpelier and Nancy, each having five chairs. Medical and pharmaceutical teaching is also carried on in "*écoles de plein service*" and "*écoles préparatoires*," of which secondary establishments there are twenty. These have, however, only authority to confer the grades of "officer of health" and "pharmacien of the second class," which only enables a pharmacien to carry on business in one department, to be selected at the time of examination, whilst the pharmacien of the first class can exercise his profession in any part of the country. During the year 1877 the three superior schools received 97 pharmaciens of the first class and 352 of the second. In Class 9 of this group, "Printing and Books," a well known pharmaceutical chemist, Mr. H. C. Baildon, of Edinburgh, appears as the inventor of a method of printing ferns by taking impressions on transfer paper direct from the frond and transferring them to stone for lithographic printing. It is also in Class 14 of this group, entitled "Medicine, Hygiene and Public Assistance," that search must be made for surgical instruments, whilst the next class, "Instruments of Precision," includes chemical and physical apparatus. The title of the third group is "Furniture and Accessories," which through the connecting link of mirrors and stained glass is made to include the exhibits of the bottle manufacturers; it is also stretched to cover the class of Perfumery, of which it is still less suggestive. Group IV., "Textile Fabrics, Clothing and Accessories," may be passed over as containing nothing specially interesting to pharmacists; but with respect to Group V., "Mining Industries; Raw and Manufactured Products," the case is different. Here are met with illustrations of the mineral and metal industries; products of the cultivation of forests, such as cork, charcoal, barks for tanning, resins, turpentines, etc.; products of the chase and fishery, which include sponges but not fish oils; a class described as "non-alimentary agricultural products," among which may be found in the French court some admirable exhibits of the Association of Herborists, and also, curiously enough, olive oil, honey and hops, though this classification of the last article doubtless accords with a widespread opinion; and lastly, the most important class of "Chemical and Pharmaceutical Products." In Group VI., "Apparatus and Processes used in the Mechanical Manufactures," there is a class for "Apparatus used in Chemistry, Pharmacy and Tanning," which, however, rather belies the promise of its name. Group VII., "Alimentary Products," includes a large number of interesting substances, such as starch, gluten, albumen, condiments, sugar, and fermented drinks. Groups VIII. and IX. relate to "Agriculture and Pisciculture" and to "Horticulture" respectively.

It will thus be seen that the exhibits to which reference will have to be made are distributed freely through the various groups and classes, and that sometimes substances that would appear nearly allied, in dealing with them for the purposes of this article, are widely separated in the classification adopted in the exhibition. Of course in the smaller courts this is not much noticed and it is practically impossible to invent a scheme that shall provide for every contingency. The official one appears on the whole to be admirable, but it has its ludicrous points of incongruity; for instance, feeding bottles are to be found in Group II., as illustrative of "apparatus and processes of the liberal arts," whilst the only Algerian exhibits in the class of "chemical, pharmaceutical and tanning apparatus" are two washing machines.

As before mentioned the greatest amount of interest to the readers of this Journal will be found in Class 47, Group V., "Chemical and Pharmaceutical Products," and to it therefore a few lines may be devoted in this preliminary sketch. The catalogue of French exhibitors in this class contains about 450 names, but the connection of a large proportion of them with pharmacy is rather remote. Nevertheless, though soaps, candles, varnishes, glues, pigments, india-rubber and gutta percha goods, inks, machine oils, harness polish and blacking might be expected to give the department the appearance of a medley, still there are probably at least one hundred exhibits by pharmacists, and the strictly chemical and pharmaceutical elements are sufficiently predominant by their number and excellence to preserve its titular character. Next to France in point of numbers comes Spain, with 126 exhibitors, followed by Great Britain and Ireland and Austria, each with 90, Russia with 51, Algeria with 45, the United States with 43, and Norway with 28, etc. These figures are quoted simply as indicating the relative numbers of the exhibits from different countries in this the specially chemical and pharmaceutical section, but they must not be presumed to represent their relative importance in respect to those subjects.

The arrangement of the exhibits in the French department differs very much from that in the other departments. The native exhibitors appear to have been under somewhat strict control as to the style

and size of the cases, whilst on the other hand the foreign exhibitors appear to have been allowed to carry out their own ideas, without much other limitation than might be suggested by monetary considerations. The result has been on the whole of advantage to the latter, who have produced many really handsome cases, some of the best of which are to be seen in the British court. This liberty has, however, been purchased at the cost of considerable disproportion and want of uniformity; for instance, the structure of Messrs. Tilden, of New York, who in one sense may be credited with the greatest pharmaceutical show in the whole building, would probably still admit in addition the goods from any half a dozen pharmaceutical cases in the French section.

The French cases are as a rule uniform in size; they are constructed in blocks, which are divided into sections generally about two feet wide and eight feet high, two feet out of this, at the base, consisting of a closed cupboard. The cases are painted black and the divisions between the glazed portions are faced by slender black columns enriched by ornaments in gilded copper. The glass is set in frames of lacquered iron, ornamented at the angles. The uppermost moulding is surmounted by sculptured flowers. Many of the cases are subdivided at half their height, and thus made to serve for two exhibitors, the names of whom are painted above and below in gold letters. Under these conditions the end cases of the blocks fixed against the walls and those that form the angles of the blocks in the centre of the room have considerable advantage over the others, of which the well known taste and skill of the Frenchman have made the most.

Having thus described briefly some of the features of that portion of the exhibition in the French capital which is to be the topic of succeeding papers, it is necessary in this preliminary sketch to indicate the order in which it is proposed to deal with the subjects. Speaking generally the plan will be to begin first with the crude materials and then pass on to the products obtained from them by various processes of manufacture. The arrangement followed will be as nearly as possible the following :—

A. Pharmaceutical and Medical Materials and Preparations.

(1) Crude Materials used or applicable in Medicine and Pharmacy.
(2) Preparations.
  (*a*) Galenical Preparations: Extracts, Pills, etc.
  (*b*) Chemical Preparations: Salts, Alkaloids, etc.
  (*c*) Miscellaneous and Proprietary Preparations.
  (*d*) Perfumery.

B. Chemical Manufactures.

(1) Crude Materials used or applicable in the Arts.
(2) Manufactured products.
  (*a*) Acids.
  (*b*) Alkalies and salts.
  (*c*) Soap.
  (*d*) Candles.
  (*e*) Glue, Gelatine, etc.
  (*f*) Iodine, bromine, sulphur, phosphorus, etc., and articles in the making of which these products are used.

C. Alimentary Materials and Preparations.

(1) Cereals and Products obtained from them: Starch, Gluten, Glucose, etc.
(2) Saccharine Materials and Products: Sugar, Alcohol, Fermented Drinks, etc.
(3) Oleaginous Materials: Vegetable and Fish Oils.
(4) Preserved Meat, Vegetables, etc.

This arrangement will also incidentally establish a division between the new and old groups of countries, if such a phrase be allowable. Nothing is more remarkable in the Exhibition than the great wealth of raw material brought forward by the British, French and other colonies, while on the other hand the old countries show evidence of great progress in the manufactures.

In addition to the difficulty, already referred to, of making anything like a thorough examination of the various objects exhibited, there is another, and perhaps a more serious difficulty, in comparing the exhibits themselves so as to arrive at a just estimate of the relative excellence of the particular manufacturers by whom they are exhibited. In some instances the exhibits comprise remarkably fine specimens of various articles, noticeable not only for the quantity in which they are shown but also for their good condition. This is very marked in some of the exhibits of chemical products, though there is not, at the same time, any recognizable criterion by which to estimate the extent that these fine exhibits may be regarded as representing the position of the respective manufacturers. Instances are also to be met with in which elaborate ornamentation of the exhibitor's case, the elegant form and disposal of the bottles containing the articles shown, and the application of mirrors and other devices of decoration are not always in accord with the intrinsic merit of the exhibits, or with the industrial status of the exhibitor. On the other hand, some of the exhibits whose importance and interest are in every respect considerable, are set out in a manner so unpretending as to appear almost mean and insignificant, unless one's judgment is aided by a special knowledge which the majority of visitors to an exhibition of this kind cannot be expected to possess.

This difficulty, however, is one almost unavoidable, and though it is perhaps one of the most valid reasons that have been urged for questioning the utility of exhibitions as a means of illustrating the state of industry in different countries, careful consideration of the accessory data that should be furnished by a good descriptive catalogue would do much to prevent the formation of erroneous impressions. It has been deemed desirable to refer to these points, because in some instances it will be necessary to mention certain exhibits on account of their special excellence as such.

Another point which characterizes the Exposition Universelle Internationale is the greater extent to which the commercial element has been developed in some of its departments as compared with most of its predecessors. It is no disparagement to say that in this respect it partakes very much of the nature of a vast bazaar. Extension of trade is unmistakably the main object of many of the exhibitors, even if it be not the only one. Not unfrequently prices of articles are to be seen marked up, and in some cases articles of furniture and ornament that have attracted special attention have conspicuous labels attached stating that orders are received for

duplicates, while in the Chinese and Japanese sections numerous assistants are actively engaged in tempting customers. Considering the heavy expense incurred by some of the exhibitors, however, it can scarcely be matter for surprise that they should thus turn to account the chance of effecting a sale of their goods which is after all the main object they have in producing them.

ASPIDIUM MARGINALE, SWARTZ.*

BY CHARLES H. CRESSLER, PH.G.

In September, 1874, Dr. J. L. Suesserott, of Chambersburg, requested me to prepare for him an emulsion of oleoresin of male fern, which he administered with the result of the expulsion of but a small portion of tænia. The oleoresin furnished the doctor was bought from a wholesale druggist of good repute, and had the appearance of a pure article, but his failing to get a satisfactory result caused me to think that if our indigenous fern had any comparative virtues we could furnish a reliable preparation, which would be one advantage; and even if it were not so active as the European plant, that this might be more than counterbalanced by having the control of its preparation. I at once collected what I had thought to be *Filix mas*, selected the greenish coloured remains of the leaf stalks, with an adhering portion of the rhizome, dried them by means of a gentle artificial heat, and made an oleoresin according to the British formula. Dr. Suesserott administered the same quantity of this oleoresin that he had of the other to the same patient, the result of which was the expulsion of nine feet of tænia, including the head.

Believing this result sufficient for further trial, I gathered in October of the same year, 1874, more of the fern and made four ounces of the oleoresin. I did not dispense this on prescriptions, however, but in August, 1876, a friend of mine stated to me that he was passing sections of tape-worm. My anxiety to test still further the virtues of our indigenous fern led me to violate my usual custom of not prescribing. Two drachms of the oleoresin were put into nine gelatine capsules, of which three were taken at 10 p.m., and two at 12 p.m. Unpleasant eructations followed, so that no more of the preparation could be taken. A bottle of citrate of magnesium was taken at 6 a.m. next morning, and, after an hour and a half, the subject passed over twenty-four feet of tænia, tapering down apparently close to the head, which, however, was not found. In the latter part of October, about two months after the expulsion of the twenty-four feet, the same person began to void fully developed sections of tænia. Two drachms more of the oleoresin were put into nine gelatine capsules. The subject, after fasting from 12 m., took three of these at 10 p.m., and one more at 12 p.m., and followed them in six hours with emulsion of castor oil, and in two and a-half hours he discharged eight feet of the worm, tapering down apparently to the head, which, however, was not found in this instance either. To this date careful observation has failed to discover any further evidence of the presence of the parasite.

The fern used is an evergreen, and, according to Wood's 'Botany,' seems to be the *Aspidium marginale* described by James Lemon Patterson in vol. 47, p. 292, *American Journal of Pharmacy*, 1875. It grows along the banks of the Conococheague creek and other streams that wind through the fertile region of the Cumberland valley, but only on the rocky ledges that face northward. I never found it on those facing directly southward, and never on the mountain ranges that border our valley except a few stocks at springs along the foot of the mountain.

An interesting fact in support of this statement was noticed this morning on a visit to the yard of Dr. Suesserott. In a shaded portion of the ground on an elevated bed, having an evergreen honeysuckle as its principal occupant, a circular and marginal belt of these ferns had been planted in October, 1874. At this date they are still flourishing luxuriantly on only about two-fifths of the circle facing northwards, while none whatever remain on the three-fifths of the circle facing southward, notwithstanding the fact that the north, east and south sides of this mound are surrounded at about equal distances with buildings of similar height.

The following note by Professor Maisch is appended to this paper:—

"Mr. Cressler has very kindly accompanied the preceding communication with various specimens comprising the tape-worm expelled in August and October, 1876; specimens of the rhizome and stipes as used by him in preparing the oleoresin, and living plants and herbarium specimens of the same. As indicated by Mr. Cressler, the plant is *Aspidium marginale*, Sw., which, according to Gray, is very common on the northern section of this continent, is of frequent occurrence in the rocky woodlands of Pennsylvania, and is met with farther south to the mountains of North Carolina (Chapman's 'Flora of the Southern United States'). Our native species of *Aspidium*, as arranged in Gray's 'Manual,' belong to two sub-genera, viz., *Polystichum*, which has the indusium or shield-like covering of the sori (fruit patches) orbicular, entire and attached by the depressed centre, while in the sub-genus *Dryopteris*, the indusium is more or less kidney-shaped and notched at one side. The latter comprises the larger number (8) of species, which include both *Aspidium marginale* and *Aspidium Filix-mas*. The true male fern occurs in rocky woods of the Keweenaw peninsula of Lake Superior and westward, and, according to Porter and Coulter's 'Flora of Colorado,' also in the Grand Canon of the Arkansas, and along the foot-hills west of Denver. It agrees with *Aspidium marginale* in having the stipes or leaf stalks covered at the base with a copious chaff of brown glossy scales, the fronds or leaves twice pinnate with the upper pinnules confluent, and the lower ones more or less pinnatifid-toothed and with some of the veins repeatedly forked. But the two species differ in the frond of *Aspidium marginale* being evergreen and having the fruit dots close to the margin, while in *Aspidium Filix-mas* the fruit dots are near the mid-vein and the fronds do not survive the winter. The rhizome of the latter attains a thickness of one inch, and shows upon the cross section about ten larger, besides several smaller, and in the stipes about eight irregular wood bundles, the former being arranged in a loose circle. The rhizome of *Aspidium marginale* is thinner, about three-eighths of an inch in diameter, and contains a loose circle of about six larger and smaller, and the stipes six very small wood bundles; otherwise in appearance and sensible properties the subterraneous portions of the two plants resemble each other very closely.

"Since the constituents of the latter species have been proved by Mr. Patterson to be identical with those of the male fern, and since the efficiency of the American species has been shown through Mr. Cressler to be equal to that of *Aspidium Filix-mas*, it is to be hoped that the next pharmacopœia will place the two species on an equality, and authorize the indiscriminate use of the one which may be most convenient to collect. In the meantime, it is suggested that, if occasion offers, pharmacists will submit preparations of *Aspidium marginale* for the use of physicians, and that the results obtained be duly recorded. In preparing the oleoresin it must not be overlooked that only the green portion of the subterraneous parts should be used, and that all the brown and decayed portions should be rigidly excluded."

THE MEDICAL ACTS AMENDMENT BILLS

ACCORDING to the orders of the day the second reading of the Government Medical Bill, as well as the adjourned debate on the second reading of the No. 2 Bill brought in by Mr. MILLS, and the second reading of Dr. LUSH'S Bill will now be brought forward on Thursday next, the 11th inst. In reference to these Bills several notices of motion have been given; thus Mr. MELDON and Mr. MCLAREN have given notice that they will move that the Government Bill be read a second time that day three months, or to speak more plainly, either abandoned or postponed to another Session. Mr. MITCHELL HENRY is to move "That no measure of medical reform can be satisfactory which does not provide for the affiliation of all licensed practitioners to one or other of the Medical Corporations either in England, Ireland, or Scotland, and further that provision should also be made for the direct representation of the profession on the Medical Council. Mr. ERRINGTON has given notice that after the second reading of the Government Bill he will move that it be referred to a Select Committee, and Dr. LUSH will add to this motion that the Committee shall have power to take evidence. In reference to Dr. LUSH'S Bill, which deals chiefly with the penal clauses of the Medical Act, 1858, Mr. JAMES BARCLAY is to move that it be read a second time that day three months, and Mr. SERGEANT SIMON has given notice of a similar motion in reference to the No. 2 Bill of Mr. MILLS, while Mr. ERRINGTON will move that it be referred to a Select Committee.

Certainly the prospect afforded by these notices is not at first sight such as to encourage hopes of a satisfactory termination of the efforts to bring about medical reform; but there are at the same time indications that consistently with the appreciation of the merits of compromise, which is said to characterise the proceedings of other negotiating parties, informal discussions have been carried on by those interested, in such a way as to induce concession on all sides and justify the belief that while the provisions of the Government Bill would not be altogether distasteful to the profession generally they might be accepted without serious cavil by the corporations and universities.

The proposed second reading of the Government Medical Act Amendment Bill did not take place last Monday week as had been expected, and since that time a considerable change appears to have been effected, so far as regards the reference of the whole subject of medical reform to a Select Committee of the House of Commons, which seemed at one time to be probable. One great disadvantage of that course, had it been followed, would have been the postponement until another session, at least, of legislation that is admitted to be urgently required, though there are still some differences of opinion as to certain details.

On Thursday evening Lord GEORGE HAMILTON distinctly stated, in reply to a question put by Mr. ERRINGTON, that the Government would decline to entertain the proposal of referring the Bill to a Select Committee, feeling sure that, if time would permit the discussion of its proposals, the assistance of the House might be reckoned upon to help in carrying through reforms so earnestly desired by the great majority of the medical profession. In support of this view his Lordship pointed out that the whole subject of medical education and reform had been very thoroughly discussed by the many and various deputations visiting the Lord President and himself, and that while the objects of all the Bills now before Parliament were really the same, and could be covered by the Government Bill, the main question as to a Conjoint Board presented no difficulties that could not be satisfactorily settled when discussed. The only question not yet ripe for legislation is that affecting the reconstruction of the Medical Council, to which the Bill of Mr. MILLS is especially directed; but though this matter requires further consideration, that need not in any way prevent the passing of the Government Bill this session.

One material feature of progress is presented by the official recognition by the Medical Council that its constitution needs revision, and by the declaration that it will at once consider what modifications of constitution are demanded and required, and report to the Government accordingly. Consequently we are not by any means surprised to find it predicted by a medical contemporary that the recent sitting of the General Medical Council will possibly prove to be the commencement of a new era in the history of the organization of the medical profession.

We have already pointed out that the effect which the Government Bill would have upon chemists and druggists, if it were passed as it now stands, is scarcely so favourable as would have been the case had the original draft of the Bill remained unaltered. We refer here to the practice of counter prescribing and to the circumstance that the penal section of the Apothecaries Act, originally proposed to be entirely repealed, is now left in operation as against chemists and druggists. It is not surprising to find that the Executive of the Chemists and Druggists' Trade Association views this amendment with apprehension, or that it should feel the need of taking some

action in reference to it. Through the courtesy of the Secretary we are enabled to state that in pursuance of the resolution passed at a meeting of the Law Committee on the 14th ult., a deputation has waited on the Duke of RICHMOND and Lord GEORGE HAMILTON who has charge of the Government Medical Act Amendment Bill in the House of Commons, mainly with the object of urging them to repeal the 20th section of the Apothecaries Act, instead of leaving it as it now stands. Their Lordships, we understand, declined to commit themselves to any alteration of the kind desired, but stated, somewhat ambiguously, that they clearly understood the objects of the deputation, and requested that a memorandum might be forwarded to them, stating the modifications desired, which they promised should receive careful consideration.

This memorandum has been drawn up and copies of it have been circulated to members of Parliament as well as to prominent members of the trade, together with the draft of a petition to be presented to Parliament praying for the total repeal of the 20th section of the Apothecaries Act.

We have not this week space to deal with the substance of the memorandum of the Trade Association, but we cannot refrain from expressing the opinion that the action that body is now taking, and the agitation which it is deemed necessary to instigate, are to be regarded as having been rendered necessary only in consequence of the impolitic attempt to defend an acknowledged indefensible case of prosecution under that very section of the Apothecaries Act, the repeal of which is now demanded.

We strenuously deprecate any strained interpretation of the 20th section of the Apothecaries Act to the prejudice of chemists and druggists as regards that kind of "counter practice" which may fairly be deemed legitimate and even necessary in some instances, though it may not in the abstract be desirable; but we cannot shut our eyes to the fact that the unwise action of the Trade Association in defending the case recently tried has had a very mischievous effect in unnecessarily drawing attention to those cases in which chemists and druggists do overstep the limits within which "counter practice" ought to be confined and within which the medical profession generally has no desire to interfere with the practice of chemists and druggists.

We regard the amendment in the Schedule of the Government Medical Bill as being a direct result of the injudicious course pursued by the Executive of the Trade Association, and we regret not only that the possible utility of its career has thus early been marred by this mistake, but also the probability that the efforts of the Council of the Pharmaceutical Society to protect the interests of chemists and druggists may thus have been at the same time rendered more difficult of realisation than they otherwise might have been.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, July 3, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Fairlie, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Rimmington, Robbins, Sandford, Schacht, Shaw and Woolley.

The minutes of the previous meeting were read and confirmed.

A letter was read from M. Petit, of Paris, thanking the Council for electing him an honorary member.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the seal of the Society:—

Hall, Richard Arthur.
Hugill, John Howden.
Tharle, Charles Albert.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Tharle, Charles Albert.....London.

Chemists and Druggists.

Dean, Charles Geldard.....Chesham.
Wild, Frederick .....Hyde.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Carlton, Arthur.....Peterborough.
Markham, William Charles.....San Francisco.
Matthews, John Henry .....London.
Pownall, Thomas .....Mold.
Richards, Philip .....East Harling.
Richardson, Thos. Plowman ...Alford.
Temple, Frederick Staveley ...Hull.
Thomas, John .....Llannon.

ASSOCIATES.

The following having passed their respective examinations and tendered (or paid as Apprentices or Students) their subscriptions for the current year were elected "Associates" of the Society:—

Minor.

Allen, Henry.....London.
Brown, Thomas..... .....Hull.
Brown, Thomas Land .....Ripon.
Clough, Alfred.....Northwich.
Crowther, William Charles.....Tickhill.
Gulliver, George Ekins .....Holdenby.
Mason, William Drury .....Louth.
Naylor, Thomas Hamilton .....Newcastle-on-Tyne.
Place, Thomas .....York.
Smailes, Robert.....Grantham.
Taylor, John.....Bolton.
West, William Painter .....Liskeard.
Williams, Robert William .....Cheltenham.
Wing, William .....Sheffield.

Modified.

Smith, John Charles .....Ventnor.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Dods, John Henry .....Market Deeping.
Elkins, Frank Ashby .....Northampton.
Parker, William Henry .....Hitchin.
Paterson, James Smith .....Castle Douglas.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The Pharmaceutical Conference.

The President said he had received a letter from the Editor, stating the time was approaching when it would be necessary to arrange for reporting the proceedings at the Conference at Dublin, and containing an estimate of the expense.

The letter was referred to the Library, Museum and Laboratory Committee.

Reports of Committees.

Finance.

The report of this Committee recommending the payment of sundry accounts was adopted.

Benevolent Fund.

The report of this Committee included a recommendation of the following grants:—

£20 to a pharmaceutical chemist, connected with the Society as associate or member from 1842 to 1877, and formerly in business for many years, but now suffering from an incurable disease.

£15 to the widow of an associate, who died suddenly, leaving applicant with two young children; and another has since been born.

£10 to a former member, many years in business, but latterly an assistant, who has lost his savings through the failure of a bank.

£10 to the widow of a chemist and druggist. Applicant has had two previous grants of like amount.

£20 to the widow of a chemist and druggist who received a grant of £15 in 1875.

£20 to the widow of a late member many years in business.

£10 to the widow of a registered chemist and druggist.

Several other cases were deferred for further consideration, and in one case, in which a widow with five children under 11 years of age applied for assistance to secure the election of a girl into an orpham asylum, the Committee recommended that £52 10*s.* be granted, to be placed in Mr. Owen's hands to be used as desired if there should be a good prospect of success.

The Secretary reported that Mr. Owen had attended the election of the St. Anne's School and had expended the fifty guineas which the Council had voted to assist in securing the election of an orphan to that institution. Unfortunately the election was lost by seven votes.

The President said the Committee had a very long sitting on the previous evening and saw many of the candidates; and he could only say that the more he saw of the work of the Committee the more he was convinced that the Benevolent Fund was doing an immense deal of good, and he was quite sure that many who now refused to subscribe to it, if they had an opportunity of seeing the work which was being done, would reconsider their determination. It would be noticed that the Committee had availed itself of Mr. Owen's kind offer to render any aid he could at future elections to orphan asylums. The members of the Council were all much indebted to Mr. Owen for his past services, and they showed it by again calling upon him.

Mr. Greenish brought forward one case which he wished more fully discussed, and the Council accordingly resolved itself into Committee for the purpose. After some discussion this particular case was referred back to the Committee for further consideration.

The Council then resumed.

Mr. Shaw suggested that a list of subscribers to the Benevolent Fund should be prepared and issued separately. He thought it would tend to increase the number of subscribers.

The President did not see the advantage of such an arrangement, and thought it might interfere with the sale of the Calendar.

Mr. Betty thought such a list would only lead to an extension of the system of canvassing, which Mr. Shaw so much deprecated.

Mr. Mackay said the list of subscriptions was published in the Journal. At any rate if a list were published it should be done at the same time as the Calendar was issued.

Mr. Shaw said that was what he meant.

The Vice-President thought this would be a good plan.

Mr. Shaw said he would bring the subject forward again at the proper time.

The report and recommendations of the Committee were received and adopted.

A resolution was passed thanking Mr. Owen for his services in endeavouring to secure the election of an orphan into the St. Anne's School.

Library, Museum and Laboratory.

The report of this Committee included the report from the Librarian for the preceding month, showing the average attendance in the Library to have been, day, 24; evening, 10. Circulation of books, town, 193; country, to 36 places, 64. Carriage paid, 20*s.* 0½*d.* He also reported the following Donations to the Library:—

'Etude sur les Rapports entre les Principes actifs et les Caractères botaniques des Plantes officinales,' 1878. 2 copies. From Professor A. Herlant (Author).

'De la Toxicité des Sels de Cuivre et de l'Emploi du Sulfate dans la Panification.' 1878. From Dr. J. Morel.

Stackmann's 'Studien über die Zusammensetzung des Holzes.' 1878. From Professor Dragendorff.

Cooley's 'Practical Receipts.' 6th Edition. Part 3. 1878. From Messrs. Churchill.

'Sixteenth Annual Report, 1877.' From the Birmingham Free Libraries Committee.

Thomson's 'Chemistry.' 6th Edit. 4 vols. 1820.

Quincy's 'Dispensatory.' 14th Edit. 1769.

From Mr. Joseph Stapleton.

Priestley's 'Experiments on Air and in Natural Philosophy,' 6 vols. 1777–86.

Alpinus' 'De Medicina Ægyptiorum, etc., 1719.'

Alpinus' 'De Medicina methodica, 1719.'

Bate's 'Dispensatory,' by Salmon. 3rd Edit. 1706.

Bergman's 'Physical and Chemical Essays,' by Cullen. 2 vols. 1788.

Bergman's 'Elective Attractions.' 1785.

Fourcroy's 'Chemical Knowledge,' by Nicholson. 11 vols. 1804.

Jones's 'Mysteries of Opium Revealed.' 1700.

Lucretius, 'Of the Nature of Things,' by Creech. 2 vols. 1714.

Smee's 'Electro-Biology.' 1849.

Salmon's 'Medicina Practica,' 1619, with translations from R. Bacon and G. Ripley.

Cullen's 'Materia Medica.' 2 vols. 1789.

Boerhaave's 'Chemistry,' by Shaw. 3rd Edition. 2 vols. 1753.

Renodæus' 'Medicinal Dispensatory and Pharmacopœia,' by Tomlinson. 1657.

Galen's Works (in Latin), parts 3—4, 7—9, in 2 vols. 1625. From Mr. R. M. Atkinson.

The purchase of the following was recommended:—

John's 'Forest Trees of Britain.'

Dewey's 'Classification and Subject Index.'

Thomson's 'Chemistry.' 4 vols. 1802.

Chaptal's 'Chemistry.' 7 vols. 1800–7.

Jourdan's 'Pharmacopée Universelle.' 2 vols. 1828.

Parkes' 'Chemical Essays.' 5 vols. 1815.

Pearson's 'Materia Alimentaria et Medica. 1808.

Tournefort's 'Materia Medica.' 1708.

Cottereau's 'Pharmacologie.' 1839.

Nysten's 'Dictionnaire de Médecine, Pharmacie, etc.' 1840.

Cooper's 'Catalogue of Chymicall Books.' 1675.

'Philosophical Transactions, 1849–53.'

The Curator had reported that the average attendance in the Museum during the previous month had been, day, 14; evening, 3.

He had also reported the following Donations to the Museum:—

Specimens of false Sumbul, from Mr. F. J. Hanbury; Specimens of Impure Capsaicin (and a promise of the pure specimen at present in the Paris Exhibition), from Mr. J. C. Thresh; Specimens of Candle Nut Oil and Cake, from Mr. W. Cunningham.

The Curator had also reported that the North British Branch had selected several specimens of materia medica from the duplicate list. Also that he had obtained much valuable information at the Paris Exhibition, and copies of all the catalogues yet printed which contain notes relating to materia medica. That he had received further information respecting cochineal culture from Mr. Bruce, and would make a report thereon.

The list of Local Secretaries had been submitted to the Committee, and referred to the President and Secretary to complete and report.

The Committee had also considered an application for the partial return of an examination fee which had been submitted to it, and was of opinion that it would be inexpedient to return any part of such fee as there was no sufficient reason for so doing.

The Professors had attended the Committee and reported favourably of their respective classes.

Mr. GREENISH said he hoped the Society would be able to get from Paris copies of all the catalogues, which would be useful in the library. They were not yet published, but would be in the course of the year. One thing must strike every one who attended that exhibition, viz., the immense progress made by the colonies.

The report and recommendations were received and adopted.

Local Secretaries.

The SECRETARY said the desire was to appoint Local Secretaries in all towns in which there were chemists and druggists to represent the Society, but there were sixteen places which were eligible to have Local Secretaries and had not a single chemist and druggist connected with the Society. For instance at Ayr, there was a population of 18,970, and nine chemists and druggists, but not one connected with the Society. At Bury there was a population of 38,000, and twenty-three chemists and druggists, but not one connected with the Society.

Mr. ATKINS asked if there were any expense connected with appointing Local Secretaries, because if so, it seemed absurd to appoint one in a small town, which might have only one chemist and druggist in it, simply because it returned a member to Parliament.

The SECRETARY said there was no expense. The idea was that, if necessary, Parliamentary influence might be brought to bear.

It was then resolved that the persons named in the following list should be appointed Local Secretaries for the ensuing year:—

List of Local Secretaries, 1878-9.*

Towns eligible.	Names of persons appointed.
Aberdare	Thomas, Watkin Jones.
Aberdeen	Davidson, Charles.
Abergele	Hannah, John.
Aberystwith	Ellis, R.
Abingdon	Smith, William.
Altrincham	Hughes, Edward.
Andover	Madgwick, W. B.
Arbroath	Shield, George.
Ashbourne	Bradley, Edwin Silvester
Ashby-de-la-Zouch	Johnson, Samuel E.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Ayr	
Banbury	Beesley, Thomas.
Banff	Ellis, Bartlett.
Bangor	Roberts, Meshach.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow-in-Furness	Steel, Thomas.
Bath	Commans, Robert Dyer.
Beaumaris	
Bedford	Cuthbert, John M.
Belper	Ashton, John.
Berwick	Carr, William Graham.
Beverley	Hobson, Charles.
Bewdley	
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Bishop Auckland	Leigh, John James.
Blackburn	Pickup, Thomas Hartley
Blackpool	Harrison, John.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, George.
Boston	Pilley, H. T.
Bournemouth	Duncan, Alexander.
Bradford (Yorkshire)	Rimmington, Felix W. E.
Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner.
Bridlington	Forge, Christopher.
Bridport	Tucker, Charles.
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, William W.
Buckingham	Sirett, George.
Burnley	Thomas, Richard.
Burslem	Blackshaw, Thomas.
Bury	
Bury St. Edmunds	Youngman, Edward.
Buxton	Barnett, Alexander.
Calne	
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Williams, T.
Cardigan	Jones, John Edward.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard M.
Carnarvon	Lloyd, W.
Chatham	Watts, H.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Baxter, G.
Chesterfield	Greaves, Abraham.
Chichester	Long, William Elliott.
Chippenham	Coles, John Coles.
Christchurch	Green, John.
Cirencester	Mason, Joseph W.
Clevedon	Martin, J.
Clitheroe	
Cockermouth	Bowerbank, Joseph.
Colchester	Cordley, W. B.
Congleton	Goode, Charles.
Coventry	Wyley, John.
Crewe	McNeil, James Norton.
Cricklade	
Croydon	Barritt, G.
Darlington	Robinson, Alfred Francis.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Stevenson, R.
Devizes	Evans, John.
Devonport	Codd, Francis.
Dewsbury	Gloyne, C. G.
Diss	Gostling, Thomas Preston.
Doncaster	Howorth, J.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other Towns as contain not less than Three Members of the Society or Associates in Business.

Towns eligible.	Names of persons appointed.
Droitwich	Taylor, Edmund.
Dudley	Hollier, Elliot.
Dumfries	Allan, William.
Dundee	Hardie, James.
Dunfermline	Seath, Alexander.
Durham	Sarsfield, William.
Eastbourne	Provost, J. A.
Edinburgh	Mackay, John.
Elgin	Robertson, William.
Ely	Pate, Henry Thomas.
Evesham	Dingley, Richard Loxley.
Exeter	Delves, George.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, W. F.
Fareham	Batchelor, Charles.
Faversham	Underdown, F. W.
Flint	Jones, Michael.
Folkestone	Goodliffe, George.
Forfar	Ranken, J. A.
Frome	
Gainsborough	Forrest, R. W.
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Meadows, Henry.
Gosport	Hunter, John.
Grantham	Cox, J.
Gravesend	Bulgin, William.
Greenock	Fraser, Charles.
Grimsby, Great	Palmer, Enoch.
Guernsey	Arnold, A.
Guildford	Martin, Edward W.
Haddington	Watt, James.
Halifax	Dyer, William.
Hanley	Jones, C.
Harrogate	Davis, R. Hayton.
Hartlepool	Jackson, William G.
Harwich	Bevan, Charles F.
Hastings and St. Leonards	Jameson, William E.
Haverfordwest	Williams, William.
Hawick	
Helensburgh	Harvie, G.
Helston	Troake, Marler H.
Hereford	Jennings, Reginald.
Hertford	Lines, George.
Hexham	Gibson, J. P.
Heywood	Beckett, William.
Hitchin	Ransom, William.
Horncastle	Kemp, William.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Bains.
Huntingdon	Provost, John Pullen.
Huntly	Prott, William.
Hyde	Wild, Joseph.
Hythe	Lemmon, Robert Alce.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut, John, jun.
Kendal	Severs, Joseph.
Kidderminster	Hewitt, George.
Kilmarnock	Borland, John.
King's Lynn	Atmore, George.
Kingston-on-Thames	Walmsley, Samuel.
Kirkcaldy	Storrar, D.
Knaresborough	Sindall, John William.
Knutsford	Silvester, Henry Thomas.
Lancaster	Bagnall, Wm. Henry.
Launceston	Eyre, Jonathan Symes.
Leamington	Jones, Samuel Urwick.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Cooper, Thomas.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lichfield	Perkins, John Jaquest.
Lincoln	Maltby, Joseph.
Liskeard	Young, Richard.
Liverpool	Abraham, John.
Llandudno	Williams, Thomas.
Longton	Prince, Arthur G.
Loughborough	Paget, John.
Louth	Hurst, John B.
Lowestoft	Sale, Thomas J.
Ludlow	Woodhouse, G.
Lyme Regis	Thornton, Edward.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.
Macduff	Henry, James Hay.
Maidenhead	Walton, R.
Maidstone	Rowcroft, Albert Edward.
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Hardy, George.
Malvern	Metcalfe, Edmund Henry
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Knight, Alfred.
Marlborough	
Marlow	Foottit, C. M.
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Robson, James Crosby.
Midhurst	
Montgomery	
Monmouth	Key, H.
Montrose	Burrell, George.
Morecambe	Birkett, J.
Morpeth	Marshall, G. T.
Neath	Hibbert, Walter.
Newark	March, William.
Newbury	Davis, Frank Pratt.
Newcastle-under-Lyne	Cartwright, William.
Newcastle-on-Tyne	Proctor, Barnard S.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Pearman, Henry.
New Radnor	
Newton Abbot	Poulton, J.
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Northwich	Wolstencroft, J.
Norwich	Sutton, Francis.
Nottingham	Fitzhugh, R.
Nuneaton	Iliffe, George.
Oldham	Hargraves, H. Lister.
Oswestry	Saunders, George James.
Over Darwen	Hargreaves, Wm. Henry.
Oxford	Prior, George T.
Paisley	Hatrick, William.
Pembroke	
Pembroke Dock	John, D. W.
Penrith	Kirkbride, W.
Penzance	Cornish, Henry Robert.
Perth	Dandie, R.
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Balkwill, Alfred P.
Pocklington	Cundall, Robert.
Pontefract	Bratley, William.
Poole	Penney, William.
Portsmouth, etc.	Rastrick, J. L.
Preston	Barnes, James.
Ramsgate	Morton, Henry.
Reading	Hayward, William G.
Redditch	Mousley, William.
Retford	Clater, Francis.
Richmond (Yorks)	Thompson, John Thomas
Ripon	Judson, Thomas.

Towns eligible.	Names of persons appointed.
Rochdale	Taylor, Edward.
Rochester	Harris, Henry William.
Rothesay	Duncan, William.
Runcorn	Whittaker, William.
Rugby	Garratt, John C.
Ruthin	Bancroft, John James.
Ryde (Isle of Wight)	Pollard, Henry Hindes.
Rye	Waters, William Allen.
St. Albans	Ekins, A. E.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, Samuel Ralph.
Sandwich	Baker, Frank.
Scarborough	Whitfield, John.
Seacombe	Holt, R. W.
Selby	Cutting, T. J.
Shaftesbury	Powell, John.
Sheerness	Bray, John.
Sheffield	Ward, William.
Shields, South	Mays, Robert J. J.
Shipley	Dunn, Henry.
Shoreham	Barker, John.
Shrewsbury	Cross, William Gowen.
Slough	Griffith, Richard.
Southampton	Dawson, Oliver R.
Southport	Walker, William Henry.
Spalding	Shadford, Major.
Stafford	Averill, John.
Stalybridge	Brierley, Richard.
Stamford	Patterson, George.
Stirling	Duncanson, William.
Stockport	Kay, S.
Stockton-on-Tees	Brayshay, Thomas.
Stoke-on-Trent	Adams, Jonathan Henry.
Stourbridge	Bland, T. F.
Stratford-on-Avon	Hawkes, Richard.
Stroud	Blake, William F.
Sudbury	Harding, James John.
Sunderland	Nicholson, John J.
Sutton-in-Ashfield	Littlewood, John A.
Swansea	Brend, Thomas.
Tamworth	Allkins, Thomas Boulton.
Taunton	Prince, Henry.
Tavistock	Gill, William.
Teignmouth	Cornelius, Joseph.
Tenby	Davies, Moses Prosser.
Tewkesbury	Allis, Francis.
Thirsk	Thompson, John.
Tiverton	Havill, Paul.
Torquay	Smith, Edward.
Totnes	Keen, Benjamin.
Truro	Percy, T. B.
Tunbridge Wells	Howard, Richard.
Tynemouth	
Uttoxeter	Johnson, John Borwell.
Wakefield	Hick, Matthew Bussey.
Wallingford	Payne, Sidney.
Walsall	Elliott, George.
Wareham	Randall, Thomas.
Warrington	Woods, Joseph Henry.
Warwick	Pratt, Henry.
Watford	Chater, Edward Mitchell.
Wednesbury	Gittoes, Samuel James.
Wellington	Langford, John Brown.
Wenlock	
Westbury	Taylor, Stephen.

Worthing	Cortis, Arthur B.
Wrexham	Edisbury, James Fisher.
Wycombe	Furmston, Samuel C.
Yarmouth, Great	Poll, Wm. Sheppard.
York	Davison, Ralph.

HOUSE.

The report of this Committee was very brief, referring only to trifling details, and was adopted unanimously.

The Preliminary Examination.

The Secretary presented a list of centres and table of attendances at each centre since July, 1874, which is printed on the opposite page.

GENERAL PURPOSES.

The report of this Committee contained details of certain alleged infringements of the Pharmacy Acts, also of the discussion in the Committee of various measures now before Parliament. The Committee had considered the question of centres at which written examinations are held, and recommended that the following places be omitted from the existing list:—Aberystwith, Barnstaple, Berwick, Boston, Cardigan, Chester, Colchester, Doncaster, Dorchester, Dumfries, Hereford, Lymington, Leicester, Lynn, Macclesfield, Perth, Plymouth, Portsmouth, Reading, Salisbury, Scarborough, Stafford, Swansea, Taunton, and Worcester. Also to substitute Lancaster for Preston.

Mr. Schacht asked what was the principle on which the Committee had acted in this somewhat revolutionary measure.

The President said, not merely on numbers attending the examinations, but on geographical situation and facility of railway communication. It was wished to throw the examinations as much as possible into large centres like Manchester and Liverpool.

Mr. Schacht said he could understand that principle was of considerable importance, provided always there was anything like pressure or necessity to reduce the number of centres at all.

The President said that question was put to the Committee and carried unanimously, that it was advisable, and he had reason to believe that the Board of Examiners both north and south coincided in that idea.

Mr. Schacht said there were two points of view from which this question might be regarded. The more the centres were limited the greater the ease to the officials, and the less the expense; but, on the other hand, the more they were limited in number the greater was the trouble, expense, and difficulty to the pharmaceutical public at large. These were two positions to a certain extent antagonistic to each other. For his own part, remembering what had been urged at various times by the most thoughtful members of the body in favour of inducing their youths to pass the Preliminary on entering pharmacy, it occurred to him that any amount of official trouble was worth taking for securing that object. He remembered also that two or three years ago the list was looked over and cut down to its present numbers with a good deal of anxiety, and looking to what the result would now be, he could not regard favourably the proposition which would limit the number of centres to something like half what was thought necessary four years ago. Taking the first town disfranchised, Aberystwith, it was a question affecting all those in the neighbourhood of that town. Only last week he had been in South Wales, and knew the speed of railway travelling there, even on the

PRELIMINARY EXAMINATION.

trunk lines, which was very slow, and it was still more difficult when you had to change three or four times, as would be necessary in order to get to the centres now proposed. In many cases he felt sure this alteration would involve the necessity of travelling one day, sleeping a night in the place, going through the examination, and returning the next night. All this would involve, not only the candidates, but their masters, in considerable trouble and expense.

The PRESIDENT remarked that the Committee had not really considered the expense, but the efficiency of the examinations. He was sorry that Mr. Schacht had not attended the Committee on the previous evening, when the matter was thoroughly discussed.

Mr. SCHACHT said he also regretted not having been present. He would not discuss the subject further, but he should oppose the change.

Mr. ATKINS, as representing one of the disfranchised boroughs, rose to protest, not personally, because he should be very glad to be relieved of the responsibility, but in the interests of the public. He could not but think that, speaking for the south-west district, if the Committee had duly considered the matter of railway approach, it had dealt very unfairly with Salisbury in erasing it and confining the centre to Southampton. He could not conceive why that choice had been made, except for its greater population. Its railway facilities were certainly not so great, and there would now be no centre between Bristol and Southampton. The latter town was on the coast, and, of course, was not so central as a place inland. Salisbury had unparalleled facilities in railway communications with branches running in every direction, and he hoped the arrangement would be reconsidered.

The PRESIDENT said the original idea was that Salisbury, and not Southampton, should be the centre, and he should have no objection to substitute Salisbury if it were really preferable.

Mr. ATKINS did not wish to say anything against Southampton, or too much in favour of Salisbury, but neither in geographical position, or railway facilities could the former be compared with the latter.

The PRESIDENT said the real desire was to do away with small centres, and to have large ones where the superintendents would take more interest in the examination.

Mr. FRAZER said when the list was previously made he opposed it, and he must also oppose the present omissions. Formerly every local secretary was a superintendent until the present list was made, and though he did not wish to go back to the old system, he certainly thought it was wrong to introduce the new one. It was a serious mistake if men were wanted to come into the business, and looking at the numbers of rejected candidates, showing that the class of men coming up was deteriorating instead of improving, he contended that this change would tend to increase that evil. He therefore sympathized with Mr Schacht's views. He did not object to certain towns being struck out of the list, such as Perth and Dorchester, where it appeared very few were examined.

Mr. HAMPSON thought it would be wiser for the Committee to reconsider the matter.

The PRESIDENT said it was no use the Committee doing the work if the Council would not accept it; the Council must do it itself.

Mr. BETTY must protest against the matter being referred again to the Committee. He did not urge the Council to come to any decision then, but the Committee having deliberately voted on each of these centres was not prepared to go over the same ground again. Whatever further action was taken must be taken by the Council.

The PRESIDENT remarked that the proposed arrangement would only last for twelve months, when it would be subject to revision either by way of increase or decrease, but he must say he rather looked forward to further decreasing than to increasing the number of centres in future years.

Mr. SCHACHT said that a feeling of annoyance having been expressed by members of the Committee at having their judgment questioned, he must remind them that the subject had not been discussed in principle before, for he did not think the matter had been referred to the Committee. He did not wish to say it had undertaken a duty which did not legitimately belong to it, but as far as he remembered the subject had not been discussed by the Council, and it came upon him rather as a surprise that the Committee had gone into elaborate details of the scheme the principle of which had not been relegated to it. His feeling was against the principle of reduction to anything like such an extent. The omission of a town here and there was a different thing to reducing the number to something like one half.

The PRESIDENT said the General Purposes Committee was appointed to assist the Council by doing particular work which would otherwise take up its time unnecessarily, and it had appeared to him proper that the question of fixing the centres for the ensuing year where the superintendents should be appointed for conducting the written examinations was one of those questions into which the Committee might most properly go. It was of course for the Council to say whether it would accept the report. It could either accept it, reject it, or send it back.

Mr. FRAZER asked if the matter was remitted to the Committee in any form.

The PRESIDENT said the matter came on in due course, and he, as President, directed that the Committee should go into the question.

Mr. FRAZER wanted to know if the Committee had power to originate any such question as the reduction of the number of centres, which, as he understood, had never been once broached.

The PRESIDENT said the centres were fixed every year, in July. The Council was not bound to appoint the same as last year.

Mr. BETTY said Mr. Schacht was quite right in stating that the principle of the thing had not been discussed. When he said the Commistee had done its duty he meant the Committee had done the duty which devolved upon it, which was to look at those centres and see how far it could place them on a better footing. The Committee could only go into these details, and as the principle itself was now controverted the Council itself must discuss that.

The VICE-PRESIDENT remarked that every member of the Council was a member of the General Purposes Committee.

The PRESIDENT said when the question came before the Council last July the old list was at once adopted because there was not time to reconsider it, but he himself expressed an opinion then that the list ought to be reduced.

Mr. SCHACHT said the discussion last year turned mainly on two centres.

Mr. SHAW thought the Committee was perfectly in order. The Examiners received certificates from a number of other examining bodies, amongst the rest, the College of Perceptors, which held examinations in every important town, therefore there was no very great injustice done to the young men, because they could attend those examinations if not convenient to attend the centres appointed by the Society. Having regard to some irregularities which had taken place, he thought it would be well to try the new system.

Mr. CRACKNELL quite sympathized with the Board of Examiners in wishing to reduce the number of centres, and, speaking as an old examiner, he believed the principle was perfectly correct. The towns in which the College of Perceptors held its examinations were very numerous, but the examinations were much more largely attended. He could not help thinking that the question

of inconvenience and expense had been greatly exaggerated. The inconvienence seemed to be considered to be inflicted on the masters, but this examination should be passed by the students before they went into the business at all. On the whole, he thought the proposed alteration was a good one.

Mr. ATKINS thought the work of the Committee ought to be treated with the respect due to it, but that no member should feel aggrieved at the report being sent back to be reconsidered. He had not expressed any opinion on the question of principle, and he could quite understand there were centres which it might be very desirable to remove; those which had not large populations or railway facilities. There might be, on the other hand, individual cases which were fairly defensible in detail, not as matter of principle.

Mr. BETTY said he would move a resolution which he thought might be unanimously adopted—

"That the principle or scheme of revising and reducing the list of examination centres, with a view of making such alteration as may be found expedient, be adopted."

Mr. SANDFORD thought it should be reducing not revising.

Mr. BETTY said revising would include reducing. He thought even Mr. Schacht might support that proposition.

Mr. SCHACHT said that was precisely what he could not; he did not admit the principle that it was necessary to fundamentally change the present list.

Mr. GOSTLING seconded the motion.

Mr. SCHACHT then moved as an amendment to the adoption of the report of the Committee:—

"That the report and recommendation of the General Purposes Committee be received and adopted with the exception of that portion which refers to the superintendents of written examinations."

Mr. FRAZER seconded the amendment.

Mr. HAMPSON thought it would not be desirable to vote *en bloc* for the entire change, especially after what had fallen from Mr. Atkins, and there might be other centres in the same position. The Council ought to deliberate on this matter a little longer, and he should therefore support the amendment.

The amendment was then put and carried.

Mr. HAMPSON suggested that Mr. Betty's motion ought not to come forward without formal notice.

Mr. BOTTLE said the Council had heard a great deal of "principle" in this matter, but he must confess his ignorance as to what the principle was. The only principle he knew of was that of adopting provincial centres for carrying on the written examinations. He did not know that the Council was bound to certain centres as a principle, but, as he understood, it appointed such centres as it thought convenient.

Mr. SCHACHT said he did not mean an abstract principle, but he used the word in the sense, that the details became almost a question of principle when so many centres were cut off.

The PRESIDENT said the contention was, that having too many centres decreased the efficiency of the examination.

Mr. SCHACHT said then that was a question of principle. He thought it would be well to go into all those questions: The distance was not the real point for consideration, but the time involved in getting from one place to another. It was not a question of 20, 40, or 60 miles, but of so many hours' travelling before a certain time in the day.

Mr. BETTY said all these were matters of detail.

The PRESIDENT said the Council must fix the centres that day.

Mr. SCHACHT said he should move that the present list be reappointed.

Mr. CHURCHILL moved as an amendment—

"That it is not desirable materially to diminish the number of centres for Preliminary examination."

He had felt on the previous night and still more on that day, after hearing the remarks of Mr. Schacht and Mr. Atkins, that the Council might be doing a grievous wrong to young men who lived at some distance from railway stations.

Mr. FRAZER seconded the amendment.

The PRESIDENT said this was entirely opposed to the opinion of those who were supposed to know most about the nature of the examinations. He could not see the force of the argument about railway distances. He thought young men who travelled to any centre on the morning of the examination would certainly increase their chance of failing, and that they would naturally go up the night before if they wished to pass.

Mr. CHURCHILL dissented from this view.

The PRESIDENT said he could not see what difficulty or hardship there was in going to the centre the day before.

Mr. MACKAY asked what the Council would be pledged to if this motion of Mr. Betty's were carried.

The PRESIDENT said he could not say.

Mr. BETTY wished to point out that the motion was so liberal in its terms that the amendment was quite immaterial. The Council did not know whether it would be necessary to materially diminish the centres or not, and the motion did not pledge it to anything.

Mr. SCHACHT said when it came to striking off twenty-seven towns and leaving only thirty-seven it brought the matter, in his mind, to a question of principle. The Society was not in the position of the Society of Apothecaries, or any such examining body, but in exactly an opposite position with reference to this matter. There was no particular reason why the Society of Apothecaries should endeavour to induce men to pass their examinations, but the Pharmaceutical Society had always declared that it wished to induce young men entering the trade to pass the Preliminary examination as a first step. If all sorts of impediments were placed in the way he did not call that inducing them to enter. He believed if every one entering the business could be induced to pass the Preliminary before apprenticeship, such a disgraceful state of things would not continue as had just occurred, when seventeen out of twenty candidates for the Minor examination were plucked.

Mr. Churchill's amendment was then put and lost, the numbers being twelve against and six for it.

Mr. Betty's motion was then put and carried.

Mr. SAVAGE then moved, and Mr. SHAW seconded, and it was carried unanimously:—

"That superintendents of written examinations for the ensuing year be appointed at the following centres, and that the appointments be offered to the Local Secretaries at those centres, with the exception of Newcastle and London:—

Aberdeen.	Dundee.	Manchester.
Birmingham.	Edinburgh.	Newcastle.
Brighton.	Exeter.	Northampton.
Bristol.	Glasgow.	Norwich.
Cambridge.	Guernsey.	Nottingham.
Canterbury.	Hull.	Oxford.
Cardiff.	Inverness.	Peterborough.
Carlisle.	Jersey.	Sheffield.
Carmarthen.	Lancaster.	Shrewsbury.
Carnarvon.	Leeds.	Southampton.
Cheltenham.	Lincoln.	Truro.
Darlington.	Liverpool.	York."
Douglas (I. of M.).	London.	

Mr. SCHACHT said he should be obliged to move one by one the insertion of the names which had been struck out. He then moved the addition of Aberystwith.

On being put to the vote the motion was lost by 14 to 5.

The PRESIDENT asked what was the next town to be proposed.

Mr. SCHACHT said he should give it up.

The PRESIDENT was proceeding to read the list of towns struck out, when

Mr. SANDFORD rose to order, and protested against the waste of time.

Mr. SCHACHT said he could understand how the list had been passed on the previous night in Committee if it was considered waste of time to go into it.

Mr. SANDFORD said that on the previous night the name of every place was called over, and its merits canvassed.

Mr. WOOLLEY said he considered the alterations made in his district were very good.

Mr. CHURCHILL moved that Chester be made a centre, but on being put to the vote the motion was lost.

Mr. HAMPSON moved the addition of Salisbury.

Mr. ATKINS said the Council had already voted for Southampton, and it would be absurd to have both. He then moved the addition of Leicester.

This motion on being put to the vote was lost, and Mr. Hampson withdrew his proposition for Salisbury.

THE CASE OF THE LONDON SUPPLY ASSOCIATION.

The PRESIDENT read a letter from the solicitors, enclosing a copy of the special case, which had been prepared relating to the appeal against the recent judgment of the Judge of the Bloomsbury County Court.

THE MEDICAL ACT AMENDMENT BILL.

The Special Committee appointed to watch the progress of this Bill reported that it had held a meeting, when a memorial was drawn up for presentation to the Duke of Richmond. It was forwarded, with a request that the Duke would receive a deputation. Owing to his Grace leaving town he could not do so, but promised to consider the views set forth in the memorial.

The report of the Committee having been received,

Mr. CHURCHILL suggested the addition of Mr. Greenish to the Committee, which was seconded by Mr. HAMPSON and carried unanimously.

Mr. ATKINS hoped the Committee would be very watchful over the future progress of the Bill, as he was quite convinced much good might be done by speaking the right word at the proper moment.

The PRESIDENT said he understood on the previous evening that another body, the Chemists and Druggists' Trade Association, had succeeded in having the interview which that Society had asked for and had not succeeded in obtaining, and it struck him on thinking over the matter that possibly the Duke of Richmond supposed they were one body, and that he had really received a deputation from that Society. He did not know whether Mr. Greenish and Mr. Hampson formed part of the deputation which waited on His Grace.

Mr. GREENISH and Mr. HAMPSON said they did.

The PRESIDENT said under these circumstances the deputation would be represented by two members of Council who had already appeared, and as he understood had not been very favourably received.

Mr. HAMPSON: Not at all.

The PRESIDENT said he doubted whether he ought not to withdraw from the Committee. He should feel himself in a very painful position appearing as a kind of second edition of that which had gone before, the nature of which he did not thoroughly know. If he understood rightly the Council was going to take rather a different position to that which the Trade Society would take; it was not going to defend the principle of chemists prescribing; it never had supported that principle and he trusted it never would.

Mr. GREENISH: Nor would the Trade Association.

The PRESIDENT said that was his difficulty. He felt it would be a most difficult thing now for him to follow another deputation, with gentlemen who were really the same, and who had already appeared, and had committed themselves or been committed by the Association and would apparently commit the Society to an extent he was not at all acquainted with. Therefore, he felt some difficulty in the Committee continuing its action and seeking an interview with the Duke of Richmond. Possibly it might be useful to wait on the gentleman who had the management of the Bill in the House of Commons.

Mr. HAMPSON said it so happened that he was appointed on the two deputations to wait on the Duke of Richmond, but he did not think the Society had been committed in the least.

The PRESIDENT said it placed him in an awkward position.

Mr. ATKINS said it appeared to him the President's only difficulty arose from the fact of two members of the Council forming part of both deputations. He was not going to argue the position of the Pharmaceutical Council as against the Trade Society, but he thought the President had supplied the most cogent reason why he should go to represent the position which the Pharmaceutical Council took in the matter. He would again repeat, and he had good reason for saying that the Committee should be exceedingly watchful, and in the most delicate and persistent way becoming the Society put forward the claims at the right moment, and then he believed they would not be ignored. He hoped any impression of a difficulty having arisen from a deputation from another organization having had a previous interview would be removed.

Mr. SANDFORD had not the smallest objection to the interview Mr. Hampson and Mr. Greenish had had with the Duke of Richmond, but as it seemed to make a difficulty he would suggest that Mr. Hills' name should be added to the Committee. He was not afraid of either Mr. Hampson or of Mr. Greenish, but he should scarcely like to go between them without someone to support him.

Mr. GREENISH thought it quite impossible that the Duke of Richmond could have mistaken one body for the other, considering that the President of the Trade Association wrote from Leamington asking for an interview, and when the deputation waited on him the names were handed in with the title of the Association at the head of the list. Even if Mr. Hampson and himself happened to go with the deputation from that society, he fancied that their interests were identical in this matter. What they asked for was that the chemists and druggists should retain the privileges which they had had from time immemorial; that they should give simple remedies in simple cases. They maintained that they had that right and intended to hold to it. As to assuming the position of medical men, that they had never claimed, and never intended to. He should be quite willing, however, to resign his position in connection with the Committee if it was thought right and proper.

Mr. SHAW said a most admirable letter had been penned by the Special Committee, representing the position of the Council, and he regretted very much that the President should hesitate to attend a deputation supporting that.

The PRESIDENT said he was perfectly prepared to do his duty whenever the opportunity offered, and he was prepared to support all that was in the memorial. But he did not know what he had been committed to by gentlemen who had formed part of the former deputation, or whether they had committed him to any course of conduct which he could not concientiously support.

Mr. HAMPSON altogether demurred to these remarks. Did the President suppose for a moment that two members of that Board had been so indiscreet as to represent themselves as representing the Society, or to present to the Duke of Richmond an exaggerated view of the whole question? The deputation which had already waited on the Duke of Richmond represented the case as independently and fairly as could be wished.

Mr. BOTTLE thought it would be desirable to send a deputation to the Duke of Richmond differing as regards individuals from that sent by the Trade Association. The Duke being deeply engaged in other important affairs would naturally look at one or two gentleman who had been before him on the same question on a previous

occasion, and would wish to get rid of them as soon as possible.

Mr. SCHACHT thought that if the whole subject of legislation on this matter were to be referred to a Committee of the House of Commons the Committee of the Council which was charged with the observation of those Acts should be a little better primed with the views of the Council as to what course it should adopt than simply having a general commission to do the best it could under the circumstances. He should prefer a more precise expression of opinion than had yet been given. He could believe that some members of the trade would like a sort of *carte blanche* to do what they liked in the way of medicine, and provided they did not kill any one they would like full liberty to treat them. He did not charge any member of the Council with that view, but he knew it existed in the trade. On the other hand there were many who wished a limit placed on their powers to prescribe. Under these circumstances he could understand the feeling of responsibility which made the President hesitate to undertake this duty without further discussion. He hardly knew what his own opinion was on the matter, but at present he certainly had not heard any opinion with which he thoroughly coincided.

Mr. BETTY thought it would be well if they understood what were the views advocated by the former deputation. If two deputations waited on his Grace, and they were at all divergent in their views, they would be put down as a divided body and no attention would be paid to them. Their only chance of success was by appearing as a united body. He remembered that years ago, when it was his duty to wait on several members of Parliament with reference to an important measure, the first questions put to him were, what was the Council doing, and what was the Trade doing, and were they unanimous, and the result was that until they became unanimous and spoke with one voice they had no influence whatever. He thought, therefore, for the benefit of the pharmaceutical cause in general, there should be a distinct understanding before the Council committed itself to any official explanation of its position.

The PRESIDENT said the Council had no official knowledge of any deputation at all from the Trade Association; it was only by hearsay he was made acquainted with it on the previous evening.

Mr. SHAW suggested that the deputation to wait on the Duke of Richmond should take the letter written from the Council as the basis upon which it was prepared to act, and so far there was no discrepancy.

The PRESIDENT said certain matters had occurred since, which altered the position. The Trade Association had defended certain cases of counter practice, so-called, and he took that as a guide to his own mind of what the theory of the Association was, and it did not coincide with his view and his theory.

Mr. WOOLLEY thought that one point had been rather overlooked. Mr. Churchill had stated in Committee that the Council had applied for an interview and had been unsuccessful, but the Trade Society had been more fortunate. He thought there might be a little method about that, and that the Duke of Richmond wanted to see if there was any difference between the two parties.

Mr. SANDFORD said, according to Mr. Betty's opinion if Mr. Hampson gave a narrative of what occurred at the interview, the deputation would be rather bound by it, if it were anxious to avoid any discrepancies, and therefore he thought it better not to go into it. He did not think it was for that Society to go into the communications which had taken place between the Duke of Richmond and the Trade Association. They were two perfectly independent bodies, and as such he hoped they would remain.

Mr. ATKINS said, Mr. Bottle has raised a most important practical question, whether the two members of the previous deputation should form part of the one now proposed.

Mr. SHAW said Mr. Schacht had said he had never heard any statement formulated which he could absolutely adopt as his own, and that was precisely the same position in which they were all placed. It was not possible to formulate anything which expressed all their views.

Mr. HAMPSON said he was perfectly willing to withdraw from the proposed deputation. He could see it would be desirable to invite other gentlemen to represent the Council at any interview that might be had with the Duke of Richmond, because persons he had not seen before might produce a different impression on his mind than those he had already seen.

The question was here raised whether the Council should go into committee to discuss this matter, but after a short conversation it was negatived.

Mr. HAMPSON said that he, as one of the deputation, had the letter of the Council in his mind during the interview with the Duke of Richmond, and nothing was stated beyond what was known as occurring in nearly every chemist's shop in the kingdom. The deputation also asked for the repeal of the 20th section of the Apothecaries Act.

Mr. CHURCHILL said there appeared to be an impression on the minds of many members of the Council that there was a divergence of opinion between that Council and the Executive of the Trade Association, as to what constituted counter practice. He assured members that the Executive of the Trade Association looked upon the matter of counter practice, as far as he could see, in precisely the same light as they did, and in fact in the first resolution passed by the executive committee of the Association, it pledged itself to support chemists and druggists prosecuted for simple counter practice, but to discountenance indiscriminate counter prescribing.

Mr. BETTY asked how that was reconcilable with the defence of Wiggins's case.

Mr. CHURCHILL said the course taken in that case was not due to the action of the Trade Association, but to the peculiar action of the Medical Defence Association, which kept back all particulars until the parties were actually in Court. The Association had not any notion until going into Court what sort of a case it was.

Mr. FAIRLIE said chemists and druggists in Glasgow were placed in a very peculiar position, owing to the special laws which prevailed there, under which medical men were entitled to keep open shop without having undergone any efficient pharmaceutical education, and he hoped that matter would be mentioned by the deputation.

Mr. FRAZER said medical men were as much entitled to keep open shop as he was.

Mr. FAIRLIE said medical men in Glasgow had only to spend two months behind a druggist's counter, and that was all the pharmaceutical education they had. He thought that ought to be mentioned by the deputation.

Mr. FRAZER said it was all according to law, and it was no use trying to alter it by a side wind.

Mr. FAIRLIE replied that it was not a side wind; there was now a proposition to amalgamate all the medical Acts, and this matter might fairly be mentioned.

The report of the Committee was then received and adopted. Mr. Hills and Mr. Greenish to be added to the Committee.

Mr. HAMPSON moved and Mr. ATKINS seconded:—

"That the Council considers it desirable that the Committee selected to watch the progress of the Medical Bills in the House of Commons should obtain an interview with the Duke of Richmond to bring under the notice of his Grace the views of this Council on the Medical Bills as they affect chemists and druggists."

Mr. SANDFORD thought the Committee had already brought under the notice of his Grace the views of the Council, and he did not think its members should force themselves on the Duke unnecessarily. He rather thought it should be left to the Committee to ask for an interview

if it appeared necessary. The probability was that all these bills would be sent next week to a Select Committee, which would prepare a Bill for next session.

Mr. BETTY agreed with Mr. Sandford that it would be unwise to press for an interview at present.

Mr. SHAW suggested that the resolution might be so worded as to leave it to the discretion of the Committee.

The PRESIDENT said the Committee already had that discretion.

After some further discussion Mr. Hampson withdrew the motion.

APPOINTMENT OF PROFESSORS AND CURATOR FOR THE ENSUING YEAR.

Professor REDWOOD was re-appointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor BENTLEY was re-appointed Professor of Botany and Materia Medica for the ensuing year.

Professor ATTFIELD was re-appointed Professor of Practical Chemistry for the ensuing year.

Mr. HOLMES was re-appointed Curator of the Society's Museum for the ensuing year.

THE COUNCIL EXAMINATION PRIZES.

On the motion of the President, Mr. Borland, Kilmarnock, and Mr. Gilmour, Edinburgh, were appointed to conduct the examination for the Council examination prizes in the present month.

REPORT OF THE BOARD OF EXAMINERS.

June, 1878.

ENGLAND AND WALES.

	Candidates.		
	Examined.	Passed.	Failed.

Preliminary Examination.

Nine certificates were received in lieu of examination:—

3 College of Preceptors.
1 Royal College of Surgeons of England.
2 University of Cambridge.
2 University of London.
1 University of Oxford.

ADMISSION OF REPORTERS.

Mr. HAMPSON then moved according to notice—

"That a reporter from the *Chemist and Druggist* be permitted to attend the meetings of the Council of the Pharmaceutical Society,"

He felt some confidence in bringing this forward, although a similar motion had been brought forward on more than one occasion before. He felt that the Council, taking into consideration the condition of the Society, would view with something like gratification the opportunity that this motion would afford, namely, that the Council should decide to admit a reporter representing another journal. He could not help considering how other bodies had acted towards their members. From the House of Commons to the vestries, in every village almost, the proceedings were invariably reported by independent reporters, and it was desirable that those interested in questions brought before the various bodies should receive a fair, impartial, and, where possible, an accurate report of what took place. It was known that an artist might paint his own portrait with very considerable success, but it was also known that when a portrait was to be painted it was much better that a person capable of painting the picture should paint it from a proper position, and it would be more fairly represented when done by an independent person. He must say at the outset that he had nothing at all to complain of, and not a word to say against the reporter himself and the manner in which he did his work, but it was well known that he was surrounded by influences which acted upon him in a measure that he himself could perhaps scarcely understand. He gave such a report, perhaps, as was asked for, but when the report left his hands it passed into the hands of the editor. The editor of course was responsible for what was published, and, as he had stated before, members residing in London had the opportunity of adding to or taking from the report which was ultimately published. He did not mean to say that this had been done in an unfair manner, but it was impossible for any person having this opportunity, which country members did not enjoy, to act with perfect impartiality. It was extremely important that the members of the Society should feel sure that they had an independent and accurate report; that was certain to produce confidence in their minds, and not only would it produce confidence but it would give them a great advantage in considering any question which was brought before the Council. It would also produce much more interest in the minds of members when they had to vote for the election of members of Council. He would ask the Council to vote this motion because he believed it was necessary. The Society was no longer a private society, but represented most important public functions, and all other bodies found it necessary to adopt this plan. The Medical Council, for instance, had its independent reporters. He would ask the members of that Council not to have anything like trade jealousy in the matter. They of course occupied a position as publishers of the Journal, but he hoped that fact would not bias the minds of any of them in voting on the question. The two journals which circulated in the trade should be placed on equal terms.

Mr. ATKINS, in seconding the motion, said it was not necessary to repeat the arguments used by Mr. Hampson, but he wished to say he thought the application was a reasonable one. There could be no legal claim whatever, but he thought the moral claim was one which they as reasonable men could not ignore. He had no complaint whatever to bring against the report which already existed, which as matter of condensation was admirable. He was disposed to think at times it was too much condensed to satisfy the outside public. The reason he was disposed to advocate the admission of another reporter was that the Council was not a private body, but representative, and it was to the interest of the constituents who returned its members to know all that possibly they ought to know with regard to its transactions. It might be said that they could know this if they read the Journal, but unhappily they did not read the Journal to the extent they ought. This might improve, but at the present time it was very disheartening to find the indifference which existed amongst large numbers of provincial chemists with regard to the action of the Council. Now, if the Council could stimulate a greater interest by printing more widely the report of its transactions, it would tend to dissipate that indifference which all felt so much. He went mainly on the ground that the Council was not a private body, and that it was desired to disseminate as far as possible the result of its proceedings, and he knew no better means than the admission of a reporter of a journal which had its own special function. It might represent what was called the trade section, whilst the *Pharmaceutical Journal* represented the scientific section, but unfortunately they were more trade than scientific at present. In his belief no prejudice would arise to the Society's Journal, and no harm would ensue to the Society.

Mr. SANDFORD said he did not rise to propose an amendment, because he thought it would save time if the question were met with "Yes" or "No." He must say he failed to see that Mr. Hampson or Mr. Atkins had shown any reason why the Council should admit any

other reporter than its own. They said that if a report of the meetings went into another journal it would create greater interest and be more widely spread, certainly not amongst the members, because the Journal went to every member and associate of the Society, and it was the members and associates who were interested in what was said, not the outside members of the trade particularly. Then Mr. Hampson said he wished everything to be correct and impartial, but he added that he had no reason for saying that the present reports were not correct and impartial. Therefore that supplied no reason why the Council should admit another reporter. Then he said the members in London had an opportunity of adding to or taking from what they said in that room, but he would ask whether any member of the Council would add to or take from anything important he had said there. If he did Mr. Hampson or some one else at the next meeting would call him to account for having altered the report, and he had never heard such a complaint made. Then it was said that the Council had an interest as publishers of the Journal. He did not think that as publishers they gained anything by keeping it to themselves. They had been told by the editor of the *Chemist and Druggist* that he did not look at it at all as a trade question, or as a thing which would be attractive in his journal or increase its sale, therefore he did not think that could have any weight at all. Then it had been said that the Council must go into committee from time to time, and it was true it must. Taking the experience of that day, when one subject had been got half through it was proposed to go into committee, but what was the result? Mr. Hampson did not wish something he was going to say to be reported, and he simply turned to the reporter and expressed that wish, but if there had been a strange reporter present such a thing could not happen. He had received a letter from the editor of the *Chemist and Druggist*, as no doubt every other member had, saying he was going to ask not merely for the admission of a reporter, but of himself to watch their proceedings for editorial purposes, but the Council had never admitted even the editor of its own Journal.

Mr. HAMPSON said he did not ask that.

Mr. SANDFORD could not help thinking that the reports now sent out were so full that there really was no occasion to increase them, and that it would land the Council in great difficulties if there were a reporter present whom it could not control. It exercised no authority over its own reporter, but there was a usage or understanding as to what was proper to be reported, and he appealed to all members whether there had been any falsification or mystification of the reports, or whether there was any occasion to introduce a change. He should decidedly vote against the motion, and he hoped he should have a majority with him.

Mr. MACKAY approved of most of what Mr. Sandford had said, and had intended to follow very much the same line of argument, but would not now do so. He could not, however, quite agree with all Mr. Sandford had said, because he had a certain amount of sympathy with this resolution, inasmuch as he knew that country members would like the reports of the meetings extended to a greater length then they were. It would be in the remembrance of the Council that more than once this subject had been brought forward, and it had resulted in this, when the editor of the Journal was spoken to he said that if he were allowed a seat in the Council room during the discussion there would be more lengthened reports, but again and again that had been most positively refused. If the Council were now to relax the rule and admit a strange reporter, he thought it would be neither consistent or fair to its own editor. He also took exception to what Mr. Hampson had said as regards the opportunity given to London members of altering what they said in discussions so as to put another face on what was said. Mr. Sandford had given an answer to that, because it would not only be dishonourable but it would be soon found out and other members would not submit to it. He could not conceive why the editor of the *Chemist and Druggist* should be so extremely anxious to come there. He had the same report furnished to him in the beginning of the month as the other members, and was at liberty to use it in any way he thought fit in his own Journal. He could not see the correctness of the argument adduced by Mr. Atkins that because members to whom the Journals were sent failed to read them in the beginning of the month, they would read the report in the middle of the month in the *Chemist and Druggist*. The reports as a rule were very fair and impartial; his own feeling was that perhaps they were a little too short, and if this discussion should be the means of lengthening them he had no objection to that, but he certainly had a strong objection to the motion.

Mr. FRAZER said he intended to vote for the introduction of the reporter of the *Chemist and Druggist*, but he did not think the grounds upon which Mr. Hampson put his motion were very happy. The members of the Council had nothing to complain of in the reports, but he could not see that any harm would arise from an independent reporter being present. There was a feeling outside, which it would be well to remove, that things went on which the Council wanted to conceal. The Council always had the power of going into committee on any matter which was not to be published. He thought himself the editor of the *Chemist and Druggist* would gain nothing by his application being granted; at the same time it would cost the Society nothing, and would do no harm.

Mr. SHAW endorsed the remarks of Mr. Hampson and Mr. Atkins. He had been always thoroughly desirous that the fullest information should be given as to everything which took place in the Council. It was a public body charged with the administration of the Pharmacy Act, and therefore everything which took place during its deliberations which could be published ought to be published. This was a progressive age, and if the character of the reports of the Council meetings were considered during the whole of the Society's history, they had been progressing from one point to another. Was there any gentleman who wished to go back to the state of things at any former time? At the time of the passing of the Pharmacy Act, what kind of reports reached country members? And as a consequence, very little interest was excited throughout the country. It had been said that the notes taken by the reporter were sent to the editor who published them at his discretion, but it had also been stated by another authority that what the editor received he could neither alter, lengthen, nor shorten, so that he scarcely knew how the matter stood with regard to the reporting at the present time. He could hardly understand if a full report were given why the editor should have made it a special point that if he were present himself he would have given a more extensive report. With regard to what ought not to be reported, that was surrounded with quite sufficient safeguards. It was quite possible for the Council to go into committee at any moment, and he thought it was necessary that that rule should be more strictly observed. If there were an independent reporter present, the standing orders, which at present were almost a dead letter, would be more strictly observed. He presumed that although the editor of the *Chemist and Druggist* had made an application to be admitted, that formed no part of the question before the Council then. It had been said that the *Chemist and Druggist* was more or less a trade speculation, but he should like to say that that journal was dependent entirely on the trade, and he could not imagine that the *Chemist and Druggist* would report anything which took place at the Council which would be detrimental in any way to the trade in general. His impression was that the Society did not include more than about one-third of the chemists and druggists on the register, and it would be politic to admit a reporter, so that a full report of anything which took place might be conveyed to them. If they looked at what occurred

in parliamentary and municipal proceedings there was quite as much reason for excluding reporters from those bodies as there was from the Council.

Mr. BETTY said this was too important a matter to vote upon without fair and full discussion. It was a most radical change, the limits of which no man present could fully foresee. He did expect that the reasons given to induce the Council to take this step would have been of a far more decided character. The four principal reasons given by the proposer and seconder had been these. Not a word was said against the reports as they now appeared, but it was said the reports and the reporter were surrounded by influences not understood, and it was on this chimerical idea that the Council was asked to alter its proceedings. This was followed up by another idea that there was an undefined fear of an independent reporter, but these were merely mythical arguments. Again, Mr. Shaw urged very strongly why in his opinion this change should take place. He asked certain questions and founded his opinion on the answers to those questions which he supplied in his own mind. He said he did not know the mode of procedure at present, and yet he implied an answer, and stated he should record his vote in a certain way. He did not know whether the matter all got to the editor, and whether the editor was bound to publish everything, and yet on that ignorance he advocated this change. Mr. Atkins gave a cogent reason; that the debates were not sufficiently read by the publication in one journal, that they did not excite sufficient interest, and therefore they should be published in a second, in other words, people who would not read one journal would read two. That might be the way people reasoned in the west, but it did not commend itself to his mind. If the reports in the Society's Journal were not sufficient in importance when condensed as they were, could it be expected that a more watered report, which might be spiced up occasionally to suit the taste of casual readers, would excite sufficient interest to cause those reports to be more extensively read. When it was found that the four principal reasons given by gentlemen of great ability, who never left a point unnoticed when they urged a measure, were of this character, when there was this influence not understood, an undefined fear, and a question to which there was no answer, but on the answer to which the motion was supposed to depend, and the suggestion that people would read two papers because they would not read one, what was the value of such arguments? Speaking of the question now *de novo*, he said the present system was not a failure, and he appealed to the experience of every gentleman who had spoken, was there any one who dared to say that the present system was anything but a fair and impartial one? and if it was fair and impartial what more did they really want? It might be proposed to admit the whole press, and if one member of the press were admitted, the Council would be bound in consistency to admit whoever chose to apply. If the proceedings were fairly reported, why was such a radical change desired? If the reporter from the *Chemist and Druggist* were admitted, any one who spoke in the Council would not be speaking against a power which met him openly and combatted his arguments, but against an institution which stabbed him in the dark, a man whom he could not answer. Mr. Betty proceeded to give instances, which he did not wish reported, showing the style of comment adopted in the *Chemist and Druggist*, from which he argued that the editor of that journal had no claim to be admitted to hear the deliberations.

Mr. HAMPSON said he believed since the article quoted by Mr. Betty appeared in the *Chemist and Druggist*, that gentleman had himself moved a resolution similar to that he had now brought forward.

Mr. BETTY replied that it was his impression he had brought forward the motion before the appearance of the article referred to; the article had helped to alter his opinion. He contended that if the resolution were carried it would result in crippling all freedom of debate; and concluded by asking members of Council to pause before voting for the motion, and to be guided by those who had had long experience at that Board and knew the practical difficulties which would arise.

Mr. SCHACHT thought Mr. Betty, whilst ostensibly giving reasons for voting against the proposition, had really supplied a strong argument in its favour. His chief objections seemed to be founded on the fact that the editor of the journal who now made application for the admission of a reporter did not deal kindly, generously, or fairly with the Council. He did not wish to defend everything he had read in the *Chemist and Druggist*; if he did he should be stultifying himself, for he had several times fallen under the lash. He did not know that it had done him much harm, and he had always said there was some excuse for the editor, because he did not know what occurred in the Council. His feeling was that the true security against all those misrepresentations which had occurred or might be supposed to occur lay in the one principle now generally admitted, namely, the most thorough and complete publicity, by which all misrepresentations were in the long run corrected and set right. The position to-day was simply like what it would be in the House of Commons if all reporting except Hansard's authorized reports were forbidden. The idea that because a Conservative Government at the present moment ruled the country, the editor of the *Daily News*, for instance, should not be permitted to send a reporter to take the speeches in Parliament, because he had made vehement, and even, in the opinion of the Government, incorrect representations about the authorities was simply ridiculous. He would let the editors of all the journals in town send reporters if they pleased. The facts would speak for themselves. If his conduct deserved criticism let it have it, and he knew that in the long run he should be done justice to. Supposing the editor of the *Lancet* were to apply for permission to send a reporter he should support it, or, being regarded as administrators of a certain law, if the *Times* thought right to seek admission for a reporter he should welcome the application. The Council was a public body, doing public work, and in his opinion it would be safe in the hands of those whose business it was to report the proceedings of public bodies. He believed the editor of the *Chemist and Druggist* would give a better report of what occurred than he had done if a reporter were sent, simply because he could be pinned to his own report. The fact could not be ignored that the *Chemist and Druggist* had a large circulation amongst those who did not take in the *Pharmaceutical Journal*. It was important that the proceedings of the Council should be reported widely. He should support the motion because when a broader question came before the Council he had voted for admission of all reporters.

The PRESIDENT said he had had an amendment placed in his hands that the debate be adjourned, which he would at once put to the vote.

On being put the amendment was lost, and the debate therefore continued.

Mr. GREENISH said there appeared to be a growing interest in the country with regard to the proceedings of the Council, and he really was not surprised at it when so many pressing questions were continually coming before them affecting the very existence of the trade. He thought it was a very good sign and a very hopeful sign, and he should not object to see the whole of one number of the Journal devoted to the proceedings of the Council. He had no objection to the proceedings as now reported, for it seemed to him they were reported with remarkable accuracy and great fairness, but if the members outside wished a reporter from another journal to be present, by all means let him be admitted. It would then be necessary for the President to keep the Council to the standing orders. It had been hinted that the Society's own Journal would suffer, but he did not consider that that Journal was so inefficiently conducted or so artificially supported

as to require such a monopoly. He had full confidence that it would hold its own.

Mr. WOOLLEY said one point did not seem to have been pressed, namely, that the *Chemist and Druggist* was a trade organ. The *Pharmaceutical Journal* did not get to all the members of the trade, and he thought it highly desirable that they should all have the means of knowing everything that took place in that room. Mr. Betty had alluded to some of the imperfections of the *Chemist and Druggist*, and he was not going to say it was perfect, neither was any one perfect, not even Mr. Betty, nor even the *Pharmaceutical Journal*, as witness, a letter that appeared on page 1019, which he considered a most disgraceful production, and which ought never to have been published. He did not think anything worse had ever appeared in the *Chemist and Druggist*.

Mr. FAIRLIE said his object in asking for an adjournment was that the matter might be gone into more fully. He came to the Council fully prepared to vote for the admission of reporters, and he should vote in favour of the motion, although he should be in favour of going a little further and admitting the editors of the two journals as well. In the meantime this was an instalment in the right direction. Mr. Sandford referred to people outside the Society taking no interest in the proceedings of the Council, but he fancied that was a mistake. At any rate if they did not the sooner they could be got to take an interest the better. The question of going into committee had been talked of, and the objection had been made that if any gentleman wished to make a particular observation, which he did not want reported, there would be no opportunity of doing so. But even in public meetings, where reporters were present, members of Parliament and others frequently made remarks with a previous intimation that they did not wish them recorded, and that was attended to. He thought they could trust any reporter who might be sent there. With regard to the correctness of the report he wished to mention one point with reference to the last number of the Journal, which he thought ought to be noticed, although no doubt it was done inadvertently. When he called attention to the position of the Registrar and Secretary, a remark was made by the President that by the bye-laws the two offices were combined. He called that in question at the time, though he did not wish to put his opinion against the President's, and on looking again he did not see anything in the bye-laws uniting the two offices. The fact of the matter was the two offices, both in the Act of Parliament and bye-laws, were distinct and separate.

The PRESIDENT said the report exactly represented what occurred at the Council.

Mr. FAIRLIE said except that he called the President's statement in question. Remarks had been made about the personal character of the *Chemist and Druggist*, but it was undoubtedly the representative of the trade outside the Society, and as such he thought it would be an advantage to the Council that the reporter should be present. He believed that members then would take more care what they said, and that they could keep their proceedings in better order. He had only been there a very short time, but he had been connected with other organizations, and he had never seen any such disorder in the conduct of any number of business men. They ought to keep closer to the standing orders if they were to get through the business in a proper and business-like way.

The PRESIDENT said when he heard that this resolution was to be proposed, he wrote to the editor of the *Chemist and Druggist* and told him he should oppose it, giving his reasons. And when he found it was to come forward he thought at first that though Mr. Hampson might move such a resolution, he would hardly obtain a seconder. However, he found that a great number of the Council took the extraordinary view, as he thought, that it was a perfectly reasonable request and a proper thing to ask. He could not help putting the question to himself, what was this gentleman going to be present at the Council for? He supposed he was not wrong in saying that the reporter would mean the editor himself, because his Journal came out ten days after their own, and he would have the benefit of its report, which probably would be his pabulum, and then he probably intended to spice it, as he found the report of the last annual meeting of the Society was treated. He asked the gentlemen present whether they would deliberately allow themselves to be ridiculed and insulted in every way, and to be held up to derision before the whole trade. He should be sorry to do so, and would ask members to reflect before they voted for the motion. The question as put by Mr. Betty was whether the Council would give up all control over the report of the proceedings of the Council as it now appeared, which report, all agreed, was reasonable and proper, and leave it to an outside person who would not be answerable to anybody.

Mr. BOTTLE said he intended to vote against this motion very much against his own wish, for he felt that as the Society was advancing one would like to see its proceedings spread far and wide, fairly and honestly; but he must confess, judging by the reports which had appeared in the *Chemist and Druggist* during the last year or two, reflecting on the Council and on the members, from the President downwards, that he had no confidence in the editor of the journal, and on that ground he should vote against the motion.

Mr. HAMPSON in reply said he should first call attention to the remark of the President, who spoke of giving up control of the report, and Mr. Sandford also stated that the Council could not control this reporter if it admitted him. Did it wish to control him?

Mr. BETTY remarked that Mr. Hampson himself wished it when he asked, during that very debate, that certain observations of his own should not be reported.

Mr. HAMPSON said he was bound to utilize the present position of things. He was confident that if an independent reporter had been present he would be placed on his honour as a gentleman, and there would be less liability to those attacks which had been referred to than at present. It was quite possible the motion might not be carried, but he did hope that members of Council would hesitate before they voted against it. The report as at present issued, controlled by the Editor or by Mr. Sandford, or by the President, was not a free and independent report. He wanted the report to be such as would produce confidence in the minds of the members at large. If there were a report by an independent man it would do a great deal of good, and a little healthy criticism from the *Chemist and Druggist* would be no disadvantage. He did hope that at this time of the nineteenth century, when all bodies, high and low, were bound to conform to what was considered desirable, equitable and right, that such a simple request as the one now made would not be refused.

The motion was then put with the following result :—

For—Messrs. Atkins, Fairlie, Frazer, Greenish, Hampson, Savage, Schacht, Shaw and Woolley.

Against—Messrs. Betty, Bottle, Cracknell, Hills, Mackay, Rimmington, Robbins, Sandford and Williams.

The numbers being equal, the President gave his casting vote against the motion.

ELECTION OF MEMBERS OF COUNCIL.

Mr. FRAZER then brought forward the motion of which he had given notice as follows :—

> "That a Special Committee be appointed to consider the practicability of effecting a change from the present imperial mode of electing members of Council to one of district or territorial representation, and to report at the Council meeting in October next."

The PRESIDENT said when he saw the notice of motion he thought there was an illegality in it, and wrote to the solicitor for his opinion upon it. The reply was in effect that the proposed alteration could not be made without a special Act of Parliament.

Mr. Frazer said he thought all that would be required would be an alteration in the bye-laws. His idea was that the question should be considered and that it should then be brought forward at the next annual meeting. If it required an Act of Parliament it might be introduced at any time the Society was going to Parliament for any other purpose.

Mr. Fairlie suggested that it should be remitted to a special committee to bring up a report at the next meeting.

Mr. Hills thought it would be better to refer it to the sub-committee of the Parliamentary Committee.

The President said he had no doubt that the question having been raised it would be considered by that sub-committee when the question of a fresh Act of Parliament came up.

Mr. Bottle thought the principle should be settled by the Council before it was sent to a committee at all. He objected to it *in toto*, and thought the present mode was preferable.

Mr. Shaw also objected to the principle of the motion.

Mr. Hampson suggested the desirability of deferring the discussion, to which Mr. Frazer consented.

Proposed Grant to the Chemists and Druggists' Trade Association.

Mr. Fairlie then brought forward the following motion, of which he had given notice:—

"That the Treasurer be requested to pay to the Treasurer of the Chemists and Druggists' Trade Association of Great Britain, the sum of One hundred pounds sterling (£100), for the purpose of assisting that association in its defence of the case 'Apothecaries' Company *v.* Shepperley,' now pending in the Law Courts."

Some difficulty having been found in obtaining a seconder, it was suggested that as the case referred to was *sub judice* the matter should be discussed in committee.

This was agreed to, but after some discussion Mr. Fairlie withdrew the motion, saying he saw pretty plainly that he should not be able to carry it.

A report of a meeting of chemists and druggists at Hull was read, with resolutions, urging the Council to take steps to reverse the decision of the County Court Judge in the case of the Society *v.* the London and Provincial Supply Association.

A letter was also read from the Local Secretary at Halifax, containing a resolution from the Chemists' Association of that district, in reference to the right of chemists and druggists to prescribe in simple ailments, and urging the Council to give substantial pecuniary assistance to the Chemists and Druggists' Trade Association in its efforts to defend and maintain that right.

The sitting was concluded at six o'clock.

Violet Powder.

Sir,—In common, no doubt, with other analysts, I have received a great number of samples of violet powder for analysis, and without offering an opinion as to what the composition of articles bearing that name ought to be, I have considered it my duty to endeavour to allay any unnecessary alarm which recent lamentable accidents connected with the use of such articles have tended to produce. You have, I think, sufficiently indicated in your leader last week that the term "violet powder" is applied to several preparations, differing greatly in composition, and not always used for the same purpose. I can fully confirm your statement that there are two principal varieties of so-called violet powder in commerce, starch forming the basis of one, and hydrated sulphate of calcium that of the other, while there are several sub-varieties produced by the addition of other ingredients. But while I admit the justness of your remarks in some respects, I cannot agree with your implied objection on merely inferential grounds to the use of hydrated sulphate of calcium as a dusting powder. It has been long and very extensively used, without, as I am informed, any fault having been found with it, and in cases that have come under my immediate observation it has proved very beneficial, and in the estimation of those using it sometimes preferable even to starch.

July 3, 1878.

The Recent Case of Poisoning by Strychnia.

Sir,—The case reported in the Journal of the 22nd ult. should scarcely pass without comment. Both jury and medical press attach the chief blame to the pharmacist who dispensed the medicine and we thus get verdicts from the public and medical points of view. Looked at pharmaceutically, however, the matter bears a different aspect, and tracing the evil to its source we find it arises from the prescriber ordering poisonous medicines in a concentrated form. Most of us dispense such prescriptions under a moral protest and with a feeling that no apparently reasonable charge compensates us for the responsibility; therefore, when an accident such as that recorded does occur it can scarcely be regarded as just that the dispenser should bear the blame.

Charles Symes.

Liverpool.

The Admission of Women to the Society.

Sir,—I only know by hearsay that a controversy has been kept up in your columns upon the manner in which the recent annual meeting dealt with the claims of "examined" women to the rights of membership of the Society. I have not read the correspondence, nor is it likely that my observations, which will abstain from collateral issues, will touch any of its points; yet I believe they will be found to contain the most practical solution of the question.

The Society admits women to its examinations and has thereby rendered women as a class eligible to become "members of the Society" by the most honourable mode of qualification. Is it not absurd then to declare that as a class women shall not be elected?

A speaker at the annual meeting stated his intention, in conjunction with others, to bring the case before the Courts for decision upon its legal merits, and I have no doubt that judgment would be given in favour of the women's claims and against the hot and cold action of the Society.

It seems a pity that men, who have so unmistakably the best of it in the affairs of life, should grudge so small a grace to women, when it can only be withheld by a questionable interpretation of their executive powers.

THE PARIS EXHIBITION.

Crude Materials applicable in Medicine and Pharmacy.

In the French department, as distinguished from the French colonies, the exhibit of crude drugs is remarkably small, and the specimens do not form a special collection but are intermixed with the chemicals and galenicals. As might be expected, Senegal gum is well represented, the specimens exhibited by Messrs. Rousin-Morel containing two fine tears about 5 inches in length by 3½ in diameter. The varieties here exhibited are very numerous, comprising about fifteen different commercial kinds. Some fine specimens of tragacanth are also contained in the same case.

The show case of M. Coutela, Paris, contains very fine specimens of tonquin musk, and cantharides; also, specimens of castoreum, rose petals, Pará rhatany, yellow calisaya bark, and Ignatius beans, all of the specimens being evidently carefully selected. Some belladonna and jaborandi leaves are excellent examples of careful drying. The name at the foot of the case is tastefully made up of various blistering insects and their adulterations, among which are Spanish flies, Chinese cantharides, rose beetles (*Cetonia aurata*), *Chrysomela fastuosa*, and a small brilliant pale blue insect, which was labelled *Hophia brunipes* in the collection of forestry products. The effect thus produced is remarkably pretty and effective, and is well adapted to imprint the name of the firm on the memory.

In Class 46, which consists of agricultural products not used as food, may be found a few exhibits to which pharmacy may justly lay some claim. Among these are hops, wax, and honey, saffron, madder, linseed, and other oil seeds, and resin.

During the past ten years the cultivation of the hop has become considerably extended in France, especially in the Nord, Pas de Calais, Aisne, Meurthe-et-Moselle, Vosges and Côte d'Or departments, the total annual yield being now about 4,400,000 kilogrammes. Nevertheless in 1876 hops were imported into France to the value of 28,381,914 francs, and, what is more singular, the exports of hops were about half that value during the same period. The exhibits of hops include specimens among which are compared side by side hops from North America, California, Kent, Belgium, Bohemia, Molsheim, Wissembourg, Burgundy, Lorraine, and the Côte d'Or. Of these the American and Californian are remarkable for their pale colour; those from Belgium approach most nearly in appearance to Kentish hops, while all the other varieties have a decidedly green tinge.

Some very good specimens of saffron are exhibited in this class, notably those of Messrs. Chapellier and Marchenay. Here may be seen, compared side by side, saffron from the ordinary saffron crocus and from those of China and Greece. The specimens are also accompanied with dried specimens of the flowers and bulbs, and mounted specimens of the stigmas, as well as seeds and specimens of the colouring matter (polychroite), which thus form a valuable and instructive series. M. Chapellier attaches to his exhibit some remarks, from which the following information is taken :—

The Greek saffron crocus was introduced into France in 1862, by Mons. Paul Chapellier, and at his suggestion a quantity of bulbs were imported from the Greek Archipelago by the Conseil Général of the Loiret, and distributed to the various cultivators of saffron in the Gâtinais. M. Chapellier has now ten thousand of these bulbs in cultivation. He gives as his experience that the Greek crocus exhibits a great tendency to sport and form varieties. The ordinary saffron crocus cultivated in the Gatinais appears to have lost the power of producing fertile seeds, and varies but little. It is, however, easily fertilized by the Greek plant, and M. Chapellier is at present engaged in selecting and cultivating the best hybrids so obtained, in the hope that a variety may result which will be more valuable than either of the parents, the Greek crocus giving a larger yield of saffron and the Gatinais plant saffron which is richer in colour and flavour. Other specimens of Greek saffron may be seen in the Greek department.

The Chinese saffron crocus was introduced in 1868 by the Société d'Acclimatation, at the instance of the same enterprising gentleman, who has during the last thirty-five years paid considerable attention to the genus and for the purpose of experiment has in cultivation about forty species of crocus, as well as a great number of varieties. The general opinion of saffron cultivators appears to be that the Chinese saffron is superior to that of the Gatinias.

Other specimens of saffron from M. Grasas, of Marseilles, exhibit different qualities as used for colouring vermicelli, for baking, powdering, and dyeing.

The exhibit of resin by M. Lesca, of La Teste, Gironde, is particularly interesting, since it not only shows the different products obtained from the fir tree, but the instruments used in collecting them. The resin is chiefly obtained from the "pin maritime" (*Pinus Pinaster*, Sol.), and the yield is said to have considerably increased since this species has been cultivated on the sand dunes of the shore of Gascony and the replanting of the hills of the southern districts. In 1874 the quantity collected amounted to 29,395,417 kilogrammes.

To obtain the resin, incisions are made into the tree with a kind of curved axe, and the resin is allowed to run into vessels which bear some resemblance in shape to a flower pot. For removing the resin which adheres to the bark another instrument called a *racloir*, which reminds one of a hoe, appears to be used. The products obtained are the *barras* or crude turpentine which dries on the tree, answering to what is known in England as gum thus; the *galipot* which is the same product but of better quality; the *gomme* or liquid turpentine as collected; and the *essence de terebinthine*, the *colophane* and the *resine jaune*, obtained by distilling it; *brai gras* (pitch), and *goudron* (tar). A fir tree 60 to 70 years old is said to furnish 6 to 8 kilogrammes of crude turpentine, equal to 2 kilogrammes of *barras* or *galipot*. The home consumption of these products amounts to about nine millions of francs, and that exported to Belgium, England and Germany to another six millions.

Other specimens of these products, of excellent quality, are exhibited in the building devoted to agriculture and horticulture, near the banks of the Seine, by Mons. Dive, pharmacien, Mont de Masson.

In this class (46) also the herbalists are well represented. The specimens of dried coltsfoot, violet, red poppy and camomile flowers exhibited by M. Lemonnier, are remarkable for the brightness of their colour, and in the collection sent by the Association General des Herboristes, the cowslip, daffodil, and marigold flowers seem scarcely to have been altered during the drying process. The rhubarb root will not, however, bear any comparison with that pro-

duced in England. To see the perfection to which it is possible to carry the drying of flowers the visitor should go to the Belgian department, where those exhibited by M. Cornelis, of Diest, must carry off the palm. At the first glance it is difficult to say whether the flowers are real or artificial, so beautifully are the colours and form preserved, while the colour and odour of the powders, preserved in the bottles containing lime in their stoppers, leave nothing to be desired.

To return to the French department, a collection of exotic drugs by M. F. J. Key, contains several Brazilian remedies which have of late years attracted attention. One of the most striking and amusing specimens of advertisement to be seen in this group is a glass jar of about three pints capacity full of cockroaches, said to have been killed in one night by the insect powder sold by the exhibitor.

Not far off from this exhibit is the *Zostera marina*, which is used instead of wicker-work for protecting glass bottles, stone jars, steam tubes, etc., besides many other uses which pertain rather to upholstery than pharmacy.

Some excellent specimens of dried herbs compressed into packets are exhibited in the agricultural building by M. J. Gautier, pharmacien, of Clermont-Ferrand, a carefully dried specimen of each plant being placed in front of but under the glass of each glazed box.

Other well prepared specimens in bottles are from M. Olivier, pharmacien, of Chalons-sur-Marne. In this department also may be seen, labelled "roses papales," the malvaceous flowers (apparently the dark variety of *Althæa rosea*) which are said to be used extensively to colour wines.

In Class 45, which includes products of hunting and fishing, may be seen a collection of seaweeds and their products, exhibited by M. Stenfort, including specimens of the *Eucheuma spinosa*, used in Australia for making jelly (specimens of which occur also in the West Australian department), *Gelidium spinosum*, used in Eastern Asia for making Chinese and Japanese "isinglass," and edible swallows' nests. Artificial leather for binding books, purses, boxes, artificial flowers, pastilles, dragées, size, and numerous applications bear witness to what account it is possible to turn even seaweeds. One of these, a powder made in France from indigenous algæ, in imitation of Chinese isinglass, has been used at Rouen with considerable success as a dressing for calico, etc. A description of this article is deferred until the *thao* in the Cochin China and Japan collections is alluded to.

The exhibit of sponges in this class (45) is very good, and comprises an infinite variety of forms. Some remarkably fine specimens are exhibited by Messrs. Cresswell and Hersent, which are from one to two feet in diameter. The natural mode of growth is shown by specimens *in situ* on old vases, coral and shells, which are tastefully displayed by these exhibitors. Messrs. Coulombel Frères and Devismes, who also show some magnificent specimens, have rendered their collection especially interesting by exhibiting a sponge preserved in liquid, exactly as it grows before the soft animal matter has been destroyed. The appearance of the sponge in this state is by no means attractive, being apparently of a dark greenish colour. Messrs. Leroux and Fedit exhibit sponge mounted for various purposes, such as for washing the interior of the ear, for washing plants, for cauterizing; also compressed in cones, pencils, and cylinders, in flat sheets for grooming, etc. The imports of sponges into France amounted in 1876 to 257,878 kilogrammes, about one-third of which was afterwards exported.

In Class 44 are numerous exhibits of cork, both raw and manufactured. The Société Anonyme des Liéges de l'Edough shows an instructive series of sections of trees of various ages, demonstrating the thickness of the layers of cork at the different stages of growth. The various applications of cork, such as covers for glass stoppers, and cork dust made into a coating for bottles or steam pipes, are well represented by several firms. The manufacture of corks in France is stated to occupy the population of about forty parishes. Formerly a workman could only make 1200 to 1500 corks a day, but since the introduction of machines 4000 to 6000 can be produced, according to the size required. The cork trade appears to be increasing considerably in France, the importations of the bark having risen during the last twenty years from 257,000 francs to 2,940,000 francs. The bark collected during the first twelve or fifteen years of the growth of the cork tree is used for life buoys and ornamental gardening, or burned in close vessels to form Spanish black, the superior kind used for corks being obtained from the sixteenth to the twenty-sixth year of its age, during which period it is softer and of finer grain. In the left annex may be seen cork-cutting machines in action, and in the Algerian house, near the Trocadero, the advantages and disadvantages of hand and machine cutting may be compared together, a native man being employed there constantly to cut them by hand, while a woman cuts them by machinery.

The building devoted to the exhibits of the Administration of Forests contains much that is interesting and instructive. Here are numerous herbaria containing specimens of trees and plants having medicinal and economical uses, each specimen having notes attached as to the geological formation in which it grows, the limits of latitude, longitude, and altitude to which it is confined, its rate of growth, average height and age, the time of appearance of the leaf, flower and fruit, and the proportional importance of its distribution and uses, thus giving at a glance a condensed natural history of the plant.

The collection of insects useful and injurious in forests also claims attention, since it comprises bees and their products, wax and honey, cantharides and gall insects. A very interesting specimen exhibits the influence exerted by insects on the growth of trees. This consists of a transverse section of an oak trunk in which every third ring is much narrower, and evidently points to a starved condition of the tree during the year of its formation. This is attributed to cockchafers stripping the tree of leaves, it being well known that the larva of this insect takes three years to come to perfection.

Among the galls are exhibited the knoppern gall, the Medusa's head gall, and a large gall very similar in appearance and size to the Bussorah gall, but not red or polished like that kind; it is produced by *Cynips argentea*. These galls are rarely if ever seen in England, growing chiefly on *Quercus Cerris* and *Q. pubescens*. The common English oak gall (*Cynips Kollari*, Hart) and the artichoke gall are also noticeable.

These are the principal crude materials interesting to the pharmacist in the French court, but a much richer harvest awaits him in the section devoted to the

FRENCH COLONIES.

Under this head it is purposed to describe the specimens of drugs exhibited from French Guiana, Martinique, Guadeloupe, Senegal, the Gaboon, Cochin China, the French colonies in India, and the islands of Reunion, Tahiti and New Caledonia. The collection is arranged in a long room at the end of the Exposition near to the Ecole Militaire, and comprises many hundreds of specimens neatly arranged on rectangular stands furnished with shelves. The specimens are mostly contained in stoppered bottles, and are carefully labelled.

Algerian products will be afterwards treated of, as these are contained in a separate building near the Trocadero. The exhibit of drugs in the French colonial department may be considered, both for number, arrangement, excellent preservation of the specimens, and value, one of the best in the Exhibition. An excellent descriptive catalogue of the products, which greatly enhances their value, has been published, for an early copy of which the reporters are indebted to the kindness of M. Aubrey Lecomte, the able commissioner of this department.

French Guiana.

From this colony several well known drugs, such as citronelle, sarsaparilla, grains of paradise, curari poison and darts poisoned with it, from Rio Negro and Cayenne, *Cissampelos Pareira*, lime juice, and *Simaruba*, *Quassia amara* (called here "quinquina de la Guiane"), are exhibited. The bark of the tamarind tree is used as an astringent. Balsam of copaiba is said to be procurable in large quantity in the neighbourhood of Oyapock, especially on the mountain Racaoua. Guarana is rather scarce. The root of *Abuta amara*, which is called in 'Pharmacographia' yellow pareira brava, is exhibited in this collection as a remedy not for diseases of the bladder, but for obstruction of the liver, a use to which its yellow colour has probably served as an indication. Under the familiar name of centaurée the *Coutoubea spicata* is used as a stomachic and febrifuge.

Several plants used in British India are also to be found here. Among these may be noticed a species of *Plumbago*, of which the leaves and roots are used as a vesicant; *Ocymum basilicum* and *O. sanctum*, employed in the form of tea as a sudorific; the purgative seeds of *Jatropha multifida*; and the astringent leaves and roots of *Psidium pomiferum*, and *P. grandiflorum*. *P. aromaticum*, a nearly allied species, which, from its name of "citronelle grand-bois," might be supposed to have a citronelle odour, is used in the form of infusion of the leaves as a stimulant and antispasmodic. The leaves of *Ayapana* (*Eupatorium ayapana*) appear in this list under the name of "thé de l'Amazone." Among the remedies for worms are *Chenopodium anthelminticum* and the seeds of the papaw tree (*Carica papaya*).

The drugs apparently peculiar to this colony are as follows:—

Anona muricata, natural order, Anonaceæ (Corossolier).—The leaves are used as a valuable antispasmodic; the seeds as an emetic.

Astrocaryum vulgare, natural order, Palmaceæ.—Under the name of Aouara the root is used as an antisyphilitic remedy.

Boerhavia diandra, natural order, Nyctaginaceæ. Used as an emetic and cathartic under the name of "ipecacuanha du pays." In Martinique it is known as "ipeca de Guiane."

Bignonia copaia, natural order, Bignoniaceæ.—The bark is used as a purgative, and the leaves as a remedy for the yaws or pian.

Bignonia alliacea, called "the garlic shrub" from its powerful odour, is used as a febrifuge.

Carapa guianensis, natural order, Meliaceæ.—Bark used, and also in Martinique, as a bitter tonic and astringent, and the oil from the seeds for healing wounds. (This oil will be further alluded to under British Guiana.)

Cedrela guianensis, natural order, Cedrelaceæ.—Bark used as a tonic and febrifuge.

Coccocypselum tontanea, natural order, Rubiaceæ.—Used for congestion of the liver. The entire plant is used. It might perhaps be worth a trial in this country.

Eryngium fœtidum, natural order, Umbelliferæ (Azier la fièvre).—Used as a sedative in asthma, and in Martinique the roots are used as an emmenagogue and diuretic under the name of "chardon étoile" or "benit."

Guarea Aubletii, natural order, Meliaceæ.—Root-bark possesses powerful emetic and purgative properties.

Hypericum lactiferum.—The resinous juice is purgative.

Hyptis capitata, natural order, Labiatæ (Mélisse indienne).—Used as a pectoral and sedative.

Justicia pectoralis, natural order, Acanthaceæ.—A tea made from the leaves is used as an aromatic pectoral.

Lonchocarpus Nicou.—Used to intoxicate fish.

Mucuna urens, natural order, Leguminosæ.—The seeds of this plant, commonly known as "asses eye bean," are used in French Guiana for hæmorrhoids. They are slightly diuretic, but have a considerable hold upon popular estimation, both in French Guiana and in Martinique.

Myristica sebifera.—The bark is astringent.

Potalia amara (Grand Matévé).—The infusion of the leaves is used as an emmenagogue and antisyphilitic; in large doses it is emetic.

Vateria guianensis, natural order, Leguminosæ.—The seeds are rasped, and mixed into a paste with vinegar as a tropical remedy for ringworm, hence the tree is known as "bois à dartres."

A CONTRIBUTION TO OUR KNOWLEDGE OF THE ALKALOIDS OF ERGOT.*

BY T. BLUMBERG.

I. Ecboline and Ergotine.

Under the title, "On the Active Constituents of Ergot," Wenzell published in 1865 the results of his work, having for its object the isolation of the active substance of ergot. His investigation led him to the discovery of two alkaloids, one of which he named "ecboline," the other "ergotine." The action of ergot he attributed to ecboline. His method of procedure was as follows:—

An extract of ergot prepared with cold water was precipitated with sugar of lead, dissolved lead was removed with sulphuretted hydrogen, and the clear liquid after separation from the resulting precipitate was treated successively with equal parts of a concentrated solution of mercuric chloride and a similar solution of potassium carbonate. The precipitate formed was washed, suspended in pure water, decomposed with sulphuretted

* Inaugural Dissertation presented by the author upon attaining the grade of Magister of Pharmacy at the Imperial University at Dorpat.

hydrogen and the mercuric sulphide removed by filtration.*

One portion of the filtrate deposited upon slowly evaporating small cubic crystals. Another portion when heated gave off an odour of trimethylamine. Phosphorus molybdate produced in it a yellow flocculent precipitate. The residue from the evaporation of the filtrate yielded upon stronger heating a sublimate of trimethylamine hydrochlorate, besides free hydrochloric acid and a coaly mass.

A portion of the filtrate was treated with potash in excess, heated until all the trimethylamine was driven off, again acidified with hydrochloric acid, and phosphomolybdic acid added. A flocculent precipitate resulted, which pointed to another alkaloid.

To separate the two bases a watery extract prepared from 250 grams of ergot was saturated with potash, precipitated with barium chloride, filtered, the filtrate decomposed with 15 grams of potassium bicarbonate and again filtered. This filtrate was decomposed with 120 grams of a concentrated solution of mercuric chloride, allowed to stand twelve hours, the precipitate collected, and, after washing, decomposed with sulphuretted hydrogen. The liquid filtered off from the mercuric sulphide had an acid reaction. It was freed from sulphuretted hydrogen by heating, and then fractionally decomposed with solution of mercuric chloride. In this way six precipitates were obtained, of which the first three were greyish-white and voluminous, the last three were dense and almost white. The liquids obtained by the decomposition of the first and second precipitates with sulphuretted hydrogen were of a sherry wine colour, had an acid reaction, yielded no crystallization upon evaporation, and, in Wenzell's opinion, gave off no trimethylamine when warmed with potash. They contained ecboline with a little ergotine. The solution from the third precipitate had the same colour and reaction, but became dark upon evaporation. It gave off no trimethylamine and contained no ecboline, being principally ergotine. The solutions obtained from the fourth, fifth, and sixth precipitates consisted of hydrochlorate of trimethylamine, ergotine, and much free hydrochloric acid.

Wenzell considered that by these fractional precipitations the presence of two new bases, besides trimethylamine, had been demonstrated. He effected their complete separation by treating a fresh quantity of aqueous extract of ergot with sugar of lead, removing excess of lead from the filtrate with sulphuretted hydrogen, concentrating the liquid and adding powdered mercuric chloride as long as a precipitate was produced. The precipitate was removed by filtration, washed, suspended in pure water, and decomposed with sulphuretted hydrogen. After filtering off the mercuric sulphide the liquid contained only ecboline as a hydrochlorate. The filtrate from the mercuric chloride precipitate was decomposed with phosphomolybdic acid which threw down the ergotine. This precipitate was suspended in water, digested for some time warm with barium carbonate, and the solution of alkaloid, after filtering, carefully evaporated. In this way the ergotine was obtained in a pure state.

The solution of hydrochlorate of ecboline was treated with freshly precipitated silver phosphate, the silver chloride filtered off, lime added to the filtrate to fix the phosphoric acid, again filtered and carbonic acid gas passed in to separate excess of caustic lime. The calcium carbonate being removed by filtration, the alkaloidal solution was evaporated to dryness at a moderate temperature.

Both alkaloids formed, when dry, an amorphous brownish varnish, having a slightly bitter taste and an alkaline reaction, and dissolving in water and in alcohol. They were insoluble in ether and in chloroform, and difficultly soluble in methylic alcohol. With acids they formed amorphous deliquescent salts. When boiled with potash solution they gave off no ammonia, but yielded it abundantly when heated with soda-lime. When heated they puffed up, carbonized, and finally burnt without leaving any ash.

The ecboline was said to be distinguishable from ergotine by its behaviour towards a group of reagents. When isolated they both gave with mercuric chloride a precipitate, the ergotine precipitate being slightly soluble in water. Ecboline gave with platinum chloride at once an orange-yellow amorphous precipitate, but ergotine only upon the addition of ether-alcohol. Potassium cyanide precipitated ecboline, but not ergotine. Tannic acid gave with ecboline a flocculent precipitate, soluble in alcohol, but gave with ergotine a precipitate only in concentrated solutions.

Manassewitsch* obtained through fractional precipitation with mercuric chloride four precipitates, which after decomposition with sulphuretted hydrogen all yielded solutions that gave off trimethylamine upon boiling with solution of potash. The solutions of the first two precipitates were yellowish and had an acid reaction, and upon evaporation left a dirty-brown residue soluble in water and alcohol. Phosphomolybdic acid gave with this a precipitate. Platinum chloride produced in the aqueous solution no precipitate, one forming first on the addition of ether-alcohol. Manassewitsch compared the reactions of pure ergotine with those of this residue and came to the conclusion that they were identical.

The third and fourth precipitates yielded after decomposition with sulphuretted hydrogen solutions which he could not in any way distinguish from the first and second.

Wenzell obtained ecboline from his first two precipitates, but found no trace of trimethylamine. Manassewitsch was unable to accept the existence of ecboline, because though it should have been precipitated by potassium cyanide, he never observed any such a precipitation.

Manassewitsch says further that he did not succeed in preparing ecboline; he obtaining on each occasion, instead of that alkaloid, a brownish-black substance insoluble in alcohol, which when ignited with soda-lime gave off no ammonia.

Manassewitsch prepared ergotine by precipitation with phosphomolybdic acid, obtaining 25·13 grams from about $1\frac{1}{2}$ kilos. An elementary analysis of this body gave figures corresponding with the following percentage composition :— C = 82·60 ; H = 7·25 ; N = 3·98 ; O = 6·17 ; agreeing with the formula $C_{50}H_{52}N_2O_3$. To the platinum salt was attributed the formula $C_{50}H_{52}N_2O_3HCl+PtCl_2$; but he obtained 9·81 per cent. of Pt, instead of 10·5 per cent.

Manassewitsch also obtained ergotine, as he believed, in a pure condition by the following process. Ergot was macerated during three weeks in water acidulated with hydrochloric acid. The extract was filtered and evaporated at 35° R. The residue was diluted with water, filtered, the filtrate treated with phosphomolybdic acid in excess, the precipitate dried at a moderate temperature, then mixed with caustic baryta, and the mixture ignited in a retort connected with a vessel containing hydrochloric acid. Upon increasing the temperature trimethylamine was volatilized. The residue in the retort was boiled with 90 per cent. alcohol, the baryta removed with carbonic acid, and the filtered alcoholic solution evaporated. The residue formed a brownish-black varnish-like substance, which gave off ammonia when ignited with soda-lime. It was soluble in water and in alcohol, but insoluble in ether.

In 1869 Wenzell's statements with respect to ecboline were confirmed by Hermann.† A year later ecboline and ergotine were prepared by Ganser.‡

* Vierteljahresschrift f. prakt. Pharm. (1865), xiv., 18.

* *Pharmaceutische Zeitung f. Russland*, vi., 387.
† *Pharmaceutische Vierteljahresschrift*, vol. xviii., p.481.
‡ *Archiv der Pharmacie*, 1870, vol. 144, p. 195.

Hermann modified Wenzell's method somewhat. From the ergot extract purified with lead acetate he removed excess of lead with sulphuric acid, neutralized this with sodium carbonate, and precipitated the ecbolinc with mercuric chloride.

Hermann digested one part of the precipitate with lead oxide, dried the mixture and exhausted it with alcohol. The alcoholic extract left upon evaporation only a small residue which was not bitter, but tasted strongly of sublimate. Another portion of the precipitate was dried with basic lead carbonate and exhausted with 90 per cent. alcohol. This time the residue from evaporation formed a brownish varnish having a disagreeable smell and a bitter taste. Mercuric chloride was no longer recognizable, but probably some lead chloride was present, only 90 per cent. alcohol having been used. The product possessed all the reactions described for ecboline. The remainder of the mercuric chloride precipitate Hermann decomposed with sulphuretted hydrogen, and treated the alkaloidal solution according to Wenzell's method. He mentions that the platinum chloride precipitate did not form directly.

Ganser prepared ecboline and ergotine according to Wenzell's method, the results only differing slightly. Boiled with caustic potash both alkaloids gave off ammonia, and developed in contact with hydrochloric acid a smell resembling that of *Chenopodium Vulvaria*. The ecboline prepared by Ganser had a bitter taste ; the ergotine on the contrary tasted saltish, and did not act so energetically as ecboline, which in small doses excited nausea and eructations. According to Ganser the hydrochlorate of ergotine crystallizes in long needles.

In 1872 Wenzell published an appendix to his previous memoir. He maintained the correctness of his opinion that in ergot there are two amorphous alkaloids, and gave instructions for their preparation essentially differing from his former method. It consisted in exhausting a pound of coarsely powdered ergot twice with dilute alcohol ; separating the potash salts from the extract by treatment with a little tartaric acid, filtering, and evaporating the filtrate to dryness with caustic lime and animal charcoal in a water-bath. The dry mass was exhausted with 24 ounces of boiling absolute alcohol, and this was evaporated to one-fourth of its original volume, by which a small quantity of mycose was separated. This was filtered off and the solution treated with an equal volume of ether. This precipitated the ecboline, which formed at first a white flocculent mass, but after the evaporation of the ether quickly melted and became brown. The ecboline so obtained had an alkaline reaction, and was precipitated by mercuric chloride and phosphomolybdic acid. The filtrate from the ecboline was heated until all ether was driven off, then evaporated to one-twelfth its original volume, and treated with two volumes of ether. The ergotine was thus precipitated in a semi-fluid condition. In aqueous solution it was precipitated by tannic and phosphomolybdic acid but not by mercuric chloride.

At the end of Wenzell's communication, published in 1865, was a chapter treating of the physiological action of the two alkaloids, the experiments having been carried out by Wenzell upon himself. In his opinion 0·03 gram of ecboline had an action equally strong with 2 grams of ergot. This dose is said to have exercised a kind of intoxicating influence on the brain, which was communicated to the muscular system, causing involuntary contractions of the muscles. This was followed soon by nausea, loss of appetite, a feeling of heaviness and shifting pains in the head, irritation of the muscles, a creeping sensation along the spine and general weakness. The ergotic action lasted about three hours. When the dose was doubled the excitement did not last so long, but it was followed by a greater weakness, accompanied by trembling of the limbs and pains in the chest. The ergotine was stated not to act upon the spine or muscular system.

Quite different results were obtained by Haudelin.* According to his experiments, which were carried out upon cats, both the alkaloids behaved indifferently. He was also unable to distinguish the reactions with potassium cyanide and platinum chloride described by Wenzell, Ganser and Hermann.

Dragendorff and Podwissotzky found both ecboline and ergotine, prepared according to Wenzell's method, without action on frogs. Both alkaloids were obtained by them from the filtrate after the precipitation of sclerotic acid. They also isolated ecboline and ergotine direct from ergot and found that the products could scarcely be distinguished.

I have prepared Wenzell's alkaloids only from the above-mentioned filtrate. This was concentrated in Rostock, where the preparation of sclerotic acid is carried on upon a considerable scale, and sent in the form of extract to Professor Dragendorff, who kindly placed it at my disposal. This extract was treated with warm water, which left undissolved flocculent masses, consisting principally of phosphate of lime that was removed by filtration. The extraction with water was continued as long as the water was coloured. The filtrates were united, slightly concentrated, and treated with neutral acetate of lead, which produced a plentiful precipitate. From the filtrate from the precipitate excess of lead was removed by sulphuretted hydrogen and this driven off by heating. The liquid was then evaporated to a small volume and treated with mercuric chloride in powder and in strong solution. After standing some time a precipitate formed, which was so finely divided that it passed partially through the filter and the filtration had to be repeated several times before the liquid was obtained quite clear. This precipitate would contain Wenzell's ecboline, whilst the filtrate would contain Wenzell's ergotine. It was freed from mercuric chloride by sulphuretted hydrogen and further evaporated. From the concentrated liquid mercuric chloride threw down a further precipitate, but in smaller quantity than the first. Both of the precipitates, after being washed, were decomposed with sulphuretted hydrogen and the mercuric sulphide filtered off ; this was boiled in 70 per cent. alcohol so as not to lose any alkaloid that might be retained in it mechanically.

The filtrate from the mercuric sulphide, which contained the hydrochlorate compound of the alkaloid, was evaporated to a small volume at not too high a temperature, and then dried *in vacuo* over sulphuric acid. In the dry varnish-like residue there were scattered numerous transparent cubical crystals having a salt taste.

I dissolved a portion of the hydrochlorate in water, supersaturated the solution with potassium carbonate, and tried to obtain the alkaloid by agitation. Ether and chloroform however took up so small a quantity that I had to abandon this method of obtaining the pure alkaloid. In order to remove the hydrochloric acid I dissolved the brown varnish in water, and allowed the solution to stand with lead hydrate at the ordinary temperature. After about twelve hours the mixture was exhausted with absolute alcohol. This was distilled off and the residue examined with silver nitrate, which gave a precipitate insoluble in nitric acid. Also upon heating it with potash solution I could detect the smell of trimethylamine that had passed into the alcohol in which the hydrochlorate of that base is easily soluble. The residue from the distillation I dissolved in water and hoped to be able to separate the alkaloid from the trimethylamine by repeated precipitations with mercuric chloride ; but still, after the decomposition of the precipitate with sulphuretted hydrogen trimethylamine could be detected, and I also observed that the whole of the alkaloid was not precipitated by mercuric chloride, showing that the mercuric precipitate is not very insoluble.

(*To be continued.*)

THE PREPARATION OF SAPO VIRIDIS.*

BY E. B. SHUTTLEWORTH.

During the past two or three years several formulæ have been published for the preparation of substitutes for green soap, but, as far as my own experience goes, none of them give satisfactory results. A so-called green soap, used until lately in the hospitals here, consisted of a partly saponified, yellowish and almost odourless mass, formed by boiling together, for a considerable time, a mixture of two parts spermaceti and one of solution of potash, sp. gr. 1·300. Another formula, much nearer the mark, directs the saponification of one part of linseed oil by an equal weight of solution of potash, sp. gr. 1·130, The quantity of potash is, however, insufficient, and as one of the therapeutical essentials of the preparation is that the alkali be in slight excess, the effects realized are not always those which are anticipated. Lastly, we have a recipe given in a short paper by Mr. Herman Betz, in the *American Journal of Pharmacy*, from which it has been reproduced in most of the pharmaceutical serial publications of the time—this journal among the rest.†

On first looking over this formula, I did not notice that the solution of potash—presumably that of the U. S. P.—is ordered in only about one third the quantity required for saponification, and consequently any attempt to follow this recipe strictly would certainly end in failure and disappointment. Druggists are not always skilled soap boilers, and though the operation is simple it requires considerable experience. I have, therefore, taken the liberty of correcting this error and also beg to add a few plain and practical directions regarding the process.

In a clean pot or dish, preferably of iron or copper, and capable of containing at least three times the quantity, put one part, by weight, of linseed oil; heat gently and add in two portions, three parts in all, by measure, of liquor potassæ, U. S. P. or B. P., providing either come up to the standard requiring 5·8 and 5·84 per cent. of hydrate of potash. Boil quietly and stir frequently until the mass becomes clear, which, with four ounces of oil and twelve fluid ounces of liquor, will require about an hour, and with ten pounds of oil about five hours. If, during the process, the mass becomes too thick to stir easily, add a little water. Allow the soap to become cool, but before it sets, work in the colouring matter, which must be previously prepared by boiling finely powdered indigo with water until the colour is formed into a thin paste. Twenty grains of indigo, boiled with one and a half ounces of water, until the mixture is reduced to about one drachm, will answer for the soap from four ounces of oil. The soap must not be too hot, nor must it be reboiled after adding the colouring, or the green will be destroyed. Mr. Betz's statement that nothing answers so well as "the green colouring matter precipitated from a solution of indigo by lime," is, to say the least of it, very vague. The method I have given is that pursued by continental makers of green soap,‡ and works well. A Berlin ware or Wedgewood dish may of course be used instead of iron or copper, but as the boiling point of the mixture is high, there is great liability of fracture, and cold water must be added very cautiously, and the stirring must be almost continuous.

The proportions of oil and alkali given above are such as will turn out a satisfactory article, with most samples of linseed oil, and with ley of the proper strength. I think these definite directions regarding quantities advisable for those who have not had much experience in saponification. The best guide in soap making, where the strength of the ley is not known, is that afforded by applying a very small portion of the soap to the tip of the tongue. The sharp taste of the alkali indicates more boiling, or more oil, or perhaps more water. This test, though not very scientific, is eminently practical and is very generally employed.

The product will be about twice the weight of the oil used, and should be of a dull bottle-green colour, and in consistence at least not thicker than lard or butter at moderate temperatures, just so that it will retain its form, and might be carried on paper.

Genuine green soap should be made from hempseed oil, and is largely used in France (*savon vert*), Germany (*grune seife*), and other continental countries, where it is almost universally employed in the household. It is not, however, always made from this stock, but often from other vegetable and, perhaps, animal oils, and is then coloured in the manner I have indicated. Under the name *Sapo Viridis* it is official in the German Pharmacopœia, but this authority does not afford any other information than that the soap is "a lubricous, soft, yellowish-green mass, of a nauseous smell." A tincture, or solution in spirit, is used in some parts of Canada, but I am not aware of the exact strength.

THE DETECTION OF MERCURY IN URINE.

The Schneider-Ludwig method of detecting quicksilver in animal tissues and liquids, by the electrolytic process, and amalgamation with copper or zinc filings, subsequent reduction of the amalgam by heat, and production of a combination of mercury and iodine, has been modified, and, for clinical purposes, greatly simplified and improved by Dr. Paul Fuerbringer, of Heidelberg. His proceeding, as described in the *Berlin Klin. Wochenschrift* (No. 23, 1878), is as follows: In 500 to 1000 c.c. of urine, previously acidulated by some mineral or strong vegetable acid, and heated to 60° or 80° C., 0·25 or 0·5 gram of fine brass shavings or brass wool (messingwolle), as he calls it, are immersed, and stirred for about ten minutes. The urine is poured off, and the brass shavings, which have taken up and amalgamated with the mercury, washed in succession with hot water, absolute alcohol and ether, to remove all organic matter. Albumen and glucose in such urine do not at all impede the electrolytic extraction of the mercury, but the presence of purulent and mucous deposits necessitates previous filtration. After the ether has evaporated, the spongy metal is thoroughly dried by squeezing it in filter paper, and then pressed into a solid spindle-shaped mass, which is put into a capillary glass tube of 0·8 ctm. interior diameter, and 15 ctm. length. Both ends of the tube are to be drawn to a thinner volume, of at least 0·1 ctm. diameter, the amalgam remaining inside the wider middle part of about 4 ctm. length. By rotating the latter cautiously over a Bunsen's lamp, and not allowing the temperature to exceed the beginning of a dark red heating of the metal, the amalgam becomes reduced, and annular deposits of quicksilver formed in the narrow capillary tube ends, generally also some deposits of zinc oxide will be formed, but they always appear as rings inside the quicksilver. The yellow and red combinations with iodine are produced by putting a few grains of this metal inside, and heating slowly over a very small flame. The red rings of biniodide that form will show for years, and quantities down to 0·00025 gram of mercury have shown distinct reactions in a course of several hundred urine examinations. With quantities of only 0·0001 gram the test sometimes failed, no red rings made their appearance, but this happened to the author likewise with the more circumstantial examination by Ludwig's method. Dr. Fuerbringer promises to adapt his method for testing other animal liquids, and it is to be hoped he will improve it for the purposes of qualitative tests. It need not be remarked that it applies to all pharmaceutical preparations of mercury, and will be of especial interest and value in determining the quantities of excreted metal in courses of bichloride treatment, inunction, mercury baths, and in cases treated by large calomel doses. In cases of

acute poisoning by corrosive sublimate, the secretion of urine is either scanty or altogether suppressed, so that attempts to ascertain the presence of mercury in the kidney secretions would be, very likely, unsuccessful.

CHILIAN SALTPETRE.*

For some time past, frequent mention has been made of the rich deposits of nitrate of soda and guano, and of mines of silver and copper which were supposed to exist at the northern extremity of the Chilian territory. A few adventurous explorers had attempted and accomplished expeditions of discovery into those parts, and some daring capitalists had based speculative projects for working the country. But all these attempts which were made by private individuals were met by considerable obstacles in a barren desert, separated from the sea by an almost continuous chain of mountains, called the Cordilleras of the Coast, where means of communication are rare and transport costly, and where even water fit to drink cannot sometimes be found. The Chilian Government at length decided, in its own interests, to assist private enterprise, and sent out Commissions, one to explore, as far as possible, the natural riches which are lost to the world in the desert of Atacama; the other to study the means of communication by which these riches could be made marketable. The Chilian Government has now made known the results of these two exploring Commissions, giving the information just as it was received, and publishing in the form of a pamphlet† the full text of the reports addressed by the Commissioners to the Minister of the Interior.

The most important of these documents is undoubtedly that of M. Pissis, who, although the work executed by the Commission over which he presided was merely one of summary exploration, has been enabled to verify the existence of abundant natural riches in the desert of Atacama; and although the deposits of nitrate of soda found by the Commission were considerable, it may reasonably be conjectured that they are only a small portion of those which exist. The same may be said of the guano and of ores of silver and copper.

Although it was impossible to explore thoroughly the riches of the desert in a short time, it sufficed to indicate scientifically, and with certainty, the points of attack. The operations of working once commenced, the explorations could be pushed further and further, and without much trouble, until the whole should be accomplished. The Commission charged with the discovery of a spot where the works established in the north of the desert could, without difficulty or expense, communicate with the sea for the purposes of sending their produce and receiving provisions, found a very convenient port, which it is hoped will soon be put in communication with the interior of the desert by a good road. This is most essential and urgent—time will work the rest.

The Chilian Government hastened to profit by the studies of the two Commissions, and to undertake, without loss of time, the necessary works at the ports Blanco Encalada and Taltal. The construction of the roads will shortly commence.

Thus, European capitalists, engineers, and contractors, who are inclined to turn their attention to the *exploitation* of the nitrate of soda and other products of the desert of Atacama, have at their disposal precise information, which they may easily study to their profit; and to them the Chilian Government, whose sympathy for industrial and commercial enterprise is well known, specially addresses this information.

The first four chapters of the pamphlet treat of the geographical position, general aspect, and geology of the desert; and in the fifth we have M. Pissis' theory of the origin of saltpetre, from which we now translate the following:—"The presence of chloride of sodium in all the *salpêtrières*,* and the fact that this salt is found in vast tracts, as in the salt field of Aguas Blancas, suggests a relation between the sea and these deposits, and that they must be the result of ancient marine formations; but, studying more attentively the situation of these deposits, and the substances contained in them, we do not find in any of them either calcareous formations or stratified rocks, as would be present if the matters were deposited in some ancient gulf; we further observe that in none of these deposits are any vestiges of marine shells to be found, and the only characteristics which these deposits and those formed by the sea have in common is the presence of salt. Further than this, the saltpetre is frequently found mixed with small stones, whose presence negatives the idea of a deposit slowly formed in the water, or left on its evaporation. Instead of being formed on the lower levels the saltpetre is accumulated on the hills, or even on considerable elevations, as at the mines of Paposo, and even on the Cordillera of Maricunga, at an altitude of more than 4000 metres. Therefore it is evidently of local origin, was not transported from other localities, and was formed on the same spot where it is found. The question is, from whence came the constituent elements of nitrate of soda and the other bodies, such as sulphates of lime and soda, and chloride of sodium, which always accompany it? The constituent elements are soda, lime, nitric acid, sulphur, and chlorine. All the salpêtrières are surrounded by heights composed of feldspathic rocks; the sand which covers the plain and the ground on the slopes of these heights is of the same constitution. The feldspaths of which these rocks are composed are the labradorite, the albite, and the oligoklase. The labradorite contains a large quantity of lime, the albite from 8 to 10 per cent. of soda, and the oligoklase contains soda and potash. In these substances are the bases of the salts met with in the salpêtrières; the acids only are wanting. All these rocks contain pyrites, the oxidation of which could furnish sulphuric acid. It is also known that volcanic emanations contain large quantities of chlorine, and that many of the waters which issue from the *trachytes* contain considerable quantities of chlorides. The formation of nitric acid seems at first sight to present more difficulties, but the experiments of Chlöes prove that alkaline carbonates, when in the presence of oxidizable matters, possess the property of condensing the elements of atmospheric air and transforming them into nitric acid. It is also known that feldspaths, under the influence of the air are changed into kaolin, abandoning their alkaline bases, which pass into the state of carbonates, while the silicates of iron, augite, and amphibole, under the influence of air, are oxidized. Considering the rapidity with which the rocks in the desert are decomposed, it is easy to understand the formation of saltpetre, and its situation at the foot of mountains. The rocks, by gradually crumbling away are reduced to coarse sand, which spreads over the slopes of the mountains, and is from thence conveyed by the copious, although rare, rains, into the plains of the desert. This feldspathic sand undergoes decomposition, as above described, and is reduced to an earth composed of kaolin, oxide of iron, sulphate of lime, chloride of sodium, and carbonate of soda. This last is changed in its turn into nitrate. The next rains filter away the most soluble salts to the foot of the mountains, while the sulphate of lime, being much less soluble, remains mixed with the kaolin. This bed of sulphate of lime and clay, which forms the crust of the salpêtrières, is found not only in the plains, but even to the summit of the mountains, and on removing at any place the sand from the surface, a white, porous substance, consisting mostly of sulphate of lime, is found. On the

* From the *Journal of Applied Science*, July, 1878.

† *Salpêtres et Guanos du Désert d'Atacama.*

* The saltpetres mentioned in the Report are native *nitrates of soda*. The Spaniards and the French give the name *Salpêtrières* not only to saltpetre refineries, but also to mines in which those nitrates are found.

evaporation of the water which has filtered downwards, the salts which it held in solution crystallize, and this explains why the saltpetre is always found mixed, more or less, with sand and earth.

"It being thus established that saltpetre can only be formed by the decomposition of feldspathic rocks, and that such rocks form the central portion of the desert, from Rio Salado to the 24th degree, it is unquestionable that, besides the saltpetre deposits already known, there should exist many others south of the 26th degree and north of the 25th degree, and, following the indication above given, it would be easy to find them."

This theory of the formation of saltpetre is at variance with that of Dr. Sieveking, published in this pamphlet, and which we will now translate, prefacing it with his description of a saltpetre deposit, as found in the province of Tarapaca:—"Beneath a bed of sand mixed with clay, containing stones of porphyry, quartzites, etc., is found a second layer, more firm, which, in a mass of salt and gypsum, contains a conglomeration which covers the native saltpetre, mixed with nitrate of soda, chloride of sodium, iodide of sodium, sulphates of potash and soda, sand, and stones. Generally, beneath the saltpetre, is found a layer of pure salt on one of clay, which last rests on the solid rock of porphyry or granite. Mr. George Hilliger, who has long resided at Iquique, believes that the saltpetre is formed by the decomposition of guano; but, without examining the details of this theory, it is sufficient to state one fact which renders it very improbable, viz., that in the neighbourhood of the salpêtrières are not to be found any phosphates, which would have been formed at the same time as the saltpetre. The theories of Schœnbein and of Nœllner are so similar that they may be examined together. Both of them seek the origin of saltpetre principally in the decomposition of marine plants, most of which contain the elements necessary for its formation. According to Girardin, the ashes of such plants are composed as follows:—

	Cherbourg.	Cherbourg.	Viliette.	Alicante.
Sulphate of Potash	22·19	42·54	20·35	—
Chloride of Potassium	16·00	19·64	10·53	—
Chloride of Sodium	45·78	25·38	54·11	65·00
Carbonate of Soda	9·53	3·71	13·76	2·00
Sulphate of Soda .	—	—	—	30·00
Water, Iodides and insoluble matters	6·50	8·73	1·25	3·00
	100	100	100	100

"Of course the incombustible matters only are found in the ashes, the nitrogen and the greater part of the organic matters being volatilized. The result would be very different if oxidation had taken place slowly, by natural decomposition, especially under the conditions which existed at the time when the saltpetre deposits were formed, and this was probably during the tertiary period. The earth was then enveloped by an atmosphere charged with moisture, through which only a diffused light penetrated—conditions so favourable to certain chemical reactions, especially the formation of nitrate of ammonia, and as may now be noticed by the formation of nitrate of lime on damp bricks in stables, etc.

"The great plains on which the deposits of saltpetre are most frequently found must formerly have been extensive low-lying flats, sloping very gently towards the sea, or shallows covered by its waters, and in support of this solution of the problem, it may be surmised that on these flats grew marine plants which, on decaying, were carried by the current, or by the waves, to the edges. As the level of the coast gradually rose, and as it still rises from the sea, these flats were converted into lakes, the sea only entering them at high water, the plants and shells there accumulating produce what are now deposits of saltpetre." . . . .

"The northern coast of Chili rises abruptly from the sea, and there are but few points or gorges through which it is possible to ascend to the plateau which extends from the foot of the Cordillera in the east, and from the latitude of Copiapó to the frontiers of the Republic in the north. The climatic conditions, principally the almost total absence of rain and the geological formation of this tract of country (very analogous to that of Tarapaca), gave reason to expect similar deposits of salt to those of Peru; and, in fact, the first salpêtrières were found in the rear of the port of Taltal. On ascending a gorge which debouches into the Bay of Taltal, we arrive, after having journeyed about eighteen miles, to the waters called Cachiyuyal. At this point the gorge is of considerable width, and traversed on one side by the bed of a watercourse, now dry and covered with a vast deposit of salt, beneath which, however, and at only a slight depth, tolerably pure water is found. Following the valley a mile further to the east it opens out and becomes confounded with the plateau above mentioned, and there, at the foot of hills which seem to have formed the banks of an ancient lake, deposits of saltpetre are found, not in regular layers, but in agglomerations here and there, and sometimes of considerable thickness. This saltpetre is mixed with a variable, but always considerable, quantity of salt, and is covered over by a very thin coating only of sand. The rocks forming the hills and mountains surrounding this plain are entirely plutonic, consisting of granitic, augitic, amphibolic, and hyperstenic rocks, in many places being very nearly of the granitic formation, in which mica is replaced by amphibole. These deposits were not thoroughly explored, so we did not observe whether there was a clayey or saline substratum, as in Peru. Following up the gorge towards the point which was formerly the source of the watercourse, deposits of saltpetre are found on either side, little explored as yet, but having the appearance of being a more regular formation than the above mentioned; the saltpetre is here only covered by a very thin coat of sand, and the *caliche* (or granular layer of crude nitre) is about the same sort as that found in Peru. The deposits are found on the sides of the valley which slope gently up to the neighbouring heights, and not at its lowest part, where accumulations of salt are to be observed. The salpêtrières in this part of the desert much resemble in aspect those of Peru. It seems at first strange that the saltpetre is found above the level of the valley and the salt beneath it, but this is accounted for by the theory of the probability of the deposits having their origin in lakes near the coast, which were flushed by the high tides. If this theory is accepted as probable, it may be deduced that by the natural decomposition of organic and animal matter deposited in the lakes, nitrate of ammonia, sulphates of soda, etc., were formed, whilst the adjacent rocks furnished silicates, carbonates of soda, of lime, of potash, etc. By the reciprocal action of the different salts, nitrate of soda, sulphate of lime, etc., were formed, and a large portion of these salts remained in suspension in the salt water. The gradual concentration of the sea-water by evaporation, especially near the edges, caused the precipitation of the salts, and this in proportion as the concentration increased. As nitrate of soda is but slightly soluble in a solution of chloride of sodium, it would naturally be precipitated at that point where the concentration of the solution of chloride of sodium is the greatest. Therefore the *caliche* must be sought for at the edges of the deposits. It may also be found in the centre, but would there be covered with salt. In this theory it is inferred that the rocks furnished their contingent for the formation of the deposits, and this inference is confirmed by facts. Everywhere are found great masses of clay, gypsum and chalcedony, which could hardly have been formed otherwise than by the decomposition of the rocks. The extent of the salpêtrières to the east of Cachiyuyal does not appear to be less than ten miles, following the dried bed of the watercourse.

"To the north-east the plain is slightly undulated and

studded at various points with granitic rocks similar to those above described, which rise like islands from its surface. Throughout the whole extent of this plain, excepting on the heights, saltpetre is found in various quantities, sometimes to the thickness of three mètres, and nearly always exposed on the surface. This enormous deposit, extending over many square miles, is very different in character to that above described. The *caliche* is less mixed with other salts, and in many places it is found impregnated with sand and rock, without any accumulation of salt or gypsum to be met with in the vicinity. Another remarkable difference consists in the *caliche* being found mostly in the *depressions* of the ground. Consequently the theory above described is not applicable in this case, if the actual condition in which the deposits are now found is accepted as the primitive one; but it would be applicable if considered as a secondary one. The configuration of the ground permits the supposition of deposits having formerly existed at greater elevations, from which the saltpetre was dissolved out by the rain and washed into the lowest parts of the plain, there forming, by evaporation of the rainwater, the deposits as now found."

Resuming our perusal of the report of M. Pissis, we will limit our extracts therefrom to a few statistics concerning the salpêtrières of Cachinal and d'Aguas Blancas, and a detail of his method of estimating or assaying the crude nitre:—

"The salpêtrières of Cachinal and d'Aguas Blancas have as yet been so imperfectly explored that it would be rash to attempt to estimate, even approximately, the quantities of saltpetre contained in them. All that is known for certain is, that that quantity is immense, and to give an idea of it I will limit my examination to the salpêtrières, Nos. 2 and 3, of the Guzman Company, which are those which have been most explored. These cover an extent of 600 hectares, or 6,000,000 square metres. In many of the pits, sunk at hazard, the thickness of the saltpetre varies from 1 to 2½ metres, so that we in fact underestimate when we state the average thickness to be 1 metre, giving 6,000,000 cubic metres. As the density of saltpetre is double that of water, these 6,000,000 cubic metres give 240,000,000 quintals of crude saltpetre, and, supposing it to yield 20 per cent., the result would be 48,000,000 quintals refined of saltpetre. Should the annual production amount to 1,000,000 quintals, these two concessions would not therefore be exhausted in less than forty-eight years. Therefore, there is no exaggeration in stating that the Chilian portion of the desert of Atacama can furnish during more than a century immense quantities of saltpetre.

"The methods of assay or estimation of saltpetre at present known are very complicated, and as regards accuracy leave much to be desired. I have arrived at a more simple and exact method, and one which may be employed by all who are occupied in the saltpetre industry. It may be described as follows:—Equal parts of saltpetre and charcoal are thoroughly mixed and heated in a crucible to a dull red heat. All the nitrates are thereby transformed into carbonates. The resulting matter is then mixed with water and washed on a filter until the water coming from it gives no alkaline reaction; the quantity of carbonates is then estimated in the usual manner by the alcalimeter, and the quantity of nitrate deduced on the basis of 1000 parts of carbonate equalling 1602 of nitrate. This method is so simple that it may be employed on the spot. The quantity of nitrate may be further approximately estimated by the following indications:—The decomposition takes place, without apparent deflagration, when the proportion of nitrate is less than 15 per cent.; if present between 15 and 25 per cent. the deflagration is visible, but is of little intensity; between 25 and 40 per cent. it is rather brisk, and above 40 per cent. it is so brisk as to cause projection, to avoid which the quantity of charcoal must be augmented even to twice the quantity of crude nitre to be assayed. The crucible must not be too highly heated, otherwise a portion of the sulphate would be transformed into sulphuret, and the results would cease to be exact.

"The whole process of the manufacture of saltpetre depends on the property which nitrate of soda possesses of being so much more soluble in hot than in cold water. Water at 10 degrees dissolves 0·78 of nitrate of soda, while at 100 degrees it dissolves 1·77; this difference of 0·99 separates and crystallizes from the solution in cooling. Therefore, for the local manufacturer, fuel is the greatest item in the expense of this industry. Also, it may be mentioned that the most profitable saltpetres for working (locally) are not those which contain the greatest amount of pure nitrate, the compact saltpetres being more difficult to dissolve and necessitating a machine to crush the salt into small pieces; the saltpetres mixed with the sand, on the contrary, dissolve with great facility.

"The salpêtrières generally contain, besides saltpetre, several products which might be utilized, such as sulphate of soda, which might be employed in the manufacture of soda and iodine, which is sometimes found in quantities sufficient to be worth extraction."

DISTILLATION OF CASTOR OIL UNDER REDUCED PRESSURE.*

BY F. KRAFFT.

When castor oil is distilled under a very low pressure, there passes over first a colourless oily distillate, equal to about one-third or one-half of the oil used, and then a small quantity of an oily liquid, whilst a slimy saponifiable mass remains in the retort. Half of the oily distillate consists of œnanthol, which is separated by distillation; after the œnanthol has distilled over, the temperature suddenly rises above 100°, and then remains stationary. The distillate which now comes over solidifies to a crystalline mass, the analysis of which led to the formula, $C_{11}H_{20}O_2$; this melts at 24·5°, and boils at 198–200° under a pressure of 90 mm.

It appears to be a new member of the oleic series, forming a crystalline barium salt; on fusing with potash it gives acetic and nonylic acids; with bromine it forms a crystalline addition product, melting at 38°. The following equation represents the formation of œnanthol, and of the new acid from ricinoleic acid:

$$C_{18}H_{34}O_3 = C_7H_{14}O + C_{11}H_{20}O_2.$$

The remainder of the distillate obtained from the castor oil distilled under the above pressure chiefly at 250–265°, but has not yet been investigated.

SILPHIUM LACINIATUM.†

[*Compass Plant, Resin Weed*]

The Nashville *Journal of Medicine and Surgeory* for August, 1877, contains an extract from the MSS. of Materia Medica by Q. J. M. Goss, A.M., M.D., of Marietta, Georgia. It says:—

"There are several species of silphium. This one, *S. laciniatum*, grows on the open prairies of Illinois and Wisconsin, and southward and westward, and flowers in July. It is said that the lower leaves (cup-shaped) present their edges uniformly north and south. It is a rough and bristly plant, with a stout stem, pinnate leaves, petalled and clasping at the base. The heads are recemed and few. It contains a balsamic and resinous juice, which, when dry, resembles resin, hence called *resin weed*. The *Silphium perfoliatum*—Indian cup-plant—is a large perennial rooted plant, with smooth herbaceous stem, from four to seven feet high, bearing yellowish flowers, and an ovate winged achenium. It grows in the Western States,

* *Deut. Chem. Ges. Ber.*, x., 2034–2036. From the *Journal of the Chemical Society*, April, 1878.

† From *The Druggists' Circular and Chemical Gazette*, June, from 'Half-Yearly Comp. of Med. Science.'

in rich bottoms, flowering in August. The root is long, large, crooked, and contains a bitterish gum. It is the part used as medicine. These are the two species used.

"*Medicinal properties.*—The *Silphium laciniatum* has proved a valuable remedy for many diseases of the mucous membranes, as it has a direct affinity (like the balsams, turpentine, and cubebs) for the mucous tissues. In catarrh and chronic bronchitis it has a fine effect, allaying the irritation in bronchial inflammation, lessening the frequency of the cough, and checking the excessive expectoration. In catarrh it relieves the mucous irritation, and aids other remedies in the final cure. But it is in asthma that it acts so charmingly; I have permanently cured several cases of confirmed asthma with these articles, alternated with *Ptelia trifoliata*. A lady consulted me for asthma of long standing. I put her upon the tinctures of the silphium and ptelia, equal parts, and gave a tea-spoonful three times a day, which relieved the disease in two months. I was called to a little girl, some fourteen years of age, who was labouring under a violent attack of asthma, for which I gave an emetic, which gave temporary relief of attack. I put her upon the tincture of the *Silphium trifoliatum*—rosinwood (the saturated tincture of the root)—and the tincture of ptelia, which has effected a final cure of the asthma. A lady, some fifty years old, applied to me for treatment for asthma of several years' standing. I gave her a tea-spoonful of the tincture of silphium (the resin weed) and *Ptelia trifoliata* three times a day, which has effected a complete cure, as she still lives near this city. A gentleman from an adjoining county applied to me for treatment of asthma of long standing, informing me that he had not slept in bed for fourteen years. I put him upon the tinctures of silphium and *Ptelia trifoliata;* in three days he informed me that he had slept well in bed, and in two months he was dismissed cured. I am not certain that the silphium would cure the disease without the *Ptelia trifoliata*, but I am certain that it will when combined as above. I am not certain which is the best, the *Silphium laciniatum* or the *Silphium gummiferum*—the resin weed. I present them for trial. I am now treating a case of long standing, and it is fast mending."

HYPOPHOSPHITE OF ZINC.*

BY ROBERT W. GARDNER.

This salt has never, so far as I can learn, been used internally for medical purposes, and the object of this paper is to explain its peculiar advantages and to call professional attention to it.

The only combination of phosphorus and zinc heretofore used is the phosphide of zinc. The formula for this, as given in Soubeiran's work as recently revised by Regnault, is PZn_3. This shows it to consist of phosphorus and metallic zinc in the proportion of one part of the first to about six parts of the latter, and both unoxidized. As no oxygen enters into its combination, the phosphorus produces the same irritant effect in the stomach as if given in the free state, its irritant action being caused by its oxidation.

The ordinary dose of phosphide of zinc is one-tenth of a grain. This quantity cannot be largly increased. The proportion of zinc contained in this quantity is too infinitesimal to prove a very powerful nervous tonic, while the proportion of phosphorus is still less.

I therefore propose the use of hypophosphite of zinc. The formula for this is (ZnO,6HO,PO); (O=8).

In this salt both the zinc and phosphorus are in a protoxidized state, in which condition the phosphorus is rendered non-irritant, admitting the use of such quantities as to fully meet all indications for either phosphorus or zinc. The salt being perfectly soluble is at once assimilated, while both elements in the phosphide must be oxidized previous to assimilation; its advantage in most nervous diseases over zinc oxide, zinc sulphate, etc., being that the very desirable effects of phosphorus in its best condition for assimilative action are also available by its use.

The condition of absolute purity is essential to this, as to all hypophosphite salts, for unless used in this condition their therapeutic effect is either very much impaired or wholly lost.

I recommend the use of the syrup, as the sugar is a most efficient preservative against atmospheric influence, and renders the preparation more palatable, though the salt has scarcely any taste at first, the slight metallic after-taste being perceptible.

It is prepared in the form of syrup, eight grains of the salt to one fluid ounce, of which a teaspoonful (one grain) is the usual dose, and may probably be given in twice or thrice that quantity three times a day.

The salt used is purified and neutral. It has been therapeutically tested with very satisfactory results.

* *The Druggists Circular and Chemical Gazette*, June, from the *Medical Record*.

CHEMICAL AND PHYSICAL PROPERTIES OF AMBER.*

BY O. HELM.

Amber, the fossil resin of *Pinites succinifer*, is found in primary deposits on the coast of East Prussia. The amber-bearing stratum, which lies partly below the sea-level, partly above, is of a bluish-green colour, and consists of a coarse-grained sand, whose particles have a yellow coating. Scattered amongst the sand are particles of mica and glauconite; and in this "blue earth" is found the amber, to the amount of one kilo. per twenty cubic feet. The pieces of amber found are generally weathered, but have retained their original shape, showing that the sea has had but little action on them. The author doubts that amber found in other countries and which has evidently suffered more from the action of the sea, is of the same kind as that found in Prussia. The quality of amber varies, not only in its appearance, but also in its chemical composition, as well as its specific gravity. The specific gravity, as a rule, lies between 1·05 and 1·095; the sort known as "bone" is even lighter, and some sorts are lighter than water. The colour is far from constant, being of all shades of yellow and brown, some ambers from Sicily being green or violet-blue. The blue colour is due to ferric phosphate, and the "clouding" is due to water enclosed, as by boiling in oil the cloudiness disappears; the bone-like amber, however, does not contain water, and the appearance in this case is due to the fact that the amber is of different origin, containing a larger quantity of succinic acid, which is often in the free state. If light-coloured amber be exposed to the light for a long time, its surface becomes darker, and at the same time is found to be covered with innumerable fine fissures, but the whole may be flaked off, leaving beneath amber of the original colour. Of the ordinary yellow amber, about one-fifth is soluble in ether, alcohol, turpentine, or chloroform. Alcohol or ether extracts a little resin, but ether extracts a portion which is insoluble in alcohol. This resin melts at 146°, whereas that soluble in alcohol melts at 105°. Besides these resins, succinic acid and a bitumen are found, having the composition of ordinary laurel-camphor, $C_{10}H_{16}O$. The proportion of succinic acid is generally from 3 to 5 per cent., but some specimens contain as much as 8 per cent., the larger quantity occurring in the purer specimens.

The ash, which consists of silica, lime, ferric oxide, and sulphuric acid, varies from 0·08–0·12 per cent. Amber is easily distinguished from other resins, copal, for instance, by the succinic acid present, as well as by the melting point (about 300°). It is for the above reasons that the author considers that the "ambers" of other countries are not the same as that found in Prussia.

THE MEDICAL ACT AMENDMENT BILL

THERE seems to be some uncertainty whether at the time of going to press the business of the House of Commons will have been advanced so far as the second reading of the Medical Act Amendment Bills, according to the announcement in the orders of the day for the 11th instant.

In addition to the notices of motion which were mentioned in last week's Journal as having been given at that time, another has now been placed on the paper by Mr. FRESHFIELD, the member for Dover, having for its object the introduction of a proviso that the Act is not to affect chemists and druggists. To that end it is proposed to introduce into the Bill, when in Committee, the following clause, that "Nothing in this Act contained shall extend or be construed to extend to prejudice, or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, or vending drugs, medicines, and medicinal compounds, wholesale and retail, but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise and carry on the same trade or business in such manner and as fully and amply, to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act."

This clause is verbatim the same as the 28th section of Apothecaries Act, 1815, and if it were inserted without qualification in the Medical Act Amendment Bill now before the House, its effect, as a protection to chemists and druggists in regard to counter practice, would undoubtedly be much greater than that of the 28th section of the Apothecaries Act, in regard to which there is the difficulty of proving what was the manner of using, exercising, and carrying on the trade of a chemist and druggist prior to 1815.

If, however, we may judge from the probable nature of the influences which led to the amendment of the Bill by the revival of the penal section of the Apothecaries as regards unregistered persons, there is much reason to doubt whether this proposal of Mr. FRESHFIELD'S would be adopted. Unquestionably it appears now to be the intention of the Government to prohibit all persons who are not duly registered medical practitioners from carrying on the practice of medicine or surgery for gain. Having regard to the interests of the public and of qualified medical men we cannot consider that as being unreasonable or oppressive to chemists and druggists, for it is merely a kind of protection similar to that which the qualified chemist and druggist desires to have against the encroachments of co-operative stores, general dealers and the like. The chief difficulty, however, and indeed the circumstance which renders any legislative settlement of this matter almost impracticable is the entirely arbitrary nature of the distinction between medical practice and that kind of recommendation or prescription of remedies for simple cases and minor ailments, which may fairly be called "counter practice," of such a nature that neither the Apothecaries' Society nor the medical profession at large are at all disposed to cavil at. Even mere differences of locality may necessitate much greater laxity in drawing the line of demarcation in some instances than would be requisite or desirable in others, and in poor districts where a mother may have but a few pence to spare, the chemist and druggist is often the only person to whom she can resort for medicine for her children. Wherever individual discretion is exercised in restricting "counter practice" within such appropriate limits, and with due regard to the principle that since pharmacy is the handmaid of medicine, it is desirable that the trade should command the esteem and sympathy of the medical profession, we believe that there is rarely any attempt at interference on the part of medical men as has been well pointed out by our correspondent Mr. PARTRIDGE.

But, as we have on previous occasions had to admit, there are, in some cases, reasonable grounds for the objections raised by medical men to the practice of chemists and druggists. This fact has always been recognized by the authorities of the Pharmaceutical Society, and it has always been their aim to discountenance interference with medical practice.

It is in regard to this point chiefly that we feel constrained to take exception to some of the statements in the Memorandum issued by the Chemists and Druggists' Trade Association, the general tenour of which is to misrepresent the facts of the case as between chemists and druggists and medical practitioners as represented by the Apothecaries' Society. In the first place the statement put forward as defining the present manner of carrying on the trade of a chemist and druggist is at least incomplete, and, without raising any question as to what he is described as doing in two phases of the trade, we must point out that there is a third phase of action to be comprised within such a general definition, which consists in the treatment of disease and the practice of medicine to an extent outside the widest admissible limits of counter practice and so far as to constitute "acting and "practising as an apothecary."

It has never yet been established that such action as this was comprised within the mode of conducting the business of a chemist and druggist prior to 1815, and the very witnesses brought forward at the late trial not only failed to give any support to such a view but pointedly acknowleged that they would not have done what the defendant was prosecuted for doing.

It is not without regret that we find ourselves compelled to go into details of this kind in a manner that some will no doubt think betrays a disregard for trade interests, and the prevalence of views inconsistent with a country chemist's welfare; but we do so notwithstanding that possibility, because we feel convinced that the real interests of the trade at large are not to be permanently promoted or even temporarily served by raising a false issue between the chemist and druggist and the Apothecaries' Society by the apparently authoritative circulation of a statement such as the following:—

"The Apothecaries' Society would limit the busi-
"ness of a chemist and druggist to the mere prepa-
"ration and sale of medicines and drugs, and would
"deprive him of all power to dissuade the intending
"customer, when palpably wrong in his desire to
"purchase a certain medicine or to advise him what
"to buy even when his need of a medicine to pro-
"duce a particular effect is most obvious and could
"be most readily and simply supplied."

We care little whether the issue of a memorandum containing such a total perversion of fact as the foregoing is to be regarded as the effect of an illusion or as the possible means of deluding others since the result to be apprehended would be the same in either case. Moreover its general inconsistency with facts, and even with circumstances recorded in the same document, such as the statements of Mr. JOHN NUSSEY, Master of the Apothecaries' Society, and of Mr. R. D. UPTON, the Clerk to the Society, is so flagrant that one is startled at seeing the two side by side.

The agitation sought to be raised by means such as these cannot fail to recoil upon the heads of its promoters, and instead of advancing even trade interests, will more probably tend to place the whole body of chemists and druggists under the incubus of restrictions that they would otherwise have escaped. Such a fate befell the Apothecaries of the early part of the century, who—after having for years encroached upon the province of the physician by practising medicine to such an extent that, though unqualified, they regarded themselves as medical men, and were so regarded by the public—in 1815 acquired the right to continue such practice only on condition that they underwent an examination in the science and practice of medicine.

Those chemists and druggists who practise medicine and in whose behalf the present agitation is being promoted are in precisely the same position relatively to the apothecaries, that the apothecaries of that day were to the physicians, and if we take into account the tendency of modern legislation towards establishing, in the interests of the public, tests of qualification in certain occupations, there is little reason to expect exceptions to be made in favour of the chemist and druggist, who without such qualification trenches upon the province of the medical man. Those who do so constitute but a section of the trade, but the appeal made in the memorandum issued from Birmingham would make it appear that the interests of the entire body are imperilled by the proposed provisions of the Duke of RICHMOND'S Bill. We dispute that position altogether, and though the Bill is not now so favourable to the interests of chemists and druggists who practise medicine as it was before the untimely defence of the Bermondsey case, the Trade Association must be held as solely responsible for such accruing disadvantage.

We cannot perceive anything to justify the assertion made by Mr. URWICK that the trade is indebted to the Association for obtaining from the Duke of RICHMOND a satisfactory hearing in regard to the Medical Act Amendment Bill, or that the Council of the Pharmaceutical Society has in this respect any reason to be grateful to the Association. On the contrary, we have good reason for the opinion that the mischievous activity of the Association has had the effect of strengthening, if not of creating, a disinclination on the part of the Duke of RICHMOND to admit into the Bill any lowering of the restriction to which chemists and druggists in common with other unregistered persons have hitherto been subject.

This position on the part of the Duke of RICHMOND is consistent with the statement made by Mr. MORGAN HOWARD at the close of the Bermondsey case.

Not less to be deprecated than the circumstances above mentioned is the perverse attempt to induce the Council to reverse the position taken in regard to the SHEPPERLEY case by applying for a donation in aid of the prosecution of the appeal in that case, and we cannot perceive any possible result that could have been expected beyond the somewhat undesirable inference that may be drawn from the issue of that application as regards a case that is still *sub judice*. Such steps on the part of the Trade Association are not consistent with the originally avowed intention to supplement the action of the Council in promoting the interests of the trade, and though we have always advocated the maintenance of cordial relations between the two bodies we cannot wonder that the late action of the Association should have been productive of irritation and annoyance.

THE PERI AT THE GATE.

WE have been requested by the President to point out for the satisfaction of the Editor of the *Chemist and Druggist* that the remarks made by the President at the last meeting of the Council as to the report of the Annual Meeting of the Society having been in his opinion unfairly treated applied to the editorial article at page 268 of the June number of the *Chemist and Druggist*.

It seems, however, scarcely credible that any one should seriously have felt the necessity of this explanation of a fact so self-evident as the application of the remarks made by the President on the occasion referred to, which were substantially correct in

their general purport, notwithstanding the apparent confusion of the actual substance of the report of the annual meeting with its editorial shadow.

As connected with this matter we may here call attention to the opinion expressed by Mr. URWICK in his letter at page 39, to the effect that the strictures upon the business of the annual meeting of the Society in the *Chemist and Druggist* are "within the bounds of fair, impartial and independent criticism." We decidedly demur to this view, and to justify our objection we think it unnecessary to go further than to instance the suggestion that the policy of the President and of the majority of the Council is scheming, wriggling and serpentine, as well as the reference to the effect to be produced by asking an opponent to dinner, coupled with the insinuation conveyed in a former article that the action of some members of the Council was in this way influenced and controlled by others. A baser or more gross suggestion we cannot conceive possible, and we regard these instances of the criticism of the *Chemist and Druggist* not only as being alone sufficient to justify the President in asking his colleagues whether they would deliberately allow themselves to be ridiculed and insulted in every way and held up to derision before the whole trade, but also as constituting an unanswerable argument against the adoption of Mr. HAMPSON'S proposal.

SALE OF ADULTERATED SWEET SPIRIT OF NITRE BY GROCERS.

LAST week, two grocers, living at Stannington, near Sheffield, were fined 40*s*. each for selling adulterated sweet spirit of nitre. Judging from past experiences, the subject of these incidents, having a relation to the selling of drugs, may a few months hence, together with some untested reports from public analysts, be elaborated by some of our medical and analytical contemporaries into homilies upon the peccadilloes of pharmaceutical chemists and the *laches* of the Council of the Pharmaceutical Society. And why not? "The situations look you is both alike. There is a river in Macedon; and there is also moreover a river at Monmouth; it is called Wye at Monmouth; but it is out of my prains what is the name of the other river; but 'tis all one, 'tis as alike as my fingers is to my fingers, and there is salmons in both."

AWARD OF A PHARMACEUTICAL PRIZE.

AT the recent meeting of the Union Scientifique des Pharmaciens de France, the sum of five hundred francs, placed at the disposal of the Society for the best essay upon some subject in the sciences allied with pharmacy, was awarded to Messrs. OBERLIN and SCHLAGDENHAUFFEN, Professors in the School of Pharmacy at Nancy, for a histological and chemical study of some barks of the Rutaceæ. The authors have arrived at the conclusion that the neutral substance discovered by SALADIN in cusparia bark and named by him "cusparine," is really the hydrochlorate of an alkaloid contaminated with resinous matter, and they claim to have isolated the alkaloid, which they have named angusturine, and represent by the formula $C_{20}H_{40}NO_{28}$. They have also isolated an alkaloid from the Bahia angustura bark (*Esenbeckia febrifuga*, Mart.; *Evodia febrifuga*, St. Hil.), which they have named "evodine," and represent by the formula $C_{12}H_{18}NO_{12}$.

DUPLICATE SPECIMENS OF MATERIA MEDICA.

By order of the Council the following specimens of Materia Medica have been set aside for the use of Provincial Associations, and such Associations are invited to apply to Mr. Holmes, the Curator of the Museum, 17, Bloomsbury Square, for any which may be required by them.

It is of course desirable to aid such local societies as are endeavouring to advance pharmaceutical education in their districts; the applications will therefore be submitted to the Library and Museum Committee at its sitting in October for decision as to the disposal of the specimens.

In addition to the articles enumerated below, a number of loose duplicates of dried specimens of the wild plants of Britain, which although scarcely suitable for herbarium specimens would serve admirably for purposes of comparison and identification, may be obtained.

The specimens marked with an asterisk are in the compressed packets prepared by the Shakers of New Lebanon.

Adansonia digitata (fruit and section of trunk).
Ailanthus Malabarica (extract).
* Aletris farinosa (root).
Alstonia scholaris (bark, from Manilla).
Althæa species (seeds, from Calcutta).
Amomum Melagueta (fruit preserved wet).
Amomum Xanthioides (seed).
Andropogon muricatus (root).
Andropogon Schænanthus (leaves).
* Anthemis Cotula (flowers).
* Apium involucratum (fruit).
Aplotaxis auriculata (root).
* Apocynum cannabinum (herb).
* Aralia nudicaulis (root).
* Aralia spinosa (root).
Archangelica officinalis (fruits).
Arctopus echinatus (root).
Aristolochia reticulata (root).
Artemisia Africana (herb).
* Arum triphyllum (root).
Asarum Europæum (leaves).
* Asclepias incarnata (root).
* Asclepias Syriaca (root).
* Asclepias tuberosa (root).
Barba-timao bark.
Barringtonia acutangula (fruit).
Batta (from India, use unknown).
Berberis Lycium (rusot or extract).
Berberis vulgaris (bark).
Bombax heterophyllum (gum).
Borocalcite (from Iquique).
Calcium carbonate (precipitated).
Calophyllum inophyllum (bark).
Calotropis gigantea (root).
Camphor oil, residue of.
Canedillo (stem, from British Guiana).
Carapa Guineensis (seeds).
Cardamine pratensis (flowers).
Carthamus tinctorius (flowers, in cakes).
Caryocar butyrosum (seed).
Casca pretiosa (bark, from Brazil).
Cassia auriculata (leaves).
* Cassia Marilandica (leaves).
Cassia obovata (pods and leaves).
Cassia bark (spurious).
Cassyta filiformis (stems).
Catechu, pale (in strips).
Celastrus paniculatus (oil).
* Chenopodium Botrys (herb).
Chenopodium anthelminticum (essential oil).

Chimaphila maculata (leaves).
Cichorium species (seeds, from Calcutta).
Cinchona laurifolia (bark).
Cinchona succirubra (grown in St. Helena).
Cissampelos capensis (root).
Cissampelos Pareira (root).
Citrus Bigaradia (flowers),
Cliffortia ilicifolia (herb).
Coccoloba uvifera (extract).
Colchicum autumnale (corms and starch).
* Collinsonia Canadensis (root).
* Comptonia asplenifolia (leaves).
Condurango bark.
Copalchi bark.
Cork wood (from British Guiana).
Cornus sericea (bark).
* Cornus Florida (bark).
Corydalis species (tubers, from China).
Croton oil, old.
Curcuma aurea (tubers, from China).
Curcurbita Pepo (seeds).
Cyclopia genistoides (leaves, from the Cape of Good Hope).
Cypripedium pubescens (root).
Dammara orientalis (resin).
Dictamnus albus (leaves).
Dictamnus Fraxinella (root).
Dicypellium caryophyllatum (bark).
Dioscorea triphylla (root, from Manilla).
Dorstenia Contrayerva (root).
Elytropappus rhinocerotis (herb, from the Cape of Good Hope).
Emblica robusta (fruit).
* Erigeron Canadensis (herb).
* Erigeron heterophyllum (herb).
* Erigeron Philadelphicum (herb).
Eucalyptus amygdalina (essential oil).
Euonymus atropurpurea (bark).
Eupatorium Ayapana (herb).
Fennel (short, and long fruits).
Fumaria officinalis (herb).
Galipea Cusparia (bark).
Galls, Aleppo, roasted.
Galls, Bussorah
Galls, English.
Galls, Kakrasinghi
Galls, Pistachia.
Gaultheria procumbens (leaves).
Goa powder.
Gum, Caramania.
Gum, Kauri.
Gum, Kuteera.
Gurjun oil.
Hancornia speciosa (fruits, preserved wet).
* Hedeoma pulegioides (volatile oil).
Helichrysum serpyllifolium (herb).
Helicteres Isora (fruit, from Calcutta).
Hepatica triloba (leaves).
Heracleum lanatum (herb).
Holarrhena antidysenterica (bark).
Hygrophila spinosa (herb).
Hymenæa Courbaril (resin).
Indian copal.
Indian paint (from Demerara).
Ionidium Ipecacuanha (root).
Ivory dust.
Jalap root, false.
Jatropha Curcas (seed).
Jessamine and other flowers for flavouring teas (from Canton).
Kalmia latifolia (leaves).
Koegoed root (Mesembryanthemum species).
Khetmul (Malva species).
Kino (from Mysore).
Lac, in sticks (small variety).
* Laurus Benzoin (bark).
Leaves, Buchu.
Leaves (Cape of Good Hope, cure for consumption).
Leonotis Leonurus (herb, from the Cape of Good Hope.)
Leyssera gnaphalioides (herb, Cape of Good Hope).
Limonia laureola (leaves, from Manilla).
Magnesia, light carbonate of (in cakes).
Melanorrhæa usitatissima (oleo-resin).
Melianthus major (leaves).
Mimusops Elengi (bark).
Mohria thurifraga (herb, from the Cape of Good Hope).
Monesia.
Mundtia spinosa (herb, from the Cape of Good Hope).
* Myrica cerifera (bark).
Myrica cerifera (wax).
Oden-el-haloof (root, from Morocco).
Oil, camphor, residue of.
Osmitopsis astericoides (herb, Cape of Good Hope).
Panax quinquefolium (root).
Papaver somniferum, fixed oil from the seeds.
Paraffin, brown.
Pellets (of earth ?) (Bengal).
Pelargonium antidysentericum (root, Cape of Good Hope).
* Phytolacca decandra (root).
Picrorhiza Kurroo (root).
Piney resin.
Pitch.
Polanisia icosandra (root and herb).
Prinos verticillatus (fruit and leaves).
Psychotria emetica (root).
Pyrethrum roseum (flowers).
* Quercus tinctoria (bark, in coarse powder).
Quercus alba (bark).
Quinine, acid sulphate.
Rhamnus catharticus (bark).
Rhus glabra (fruit).
Rubia tinctoria (root).
Rumex crispus (root).
Rumex (fruits).
* Rumex obtusifolium (leaves).
Rubus villosus (root, from the United States).
Rubus trivialis (root, from the United States).
* Sabbatia angularis (herb).
Sagapenum (in tears).
Saline ash (from Demerara, used by Indians for salt).
Salep (long narrow bulbs).
* Sambucus Canadensis (flowers).
Sassafras officinale (bark).
* Satureja hortensis (herb).
Scammony (Indian).
Senna, Alexandrian (containing argel leaves).
Senna, Bombay.
Sesamum Indicum (white seeds).
Shea butter (Bassia Parkii).
Shorea robusta (resin).
Smilax species (chumps).
* Solidago odora (herb and essential oil).
Sophora Japonica (flowers).
Styrax benzoin (from Siam).
Sulphur (small prismatic crystals).
Sulphur, native Sicilian (rough).
Sunflower seeds.
Syzigium Jambolanum (bark).
Tanacetum multiflorum (herb, from the Cape of Good Hope).
Terminalia Benzoin (resin).
Timbo root.
Tinospora cordifolia (stem).
Toluifera Balsamum (seeds).
* Triosteum perfoliatum (root).
Trillium pendulum (root).
Ulmus fulva (powder).
Vateria indica (resin).
Vernonia anthelmintica (seed).

Vitis latifolia (root).
Wax, Karriman (from British Guiana).
Wood oil, result of distillation of.
Wrightia antidysenterica (seeds and bark).
Xanthium spinosum (herb).
Xanthoxylon piperitum (flowers).
Xanthorrhœa arborea (resin).
Xanthorrhœa australis (resin).
Zinc, carbonate of (native).
Zizyphus Jujuba (fruit).

Provincial Transactions.

HALIFAX AND DISTRICT CHEMISTS AND DRUGGISTS' ASSOCIATION.

At a meeting held June 20, at the Old Cock Hotel, Halifax, Mr. Brooks, President, took the chair and delivered the following address:—

"The subjects for discussion this evening are the Government Medical Bill which has just passed the Lords, the recent trial for counter prescribing, and the appeal for support from the Trade Defence Association at Birmingham to enable the committee to defend the rights and interests of the chemists. And perhaps at no time since this Association was formed have we met together to discuss questions more vitally affecting not only our rights but even our means of obtaining a livelihood. It is so very easy to be wise and criticize after the trial is over, but it is a great blow to our future rights that the Shepperley appeal case did not precede the late trial and thus have probably avoided a second defeat. The aged gentlemen who were summoned to give evidence as to the practice of the trade in ancient times did not improve our position, but rather the reverse. Mr. Justice Field evidently saw the position we stand in with regard to the public convenience and must have thought, as Baron Bramwell did in a former trial, that it would be very unwise for the Apothecaries' Company to press the Act in all cases. Still his summing up if not hostile to our body was certainly in favour of the penal clause of the Apothecaries Act in the case before him. I think we may rest assured that the best was done by the counsel engaged that could have been done, but the fact remains that upon two occasions before superior judges and a common jury—putting on one side altogether county court decisions against us—we have altogether failed to hold the right of counter prescribing, and the question is, What next? The Executive of the Trade Defence Association inform us that they intend to carry out the Shepperley appeal case from the Exchequer even to the House of Lords if necessary, provided they are supported by the trade at large. The question is therefore—wisely I think—remitted to the country for consideration, and we are asked for our support and assistance. I appeal to you, therefore, to-night to do your part in cashing the cheque of £2000 which the executive have drawn upon us for the purpose of defending what we believe to be our ancient and legitimate rights and interests, and I feel sure I shall not plead in vain.

"One word as to the Medical Bill. This will require careful watching and possibly vigilant action. Though the Duke of Richmond positively declared that the Government did not intend to interfere with what he called "illegal practice," a clause has been added giving the Medical Council the same penal power against us as is now possessed by the Apothecaries' Company. If this is carried it will prove a serious blow to the trade. For whatever we may think of the Apothecaries Act it would practically remain a dead letter as far as we are concerned were it not for the doctors—in a selfish spirit, I fear, more than for the public good—employing spies, getting up evidence and setting the Act in motion, whilst they themselves are daily infringing the Act by employing unqualified assistants and even pupils to visit patients. Let us then press upon both the London executive as well as the Birmingham one to watch keenly the progress of this Bill through the Commons. Let us also press upon the Council to give a generous and sympathetic support to the Trade Defence Association in their earnest endeavour to place the question of counter prescribing in a clear and legal position, free from doubt and fears, and honourable to all."

These remarks received the cordial approval of the meeting.

Mr. Jessop, Vice-President, then proceeded to give an interesting account of the annual meetings of the Pharmaceutical Society and the General Committee of the Trade Association, and proposed, Mr. Hebden seconding and Mr. Dyer supporting, "That this meeting unanimously approves of the vigorous action taken by the Chemists and Druggist's Trade Association in defence of the interests and privileges of chemists, and cordially recommends the appeal for a large defence fund to the generous support of the chemists and druggists throughout the district."

Messrs. Jessop and Dyer were requested to solicit donations, and undertook to do so.

The Hon. Secretary (Mr. Shaw) moved and Mr. Jessop seconded, and it was carried *nem. con.*, "That this Association considering the legal settlement of the right of chemists and druggists to prescribe in simple ailments to be of very serious importance to their interests, respectfully urges the Council of the Pharmaceutical Society to give substantial pecuniary assistance to the Chemists and Druggists' Trade Association in its efforts to defend and maintain that right."

Mr. Hebden proposed and Mr. Dyer seconded, that a full report of this meeting be sent to the trade journals for publication.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

Matter and Ether.*

BY JOHN FLETCHER MOULTON, M.R.I.

All are familiar with the process by which the discovery of the laws that govern phenomena is effected. Close study of various instances of some one phenomenon, with their general likeness and their individual peculiarities, leads, either by the slow process of trial and error or by some happy guess, to the discovery of the law to which the observed variations all conform. When this is once ascertained, the whole group of phenomena fall into harmony, and instead of a mass of separate observations, science seems but the exemplification of a single law. This step in the simplification and unification of nature taken, the human mind is free to seek further conquests. But great as is the advance made by such a step, the mind cannot rest content with it. The dry mathematical expressions which we know as the laws of nature, are soon felt to assuage scientific curiosity to a very imperfect degree. No sooner have we discovered the law that governs any set of phenomena, than we are irresistibly drawn to ask the question, How comes it that this is the governing law? of what set of hidden causes is it the outcome? And thus we are led to seek for the mechanism of nature and to find the physical causes of its laws. Nay, we go further; we cannot be content till we discover the nature and properties of the subject matter of its phenomena, and can deduce from these the previously discovered laws as necessary consequences. And the complete realization of one part, at least, of this search is not beyond the bounds of possibility. It prob-

* Lecture delivered at the Royal Institution of Great Britain, Friday, February 23, 1877.

ably will some day be known to the human race that the whole of nature is but the manifestation of a very few distinct physical existences, possessed of known properties of so simple a kind and so universal in their presence that experience can never enable us to analyse them further. The possible forms assumed by these elements will be deducible from their properties; and the more complex laws that will regulate the behaviour of the resulting substances, will be problems determinable from their known structure. Thus all nature will be theoretically the resultant of the interaction of known agencies, and the solution will be complete, even though the stupendous difficulties of the analysis necessary to deduce the laws of even the more simple phenomena from the properties of these elements should compel the men of that far distant future to arrive at laws by induction from experiment, just as we do now already in the simplest of all sciences—astronomy. In this science, the phenomena of which are due to only four laws, each of which is capable of statement in most simple terms, the complexity of the analysis well-nigh drives astronomers to abandon calculation for observation, in the more delicate refinements of accuracy in which they indulge. Similar considerations will always operate to keep distinct the sciences that deal with distinct classes of phenomena, long after it has become a recognized truth that they are all the more or less complex manifestations of some few known elemental, physical existences. And certainly no considerations of the limits of possible success can avail to destroy the fascination of researches into the ultimate constitution of the existences of which nature is built up—the minute anatomy of the universe.

But although investigations of this nature are so interesting, and promise not only success, but success of the highest order, and although the interest of the research is common to the devotees of every science, inasmuch as it deals with that which underlies them all, it is most remarkable that so little advance has been made in this direction. And not only is it the case that we are compelled to admit that our ignorance of the ultimate constitution of matter is well-nigh as dense now as it ever was, but if we examine the attempts at solving the problem, hitherto made, they strike us at once as having the strangest characteristics. While in most of the other regions of research the results of all investigators have a certain family likeness, and the theories they propose—though perhaps mutually exclusive—have many points in common, yet here we find that the different solutions proposed have the wildest dissimilarity, and many of them present so fantastic an appearance, that it is difficult to believe that they are the productions of the sober investigators whose names they bear. We are too apt to pass lightly over the lesson taught us by the contemporaneous existence of the corpuscular and the undulatory theories of light. That two theories so diametrically opposite in nature, hypothesizing such utterly different constructions and properties of matter, could at a time not so very long past have been considered as possessing tolerably equal claims to acceptance, opens up a vista of ignorance as to the ultimate constitution of matter which is very humiliating. Nor will it suffice to say that those were the days when true science was in its infancy. Though the dispute between the two theories of light was speedily settled by the complete defeat of the corpuscular theory, and our ignorance of the real mechanism that produces and transmits light was rendered thereby less total—in fact we may say that it was so far dispelled that only those capable of thoroughly understanding the subject can feel the difficulties and imperfections of the accepted theory—yet similar struggles are still going on in other kindred subjects, and for them no such excuse can be pleaded. Take, for instance, electricity and magnetism. Our knowledge of their phenomena is extraordinarily wide; such a book as Wiedemann's 'Galvanismus' shows an accumulation of observations on one simple branch of the subject that can scarcely be paralleled in any other science. Yet if we look at the rival theories as to the nature of electricity, and its connection with matter, they seem so grotesque and so dissimilar—so like mere guesses in short—that we can scarcely help fancying that we are back in the days of Lucretius, when the best qualification for being a philosopher was to be an imaginative poet. And indeed in fertility of imagination, the authors of such theories as those to which we are referring seem not unworthy rivals of the Roman poet, and they make similar demands on our powers of belief. Weber and Ampère's ideas of magnetism being caused by each molecule of matter having its own special electric current circulating round it everlastingly; Poisson's idea that it is caused by each molecule being permeated by two mutually neutralizing fluids, capable of being separated by external attraction, but incapable of being removed from the molecule; the rival theories of two fluids, of one fluid, and of no fluid, in electricity, the numerous theories as to the nature of the luminiferous ether and its relation to matter, and the vortex theory of atoms, suffice to show that no effective check has as yet been placed on the free use of the imagination in this department of research, and seem to give some colour to the suggestion that the intolerance of credulity, professed by men of science, is easily relaxed by them in favour of their own pet theories.

The chief and immediate cause of this is not far to seek. Any attempt to arrive at the hidden mechanism which causes a phenomenon must be a direct reflex of the knowledge and the ignorance of the age in which it is made. Let us take the case of some ingenious machine performing some known operations. If a person wholly ignorant of mechanism, save so far as the objects of common life teach it to intelligent observers, were to attempt to solve the problem of its construction, he would seek for some arrangement of levers or other mechanical appliances of the simplest and most elementary nature, which would give the desired result. If a mechanician were to apply himself to the same problem, he would have present to his mind all the refinements of mechanical science, and would probably arrive at a solution, no portion of which would resemble the one composed of the simpler elements, while his might in no respect resemble that which would be arrived at by one who, in addition to possessing a knowledge of mechanism, was also a skilled electrician. Each of the solutions would consist of the elements which the experience and knowledge of the maker enabled him to use, and there would be no probability of any of them representing the actual construction of the machine in question, unless the artifices used in its construction were such as were known to some of the persons who were thus attempting to reconstruct it. Just so is it with the attempts we make to arrive at the mechanism of nature. They are charged to the full with our ignorance. If we happen to be acquainted with structure similar to the actual structure sought for, then success is possible, and some discoverer will in all probability arrive at a close approximation to the real state of things. If we do not, then all our efforts will but lead us to the discovery of a *possible* mechanism—one which might cause the phenomenon, but which is not the one which actually does cause it; and with this we must rest content, till in some way or other our knowledge of possible elements of construction is widened, when we may return again to the problem and find a new solution, which may in its turn have to be replaced by future ones. Take, for example, the question of the structure of matter. Matter was known to move with little or no resistance through the ether, to attract other matter, to be capable of great complexity in its nature, inasmuch as the light proceeding from elements, when in a state of incandescent gas, shows that they are capable of a large number of fundamental vibrations. To explain all this many most ingenious hypotheses were devised, both as to ether and matter; molecules or atoms were viewed as

complex arrangements of parts vibrating or revolving under their mutual attractions. Ether was made an imponderable. Space was filled with ultra-mundane corpuscles, which, by their perpetual rain on all masses of solid matter, caused the phenomenon of gravitation. At length Helmholtz discovered vortex-motion. Vortex-rings were found to move with little or no resistance in the medium, whether fluid or gaseous, in which they were formed; they were sensible of the presence of one another though not in contact;- they were capable of being made to have the most intricate forms, and to take up the most complicated systems of vibrations. Instantly a vortex theory of matter was devised, which has very much to recommend it, and which is at present the one in highest favour. But just as it was only rendered possible by Helmholtz's discovery of the new form of motion after which it is named, so it may in its turn have to give way to other theories which enlarged knowledge shall have enabled us to suggest.

The difficulty at once suggests itself, that if we admit that these theories as to the actual mechanism of nature are so intimately dependent on the state of the ignorance or knowledge in which we are when they are framed, how can it be right to attach any credence to them? How can we believe a theory at the same time that we admit that it will be probably displaced by another and a different one which will have at least as high claims to our belief? Science would at once lose all claim to be called the strictest school of belief, if it countenanced any such moral gymnastics as a belief which could thus co-exist with disbelief. And yet so great is the assistance derived from a well-constructed theory as to the mechanism producing phenomena, that she cannot afford to allow all efforts at solving such problems to be delayed until there comes a stage of such perfect knowledge that the mind might claim to be capable of pronouncing on them with certainty—if indeed such a time could ever come. So she boldly faces the difficulty of which we have spoken—the difficulty of showing any other choice open to scientific men than either to be credulous or to be timid—by distinctly recognizing a class of scientific fictions, or, as they are usually called, hypotheses. These are theories as to the mechanism of nature which, either completely or to a great extent, account for some set of phenomena, and which therefore, so far as our knowledge goes, may correctly describe the whole or some part of the actual cause of the phenomena, *i.e.*, the mechanism that produces them.

Nothing is more important in scientific thought than to distinguish between these hypotheses and laws. The discoverer of laws has nothing to do with actual causes. He only notices and formulates connections and relations between phenomena, and these formulations are laws. So far as the law is concerned, it is immaterial whether the one of two connected phenomena is the cause or the effect of the other, or whether the relation between them arises from their being both connected with a third phenomenon; the law is equally true in all cases. So long as the induction which has led to it has been duly and carefully performed, it is true and will never be displaced or superseded, however mistaken were the ideas which its framer possessed of the nature or causes of the phenomena to which it relates. Newton was quite right when he said, *hypotheses non fingo*; for the portion of his great achievements to which he was referring consisted in the demonstration of the existence of certain laws, and not in the explanation of their causes. But he, as well as all other great men of science, when the right time came, was ready to frame hypotheses, to start these scientific fictions, which were to be thankfully received, studied, tested, respected, worked from, and in short, everything but actually believed in. And he least of all would have, on the one hand, despised these tentative solutions, or, on the other hand, lightly believed in their truth. The whole of his work shows that he appreciated the full value of hypotheses, a value which it is difficult to express clearly, but which every learner or teacher of science feels only too keenly. For, without some guiding idea as to the nature and causes of phenomena, the mind is very sluggish in devising good methods of investigation; but so soon as a good hypothesis has been formed, it is so suggestive of fields of research and of experiments, that, whether it be true or false, there follows an immediate and rapid increase of knowledge. For a hypothesis may be a good one without being a true one. It may render the greatest assistance to the mind, it may be so well chosen that it accounts for kindred phenomena, not known at the time when it was first suggested, it may lead to the discovery of new laws, and it may enable calculations to be made which are of the highest value, and yet it may turn out to be radically false. Even the theory that heat was an imponderable fluid might put forth a strong claim to our gratitude for the assistance it gave to early discoveries. To be thus useful for a time, it is not necessary that the assigned mechanism should be the true one, but only that the laws that result from its structure should closely correspond with the more potent of the laws that actually direct the observed phenomena. And just as this is all that a hypothesis need do, so is it all that its success entitles us to believe that it is doing; and the true scientific attitude of mind towards hypotheses is to recognize them as describing causes which would produce results similar to those observed, and which, if not truly representing the mechanism which actually causes the results, at all events would produce results governed by the same laws.

Parliamentary and Law Proceedings.

Poisonous Violet Powder.

Mr. Humphreys, coroner for the Eastern division of Middlesex, resumed an inquiry on Tuesday at the Town Hall, Hackney, into the cause of the death of the infant child of Francis and Mary Ann Ringrose, who, it is alleged, was poisoned by the application of violet powder manufactured by Mr. T. G. King, of Abbott Street, Kingsland. Mr. Poland, instructed by Mr. Barnard Thomas, of the Treasury, appeared for the Crown; Mr. Byfield, solicitor, watched the case on behalf of several wholesale chemists; and Mr. H. H. Wills appeared for Mr. King.

Mr. Fox, wholesale chemist, of Bethnal Green Road, was recalled, and in answer to Mr. Wills, he said that he did not superintend the sending out of orders from customers, his duties being principally in the counting house. The dates and the names and addresses of the persons to whom poisons were sold were entered in the books. He could from his experience, he believed, be able to distinguish between terra alba and white arsenic.

Mr. Wills produced four small packets of powder which he placed before the witness, and asked him what they were.

Mr. Fox replied that he thought the first was terra alba, the second arsenic, and the third he thought partook of the nature of terra alba; but he could not venture an opinion as to what the fourth was.

Mr. Wills said that he would prove that the first was cream of tartar, the second arsenic, the third terra alba, and the fourth barytes.

Mr. Fox, jun., said that there was no entry in their books of any terra alba having been sold to Mr. King. Any one acquainted with chemicals could easily recognize the difference between terra alba and white arsenic, as 14lb. of the former was equal in bulk to 20lb. of the latter.

Mr. John W. Francis, of Messrs. Bush and Co., wholesale chemists, Artillery Lane; Mr. Frederick W. Thorpe, in the employ of Messrs. Thorogood, drysalters, Holborn; and Mr. Weller, manager to Messrs. Solomons, Cross

Lane, Eastcheap, said that Mr. King had dealt with their firms, and each denied that they had ever sold him any arsenic.

Professor Tidy, who has analysed the powders, said that he had no doubt the arsenic had got mixed with the powders instead of terra alba, as the poisonous ones contained almost the same percentage of arsenic as the pure ones did of terra alba.

The Coroner then summed up the evidence to the jury, and left to them the following questions :—1. Was the death of the child due to arsenical poisoning?—and, after having heard medical evidence, he did not think there could be much doubt about that. 2. Was the arsenical poisoning due to the use of a powder made and sold by one King as violet powders? 3. Did King, being a druggist, exercise reasonable and proper care before making and selling the said violet powder that it was composed of harmless ingredients? 4. Was King guilty of gross and culpable negligence in not ascertaining or examining the nature of the ingredients comprising the said powder before making and selling the same, whereby the death of the child was occasioned?

After having retired for an hour the jury returned answers in the affirmative to the first, second, and fourth questions, and "No" to the third.

The Coroner said the answers were equivalent to a verdict of manslaughter, and an order was made out for the committal of King to the Old Bailey on that charge.

The grand jury on the South Eastern Circuit at Chelmsford have returned three true bills for manslaughter against Mr. King, for selling violet powder containing a large quantity of white arsenic, and thereby causing the death of a number of young children. As has been already stated the case has been removed, under Palmer's Act, to the Central Criminal Court. The defendant has been admitted to bail.

Review.

A Key to Organic Materia Medica, written for the Students of the South London School of Pharmacy. By Dr. John Muter, M.A., F.C.S., etc. Second Edition. London: W. Baxter.

The present edition differs in several points from its predecessors. The pages are no longer interleaved, and the book is considerably enlarged, being nearly three times as thick as formerly. The plan also is altered; the articles of materia medica being arranged according to the natural system of classification followed in most treatises on materia medica. Its adaptability for use in the museum of Dr. Muter's school is, however, still retained by means of an appendix at the end of the book, where the contents of the drawers are tabulated and annotated.

A number of drugs have been added to the list, some without any apparent reason, as they are not used to any extent in this country, such as Gulancha, Kokum butter, etc.

Why a few Indian and American drugs should be enumerated and described and not others, is at first sight difficult to understand. One need not go far, however, to discover that 'Pharmacographia' has been somewhat blindly followed; and this will account for the work not being up to so recent a date as might have been expected. Had the careful wording of that excellent work been followed, such dogmatic statements as that regarding aconitine would not have occurred. Thus on p. 4, in Dr. Muter's work, the formula which is given, without qualification, as that of amorphous aconitine differs considerably from that of the crystalline alkaloid given on p. 7, in fact by nearly double the amount of carbon. Aconella also is mentioned without any remark as to its alleged identity with narcotine.

The botany and materia medica are rather weak throughout. Thus *Actæa spicata*, which is both rare and local in the North of England, is spoken of as "the *Actæa spicata* of English lanes"; Marsh mallow flowers are described as being of a pinkish-blue colour, and those of *Malva sylvestris* as pink; Arnica rhizome is described as being two to three inches thick; Dandelion root is said to have "a white meditullium." Nor is the acquaintance with the commercial varieties of drugs manifested particularly extensive; thus no mention is made of catechu in strips or parallelograms, small castor oil seeds, Morea galls, spurious jaborandi, false cusparia, and various others equally well known, although some varieties less often met with are described.

In the preface the author speaks of his intention to have published illustrations of each of the drugs referred to in the appendix, but states that through the sudden exhaustion of the first edition he has been compelled to publish without them. Probably this may account for the hurried manner in which many portions of the work have been revised. For instance, under nataloin, the bluish-green colour caused by the vapour of nitric acid has evidently been omitted by accident; whilst the statement on p. 190 that umbelliferon is yielded by all umbelliferous resins scarcely agrees with the statement on p. 194, that asafœtida from *Ferula alliacea* and Persian ammoniacum, p. 195, yield no umbelliferon.

Much has doubtless been published since this work was printed, and it, therefore, behoves the students at the South London School to acquaint themselves with what has been written; for instance, concerning the bassorin of tragacanth, the alkaloids of aconite, calabarine, the colouring matter of *Rosa gallica* and many other matters of which no mention is to be found in this work.

There is a positive tone about many of the statements which, while it doubtless possesses certain advantages for students, is certainly liable to mislead. Thus under specially distinctive tests Siam benzoin is said to evolve no odour of benzoic aldehyde when heated with sulphuric acid and potassium dichromate, although Kolbe and Lautemann state that they found cinnamic acid in Siam benzoin. As a rule, however, the specially distinctive tests are likely to prove very useful.

The appendix, containing a classification and description of the chief starches existing in the commoner articles of materia medica and food, is evidently the outcome of considerable personal experience and contains a large amount of valuable information. The book is clearly written and the arrangement very good. It is to be hoped that the next edition will be prepared with more care and that the revision of the proof sheets will be entrusted to a gentleman who will satisfactorily perform that duty, and that it will be more worthy of Dr. Muter's reputation as a teacher.

Dispensing Memoranda.

[127]. A few days ago a prescription was left by a young man at a pharmaceutical chemist's in one of the leading thoroughfares of London, for the purpose of being dispensed. He inquired, "How many pills does it order?" "Eighteen." "Oh! that will not be nearly enough. It is not for me but for a friend going abroad. Make a hundred, and I will call for them to-morrow morning."

On carefully reading the prescription after his departure, the spelling of the genitive terminations, the peculiar combination of drugs and the doses, attracted attention. The following is a true copy:—

℞	Sesquibromid. Ferri	gr. xxxvi.
	Extr. Nucis Vomicae	gr. iij.
	Extr. Ergotae Aquos.	gr. xxiv.
	Pulv. Cantharidis	gr. xxiv.

M. ut ft. massa et div. in pil. xviij.

One pill to be taken three times daily.

The next morning on the customer presenting himself, the name of the prescriber was asked for and given without hesitation. It proved to be that of a medical man residing more than two hundred miles from London. In due time he replied as follows:—

"The doses are *not* poisonous. The prescription has certainly my professional sanction. The patient might be put on his guard so far as irritation of the bladder might occur; but this is not likely. I note the doses again and return your note that you may see."

It was thus plainly apparent that the chemist was required to dispense and order to be taken four grains of powdered cantharides in a day, and that this quantity was to be repeated for six days.

After deliberating on the duty owing to the prescriber and to the patient, as well as on the responsibility that might be incurred; and after consulting with friends of large experience in the medical profession and in pharmacy, the prescription was returned to its owner undispensed.

June 29, 1878. BETA.

Obituary.

JAMES GARDNER.

On Tuesday, the 9th inst., James Gardner, one of the oldest of our pharmaceutical chemists, the senior partner of the well known firm of Gardner and Ainslie, passed away at the ripe age of 78.

James Gardner was born in Edinburgh, in the first year of the present century. His father who had been in business since 1778, was the person with whom he served his apprenticeship. He attended most of the medical classes, and acted for some time as assistant in the laboratory of Dr. Fyfe, one of the best extra-academical lecturers in chemistry at that time and author of a work on the science which was for many years held in high repute. Succeeding at his father's death to a first-class dispensing business, James Gardner, continued to carry it on with success many years, until his health gave way. After repeated attacks of inflammation of windpipe, Professor Symes found it necessary to perform the operation of tracheotomy. About ten years after his recovery, Mr. Gardner took Mr. William Ainslie as his partner in the business, which has since been carried on under the firm of Gardner and Ainslie. With one exception, Mr. Gardner was the oldet chemisst in Edinburgh, and from the earliest days of the Pharmaceutical Society took the warmest interest in its affairs; no one watched with more care, or rejoiced more sincerely at the success of the Society than he did. He not only was a constant member of the North British Branch Council, but acted for one year as its President.

By Mr. Gardner's death another link has been snapped between the past and present race of pharmaceutists, and it is not too much to say that few more warm-hearted and genial men have been connected with pharmacy. In private life he was much esteemed for his many virtues, and his high sense of rectitude was well worthy of being followed. Increasing infirmities caused him to be laid aside from active business pursuits about three years ago. He leaves no family, his wife having predeceased him several years ago. It may be mentioned that Mr. Gardner survived the operation of tracheotomy forty years, the longest period we believe on record of any patient surviving such a delicate operation.

Information has also been received of the deaths of the following:—

On the 23rd of May, 1878, Mr. James Hunter, Chemist and Druggist, Dewsbury. Aged 54 years.

On the 13th of June, 1878, Mr. John Saffery, Chemist and Druggist, Sheerness. Aged 81 years.

On the 16th of June, 1878, Mr. William Moffat, Chemist and Druggist, Orton, Westmoreland. Aged 68 years.

On the 24th of June, 1878, Mr. William Priestman, Chemist and Druggist, Waterloo Town, Bethnal Green, E. Aged 65 years.

On the 24th of June, 1878, Mr. James Peter Perkins, Chemist and Druggist, Parker's Row, Bermondsey, S.E. Aged 28 years.

On the 25th of June, 1871, Samuel Oldknow Bullivant, Chemist and Druggist, Bury, Lancashire. Aged 59 years.

On the 25th of June, 1878, at Leamington, Mr. William Jennings, one of the Founders of the Society. Mr. Jennings was formerly in business in Halifax, but retired in 1868.

On the 26th of June, 1878, Mr. William Wilson Gibson, Chemist and Druggist, Hexham, Northumberland. Aged 66 years.

On the the 27th of June, 1878, Mr. Arthur Binstead, Chemist and Druggist, Ebury Street, Pimlico, S.W. Aged 69 years.

On the 3rd of July, 1878, Mr. Fearnley Hill, Chemist and Druggist, Bradford, Yorks. Aged 38 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE COUNCIL REPORTS.

Sir,—Always having taken a lively interest in the reports of meetings of the Council, I cannot refrain from writing to congratulate you on the full report you have given of the last meeting, and as appears to me free from the control or cooking of any one; thus I trust you will be allowed to continue to report, by which means I hope to see a lively, manly, and wholesome interest taken in all that concerns the wellbeing of the Pharmaceutical Society of Great Britain and the trade.

Though I take a broader view than Mr. Hampson on the admittance of reporters, I regret his motion was lost and was surprised to find a former mover of a similar resolution of some six years ago playing at "Jim Crow," and voting against the child of his own brain.

Angry feeling seems also to have warped the judgments of members in this vote and led them to vote on personal grounds rather than on broad principles, and perhaps to influence the vote, an attack was made on the editor of the *Chemist and Druggist*, a journal which has been conducted in a way which has commended itself to a very large portion

of the trade and rests solely on its own merits for support. Allusion was also made to the report of the *Chemist and Druggist* on the annual meeting of the Society. I venture to say that though the strictures in that journal were severe, they were within the bounds of fair, impartial, and independent criticism.

I feel every one must regret to see a jealous and angry feeling manifested against the *Birmingham Association* which I cannot account for except that the dog-days have come upon us suddenly and rendered us rather snappish.

The Council should not forget that to the Association the trade owe it that they obtained a satisfactory hearing with the Duke of Richmond on the "Medical Act Amendment Bill," which hearing it appears was not granted to the Council of the Pharmaceutical Society of Great Britain, therefore I think the Council should be grateful to the Trade Association for doing what they for some reason could not do.

If the Council would keep in view that they are at Bloomsbury Square to protect the rights of the trade at large, whatever those rights are, and to elevate it by education, and to these objects give their best efforts, instead of to personal quibbling, when action is demanded, they would gain the respect and best thanks of every member of the Society.

60, *St. George's Road, S.W.* W. W. URWICK.

[*** Though we are obliged to Mr. Urwick for his congratulations, we cannot take credit for the report which was furnished as usual by the official reporter, and it was no more "free from the control or cooking of any one" than has so far as we are aware hitherto always been the case within our experience. This notion of the exercise of occult influences appears to be like Mr. Cross's "lying spirit" an unexorcisable bogie.—ED. PHARM. JOURN.]

THE MEDICAL ACTS AMENDMENT BILL.

Sir,—I trust your remarks upon the Medical Acts Amendment Bills contained in the Journal of the 6th instant will receive the serious consideration of the Executive of the Chemists and Druggists' Trade Association and that their zeal in taking up prosecutions in the future will be tempered with more discretion.

I have been in the habit of prescribing over the counter in simple cases for seventeen years without any attempt on the part of "the profession" to interfere with me, but I have always avoided going beyond this, and I think such a course more worthy of the trade than indiscriminate prescribing.

Without entering into the merits or demerits of the case lately tried before Mr. Justice Field, I think a little consideration will convince the majority of my brother chemists that to undertake the duties of "the profession" without the qualification is highly reprehensible, to say the least. Had a duly qualified medical man prescribed for the child the resulting death might not have taken place and the painful recollection of incompetency spared the defendant.

WILLIAM PARTRIDGE.

288, *Moseley Road, Birmingham, July* 9, 1878.

HOW THE SOCIETY CAN HELP US.

Sir,—I think times have changed considerably since Mr. Leay retired from business, or, at all events, prices have altered very much for the worse.

I guess Mr. Leay was never asked to supply 2*s*. Nestle's Food at 1*s*. 5*d*., as that was the price at the stores, and so on *ad nauseam*.

With regard to protection we have only ourselves to look to, and I maintain the Society could help us very materially by issuing a dispensing price list, marked 1, 2 and 3, with prices varying to suit all classes of medicines, from the very concentrated, now so much in vogue, to the simple mixtures for children.

We cannot have absolute uniformity in prices, but a guide would be useful to many dispensers.

As for competing with the stores in dispensing or retail it is out of the question, and when a stranger hands me a prescription with the store mark on it I invariably mention the price before compounding it, to avoid any disagreeable remarks afterwards.

The Pharmacy Act was passed for the protection of the public, and they cannot reasonably expect to be protected without a charge in some form or other.

The barrister, who had his medicine made up so cheaply, would not think of carrying out the law for his clients free of cost, and we have equally as much right to charge for carrying out the provisions of the Pharmacy Act in copying prescriptions, etc., and for our time and skill in dispensing them.

All this I admit is not expressed in the Act itself, and that is all the more reason why we should look after ourselves, as the public can take care of themselves very well in a pecuniary point of view.

Looking at the matter seriously, I ask is there any other class of educated men who do so much work and incur so great responsibility at the price we do?

I hope all the chemists throughout the country will petition the Society to appeal against the decision in Mackness and Co., *alias* The London and Provincial Supply Association, Limited, which certainly was not a *bonâ fide* co-operative store. The business had formerly been carried on by Mr. Mackness, against whom convictions under the Act had previously been obtained.

If the Society requires funds for the purpose I feel sure that the majority of chemists on the register would gladly subscribe towards such a cause.

If we carry out the Pharmacy Act in its integrity and guarantee all our drugs, chemicals, and preparations equal to the B.P. standard we have fulfilled our part of the agreement, and in return we have a right to ask a *quid pro quo* in the shape of fair and legitimate profit.

Sandown, I. W., July 1, 1878. GEORGE BROWN.

[*** By reference to the report of the proceedings of the Coun cil at the June meeting, page 991, our correspondent will see that the course suggested by him was adopted. ED. PHARM. JOURN.]

WHAT IS VIOLET POWDER?

Sir,—I have been connected for more than forty years, man and boy, with the retail drug trade, and have during that rather lengthened period always understood that what is called "violet powder" was a composition of starch powder, orris root powder and a little perfume; the first article being about 95 per cent. of the whole. It seems, however, that I have been mistaken, and that terra alba, magnesia, etc., are the legitimate ingredients. When such an authority as Professor Redwood speaks there is nothing left for a humble mortal like myself than to "baisser la tête et croire." DUM VIVO DISCO.

G. B.—By the 31st clause of the Dental Practitioners Bill it is provided that any person who has been articled as a pupil and has paid a premium to a dental practitioner entitled to be registered under the Act, in consideration of receiving from such practitioner a complete dental education, shall, if his articles expire before the 1st of January 1880, be entitled to be registered under the Act as though he had been in *bonâ fide* practice before the date of its passing.

O. P. O.—(1) *Chiococca racemosa;* (2) *Spiræa salicifolia;* (3) *Garrya elliptica;* (4) *Calamintha Clinopodium;* (5) *Spiræ ariæfolia.* See the erratum on p. 20.

F. A. Brown.—*Senecio Jacobæa.*

J. Walker.—Your advertisement should have been sent to Messrs. Churchill, 11, New Burlington Street.

"*Chemist.*"—Cooley's 'Cyclopædia,' a new edition of which is now in course of issue in monthly numbers, or Beasley's 'Druggists' Receipt Book,' both published by Messrs. Churchill.

G. Gowland.—See the answer to G. B., above. Copies of the Bill may be obtained from Messrs. Hansard, Great Queen Street, W.C.

W. F. Haydon,—We are obliged to you for the copy of correspondence forwarded on the 10th inst., but cannot comply with your request since we do not consider the publication of the letters in these columns desirable unless by the direction of the Council. The facts referred to in the several letters are, moreover, sufficiently within the cognizance of the readers of this Journal to render such a course quite unnecessary for the purpose of information.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Walker, Messrs. Haas and Rosenfeld, Mr. Bouyer, Mr. Hanart, Mr. Grohs, Messrs. Cook and Co., Messrs. Weiner and Son, Messrs. Muller and Co., Mr. Symons, Mr. Brett, Mr. Callanan, Mr. Watson, Mr. Rimmington, Messrs. T. and H. Smith, S. J. W., G. B., G. S. L., Fellow of the Meteorological Society, Fair Play.

THE DETECTION OF ALUM IN FLOUR AND BREAD.

BY F. M. AND GEORGE RIMMINGTON.

Hitherto the detection of adulteration of flour and bread by the addition of alum has been entirely based upon the assumption that the alumina phosphate found above a certain percentage existed as a soluble salt of alumina, or, in fact, that an addition of alum had been intentionally made. This subject engaged our attention some months prior to the Selby prosecutions, and in the prosecution of these inquiries we had occasion to make analyses of flour from widely different parts of the country, as well as some samples of foreign wheat, and the results we obtained were such as to lead us to the conclusion that alumina in much larger proportion than was generally thought was quite compatible with freedom from alum. Satisfactory as this conclusion was in one direction, it left us in a most unsatisfactory state of uncertainty how to prove the presence of the salt when actually present. Until this point was settled no more prosecutions for using this substance as an adulterant could take place.

The most obvious thing that occurred to us was to attempt the estimation of the sulphuric acid; the estimation of the ammonia or the potash appearing beyond the power of analysis. Three modes suggested themselves to us as practicable, viz., combustion, solution (elutriation), and dialysis. Combustion was a failure in every way we tried it; solution, that is by mixing a certain portion of flour with a diluted solution of alcohol and filtering out the solution and rendering it clear by boiling, or the addition of acetic acid, and precipitation by chloride of barium, proved much more practicable and satisfactory, and, if not giving perfectly concordant results, it is strong confirmatory evidence.

Dialysis also yielded results that have given us strong hope that it is to be the process of the future, but it is tedious and slow.

Our mode of procedure is much the same as for solution:—We take 50 grams of the flour and put into a litre flask 200 c.c. of rectified spirit and to this add the flour and agitate until a perfectly smooth mixture is effected, then add distilled water to make up the measure one litre. This is allowed to stand with occasionally shaking for twenty or thirty minutes and then poured upon a large filter. Take any proportion of the filtrate and place it in a dialyser and allow it to dialyse twelve hours; at the expiration of that time pour out the dialysate into a beaker and put more water into the dialysing dish and continue the process for another twelve hours, and it may be repeated a third and fourth time until no trace of sulphuric acid is obtained. These solutions may be dealt with separately or collectively by evaporation to a small volume and the sulphuric acid precipitated by a barium salt, collected, and weighed. It will be obvious to every one that any salt of sulphuric acid that is present in the flour must make its appearance in the dialysate, and the only problem to settle will be its proportion to the alumina found by incineration. The dialysate may likewise be tested for alumina.

Should the amount of sulphuric acid be small or insignificant, it must not be ascribed to alum, but to one of the constituents of the flour, and flour does contain a small quantity of this acid in some combination or other.

In the case of bread a modification of the above process has to be adopted. The bread should be dried and powdered and digested in the diluted spirit and then filtered. This filtrate can be used in exactly the same way as in the former processes. But the fact that soluble sulphates may exist in the water with which the bread has been made must not be overlooked. This difficulty may be met by testing the filtrate with the logwood test, the operation being performed in Nessler glasses on a white ground.

Addendum.—As the above has been written some time, and as further experience has brought out some new facts, we think proper to append the following:—

We find the logwood test most valuable and extremely delicate. It is capable of detecting alum as distinctly as Marsh's test will detect arsenic, 1 part in 1,000,000. As some ambiguity in the use of this test has evidently occurred to others, as to ourselves, this statement may excite some incredulity, and we were certainly no believers in its value until we discovered the reason why.

There are several kinds of logwood in use, and some of these are useless for the purpose. But on applying to a friend for a supply of some of the best kind, we obtained splendid results; not merely an equivocal and hazy shade of blue or lilac, but colours clear and bright, as if produced by aniline salts.

Extract of logwood dissolved in diluted spirit gave also almost equally good results. It is, therefore, by the use of this agent as a discriminating test that the presence or absence of alum in flour or bread may be determined with ease and certainty.

Three modes may be followed:—

(1) A portion of the filtrates obtained from the flour or bread by elutriation may be tested as for ammonia in a Nessler glass.

(2) The dialysate may be tested in the same way.

(3) The flour itself may be tested by mixing in a small porcelain dish 2 grams with 2 c.c. of water, and adding 1 c.c. of the test.

If comparative trials be made at the same time with pure water and pure flour the difference is most remarkable.

For a while the colour develops and grows deeper, then changes colour a little, and finally fades.

THE PARIS EXHIBITION.

CRUDE MATERIALS APPLICABLE IN MEDICINE AND PHARMACY.

FRENCH COLONIES—*continued.*

Martinique.

From this island a very large number of drugs are exhibited. Some of these are well known West Indian drugs, and others more properly belong to the East Indies, while a few, such as Paraguay tea and coca, can scarcely be admitted as belonging to the drugs of the island since they are only cultivated in the botanical gardens.

Among the better known West Indian drugs may be seen specimens of *Asclepias curassavica*, *Cissampelos Pareira*, cowhage, *Cassia fistula* and *C. Brasiliensis*, guaiacum, logwood, quassia, simaruba, *Petiveria alliacea*, and *Coccoloba uvifera*. Those which are more frequently seen from the East Indies are *Abrus precatorius*, *Datura Tatula*, cloves, guava bark,

henna, patchouli, and sesamum leaves, and the bark of *Terminalia Catappa*, the seeds of *Moringa pterygosperma*, and *Guilandina Bonducella*, fruits of *Semecarpus Anacardium* and *Amomum Cardamomum*, also the leaves of *Cassia alata*.

In 1862 *Cinchona Calisaya* was introduced into the island by M. Belanger, and the results obtained are such as to leave no doubt in his mind that at a height of 600 to 700 metres the Peruvian cinchonas could be sucessfully cultivated and that barks rich in quinine could be obtained. *Cinchona nitida* bark is also exhibited from this island.

The following list represents such of the principal drugs exhibited from this colony as are not generally known:—

Acalypha carpinifolia (Euphorbiaceæ), used as an antispasmodic.

Adansonia digitata (Sterculiaceæ). In this colony the leaves are used as a pectoral and emollient; in Réunion the pulp of the fruit is used to form a cooling drink, and in Senegal the bark forms a tonic and febrifuge.

Amomum angustifolium and *A. macrospermum* (Zingiberaceæ). The seeds are used as a stimulant tonic.

Andira inermis (Leguminosæ). The bark is used as a vermifuge. It was formerly officinal in this country under the name of cabbage-tree bark, but it is powerfully narcotic and rather dangerous to use.

Anona squamosa. The root and leaves are used as an astringent. The seeds contain a principle poisonous to insects. The plant is properly a native of the Malay Islands and is only cultivated in Martinique.

Aralia arborea. Root and leaves sudorific.

Aristolochia odoratissima and *A. trilobata*. Used as a remedy for the bites of serpents.

Atropa arborescens. Narcotic. It might be advantageous to compare the strength of this plant with belladonna.

Bauhinia variegata (Leguminosæ). The roots and stem are used as a vermifuge and the flowers as a laxative.

Bignonia ophthalmica. Used in diseases of the eye.

Calophyllum Calaba (Clusiaceæ). The oil of the seeds is used for skin diseases.

Caryota urens (Palmaceæ). The seeds are said to

Cestrum nocturnum (Cestrineæ). Narcotic; used

be escharotic.

for epilepsy.

Chloris radiata (Graminaceæ). Rhizome used as a diuretic.

Clitorea ternata (Leguminosæ). Root and seed used as an emmenagogue. In India they are believed to possess emetic and diuretic properties.

Clusia alba (Clusiaceæ). Baths made with the bark and root infused are said to cure the leprosy.

Comocladia ilicifolia (Anacardiaceæ). The powdered leaves form a sternutatory.

Crotalaria sagittalis (Leguminosæ). The whole plant is purgative.

Croton origanæfolium (Euphorbiaceæ). Possesses sudorific properties.

Cuscuta americana (Convolvulaceæ). This plant is said to possess alterative properties and to be especially useful in liver complaints.

Dipteracanthus patulus (Acanthaceæ). Root emetic; said to be preferable to ipecacuanha.

Dracontium polyphyllum (Araceæ). Root purgative.

Egletes domingensis (Compositæ). Powerfully active in affections of the liver.

Exostemma floribundum (Cinchonaceæ). Possesses emetic and febrifuge properties. The bark of this plant has sometimes been offered in commerce as cinchona bark under the name of Quinquina Piton.

Gouania domingensis (Rhamnaceæ). The juice of the bark is employed as a stomachic drink. The thin flexible stems of this creeper form the "chew-stick" of Jamaica. The stick is cut in pieces and the end frayed out by chewing or otherwise, and used as a tooth-brush. A tooth-powder is also formed of the powdered stems.

Gynærium saccharoides (Graminaceæ). The rhizome is used as a diuretic.

Hamelia patens (Cinchonaceæ). The leaves are employed as a remedy for itch.

Homalium racemosum (Homaliaceæ). A decoction of the root and bark is used to restrain mucous discharges.

Hippomane mancinella (Euphorbiaceæ). The leaves are of service for the itch, and the fruit possesses diuretic properties. The acrid nature of the juice renders the use of the leaves in the fresh state rather dangerous.

Ipomœa asarifolia. Root purgative. This species grows near the seaside.

Iris Martinicensis. The roots are used as an emmenagogue.

Lagetta funifera (Thymelaceæ). The bark of this tree possesses vesicant properties.

Lobelia longiflora. The plant is used for syphilis and asthma.

Loranthus americanus (Loranthaceæ). Given as an antidote to the bite of serpents.

Lantana camara (Verbenaceæ). The leaves are used as a stimulant in atonic states of the intestines.

Leucas Martinicensis (Labiatæ). Used as a tonic in intermittent fever.

Marcgravia umbellata. The roots are said to possess diuretic properties.

Mikania Pœppigii (Compositæ). The root is one of the numerous remedies called guaco, used for the bites of serpents.

Mimosa pudica (Leguminosæ). The seeds form a good emetic. The leaves are used for dysentery and as a bitter tonic.

Oldenlandia corymbosa (Cinchonaceæ). Used as a vermifuge.

Oxalis Plumierii. The herb is employed as an antiscorbutic.

Parkinsonia aculeata (Leguminosæ). The plant possesses febrifuge and antiseptic properties.

Parthenium Hysterophorus (Compositæ). Used as an emmenagogue.

Physalis pubescens. Possesses narcotic properties.

Piper macrophyllum. Sudorific. *P. peltatum* is used as a diuretic, and *P. macrophyllium* as an antidote to the bites of serpents.

Piscidia erythrina (Leguminosæ). The leaves, bark, and fruit are powerfully narcotic and are used to catch fish.

Plumbago scandens. The roots and leaves are vesicant.

Plumiera rubra (Apocynaceæ). The root bark is a drastic purgative. The flowers of this plant have a delicious perfume. It is the Franchipannier rose of the French, and the red jasmine of the West Indies.

Sapium aucuparium (Euphorbiaceæ). The leaves

are used for the itch. The milky juice produces on the tongue a sensation like that of capsicum.

Sargassum vulgare (Algæ). This seaweed is used as an antiscorbutic.

Sauvagesia erecta (Sauvagesiaceæ). The leaves are made into tea and used as a demulcent tonic for the digestive organs, also as a diuretic. In Brazil it is applied to the eyes in the form of lotion, and in Peru it is given internally in disorders of the bowels.

Scoparia dulcis (Scrophulariaceæ). Astringent, used in syphilis. In Liberia it is given in kidney or bladder complaints.

Solanum triste. Narcotic and sedative. The root of *S. acanthifolium* is diuretic. *S. mammosum* is used for the itch.

Spigelia anthelmia (Loganiaceæ). An active vermifuge, but possessing also narcotic properties.

Spilanthes uliginosa (Compositæ). Stomachic and diuretic. The French name of this plant is "créosote pays."

Stachytarpheta jamaicensis. Diaphoretic. The leaves of this plant are much esteemed by the Brazilians, and have been sold in Austria under the name of Brazilian tea. They are stated also to have been used to adulterate tea.

Cassia occidentalis deserves a separate notice on account of its extended use in various countries. In Martinique the roots are used as a diuretic and the leaves as a purgative, and they are used for the same purposes in Liberia, Senegal, the Gaboon, Mauritius, etc. The seed, however, is the part of the plant most used. When roasted it is said to form the best known substitute for coffee, so that if mixed with ground coffee in a proportion not greater than one-fifth it is impossible to detect it either by sight or taste. The "café nègre," as it is called, is used as a beverage in dyspepsia, nervous asthma and malarial fever, also as an emmenagogue. In Senegal the *Cassia occidentalis* is known as "bentamare." It is very abundant in that colony and could be obtained in considerable quantities at a low price. Already it is said to have been sent to England, Belgium and Germany in large quantities, and it can be bought in Paris of the fruiterers who supply Algerian produce. It behoves analytical chemists, therefore, to make themselves acquainted with the microscopical structure of the seeds.

Café nègre is commonly used by the negroes as a beverage when the coffee crop has been a bad one.

Guadaloupe.

The exhibits of this colony contain very few crude drugs, which are mostly identical, as might be expected, with those of Martinique. A considerable number of mineral waters, which are abundant in this colony, are, however, exhibited.

Isles of St. Pierre and Moquelon.

Only a few drugs are exhibited by these colonies, and these consist almost entirely of such as are well known to occur in the United States. Of these the leaves of *Gaultheria procumbens*, *Ledum latifolium*, and *Vaccinum hispidulum* are made into tea and are called respectively "thé rouge," thé de James, "and thé d'anis." *Coptis trifoliata* and *Sarracenia* are abundant on these islands. The latter is said to form quite a carpet on all the turbaries. The young shoots of the hemlock spruce (*Abies Canadensis*) are used in the manufacture of beer and for tonic baths. The spruce beer is made by adding treacle to a decoction of the twigs and allowing it to ferment for twenty-four or forty-eight hours.

Senegal.

By far the largest exports from this colony consist of ground nuts (*Arachis hypogæa*) for making nut oil, india rubber, and Senegal gum. The india rubber appears to be collected chiefly from *Ficus racemosa* and a creeping plant belonging to the *Apocynaceæ* (*Carpodinus sp.*) and appears to be of good quality. The catalogue of the products contains some interesting information concerning Senegal gum, which, as comparatively little is known concerning Senegal gum in this country, may be worth recording.

The annual export of gum from this colony amounts to about 3,000,000 kilogrammes. The gum is collected in November in the windy season after the periodical inundation is over. It is gathered from several species of acacia, especially *Acacia Verek*, *A. Neboued*, *A. albida*, *A. Adansonii*, etc. The first gathering, called "gomme du bas du fleuve," is generally buried in the still damp soil, to dry it, by the Moorish slaves who are sent to gather it. It loses much of its weight and value by drying, and is generally covered with a thin coat of sand.

The gum of the second season, which is completely dried when gathered from the trees, and is therefore carried direct to the storehouse, is of much better quality.

A third quality of gum is collected in Upper Senegal; this is extremely friable owing to the annual conflagrations in the forests, and is worth only from 40 to 50 francs per 100 kilogrammes. The gum is generally obtained by barter from the collectors, cloth, coral, amber, ammunition, and a variety of trifles being given in exchange for it. The principal districts in which the gum is produced on the right hand river, are the country of the Brakna and Trarza Moors, who make their slaves collect the gum while they themselves encamp near the forests, the Galam country, Bondou and Bambouk. On the banks of the left river, gum is collected in Oualo, Cayor, and Djolof. The principal emporium in France for Senegal gum is Bordeaux, where the gum is sorted into different qualities. Those which are chiefly to be met with in French commerce are:—

Gomme blanche, a fine white gum used in pharmacy, confectionery, distillery, and for dressing calico, linen, and lace.

Gomme petite blanche, similar to the last but in smaller pieces.

Gomme blonde, fine gum having a pale brown tint.

Gomme petite blonde, similar to the last but in small pieces. This is used for gumming envelopes, dressing ordinary cotton fabrics, etc.

Gomme 2° blonde, of rather inferior quality to the last and darker in colour, but used for similar purposes.

Gomme gros grabeaux, *Gomme moyen grabeaux*, *Gomme menus grabeaux*, and *Gomme grabeaux triés* appear to be different qualities of the more friable gum, being less clear and more cracked in the interior of the pieces than the first five qualities. Of the other varieties, *Gomme friable blanche* and *Gomme friable blonde* appear to be better qualities of the same gum, *Gomme fabrique* and *Gomme petite fabrique*, are gums especially selected for dressing fabrics; *Gomme poussière*, which consists of the siftings, is used for ink, blacking, paint, etc.; *Gomme marrons et bois* is a gum which contains wood disinte-

grated by insects, and is used for similar purposes; *Gomme boules naturelles* is a kind used largely in the silk manufactories of Lyons; *Gomme bdellium* is said to be used in pharmacy; in this country it has no use except for varnishes.

A large portion of the table devoted to Senegal products is occupied by these gums, several firms having contributed distinct series of specimens. Those of M. Marc Merle nephew and Roberts, of Bordeaux and Senegal, especially deserve notice on account of the botanical sources of the different specimens being given. They include the gums of *Acacia Verek* ("gomme dure de galam"); *A. albida* ("Sadra beida"); *A. Neboued; A. Adansonii* ("gomme de gonakie"); *A. nilotica; Khaya senegalensis* ("gomme de cailcedra"); *Adansonia digitata* ("gomme de baobab") and *Ficus species* ("gomme de kell"). The last is said to be very abundant in Bondou and Bambouk.

The gum of *A. Adansonii* is of dark colour and very astringent. It is used by the Moors for dysentery. Of *Acacia albicans* the powdered twigs are used as an expectorant under the name of "kadd," as well as the roots of another species known as "N'debarga" (*A. microphylla* ?). The very astringent pods called nebneb and the bark of *A. arabica* as well as that of *Acacia Sing* ("Singdour") are used in diarrhœa and dysentery. Another species, which has not been determined, but is known under the native name of "Bouillé-Bété," is extolled as the antidote to the sassy bark, which is called "Mancona" or "Teli" bark in Senegal. The infusion of this acacia is a powerful emetic.

In this collection may be seen a few specimens of isinglass. This is a new industry in Senegal. The specimens exhibited are:—(1) In thin apparently rolled sheets, about twelve inches long by four wide; (2) Small entire bladders, somewhat like East India tongue isinglass, from three to eight inches long and one to two inches in diameter: this kind is of two qualities; (3) Swimming bladders split open. Ægyptian soap root, *Balanites ægyptiaca* (Olacineæ) is also exhibited. This root is often erroneously attributed to *Gypsophila Struthium*.

The Gaboon.

Although the number of exhibits from this colony are not large, several of them are of considerable interest.

The india rubber exhibited is obtained from a species of *Landolphia*, a climbing plant, belonging to the Apocynaceæ. It has been exported annually to the extent of 400 tons from the Gaboon and its dependencies. Dika bread, from the seeds of *Irvingia Barteri*, an account of which has been given in this Journal, occurs among the exhibits of oils and oil seeds. Kola nuts, remarkable for containing theine, and used by the natives as coca is used in Peru, will also attract attention. In Senegal the nuts are worth five francs the kilogramme.

Among the more remarkable drugs of this colony are—

Atchimé. These poisonous seeds are referred to an undetermined species of *Ignatia*.

Amomum citratum (Zingiberaceæ). The seeds of this cardamom are remarkable for their strong verbena flavour.

Bassia Djavé and *B. noungou*, sp. nov. The fatty oil from the seed is used for rheumatism.

Camma bark. This bark, the botanical source of which is undetermined, is said to be poisonous.

Haronga paniculata (Hypericaceæ). The bark and leaves of this plant, called *Ogina-gina* by the natives, is used in the form of fumigation for fistula.

Ilango. This is a poisonous plant belonging to the orchidaceæ, and has not yet been examined. The specimen sent to the Exposition was unfortunately stolen from the bottle on the first day that the building was opened.

Icaja or *Casa*. This is the M'boundou or ordeal poison of Cape Lopez. It is referred to a species of *Strychnos*. The shrub yielding it grows in inundated districts, and is from six to eight feet high; the long taproot is covered with a reddish bark, which is said to contain the active principle. This is soluble in water and alcohol, according to MM. G. Pécholier and C. Saint Pierre, and has an action analogous to that of nux vomica.

Inée or *Onaye*. This is another powerful poison, consisting of the pounded seeds of *Strophantus hispidus* (Apocynaceæ). According to the researches conducted in Russia, England, and France, since 1865, this is one of the most powerful of cardiac poisons.

Okanyago. This is another poison, the botanical source of which is at present unknown.

Tephrosia Vogelii (Leguminosæ). The leaves and pods are used to stupefy fish.

Tetrapleura Thonningii (Leguminosæ). The decoction of the bark is emetic.

Ximenia gabonensis (Olacineæ). The fruit is laxative, and the seed purgative.

Calabar beans are also exhibited from this colony but are said to be of rare occurrence there. Among the drugs without name are two which may be worth examining, one of which is a bark used to hasten the fermentation of palm wine, and the other is a root which produces intoxication.

French Cochin China.

The exhibits from this colony consist almost entirely of well known drugs, and include Socotrine and caballine aloes, China root, galangal root, areca nut and betel pepper, long pepper, rhubarb, cinnamon, sandal wood, nux vomica seeds, anise, cummin, asafœtida, cocculus indicus, gurjun oil, croton and castor oil seeds, liquorice, camphor, benzoin, and anime resins.

The few which are less known are—

Casuarina latifolia (Casuarinaceæ). The bark possesses astringent properties.

Cassia Roxburghii (Lauraceæ). This yields a kind of cassia bark.

Sterculia scaphigera (Sterculiaceæ), native name "Luoi Noi" or "Tambayan." These remarkable fruits contain a quantity of insoluble gum and tannin. They are used for affections of the throat and for dysentery. They have already been described in this Journal under the name of Bootam-paijang. See vol. viii., pp. 747, 784.

Aquilaria Malaccensis.—The swellings produced on this tree where branches have been broken off yield a perfume known in Cochin China under the name of "Tramtoc," and which is highly prized, costing in the market at Saigon not less than 34 francs the kilogramme. This is probably one of the aloes woods used in the East. It has a somewhat variegated appearance, owing to the presence of dark resinous stripes.

Thao.—This is a very interesting substance and one which is likely to come into considerable demand in the future. It is a gelatinous preparation made in Cochin China as well as in other eastern countries, from seaweed. In the English market it has frequently appeared, under the name of Chinese or Japanese isinglass, in three different forms. That which is prepared in Cochin China is in bundles of thread-like pieces a foot or more long, about the thickness of whipcord.

The specimens prepared in Japan, numerous examples of which may be seen in the Japanese department, occur in two forms, one in square sticks about 11 inches long and from 1—1½ inches in diameter, and full of cavities, each weighing only about three drachms, and the other in bundles of long shrivelled pipe-like pieces about ⅛th to ¼ inch in diameter and about 14 inches long. The bundles are fastened at the ends with the stems of some grass. When immersed in water these pieces are seen to have the same square shape as the other varieties. One side of the pieces is always more full of diatoms and other foreign bodies, as if the pieces had been formed in a mould in which the sediments of the jelly had gone to the bottom. The cord-like variety made in Cochin China is in long loose bundles. It has much the polished appearance of the Chinese vermicelli made from rice, but that substance will not bend and is much more slender. The following particulars from the catalogue may prove interesting. Various trials have been made with it in France since 1874, especially by MM. D. Gantillon and Co., at Lyons, and the Industrial Society at Rouen. The thao is prepared for use in the following way:—After having been soaked in cold water for about twelve hours, it is boiled for a quarter of an hour, during which it absorbs about 100 times its weight of water. If allowed to cool it becomes a jelly, but if passed through a sieve and stirred until cold it remains fluid and in this state is more easily employed than when hot. The yellowish matter which some specimens contain can be removed by boiling for some time, when it forms an insoluble scum, which appears to consist of very thin fibres and which remain attached to the sides of the vessel.

A singular property and one which perhaps might be turned to valuable account is, that thao jelly does not decompose solution of permanganate of potash even when left in contact with it for twenty-four hours.

According to M. Heilmann, of Rouen, thao produces, in the proportion of 1 part to 100 of water, a dressing, which is supple and strong, and which gives substance rather than stiffness to calico, while dextrine, like starch, makes the tissue drier and harder and gives less facing to the thread. The addition of glycerine gives a dressing still more flexible and soft, and while rendering the tissues less stiff it communicates more body to them.

The addition of talc gives still greater smoothness. Once dissolved, according to M. Gantillon, thao will mix while hot with any gum, starch, dextrine or gelatine. The principal advantage of thao in dressing silk fabrics is that while preserving their suppleness it gives them greater glossiness and makes them soft to the touch. The mixture of thao with gum tragacanth is said to be the best method of using it. Thao should, however, be used alone for materials which it is not necessary should be stiffened. As thao is only soluble at a high temperature, a moist atmosphere, fog, or even rain does not affect the material dressed with it.

It combines well with sulphate of copper and the chlorides of aniline and potassium, and can be used in double dyeing.

It also answers well for sizing paper, etc. The only obstacle to its extensive use is its high price. There is, however, no reason why a similar substance should not be made from our common native seaweeds, of which *Gelideum corneum* and *Gracilaria confervoides* approach most nearly in character the algæ from which thao is made. Gelose, of which thao consists, differs from the carrageenin obtained from *Chondrus crispus* in its power of combining with a very large quantity of water to form a jelly; it yields ten times as much jelly as an equal weight of isinglass. For purposes of food thao jelly is not quite so pleasant as animal jelly, as it does not melt in the mouth; it also contains no nitrogen. A great advantage which it possesses is, that it is but little prone to undergo change, so much so that the jelly is sometimes imported from Singapore, sweetened, flavoured and ready for use, and may in this state be kept for years without deterioration. The West coast of Australia also yields a seaweed possessing similar properties, which will be referred to under that country.

In this collection *Porphyra vulgaris* (the "laver" of English coasts) is given as the source of the seaweed isinglass in square sticks. In Cochin China this variety appears to be known under the name of "mat."

A number of other seaweeds are, however, collected, and are known to the Annamites under the general name of "rau-cau," while in Chinese medicine they are called "hai-thao." These algæ are gathered in considerable quantities in the islands of Cu-lao-Khoai and Cu-lao-ré, those collected in the latter being considered to be of the best quality. Of these weeds 15,000 grammes yield about two litres of jelly.

A small quantity of fish isinglass is exhibited in this department in the form of tongue and sheet isinglass, but the quality appears to be very inferior.

The edible swallows' nests are exhibited in variety both in this department and in that of Réunion. Of these the local service of Saigon show a fine collection. These nests are objects of considerable trade with China. In lower Cochin China they are collected to the extent of about one hundred kilogrammes per annum, the price varying from 290 to 405 francs per kilogramme. They are collected chiefly on the coasts of Hatien, Binh-Thuan, and Poulo-Condore. On account of the dangerous character of the trade but few people venture to engage in it, and the collection is farmed out by the Government of the colony.

The nests in which the birds live are said to be extremely clean, while those which are abandoned contain often a quantity of feathers and excrement agglutinated together. Both kinds are collected, the price varying according to purity. Those collected in the Réunion generally contain a number of pieces of lichen (probably *Usnea sp.*) which must to some extent depreciate their value. In the collection of the Dutch colonies a model of the process of collecting the nests may be seen. To use the nests, they are washed in cold water and then heated in a water-bath for about eight hours. The product is then ready to mix with food, meat juice and seasoning, as may be required, after which it is boiled for about a quarter of an hour. To produce about half

a litre of soup about 120 grammes of the nests are required.

The specimens of pepper exhibited seem remarkably good. The cultivation of this article is one of considerable importance in Cochin China, the produce of the provinces of Hatien and Thu-dau-mot having reached the extent of 800 tons. Some interesting information concerning the details of its cultivation is given in the catalogue, and appears to be worthy of introduction here.

The plantations as a rule do not contain less than fifty hectares of land, and the pepper plants are grown at the rate of about 2500 to the hectare. The proprietors of the pepper gardens are almost all Chinese. Every year Chinese junks make the voyage from Hai-nam to Hatien to bring a certain number of Chinese, and to carry back others who wish to visit their families or to retire from business and return home to China to enjoy the fruits of their labours. In the latter case the plantation is generally given up to some family relation who comes over for the purpose. More frequently, however, the Chinese live and die in the country of their adoption.

The pepper plant is usually propagated by slips, which are put into the ground in November or December, after the rains are over. The cultivation requires constant care all the year round. One coolie can attend to about 1000 plants. The men employed for this purpose are usually Chinese who have recently arrived, and who endeavour in this way to save up enough money to set up a plantation for themselves. They are fed by their masters and receive a complete suit of clothes every year, beside their wages. The yield of each pepper plant in a good year is about one kilogramme.

Once arrived at maturity, a pepper plantation, carefully tended, will last forty or fifty years or even longer, for the oldest inhabitants of the peninsula of Hongkong can point out plantations which bore fruit when they were children.

The pepper of Hatien has a greyish appearance which, however, does not affect its quality. That of other provinces, and of Cambodia, is more black. All these qualities are preferred by the French to the pepper of Singapore, which they state is generally adulterated, and gives 10 to 12 per cent. of loss.

The hairy Chinese cardamoms, xanthioid, and round or clustered cardamoms are also exhibited from this colony.

HYDRARGYRUM SUBCHLORIDUM.

BY H. W. LANGBECK.

The *Bunzlauer Pharmaceutische Zeitung* contains in No. 39, a notice taken from the 'Osservatore Med. Siciliano,' I. and II.' 1877, by which attention is called to the possible danger in keeping subchloride of mercury mixed with sugar, the mixture containing, after some time, perchloride of mercury, as proved by chemical analysis.

In this way the sugar would have been changed through the influence of humidity, contained in the atmosphere, into glucose and exercised a reducing action; for instance:—

Subchloride of Mercury. Cane Sugar. Humidity.

$$100Hg_2Cl + 100C_{12}H_{11}O_{11} + HO =$$

Merc. Perchl. of Merc. Subchl. of Merc. Cane Sugar. Glucose.

$$1Hg + 1HgCl + 99Hg_2Cl + 99C_{12}H_{11}O_{11} + 1C_{12}H_{12}O_{12}.$$

According to my own experience, I doubt that sugar perfectly dried, and mixed with well-washed calomel, kept in a stoppered coloured bottle, will change into glucose, and thus act reductively; but I fear that in some places too little care is taken in producing blameless preparations.

I have three samples of calomel before me; two of them present the appearance of light white powder, prepared, I believe, by introducing into the chamber in which the sublimate is received the steam of water, whilst the third sample, having a dull white aspect, appears to be prepared without water vapour.

Each sample has been subjected, successively, to the following treatment: ten grams of each were shaken with hot distilled water, poured on a filter, and the washing, in the same way, continued until the water ceased to give a reaction with sulphuretted hydrogen. The collected liquids were treated with sulphuretted hydrogen as long as the latter was absorbed. In all three cases a black precipitate was formed, which through its insolubility in hydrochloric or nitric acid characterizes itself as sulphuret of mercury. Each of the light white samples gives 0·008 = 0·08 per cent. HgS; the third dull white sample, 0·009 = 0·09 per cent. HgS.

HgS. HgCl.

$$116 : 0{\cdot}09 = 135 : x;$$

$$x = 0{\cdot}105 = HgCl.$$

In order to confirm my opinion I have mixed one part of well-washed calomel with powdered loaf sugar, another part with milk sugar, and a third part with powdered loaf sugar to which 1 per cent. of glucose is added, and after a space of two months I shall try again if perchloride of mercury and, *eo ipso*, glucose is formed.

A METHOD OF DISTINGUISHING GALLIC, TANNIC, AND PYROGALLIC ACIDS.

BY WM. WATSON, F.C.S.

To about ½ grain of each acid in a little water add NH_4HO.

Gallic.	*Tannic.*	*Pyrogallic.*
Pink, rapidly changing to deep orange solution.	Same as gallic.	Lemon coloured solution.

To each ammoniacal solution, add HNO_3.

Gallic.	*Tannic.*	*Pyrogallic.*
Red	Purple precipitate insoluble in excess.	Red.

Substituting HCl for HNO_3.

Gallic.	*Tannic.*	*Pyrogallic.*
Red . : . .	Pink precipitate soluble in excess.	Pink, quickly changing to red.

CANTHARIDIZED COLLODION.

Pro. Gubler recently stated, at the Therapeutical Society, that cantharidized collodion forms the most practically useful of vesicants, all that is necessary being to paint with a brush within the exact limits to which blistering is required to be confined. The collodion dries, and the blister is formed. So complete is the adhesion, that when applied to an indocile child he is unable to remove the collodion before the vesicating action occurs.

The Pharmaceutical Journal.

SATURDAY, JULY 20, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEDICAL ACTS AMENDMENT BILL.

ON Thursday the 11th inst., the President of the Pharmaceutical Society, attended by Messrs. HILLS and SANDFORD, had an interview with the Duke of RICHMOND and GORDON at the Privy Council Office, respecting the Medical Act Amendment Bill now before Parliament. A memorial setting forth the views of the Council had been some time previously submitted to His Grace, and had been placed by him in the hands of the Parliamentary Draftsman.

The Bill in no way names or deals directly with chemists; but an indirect benefit would have resulted from it as orginally drawn, inasmuch as certain powers of prosecution now existing which may be brought against chemists for what is called "counter practice" would have been abrogated.

In its progress through the House of Lords this provision was altered, and the object of the deputation was to induce the Duke of RICHMOND to restore the original proposition. Unfortunately great attention has been drawn to this subject of late, and the work of the Council thereby rendered more difficult, if not absolutely futile. That which might have passed *sub silentio* has been a prominent question of contention between the parties interested for and against the power of prosecution.

The deputation on this occasion advanced all the arguments which could be brought forward in favour of the change; the absolute impossibility of defining a strict line between that which is the legitimate right of a chemist in the daily exercise of his business and that which is properly called "medical practice," the different requirements of the public in different localities, and the persistence with which they demand advice from chemists.

Other points were mentioned, although at the same time it was clearly stated to His Grace that it had ever been, and the deputation hoped it ever would be, one of the objects of the Pharmaceutical Society to discourage medical practice by unqualified men and, specially by advancing the education of chemists, to impress on them the propriety of confining themselves to their own proper business.

The Duke of RICHMOND entered very fully into the question and promised to give future consideration to the points urged; but he at once stated frankly that the words in the first draft of his Bill, which had been brought forward as an argument by the deputation, were inserted inadvertently and that he could not see his way to restoring them. Beyond this His Grace said the Bill if passed would leave chemists in precisely the same position as that now occupied by them, and he thought under the circumstances the Medical Act would not be the proper channel through which to enlarge their privileges.

THE COUNCIL REPORTS.

THE remarks in reference to this subject which were appended to the letter of Mr. URWICK in last week's Journal seemed to us to be indispensable as a means of correcting the erroneous idea under which he described himself as writing, and we were in hope that they would be sufficient for that purpose. We regret that this has not been the case, and that according to a letter we have since received from Mr. URWICK we appear to have failed either to satisfy or convince him, or even to enlighten him, as to the actual position of this Journal as regards the report of the proceedings of the Council.

The implication conveyed by Mr. URWICK'S letter is virtually a reiteration of a charge that has before been made concerning the reports referred to, but has never been in any degree substantiated. Hitherto we have refrained from discussing this subject because it has generally been dealt with by the Council, and because we did not consider it desirable to enter into any critical discussion of the proceedings of that body. But the charge made against the reports of the Council meetings has now been developed from the vague form in which it was previously urged, and has acquired from the words of Mr. URWICK'S letter a character so definite that further reticence in regard to it might be accepted as an admission of its justice. That charge is, moreover, of such a nature as to call in question the honourable conduct of this Journal, no less than the action of certain unnamed members of the Council who are assumed to act the part of censors and that unfairly.

Mr. URWICK implies, if he does not directly assert, that the reports of the Council meetings have been subject to "control or cooking," and in reply to our repudiation of this charge he states in the letter just received from him, that the editorial foot note appended to his letter last week is not clear, but will at least admit of two constructions, and with a strange perversity of interpretation he represents himself as supposing that he is to conclude from the footnote that he had previously deceived himself by considering the last report of the Council free from "control or cooking." The account which Mr. URWICK gives of the reasoning process, by which he first arrived at the opinion that this particular report had

not been "controlled or cooked," is, however, equally remarkable for its want of logical coherence, the chief reason assigned for that conclusion being "that there appeared less restraint and study in the speeches." Reversing this line of argument we suppose that if for any reason the speakers had shown more restraint and study in expressing themselves, the effect upon Mr. URWICK's mind would have been to lead him to suppose the report had been "controlled or cooked."

So much for one of the reasons assigned by Mr. URWICK for considering the last report of the Council free from "control or cooking." The other reason being one beyond our power to express an opinion upon we can only give it in Mr. URWICK's own words, "that what had been kept back at a previous meeting was reported at the last."

But though we cannot accept the reasoning by which Mr. URWICK sought at one and the same time to sustain his position, and to cast an imputation upon certain members of the Council, as well as upon the editorial conduct of this Journal, a reference to the report of the last Council meeting will perhaps indicate more rationally the influences which led him to insinuate the charge of "control or cooking."

In Mr. HAMPSON's speech, on bringing forward the motion on reporting, he appears to have stated that, in the first place, the reporter employed by the Council was surrounded by influences which acted upon him in a measure that he himself could perhaps scarcely understand. Secondly, that when the report passed from his hands to the Editor opportunity was afforded to members of Council residing in London "of adding to or taking from the report which was ultimately published."

It is not the first time that Mr. HAMPSON has made these statements, and we must admit that he has always done so as frankly as on the present occasion. Those statements constitute the main part of the argument, so far as this Journal is concerned, by which he seeks to urge the adoption of the course he advocates, and if they were maintainable they might be useful for the purpose. But this is precisely what we deny most emphatically, and it is this weakness in Mr. HAMPSON'S argument which has rendered it altogether inoperative with at least one-half of the members of the Council, while others gave it but a qualified support.

As to the effect of the influences by which, according to Mr. HAMPSON, the reporter is surrounded, it is true we have no means of judging, since Mr. HAMPSON offers no explanation as to their nature; but we are utterly at a loss to conceive what influences would induce a person in the capacity of an official reporter to give a false, strained, or even a coloured report of the proceedings of the Council. This inability on our part, however, may not count for much with those who are possessed with a belief in the agency of occult influences surrounding the reporter, and therefore it will be more to the point to remind those interested in this matter that since the reports of the Council have been published in the present mode there has never been an instance in which the substantial accuracy of the published report has been called in question. Beyond this point we cannot carry our argument against the statement of Mr. HAMPSON, since the report handed in by the Council's official reporter is the only means by which we can judge of what takes place. But if "control and cooking" of the report had resulted in the alteration or suppression of anything said, or the misrepresentation of anything done at the meeting, is it likely that such a circumstance would have been passed over in silence?

As to the editorial manipulation assumed by Mr. HAMPSON and his supporters to be exercised upon the report, if it had extended to suppressing or adding to any part of the proceedings recorded by the reporter, is it to be supposed that no member of Council who had experienced such treatment would have ventured to protest against it? No protest of the kind has ever been made and we do not hesitate to say that there has never been the slightest reason for protesting.

Nevertheless Mr. HAMPSON again repeats as a complaint the statement that members of the Council residing in London have the opportunity afforded them of amending, improving, or adding to or possibly suppressing a portion of the report, and that being the case we think it desirable again to state in reference to this portion of his argument, what we have already stated to the Council, viz., that no opportunity is given for any amendment of the report beyond such verbal corrections as will not affect the general tenour and purport of the speakers' remarks, neither is any opportunity furnished for adding to or suppressing any portion of the report as it is handed to the editor by the official reporter.

The letter addressed to the Council on this subject bears date July, 1877,—neither so recent as to have escaped Mr. URWICK'S notice nor so far back as to have been forgotten,—and its terms are sufficiently explicit in regard to all complaints and charges to make us wonder that they should have been so completely ignored by him and so little regarded by Mr. HAMPSON himself.

With the discussion of the general question, whether representatives of the press should be admitted to the Council room of the Society while its business is being transacted, we do not propose to occupy the patience of our readers or the space at our disposal for their possible edification; but it does appear to be appropriate to combat the erroneous impressions prevailing in reference to the Council reports, and to that end perhaps we cannot do better than refer to the record of the instruction given by the Council to its official reporter in July, 1872, informing him

that in future his reports of the proceedings of the Council were to be furnished direct to the Editor, who alone would exercise any supervision over them, and that, subject to this editorial control, he must use his own discretion in condensation or otherwise.

This instruction was the outcome of the deliberations of a committee appointed to consider the question of reporting in the previous month and consequently upon the motion of Mr. BETTY for inviting reporters. Mr. URWICK, then a member of Council, served on that committee, and we do not believe that he or any other member of the Council can show that there has been any departure from the spirit or the letter of that instruction, on the part either of the official reporter or of the Editor of this Journal.

COUNTER PRESCRIBING AND TRADE INTERESTS.

"No chemist should undertake the treatment of disease, and if he does so, he is doing wrong in attempting that for which he has had no proper training."

This axiom laid down by Mr. URWICK as one that he strongly holds, is so consistent with the views expressed by the President, and so truly representative of the principle which has always guided the action of the Pharmaceutical Society in regard to a matter of very difficult relationship between chemists and druggists and medical men, that we rejoice to be able, on his authority, to place it before our readers, and to commend it to the consideration of those members of the trade who think that our condemnation of the course pursued by the executive of the Trade Association is in any degree instigated by hostility to trade interests or to the Association which aspires to protect them.

Those correspondents who have written to us on this subject with various degrees of vehemence are mistaken. We have from the first endeavoured to promote a cordial relation between the Pharmaceutical Society and the trade organization established in Birmingham,—indeed have gone somewhat out of our way to do so—but it does not follow that we, any more than the Council of the Society, are bound to applaud all the proceedings of that organization, or that we should be fulfilling our duty if we failed to point out what we conceive to be its errors. It is in this spirit that we have expressed our view of the action taken by the Association in the matter of counter practice, and in reference to the Medical Acts Amendment Bill.

We consider that in the one instance a grave mistake has been made, which places the Association in the false position of defending that which, in the words of Mr. URWICK, it is wrong to attempt, and that in the other instance, the executive of the Association has, by the issue of the memorandum upon which we commented last week, taken a step highly prejudicial to the real interests of pharmacy, and one which cannot be justified by any existing circumstances.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Tuesday, July 16, 1878, the report of the College of Preceptors on the examination held on July 1 was received.

Two hundred and ninety-eight candidates had presented themselves for examination, of whom *one hundred and fifty-four* had failed. The following *one hundred and forty-four* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically.)

Alexander, George .....Liverpool.
Alvey, William Smith.....Nottingham.
Andrews, Frederick Neville ...Bristol.
Armitage, James Reuben .....Stalybridge.
Arnott, William .....Greenwich.
Atkins, Ernest .....Southampton.
Atmore, William Smith Simpson...Lynn.
Badcock, Henry Southgate.....South Petherton.
Baldwin, George Joseph .....Loughborough.
Bamforth, Joseph.....Manchester.
Banks, Arthur Edward .....York.
Baselow, Arthur Aug. Johannes...Cardiff.
Bennett, Arthur .....Bury St. Edmunds.
Brandsma, Dirk Gerhard .....London.
Brearley, Richard.....Torquay.
Brooks, Henry James Robert...Oxford.
Bunn, James Early Smee .....Halstead.
Burgess, William .....Runcorn.
Burn, Barnabas Pearson.....Durham.
Chappell, John Chater.....Boston Spa.
Clark, Alexander Gibson.....Edinburgh.
Clark, Arthur William .....Dorking.
Clark, Tom .....Penrith.
Cockerill, Thomas.....Lynn.
Codd, Henry Robinson.....Leamington.
Coleman, Edmund Francis .....Wolverhampton.
Coleman, Edward.....Kidsgrove.
Cooper, George Henry.....Oldham.
Daniel, George .....Holsworthy.
Drury, Arthur .....Halifax.
Ekins, Arthur Dearlove .....Bedford.
Elliott, S. George Needham ...West Drayton.
Ellis, Henry Austin.....Plymouth.
Escreet, William Myers .....Hull.
Evans, David John .....Llandyssul.
Evans, David Robert Powell ...Rhyl.
Evison, Alfred .....Alfreton.
Farr, Edward Henry .....Monmouth.
Flint, Richard .....Loughborough.
Fox, Thomas Alfred .....Hawarden.
Fraser, Alexander.....Lochmaben.
Fryer, Edwin .....Market Deeping.
Garnett, James.....Kendal.
Gibbon, Ernest Henry .....Seaham Harbour.
Gilby, Herbert .....Long Sutton.
Gilford, Hastings .....Dorking.
Gill, William.....Nottingham.
Gilmour, George .....Glasgow.
Goodwill, William Ernest .....Darlington.
Goose, William.....Aberystwith.
Goundry, John George Harling..Durham.
Gray, Alfred Francis .....Leicester.
Grieve, John.....Hawick.
Griffiths, Robert Edwin .....Manchester.
Grime, Edwin .....Over Darwen.
Gudgen, Alexander John.....Lewisham.
Hambrook, Edward Odden.....Dover.
Harris, Edward John .....Taunton.
Hartley, Walter Edward.....London.
Herring, Joseph .....Caistor.

Heynes, Thomas Edward .....Maidenhead.
Hopkins, Tom Harry .....Thrapston.
Hordley, Edward Ralph .....Stoke-on-Trent.
Horner, Thomas William .....Leeds.
Howston, Frederick John .....Chesterfield.
Hughes, Howel James.....St. Clears.
Hughes, John .....Aberystwith.
Huyton, John .....Manchester.
Jackson, Thomas .....Scorton.
Jackson, William .....Northampton.
Jardin, Peter Forbes .....Glasgow.
Jenkins, John Lewis .....St. Clears.
Jessop, Ernest Charles Hale ...Cheltenham.
Jewell, John Ernest.....Liverpool.
Johnson, Joseph Thomas .....Darlington.
Jones, William .....Carmarthen.
Kerr, William .....Edinburgh.
King, Frederick Herbert .....Market Drayton.
Laing, Arthur Laurenson .....Edinburgh.
Lamb, John Amos .....Bathgate.
Lamb, J. M. A. .....Windsor.
Lamb, Thomas .....Sleaford.
Lambert, John Thomas .....Hoyland.
Livesley, Thomas Henry.....New Mills.
Lubbock, Edgar Ashby .....New Barnet.
Mackay, William Gunn .....Lauriston.
Mander, Frederic .....Allesley.
Marples, Thomas .....Sheffield.
Middleton, David.....Aberdeen.
Miller, James Graham .....Leith.
Mitchell, Charles Edward .....Bolton-le-Moors.
Morgan, Noah .....Glamorgan.
Owen, David James.....Swansea.
Owens, David Picton .....St. Clears.
Parry, Richard .....Liverpool.
Parsons, Thomas .....Bourton on-the-Water.
Pattinson, William .....Hexham.
Pattison, Sidney .....London.
Pell, Alfred .....Wisbeach.
Penberthy, John .....Redruth.
Perry, Robinson .....Cockermouth.
Pimm, F. A. .....Torquay.
Pollitt, William Dibble .....Leeds.
Powell, Edith Marion .....Birmingham.
Pratt, Alfred James.....Chichester.
Priestley, Sydney Herbert .....Alresford.
Procter, William Manning .....Kidderminster.
Pullan, George Ellard .....Gainford.
Puntan, H. Harding Cruickshank...Turriff.
Radcliffe, John Collister.....Castletown.
Rainer, Charles Oliver.....Queenborough.
Rawling, William John .....Devonport.
Raywood, John J. R. .....Thorne.
Read, John Henry .....Lowestoft.
Reid, Charles Stewart .....Aberdeen.
Richardson, Robert Railston ...Alnwick.
Rickard, William .....Normanton.
Ridley, Henry .....Ipswich.
Robinson, Richard Fredk. Wm...Manchester.
Scott, Henry Andrew .....Rothbury.
Seely, Herbert William .....Lincoln.
Sharp, John .....Galashiels.
Smith, Edwin Wells .....Sheffield.
Snow, Charles Metcalfe .....Sheffield.
Snowdon, John.....Gainford.
Tait, John..... .....Edinburgh.
Tharp, Arthur .....Croydon.
Thompson, Charles .....Liverpool.
Thomson, Alex. Robertson .....Buckhaven.
Thorburn, Edward William ...Tottington.
Thorp, Arnold Edward .....Northampton.
Tovey, Albert .....Evesham.
Walker, John .....Rothney.
Walker, Sandford.....March.
Walker, William Robert.....Birmingham.
Watts, Francis .....Banbury.
Watts, Robert .....Chatham.
Webster, Edward.....Hull.
Wilson, James .....Leith.
Wilson, Richard Frank .....Caistor.
Wood, Walter .....Hunslet.
Wray, John .....Harrogate.
Wright, William .....Dumfries.
Yates, George Albert .....Manchester.

The following is a list of the centres at which the examination was held, showing the number of candidates examined at each centre and the result:—

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Aberdeen	12	4	8	Leeds	15	6	9
Aberystwith	4	3	1	Leicester	3	3	0
Berwick-on-Twd	2	1	1	Lincoln	5	3	2
Birmingham	10	5	5	Liverpool	14	3	11
Boston	2	2	0	London	34	12	22
Brighton	2	0	2	Macclesfield	1	0	1
Bristol	5	1	4	Manchester	17	10	7
Cambridge	4	3	1	Newcastle-on-T.	6	5	1
Canterbury	4	2	2	Northampton	3	3	0
Cardiff	5	2	3	Norwich	3	1	2
Carlisle	3	3	0	Nottingham	8	3	5
Carmarthen	4	4	0	Oxford	3	2	1
Cheltenham	1	1	0	Peterborough	2	2	0
Chester	5	4	1	Plymouth	5	3	2
Colchester	7	2	5	Portsmouth	3	1	2
Darlington	10	4	6	Preston	4	2	2
Doncaster	2	1	1	Reading	2	1	1
Douglas, I. of M.	1	1	0	Salisbury	1	0	1
Dumfries	2	2	0	Scarborough	1	0	1
Dundee	4	0	4	Sheffield	8	5	3
Edinburgh	17	11	6	Shrewsbury	2	1	1
Exeter	3	2	1	Southampton	4	2	2
Glasgow	9	2	7	Stafford	3	2	1
Hereford	2	1	1	Swansea	3	1	2
Hull	6	2	4	Taunton	4	2	2
Inverness	1	0	1	Truro	1	1	0
King's Lynn	3	2	1	Worcester	2	1	1
Leamington	7	2	5	York	4	2	2

The questions for Examination were as follows:—

FIRST OR PRELIMINARY EXAMINATION.

July 1*st*, 1878.

(*Time allowed: Three hours for the three subjects*).

I. LATIN.

1. Translate into English the following passages:—

(A.) Eo, ut erat dictum, ad colloquium venerunt. Legionem Cæsar, quam equis devexerat, passibus ducentis ab eo tumulo constituit. Item equites Ariovisti pari intervallo constiterunt. Ariovistus, ex equis ut colloquerentur, et præter se, denos ut ad colloquium adducerent, postulavit.

(B.) Tum demum Ariovistus partem suarum copiarum, quæ castra minora oppugnaret, misit. Acriter utrimque usque ad vesperum pugnatum est. Solis occasu suas copias Ariovistus, multis et inlatis et acceptis vulneribus, in castra reduxit. . . . "Non esse fas Germanos superare, si ante novam lunam prœlio contendissent."

2. (A.) Parse fully the first line, and give the present, perfect, infinitive, and supine (where found) of *venerunt, devexerat, constituit, colloquerentur, adducerent.*

3. (B.) Parse the last six words of this extract, and give the present, perfect, infinitive, and supine of *oppugnaret, misit, reduxit, superare, contendissent.*

4. Decline fully—*equis, equites, castra, vulneribus*; and give the case and government of each.

5. What are the "three concords"? Put into Latin, if you can:—*At home, in the evening, at night, at sunrise, at sunset, take care of your health.*

II. ARITHMETIC.

(The working of these examples, as well as the answers, must be written out in full.)

6. The product of two numbers is 3270069; one of the numbers is 5423: find the other number.

7. Resolve into its prime factors 2431 and 770; and find the L. C. M. of 16, 9, 12, 18.

8. Find the value of $\frac{\frac{1}{2}+\frac{1}{3}+\frac{1}{4}}{\frac{1}{2\frac{1}{2}}+\frac{1}{3\frac{1}{2}}+\frac{1}{4\frac{1}{2}}}$; and reduce 11*s.* $9\frac{3}{4}$*d.* to the decimal of £2.

9. What is the difference between the *simple* and *compound* interest of £150 for 3 years, at $4\frac{1}{2}$ per cent. per annum?

III. ENGLISH.

10. Explain the terms *abstract noun, noun in apposition* —give *one* example of each; and write the possessive case, singular and plural, of *chimney, child, mouse, thief.*

11. Show how adjectives may be converted into adverbs (six examples). Give the diminutives of *stream, river, lad, hill*; and the past participle of *forget, swim, drink, lie.*

12. Parse fully the following:—

"Red battle stamps his foot, and nations feel the shock."

13. Write a short account, recording *leading* incidents *only*, in order, of Sir Isaac Newton, Simon de Montfort, Lady Jane Grey; a *short* essay, on Self-Reliance, Examinations, a description of the Telephone, *or* Microphone (*one only*).

EXAMINATIONS IN LONDON.

July 10, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Nine candidates were examined. *One* failed. The following *eight* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Ashweek, John Sydney .....Torquay.
Eardley, James Furnival.....Hulme.
Flemons, Joseph .....Northampton.
Hogg, Edward Grindle .....Ealing.
Jackson, Alfred Henrick.....Manchester.
Oldham, William.....Peterborough.
Sangster, John Graham .....Southsea.
Thompson, John Hartley .....Sheffield.

MINOR EXAMINATION.

Sixteen candidates were examined. *Six* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Crane, William Clifton .....Market Harborough.
Drew, John .....Wednesbury.
Harwood, George Rosamond ...Folkestone.
Holden, John .....Burnley.
Knowles, James .....Burslem.
Lewis, Llewelyn .....Neath.
Llewellyn, Thomas .....Pembroke.
Pritchard, Edward Thomas ...South Norwood.
Simpson, John George Povey...Manchester.
Stephens, Stephen .....Llandilo.

MODIFIED EXAMINATION.

Four candidates were examined. *Three* failed. The following passed, and was declared qualified to be registered as a Chemist and Druggist:—

Hyett, Henry .....Lincoln.

July 11, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

MAJOR EXAMINATION.

Eight candidates were examined. *Two* failed. The following *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Abraham, Alfred Clay.....Liverpool.
Glaisyer, Edmund.....Brighton.
Phillips, John Edwards .....Cheltenham.
Savory, John Field .....London.
Stonham, William Burne .....Maidstone.
Ward, John Septibo.....Stamford.

MINOR EXAMINATION.

Twenty-two candidates were examined. *Eight* failed. The following *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cooper, Albert Henry .....Walmer.
Furness, Joseph Machin .....Liverpool.
Gallienne, Wm. James Norman.Torquay.
Homes, Joseph Peter .....Dudley.
Humfrey, Raphael Charles.....Colchester.
Lovely, Ernest .....Shepherd's Bush.
Lumby, Fred.....Nottingham.
Mawson, Thomas Oliver.....Sheffield.
Paterson, James Smith .....Castle Douglas.
Powell, Cuthbert .....Bristol.
Simnett, Thomas .....Wandsworth.
Smith, Joseph .....York.
Wright, Harry.....Bradford.
Wright, Joseph Newton .....Newport, Salop.

July 16, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-eight candidates were examined. *Nineteen* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ashmead, John Stubbings .....Clifton.
Bailey, John Harvey .....Winchester.
Collins, Robert Enos .....Boston.
Dunn, William Arthur .....Newark.
Manners, John .....Shildon.
Mitchell, Joe Charles .....Barnsley.
Waites, Richard Foulstone.....Rotherham.
Williams, Samuel Roskelly.....Devonport.
Yeats, John Williams.....London.

July 17, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Seventeen* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Clarke, Ralph Tate .....Workington.
Cullen, Harry Harker .....Tewkesbury.
Gibson, Frederick.....Blackpool.
Goodall, Thomas Sorby .....Derby.
Monkton, George Joseph.....London.
Petter, Walter .....Newport, Mon.
Stevenson, John Joseph .....London.
Symons, Netherton Hosking...Penzance.
Townsend, Joseph Edward.....Peterborough.
Walker, Robert .....Royston.

July 18, 1878.

Present— Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Twenty* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists :—

Evans, John .....London.
Gange, George .....Ludlow.
Hart, Arthur .....London.
Jackson, George .....Heywood.
Southgate, Wilfred Burnham...Hull.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's Examination:—

Certificate of the University of Cambridge.

Briggs, George William .....Bulwell.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday evening, June 27, Mr. W. R. Atkins in the chair. A paper by Mr. E. Bridges Walton on the "Form of Leaves," was read by the Secretary in the absence of the author. The paper commenced with a description of the leaf in its complete, that is its most fully developed state, the parts into which the perfect leaf may be divided, and the variations which those parts may undergo. These varieties of the form of the leaf, outline, margin, etc., were described, and illustrated by dried specimens. The most interesting part of the paper was that devoted to an explanation of the use of the leaf in referring a plant to its natural order, showing that by its help it is possible to distinguish with but few exceptions between endogens, exogens, and acrogens. In the exogens many of the natural orders possess leaves which bear a considerable similarity. The umbelliferæ are characterized by their decompound leaves, the caryophyllaceæ by their entire and opposite leaves; those of the rosaceæ vary considerably but may generally be distinguished by their adnate stipules; a pinnate form of leaf is common to many species. Numerous specimens of dried plants illustrated the paper in a most satisfactory manner. After an animated discussion a vote of thanks to Mr. Walton was passed, and the meeting adjourned till July 4.

EDINBURGH UNIVERSITY CHEMICAL SOCIETY.

At the tenth meeting of this Society, held May 29, 1878, Mr. John Gibson, Ph.D., in the chair, a paper was read by Mr. George Macgowan, F.R.S.E., on "The Action of the Chlorides of Iodine on Ethylene and Acetylene."

The following were the chief points in the paper:—(1). The formation (in theoretical quantity) of chloride and chloriodide of ethylene, on passing the latter slowly over pure iodine trichloride at 0°C.; (2). The formation of the new compound acetylene chloriodide (C_2H_2ICl) by passing acetylene through a solution of iodine monochloride in ether at 0°C.; (3). The author did not succeed in forming any acetylene cyanogen compounds.

Parliamentary and Law Proceedings.

A Bill to Amend the Sale of Food and Drugs Act, 1875.

The following bill has been introduced into the House of Commons and read a first time:—

Whereas doubts have arisen as to the bearing of certain provisions in the Sale of Food and Drugs Act, 1875, through which doubts it has become impracticable to enforce portions of that Act in the interests of the public health:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited for all purposes as the Sale of Food and Drugs Act Amendment Act, 1878.

2. In any prosecution under section 6 of the Sale of Food and Drugs Act, 1875, a sale of any article of food or any drug shall be held to have been made to the prejudice of the purchaser if such article of food or drug is not of the nature *or* substance *or* quality demanded, although such article of food or such drug may have been purchased for the purpose of analysis; *and the seller shall be held to be guilty of an offence against said section if the article of food or the drug sold by him is proved to be not in all respects of the nature or substance or quality of the article demanded, and it shall be no defence to any such prosecution to allege that the purchaser having bought only for analysis was not prejudiced by such sale.*

Mr. Isaac has given notice of his intention to move as an amendment to change the word "or" occuring twice in the fifth line of the second clause and printed in italic, into "and," and to omit the whole of the latter part of the clause, also printed in italic.

An Act to Amend the Law relating to Dental Practitioners.

This Bill has now passed the House of Lords, and the Lords' Amendments have been accepted by the Commons; it therefore only waits the royal assent to become law. Meanwhile, as the Act may not be issued for several days and many inquiries are being made with respect to details, it has been thought advisable to collate the Lords' amendments with the Bill as introduced into the upper house, and to place the result before our readers. It is quite possible there may be some few variations in the Act when it is issued, such as the numbering of the clauses, but it is believed there will be none of any importance.

Whereas it is expedient that provision be made for the registration of persons specially qualified to practise as dentists in the United Kingdom, and that the law relating to persons practising as dentists be otherwise amended:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may for all purposes be cited as the Dentists Act, 1878.

2. In this Act "General Council" means the General Council of Medical Education and Registration of the United Kingdom, established under the Medical Act, 1858, and "Branch Council" means a branch of the said council as constituted by the same Act; "General Registrar" means the person appointed to be the registrar by the General Council, and "Local Registrar" means the registrar by a Branch Council under the Medical Act, 1858; "British Possession" means

any part of her Majesty's dominions exclusive of the United Kingdom; "Medical Authorities" means the bodies and universities who choose members of the General Council.

Registration.

3. From and after the first day of August, one thousand eight hundred and seventy-nine, a person shall not be entitled to take or use the name or title of "dentist" (either alone or in combination with any other word or words), or of "dental practitioner," or any name, title, addition, or descriptlon implying that he is registered under this Act or that he is a person specially qualified to practise dentistry, unless he is registered under this Act.

Any person who, after the first day of August, one thousand eight hundred and seventy-nine, not being registered under this Act, takes or uses any such name, title, addition, or description as aforesaid, shall be liable, on summary conviction, to a fine not exceeding twenty pounds; provided that nothing in this section shall apply to legally qualified medical practitioners.

With respect to the offence of a person not registered under this Act taking or using any name, title, addition, or description as above in this Act mentioned, the following provisions shall have effect:

(1). He shall not be guilty of an offence under this Act—

(*a*). If he shows that he is not ordinarily resident in the United Kingdom, and that he holds a qualification which entitles him to practise dentistry or dental surgery in a British possession or foreign country, and that he did not represent himself to be registered under this Act; or

(*b*). If he shows that he has been registered, and continues to be entitled to be registered under this Act, but that his name has been erased on the ground only that he has ceased to practise.

(2). A prosecution for such offence shall be instituted only as hereinafter mentioned.

If a person takes or uses the designation of any qualification or certificate in relation to dentistry or dental surgery which he does not possess he shall be liable, on summary conviction, on such prosecution as hereinafter mentioned, to a fine not exceeding twenty pounds.

A prosecution for any of the offences above in this Act mentioned shall not be instituted by a private person, except with the consent of the General Council or of a branch council, but may be instituted by the General Council, by a branch council, or by a medical authority, if such council or authority think fit.

4. A person registered under this Act shall be entitled to practise dentistry and dental surgery in any part of her Majesty's dominions, and from and after the first day of August, one thousand eight hundred and seventy-nine a person shall not be entitled to recover any fee or charge, in any court, for the performance of any dental operation or for any dental attendance or advice, unless he is registered under this Act or is a legally qualified medical practitioner.

5. Any person who—

(*a*). Is a licentiate in dental surgery or dentistry of the medical authorities; or

(*b*). Is entitled as hereinafter mentioned to be registered as a foreign or colonial dentist; or

(*c*). Is at the passing of this Act bonâ fide engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy,

shall be entitled to be registered under this Act.

6. Where a person entitled to be registered under this Act produces or sends to the general registrar the document conferring or evidencing his licence or qualification, with a statement of his name and address, and the other particulars, if any, required for registration, and pays the registration fee, he shall be registered in the dentists register.

Provided that a person shall not be registered under this Act as having been at the passing thereof engaged in the practice of dentistry unless he produces or transmits to the registrar, before the first day of August, one thousand eight hundred and seventy-nine, information of his name and address, and a declaration signed by him in the form in the schedule to this Act or to the like effect; and the registrar may, if he sees fit, require the truth of such declaration to be affirmed in manner provided by the Act of the session held in the fifth and sixth years of the reign of King William the Fourth, chapter sixty-two, intituled, "An Act to repeal an Act of the present session of Parliament, intituled An Act for the more effectual abolition of oaths and affirmations taken and made in various departments of the State, and to substitute declarations in lieu thereof, and for the more entire suppression of voluntary and extra-judicial oaths and affidavits; and to make other provisions for the abolition of unnecessary oaths."

A person resident in the United Kingdom shall not be disqualified for being registered under this Act by reason that he is not a British subject; and a British subject shall not be disqualified for being registered under this Act by reason of his being resident or engaged in practice beyond the limits of the United Kingdom.

7. Where a person who eithe is not domiciled in the United Kingdom, or has practised for more than ten years elsewhere than in the United Kingdom, or in the case of persons practising in the United Kingdom at the time of the passing of this Act for not less than ten years either in the United Kingdom or elsewhere, shows that he holds some recognized certificate (as hereinafter defined) granted in a British possession, and that he is of good character, such person shall upon payment of the registration fee be entitled, without examination in the United Kingdom, to be registered as a colonial dentist in the dentists register.

8. Where a person, who is not a British subject, or who has practised for more than ten years elsewhere than in the United Kingdom, or in the case of persons practising in the United Kingdom at the time of the passing of this Act for not less than ten years, either in the United Kingdom or elsewhere, shows that he obtained some recognized certificate (as hereinafter defined) granted in a foreign country, and that he is of good character, and either continues to hold such certificate, or has not been deprived thereof for any cause which disqualifies him for being registered under this Act, such person shall upon payment of the registration fee be entitled, without examination in the United Kingdom, to be registered as a foreign dentist in the dentists register.

9. The certificate granted in a British possession or in a foreign country, which is to be deemed such a recognized certificate as is required for the purposes of this Act, shall be such certificate, diploma, membership, degree, licence, letters, testimonial, or other title, status, or document as may be recognized for the time being by the General Council as entitling the holder thereof to practise dentistry or dental surgery, in such possession or country, and as furnishing sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery.

If a person is refused registration as a colonial dentist, or as a foreign dentist, the general registrar shall, if required by him, state in writing the reason for such refusal, and if such reason be that the certificate held or obtained by him is not such a recognized certificate as above defined, such person may appeal to the Privy Council, and the Privy Council, after hearing the General Council, may dismiss the appeal or may order the General Council to recognize such certificate, and such order shall be duly obeyed.

10. A register shall be kept by the general registrar to be styled the dentists register; and that register shall—

(*a*). Contain in one alphabetical list all United Kingdom dentists, that is to say, all persons who are registered under this Act as having been at the passing thereof engaged in the practice of dentistry or dental surgery, and all persons who are registered as licentiates in dentistry or dental surgery of any of the medical authorities of the United Kingdom; and

(*b*). Contain in a separate alphabetical list all such colonial dentists as are registered in pursuance of this Act; and

(*c*). Contain in a separate alphabetical list all such foreign dentists as are registered in pursuance of this Act.

(2). The dentists register shall contain the said lists made out alphabetically according to the surnames, and shall state the full names and addresses of the registered persons, the description and date of the qualifications in respect of which they are registered, and, subject to the provisions of this Act, shall contain such particulars and be in such form as the General Council from time to time direct.

(3). The General Council shall cause a correct copy of the dentists register to be from time to time, and at least once a year, printed under their direction, and published and sold, which copy shall be admissible in evidence.

(4). The dentists register shall be deemed to be in proper custody when in the custody of the general registrar, and shall be of such a public nature as to be admissible as evidence of all matters therein on its mere production from that custody.

(5). Every local registrar shall keep such register and perform such duties in relation to registration under this Act as the General Council from time to time direct, and receive such remuneration out of the registration fees as the General Council assign him.

Every registrar shall in all respects in the execution of his discretion and duty in relation to any register under this Act, conform to any orders made by the General Council under this Act, and to any special directions given by the General Council.

(6.) The General Council may, if they think fit, from time to time make, and when made, revoke and vary, orders for the registration in (on payment of the fee fixed by the orders) and the removal from the dentists' register of any additional diploma, memberships, degrees, licences, or letters held by a person registered therein, which appear to the Council to be granted after examination by any of the medical authorities in respect of a higher degree of knowledge than is required to obtain a certificate of fitness under this Act.

11. The general registrar shall from time to time insert in the dentists register any alteration which may come to his knowledge in the name or address of any person registered.

(2). The general registrar shall erase from the dentists register the name of every deceased person.

(3). The general registrar may erase from the dentists register the name of a person who has ceased to practise, but not (save as hereinafter provided) without the consent of that person; and the general registrar may send by post to a person registered in the dentists register a notice inquiring whether or not he has ceased to practise, or has changed his residence; and if the general registrar does not, within three months after sending the notice, receive any answer thereto from the said person, he may, within fourteen days after the expiration of the three months, send him by post in a registered letter another notice, referring to the first notice, and stating that no answer thereto has been received by the registrar, and if the general registrar either before the second notice is sent receives the first notice back from the dead letter office of the Postmaster General, or receives the second notice back from that office, or does not within three months after sending the second notice receive any answer thereto from the said person, that person shall, for the purpose of the present section, be deemed to have ceased to practise, and his name may be erased accordingly.

(4). In the execution of his duties the general registrar shall act on such evidence as in each case appears sufficient.

12. The General Council shall cause to be erased from the dentists register any entry which has been incorrectly or fraudulently made.

Where a person registered in the dentists' register has, either before or after the passing of this Act, and either before or after he is so registered, been convicted either in Her Majesty's dominions or elsewhere of an offence which, if committed in England, would be a felony or misdemeanor, or been guilty of any infamous or disgraceful conduct in a professional respect, that person shall be liable to have his name erased from the register.

The General Council may, and upon the application of any of the medical authorities shall, cause inquiry to be made into the case of a person alleged to be liable to have his name erased under this section, and, on proof of such conviction or of such infamous or disgraceful conduct, shall cause the name of such person to be erased from the register:

Provided that the name of a person shall not be erased under this section on account of his adopting or refraining from adopting the practice of any particular theory of dentistry or dental surgery, nor on account of a conviction for a political offence out of Her Majesty's dominions, nor on account of a conviction for an offence which, though within the provisions of this section, does not, either from the trivial nature of the offence or from the circumstances under which it was committed, disqualify a person for practising dentistry.

Any name erased from the register in pursuance of this section shall also be erased from the list of licentiates in dental surgery or dentistry of the medical authority of which such person is a licentiate.

13. Where the General Council direct the erasure from the dentists register of the name of any person, or of any other entry, the name of that person, or that entry shall not be again entered in the register, except by direction of the General Council, or by order of a court of competent jurisdiction.

If the General Council think fit in any case, they may direct the general registrar to restore to the dentists register any name or entry erased therefrom, either without fee or on payment of such fee, not exceeding the registration fee, as the General Council from to time fix, and the registrar shall restore the same accordingly.

The name of any person erased from the dentists register at the request of such person or with his consent shall, unless it might, if not so erased, have been by order of the General Council, be restored to the register on his application, on payment of such fee not exceeding the registration fee as the General Council from time to time fix.

When the name of a person restored to the register in pursuance of this section has been erased from the list of licentiates in dental surgery or dentistry of any medical authority that name shall be restored to such list of licientiates.

14. The General Council shall for the purpose of exercising in any case the powers of erasing from and of restoring to the dentists register the name of a person or an entry, ascertain the facts of such case by a committee of their own body, not exceeding five in number, of whom the quorum shall be not less than three, and a report of the committee shall be conclusive as to the facts for the purpose of the exercise of the said powers by the General Council.

The General Council shall from time to time appoint and shall always maintain a committee for the purposes of this section and subject to the provisions of this section may from time to time determine the constitution and the number and tenure of office of the members of the committee.

The committee from time to time shall meet for the despatch of business, and subject of the provisions of this section, and of any regulations from time to time made by the General Council, may regulate the summoning, notice, place, management and adjournment of such meetings, the appointment of a chairman, the mode of deciding questions, and generally the transaction and management of business, including the quorum, and if there is a quorum the committee may act notwithstanding any vacancy in their body. In the case of any vacancy the committee may appoint a member of the General Council to fill the vacancy until the next meeting of that Council.

A committee under this section may, for the purpose of the execution of their duties under this Act, employ at the expense of the Council such legal or other assessor or assistants as the committee think necessary or proper.

15. There shall be payable in respect of the registration of any person who, before the first day of January, one thousand eight hundred and seventy-nine, applies to be registered under this Act, a fee not exceeding two pounds ; and, in respect of the registration of any person who after that day applies to be registered, a fee not exceeding five pounds.

16. Subject to the provisions of this Act, the General Council may from time to time make, alter, and revoke such orders and regulations as they see fit for regulating the general register and the local registers, and the practice of registration under this Act, and the fees to be paid in respect thereof.

Examinations.

17. Notwithstanding anything in any Act of Parliament, charter, or other document, it shall be lawful for any of the medical authorities (hereinafter referred to as colleges or bodies) who have power for the time being to grant surgical degrees from time to time to hold examinations for the purpose of testing the fitness of persons to practise dentistry or dental surgery who may be desirous of being so examined, and to grant certificates of such fitness ; and any person who obtains such a certificate from any of those colleges or bodies shall be a licentiate in dental surgery or dentistry of such college or body, and his name shall be entered on a list of such licentiates to be kept by such college or body.

Each of the said colleges or bodies shall admit to the examinations held by them respectively under this section any person desirous of being examined who has attained the age of twenty-one years, and has complied with the regulations in force (if any) as to education of such college or body.

18. Subject to the provisions hereinafter contained with reference to a medical board, the council or other the governing body of the Royal College of Surgeons of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow, and of the Royal College of Surgeons in Ireland, and of any university in the United Kingdom respectively, may from time to time appoint a board of examiners for the purpose of conducting the examinations and granting the certificates hereinbefore mentioned.

Each of such boards shall be called the Board of Examiners in Dental Surgery or Dentistry, and shall consist of not less than six members, one half of whom at least shall be persons registered under this Act, and such registration shall (notwithstanding anything in any Act of Parliament, charter, or other document) be deemed the only qualification necessary for the membership of such board.

The persons appointed by each such couucil or other governing body shall continue in office for such period, and shall conduct the examinations in such manner, and shall grant certificates in such form, as such council or other governing body may from time to time, by byelaws or regulations respectively direct.

A casual vacancy in any such board of examiners may be filled by the council or other governing body which appointed such board, but the person so appointed shall be qualified as the person in whose stead he is appointed was qualified, and shall hold office for such time only as the person in whose stead he is appointed would have held office.

19. Such reasonable fees shall be paid for the certificates to be granted under this Act by the board of examiners of the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and of the Royal College of Surgeons in Ireland, and of any such university as aforesaid respectively, as the council or other the governing body of each of those colleges or bodies may from time to time, by byelaws or regulations respectively direct.

20. The Royal College of Surgeons of England shall continue to hold examinations and to appoint a board of examiners in dentistry or dental surgery for the purpose of testing the fitness of persons to practise dentistry or dental surgery who may be desirous of being so examined, and to grant certificates of such fitness, subject and according to the provisions of their charter, dated the eighth day of September, one thousand eight hundred and fifty-nine, and the byelaws made, or to be made, in pursuance thereof ; and any person who obtains such a certificate shall be a licentiate in dental surgery of the said college, and his name shall be entered on a list of such licentiates to be kept by the said college.

21. Every medical authority shall from time to time, when required by the General Council, furnish such council with such information as such council may require as to the course of study and examinations to be gone through in order to obtain such certificates as are in this Act mentioned, and generally as to the requisites for obtaining such certificates ; and any member or members of the General Council, or any person or persons deputed for this purpose by such council, or by any Branch Council, may attend and be present at any such examinations.

22. Where it appears to the General Council that the course of study and examinations to be gone through in order to obtain such certificate as in this Act mentioned from any of the said colleges or bodies are not such as to secure the possession by persons obtaining such certificate of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery, the General Council may represent the same to Her Majesty's Privy Council.

23. The Privy Council, on any representation made as aforesaid, may, if they see fit, order that a certificate granted by any such college or body after such time as may be mentioned in the order shall not confer any right to be registered under this Act.

Any such order may be revoked by the Privy Council on its being made to appear to them, by further representation from the General Council or otherwise, that such college or body has made effectual provision, to the satisfaction of the General Council, for the improvement of such course of study or examination.

24. After the time mentioned in this behalf in any such Order in Council, no person shall be entitled to be registered under this Act in respect of a certificate granted by the college or body to which such order relates after the time therein mentioned, and the revocation of any such order shall not entitle any person to be registered in respect of a certificate granted before such revocation.

25. If it appears to the General Council that an attempt has been made by any medical authority to impose on any candidate offering himself for examination an obligation to adopt or refrain from adopting the practice of any particular theory of dentistry or dental surgery as a test or condition of admitting him to examination, or granting a certificate of fitness under this Act, the General Council may represent the same to the Privy Council, and the Privy Council may thereupon issue an injunction to the authority so acting directing them to desist from such practice, and in the event of their not complying therewith, then to order that such authority shall cease to have

power to confer any right to be registered under this Act so long as they continue such practice.

26. A certificate under this Act shall not confer any right or title to be registered under the Medical Act, 1858, in respect of such certificate, nor to assume any name, title, or designation implying that the person mentioned in the certificate is by law recognized as a licentiate or practitioner in medicine or general surgery.

27. In the event of a board being at any time after the passing of this Act established, whether under the name of a medical board or otherwise, for nominating on behalf of any two or more of the medical authorities examiners of persons desirous of practising medicine and surgery, whether such board (in this Act referred to as a medical board) is established under the Medical Act, 1858, or otherwise, a person shall not receive a certificate of fitness to practise as a dentist from any medical authority represented on such board, or, if such board is established for the whole of England, Scotland, or Ireland, shall not be entitled to be registered in respect of any certificate obtained in England, Scotland, or Ireland, as the case may be, unless he has obtained from such board a certificate that he has shown by examination that he is qualified to practise dentistry or dental surgery.

Provided that one-half at least of the examiners at any such examination shall be persons registered under this Act.

The medical board shall, in such manner as may from time to time be directed by the General Council, certify to the general registrar and to the medical authorities the persons who have shown by examination that they are qualified to practise dentistry or dental surgery, and every person so certified shall on application receive from the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Faculty of Physicians and Surgeons of Glasgow, or the Royal College of Surgeons of Ireland, a certificate of fitness constituting such person a licentiate in dental surgery or dentistry of such college or faculty.

If a medical authority certify to the general registrar the names and addresses of the persons who, having been so certified by a medical board, have received certificates from that authority, together with the other particulars required for the registration of such persons, the general registrar may, upon payment of the registration fee, register every such person in the dentists register without application from that person.

The General Council shall have the same power of making rules respecting the examination of persons desiring to obtain certificates of being qualified to practise dentistry or dental surgery as they have for the time being in respect of the examination of persons desiring to obtain a qualification to practise medicine and surgery, and there shall be the same right of appeal to the Privy Council against such rules.

The General Council and the Privy Council shall have the same control over the medical board, so far as regards the examination of persons desiring to practise dentistry or dental surgery, as they have as regards the examination of persons desiring to practise medicine and surgery, and shall have the same power of dismissing the members of such board.

The General Council may cause to be framed, and may approve, and when approved submit to the Privy Council, a scheme to carry into effect the provisions of this Act with respect to a medical board, and rules respecting examinations, and for extending, with or without any exception or modification, to the examination of persons desirous of practising dentistry or dental surgery, the provisions of any Act for the time being in force with respect to the examination of persons desiring to practise medicine or surgery, and any such scheme when confirmed by the Privy Council shall have full effect.

Any such scheme may provide for the fees to be paid on admission to the examinations, and for the application of such fees for public purposes, and generally for such matters as appear to be necessary or proper for carrying into effect the scheme and regulating the examinations.

Supplemental.

28. A copy of the register of dentists for the time being, purporting to be printed and published in pursuance of this Act, shall be evidence in all cases (until the contrary be made to appear) that the persons therein specified are registered according to the provisions of this Act; and the absence of the name of any person from such copy shall be evidence (until the contrary be made to appear) that such person is not registered according to the provisions of this Act: Provided that, in the case of any person whose name does not appear in such copy, a certified copy under the hand of the registrar of the General Council of the entry of the name of such person in the dentists register shall be evidence that such person is registered according to the provisions of this Act.

29. Every person registered under this Act shall be exempt, if he so desires, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and from serving in the militia; and the name of any registered person shall not be returned in any list of persons liable to serve in the militia or in any such office as aforesaid.

30. The powers by this Act vested in the Privy Council may be exercised by any two or more of the Lords and others of Her Majesty's most honourable Privy Council.

Any order made by the Privy Council, or any appeal to them under this Act, may be made conditionally or unconditionally, and may contain such terms and directions as to the Privy Council seem just.

31. All moneys arising from fees paid on registration or from sale of copies of the registers, or otherwise received by the General Council, under this Act shall be applied in accordance with such regulations as may be from time to time made by the General Council, in defraying the expenses of registration and the other expenses of the execution of this Act, and subject thereto, towards the support of museums, libraries, or lectureships, or for public purposes connected with the profession of dentistry or dental surgery, or towards the promotion of learning and education in connection with dentistry or dental surgery.

32. The treasurers of the General and Branch Councils shall enter in books to be kept for that purpose a true account of all sums of money by them received and paid under this Act; and such accounts shall be submitted by them to the General Council and Branch Councils respectively at such times as the councils may respectively require. Such accounts shall be published annually, and shall be laid before both Houses of Parliament in the month of March in every year, if Parliament be then sitting; or, if Parliament be not sitting, then within one month after the commencement of the next sitting of Parliament.

33. Any registrar who wilfully makes or causes to be made any falsification in any matter relating to any register under this Act shall be guilty of a misdemeanor in England or Ireland, and in Scotland of a crime or offence punishable by fine or imprisonment, and shall, on conviction thereof, be liable to be imprisoned for any term not exceeding twelve months.

34. Any person who wilfully procures or attempts to procure himself to be registered under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding and assisting him therein, shall be deemed guilty of a misdemeanor in England and Ireland, and in Scotland of a crime or offence punishable by fine or imprisonment, and shall, on conviction thereof, be liable to be imprisoned for any term not exceeding twelve months.

35. Every registrar of deaths in the United Kingdom, on receiving notice of the death of any person registered under this Act, shall forthwith transmit, by post, to the

registrar of the General Council and to the registrar of the Branch Council for that part of the United Kingdom in which the death occurs, a certificate under his own hand of such death, with the particulars of the time and place of such death, and may charge the cost of such certificate and transmission as an expense of his office.

36. Any person who has been articled as a pupil and paid a premium to a dental practitioner entitled to be registered under this Act in consideration of receiving from such practitioner a complete dental education, shall, if his articles expire before the first day of January, one thousand eight hundred and eighty, be entitled to be registered under this Act as though he had been in *bonâ fide* practice before the passing of this Act: Moreover it shall be lawful for the General Council by special order to dispense with such of the certificates, examinations, or other conditions for registration in the dentists register required under the provisions of this Act, or under any byelaws, orders, or regulations made by its authority, as to them may seem fit, in favour of any dental students or apprentices who have commenced their professional education or apprenticeship before the passing of this Act.

37. All byelaws, orders, and regulations made by the General Council, or by any medical authority under the authority of this Act, shall be made and may be from time to time altered or revoked in such manner, and subject to such approval or confirmation (if any), as in the case of other byelaws, orders, or regulations made by such college or body.

38. Subject to the other provisions of this Act, all notices and documents required by or for the purposes of this Act to be sent may be sent by post, and shall be deemed to have been received at the time when the letter containing the same would be delivered in the ordinary course of post; and in proving such sending it shall be sufficient to prove that the letter containing the notice or document was prepaid, and properly addressed, and put into the post.

Such notices and documents may be in writing or in print, or partly in writing and partly in print, and when sent to the General Council, or a medical board, or a medical authority, shall be deemed to be properly addressed, if addressed to the General Council, medical board, or medical authority, or to some officer of such council, board, or authority, at the principal office or place of business of such council, board, or authority; and when sent to a person registered in the medical register, shall be deemed to be properly addressed if addressed to him according to his address registered in that register.

39. All fees under this Act may be recovered as ordinary debts due to the General Council, and all penalties under this Act may be recovered and enforced as follows, that is to say:—In England, before two or more justices of the peace, in manner directed by the Act of the session of the eleventh and twelfth years of the reign of Her present Majesty, chapter forty-three, intituled "An Act to facilitate the performance of the duties of justices of the peace out of sessions within England and Wales with respect to summary convictions and orders," and any Act amending the same; and in Scotland, before the sheriff or sheriff substitute or two justices, in manner provided by the "Summary Procedure Act, 1864, and any Act amending the same; and in Ireland within the police district of Dublin metropolis, in manner directed by the Acts regulating the powers and duties of justices of the peace for such district or of the police of such district, and elsewhere in Ireland, before two or more justices of the peace, in manner directed by the "Petty Sessions (Ireland) Act, 1851," and any Act amending the same.

The Schedule.

Declaration required to be made by a person who claims to be registered under the Dentists' Act, 1878, on the ground that he was *bonâ fide* engaged in the practice of dentistry at the date of the passing of the Dentists Act, 1878.

I, residing at , hereby declare that I was *bonâ fide* engaged in the practice of dentistry at , at the date of the passing of the Dentists Act, 1878.

(Signed)

(Witnessed)

Dated this day of , 18

Note.—Any person who wilfully procures or attempts to procure himself to be registered under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding and assisting him therein, is liable under the Dentists Act, 1858, to imprisonment for twelve months.

Dispensing Memoranda.

[126]. Ergotine Pessaries.—If "Dispenser" proceeds in the following manner a thorough admixture results; specimen enclosed, ℥j size. To the ergotine in a mortar, add water to a semi-fluid consistence, with this mix gradually about half the ol. theobrom. previously liquefied. The tannin in fine powder is to be mixed with the remainder; now transfer the congealed ergot portion to the tannin mixture, and apply just sufficient heat to enable it to be poured into moulds which may be chilled if necessary, the addition of lard and wax is unnecessary in the majority of cases, as morphia etc., may be rubbed down with a llttle of the melted ol. throbrom on a warm slab.

F. W. Branson.

---

[128]. I received the following to dispense. Which would be the proper way to proceed, and what quantity of gum or gelatine should be used, so as to make a good emulsion, also the right quantity of bitter almond oil?

℞ Ol. Morrhuæ . . . . . ℥v.
Sacchari alb. . . . . ℥ij.
Calcis Hypophosphitis. . . . . ℈ij.
White Jamaica Rum . . . . . ℥j.
Aq. Destillat. . . . . ad ℥x.

Gum tragacanth vel. gelatine q.s. ut fit. emulsio, flavour c. essential oil of almonds.

---

[129]. Will any of your readers kindly furnish me with the best methods of preparing the following?—

℞ Ferri sulph. . . . . ℥ij.
Excip q. s.
Ft. bol. Mitte vj.

℞ Cupri Sulph.. . . . . ℥iss.
Pulv. Canthar . . . . . grs xx
Excip q. s.
P. Glycyrrhizæ . . . . . ℥iiss.

M. ft. m. Div. in Bol. iv.

Apprentice,

---

[130]. What is the reason that the following ointment turns a bright yellow colour after it has been made a few hours?—

℞ Liq. Plumbi Diacet. . . . . ℥j.
Ung. Cetacei . . . . . ℥j.

M. ft. ungt.

The ung. cetacei is freshly prepared in a porcelain water-bath at the lowest possible temperature, and stirred with a glass rod, the liq. plumbi being added towards the end of the process. Perhaps some of your readers can explain the cause and suggest a remedy.

S. J. W.

Notes and Queries.

[508]. INSECTICIDE POWDER.—G. H. D. will find the powder of the flower heads of the *Pyrethrum roseum*, commonly called "Persian" Insect Powder, to be the best, and not injurious to animals.

"TENENS."

[509]. LINIMENTUM PETROLEI.—Would any correspondent kindly give me a form for Linimentum Petrolei? W.

Correspondence.

COUNTER PRACTICE.

Sir,—As pharmacy seems now to be upon its trial, and the minds of many are filled with evil forebodings concerning the result, I may perhaps be allowed a brief space wherein to jot down not only my own feeble reflections but also some appertaining to older and wiser heads than mine.

Events have apparently divided the trade into two camps, which though not in a state of actual hostility are verging upon it. One camp is filled by those to whom counter practice is bread and cheese; they wave aloft their banner of defiance and dare the foe to do his worst. The other camp is occupied by those who from various circumstances are not vitally interested in counter prescribing.

This being the condition of affairs, it follows that the party of defiance is enraged at the seeming lukewarmness in the cause displayed by the party of indifference, whilst this latter section of the trade is half inclined to laugh at the excessive and unwise ardour of their *confrères*, and thus a state of mutual irritation is kept alive between them.

It must be confessed that the desperate efforts of the thick and thin supporters of counter practice to retain what they consider to be their rights is but natural, when we reflect that to many of them the discontinuance of the objectionable practice implies the discontinuance of their means of livelihood, or the ruin of their schemes of fortune-making. And, indeed, if one might hazard a guess at the results of recent events upon the future conduct of the business, the prescribing druggists do seem to have good reason to dread that the axe is laid to the root of their most fruitful tree.

The doctors may blandly proclaim their intention not to interfere with the practice among druggists of treating simple ailments, but this simply means that "all's well that ends well," for should an apparently simple case suddenly develop into a serious one (and such things do happen), then down would come the law without mercy upon the head of the unfortunate prescriber for having treated a serious case. To indulge in dreams of safety based upon the elastic assurances of the medical gentlemen would would be to live in a fool's paradise, and the good intentions of the doctors might ultimately be found to have gone a long way towards paving the chemists' Hades.

The future may see the extinction of the prescribing druggist, with, perhaps, many others who will be unable to survive the competition of "stores," grocers, tailors, and such like vendors of those sundry articles which are now viewed as essential to the chemist's business. The fittest who shall survive these trials will then find sufficient remuneration in devoting themselves to their legitimate profession.

JUVENIS.

MEDICAL ACTS AMENDMENT BILL.

Sir,—In your editorial of the 13th, speaking of the statements of the Trade Association's memorandum respecting the animus of the Apothecaries' Society towards chemists, you remark that "its general inconsistency with facts, and even with circumstances recorded in the same document, such as the statements of Mr. John Nussey, Master of the Apothecaries' Society, and of Mr. R. D. Upton, the Clerk to the Society, is so flagrant that one is startled at seeing the two side by side." With regard to your latter alleged inconsistencies, I would remark that the testimonies of Messrs. Upton and Nussey bear the dates 1833 and 1834, and that a period of forty-four years is often amply sufficient to admit of the most radical changes in the sentiments and actions both of individuals and of corporations.

JOHN THROSSELL.

Cambridge.

[*** As to the possibility we agree with you; but as to the fact you are quite wrong, and by reference to the Journal of February the 9th (page 634) you will find two letters, dated 1st January and 5th February, 1878, written by Mr. J. R. Upton, the present clerk to the Apothecaries' Society, in which the views expressed by Mr. R. D. Upton and Mr. John Nussey upwards of forty years ago are virtually reiterated, as being those still held by that body.—ED. PHARM. JOURN.]

Sir,—Would not the difficulty of druggists prescribing be overcome by a sort of minor examination to be instituted under the Medical Act Amendment Bill, which would affiliate the prescribing chemist to the medical profession? This would increase his status in the future, without depriving the public of their common privilege of obtaining medicine and advice in their accustomed manner, a manner adopted by all grades of society, say from Justice Field himself, who consults the chemist in Chancery Lane, to the poorest dweller in the adjacent courts and alleys.

I know that at the time I was assistant in a West-End establishment I was often requested to prescribe for individuals of the highest rank, and often did so, and I have no doubt it is so now; and this was done not for the sake of cheapness, but from convenience and confidence in an established pharmacy where it was well known a good knowledge in the remedial nature of drugs must exist.

I do not think it wise to rely on the goodwill of the medical society always existing; I am afraid if they have the power they will be aggressive, even to proving that a simple ailment has complications which should only be treated by an apothecary, and that with the penalty of £20 hanging over us prescribing even in simple ailments must cease.

Then what with co-operative societies, grocers, and haberdashers attacking our profits on the one hand, the medical societies with penalties on the other, the chemist of the next generation will become a cadaverous dealer in poisons, and if he has to get a living out of them a lean and hungry one it will be.

I shall be obliged if you will bring this matter before the special committee of the Pharmaceutical Council on the Medical Act Amendment, and if you think well to introduce it in the paper of the Journal a discussion upon the subject may be of interest and service.

Stockport, July 15, 1878. K.

ELECTION OF THE COUNCIL AND PRELIMINARY EXAMINATION.

Sir,—Surely the recent discussion in the Council on Local centres for preliminary examinations should convince country chemists that the constitution of the Council is to them a matter of practical and vital interest, and it should largely tend to do away with the indifference which causes 60 per cent. to abstain from voting on the matter. A good deal has been said about the impossibility of knowing the sentiments and opinions of many of the candidates, and two definite suggestions have been made for meeting this difficulty, one which seems to find favour in Scotland is, to have district representation. Some time since I ventured to suggest the adoption of accumulative voting as it is now carried out in School Board elections. This would secure many of the advantages of district representation without its complexity.

But my chief object in writing is to suggest that all members of the Society should prepare a list of the Council for the time being and have it by them when reading the reports of the monthly meetings, and at once place a mark of approval or disapproval of the course taken on the various topics discussed and voted on. This would only take up a

page of some memorandum book or almanack, and then when the time of election comes round, each constituent would have some intelligent basis to guide him in voting for election or rejection.

In the discussion on the 3rd July, some most estimable gentlemen could not have shown a greater incapacity to realize the difficulties of country chemists, if their habitat had been the other side of the moon, and this is far from a mere sentimental question. Not the least among the practical and increasing difficulties of country chemists is getting suitable apprentices. Young men of intelligence and education realize the difficulties thrown in their way by the examinations, and if these, together with co-operative competition and analytical and apothecarian persecutions, do not repel them altogether from a calling which, at present at least, is a hybrid between a profession and a trade, having all the responsibilities of the former with the status and difficulties of the latter, yet still there are now very strong inducements to attract them towards the very few large towns where chemical and educational classes can be sustained, and from which including London, the great majority of the Council now come.

To a very great extent from these causes many country chemists now think themselves fortunate if they can secure eligible lads as apprentices without any premium whatever, yet some members of the Council suggest that apprentices shall only be selected from those who have already passed the Preliminary examination or its equivalent. Hundreds of chemists would be glad to have the opportunity of such selection, but it never comes in their way; and now by the action of the Council the difficulties of such members of the trade are greatly increased. One very worthy member of the Council suggests that as a matter of course country apprentices from a distance should (if they wish to pass) go to the examination town the night before, involving of course, board and lodging at some hotel in addition to the railway expenses and the great loss of time. It does not seem to cross the mind of some of these gentlemen that this consumption of time and greatly enhanced expense will fall on the very members of the trade to whom they will be most irksome. For one I protest against this change, not so much on my own account as on account of hundreds of chemists who will be much more seriously inconvenienced by the change. Then why is this change not only proposed but actually carried out, without giving an opportunity for those chiefly concerned to express any opinion on the matter? Because one local secretary has been remiss in his duty. Surely it would have been sufficient to disqualify him from ever holding the office again, and to insist in future that at least two chemists not interested in the examination should be present during the whole of the examination, and in some of the smaller centres half yearly examinations would no doubt be sufficient.

I am quite willing to allow that the Council are not merely delegates, but I distinctly assert my claim as one of their constituents to know who voted and how on this question, and I hereby protest against the voters being reported as they are merely in the aggregate.

W. Symons.

Barnstaple, July 8, 1873.

Centres for the Preliminary Examinations.

Sir,—The new Council appears to me to have acted in a most hasty and unjustifiable manner in striking out so large a number of examination centres from the last list.

This will entail a great amount of inconvenience and expense both to employers and young men.

I am at a loss to understand the reason of this abrupt action (taken without any previous discussion or any attempt on the part of the Council to find out the feelings of the trade on the subject), unless it is for the paltry excuse of making a little more money out of the examinations; if that is the object, let the fees be raised, as the most straightforward course, then the young man will be aware before entering the trade of the expense likely to be incurred. If the plea of a want of uniformity and efficiency in superintendence at the centres is the true one, let that be rectified, as in my opinion it is a most simple and easy matter.

The President says that young men must travel the night before the examination or their chances of failing will be increased; if so, then the day of examination must be altered, for it would be improper, uncalled for, and a *hardship* to travel for such a purpose on the Sunday; it is also a *great hardship* for young men to be put to the expense of a long railway journey, hotel charges, etc., which in large towns would be very considerable, when in a great measure this can be spared them under the past arrangements. Again, is it safe to throw young men, perhaps raw from school, into a large town alone and unprotected?

Once more, it is a hardship for the employer to lose the services of a young man for more than a day when part of one is all that is necessary, especially when the day is Monday, one of the busiest of the week.

In conclusion I may add, from my own experience, that apprentices (no matter their age) can seldom be obtained who have passed the Preliminary examination at school, and the difficulty in some parts of procuring apprentices is greatly increasing every day; parents are deterred by the expense, and it is a common remark with them now that "it costs as great a sum to make a boy a chemist as it does to make a doctor."

W. Fredk. Wright.

30, *Regent St. West, Leamington.*
July 10, 1878.

The Omission of Swansea from the List of Centres.

Sir,—I was very much struck on reading the report in the Journal of the last meeting of the Council to find that Swansea (the metropolis of Wales) had been excluded from the list of centres for halding the Preliminary examinations. Allow me therefore as a Swansea chemist and druggist this opportunity of expressing my great regret at such a change.

Now, sir, it is all very well for our respected President to state that the committee had been guided in their selection of the fortunate towns by the geographical situations and railway communications, etc., in each case as brought before them, and their wish as a committee to include only such large towns as Manchester and Liverpool, which seems to me absurd, and leads me to believe that neither the President nor any of the committee have ever been either to Cardiff or Swansea or they would certainly have not made such a glorious blunder in selecting Cardiff in preference to Swansea. I may therefore assume that such is the case, and respectfully inform them (the committee) that Swansea in the first place has a larger population than Cardiff; and secondly for scholastic facilities Swansea certainly has and always will claim precedence; and thirdly for geographical situation Swansea is undoubtedly superior, and the fact that that town having been selected by the Commisioners for holding the winter assize for the six Welsh Counties is I say sufficient evidence of its geographical position. Such being the case, I can only repeat my great surprise and regret that such a decision should have been arrived at; but on the other hand I may be wrong in censuring the committee for doing what I consider they have done hastily, not knowing myself whether something else in connection with Swansea (other than its geographical position) may have induced them to do so. It may be that part of the irregularities spoken of may be applied here. If so, then I say change the superintendent for another, and there are many in Swansea who are willing to spare the necessary time, not only for that office, but to work in this district for the good of the Society and the trade generally.

Fair Play.

The Origin of Violet Powder.

Sir,—I cordially endorse the statement of your correspondent, "Dum Vivo Disco," and confidently assert that for the forty-five years I have been connected with leading retail drug establishments I always understood that starch dressed up in some form was the sole active ingredient of "violet powder."

"*Rhizoma Iridis*," or more familiarly speaking, "orris root," from, and doubtless antecedent to, the days of Theophrastus and Dioscorides, has been appreciated for its supposed medicinal properties, and from its pleasant violet odour was largely used in perfumery by the Greeks and Romans.

It has been widely known as "violet root," and the starch of this rhizome was formerly reckoned medicinal, and directions for its preparation are to be found in the

'Traicté de la Chymie' of Le Febvre, published in 1660.* The rhizome finely powdered has for ages been highly prized as a pleasing and healing application to the skin; it contains a large percentage of starch, and I contend the origin of "violet powder" is to be traced exclusively to this source.

TOUCHSTONE.

VIOLET POWDER PROSECUTIONS.

Sir,—Proceedings having been taken under the Sale of Food and Drugs Act against some parties for selling so-called adulterated violet powder, and other prosecutions being threatened, it may be well to indicate some lines of defence should any of our brethren be unlucky enough to fall into the hands of some over-zealous but not very wise analyst or inspector.

It seems to me that there are two lines of defence, either of which ought to secure dismissal of the case, and one at least should carry costs against the prosecution.

In the first place, violet powder is not an article to which the Sale of Food and Drugs Act applies; the only articles subject to its provisions are food, drink and drugs. Now violet powder is neither food nor drink, and it certainly is not a medicine for internal or external use, but really and simply a cosmetic or article of perfumery for the toilet, and as such cannot be affected by the Act.

In the second place, if it be argued that it is used as an application to excoriated surfaces and is therefore a medicine for external use, the question arises, What is genuine violet powder? and what constitutes an adulteration? It is very easy to say that true violet powder consists of so much starch and so much of something else, but the proof is by no means so easy. It may be admitted that formulæ for violet powder, consisting chiefly of starch, have been published in various books of recipes under the head of cosmetics and perfumery, but can anyone bring forward an authorized official English formula for its manufacture? I guess not, and unless that can be done no charge of adulteration can be substantiated.

But supposing it to be urged that certain violet powders are injurious because not composed chiefly of starch, I conceive that assertion has yet to be proved. It is quite certain that violet powders, not only not composed chiefly of starch, but containing no starch at all, have been selling all over the country for a considerable time without any ill effects being produced thereby. This, however, although chiefly relied on in the Hyde case, is not the true line of defence and is very likely to fail; but if the bolder course indicated above be followed the prosecution can hardly have a chance of success.

W. WILKINSON.

Manchester, July 16, 1878.

THE SALE OF PATENT MEDICINES, ETC.

Sir,—Allow me a little space for a remark upon A. H.'s letter in this week's Journal.—

"I have frequently found that when some customers come for a box of Professor Pilloway's pills," etc., "you can persuade them to have a bottle of mixture or box of pills made specially to suit their case."

This does not speak well of A. H.'s counter morality, although it shows up to advantage his persuasive powers, unless it happens that the majority of his customers (since "he frequently found") belong to that class of intellects which it is easy to impose upon. But then to imagine that the bulk of chemists throughout the country have only such customers as can be so easily "persuaded" pays them indeed but a very poor compliment, especially now that we are aspiring to the professional. I ask A. H. which is the most honourable line of action, to persuade a customer to take what he does not require and at the same time practising as a medical man without his diploma, or to supply him with what he asks for, even should he ask for a box of Professor Pilloway's pills?

EGROEG.

Hirwain.

Sir,—When drapers, hairdressers, grocers, and oilshops take advantage of the 5*s.* licence and vend patent medicines, let the pure pharmacist retire; I for one deem it time. But also cease circulating the bills relative to advertised remedies, and generally discountenance their sale. To those who have been in the habit of regularly supplying these papers, I have given written notice, and multiplied cases may perhaps induce consideration from the proprietors, and tend towards restoring the sale to its legitimate channel.

In these cases here union indeed asserts itself to be strength.

BYATT WALKER, M.P.S.

26, *Clapham Road, July* 5, 1878.

W. J. Williams.—(1) *Lonicera Periclymenum;* (2) *Urtica dioica*; (3) *Chærophyllum temulum.*

P. B.—*Linaria Cymbalaria.*

W. Greig.—Probably *Pteris serrulata:* too imperfect to state with certainty.

W. J. Rogers.—The Dental Practitioners Act provides that any person who has previous to the passing of the Act been *bonâ fide* engaged in the practice of dentistry, either separately or in conjunction with the practice of medicine, surgery, or pharmacy, shall be entitled to be registered as a dentist under the Act.

T. Hambridge.—Your letter betrays inability, either natural or assumed, to distinguish between things that differ.

D. M. S.—The tincture is prepared of various strengths. One made by percolation with two ounces of powdered root to the pint of proof spirit has been recommended for reasons that will be found in vol. vi., p. 562 of the present series.

J. R. C.—The first section of the Act to amend the Pharmacy Act (32 and 33 Vict. cap. cxvii.) provides that nothing contained in the first fifteen (registration) sections of the Pharmacy Act shall prevent any person who is a member of the Royal College of Veterinary Surgeons of Great Britain, or who holds a certificate in veterinary surgery from the Highland and Agricultural Society of Scotland, from dispensing medicines for animals under his care. If you think the terms of this exemption are being exceeded by any person you are recommended to communicate the particulars to the Registrar, 17, Bloomsbury Square.

"*Chemist.*"—You will find some recipes for hair dyes in Canning's 'Select Practical Notes and Formulæ," published by Davis, Old Kent Road, price 3*s.* 6*d.* Several recipes have also appeared in the present series of this Journal.

E. Fowler.—(1) The formation of perchloride of mercury in such powders has been observed. See a note on p. 46 of the present number. (2) Several preparations are "known" under the name that have little to justify their title.

H. R. Mansell.—*Solanum Dulcamara.*

E. Worth.—For the first preparation see the answer to "*D. M. S.*" above. The second is a manufacturer's preparation, concerning the formula of which we know of nothing published beyond what is revealed in the name.

G. E. O.—*Lacnanthes tinctoria* (Hæmodoraceæ), is the "red root" of the United States, where a saturated tincture of the whole plant is used. See 'King's Dispensatory,' p. 472.

"*Aberdonia.*"—We cannot advise you upon the subject of the latter of your questions. The seeds are those of *Sesamum orientale* (gingelly seed), and the oil can be readily obtained in commerce.

G. Durrant.—We think a very small amount of effort will enable you to find a more appropriate receptacle for your communication than the columns of the *Pharmaceutical Journal.*

P. Smyth and "Tenens."—The final arrangements in connection with registration under the Dental Practitioners Act have not yet been made, some of the details being left to the Medical Council. You will find a collation of the Bill and its Amendments on p. 52 of the present number.

J. Farmer.—'How Crops Grow,' published by Macmillan and Co.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Smith, Dobel, Inchiostri and Son, Schacht, Tichborne, Proctor, Davies, Fryer, Smith, Woltz, Barnaby, Saccharum, Juxta, Student, Alpha, Chemist and Druggist.

* 'Pharmacographia,' p. 599.

"THE MONTH."

Holiday-time is fast approaching, and the mountain side, the sequestered country village and the fashionable seaside resort will soon be crowded with eager and happy faces. Here and there the inevitable botanical tin-case will doubtless put in an appearance, and many a rare specimen will be brought home in triumph, while some of the more plebeian of Nature's products will probably be passed by in undeserved contempt. Some of the more insignificant of our native plants, however, would well repay examination.

The common pellitory of the wall (*Parietaria diffusa*), whose brittle pinkish stems and hairy lanceolate dull green leaves, too often covered with dust, may be seen on almost any old wall, is one of these. The flowers, which are very small and green, form dense clusters in the axils of the leaves. These clusters are really composed of two dense cymes contained in a two-leaved involucre, each half of which is multipartite; in the angle between the two cymes will be generally found a solitary female flower, for the flowers are polygamous, the unisexual ones differing from those which are perfect only in having the pistil abortive in the male flowers, and the stamens abortive in the female flowers.

The calyx of the fertile flowers is four-cleft, and the flower has a reddish stigma which stands out beyond it. The barren flowers have stamens, of which the anthers are curled inwards, upon the filament, and from the shape of the sepals, which bend over the stamens, are kept in their place, something like those of the *Kalmia*, only in that plant the filaments are bent outwards. When the stamens are mature the slightest touch of the sepals causes the anthers to uncurl with considerable force and expel their white pollen in quite a little cloud. If this phenomenon were caused by an insect alighting on the flowers, naturally it would be dusted with the pollen and might carry it to other flowers; but from the absence of odour and the inconspicuous character of the flowers, it is probable that the plant is only visited by such small insects as are found in crevices of walls. The motion of the stamens appears to be due to tension of the cells on the inner side of the filament, since it does not take place until the anthers are mature and there is no peculiar structure in the filament, which consists of simple parenchymatous cells with a cord of spiral vessels in the centre. The pollen grains are singularly variable in size.

There are two forms of the plant to be met with, one (*P. diffusa*) having branched stems and lanceolate leaves and the perianths of the outer fertile flowers somewhat elongated, the other (*P. erecta*) having a more slender habit, nearly simple stems, and leaves broader in proportion to their length, so as to be somewhat rhomboidal in outline.

The plant derives its name of *Parietaria* from the Latin word for a wall, *paries*, on account of its being almost always found growing on walls.

The ash of the plant is said to contain a quantity of nitre, which will explain the success which is said to attend its use in dropsy, gravel, and other urinary disorders. The juice, according to Dioscorides, is a remedy for old coughs, and also for swollen glands in the throat if it be used in the form of a gargle.

The centaury (*Erythræa centaurium*), sometimes called the lesser centaury to distinguish it from the greater centaury (*Centaurea scabiosa*), is now to be found in blossom in dry grassy places and thickets. The plant is very variable, so much so that it is very difficult at times to distinguish to which of the four species described in most British Floras a specimen may belong. The flowers close directly the sun is hidden behind a cloud, and the anthers become twisted almost immediately after shedding the pollen. The edges of the carpels also are so curved inwards as almost to make the capsule two-celled. The object of the sensitiveness to sunlight of the flowers of the centaury and that of the irritability of the stamens in parietaria do not appear to have been investigated, and offer a field for observation by young naturalists. Occasionally a white-flowered variety of the centaury is met with. Dr. Prior tells us that the plant derives its name from the centaur Chiron having cured himself of a wound which he had accidentally received from an arrow poisoned with the blood of the hydra. The famous Portland powder for the gout is said to have had this plant for its basis. From its intense bitterness this plant was formerly called *Fel terræ*, and Culpepper alluding to the same fact says, "'Tis very wholesome but not very toothsome." It is now used in country districts chiefly as a remedy for indigestion and for worms in children.

Another plant, far more curious than the two preceding, and which may now be found in blossom, is the sundew (*Drosera rotundifolia*). The admirable researches of Mr. Darwin on the life-history of this plant are probably well known to all our readers. The sundew may usually be found at the boggy head of streams on heaths, growing mixed up in the bog moss which abounds in such places.

> "By the lone fountain's secret bed
> Where human footsteps rarely tread,
> Mid the wild moor or silent glen,
> The sundew blooms unseen by men."

It is rare to find the flowers open. According to Darwin, on the authority of Mr. Wallis, they open only in the early morning. A few days ago, however, the writer observed those of *Drosera intermedia* open between the hours of eleven and two o'clock in the day. Many of the flowers, especially those first produced, are cleistogamous, and therefore fertilize themselves; those produced later in the season open their flowers, while some are found in an intermediate stage, opening slightly, but the flowers being self-fertilized. According to Gerarde, it derives its name of sundew and its old name of "ros-solis" from "the dew which hangeth upon it when the sun is at the hottest." The Italian liqueur rossoli, in which it forms an ingredient, derives its name from this plant. The same writer speaks of it as acrid and caustic, and says, "The leaves being stamped with salt, etc., exulcerate and raise blisters to what part of the body soever they be applied." By homœopaths a weak tincture is used as an internal remedy for spasmodic coughs, more especially whooping cough.

At the various botanical gardens a very large number of medicinal plants are now in blossom. Many that are usually not open until August are now in flower, owing probably to the extreme heat of the last few weeks. Among these, scammony, chamomile, peppermint, elecampane and tansy may be noticed.

In the Economic House at Kew there are very

few medicinal plants now in blossom. The coca plant is still in full bloom, the nutmeg has a few flowers upon it, and *Chloranthus officinalis* presents its spikes of singular flowers, which look like tiny white buds. In this plant the calyx, for there is no corolla, consists of a single minute scale adhering to the side of the ovary. The stamens are attached to the side of the ovary immediately above the calyx, and consist of a central two-celled anther and two lateral anthers which are one-celled. These parts are not easily distinguished by the naked eye, but require the aid of a lens. In the open air there are many plants in blossom. Among these may be noticed, *Argemone Mexicana* with its leaves variegated like the milk thistle, *Datura tatula*, *Aconitum Napellus*, *A. Stœrckeanum*, *A. Lycoctonum*, *Actæa racemosa*, *Lactuca virosa*, lavender, hyssop, borage, white horehound, fennel, feverfew, squirting cucumber, and many others. Several American medicinal plants may also be seen in blossom now. Among these are, *Leptandra virginica*, *Apocynum androsœmifolium* and *A. cannabinum*, *Asclepias Syriaca*, *Liatris spicata*, *Gillenia trifoliata*, and *Eupatorium purpureum*.

Several rare British plants may be seen in blossom in the herbaceous ground by those who have not the opportunity of observing them in the wild state. Of these may be mentioned, *Echium violaceum*, *Scirpus Holoschœnus*, *Teucrium Chamœdrys*, *Leonurus Cardiaca*, *Verbascum Lychnitis*, and *Allium sphærocephalum*.

The root of *Echium violaceum* is of a dark red colour, like that of alkanet, and like it stains paper on which it is placed. The flowers of *Asclepias Syriaca* present an example of the pollinium or pollen mass. The flowers have a powerful honey-like odour and are much visited by the bee, which dips its proboscis into the little cup-shaped process of the petals. In doing this its legs are of necessity placed between the petals, where the pollinia are situated, and the latter becoming easily detached adhere to the legs of the bee, many of which are observable having a pollinium attached, usually to the right hind leg, or rather foot, if one may apply such a word to the extremity of a bee's leg, and by this means the pollinia are conveyed to other flowers. Recently this plant has been highly extolled in the *Louisville Medical News* as a remedy in dropsy. It is also reputed to possess alterative and expectorant properties. A full account of it may be found in Wood and Bache's 'American Dispensatory.'

Some interesting researches upon the influence of atmospheric electricity on the nutrition of plants have recently been instituted by M. Grandeau. Taking two plants of the same species, such as tobacco, maize, and wheat, and placing them under the same conditions as to soil, isolation, air, etc., he withdrew one of each from the action of atmospheric electricity by means of a Faraday's cage. Thus treated it was found that the plants so withdrawn from the influence of electricity elaborated 50 to 60 per cent. less of living matter than the others in the same time, and that they yielded more ash, but less water.

A theory as to the cause of the rapid ascent of sap in the tissues of plants has recently been brought forward by M. J. Boehm. It is based upon the elasticity of the cells. He states that "when the surface cells of a plant have lost a portion of their water through evaporation they are somewhat compressed by the air-pressure. Like elastic bladders, however, they tend to take their original form, which is only possible by their taking in air or water from without. Since, however, moist membranes are little penetrable by air, the outer cells draw from the cells which are further in a portion of their liquid contents. These again borrow from their neighbours further down, which contain more water, and so on, either to the extreme roots cells, or to those parts of the stem which are supplied with water from below through root-pressure."

In *Science Gossip* botanical readers will find every month some useful remarks. Under the heading of "Botanical Notes" attention is called to the various forms which certain species assume, and which have by some authors been distinguished as varieties, or even as species. This month those forms of the epilobium and drosera which may now be found in blossom are described. Those who are about to botanize during the coming vacation will find some excellent directions for preserving specimens of plants in the same number of that magazine.

In the *Hanover Agricultural Gazette* a new remedy for the prevention of the ravages of caterpillars is recorded, and as it concerns a medicinal plant deserves a notice here. A steward of an estate in Hanover observed that one bed of cabbages was left untouched by caterpillars, whilst others were infested by them, and found that the healthy bed had a quantity of dill growing on it. As this plant is not large, and will grow on any soil, it is recommended to grow it with other crops. The influence of the odours of strong-smelling plants upon insects is a subject that has not yet received the attention it merits.

According to *New Remedies* the revival of rose culture on the southern slopes of the Balkans has already assumed a promising aspect. The harvest this year is expected to be but little inferior to those of former years, while the more liberal protection which is expected from the new Government will probably add to the success of the enterprise.

Those of our readers who have books to spare may turn some of them to good account. Dr. Dawson U. Turner, of 13, Salisbury Street, Strand, London, W.C., is making an appeal in *Nature*, and elsewhere, on behalf of the patients in hospitals, for books to aid in keeping the patients in a cheerful mood, and distracting their attention from their sufferings and troubles. Those which Dr. Turner would be glad to receive for such a purpose are the cheap one-volume editions of our standard novelists, Scott, Dickens, Marryat, etc., and the lighter sort of serials, such as *Good Words*, *Leisure Hour*, *Cassell's Magazine*, etc., as well as picture and scrap books, especially if the pictures are pasted on linen. Those who have seen the pleasure that even the presence of flowers gives in the hospital wards will feel that this is a movement which should commend itself to all.

A new form of camera lucida, which will be a boon to microscopists, has been invented by Dr. J. G. Hoffman, of Rue Bertrand, Paris, and is figured in last week's issue of *Nature*. It possesses the advantage of permitting the point of the pencil to be seen alongside of the image to be drawn on the paper.

Henceforth there will be a distinction between corks and corks. According to a recent issue of the *Globe*, a doctor in San Francisco has invented a means of rendering wood so soft and elastic as to be available for all the purposes to which the bark of *Quercus suber* is now applied. The process by which this is done is at present kept a secret. The new cork, which must be distinguished as "wood-cork," is elastic, and yields only when pressed laterally, but resists pressure applied in the opposite direction. Corks thus made are said to be superior to "cork corks" in not being acted upon by ammonia and other liquids which affect the corks in ordinary use. Wooden corks also cost only half as much. A factory has already been established at Sonoma, and wooden corks may soon be expected to become an article of commerce. From the description above given it would appear probable that wooden corks are less liable to break transversely than ordinary corks.

According to the *Pharmaceutische Centralhalle*, a new method of preserving the aroma of hops has recently been devised. The ethereal oil is separated and sold to the purchaser with a corresponding quantity of the deodorized hops.

In a Portuguese paper, *Boletin del Collegio de Farmaceuticos de Barcelona*, aromatic spirit of ammonia is recommended for the purpose of making tincture of hops, since neither water nor alcohol completely extracts the active principles of that drug.

Arseniate of gold appears to be attracting some attention as a remedy for diseases, such as lupus and others, which are dependent on scrofula, this remedy increasing the appetite, exciting peristaltic contractions of the intestines and promoting absorption.

In the *Medical and Surgical Reporter* Mr. J. W. Bard advises the smoking of a mixture of two parts of powdered cubebs to one part of chamomile flowers in post-nasal catarrh, the smoke to be expelled through the nostrils.

A new antiseptic, xanthate of potassium, has recently been introduced into notice. It is prepared by mixing disulphide of carbon with an alcoholic solution of potash and recrystallizing the resulting salt from water. The crystals are colourless but the solution colours the skin yellow. Urine, blood, grape juice, and other easily decomposable substances have been found to remain unaltered after some months when a small proportion of this salt has been added to them.

Mr. W. J. H. Wood, of Boston, writing in the same journal recommends very strongly the trial of pure salicylic acid used as snuff in hay fever. About 10 to 15 grains are snuffed up the nostrils daily.

Lecoq de Boisbaudran and E. Jungfleisch have obtained* gallium in the form of octahedral crystals by introducing into the fused metal a piece of platinum wire to the end of which a fragment of solid gallium is attached. The metal preserves its lustre in the air and in water when free from air, but in aerated water it tarnishes. Chlorine gas attacks gallium in the cold, forming a crystalline and nearly colourless product which is very fusible and easily volatile. Bromine and iodine also attack gallium, although less energetically, and in the case of iodine a gentle heat is even required.

A short time ago, Emmerson Reynolds determined the specific heat of glucinum, and from this he calculated that the atomic weight of the metal is 9·4. L. F. Nilson and O. Pettersson have repeated* these observations, but with different results: they find the specific heat of the metal to be 0·4079 at 100°C., so that the atomic weight becomes 13·8 and not 9·2 as usually accepted. Consequently the oxide has the formula G_2O_3 and glucinum therefore belongs to the aluminum group. L. Meyer, however, raises some objections† to the conclusions of Nilson and Pettersson, which are sufficiently strong to render further observations desirable and even essential to clear up all doubts.

C. Tanret has obtained a hydrate of ordinary (ethylic) ether of the formula $C_4H_{10}O2H_2O$, by allowing ether to evaporate from a surface of bibulous paper. The product is of the nature of a cryohydrate, the solid having the temperature 3·5°, which is the constant minimum observed in mixtures of ether and ice.

Some recent researches‡ of E. Paterno and P. Spica on some new hydrocarbons are of peculiar interest. Not long ago it was shown that zeorin, $C_{13}H_{22}O$, and betulin, $C_{12}H_{20}O$, both appeared to be homologues of ordinary camphor, $C_{10}H_{16}O$, and by the recearches in question this seems to be established. When betulin is distilled with phosphoric anhydride an oil is obtained which boils at 245-250°, and which contains 89·23 per cent. C and 10·74 per cent. H. These figures agree better with the formula $C_{11}H_{16}$ than with what would have been expected to be the formula of the obtained body, namely $C_{12}H_{18}$. Thus $C_{12}H_{20}O=C_{12}H_{18}+H_2O$. The authors had not sufficient zeorin to place it under a similar examination, but it is to be hoped that they will find an opportunity of prosecuting still further a research which must evidently terminate in extremely useful results.

C. Liebermann§ states that the blue or green colour of birds' eggs is due to a bile pigment, which resembles biliverdin in some characters. The shells often contain a second colouring matter, which exhibits a characteristic absorption spectrum. In relation to this last mentioned matter it may be remembered that at the soirée of the Chemical Society in May last, Dr. Thudichum demonstrated the absorption spectrum of the colouring matter obtained from egg-shells by means of hydrochloric acid. The bands are identical with those presented by cruentin from blood, and hence Thudichum calls the new colouring matter ovocruentin. Who discovered this colouring matter?

N. Lubavin‖ finds that nuclein (from milk) is not a phosphate of casein, but some other compound of phosphoric acid, forming a lead compound in which the relation of the lead to the phosphorus is Pb_3 to P_2!! N. Lubavin has yet to learn that nuclein is not a compound at all, but only a dirty mixture of an albuminoid with some lecithine (which contains phosphorus); it is this latter substance which forms the lead compound, and if the author alluded to, would consult the reference¶ given below, he would find something to his advantage.

¶ "Essay on Physiology and its Chemistry."—*Quarterly Journal of Science*, January, 1877.

Schützenberger has published* the results obtained by decomposing 100 grms. of purified wool by a strong solution of caustic baryta at 170° C. They are as follows:—

Nitrogen (as Ammonia)	5·25
Carbolic Acid	4·27
Oxalic Acid	5·72
Acetic Acid	3·20
Pyrrol and other volatile products	1 to 1·5

The fixed residue contained leucine, tyrosine, etc., in such proportions as to reveal an elementary composition as here represented—

C = 47·85
H = 7·69
N = 12·63
O = 31·83

These results support that which was previously known, namely that wool is an albuminoid of constitution approximating to that of fibroin and seracin from silk, but they teach nothing of the absolute differences which must exist between the many members of this group of principles.

In a recent publication,† styled, 'Researches on the Peptons,' by A. Henniger, which, from its title, might have been expected to contribute towards the solution of an important problem, the author announces his conclusion that the peptons result from the fixation of water upon the albuminoids!! Surely it was not necessary for A. Henniger to publish a conviction which all who know anything about the subject have had for many years.

Again Em. Schöne has estimated‡ the peroxide of hydrogen present in the atmosphere, and G. Salomon§ finds it is possible to produce hypoxanthine and perhaps even xanthine from blood fibrin by the action of the pancreatic ferment! Thus it is shown that fibrin is an albuminoid and the ferment fixes water upon it. Who is not stirred to praise and emulation by such accomplishments?

L. Barth has studied‖ some of the derivatives of thymol. By melting the substance with potash four acids are obtained, namely, oxybenzoic and oxyterephthalic acids, a third acid of the formula $C_{10}H_{12}O_3$ (termed by Barth, thymoloxycuminic acid), and a fourth—thymolic acid—of the composition $C_{10}H_{10}O_5$. Thymolic acid dissolves easily in water and gives an insoluble lead salt. It is dibasic in character and with ferric chloride yields an intense red coloration.

Dr. Goldschmidt¶ has examined gum ammoniacum (from Morocco) and finds that if it be heated in contact with potash it yields resorcin and a small quantity of some acid of the empiric composition represented by the formula $C_{10}H_{10}O_6$, and isomeric with hemipinic acid.

Dr. Dormon has made a number of observations in Cochin China upon dysentery, from which he concludes that this disease is due to certain animalcules which get into the intestinal canal by means of polluted waters. By purifying the water with alum or by boiling before consumption, the disease is obviated. The natives of Annam have employed the alum process from time immemorial, and for six years the French troops in Cochin China have been entirely preserved against the scourge by the same treatment.

Some seven years ago Feltz and Coze observed an organism in the blood in cases of typhoid fever, and just lately Feltz states to have succeeded in cultivating typhoid blood. It is not shown, however, that this cultivated blood will produce typhoid fever in healthy persons, and, even supposing that it does, it has yet to be proved that the initial changes are due to the observed organisms, and it has yet to be demonstrated in what precise way such initial changes are induced and by what gradations they lead to the disease in question.

A. E. Menke has called attention to the liability of canned foods to contamination with tin. Thus he relates that on opening a tin can of pine-apple he found the tin corroded where the soldering had been effected, and consquently he was induced to analyse the contents. The tin of pine-apple weighed 1¾ lbs. and contained 0·1513 grm. of tin in a dissolved state; one of lobster contained 0·010 grm. and one of apples 0·0067 grm.

Messrs. Swan and Proctor have secured letters patent for the treatment of opium in such a manner that the narcotine and other objectionable matters are removed by solvents which do not affect meconate of morphia, and there is thus obtained a product which for medicinal purposes is said to be of an uniform character and exempt from certain deleterious effects. The details of the process will be given when the product is referred to in the report on the Paris exhibition.

Dr. A. Janisch, clinical assistant to von Hebra, records in a paper in the *Wiener Medizinische Blätter*, No. 7, 1878, some investigations recently carried out by him under Hebra's direction in respect to the use of chrysophanic acid. He confirms the researches of Mr. Balmanno Squire, of London, as to the efficacy of an ointment of the acid in psoriasis, and in some other diseases of the skin, and states that he prefers an ointment of 20 per cent. to one of 5 per cent. of the acid. Dr. Janisch further goes on to point out that chrysophanic acid is said to be identical with bioxymethylanthrachinon, a derivative of methylanthracene ($C_{15}H_{12}$) by the substitution of two atoms of oxygen for two of hydrogen, and by the substitution of two atoms of hydroxyl (HO) for two other atoms of hydrogen, so that the rational chemical formula of bioxymethylanthrachinon, or chrysophanic acid, stands thus:—

$$C_{14}H_5\begin{cases}CH_3\\O_2\\(OH)_2\end{cases}$$

The colouring matter of the madder-root (alizarin) is bioxyanthrachinon, differing from chrysophanic acid in chemical composition only by a methyl-equivalent (CH_3). Dr. Janisch therefore announces his intention to test alizarin clinically in skin disease on the strength of its chemical analogy to chrysophanic acid. However, in this research he has just been forestalled, for in the *Edinburgh Medical Journal* for July, 1878, Dr. James Adams, of Glasgow, states that being similarly struck by the chemical analogy of the two substances he has already tried an ointment of alizarin in psoriasis in two cases with satisfactory results.

Last week a large travelling tank containing commercial creosote gave way at the Hereford railway station, and the liquid, finding its way to the river Wye, quickly spread over the surface and rendered the water undrinkable. The effect of the creosote

on the fish in the river was very marked, and large numbers that had been killed or rendered insensible were taken.

A remarkable accident is reported from Malta, where it is said that forty-eight soldiers have been poisoned by swallowing carbolic acid that had been served out to them in mistake for lime juice. The subject was mentioned in the House of Commons on Monday, when Colonel Stanley admitted that there was some foundation for the report, and promised that a searching inquiry should be made. Such an accident would appear most improbable were it not for the remarkable fact that numerous cases have been recorded in which carbolic acid has been drunk in mistake for some beverage.

The first prescription calling for remark this month is that of No. 122. If the citrate of iron and quinine, citrate of lithia and iodide of potassium be separately dissolved and the solution of iodide of potassium first added to the solution of citrate of iron and quinine, and afterwards the solution of citrate of lithia, an opaque mixture will be formed, from which there will be subsequently a very gradual separation of quinine. If the ingredients be mixed in an order different to that just mentioned there will result an immediate separation of quinine as a gummy substance which adheres to the sides of the bottle and cannot afterwards be suspended, but in the former case a little mucilage of gum arabic will prevent the finely divided quinine agglomerating into gummy masses and will keep it fairly suspended.

In No. 123 the question is asked, Does the oil of bay leaf from the sweet bay (*Laurus nobilis*) contain traces of hydrocyanic acid? The colourless volatile oil is contained in the globular cells of this leaf, but there is no mention of hydrocyanic acid being one of its constituents. Probably some confusion exists with regard to the products of this leaf and those of the leaf of the cherry-laurel. In the *Pharmaceutical Journal* (series iii., vol. v., No. 248, p. 761) will be found some remarks by Tilden and Umney on the quantity of hydrocyanic acid as a product of the leaves of the cherry-laurel. Husemann, who gives several analyses of the ethereal oil of the leaf of *Laurus nobilis*, makes no mention of the presence of hydrocyanic acid. It may, therefore, safely be concluded that the oil of bay-leaf from the sweet bay (*Laurus nobilis*) contains no traces of hydrocyanic acid either as an educt or a product.

The next prescription is that of No. 124, in which pills are ordered containing each one-quarter of a grain of phosphorus; the dose of phosphorus is unusually large, and has attracted the dispenser's attention. Very possibly it is intended for one-fortieth of a grain. There would be more danger in administering an excessive dose of phosphorus in a pill than dissolved in an oil. It has on several previous occasions been observed that when the phosphorus is ordered in pills bisulphide of carbon may be used as a solvent, and to the phosphorus thus dissolved oil of theobroma should be added in the proportion of one grain to each pill to prevent oxidation, so as to retain the phosphorus in a free state. Phosphorus could not be retained in that condition if combined with an extract such as hyoscyamus; it would rapidly oxidize and would no longer be that which it is evident the prescriber intended should be given when he ordered a definite quantity of phosphor. pur. in each pill. This prescription should not be dispensed without the writer's attention being previously drawn to the unusually large dose of phosphorus, if intended to be dispensed as written.

The dispenser must in the absence of the writer, and when he cannot be referred to, use a certain amount of discretion in dispensing such a prescription as that of No. 125, where ingredients with their quantities are given without at the same time stating the number of pills into which it was intended that the mass should be divided. Taking the dose of each drug into consideration, together with the quantity required to make a fair sized pill, it may be assumed that the writer intended the mass to be divided into twelve pills; each pill would then contain half a grain of each of the first three ingredients, and two and a half grains of the compound rhubarb pill, making together a four-grain pill. Of course, as has been suggested on previous occasions, the writer should, where possible, be referred to, but in probably the majority of instances this is not practicable and the dispenser must use his own judgment, guided by the amount of practical experience he may previously have obtained, always taking care to keep within the maximum dose of every ingredient, and if the result should prove that he has erred in judgment, he will have the satisfaction of knowing that he has not sacrificed the life of the patient.

No. 126 is a prescription for pessaries, containing ergotine with tannic acid. However carefully and minutely the directions may be given for pessaries such as these, success will very much depend on the intelligence which the manipulator brings to bear on the subject. A practised hand at pessaries will suit the temperature to the composition, and obtain quickly and certainly a satisfactory result, whilst another will fail successively with the same ingredients for want of the necessary practical knowledge. The detailed instructions so kindly forwarded by Mr. Branson are all that could be desired, and if intelligently followed will result in success; oil of theobroma is ordered and is quite unobjectionable, there is therefore no occasion for the admixture or substitution of wax and lard in the preparation of these pessaries.

In No. 128 cod liver oil is required to be emulsified. The inquirer would do well to consult a paper on "Emulsions," by Gregory, published in the *Pharmaceutical Journal* for April 14, 1877, p. 835. He sums up his results by stating that mucilage should be abandoned in favour of powdered gum acacia; two drachms of gum to each ounce of oil. The gum should be rubbed with the oil, and the water subsequently added. The quantity of essential oil of almonds requisite to flavour the emulsion is a matter of taste, and can easily be determined.

The two recipes under No. 129 must be required in veterinary practice. It is usual to make such substances into a mass with soap.

In No. 130 a yellow colour is observed to occur in an ointment made with liquor plumbi diacet. and unguentum cetacei. This ointment has long been known to turn yellow. Gmelin says that this salt (subacetate of lead) produces red and yellow colours with many oils, both fixed and volatile. The change is most probably due to a separation of the protoxide of lead from the subacetate.

A CONTRIBUTION TO OUR KNOWLEDGE OF THE ALKALOIDS OF ERGOT.*

BY T. BLUMBERG.

(*Continued from page* 25.)

I once more prepared some ecboline and noted that in this and all the subsequent experiments the filtrate from the first mercuric chloride precipitate, after concentration, yielded a further precipitate with mercuric chloride. The first precipitate I shall distinguish as *a*, the second as *b*. A corresponded with ecboline, B with ergotine.

The liquid obtained by the decomposition of *a* I evaporated at a moderate temperature to a small volume, added lead hydrate, and heated the mixture until the water was perfectly evaporated. The residue was boiled with 80 per cent. alcohol, filtered, and the alcohol distilled off. This residue formed a brown amorphous mass, which was quite broken up by crystals. This was dissolved in water, and the solution decolorized with animal charcoal and evaporated, leaving a residue almost colourless, having a faintly burning taste and containing no trimethylamine, but probably lead chloride. It was treated with absolute alcohol, which took up the varnish-like portion and left the crystals undissolved. The crystals contained nothing alkaloidal, the alkaloid being represented by the varnish-like substance.

A portion of the alkaloid was retained by the animal black; this was recovered by boiling with 80 per cent. alcohol. It was insoluble in absolute alcohol.

When heated upon platinum the crystals swelled, carbonized, and left an ash containing potash, lime and lead. Heated with sugar and sodium the crystals yielded no cyanogen; the presence of an amide compound was therefore excluded. The carbonizing of the crystals showed the presence of an organic acid, which I believe to have been lactic acid, as from the acidified solution of the crystals a body having an acid reaction could be separated by shaking with ether, which dissolved zinc oxide in the presence of water; the solution yielded crystals upon evaporation.

As the greater part of the hydrochloric acid could be separated by treatment with lead, I introduced this method in subsequent preparations of the alkaloid. To recapitulate briefly, the hydrochloric acid compound of the alkaloid was treated while hot with lead hydrate, the whole boiled with 80 per cent. alcohol, this distilled off, and the residue extracted with absolute alcohol. This dissolved a portion of the alkaloid (distinguished as *a* I), and another part remained undissolved (distinguished as *a* II). In my later experiments I have not observed the presence of crystals in the portion soluble in 80 per cent. alcohol (*a* II), although it contains plenty of lead, which is also present in *a* I, but in smaller quantity.

With the precipitate *b*, which should contain the ergotine, I proceeded similarly. Here also a portion of the alkaloid was taken up by absolute alcohol, whilst another portion dissolved only in 80 per cent. alcohol. The former is distinguished as *b* I, the latter as *b* II.

From *a* I I removed the lead still present by sulphuretted hydrogen, filtered, and after driving off the sulphuretted hydrogen by heat decolorized the alkaloidal solution with animal charcoal. In the decolorized liquor some hydrochloric acid could still be detected. This was separated by silver phosphate, the phosphoric acid combined with lime, the caustic lime separated by carbonic acid, and after filtration the solution evaporated.

The dry residue I dissolved in dilute alcohol, filtered, and evaporated the alcohol until a thick syrupy liquid remained, and this was further dried over sulphuric acid. The portions *a* II, *b* I, and *b* II were submitted to exactly similar treatment.

The preparations so obtained were of a light yellow colour, and formed a varnish-like mass. Heated with potash solution they did not give off ammonia; they had an alkaline reaction and were insoluble in ether and chloroform. *a* I and *b* I were partially soluble in mixtures of equal volumes of ether and absolute alcohol and of chloroform and alcohol. Iodide of potassium and bismuth, phosphomolybdic acid, mercuric chloride, tannic acid and potassium iodide all gave precipitates. According to Wenzell ecboline is distinguished from ergotine by its behaviour with platinum chloride, potassium cyanide and tannic acid.

a I and *a* II (ecboline) in dilute solution gave with platinum chloride no precipitate or turbidity. A precipitate was first produced upon the addition of ether-alcohol. In concentrated solutions platinum chloride produced gradually a slight precipitate which was increased by ether-alcohol. Potassium cyanide and ferrocyanide produced no precipitate; but tannic acid did give one.

b I and *b* II (ergotine) in dilute solution gave no precipitate with platinum chloride, one being first formed upon the addition of ether-alcohol. In concentrated solutions a slight precipitate was formed. Potassium cyanide and ferrocyanide gave no precipitate.

According to Wenzell ergotine is precipitated by tannic acid only from concentrated solutions, but very dilute solutions of *b* I and *b* II gave precipitates with this reagent. Also Manassewitsch stated that aqueous solution of ecboline gives no precipitate with platinum chloride, while Hermann says that the platinum chloride precipitate is only gradually formed.

Upon drying *a* I there were formed in the varnish fine spicular crystals, which contained potash and lime. In order to separate the alkaloid from this admixture I exhausted it with a mixture of equal volumes of ether and absolute alcohol, which dissolved a portion of the alkaloid. The solution was concentrated and further evaporated over sulphuric acid. At first the residue was like a varnish, but after a few days some crystals were formed in it. The portion undissolved by ether-alcohol I treated with absolute alcohol, which left behind a portion of the inorganic admixture. The evaporation residue showed no crystallization, but formed a homogeneous varnish. When this was again treated with ether-alcohol a further small portion of alkaloid was dissolved. It was evident therefore that the portion soluble in ether-alcohol, as well as that soluble in absolute alcohol, contained a considerable quantity of inorganic matter. I hoped that this would be left behind upon solution of the alkaloid in equal volumes of chloroform and alcohol. The mixture took up one portion of the alkaloid and left another undissolved. The soluble portion upon combustion left a considerable quantity of ash, containing lime and potash. The inorganic matter could not be separated by repeated treatment with chloroform alcohol. Neither could the alkaloid be obtained free from ash by converting it into sulphate, which is difficultly soluble in a mixture of ether and alcohol. I was therefore compelled to give up an elementary analysis, as the alkaloid was strongly contaminated with potassium and calcium lactates. I operated similarly upon *b* I, which was obtained from precipitate *b*, and found it to behave like *a* I.

I again prepared Wenzell's alkaloids from the sclerotic acid filtrate. The liquid purified with sugar of lead and afterwards freed from lead with sulphuretted hydrogen was evaporated to a small volume, filtered, made alkaline with sodium carbonate and mercuric chloride added. The addition of sodium carbonate was made to try whether it was more completely precipitated from an alkaline than from an acid solution. After standing twenty-four hours the resulting precipitate was filtered off. This is distinguished as *c*. The filtrate was freed from mercury with sulphuretted hydrogen, further concentrated, and again treated with mercuric chloride. This produced another precipitate which I distinguish as *d*. The precipitate *c* would correspond with ecboline and precipitate *d* with ergotine.

* Inaugural Dissertation presented by the author upon attaining the grade of Magister of Pharmacy at the Imperial University at Dorpat.

The alkaloidal solution obtained by the decomposition of precipitate *c* with sulphuretted hydrogen was shaken with ether in order to remove as much as possible the organic acid which had so much impeded the purification of the alkaloid in my previous experiments. The liquid was decolorized with animal charcoal and treated with silver phosphate to separate the hydrochloric acid. After standing several hours the silver chloride and the undecomposed silver phosphate were filtered off, and the liquor tested for hydrochloric acid with silver nitrate; there was formed a yellow precipitate of silver phosphate that was not completely soluble in nitric acid. The liquid consequently still contained a small quantity of hydrochloric acid. Moreover it contained some dissolved silver; this was removed with sulphuretted hydrogen. After the sulphuretted hydrogen had been driven off, the filtrate from the silver sulphide was heated with milk of lime, in order to fix the phosphoric acid, and to remove trimethylamine. The calcium phosphate was removed by filtration, carbonic acid passed through the filtrate, and after again filtering the alkaloidal solution was evaporated. The residue was dissolved in water and the solution once more heated with silver phosphate. Silver was again dissolved; this I separated with sulphuretted hydrogen and repeated the treatment with milk of lime, etc.

The alkaloid thus obtained gave with silver nitrate a perfectly clear solution, but upon adding some nitric acid a precipitate formed. This compelled the conclusion that either the alkaloid was contaminated with some substance that dissolved silver chloride, or that it possessed that property itself. I therefore tested the behaviour of *a* I, *a* II, *b* I, and *b* II with silver nitrate; they all gave precipitates that were soluble in nitric acid.

When heated on platinum the alkaloid puffed up considerably and gave off a readily inflammable vapour. One part was soluble in absolute alcohol (*c* I), and another only in 80 per cent. alcohol (*c* II).

I dissolved *c* I in 80 per cent. alcohol and added dilute sulphuric acid to the solution until it had a faintly acid reaction.* After standing the resulting precipitate of inorganic matter was filtered off, the sulphuric acid separated from the filtrate with caustic baryta, the barium sulphate removed, carbonic acid passed through the filtrate and the alcohol evaporated. *c* II was treated in the same way, but neither could be obtained free from ash, amongst which baryta could be detected.

c I contained with 11·96 per cent. of ash and 2·04 per cent. of chlorine, carbon = 43·77 per cent., hydrogen = 7·13 per cent., and nitrogen = 16·51 per cent.

c II contained with 5·91 per cent. of ash and 2·23 per cent. of chlorine, carbon = 41·31 per cent., hydrogen = 6·63 per cent., and nitrogen = 21·46 per cent.

Both *c* I and *c* II gave precipitates with platinum chloride also in dilute solution. Potassium cyanide and ferrocyanide gave no precipitate.

The mercuric chloride precipitate *d* was treated in the same way as *c*. The alkaloid obtained from it did not dissolve silver chloride, and could there be freed from all hydrochloric acid. It was soluble only in 80 per cent. alcohol. Silver nitrate gave with it a precipitate soluble in nitric acid. Platinum chloride produced a precipitate in a concentrated solution, but in a dilute solution a precipitate was first formed upon the addition of ether and alcohol. Potassium cyanide and ferrocyanide produced no precipitate.

I also made an elementary analysis of this product and obtained the following figures:—With 8·8 per cent. of ash the substance contained 45·77 per cent. of carbon, and 7·406 per cent. of hydrogen; of nitrogen I found in one experiment 12·28 per cent., in another 12·61 per cent. The results may be thus compared:—

From Precipitate *c*.—Ecboline.

	c I.	*c* II.
Ash	11·96 per cent.	5·91 per cent.
Chlorine	2·04 „	2·23 „
Carbon	43·77 „	41·31 „
Hydrogen	7·13 „	6·63 „
Nitrogen	16·51 „	21·46 „

From Precipitate *d*.—Ergotine. Free from Chlorine.

Ash	8·8 per cent.
Carbon	45·77 „
Hydrogen	7·406 „
Nitrogen	12·445 „

From these figures it appears that the amounts of carbon and hydrogen in ecboline and in ergotine fairly correspond; they differ chiefly in the amount of nitrogen.

The fact that mercuric chloride produces in the concentrated liquid a second precipitate shows that the chloride of ecboline and mercury is not very insoluble. In order therefore to ascertain whether the second precipitation left still some alkaloid in solution, I freed the liquid from mercury with sulphuretted hydrogen, drove this off by heat, and tested with iodide of potassium and bismuth; this produced only a very slight turbidity. Phosphomolybdic acid caused a precipitate, which was accounted for by the fact that the liquor when heated with excess of potash solution in a steam-bath gave off a distinct odour of ammonia; the precipitate was therefore due to the presence of ammonia salts.

From the foregoing it appears that from a concentrated extract of ergot the alkaloid can be precipitated nearly entirely by mercuric chloride. But on account of its solubility in water and its slight tendency to pass into ether and chloroform when shaken with them, it cannot be entirely freed from inorganic matter.

It may be that the amount of ash, when the alkaloid is contaminated with lactic acid, may be partially due to the salts of that acid. But that the alkaloid, after the removal of the lactic acid by shaking with ether, should always contains so much inorganic admixture, I can only explain by the supposition that it possesses the power of forming compounds with inorganic bases. It also appears to me probable that the alkaline reaction shown by the preparations obtained might be partially due to the presence of inorganic bases.

The alkaloid from the first mercuric chloride precipitate (ecboline) behaved towards tannic acid, potassium cyanide and sublimate similarly to that from the second. When a part of the hydrochloric acid was removed by lead, it gave in dilute solution no precipitate with platinum chloride, corresponding in this with the alkaloid (ergotine) obtained from the second mercuric chloride precipitate. Further it did not dissolve silver chloride.

On the other hand the alkaloid from precipitate *c* behaved differently. This dissolved silver chloride and gave even in dilute solution a precipitate with platinic chloride, whilst the alkaloid from precipitate *d* did not possess these properties. It is quite possible that this may be due to the presence of some foreign substance, which is decomposed when lead hydrate is used. Probably the difference in the amount of nitrogen in the alkaloid from the first sublimate and second precipitate is also to be attributed to this admixture.

As previously mentioned, Wenzell precipitated the ecboline with mercuric chloride, but has said that ergotine is not precipitated by that reagent from an acid solution. But this is contradictory to what he had stated previously, that he had precipitated the ergotine from acid solution with sublimate. My experiments show that the "ergotine" also can be obtained with mercuric chloride.

I believe therefore that I am warranted in saying that "*ecboline*" *and* "*ergotine*" *represent one and the same alkaloid*. The fact that both Wenzell and Ganser obtained a considerably smaller proportion of "ergotine" than of "ecboline" I think to be confirmatory of this opinion. Ganser obtained from 25·0 grams of ergot 0·4 gram of

* I was obliged to use 80 per cent. alcohol because the sulphate of the alkaloid is very difficultly soluble in absolute alcohol. If dilute sulphuric or phosphoric acid be added to a solution of the alkaloid in absolute alcohol, it is partially thrown down in flocks.

ecboline to 0·1 gram of ergotine. Considering the not very great insolubility of the mercuric chloride precipitate it would appear that the greater part of the alkaloid was precipitated by mercuric chloride and called by him "ecboline"; the remainder was precipitated by phosphomolybdic acid, and called "ergotine."

The statement of Ganser, that the hydrochlorate of ergotine crystallizes in long needles I cannot confirm. If he met with crystals they consisted of lactic salt.

I have also worked according to Wenzell's 1872 method.* The first time I extracted 100 grams of ergot with 75 per cent., the second time with 60 per cent. alcohol. According to Wenzell the first separation (ecboline), which is formed upon the addition of ether to solution of the alkaloid in absolute alcohol, is distinguished from the second by the latter giving a precipitate with tannic acid and phosphomolybdic acid, but not with mercuric chloride. I have found that both separations give a precipitate with mercuric chloride. A small quantity of alkaloidal substance remains after the second addition of ether, dissolved in the ether-alcohol, and this also is precipitable by mercuric chloride. In operating according to this method only the portion soluble in absolute alcohol is obtained, the portion soluble only in 80 per cent. alcohol not being extracted.

Further the portion of the alkaloid from the first mercuric chloride precipitate (ecboline) which is soluble in absolute alcohol is partially soluble in a mixture of equal volumes of ether and alcohol. That which remained undissolved in the first treatments with ether-alcohol would correspond with the first separation (ecboline); the portion going into solution would correspond with the second separation (ergotine).

BERBERIS AQUIFOLIUM.†

Berberis Aquifolium (Pursh). Leaflets 1–6 pairs, not approximated, coriaceous, ovate-lanceolate, or elliptical oblong, oblique and slightly cordate at the base, margin repand with thorny or spinulose cuspidate teeth; racemes short, nearly erect, clustered; filaments 2-toothed; berries dark purple. Leaflets generally 2—3 pairs, very coriaceous, and in this locality more or less evergreen. Flowers yellow. This is an under shrub, 8 to 18 inches, rarely, but sometimes, 3 feet high, branching, erect, but often procumbent. The leaflets 1 inch to 2½ inches long, reticulated, often obscurely, on both sides. Common to the middle elevations of the northern portions of the Hills, to the Big Horn and Wolf ranges, the middle elevations of Colorado, the head waters of the Arkansas, and in the Ratoon ranges.

The *B. pinnata* and *B. repens* seem to be but varieties of this; the characters are certainly not distinct, as far as my observation extends. This plant is generally found abundantly upon exposures to the South and East, in rich vegetable mould which covers these hill-sides. It is also found upon almost barren rocky places, especially the feldspathic granite and porphyritic formations; but, of course, less robust, the leaflets very seldom having more than two pairs, and approaching nearer the form of the *B. repens*; the berries smaller, more acid, and less pleasant in flavour. It flowers in May and ripens its fruit in August and September. The fruit is acidulous and in flavour reminding one of the lime, dark purple in colour, and covered with a bluish bloom. Root yellow.

This plant is most absurdly termed "Oregon grape;" it is difficult to conceive why it was thus named.

The root is the part which is used as a medicine; this is 1 or 2 feet or more in length, and about ¼ inch in diameter, more or less woody, and in colour a bright yellow, often orange yellow; the cortical portion thin, of the same colour, the epidermis thin and papyraceous, dull greenish or brownish yellow; the upper portion of the root is quite woody, and hardly to be distinguished from the stem above ground.

My attention was first called to this plant some years ago, by the hunters and guides; I then took but little notice of it. With them it was a remedy of great value in the treatment of the low bilious fevers of the mountains, and as a cathartic; they used it, as also did the Indians, in all forms of biliousness; and the berries (fruit) are often employed as a remedy in scurvy, and as a general antiscorbutic, and are also made into a sauce and used as food.

This plant has, in general, the medical properties common to the *Berberidaceæ*, and unites in a marked degree the properties of the *Hydrastis canadensis* with those of the *Podophyllum peltatum*; but, as far as my observations have extended, it has not the valuable and peculiar local effect upon the mucous membranes that we find in *Hydrastis*. Later my attention was again directed to it, from its value in disorders of the stomach, and especially the bowels, arising from improper and insufficient food, and privations, to which we are often subjected in this western mountain country. It is also useful in the complaint known as the "mountain fever," which is a bilious fever, often assuming the typhous forms. It is in such diseases as these that I have seen its best effects, and it is in them and their allied forms that I would suggest its use, and in such cases call the attention of the profession to the properties of the plant. The root yields its medical virtues to water and to dilute alcohol, and without any doubt contains an active principle, which, probably, is an alkaloid, similar to, if not identical with, hydrastina in the *Hydrastis canadensis*, and not a resin as in *Podophyllum*. Its therapeutical effects, however, would seem to indicate that it is combined with "a peculiar resin" which modifies the therapeutic action of hydrastina; but, situated as I am at present, I have not attempted its isolation.

Among the hunters and Indians, it is usually given in the form of a decoction—their only mode. I have also used it in the form of a strong tincture, 4 ounces to the pint of dilute alcohol, administered in accordance with the result desired—from 3 or 5 drops to a teaspoonful. In cases of bilious fever I have found that it has its best effect when given in doses of 20 to 30 drops, no regard being paid to its action on the bowel, unless it should produce catharsis, which is very seldom the case.

I would in this brief manner call the attention of the medical and pharmaceutical professions to this plant, knowing that it possesses valuable properties which will at once commend itself to them. And if, as I suppose, its active principle is hydrastina, there will then have been found a cheap and abundant source of that alkaloid.

TRIAL OF THE PYX.

The trial of the legal weight and fineness of the gold and silver coinage struck at the Royal Mint during the twelve months ended the 30th June last, took place on Wednesday the 10th inst., before a jury summoned for the purpose from the freemen of the Goldsmiths' Company—that company having supplied jurors for Pyx trials since the reign of James I. Until recent years these trials were held at very uncertain intervals, and a great hardship was in consequence put upon successive Masters of the Mint in their not being able to obtain speedier acquittances for the very responsible work performed by them, but by the Act 33 Vict., cap. 10, it was enacted that such trials should, for the future, be conducted annually, and in such manner as Her Majesty by Order in Council should direct. Consequent upon this Her Majesty issued an Order in Council, dated at Windsor, the 28th of June, 1871, setting out the mode of procedure to be observed at a trial of this nature, and giving authority to the Lords Commissioners of the Treasury, whenever they

* *Archiv d. Pharm.* [2], vol. cl., p. 256.

† From *The Druggists' Circular and Chemical Gazette*, July, 1878.

should deem it expedient, to issue their warrant appointing a day for holding a trial of the Pyx. An interesting account of the ceremony has appeared in the *Times*, from which the following extracts are taken :—

"After all the contents of the Pyx have been duly counted, the jurors select a few coins of gold and silver to be tested. Each of such coins must be within legal weight ; these coins have next to be melted into ingots, and such ingots compared with the pure metals of the standard trial plates, so as to ascertain whether they are within the legal remedy as to fineness. The residue of the gold and silver coins in bulk has also to be weighed, and certain coins taken therefrom and assayed separately. All these processes involve the most minute accuracy and most delicate manipulation by the jurors, who are bound to embody their findings on all these tests in their verdict, which will be published in the next issue of the *London Gazette*.

"To make the above more intelligible it may be well to quote the following extracts from the first schedule of the Coinage Act to show the weight and remedy (or allowance to the Deputy Master in working) of some of the coins most common in circulation, and also the standard fineness of gold and silver coins. The Imperial weight in grains only is given :—

Coin.	Weight.	Remedy.
Sovereign ...	123·27447 ...	0·20000
Half-sovereign ...	61·63723 ...	0·1000
Half-crown ...	218·18181 ...	0·90909
Florin	174·54545 ...	0·72727
Shilling	87·27272 ...	0·36363
Sixpence	43·63636 ...	0·18181
Threepence ...	21·81818 ...	0·09090

"The standard fineness for gold coins is 11-12ths fine gold and 1-12th alloy, or millesimal fineness 916·66, the remedy being millesimal fineness 0·002.

"For silver coins the standard fineness is 37-40ths fine silver, and 3-10ths alloy, or millesimal fineness 925, the remedy being millesimal fineness 0·004.

"Turning to the verdict of the jury at the last trial, held on the 4th of July, 1877, we find that of six sovereigns, weighed and assayed separately, the following was the result:—

	Weight.	Millesimal Fineness.
1st Sovereign . .	123·324 .	916·5
2nd „ . .	123·324 .	916·2
3rd „ . .	123·324 .	916·5
4th „ . .	123·324 .	916·7
5th „ . .	123·304 .	916·3
6th „ . .	123·264 .	916·4

"In the examination of the various silver coins selected by the jury the results were equally satisfactory.

"Now, although it will be seen at a glance at the above very remarkable results that this ancient trial affords a most valuable guarantee of the fidelity with which our coinage operations are conducted at the Royal Mint, still, in order to understand thoroughly the more minute points upon which accuracy depends, it is necessary for our readers to refer to the Deputy-Master's eighth annual report for 1877 ; and particularly to the scientific details therein given by Mr. W. Chandler Roberts, F.R.S., the Chemist to the Mint, which afford evidence of the high degree of accuracy attained in the standard of fineness of the metals employed for coinage purposes. It may be mentioned that during the progress of a gold coinage in the Mint, the fineness of the coins is now graphically represented by the system of rectangular co-ordinates. The curve thus produced forms a continuous record of the daily results of the Mint assays, and the exact standard of the coinage, therefore, can at once be seen. Some idea may be formed of the value of this scale when it is stated that during last year no less than 3330 assays were made of the gold, and 3389 of the silver used in the coinage.

"The work of coinage executed at the Mint since the previous trial of the Pyx took place has not been on a very large scale,—£3,246,537 altogether has been struck in gold, out of which 1579 sovereigns and 3053 half-sovereigns were placed in the Pyx. Silver coins to the value of £365,904 were also struck, out of which 626 half-crowns, 559 florins, 276 shillings, 290 sixpences, two fourpences, 98 threepences, two twopences, and six pence (the two latter being struck only as Maundy moneys) were placed in the Pyx for the purposes of this trial.

"Although the machinery in use at the Mint is of a very antiquated character and liable at any moment to be thrown seriously out of working order, fortunately, no mishap similar to that which occurred in 1876, whereby minting operations were suspended for a period of nearly five months, took place during the year just concluded ; but, if very great pressure had been thrown upon the establishment, as might well have been the case in the event of this country having become involved in a great war, or if the more desirable circumstances of a sudden revival of trade had occurred, there would have been great risk of such a serious contingency, with a consequent public inconvenience not easily to be estimated.

"In view of the possibility of such a national misfortune, it is very desirable that the Government should anxiously bear in mind the urgent necessity that so important a department as the Mint should, with the least possible delay, be provided with the newest and best machinery for turning out quickly and efficiently large relays of coinage without any chance of ever coming to a dead lock, such as that which happened in 1876. The question of a site for a new Mint has been commented upon frequently in these columns. We will, therefore now only say that the report of Mr. Bramwell, F.R.S., the eminent engineer, and that of Mr. T. W. Keates, Chemist to the Metropolitan Board of Works, both amply testify to the innocuous and noiseless character of the operations of minting, so that no fear need be entertained by owners of property that injury would be done to any neighbourhood in which the Government may determine to erect a new Mint. In Paris, Madrid, Vienna, Berlin, Brussels, and other cities the Mints are placed in central positions and in the midst of other most important public buildings. The Paris Mint is on the Quai Conti, on the banks of the Seine directly opposite the Louvre ; that at Madrid on the Prado (which is the equivalent of the drive in Hyde Park); that at Vienna on the Prater; and that at Berlin in the centre of the town and close to the Palaces of the Emperor and Crown Prince, without any injurious effects resulting to the property or localities near which they stand.

"Great efforts are being made by the Deputy-Master of the Mint to form a classified museum of coins, with a view to an ultimate improvement in the artistic designs of the dies from which our gold and silver moneys are struck, and this is a matter which might well attract the attention of some of the most eminent artists of our day. One circumstance contributed in no small degree to the excellence of coins of the Renaissance period—namely, that the training of the great painters, many of whom designed coins, commenced in the goldsmith's workshop, where they gained a practical knowledge of metal work as well as delicacy of execution.

"At the hour named by the jurors the Queen's Remembrancer again attended at Goldsmiths' Hall to receive the verdict. In pursuance with the directions of the Order in Council, it was then 'read aloud publicy and in the hearing of the jury,' and was authenticated by the signatures of the jurors and the Queen's Remembrancer. The Treasury warrant for the trial being then attached to the verdict, both were taken possesion of by the Queen's Remembrancer, to be kept of record in his office. The verdict was, as, indeed, it invariably has been, most satisfactory, both for the officers of the Mint and for the public, and, indeed, shows the most accurate Pyx since the new trial plates were made in accordance with the Coinage Act, 1870."

ACTION OF IODIC ACID, "SULPHOMOLYBDIC ACID," AND FERRIC CHLORIDE ON MORPHIA AND VARIOUS OTHER SUBSTANCES.*

In the recent Chantrelle trial at Edinburgh we had for the first time the so-called sulphomolybdic acid test for morphia brought into a prominent position. In a very valuable article on the trial which has since appeared in the *Edinburgh Medical Journal* occurs a passage so important *à propos* of the test for morphia that we venture to reprint it in its entirety. The passage is from the pen of Mr. David Brown, of the firm of Macfarlan and Co. This gentleman has taken much pains in the matter, and, as it seems to us has settled the value of the sulphomolybdic acid test. No doubt this is good when perfectly pure morphia in the solid state can be used, but such can rarely be the case in toxicological inquiries, especially in medico-legal cases. Stas's process is the basis of all now in use for the recovery of vegetable alkaloids from the stomach or other organs; and inasmuch as Mr. Brown, in a foot-note published here below, has kindly informed us that the sulphomolybdic acid test is here inapplicable, we fear it will be found of little value in any such case. This opinion we ventured to express when writing on the subject, but it is always well to have one's own private opinions confirmed by others.

Action of Iodic Acid and Starch on Morphia.—When $\frac{1}{2000}$th of a grain of muriate of morphia dissolved in a drop of water was moistened with a little starch paste, and a particle of iodic acid was added, a blue colour was instantly developed, which soon disappeared.

Action of Iodic Acid on Grape Juice.—The juice was simply squeezed from the fruit, and a few drops mixed with starch paste, a crystal of iodic acid being then added. No colour appeared even after three hours. A quantity of the same juice was evaporated to dryness at the ordinary temperature over sulphuric acid, and the residue likewise gave negative results. The dry alcoholic extract similarly treated gave at once a dirty blue colour, which gradually disappeared. With the ethereal extract prepared by Stas's process no coloration could be obtained.

Action of Iodic Acid on Orange Juice.—Orange juice, with iodic acid and starch, gave a blue colour instantly. The dried juice behaved in the same way. No definite reaction could be obtained with the alcoholic extract, only a faint streak of violet generally appearing, which did not increase. The ethereal extract prepared by Stas's process had no effect on the iodic acid.

Action of Iodic Acid on Saliva.—Iodic acid and starch produce immediately with saliva a bright blue. This reaction takes place equally well with dried saliva. When the saliva has been mixed with acetate of lead, and the lead removed by sulphuretted hydrogen, the iodic acid reaction is much less distinct.

Action of Iodic Acid on Mixture of Orange Juice and Saliva.—A violet colour is immediately produced. This reaction resembles that of morphia, but there is in this case no alteration in the colour, the blue tint not being developed.

Action of "Sulphomolybdic Acid" on Morphia.—With a drop of the sulphomolybdic acid, $\frac{1}{2000}$th of a grain of muriate of morphia gave immediately a rich purple colour, which rapidly disappeared, the liquid assuming a brown tint, which in turn passed into blue. This occupied fifteen minutes, and in half an hour the colour had altogether disappeared. The proportions of the reagents were varied, but the results did not materially differ. Free morphia deports itself in precisely the same way. The presence of water interferes with and may altogether prevent the reaction.

Action of "Sulphomolybdic Acid" on Grape Juice.—With no proportions could any coloration be obtained until the lapse of nearly half an hour, and the colour was very faint and quickly disappeared. In the case of dried juice the reaction was practically the same. The alcoholic extract gave varying results, but the shortest time in which any trace of blue appeared was five minutes, the colour taking about ten minutes to spread through the liquid, and being of an obscure, dirty shade. The yield of ethereal extract by Stas's process was extremely small. It gave an evanescent reddish tint with sulphomolybdic acid, which, however, did not develop into blue, except in one instance, when the colour appeared in a few minutes.* It must here be noted, however, that in examining the product of Stas's process, there is no use in applying the molybdic test, unless special precautions have been taken to get rid of the alcohol, as the least traces of that fluid will reduce the molybdic acid, giving the same blue colour as if morphia were present.

Action of "Sulphomolybdic Acid" on Orange Juice.—No coloration was obtained with the fresh juice. When the dried juice was employed a faint blue made its appearance in from ten to fifteen minutes. With the ethereal extract of orange (Stas's process) no blue colour was produced.

Action of "Sulphomolybdic Acid" on Saliva.—With the natural saliva no reaction was obtained, but when it was evaporated to dryness and mixed with the molybdic acid a slight blue colour appeared after the mixture had stood more than thirty minutes.

Action of "Sulphomolybdic Acid" on a Mixture of Orange Juice and Saliva.—No blue colour was obtained until about half an hour, and it was not distinct. A mixture of saliva and orange juice was evaporated to dryness and tested in the same way, with the result that the blue tint made its appearance in about twenty minutes, but was not very decided until some time longer.

Action of Ferric Chloride on Morphia.—A blue or bluish-green is produced, even with $\frac{1}{2000}$th of a grain.

Action of Ferric Chloride on Meconic Acid.—The wine-red tint is perceptible with $\frac{1}{12000}$th part of a grain, but that is about the limit of the reaction. The colour is very distinct with $\frac{1}{2000}$th of a grain.

Action of Ferric Chloride on Saliva.—A slight orange-red tint is produced both with the moist and dry saliva. This colour would not be mistaken for the wine-red of meconate of iron.

Action of Ferric Chloride on a Mixture of Orange Juice and Saliva.—Nothing but an orange colour could be obtained either with the moist or dry mixture.

Action of Ferric Chloride on Vinegar.—Samples of white, brown and French vinegar were tested, but perchloride of iron, however applied, failed to produce a red coloration. The residue from the evaporation of the vinegars was likewise tested with negative results.

Besides the experiments which have been detailed, mixtures of orange and grape juices, and of orange juice, grape juice, and saliva, both in their natural state, and evaporated to dryness, were tested with the same reagents as were used in the other cases, but the results were just such as might be anticipated from the foregoing experiments, and it would be superfluous to give them in an extended form. In every instance several experiments were tried, and that giving the most decided reaction is the one described.

* From the *Medical Times and Gazette*, July 20, 1878.

* This sentence refers to and applies to all operations when the final solvents employed are alcohol or liquids containing it—such, for instance, as ordinary ·725 ether; and it was inserted for the purpose of drawing attention to a possible source of error in applying the sulphomolybdic acid test when such solvents had been used.

The Pharmaceutical Journal.

SATURDAY, JULY 27, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POSITION OF THE PHARMACEUTICAL SOCIETY IN RESPECT TO COUNTER PRESCRIBING.

THE writer of a note, headed the "Ethics of Pharmacy," in the *Lancet* of last week, has done us the honour to quote from our editorial article in the Journal for the 8th of June the following sentence: "It is almost superfluous to say that the Council of the Pharmaceutical Society, regarding the treatment of disease as beyond the province of a pharmacist in a general way, discourages such practice." This passage has been quoted by the writer of the note as indicating some new development, or rather change of opinion in regard to counter prescribing by chemists and druggists, on the part of the Pharmaceutical Society, and it has been represented that the assumed change of views has been the result of compulsion.

The note in question appears in the editorial columns of the *Lancet*, and therefore we may fairly assume that it has been approved by the editor of that journal. Whether this is to be ascribed to want of acquaintance with the facts of the case, or to a deliberate intention to misrepresent them, we will not presume to decide, since it is difficult to say which alternative would be the least uncomplimentary, but there seems to be no other mode of accounting for the statements made in the note headed "The Ethics of Pharmacy," namely, that in regard to this question the Pharmaceutical Society has adopted a new principle or that this Journal has been wanting in courage to express its opinions.

This is not by any means the first time we have had occasion to complain of the unreasonable procedure of the *Lancet* in regard to counter prescribing by chemists and druggists, and of the perverse way in which the matter is misrepresented by that journal, especially so far as the action of the Pharmaceutical Society is concerned. At one time we find the *Lancet* assuming that the Council of the Society has pledged itself to a thick and thin defence of counter practice of that kind which may be considered so medical as to be outside the province of the chemist and druggist. At another time it is insinuated that the Council has neglected to take such a position as to the practice of counter prescribing as would tend to establish a better relation between medical men and pharmacists. It has also been averred that those members of Council who admitted the illegality of counter prescribing at the same time urged and supported the proposition to defend any chemist and druggist prosecuted under the Apothecaries Act, and in this way they were made to appear as deliberately encouraging a breach of the law.

We are wholly at a loss to understand what can be the motive for this line of action on the part of our contemporary, since the readers of that journal must be aware that the statements we have referred to, as well as the general tone of the comments upon counter prescribing, are inconsistent with fact.

There is, for instance, no foundation for the reproach thrown upon this Journal, that in consequence of its want of courage to adopt and declare a principle alleged to have been suggested by the *Lancet*, time has been lost in arriving at a settlement of this question. In the various articles dealing with this subject, we have never hesitated to avow the principle that the treatment of disease by chemists and druggists was undesirable. It is true we have not admitted that it is illegal, for we hold that there neither is nor can be a law to prevent any persons from recommending to others medical remedies, least of all should the chemist and druggist be subject to such restriction, but it has never been denied that in the interests of pharmacy generally, and with the object of maintaining a proper relation between those who practise pharmacy and those who practise medicine, it is decidedly desirable that the pharmacist should abstain from giving medical advice.

With regard, therefore, to the principle itself it is not to the *Lancet* that its origin is to be ascribed, and to show that it is not a creation of recent date we need not do more then refer to the pages of the earlier volumes of this Journal, where it is distinctly pointed out as one of the results to be hoped for from the formation of the Society that, so far from placing chemists and druggists in an invidious position with reference to the medical profession, the tendency would be to separate pharmacy from the practice of medicine by placing it on its own basis and upholding it on its own merits.

Nor was this aim of the Society ignored by the medical press of the time, for during the discussion of this matter and of the apprehensions entertained by some medical men that the practice of medicine among druggists would be encouraged, the *Medical Gazette* did not hesitate to say that no restrictions in this respect would ever be thought of if the whole body of chemists and druggists were such as the Society would make them.

We would therefore recommend our contemporary before again venturing to be oracular or authoritative on the subject of counter prescribing, and the relation of the Pharmaceutical Society to that practice among chemists and druggists, to devote some attention to what has been said concerning it, and to acquire such a knowledge of the aim and policy of the Society in this direction as will enable its

writers to deal with the question truthfully as well as fairly. In the pursuit of these researches it may also be appropriate to devote some consideration to the question how far the confusion of medicine with pharmacy has been brought about and its continuance promoted by those "qualified" and "legitimate" medical practitioners who keep open shop for the retail sale of drugs. These establishments are neither few nor far between, in some localities they are in no respect apparently different from the shop of the chemist and druggist; they are often the training school of the assistants who afterwards, as chemists and druggists, continue to carry on the medical practice that they formerly carried on in the "Medical Hall" as the deputies of their employers. It is thus that in the minds of the ignorant inhabitants of certain localities the "doctor's shop" is a place where one sees coloured bottles in the window, and can buy pennyworths of drugs or obtain medical treatment across the counter.

Chemists and druggists generally are alive to the unfairness of being placed in competition with these "Medical Halls," whose proprietors are often but slightly versed in pharmaceutic art, or at any rate are not required to pass any stringent examination in pharmacy, and if the *Lancet* would devote its energies to effecting the suppression of these institutions, it would probably render great service to chemists and druggists as well as to pharmacy, and naturally improve the relations between that class and the medical profession.

THE BRITISH PHARMACEUTICAL CONFERENCE AND OTHER SCIENTIFIC MEETINGS.

The issue of a circular by the Secretaries of the British Pharmaceutical Conference calls attention to the fact that the time for the fifteenth annual meeting of this body is close at hand. It is now announced that it will be held in the Hall of the King and Queen's College of Physicians, Kildare Street, Dublin, on Tuesday and Wednesday, August the 13th and 14th, under the Presidency of G. F. Schacht, Esq., F.C.S. The general business of the Conference will be commenced on Tuesday morning at 10·30, we presume as usual by the reading of the reports of the Executive Committee and Treasurer, although these are not mentioned in the circular; the President will deliver an address, and then will follow the reading and discussion of papers, the titles of some of which we expect to be able to publish next week.

A hearty invitation to English pharmacists to attend the Conference is given on behalf of the members of the Irish Committee by Mr. William Hayes, the Local Secretary, and also to join them on the day after the meeting in an excursion through the Devil's Glen to Glendalough, to view "the rich beauties of Wicklow." Other inducements to visit which are mentioned are Trinity College, Phœnix Park, the Botanical Gardens of Glasnevin, the recently restored Cathedrals of St. Patrick and Christ Church and the renowned brewery of Messrs. Guinness, Sons and Co.

Gentlemen intending to be present at the Conference, and wishing for information respecting local arrangements, hotel accommodation, and similar matters, are requested to apply at once to the Local Secretary, Mr. William Hayes, 12, Grafton Street, Dublin, who will be ready to answer inquiries.

The forty-eighth Annual Meeting of the British Association will commence in Dublin on Wednesday the 14th of August, on the evening of which day the first general meeting will be held, and the opening address will be delivered by the President-Elect, William Spottiswoode, LL.D., F.R.S. Besides the sectional meetings, there will be a lecture on Friday evening, the 16th, by G. J. Romanes, F.L.S., on "Animal Intelligence," and another on Monday evening, the 19th, by Professor Dewar, on "Dissociation, or Modern Ideas of Chemical Action.' There will also be soirées on Thursday evening, the 15th, and Tuesday evening the 20th. The concluding general meeting will be held on Wednesday the 21st of August.

The Annual Meeting of the British Medical Association is this year to be held at Bath, where the proceedings will commence on the 6th of August, with service in the Abbey. The President-Elect is R. W. Falconer, M.D., F.R.C.P., D.C.L.

On the Continent the German Apothecaries' Union is to hold its Annual General Meeting this year in Coblenz, on Tuesday, September 10th and three following days; whilst in the United States the twenty-sixth Annual Meeting of the American Pharmaceutical Association is to commence on Tuesday, the 3rd of September, in the city of Atlanta, Georgia.

THE WEIGHTS AND MEASURES BILL AND THE METRIC SYSTEM.

As will be seen from a report on another page, in moving the second reading of the Weights and Measures Bill in the House of Lords, on Monday last, Lord Henniker described it as a consolidating measure, with only such novelties introduced as were necessary to remove doubts and correct mistakes in the existing law. As to the metric system, he said the Bill recognized it practically without making it part of the Imperial system. Lord Henniker thinks that those who advocate the metric system should be content with this arrangement for the present, and if the system were found to work well the case for its general adoption would be the stronger. But he does not explain how any experience as to the working of the system, beyond what already exists, is to be gained whilst it remains a legal offence even to be in possession of metric weights and measures for the purposes of trade. In defining the object of all legislation upon this subject as "the maintenance of just dealing between buyers and sellers, while *giving* to science whatever assistance it

might require," the noble lord misstates the position, and appears to be oblivious of the onus that lies upon the Legislature to *accept* from science such help as it is able to give.

Thanks are due to Lord COLCHESTER for urging that the metric system should be put on a level with the existing system, and to Earl FORTESCUE for pointing out that although the metric system has lately met with so little countenance in this country, other countries, and especially Germany, have during the past few years adopted it with great success.

THE SELLING OF POISONS IN THE FAR WEST.

UNDER the somewhat dubious title of "Pharmaceutic Ignorance," the *Medical Press and Circular* quotes the result of an action at law in Chicago brought by a lady to recover damages for the inconvenience she had suffered through having been supplied by a druggist with strychnia instead of arsenic, "which she had been in the habit of taking for neuralgia." The jury awarded her 1050 dollars. This verdict appears to have provoked the editor of the *Chicago Journal* into a fit of moralizing that throws a curious sidelight upon the state of the liquor law and the inducements and possibilities to practise pharmacy (?) in that district. "Such," says he, "is the just recompense for the ignorance of a man who, *in order to sell liquors, pursued the business of a druggist*, and who when upon the witness-stand could not tell how many ounces made a pound of apothecaries' weight." After this it is not surprising to learn that a Bill introduced into the Legislature to amend the law relating to the regulation of pharmacy in another State, Pennsylvania, was referred by the House to the "Committee on Vice and Immorality."

MILK AS A SOLVENT OF QUININE.

MR. R. L. BATTERBURY, writing recently to the medical journals, called attention to a fact not generally known, that milk is not only a good solvent of quinine but that it also disguises its bitterness. He states that if one grain of the sulphate be dissolved in an ounce of milk the solution is scarcely perceptibly bitter, whilst two grains dissolved in the same quantity do not make it markedly bitter. A dose of five grains may be taken in two ounces of milk without rendering it very unpleasant and if this be thrown into a tumbler full of milk the bitterness all but disappears. The method appears to present especial advantages in administering quinine to children.

The suitability of milk for this purpose has since received confirmation, and Mr. PALMER, resident surgeon of the Birmingham General Dispensary, recommends the use of a solution of quinine in glycerine, in the proportion of one grain to one drachm, the dose being given in a wine-glassful of milk.

AT the Midsummer Quarter Sessions for the East Riding, Mr. JAMES BAYNES, jun., Pharmaceutical Chemist, of Hull, was appointed Public Analyst for the Riding for the term of one year.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday evening, July 4, Mr. W. R. Atkins in the chair. The following paper was then read:—

NOTE ON "MOLYBDIC ACID" AS A TEST-AGENT.

BY HENRY ALLEN,

Student in the Laboratories of the Pharmaceutical Society.

Molybdenum is generally classed with tungsten and uranium, the group thus formed being characterized by forming compounds with oxygen, the lower of which are basic. while the trioxide is generally acid, though sometimes feebly basic.

Molybdenum especially is remarkable for forming, as it would appear, several compounds, represented as molybdates of molybdenum, intermediate between the acid and basic oxides, and it is to the formation of these, upon certain conditions, that the value of the trioxide as a reagent seems to depend.

Of these intermediate bodies, two were described by Berzelius, the one blue and the other green, having the composition of Mo_5O_{14} and Mo_3O_8 respectively.

In Watts's Dictionary two blue compounds are mentioned; the one Mo_3O_8, obtained by heat from the compound formed by digesting ammonium molybdate with molybdenum chloride, and the other $M_2O_5 3H_2O$, formed on mixing solution of the dioxide with the hydrochloric solution of the trioxide.

The trioxide, MoO_3, is the substance which in solution (or combination) with acids forms the reagent lately introduced as a test for certain organic bodies.

In Watts' Dictionary it is said after ignition to be "sparingly soluble in boiling solution of cream of tartar. The unignited oxide dissolves in some of the stronger acids, *e.g.*, boric, phosphoric, sulphuric, nitric, and hydrochloric, forming compounds that may be called permolybdic salts." In experimenting, however, I have found it to be insoluble, or nearly so, in nitric acid, but dissolving very readily in hydrochloric, sulphuric, and tartaric acids, with the aid of a gentle heat.

The solutions I have used in the following experiments are (A) molybdic trioxide in 10 parts by weight of sulphuric acid; a clear yellow solution, with a smell of sulphurous acid (recommended by Dr. Davy as a test for alcohol and carbolic acid).

(B) Molybdic trioxide in 100 parts by weight of sulphuric acid.

(C) Molybdic trioxide in hydrochloric acid; a saturated solution (about 1 in 3 or 4), produced by boiling the two acids together a nearly colourless solution.

(A) gives a deep blue coloration with stannous chloride, hyposulphite of sodium, ferrous sulphate (but not with arsenious oxide); the same colour with methyl, ethyl and amyl alcohol and ether; it can therefore be used in detecting these substances in chloroform, chloral hydrate, and other compounds.

Glycerine in excess gives very slowly, and benzol and naphthalene at once, the same blue coloration, which is also produced by many other organic bodies.

With a small quantity of benzol it produces a strong smell of benzoic aldehyde, but the exact conditions under which the latter is formed I have not yet been able to determine.

It is (as described by Dr. Davy) a very delicate test for carbolic acid; a simple method of detecting this body in creosote being to shake the creosote with an equal volume of water, filter, and boil the solution rapidly down to about a third of its original volume and test the residue. This method answers very well for creosote containing 3 or 4 per cent. of carbolic acid.

(B) gives with benzol a bright violet coloration ; with carbolic acid (1 in 100) a dark green coloration, gradually changing to purple and finally losing colour, but leaving a sediment.

With alkaloids the following reactions occur:—

Brucia—*a deep yellow.*

Morphia—*purple, fading.*

Salicine—*purple, then red.*

(C) This solution was made in order to obviate the presence of sulphuric acid, if possible, when testing for organic bodies.

Reducing agents, such as nascent hydrogen, give with this solution a splendid emerald green solution, which on addition of water becomes of a reddish brown colour.

Carbolic acid (liquid) and creosote may be distinguished at once by adding a drop to a few drops of the reagent ; creosote becomes of a dark colour, tinging the solution pink, while carbolic acid merely turns slightly pink itself, leaving the solution colourless.

The following is a simple method for detecting carbolic acid (1 per cent. or more) in the presence of alcohol and some other organic bodies. To a few drops of hydrochloric acid add one or two drops of the suspected solution and then one drop of nitric acid, when a purplish crimson is produced if carbolic acid be present. Creosote seems however, as far as I have tried, to interfere with the reaction.

With alkaloids the following colours are produced :—

Brucia—orange, forming a violet solution.

Morphia—very pale yellow, fading.

Salicin—no colour.

Mr. Allen received the thanks of the meeting for his paper, which was thoroughly discussed.

Mr. N. C. Graham then exhibited an improved form of microphone, consisting of a sounding board on which were placed two pieces of carbon that were screwed down against the wood with two binding screws ; another longer piece of carbon was then balanced on one of these carbons so as to rest lightly on the other. The delicacy of this instrument was such that when the telephone handle was placed on a table in the middle of a room the ticking of a watch resting on the microphone was plainly heard. A vote of thanks to Mr. Graham was passed, and the meeting adjourned.

ROYAL INSTITUTION OF GREAT BRITAIN.

Matter and Ether.*

BY JOHN FLETCHER MOULTON, M.R.I.

(*Concluded from page* 37.)

How then are we to take the further step of selecting from amongst those rival hypotheses, each of which professes to give some mechanism able to produce a particular set of phenomena, the one that actually represents the mechanism by which the phenomena are in fact produced? This is the most serious and the most difficult step in discovery. And yet, at first sight, considering how complex are the phenomena that have to be explained, it would seem that any theory that succeeded in accounting for even a portion of them must be very near to the truth ; and it is so usual to consider that this is the final and sufficient test of the claims of a hypothesis, *viz.*, that it should suffice to account for the phenomena, that when they are very complex it is often considered a more than sufficient test, and the hypothesis is accepted in spite of its being in many respects undeniably deficient. But, in fact, so soon as we begin to apply ourselves seriously to the problems of the constitution of matter—the hidden mechanism of nature—we are forced to abandon in great measure all such ideas. For we find that we have no true measure of complexity. From one single simple law will follow the most various and complex results, and hence any mechanism so designed as to exemplify in its results the working of that single law would, under such a canon as the one just referred to, be able to claim as evidence of its truth all the complexity which follows from that law. Yet such evidence would equally avail to support the claims of any other mechanism, whose results similarly obeyed that law, and of such mechanisms there might be many. This has been often exemplified in the history of science. The truth of a hypothesis has appeared to be sufficiently demonstrated by the manner in which it fully accounted for complex phenomena, and it has been accepted as a physical truth on such grounds, until some other hypothesis has been shown equally capable of accounting for them ; and the success of both has been subsequently traced to their alike leading to results that were obedient to some one fundamental law, to the working of which the whole of the observed complexity was due. In the history of such deep-reaching principles as that of the Conservation of Energy this has been a common occurrence ; but other instances are not wanting. After Sir W. R. Hamilton had deduced theoretically from Fresnel's Theory of Light, that in biaxal crystals there must be internal and external conical refraction, and their existence had been thereupon experimentally demonstrated by Dr. Lloyd, one might well have fancied that the accuracy of so remarkable a prognostication was sufficient to establish Fresnel's Theory in all its details. Yet a theory framed by Cauchy, which, though in many respects similar to Fresnel's Theory, is yet in fact wholly irreconcilable with it, was subsequently found to account equally for the phenomena; and it is probable that any theory of undulatory transmission in a non-isotropic medium might be made to do the like. In fact, we can express in abstract language the weakness of the canon which would make the acceptance of a theory follow from its success in explaining complex phenomena, by saying that to render the canon a good one, complexity must be measured, not by the apparent intricacy of the resulting phenomena, or the apparent difficulty of accounting for them, but by the number of independent laws by which the phenomena are governed, and which are successfully accounted for by the proposed mechanism. And as we are seldom in a position to pronounce on the question of the independence of the laws that govern a set of phenomena, *i.e.*, as to whether they are all traceable to a very few fundamental laws or not, we are seldom able to estimate the complexity of those phenomena in the way that would alone justify us in taking it as sufficient warrant for the acceptance of a successful hypothesis.

Nor is this the only one of the well-tried and approved canons of discovery that fails us when we are engaged in researches in the unknown land of the ultimate constitution of that of which the universe is composed. There is no principle which is more constantly present to the mind of the scientific investigator in his search for the causes of phenomena than that of simplicity. Wondrously complex as are the processes that are going on all around us in nature—so apparently complex that the untaught mind has in all ages sought to ascribe them, in a greater or less degree, to consciousness and volition resident in the things themselves, or in beings possessing the power to direct them—science has so often found that these highly complex results come from the very simplest causes, that the investigator expects to find simplicity in his results, and naturally inclines to believe that explanation to be the true one which accounts in the most simple manner for the observed phenomena. This has been advanced by some persons almost to the dignity of a law of thought, and the mind is considered by them to be constrained to believe in the truth of the simplest hypothesis that explains a set of phenomena to the exclusion of all more complex ones.

It is not very easy satisfactorily to account for the undoubted value of this canon, *viz.*, that the simplest hypothesis is probably the true one. That there can be any truth in it in its abstract form (as is generally understood) is not probable. There is no reason to think that

* Lecture delivered at the Royal Institution of Great Britain, Friday, February 23, 1877.

nature has any preference for simplicity over complexity, if indeed it is possible to attach any meaning to such phrases. The deeper our knowledge becomes, the greater the complexity that confronts us, and the fainter our hope of finding that the ultimate solution will be a simple one. It is probable that much of the value of the canon arises from the fact that the simpler hypothesis will in general be the one that supposes the concurrent action of the fewest independent causes; and it is, of course, more probable that a smaller number of independent causes should co-operate than that a larger number should do so. But the value of the canon mainly lies in the view which the mind instinctively takes of simplicity. That is to us simple which is the result of means and processes to which we are thoroughly accustomed, and with the results of which we are fully familiar. Operations the most complex in their nature are often felt to be simple, and scarcely to need any explanation, solely because they are so common. It seems, for instance, almost superfluous to invent elaborate mechanism to account for such simple phenomena as evaporation or weight. And thus a hypothesis which is felt to be simple is usually one which traces the phenomena to the action of causes with which we are very familiar, *i.e.*, which are constantly at work around us, and which are therefore just the causes that are the most probable.

From such considerations we at once see how useless must the canon of simplicity be to us when investigating the ultimate constitution of the materials of which the universe is built up. For, in the first place, we have little or nothing to guide us as to the probability of the concurrence of different causes in this unknown region, and secondly, a thing which is of infinitely greater moment, we are absolutely ignorant (save in one or two isolated points) of the types of structure and action that we may expect to find commonly exemplified therein. For in seeking to determine the ultimate constitution of matter and ether, and of all that directly or indirectly acts upon them, we are going beyond all the phenomena with which we have been rendered familiar by observation, whether general or special, and we are occupied in ascertaining the mechanism by which matter and ether are enabled to produce the phenomena we see. Now, of this we have no previous experience, and it cannot be too distinctly kept in mind that where there is no experience there is absolute ignorance. In the world around us we see only the aggregate results of infinitely numerous separate actions, none of which are simply cognizable by our senses or our instruments. Every experience of matter that we have in mechanics is of matter acting in masses. Chemistry and physics give us certain phenomena, caused doubtless by a more intimate action of matter upon matter, but the results are only known to us in gross; and even if we assume that the process is uniform throughout, it is only the result of that process that we see, and its nature is wholly concealed from our view. Similar remarks apply to the other branches of science. Nowhere do we get any direct information as to the nature or details of these processes, or as to the mechanism by which they are rendered possible, and thus we nowhere get any knowledge of the types of mechanism that we may expect to find at work. It is true that in all action of matter upon matter we see that certain laws are universally obeyed. But all that this enables us confidently to enunciate is, that the nature of matter must be such that when matter acts upon matter in appreciable quantities, such and such laws obtain. We are not even justified in asserting that the most universal of these laws must necessarily hold good in the case of the separate actions of which the aggregate is made up.* Still less are we in a position to say that one hypothesis is to be preferred to another, because it hypothesizes only such types of structure or action as we are familar with in our experience of the world of visible phenomena. It is scarcely too much to say that at present our ignorance of the ultimate constitution of matter is such that no one suggested structure ought to be viewed by us as being in itself more simple or more probable than another.

Unable then to use these canons in their ordinary form, we are driven back to the truths that underlie them. It is true that we cannot rightly judge of the value of success in explaining the complex behaviour of matter as a test of the truth of a hypothesis. And it is also true that we cannot directly judge whether the causes we propose to assign for that behaviour are probable ones. But out of the combined effect of the two there arises a third canon of the highest value, specially adapted to meet the peculiar difficulties of the task. It may, perhaps, be expressed by saying that the probability of the truth of a suggested hypothesis, as to the constitution of matter or the nature and mode of transmission of its actions on other matter, is measured by the dissimilarity of the phenomena explained by it. So long as the hypothesis satisfactorily accounts for but one class of kindred phenomena, no matter how complex they may be and how satisfactorily it may account for them, its truth must still remain in doubt, inasmuch as from our ignorance we are unable to say how much is denoted by that success, in other words, how far such success may be due to these phenomena being necessary consequences of but very few laws, or even of a single one. But if the same hypothesis explains phenomena of a wholly different character to those which suggested it, and which so far as we can judge have no direct connection with them, then we are justified in accepting the hypothesis as a genuine contribution to our knowledge of nature.

This will be rendered clearer by an example. Take as an instance what is probably the most successful attempt that has yet been made to penetrate the darkness that surrounds the constitution of matter. Long ago, in order to explain the phenomena of combining proportions in chemistry, the hypothesis was framed that every element or chemical compound consisted of small atoms or molecules of definite size, constitution, and weight, and that the process of chemical combination consisted in the building up of new compound molecules out of the molecules or atoms of the combining bodies, or the atoms that composed such molecules. The impetus given to the science of chemistry by this felicitous hypothesis can hardly be exaggerated. It permeated the whole of chemical research, and gradually came to be treated as though it represented a demonstrated fact. Against this the more accurate scientific thinkers protested, and were in the right in so doing. They pointed out that the only facts relating to the matter with which we were acquainted were those expressed by the law of combining proportions—that it was true that the atomic theory satisfactorily accounted for this law, but that the mere fact of its accounting for this single law was a very insufficient ground for accepting the absolute truth of the theory. There could be no doubt of the justness of these views, and the strictly hypothetical character of the theory was once more generally recognized. But of late the investigations of physicists into the dynamical theory of gases have shown that when substances are in the gaseous condition (in which alone the separate particles of which they are composed are capable of free and independent motion, and—so to speak—of manifesting their separate constitution) they are composed of rapidly

* This is no idle refinement. No law would seem to be more absolutely without exception than that heat of itself tends to pass from a hot body to a cold body, *i.e.* that heat tends towards an equalization of temperature. Yet this has been shown to depend in some instances rather upon the law of averages than on the fundamental laws of energy, and to be inapplicable to the action of single molecules; and it is not impossible that we might be driven to take a similar view of such a law as that of the conservation of energy, though, fortunately, nothing as yet points to this, and it would, therefore, be unscientific to increase the difficulty of investigation by making such a hypothesis until it shall be found that there are good grounds for doing so.

moving minute particles, of just such size and weight as the atomic theory would lead us to expect. Now this is precisely the type of confirmation which our canon points to as justifying belief. Nothing was farther from the thoughts of the inventor of the atomic theory than the explanation of the relations between temperature and pressure in gases—it was solely to account for a law of chemical combination that he framed his hypothesis—and yet we find that when in the state of gas the substances actually consist of just such particles as the atomic theory requires. No two more dissimilar classes of phenomena could well be imagined; and it is in consequence of this wide dissimilarity of the phenomena which it explains, that, although theories have been started in other branches of molecular physics which have successfully grappled with far more intricate phenomena, there is no theory of the ultimate constitution of matter which has nearly so high a claim to be regarded as an absolute physical truth as the atomic theory.

This canon seems to have but little connection with that of simplicity, or, as we may term it, the Law of Parsimony. And the reason of this is, as has been shown, that we are too deeply ignorant of the nature of the ultimate structure of any portion of the universe to be able to tell whether any suggested structure is a probable one, *i.e.*, is one of a type frequently occurring. Slowly as we penetrate the mystery we shall acquire knowledge of particular instances or types of structure, and shall learn what sort of results to expect in our researches; and so soon as this stage is attained we shall rightly give weight to our inclination or repugnance towards any suggested hypothesis. But at present we are scarcely justified in doing so in any degree, and therefore it is of the greatest help to science that different investigators should separately work out theories depending some wholly on actions requiring a continuous medium for their transmission, and others hypothesizing action at a distance. Such as succeed in explaining the phenomena to which they relate must, in the present state of things, be held to be of an equally hypothetical character, and, on the other hand, to be equally good candidates for final acceptance. As we have said, there is good reason to hope that this state of things is but temporary; but at present it exists, and it therefore profits nothing to turn the mind inward upon itself, to ask it to pronounce on the possibility or impossibility of things as to which it knows nothing. Nothing but laborious and prolonged experimental investigations will entitle us to give the preference to one or the other of the rival theories; and this will be due to the experience so gained, and not to any process depending on considerations of what is *d priori* possible or impossible in thought.

It is this utter absence of experience—this total ignorance of what is possible or impossible, probable or improbable—which causes us on the one hand to tolerate so kindly such fantastic hypotheses as those of which we have given instances in Weber's and Ampère's ideas as to molecules, or the collision-theory of gravitation; and on the other hand to view with such doubt and suspicion, and to examine with such a jealous eye, the brilliant theories which have shed so much light on various parts of physics and chemistry. Take, for instance, the hypothesis of a luminiferous ether. In no branch of physics are the phenomena so striking as in physical optics, and no theory has ever fulfilled so difficult a task as has the Undulatory Theory in explaining and accounting for them; and yet if we deliberately consider the claims of this hypothesis to be regarded as a physical truth, we cannot free ourselves from the most serious and perplexing doubt. We must separate in our mind the laws of the Undulatory Theory from the mechanism by which the hypothesis seeks to account for them, and then if we weigh the evidence directly in favour of the existence of such a mechanism apart from such as is derived from its accounting for the laws of the Undulatory Theory, and when we contrast this with the enormous difficulty of reconciling the existence of such a mechanism with other phenomena, we are almost in despair. Remembering that light only makes itself known to us in connection with matter, the necessity of a hypothesis of so serious a character might well be doubted. If it were not for the finite velocity of light, and the great improbability (judging from our knowledge of the law and nature of energy) of there being a store of energy inherent in nothing for the time being, as there must be if the radiant light in the interplanetary spaces is not propagated through a continuous medium, it is very doubtful whether there would be any sufficient justification for the acceptance of the hypothesis of a luminiferous ether as being even a near approximation to a physical fact. At present the existence of a luminiferous ether is generally admitted, though it is very usual to doubt the existence of a medium for the transmission of electric action, and to look upon the latter class of phenomenon as an instance of action at a distance. Yet I doubt whether the evidence in favour of the existence of a luminiferous medium differs at all in kind, or even greatly in degree, from that in favour of a medium for electric action; always supposing that it can be shown satisfactorily that induction across a vacuum occupies a finite time. If then we admit the existence of a luminiferous ether to be satisfactorily demonstrated, we must also admit the existence of an electric ether, and it will probably be found that other types of action have equal claims with these to special media for their transmission. Are we then to crowd space with interpenetrating media, each having as its sole function the transmission of some special kind of action? Without pronouncing dogmatically as to whether this can or cannot be the truth, it is clear that at present we are justified in declining to regard such conceptions as having any much higher rank than that of hypotheses judiciously framed for the purpose of simplifying our analysis, and assisting our thinking powers. If it should turn out that the so-called luminiferous ether accounts for the transmission of electric action, or—as at present seems more likely to be the case—that a medium hypothesized for the purpose of accounting for electric action is capable of satisfying all the needs of the Undulatory Theory of light, then indeed we may begin to think that our hypotheses closely represent physical facts. But such recognition is rightly withheld so long as each new hypothesis suffices only to explain the special type of phenomena for which it was framed.

Many of our best physicists are at work on such subjects as these, and are making good progress. Difficult as is the task, it is still one that occupies itself with what we have reason to believe is the simplest (if such a term can be appropriately used in such a connection), and the most uniform and homogeneous type of ultimate structure. Every glimpse that we get of the nature of matter (such for instance, as the revelations of the spectroscope or the phenomena of crystallography and chemical change) makes us start back astonished at the well-nigh unimaginable complexity that it reveals. But in the case of light and electricity, although their manifestions must to some degree be bound up with matter, we have the attendant complexities of matter playing but a secondary part, and the main subject matter of the manifestations appears to be the result of some infinitely less complicated mechanism. It is true that we are at present baffled by this very difference from gross matter, which in all probability will ultimately render the problem more simple, inasmuch as our imagination is little rich in suggestions that rise above modified experience. But the fact remains that we are here brought most nearly face to face with the phenomena arising directly out of a comparatively simple type of ultimate constitution, and though the complex behaviour of matter would seem to give us more information as to its structure, and thus more guidance in our remarks, it is, as far as we can yet see, in the domain of light and electricity that we have best reason to expect success in our efforts to arrive at the hidden secrets of the mechanism of the universe.

Parliamentary and Law Proceedings.

Prosecution for Selling "Violet Powder" containing Terra Alba.

On Friday, July 19, at the Salford Police Court, Messrs. Gill and Son, chemists and druggists, 29, Broad Street, Pendleton; and Mr. Edward Brook, chemist and druggist, Cross Lane, Salford, were summoned before Messrs. C. L. Clare, J. Lowcock, and W. W. Goulden, for having sold a certain drug, called violet powder, which was not of the nature and substance of the article demanded by the purchaser.—The Town Clerk (Mr. Moorhouse) prosecuted, Mr. Herbert, of Birmingham, appeared, on behalf of the Chemists and Druggists' Association, for Mr. Brooks; and Mr. Tanner was for Messrs. Gill and Son.

The Town Clerk said the defendants were summoned under the Food and Drugs Act. He should have to prove, to obtain a conviction, that the matter in question was not of the nature, substance, and quality of the article demanded by the purchaser. In the Act the word drug was specified to mean things for external or internal purposes, and he would have to show that violet powder was a medicine for external use. Violet powder should consist principally of starch, but in this case the powder was certified to consist principally of sulphate of lime, which was a mineral, whereas starch was a vegetable. Starch was about four times more expensive than sulphate of lime; therefore, it was at once apparent that, in selling the latter instead of the former, the advantage was on the part of the seller. His case was that violet powder was scented starch, and they contended that in this matter the powder was not a medicine, but an injurious mineral.

Mr. Joseph Thompson, inspector of food and drugs, said that, acting under the instruction of the medical officer of health (Dr. Tatham) and the public analyst (Mr. J. Carter Bell) he went to the shop of Mr. Brook and asked for a penny box of violet powder, for which he paid. He divided the powder and took a portion of it to Mr. Carter Bell for analysis. On the same day he bought some violet powder at Messrs. Gill's shop. Both the boxes were labelled "superfine royal violet powder."

Cross-examined by Mr. Tanner, the witness said he did not inform Mr. Gill, jun., that he had called to purchase the powder in consequence of the disclosures made, and the discovery of arsenic in powders.

Mr. Carter Bell, public analyst for Salford, said he had examined the two samples. That from Mr. Brook's shop contained upwards of 75 per cent. of sulphate of lime. The residue consisted of water crystallized, and little traces of iron and alumina. He found no starch. Allowing for the percentage of water, the powder consisted of sulphate of lime. Violet powder ought to consist of starch, scented with orris root, or some essential oil. He had analysed about fourteen other samples, and found them pure. Sulphate of lime was known as gypsum, and consisted of sulphuric acid and lime. Starch was much more valuable than sulphate of lime, the price of one being £20 per ton and the other 30*s.* per ton. The sample from Messrs. Gill's shop contained upwards of 80 per cent. of sulphate of lime.

In reply to Mr. Herbert, the witness said he commenced analysing violet powder in consequence of what he had read about the London arsenic cases. He had found no arsenic in these powders. They had bought twenty-four samples in Salford, and seventeen of them were adulterated. He did not know who were the makers of these powders, and had never sold any himself. He arrived at the prices by consulting a price list. Until this case commenced he had not received any complaint about the powder. The powder was a drug, and his opinion of a medicine was that it meant anything which was applied for healing or soothing purposes. If the skin was excoriated sulphate of lime, when appl[illegible]d irritate, but starch would be soothing. He tested for orris root, but did not find it. He had heard of Dr. Redwood, but did not know that he had analysed the samples similar to those in question, and had given the following certificate:—"Samples of violet powder and fullers' earth prepared and supplied in packets by Messrs. Alf. Bird and Sons, of Birmingham, and bearing the trade mark representing a steamer over a globe, having been collected from wholesale houses in London, have been submitted to me for analysis, and I certify that they do not contain a trace of arsenic or anything injurious to the skin or unsuited for the purpose for which they are intended to be used as absorbent powders."

Dr. Tatham said he prescribed violet powder very largely. The powder should consist of starch and a perfume, and he quoted a work known as the 'Royal Materia Medica,' 1876, page 318; a work by Dr. Pye Chevasse, and one by Dr. G. W. Francis in support of this assertion. He could not discover starch in the samples from Mr. Brook's shop. If sulphate of lime were applied to an excoriated skin it would irritate. He was surprised to hear that sulphate of lime had been called violet powder, but he should not be surprised to hear that lycopodium was used solely as violet powder in Germany. Violet powder should be a soothing and absorbing powder. He thought it was called violet powder because it was scented with orris root.

This was the case for the prosecution.

Mr. Herbert, for the defence, said he appeared on behalf of an association who wanted to have the matter settled so that henceforth there would be no more prosecutions. If the bench ruled that the defendants had infringed the law, the case would be taken on appeal to the quarter sessions. It was a curious circumstance that no complaints had been made about the powder, and that until the arsenic case arose there had been no idea of a prosecution. It would have to be proved that the powder was sold to the prejudice of the purchaser, and that the powder was a drug. He quoted a case (Sandys *v.* Maule) to prove that as the inspector had purchased the article for analysis and not for consumption, he had not been prejudiced. It must be to the prejudice of the purchaser and not to the public at large. He submitted that the powder was a cosmetic and not a drug, and the name violet powder applied to more than one substance.

Mr. Tanner said there was no particular formula for the preparation of violet powder, and that this powder was violet powder to all intents and purposes. There were two distinct sorts of powder.

The Chairman said the bench were perfectly satisfied that the powder in question was a drug, and were also satisfied upon the question of prejudice to the purchaser.

Dr. Samuel Crompton, Manchester, was then called for the defence, and said that he preferred the violet powder in question to starch. Violet powder containing sulphate of lime was not injurious. It was capital as a dusting powder. If he was asked for advice he should recommend the violet powder, for starch was apt to become sticky.

In reply to the chairman, the witness said he should prefer if he had a burn on his arm to have it covered with sulphate of lime rather than starch. Before the present controversy about this question he always supposed violet powder was made of starch.

Mr. Siebold, analytical chemist, Manchester, said he examined the powder from Mr. Brook's shop, and found that it consisted bodily of hydrated sulphate of lime, and not of 75 per cent. of sulphate of calcium, as was stated. It was scented with orris root. He was not surprised to find sulphate of calcium, because there had been a good deal of criticism lately, and it appeared that sulphate of calcium was pre-eminently used. Other substances were also used in the making of the powders. Violet powder was not a definite powder, but an inert powder which ought to be free from alkalinity or acidity and scented

with orris root. He knew that Bird's powder, like the substance produced, was largely used.

Mr. Bird, of the firm of Messrs. Bird, Birmingham, the makers of the powder in question, said his firm made about a ton of the powder each week, and although they had been manufacturers twenty years there had not been any complaints. Different makers used different substances in making violet powder. Mr. Carter Bell had not given a correct analysis of the powder.

The magistrates then retired, and on returning into court the chairman said they were unanimous in a decision that there must be a conviction. The defendants would be fined 20*s.* and costs each.

There had been seventeen summonses issued, fifteen against other dealers, but it had been agreed that these two cases should be test cases.

Mr. Herbert said that as the corporation did not wish to make a profit he hoped the rest of the cases would be withdrawn.

The Town Clerk agreed to withdraw the cases.

Mr. Herbert gave notice of appeal to the quarter sessions, and, if necessary, to a higher court.—*Manchester Courier.*

Weights and Measures Bill.

In the House of Lords on Monday night—

Lord Henniker, in moving the second reading of this Bill, said that it was one of consolidation. It consolidated into one Act a number of enactments which had been found to be obscure in some instances and contradictory in others. In doing this it was impossible to avoid introducing some new matter, but this was confined to what necessarily arose out of the mere process of consolidation, in removing doubts and correcting mistakes of the existing law, and in introducing amendments made by the Select Committee of the House of Commons. This new matter would make the Bill complete as a consolidating measure, and would go far towards establishing and maintaining a practical uniformity of weights and measures. An able memorandum was attached to the Bill explaining the law and the amendments made, and therefore it was unnecessary for him to refer to them in detail. The Bill, after being introduced into the House of Commons, had been referred to a Select Committee, which had carefully considered it, and he ventured to say the Bill was in a very perfect state. The Board of Trade had had the advantage of the valuable information procured by the Standards Commission of 1870, and it was worthy of notice that they had been fortunate enough to secure in the counsel who drew the Bill a gentleman who thoroughly understood the subject, not only legally but scientifically. He thought he might fairly say that it was doubtful whether at any time the subject could have been dealt with more satisfactorily than at present. The Bill gave a more scientific definition of the various standards, it provided for the better care of official and local standards, and it laid down strictly and clearly the one principle that only certain standards should be used in trade. Although it was a consolidating measure, the Bill did not interfere with the old jurisdiction, beyond securing a proper performance of its duties. As to the metric system, it recognized it practically, without making it part of the Imperial system. He thought that those who advocated that system should be content with this. If it were found to work well, their case for its general adoption would be the stronger. He thought the Bill went far enough in this direction for the present. The main object of all legislation on this subject was the maintenance of just dealing between buyers and sellers, while giving to science whatever assistance it might require. This, he thought, was secured by the Bill as far as possible, without unnecessary disturbance of existing customs, and without undue interference with local authorities. He believed it not only placed the law, but also the whole practical system of standards, on a more satisfactory footing.

Lord Colchester urged that the metric system should be put upon a level with the existing system of weights and measures.

Earl Fortescue thought the metric system had rather retrograded than advanced in public favour during the last few years, although other countries in succession, and particularly Germany, had adopted it very successfully. It was a matter of great regret that while the previous Act, rendering permissive the metric system of weights and measures, was embodied in the present Bill, yet practically the metric system of weights and measures could under that Act only be verified for scientific purposes, and not for purposes of trade. However, he hailed this Bill as being, on the whole, a valuable one, and would do nothing to delay its passing into law.

The Bill was then read a second time.

Obituary.

Notice has been received of the death of the following:—

On the 10th of July, 1878, Mr. Charles Jones, Chemist and Druggist, Marlborough. Aged 51 years.

On the 11th of July, 1878, Mr. John Cheshire, Pharmaceutical Chemist, Grantham. Aged 58 years. Mr. Cheshire had been a Member of the Pharmaceutical Society since 1849.

On the 17th of July, 1878, Mr. Henry Thomas Houghton, Chemist and Druggist, Oxford. Aged 31 years.

On the 18th of July, 1878, Mr. Robert Ripley, Chemist and Druggist, Marske-by-the-Sea, Yorkshire. Aged 56 years.

Erratum.—In the obituary on page 39, col. ii., line 18 from top, for "Mr. John Saffery" *read* "Mr. Stephen William Saffery."

Dispensing Memoranda.

[131]. Syrups from Essential Oils.—Will any reader inform me of a method of making from essential oils syrups that will not become opaque, or separate?

Juxta.

[132]. Will any of your readers say how the following prescription should be dispensed, and what should be the appearance of the mixture?

℞	Quiniæ Sulph.	grs. xvj.
	Acid. Sulph. Dil.	℥ss.
	Sp. Ammon. Arom.	℥iij.
	Sp. Æth. Chlor.	℥iss.
	Tr. Aurantii	℥ij.
	Aquæ . . . . . ad	℥viij.

M.

"Dispenser."

[133]. Acid Nitro-Mur.—When acid. nitro-mur. is prescribed (say ℥j in an ℥viij mixture, tablespoonful dose), what should be dispensed? I enclose copy of a prescription which a few days ago was handed me to dispense; of course in this instance I used the B.P. dilute acid:—

℞ Acid. Nitro-Muriatici . . . . . ℥j.
Gtt. x ex aquâ bis die sumend.

Sub Umbra Floresco.

[134]. OPODELDOC.—What should be dispensed or retailed as opodeldoc? Some chemists give lin. saponis, while others always use lin. saponis ℰ opio.

SUB UMBRA FLORESCO.

[135]. UNGUENTUM GLYCEROLI PLUMBI SUBACETATIS.—I should be much obliged if some reader would kindly give me the form generally used for Unguentum Glyceroli Plumbi Subacetatis. Squire mentions the glycerole at page 234, but gives no mention of ointment. It has been supplied by a firm in the West of England of a creamy consistence and a bright orange colour.

Bridgend. D. JENKINS.

Notes and Queries.

[509]. LINIMENTUM PETROLEI.—I have used the following and find it generally useful for sprains, bruises, etc., and especially chilblains :—

℞.	Paraffin	℥j
	Camphoræ	℥ij
	Ol. Origani	℥j
	Ol. Cajeputi	℥j
	Ol. Samb. Vir.	℥ss

M. ft. lin.

H. CUMBER, Jun.

[510]. INDIA-RUBBER RINGS.—Can any reader inform me how I could remove the smell and taste of red india-rubber rings? They are used inside the mouths of some lemonade bottles, to secure them air tight, and I find that they impart a taste to the lemonade.

"TENENS."

[511]. TOOTH PASTE.—G. S. would be glad of a recipe for a good cheap tooth paste that would retain a stiff dough-like consistency. He has been much annoyed by the syrup floating up from the paste and staining the paper strip placed round the pot.

[512]. Can any of your readers inform me the best method of disguising the taste of turpentine, creasote, and aloes Bbd. when given in draught to animals?

APPRENTICE.

[513]. MIST. GENTIAN. CO. CONC. (1 to 7).—Could any of your correspondents inform me how Mist. Gentian. Co. Conc., 1 to 7, can be made so as to represent the B. P. preparation when diluted? I confess I am at a loss to know, as by calculation I find it should really be made with rectified spirit; and if that is so how could that represent on dilution the almost aqueous preparation of the Pharmacopœia in vegetable extractive?

The above remarks are occasioned by noticing quoted in some wholesale lists the above-named preparation, but one has only to see the price affixed to suspect that the manufacturers ignore altogether the spirit ordered in the B. P. It is that which imparts to it its pleasant cordial character, and which makes it more esteemed by some medical men than the infusion.

I trust these observations may be of use to some who are in the habit of using concentrated preparations, and who accept everything from their "pet" house as "all square."

J. J. SMITH.

Walton, Liverpool.

[514]. CONCENTRATED LIQUORS.—"Saccharum" asks for the formulas for making liquors for syrups, which when added to cold simple syrup, by measure, in the proportion of one part of the liquor to seven of syrup, form full-flavoured syrups of the same strength and colour as produced by the B. P. process. They are extensively used for preparing Syrup. Aurantii, Croci, Ferri Phosph., Papaveris Alb., Rhamni, Rhei, Rhœados, and Tolu. He would also like the recipe for preparing Liq. Ferri Iodidi, 1 to 12, Liq. Ferri Superphosph, 1 to 4, and Liq. Violæ, 1 to 15.

THE ADMISSION OF WOMEN TO THE SOCIETY.

Sir,—Being one of the first to open the discussion of this vexed question in your columns some months ago, perhaps, before entirely closing it and committing to the limbo of the past the vision of the equality of the sexes so zealously propounded by some, you will permit me space for reply to a few of the arguments brought forward in its favour. It is almost impossible to discuss the question seriously, as witness the shouts of laughter which hailed Mr. Hampson's announcement at the annual meeting, that it would be advantageous to bring lady pharmacists under the "moral restraint" of the Society. In common with others I was at a loss at the time to understand the meaning of the phrase, not having the privilege of knowing any of these fair dealers in drugs, until the letter of "Annie, M.P.S.," threw a ray of light upon the possibility of some needed restraint, though what and how to be exercised did not appear so clearly. Perhaps the grave gentleman on the Council who went out of his way to criticise adversely your wisdom in inserting the letter can furnish some clue. By the way, Mr. Editor, there are others besides myself (*vide* Mr. Linford's letter, p. 1038) who think the article a "pleasant little skit," and would like to see a few more like it to enliven the otherwise dull and dry details of pharmacy. Such lively satires on the follies of the age were less rare in the days of the late Jacob Bell, as any one may see on consulting the early series of the Journal, where the prescribing of infinitesimal doses is, among other things, held up to deserved ridicule.

But to return to the present pet fallacy of some otherwise sound minds, the supposed equality of the sexes. Were such actually the case, where would be the use of certain natural distinctions which cannot be denied, and a sound popular opinion only can decide where are the limits to which each sex should go in the discharge of its functions. It is not, as some assert, a matter of abstract right to be settled off hand on the narrow limits of individual merit, but it is a matter of expediency for the good of the whole community, whether certain duties, amongst others those of elective and administrative power, should continue to be exercised by the stronger sex, for the benefit of their weaker partners as well as themselves, or whether the power should be thrown hap-hazard into the whole community, to be used by all those who desire to come forward and claim it as a right. Let us examine the latter design. All are to have equal rights. Children must then have all they call for, uncontrolled by those who are better able to judge for them, and, in order to make everything just and equal, women, having a voice in the legislature, must also be willing to serve in the maintenance of order and good government in the police and military and naval service of the country. In fact the whole fabric of society would be overturned, and all the charms of womankind, as such, would be lost to mankind, and instead thereof would grow a race of blue stockings anxious only to rival those for whom Providence had designed them as kind and faithful help-meets. Each sex is at present superior in its sphere to the other; but any attempt to apply to them laws of equality in all things must signally fail. The laws of the realm wisely recognize this fact, and grant to woman protective enactments which are not needed by her stronger partner in life. Such laws have worked well in the past, and it is not worth while, unless by the common voice of the women of the country a different state of things is de-

manded, to go out of our way to grant them rights and privileges for which the sex as a rule is not adapted. True, they might be educated up to it, but would it not be to a great extent to the detriment of their better nature?

For these reasons I have opposed, and must continue to oppose, any attempt to place women on a dead level of equality with man, and this is what I understand by the proposition of Messrs. Hampson, Wade, and Co. Let us examine the reasons some of them give for the admission of women into our Society. I have already noticed Mr. Hampson's plea for "moral restraint," and will conclude by noticing a very plausible argument adopted by some, as I fear I may have already almost transgressed the limits of a reply. In your columns for July 6, p. 20, "Vir" thinks that because the Society admits women to its examinations, it must logically go a step further and elect them as members. But surely there he makes a great mistake, for the examining board is bound by law to admit all who come to its ordeal, and the examiners' certificate is the legal qualification for entering the business of a chemist and druggist, but that is no reason why an individual applying for membership in the Society should be elected irrespective of proper qualification, and I must maintain that the female sex is quite a sufficient disqualification for election to all the rights and privileges of a society hitherto composed exclusively of males. We may by courtesy allow them the free use of the museum, library, etc., but that is all which they can in reason expect. Surely it is no more discourteous to say that ladies are not likely to make good legislators than that gentlemen are unlikely to perform to satisfaction the duties of housekeeping, and either proposition may be proved without difficulty from historical fact and physiological reason.

CHARLES FRYER.

Scarlorough, July 15, 1878.

THE REMOVAL OF SWANSEA FROM THE LIST OF CENTRES.

Sir,—The letter of "Fair Play," in the last issue of the *Pharmaceutical Journal* in reference to the above, will, I have no doubt, be approved by all chemists in Swansea and district.

Is there no explanation given beyond the lame one of "railway facilities"? Another reason was that the centres must now be confined to large business towns, such as Liverpool, etc. Surely the President has never been to South Wales! Mr. Schacht might really have put in a word for Swansea as well as Aberystwith. Cardiff, in South Wales, is not considered of more importance than Swansea, in a business point of view, consequently why cancel the name of the latter from the list? Concerning irregularities, if that be the true reason, I will not say another word, as if I am rightly informed, owing to the similarity of the answers of some of the candidates at recent examinations, the Secretary was communicated with respecting it.

If this be the case, why not appoint another local secretary? We have in Swansea, as "Fair Play" says, many good men who would, I daresay, undertake the arduous (?) duties.

Such revolutionary measures passed by our Council must tend to bring about dissatisfaction among members of our profession, and the only remedy is to bear this among other acts of theirs in mind (notably that of the exclusion of reporters to the Council meetings) at the next election.

ANTACID.

CUI BONO?

Sir,—Allow me to express my surprise and chagrin, when, on looking over the list of newly appointed centres for the Preliminary examination, I found Boston was omitted. Surely the Society does not consider that in so large a county as Lincolnshire, one centre is sufficient. Under the present arrangement, candidates from here will have to go either to Lincoln or Peterborough, a distance of thirty miles at least, so that with railway fares and refreshment, ten shillings will be allowed as a very moderate estimate of the expense, not the only thing to be considered.

The number of presentations at Boston was certainly one proof of its favourable situation, for so it appers to

W. K., A BOSTON APPRENTICE.

Boston, July 22, 1878.

PATENT MEDICINES.

Sir,—Mr. Byatt Walker's letter is to the point and very good. If pharmacists would unite together and adopt the course suggested, union would indeed be strength, and I believe that if this plan was generally adopted by chemists, it would soon show a perceptible result.

The very fact of all these "inventors" coming to the chemist and being so anxions to get him to introduce an push the sale of their inventions, proves what a power lies in the hand of the chemist. Only induce chemists to persuade the public that their remedies are "the thing," and more than half the battle is won for the proprietor, but not for the chemist. The "sole agent for this district" finds that he has helped to establish a sale for an article which, now that the public are assured by their chemist is "a really good thing," they naturally go to the cheapest shop and buy, and the unfortunate chemist after spending money, experience, and energy in making the article "go," finds that he is left in the lurch. It is a question for the pharmacist to consider how he can protect his own interests.

So long as we have free trade, competition will exist, b I look upon the supply of patent medicines containing poisons in another light. Some time ago, the Government of this country considered it essential to sanction a Poisons Act, and not long ago they endeavoured to enforce strict regulations for the safe-keeping and storage of poisons, and this, in the interests of, and for the safety of the public; and while the public are flattering themselves that they are so carefully protected, any illiterate person who chooses to pay 5*s.* per annum, and use Inland Revenue labels, can ignore either the Pharmacy or Medical Acts. It is for the public to consider whether they possess the protection that they imagine they do, and for the trade to endeavour to set matters right.

J. B. PAYNE.

Manchester, July 20, 1878.

VIOLET POWDER.

Sir,—At the present time, when so much attention is directed to the preparation called violet powder, it may not be amiss to make a few observations on the subject.

It appears in the minds of some that terra alba or sulphate of lime is a very injurious article to use as a nursery powder. I fancy it cannot be known to many of the present day that the common article used in the nursery as a dusting powder for infants, forty years ago (and in some districts to the present day), was carbonate or white lead, also the impure oxide of zinc or lapis calaminaris. Now this latter article as commonly met with in shops is terra alba or sulphate of lime coloured to represent lapis calaminaris; consequently as that was the principal article used in the nursery before violet powder was introduced, it cannot be very injurious, as most of the cheap kinds of nursery powder called violet powder for the nursery are the same article which has been used for ages, but free from colouring matter.

ONE OF THE OLD SCHOOL.

R. Modlen.—We are unable to give you the information; perhaps if you were to apply to Mr. Oldridge you might be more successful.

S. M. Dalton points out that in the 'British Pharmacopœia,' followed by other works, it is stated that syrup of iodide of iron contains 4½ grains of iodide of iron in each fluid drachm, whereas a calculation based upon the B.P. proportions shows that it should contain upwards of 4·6 per cent.

T. Bodley.—Gurgun balsam.

T. Leicester.—Your advertisement should have been sent to Messrs. Churchill, 11, New Burlington Street.

W. H. L.—If the operation is on a small scale one of the cheap household dyes could be used.

E. F.—We cannot supply legal advice; you are recommended to consult a solicitor.

"*Apprentice*" and *W. M.* are referred to the rule respecting anonymous communications.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Collier, Mr. Young, Mr. Roberts, Mr. Welborn, Mr. Wilkinson, Mr. Grant, Mr. Haydon, Mr. Proctor, Mr. Blissett, Mr. Urwick, Alpha, J. H. W.

A DRYING CLOSET.

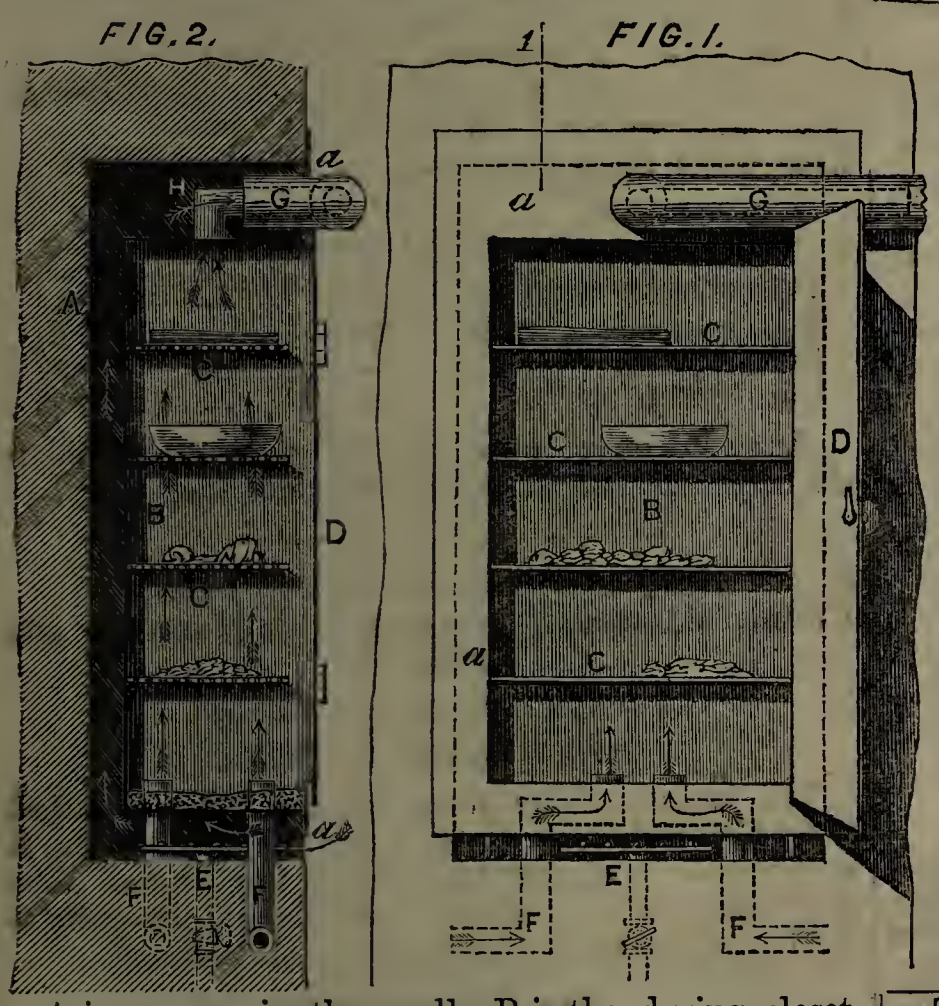
BY T. EDWARD GREENISH.

One of the most useful appliances in a well appointed pharmacy is a drying closet, it may indeed be considered an essential requisite, yet how very seldom does any such provision exist at all adequate to the requirements of the pharmacist.

The one of which the annexed is a sketch most fully answers its intended purpose; it is scarcely possible to conceive a more simple yet efficient apparatus, always ready for use, requiring little, if any, attention, and at the same time very economical as regards the source of heat.

Possessing some points in its construction of a somewhat novel character, it has been thought that a detailed description of it in the *Pharmaceutical Journal* would prove useful to those who may be looking for practical hints in this direction.

Fig. 1 is a front view of the drying closet with the door open. Fig. 2 is a transverse vertical section of the same, taken in the line 1, 2 of fig 1.



A is a recess in the wall; B is the drying closet made of thin sheet iron, and provided with wire shelves, C, and a door, D. This closet is made of such a size that when fixed into the recess in the wall a space of about two inches is left at the back and sides, and also at the top, in fact all round the closet, the space being covered in front by the flange, *a a*, formed in the front of the closet. E is a gas burner supplied from the pipe *e*, and F F are two air pipes, which enter the bottom of the closet, B; these pipes draw their supply from the air *external* to the laboratory, and their upper ends are surrounded by a layer of sand forming a sand-bath two inches deep. The gas being lighted is supplied with air from the front, and the heated air, together with the products of combustion, pass round the closet through openings made for that purpose in the sides and back of the gas chamber, up the space between the closet and the wall to a pipe, G, and thence to a chimney.

The articles to be dried or evaporated are placed either upon the shelves in the closet, or upon the sand-bath at its bottom, according to the degree of heat that may be thought desirable. The air which enters by the pipes F F, slightly warmed by the sand, will carry up any vapour therefrom to a pipe, H, at the top of the closet, and thence to the pipe G. In order to regulate the draught of air at the back and sides of the closet, and thereby to adjust the degree of heat, the pipe G is provided with a circular damper, and the gas chamber also has in front of it an arrangement for regulating the supply of air to the gas, thus preventing sudden fluctuations of temperature. By these means the heat of the closet may be adjusted to the greatest nicety.

It will be observed that the closet is heated by gas, which, as a source of heat for this purpose, possesses advantages over any other. It is always ready to hand, continuous, and can be regulated to any required temperature.

The gas, being lighted, heats the sand-bath immediately over the jets; part of the heat, passing through the openings in either side and back of the gas chamber, fills the space all round between the closet and wall, the products of combustion, escaping by the flue G into the chimney, cannot by any possibility come into contact with the contents of the closet.

It is considered *essential* to a good drying closet that it should receive an ample and continuous supply of fresh air; that of the room where laboratory operations are conducted is not suited for this purpose, being at one time contaminated with noxious gases, at another, saturated with moisture from the evaporating pan, the still, or the condenser, and always more or less filled with the dust from ground or powdered drugs. The two air tubes, F F, derive their supply from the atmosphere *outside* the building, and have no connection with the laboratory, so that when the air-tight door of the closet is closed its contents are perfectly protected from contamination whilst the drying process is in operation. These tubes pass through the gas chamber, from which they derive some heat, and as soon as they enter the sand bend at right angles, and for six inches or so traverse the hot sand; another bend upwards enables them to deliver their supply of air, fresh, and to a certain extent warmed in its passage through about ten inches of heated tube.

The moisture from the material in the course of being dried is carried off by the tube H at the top of the closet; this tube enters the gas chimney, and is carried for some distance through its interior. By this arrangement the heat of the chamber external to the closet, on its passage into the chimney, warms the interior tube, and thus contributes to the required draught.

There are four movable shelves, each made of wire, in the form of a shallow dish, and others of sheet iron, to take their place when desired. The temperature of each shelf differs; if, for instance, the one at the top be 82°, the second will be 85°, the third, 88°, the lower one 92°, whilst the sand-bath will show about 130° Fahr.

The closet may be maintained, with a very trifling variation, at the same temperature for any length of time, day and night, without requiring special attention, and the constant supply of fresh air, warmed as it enters, necessarily facilitates the drying process. Of course, extra heat can be applied, when the sand-

bath, together with the different shelves, will show a relatively elevated temperature. Under ordinary circumstances, such as those enumerated above, the consumption of gas is scarcely appreciable.

It can scarcely be necessary to advert to the varied uses of such a closet in connection with the laboratory. Where the principles on which successful percolation depends are thoroughly understood, the uniform condition of the powder to be operated on is fully recognized, and the pretty equal dryness of the several ingredients is almost essential to such a grinding as will suit a sieve of the required mesh. An extract a little softer than the pilular form may at a very low temperature be reduced to the required consistence.

Precipitates are rapidly dried. Ergot, so tough in the condition usually met with in commerce, is readily dried, and crisped for the mill, at only a summer temperature, and without detriment to its active constituents, whatever they may be. In fact, to pass in review its applicability would require a detailed notice of the materia medica, and an allusion to most of the preparations of the British Pharmacopœia.

In studying the development and progress of the yeast cell in beer, the definite and well regulated temperature of the closet has been found very efficient, and lastly, but by no means its least important use, is in offering a ready and available source of heat for the drying and finishing of specimens of materia medica illustrative of the use of the microscope in pharmacy.

The dimensions of the drying closet are thirty-one inches high, sixteen inches wide, and twelve and a half inches deep. It occupies a recess in the wall where once stood a cupboard, the size therefore was a matter of necessity, yet had it been one of choice, it could scarcely have been better suited to the daily requirements of a moderate pharmacy. The instructions were intelligently carried out by Mr. Glew, 10, Museum Street, Holborn.

GNOSCOPINE.

BY T. AND H. SMITH.

In the mother liquors from the purification of narceine we have now repeatedly met with a crystalline body, which, distinguished at first from the principles more generally met with in opium by its melting point and its slight solubility in spirit, was, upon closer examination, ascertained to be a hitherto unknown alkaloid, and which we have named Gnoscopine.

This principle is characterized by forming readily crystallizable salts, which have an acid reaction. That its salts possess this reaction, as also the fact that gnoscopine is quite insoluble in water and in alkalies, marks its strong resemblance to the papaverine group. Hence, also, it is easily separated from narceine, which is moderately soluble in boiling water, and freely so in alkalies.

Gnoscopine when pure (after being repeatedly crystallized from boiling spirit) forms long thin white needles, having a woolly character when dried. It is soluble in 1500 parts of cold spirit. It melts at 233° C., decomposing, however, at the same time, and burning with a smoky flame, leaves a skeleton of charcoal that burns entirely away at a high temperature. It forms a muriate which crystallizes in glassy prisms, apparently containing water of crystallization, which is lost at a moderate heat. A solution of this salt gives a buff-coloured crystalline precipitate with platino chloride of potassium, and a white precipitate with iodide of mercury and potassium. In pure sulphuric acid, gnoscopine dissolves with a slightly yellow colour, which becomes at once carmine-red upon the addition of a trace of nitric acid, and remains so. In this respect gnoscopine differs from rhœadine, which assumes this red colour upon the addition either of sulphuric or hydrochloric acid alone. Gnoscopine is insoluble either in aqueous or in spirituous solutions of caustic soda, also in mineral spirit, and in fousel oil, but is soluble in chloroform and bisulphide of carbon and slightly so in benzole.

According to the following analyses, the formula of gnoscopine is $C_{34}H_{36}N_2O_{11}$:—

(*a*)	Weight of substance taken	0·2840	gramme.
	,, ,, H_2O obtained	=0·1455	,,
	,, ,, CO_2 ,,	=0·6565	,,

A specimen of pure crystals of this alkaloid is shown in our case at the Paris Exhibition.

THE PARIS EXHIBITION.

CRUDE MATERIALS APPLICABLE IN MEDICINE AND PHARMACY.

FRENCH COLONIES—*continued.*

French Colonies in India.

The products from these colonies being identical almost entirely with those in the English section, it will not be necessary to describe them here. The specimens are in excellent condition and are quite as well arranged as those from the other colonies.

The Isle of Réunion.

A large number of specimens are exhibited from this colony, some of which, as might be expected from its geographical position, occur also in the Indian collection, and others in South Africa, a few being peculiar to the group of islands to which Réunion belongs.

One of the most important vegetable products of this island is vanilla. During the last thirty years the cultivation has considerably increased. In 1849, only 3 kilogrammes were exported from the island, but in 1876 the exports amounted to 27,759 kilogrammes, while the price has fallen from 500 francs to 32 francs the kilogramme. Fine qualities still command from 80 to 90 francs.

A hectare of land planted with vanilla contains about 5000 plants. The cultivation at first proved by no means easy, for the plants greatly exhaust the soil, taking from it in seven years about 932 kilogrammes of potassium and 1350 kilogrammes of phosphoric acid, besides salts of lime and magnesia. The want

of these salts and a too prolonged artificial fertility at first weakened the plants very much, so that they frequently presented symptoms of blanching followed by the presence of destructive parasites, such as *Bacterium putredinis*, and the cuttings intended for new plantations were often attacked before bearing fruit. To meet this difficulty fresh plants were obtained from Mexico, appropriate manure was used and a plan of pruning adopted, so that the plantations now present a more healthy appearance and produce freely. The method of pruning followed consists in cutting off the old branches below the lowest shoot which yielded fruit, so that the plant has not the burden of nourishing parts already exhausted.

The leaves and fruits of another orchidaceous plant, which has an odour somewhat resembling vanilla, but more like that of tonka bean, are also exhibited. This plant is the Faham (*Angræcum fragrans*) which is very abundant in the island.

Specimens of the bark of four species of cinchona, *C. Calisaya*, *C. succirubra*, *C. officinalis*, and *C. lancifolia* are exhibited. The cultivation, according to the report for 1876, is encouraging, as there were at that date 846 plants in healthy growth, besides 2410 young plants in pots and in the nurseries, grown from seeds of the best and strongest trees in cultivation in the island.

Of the well-known drugs exhibited by this colony may be mentioned sarsaparilla, Indian hemp, stramonium, fennel, patchouli, turmeric, croton and castor oil seeds, cloves, tamarinds and citronelle. Among common Indian remedies are noticeable Indian liquorice, mango seeds, ayapana, vetiver, guava bark, ben nuts (*Moringa pterygosperma*), *Hydrocotyle asiatica*, the barks of *Michelia Champaca* and *Melia Azedarach*, the fruits and leaves of *Adansonia digitata*, the seeds of *Jatropha Curcas* and *J. multifida*, and the leaves of *Tylophora asthmatica*. The other drugs which appear to be worthy of notice are as follows:—

Ambora tamburissa (Monimiaceæ). Bark emmenagogue.

Agathophyllum aromaticum. The pulp of the fruit is used as a stimulant. The seed is the Ravensara nut or Madagascar clove nutmeg.

Antirrhœa verticillata (Cinchonaceæ). For restraining hæmorrhages and mucous discharges.

Carissa xylopicron (Apocynaceæ). Febrifuge and vermifuge. Used also by the Creoles for diseases of the urinary organs.

Clematis mauritiana (Ranunculaceæ). A powerful vesicant in the fresh state.

Cookia anisetta (Aurantiaceæ). The leaves are used as an antispasmodic.

Equisetum elongatum. This plant is said to be a powerful diuretic.

Euphorbia hypericifolia. Used for dysentery and hæmorrhage from the bowels.

Gendarussa vulgaris (Acanthaceæ). Possesses emetic and resolvent properties. The French name of the plant is given as "patchouly," probably from the odour of the leaves, as they are narrower in shape than those of the patchouly plant (*Pogostemon patchouli*). The plant is also used in India to reduce swelling of the joints in chronic rheumatism.

Ipomœa angulata (Convolvulaceæ). Purgative.

Kyllingia brevifolia (Cyperaceæ). Astringent.

Mussœnda arcuata (Cinchonaceæ). Leaves and stems used as a febrifuge.

Myonima myrtifolia (Cinchonaceæ). Leaves used for the itch.

Ochrosia borbonica (Apocynaceæ). The leaves and bark are said to be tonic and febrifuge. The bark seems exactly similar in appearance to the Mongumo bark from Madagascar, which appeared in the London market a few months since.

Oxalis corniculata (Oxalidaceæ). This common European weed is used as an antiscorbutic.

Polypodium viridulum (Filices). For dysentery.

Polygonum serratum (Polygonaceæ). Astringent.

Parthenium Hysterophorus (Compositæ). Under the name of "camomile," it is said to be used as an astringent.

Quivisia ovata (Meliaceæ). An infusion of the bark is emmenagogue.

Rubus borbonica (Rosaceæ). The wood bark and leaves are astringent.

Siegesbeckia orientalis (Compositæ). The leaves are employed for cleansing and healing wounds, and from its French names "guérit vite" and "herbe divine" must be held in some estimation.

Secamone emetica (Asclepiadaceæ). Under the name of Scammonée du Bourbon it is used as an emetic and as a remedy for dysentery.

Sarcostemma mauritiana (Ascepiadaceæ). Used to stop bleeding from the uterus.

Sideroxylon borbonicum (Sapotaceæ). The bark is tonic and purgative.

Senacia undulata (Celastrineæ). Leaves used to restrain mucous discharges.

Toddalia paniculata (Rutaceæ). The leaves and bark are bitter and febrifuge.

Terminalia mauritiana (Combretaceæ). The bark possesses astringent, sudorific, and purifying properties.

Weinmannia macrostachya (Saxifragaceæ). Astringent.

Visitors to this department should not leave it without a glance at the eggs of the epiornis of Madagascar. Two specimens are shown but neither of them quite perfect. The enormous size of these eggs quite dwarfs by comparison those of the ostrich.

The Isle of Saint Mary.

Only three specimens of pharmaceutical interest are exhibited from this small island.

"Quinquina de Madagascar," a bark considered by the natives to be febrifuge, and supposed to be produced by a species of *Gaertnera*, *Tanghinia venenifera*, the (ordeal bean of Madagascar), and an aromatic bark called "avoso," the botanical source of which is unknown.

The Isle of Nossi-bé.

From this small island are exhibited fine specimens of Orcella weed (*Roccella Montagnei*), which grows abundantly upon trees. Also Tacamahac resin (*Calophyllum Tacamahaca*), and Elemi (*Canarium commune*).

Tahiti.

The exhibits of crude drugs from this island are very few, and include—

Piper methysticum (Kawa kawa). The root is used in gonorrhœa. It is capable of yielding a large quantity of alcohol.

"*Napata*." The botanical source of this drug is unknown. The bark after the removal of the epiderm is pounded and used as an application to wounds; it is said to ease the pain immediately, and promote a rapid cicatrisation.

"Paketa" or "Pahuan." Another drug possessing similar properties.

Tahiti arrowroot (*Tacca pinnatifida*), the fragrant bark of *Alyxia stellata*, smelling like tonka bean, yellow sandal wood (*Santalum insulare*), and vanilla are also among the exhibits.

New Caledonia.

A very fine series of minerals containing nickel are exhibited from this colony, but the number of crude drugs is rather small. Of these the following are worthy of notice:—

Barringtonia neo-Caledonica. The fruits of this species are used to intoxicate fish.

Calophyllum inophyllum (Clusiaceæ). The resin is used in the treatment of ulcers, and enters into the composition of stimulant plasters.

Dammara Cookei and *D. ovata.* These trees yield a resin, like kauri gum, the essential oil obtained from which is used for rheumatism, and to preserve anatomical preparations.

Fontainea Pancheri (Euphorbiaceæ). The oil has similar properties to croton oil.

Melaleuca viridiflora (Myrtaceæ). The leaves yield an oil similar to cajeput.

Polyporus betulinus (Fungi). Used as a substitute for amadou.

Santalum austro-caledonicum. Some specimens of this sandal wood are exhibited. It is now becoming very scarce.

Some fine specimens of the curious Jew's ear fungus (*Exidia* sp.) are exhibited in this collection. They are said to be exported to China for food in considerable quantities.

Algeria.

The products of this country are located in the large white building devoted to Algerian exhibits, near the right hand end of the Trocadero Palace.

The drugs, tanning, and dyeing substances are arranged together, the greater proportion of specimens consisting of tanning materials, which are very varied in character and botanical source.

A few drugs which one naturally associates with the north of Africa are well represented, such as colocynth, squills, and pellitory of Spain; *Eucalyptus globulus* and *Thapsia silphium* also occupy a conspicuous position, but of these the exhibits consist almost entirely of pharmaceutical or chemical preparations, and therefore will be described under those groups. A curious slender variety of ergot (called "ergot du diss") obtained from *Ampelodesmus* (*Arundo*) *tenax* (Graminaceæ), was observed nowhere else in the exhibition. According to M. Lallemant, the exhibitor, this ergot possesses properties identical with the ergot of rye, and is used in the same doses, but has the advantage of being less attacked by insects and is easily preserved. The ergot is from 3 to 9 centim. long, and from 2 to $2\frac{1}{2}$ millim. in diameter, a little flattened, rarely cylindrical. It is blunt at one end and pointed at the other, and somewhat gyrose; the colour is a blackish-brown, and the powder is of a greenish-brown or dirty greyish-yellow. The polished appearance and more slender character are its most striking features.

The chief exhibitors of drugs are, MM. Dyanne and Lallemant, of L'Arba, near Algiers.

The catalogue which has been published is not only difficult to obtain in the building, but when obtained presents an unfavourable contrast to that of the other French colonies, in that it contains no information about the drugs exhibited, several of which are not well known. A few, such as tamarisk galls, sanguinaire or thé arabe* (*Paronychia argentea*), called "lataie" by the natives, and *Atractylis gummifera*, have only recently been described in this Journal. Others are well-known plants or plantproducts, such as the lemon-scented verbena, borage, *Adiantum Capillus-Veneris*, *Asplenium Trichomanes* and *Asplenium Adiantum-nigrum*, fumitory (*F. parviflora* and *F. capreolata*), *Anthyllis vulneraria*, *Euphorbia helioscopia*, *Senebiera Coronopus*, *Rumex pulcher* (root), *Centranthus ruber* (root), *Juncus acutus* (flowering tops) *Erythræa Centaurium*, *Rubus discolor* (fruit), *Mercurialis annua*, *Oxalis corniculata*, *Chenopodium ambrosioides*, *Asperula Cynanchica*, *Lythrum Salicaria*, *Mentha Pulegium*, *Hypericum perforatum*, *Chamærops humilis* (root), *Salvia officinalis*, hawthorn flowers, *Glaucium luteum*, *Vinca major*, *Globularia Alypum*, *Coriaria myrtifolia*, *Equisetum variegatum*, *Erysimum officinale*.

A few others are Algerian plants which take the place of better known European species. Thus for *Calendula officinalis*, *C. algeriensis* appears, and *Anthemis fuscata* replaces *A. nobilis.* *Thymus numidica*, *Cynoglossum pictum*, *Origanum glandulosum*, and *O. floribundum*, *Artemisia arborea*, *Parietaria mauritanica*, *Ptychotis verticillatum*, *Juniperus phœnicea*, and *Ajuga iva* are other instances of the same kind.

Those which are less known and are especially characteristic of this colony are the leaves of *Xanthium strumarium*, the seeds of *Adonis æstivalis*, tubercules of *Asphodelus ramosus*, roots of the cardoon (*Cynara Cardunculus*) used by the natives in chest complaints, leaves of *Psoralea bituminosa*, herb of *Chlora grandiflora*, leaves of *Rhamnus Alaternus*, leaves and pods of *Anagyris fœtida*, reputed to be as poisonous as laburnum, leaves of *Lavatera mauritanica*, and *L. trimestris*, *Origanum glandulose*, *Centaurea algeriensis*, root of *Arisarum vulgare*, and of the dwarf palm (*Chamœrops humilis*).

Long aniseed, like that from Alicant, linseed, and castor oil seed (the latter in great variety), and some rather pale-coloured saffron are also exhibited.

El Chikh is a kind of wormwood, *Artemisia Argonensis*, Lam. (*A. herba-alba* Asso), a plant growing on the high plateaux of Algeria and much employed by the natives as a tonic, aperient and vermifuge. According to M. Lallemant the plant is nearly allied to *Artemisia Contra*, L., and has a little of the odour and taste of Santonica and might replace that drug. He has not, however, been able to obtain santonin from it, but only a colourless essential oil, which oxidizes with great rapidity.

The bark of *Eucalyptus globulus*, and of the olive tree, and pods of *Cassia obovata* are also among the exhibits. One very singular production, the curious curled up fronds of an edible lichen *Lecanora esculenta*, is interesting on account of being supposed by some to be the manna of the Scriptures. This lichen is said to be blown about into heaps by the winds in Algeria (as well as in Armenia), and the natives are said to grind it up with corn in times of scarcity. It cannot, however, be very nourishing since 66 per cent. of the lichen consists of oxalate of lime.

AUSTRALIAN COLONIES.

Queensland.

The exhibits of drugs in the Queensland court are but few in number and are mostly sent from the

* *Pharm. Journ.* (3), vol. viii., p. 521.

Botanical Gardens at Brisbane by Mr. W. Hill. The department containing the specimens is decorated with numerous pictures and photographs, illustrative of the character of the country, its vegetation, and its geological formations, etc. A large number of minerals, including some fine specimens of tin ore and metallic tin and antimony form conspicuous objects. The following drugs are worthy of notice—

Alstonia constricta (Apocynaceæ). This bark, known as Queensland fever bark, is used in the colony with considerable success as a remedy for fevers.

Araucaria Bidwillii (Coniferæ). Bunya-bunya gum, a clear transparent resin.

Callitris columellaris (Coniferæ). The resin from this tree resembles sandarac.

Eucalyptus botryoides (Myrtaceæ). The essential oil is used in putrid fevers and fetid ulcerations.

Eucalyptus species. The essential oil derived from this tree, the "scented iron bark" of the Palmer river, is said to be the most powerful and agreeable perfume derived from any species of Eucalyptus. It has an odour resembling verbena.

Eucalyptus corymbosa and *E. fibrosa*. The astringent gums of these plants are used, the latter for diarrhœa, the former in tanning.

Petalostigma quadriloculare. Crab tree bark is considered to possess the same properties as Peruvian bark. It is a very powerful bitter.

Pituri. A small specimen of this singular drug is exhibited. It has already been described in this Journal.

Sterculia rupestris. This gum somewhat resembles tragacanth. It exudes from the tree in large quantities.

Xanthorrhœa arborea (Liliaceæ). Grass-tree gum, better known in this country as gum acaroides, is a fragrant balsamic resin containing cinnamic acid. It has been used for fumigation, for making sealing wax, and as a yellow dye for calico. Acted upon by nitric acid it yields a large quantity of picric acid.

Several barks, such as those of *Eucalyptus sideroplhoria, Brugniera Rheedii, Acacia mollissima, and A. decurrens*, are exhibited as tanning materials. The dried bark of the latter is stated to contain from 18 to 33 per cent. of tannin. Specimens of tamarind, quassia, tapioca, castor oil, croton oil, senna (*Cassia acutifolia*), gelsemium, oil of orange, lime juice, and arnatto, show what it is possible to cultivate in this colony. Specimens of Dugong oil may also be seen here.

Arrowroot is exhibited by several firms and appears to be of good quality. It is cultivated with success in various parts of the colony, and the supply having already exceeded the demand, the surplus is sent to the southern colonies. The average yield appears to be about 2½ tons per acre. At present there are thirty plantations in the colony, of which nine-tenths are in the Logan district. First-class samples of arrowroot are sold in quantity at about two to threepence per pound. In some places the root is used as pig food.

Various specimens of tobacco are also exhibited. The culture is said to have proved a very profitable occupation and the cultivation of the best qualities has become general.

The stones of the fruit of *Elæocarpus grandis* look very like the quandang stones of Southern Australia, but are browner in colour, and are used in the same way for necklaces, etc.

South Australia.

In this colony flax has been cultivated with considerable success, but apparently only for fibre and not for seed, as no linseed is exhibited. Almond trees also grow well and although almonds of superior quality are gathered yearly for home consumption and for shipment, they do not appear to have been used as yet for making oil.

The olive is, however, successfully and profitably cultivated; some samples of olive oil exhibited from this colony will compare favourably with the finest specimens from Europe, both in colour, brightness, and flavour, but the whole of it is hence eagerly bought up in the local market.

Great Britain.

Although the exhibits of chemicals from this country are numerous, there is only one case of crude drugs to be seen. The articles exhibited include among other articles some fine specimens of tragacanth, star-anise, asafœtida, guaiacum in the tear, calabar beans, cascarilla bark and calumba root. All the specimens are evidently carefully selected and do credit to the firm that exhibits them, Messrs. Baiss Brothers, of London. A number of powdered drugs are also exhibited by the same firm.

Messrs. Gidney Clark and Co., of London, exhibit a very fine and tastefully arranged collection of resins used in varnish making, some of the specimens being exceedingly handsome. They include kauri gum, zanzibar anime, dammar, and copals from Angola, Benguela, Sierra Leone, and Manila.

Canada.

Mr. W. Saunders of London, Ontario, exhibits a collection of crude drugs. The specimens are small, but carefully selected, and are each labelled very neatly with the name, botanical name, synonyms, and uses.

At the time of our visit the Canada trophy was still unfinished, so that many interesting articles, such as is inglass, etc., must be left unnoticed for the present.

There is also in this department a very fine collection of dried plants of Canada, containing a large number of excellent specimens carefully dried, and including many medicinal plants.

Cape of Good Hope.

The drugs from this colony are very few in number and badly arranged. Cape aloes, long Buchu (*Barosma serrulata*) and bush tea (*Cyclopia genistoides*) only were noticeable. The latter is used in the form of tea for chronic cough and consumption. The smell of the leaves is agreeable, and the taste sweet and astringent. A large cylinder of pith close by, labelled "Tambookie pith" looks as though it would answer as well as elder pith for microscopical purposes. Some very pretty water-colour drawings of Cape flowers are exhibited by Miss A. Maclean, of Mowbray, near Cape Town, and are quite an ornament to this department.

Jamaica.

The exhibits from this island are very few and poor, considering the immense number of medicinal plants which grow wild, or are cultivated in the

island. Among those noticed were jalap, capsicum, gum of the casheu nut tree, ben nuts, the bark of *Cinchona Calisaya*, *C. officinalis*, and *C. succirubra*, sand-box seeds (*Hura crepitans*), cacoon seeds (*Feuillea cordifolia*) and *Aleurites triloba* ; all of which yield oils, and the curious seeds of *Mucuna urens*, already mentioned under French Guiana, p. 23, conclude the list of drugs visible in the case in which the objects were exposed, but a catalogue not being procurable, it is not possible to say whether this list is a complete one.

British Guiana.

The drugs from this colony are contributed chiefly by Mr. W. Fresson of Demerara. Most of them are well-known drugs, and include castor oil seeds, which are said to be produced abundantly and spontaneously, castor oil, bay rum, locust tree gum or Brazilian copal, liquid honey, balsam of copaiba, isinglass, tamarinds, simarouba bark, tonquin beans and wourari poison. The specimen of the latter is the kind which is imported in small earthenware cups. The balsam of copaiba exhibited is of a pale colour, rather fluid, and not quite clear. It resembles a specimen in the museum of the Society which was obtained from *Copaifera trapezifolia*. The isinglass is the usual kind of the peculiar torpedo shape usually imported from South America, and is the swimming bladder of the *Silurus Parkerii*. Of starches, tous les mois, tapioca starch and the starch from the seeds of the greenheart tree are exhibited by Mr. Fresson. The latter starch has a bitter taste and is said to have a tonic action in consequence. The liquid honey, slightly acid in taste, is the products of a small stingless bee, a species of *Trigona*, which deposits its honey in separate rounded pouches.

Less known is the crab oil, from the seeds of *Carapa guianensis*, highly esteemed as hair oil and used also as a lamp oil in the colony. In this country it is almost solid. It is also used in skin diseases of animals. Laurel oil, supposed to be obtained from *Oreodaphne opifera* is used by the natives in rheumatism. It is an excellent solvent of indiarubber. It is said to be obtained by boring a hole with an auger to the core of the tree, when the oil flows out and is collected in a basin, and is perfectly clear and fit for use. The oil is said also to be a cure for certain liver complaints. The seeds of the tree are used medicinally with surprising effect in obstinate fevers. The tree is said to be abundant on the lower part of the Orinoco River, but neither flowers nor leaves have yet been procured from the Indians, and its botanical name is therefore only a matter of conjecture.

A fine specimen of balata, a kind of gutta percha supposed to be produced by *Sapota Mulleri*, Miq., is exhibited by Mr. Fresson. This substance deserves more attention that it has hitherto received, the tree being plentiful in Berbice.

Several other products of British Guiana deserve attention. Among them are the bark of the root of *Eperua falcata*, of the variety called "ituro-wallaba" by the natives, and which is used by them as a remedy for toothache; the bark of the "arrisouroo," a decoction of which is used for dressing ulcers, while the sap is found efficacious for ringworm ; and the bark and seeds of awati, a decoction of which is used as a wash by the Indians in cases of small pox, and said to be very efficacious in healing the pustules. The specimens contributed by Mr. W. Fresson, of Demerara, have been kindly offered to the museum of the Society by that gentleman at the close of the Exhibition.

THE PARA AND CEARA RUBBERS, AND BALSAM OF COPAIBA TREES.*

A report on the subject of india-rubber yielding plants in their own native homes, and comprising also an account of the collecting of balsam of copaiba, has recently been issued from the India Office. It has been furnished to the Secretary of State for India by Mr. Robert Cross, who is well known for his labours in the cinchona forests of South America, and the subsequent introduction of the plants into India, since when Mr. Cross has made more than one trip to South America for the purpose of securing seeds or plants, or both, of the best rubber producing trees, and the results of his more recent expedition for this purpose is embodied in the report before alluded to. Mr. Cross gives a brief account of the habits of the Para people, which place he reached on the 15th July, 1876. The population it seems is about 40,000, most of whom are engaged in some way with the despatch of import and export produce. Notwithstanding the reputed fertility of the Amazon valley, nearly all the necessaries of life are imported, butter and fish from Norway, rice and flour from the United States, while sugar, coffee, and mandioca come from the Southern parts of Brazil. The great bulk of the citizens are described as going about more ostentatiously dressed than the people of London ; the essential costume being a fine black coat and hat, snow-white vest and trowsers, and fancy French boots. Water is supplied to the city by being carted through it in barrels, and sold at the rate of three-halfpence for about 21 English pints. Dysentery, yellow fever, and various other forms of fever are said to be prevalent, and altogether Para is considered to be more unhealthy than any city in India. The province of Para, and the islands that are scattered over the lower portion of the Amazon, are described as the great field for caoutchouc collecting. A good deal of the rubber from the Rio Negro, Madeira, and other tributaries, seems to come in the form of negro-head or sernamby, while that from the Para region is the finer kind of smoked biscuit rubber, to the preparation of which greater care is given. It is indeed reported that the Para tree is a different variety; its milk leaves no very prominent stain on the hands or clothing, while the milk of some of the varieties of rubber of the upper Amazon gives a black ink-like mark to the hands and clothes of collectors. When once in the country, how Mr. Cross started on his mission will be best described in his own words. He says :—"In order to form and establish a collection of plants, and for the purpose of making the various observations on the soil, climate, and mode of collecting and preparing the rubber, it was necessary to obtain a place to live in while so employed. Every one told me I would experience great difficulty in finding a dwelling, and this proved true. After travelling round Para and searching for about eight days I succeeded in hiring a house, but at a very high rate, as the place was large, and adapted for a family with attendants and slaves. However, it was secure, and offered every facility for my various requirements, which was important. My next work was to examine the district where the rubber trees grew, . . . and on the 25th July I made a preliminary journey to the region where the trees were wrought." Leaving Para, the high ground was traversed for several miles until the primitive forest was reached, a path used by caoutchouc collectors through the wood. The traveller soon came upon a large tree in a state of decay, which had been tapped many times. From the ground up to a height of 10 or 12 feet, the trunk was one swollen mass of warty protuberances and knots, covered with thick scales and hard, dry bark. This singular form of growth, the result of the practised system of tapping, has never previously been recorded. A few minutes of careful examination soon showed the real cause of those deformities. The collector uses a small axe-like instrument, an inch broad ; at each stroke he cuts

* From the *Journal of the Society of Arts*, July, 12, 1878.

through the bark and into the wood for fully an inch. Hundreds of these are made in the trunk of each tree in the course of a few years, and cannot heal under any circumstances; but a layer of wood is formed over the injured part, at the expense of the bark and general vitality of the tree. The newly formed wood is again cut into and splintered, and so the process is repeated on each successive layer, until the trunk becomes merely a mass of twisted wrinkled wood, with very thin insipid bark. In this condition hardly any milk flows from the cuts, and, although for years a few green leaves may continue to sprout from the points of the twigs, yet the tree may be considered as dead, and, in fact, finally withers away. It is, therefore, the injury done to the wood, and not over-tapping, which lessens the flow of milk, and ultimately causes the death of the tree. The cuts in the wood are of course unnecessary, since the milk is met with only in the bark. The healing-over process which afterwards takes place is similar to that seen where a branch has been lopped from the trunk. The wood is compact and rather hard, and for this reason the tree lives on for a number of years, although cut and hacked every season; but the flow of milk becomes so lessened that many are practically abandoned for years before they die. This and several large adjoining trees were growing in moist, deep, heavy soil, of a fertile character, but quite out of the reach of any inundation.

On the margins of both the larger and smaller streams a considerable number of rubber trees were found, mixed with cacao and forest trees. Three were observed, the bases of the trunks of which were flooded to a height of one foot, yet the roots seemed to run up to the brow of the bank, and no matted roots were observed, as is the the case with the willow tree when growing on the margin of a rivulet. Most of the others occupied dry situations. A number of good plants were met with beneath the oldest trees. At places where the ground was covered by more than two or three inches of water at flood tide, seedlings did not usually grow. By far the greatest number, however, were met with in situations above the reach of the highest tides. A few of the largest trees were measured, all of which had been tapped for periods varying from five to fifteen years. Most of the trees occurring within the limits of the worked districts are tapped if possessing a diameter of six or eight inches. Regularly tapped trees, as a rule, do not exceed 60 feet in height.

Mr. Cross relates some rough and ready experiments made by him with a view of proving the conditions under which the Para rubber plants may be best propagated. These experiments were conducted while the plants which he had previously collected, 2000 in all, were being established in three cases. He says they were commenced "in order to ascertain how the tree might be readily multiplied in a rough way by any person not specially acquainted with the principles of propagation. Two separate beds, the one of brown sand the other of decayed leaves, were formed. The terminal portions of shoots, but with a bud at the lower end, were planted in the beds in a reclining position with only two inches of the points above ground. Owing to the great distance between the buds, consequent on vigorous growth, many of the cuttings were a foot or more in length. At the same time a number were set deeply in an open vessel containing only rain water. The cuttings in the sand bed were the first to grow, and soon made strong shoots and root fibres. Those in the leaf mould pushed more slowly, but developed green leaflets of great substance. The cuttings placed in the water had a small portion of tap root at the base, as the object was to determine if the roots actually develop in water alone. Within fourteen days these plants had several roots formed, and one or two rather weak growths came up, but a few days after I had thrown into the water some burnt earth and wood ashes the increase in vigour was very apparent. After these experiences I felt convinced that the Para rubber tree delights in abundance of moisture and rich fertile deposits." Mr. Cross gives a very detailed description of the tapping of the trees, the collection of the milk, and the method of preparing the rubber, all facts of great interest, and the more so because information of this kind is not readily procurable in a collected form, being for the most part distributed in various books of travel. On this account Mr. Cross's report should be widely circulated. The fact remains, however, that these reports are not sufficiently known amongst commercial and scientific men, and consequently, the wider diffusion of the heads of Mr. Cross's experience is, perhaps, justified in the columns of this journal. The caoutchouc collectors commence work as soon as daybreak, or as soon as they can see to move about among the trees. They say that the milk flows more freely, or in larger quantities, in the early morning, but little importance is attached to this statement, the most probable reason for the early tapping is that, as rain often falls about two or three o'clock in the afternoon, it is necessary that the work should be done early, as, in the event of a shower, the milk would be spattered about and lost. The collector first of all, at the beginning of the dry season, goes round and lays down at the base of each tree a number of small cups of burnt clay. At the lesser trees only three or four are put, but at the larger ones from eight to twelve. The footpaths leading from tree to tree are likewise cleared of sapling growths. On proceeding to his work, the collector takes with him a small axe, for tapping, and a wicker basket containing a good-sized ball of well-wrought clay. He usually has, likewise, a bag for the waste choppings of rubber, and for what may adhere to the bottoms of the cups. These promiscuous gatherings are termed "sernamby," and form the "negro head" of the English market. The cups are sometimes round, but are more often flat, or slightly concave on one side, so that, with a small portion of clay, they may be easily stuck against the trunk of the tree. The contents of fifteen make one English imperial pint. When the collector arrives at a tree, he strikes with his axe in an upward direction as high as he can reach, making a steep, upward, sloping cut across the trunk, which penetrates the bark and an inch or more into the wood, and is often fully an inch in breadth. Frequently, a small portion of bark breaks off from the upper side, and, occasionally, a thin splinter of wood is raised. A cup is next quickly fixed with clay against the trunk, just beneath the cut. The milk, which is of dazzling whiteness, now begins to exude. At a distance of four or five inches, but at the same height, another cup is similarly fixed, and then another, until a row of cups encircle the trunk at a height of about six feet from the ground. Tree after tree is treated in this manner until the day's tapping is finished. The earlier the gashing of the trees and the fixing of the cups is done the better, for the milk often continues to exude slowly for three or more hours. The collectors vary very much in the tact and ability shown in the performance of their duties. Some take care to get good clay previously, and to incorporate it well, so that a very small portion is needed to fix the cups to the trunks; they also work with neatness and intelligence, and invariably collect large quantities of milk. On the other hand, there are some who exercise no forethought in the preparation of their clay, merely scraping up a handful when they need it. This class of collectors often have many fragments of clay and other impurities in their rubber. The quantity of milk that flows from each cut varies. If the tree is large and has not previously been twice tapped, the cups will for the most part be more than half full, and occasionally a few may be quite full, but if the tree is much gnarled from tapping, whether it grows in the rich sludge, by streams, or on dry soil, many of the cups will be found to contain only about a table-spoonful of milk, and sometimes scarcely that. On each succeeding day a similar operation is carried on, with the exception that the cups are placed from six to eight inches lower down, until the ground is reached. The collector thus begins as high as he can

reach, and descends as before, taking care, however, to make his cuts in distinct places from those previously made. When the produce of milk diminishes in long wrought trees two or three cups are put on various parts of the trunk where the bark is thickest. Although many trees are large, the quantity of milk obtained is surprisingly small. This has been described as the result of over-tapping, but Mr. Cross thinks it is not possible to over-tap a rubber tree, if in the operation the wood is not left bare or injured; but the collector's axe always enters the wood, and the energies of the trees are required to form new layers to cover these numerous wounds. The best milk-yielding tree examined had the marks of twelve rows of cups, all the work of one season. The rows were only six inches apart, and in each row there were six cups, so that the total number of cuts made within the period of three months numbered seventy-two. Though this tree grew in a favourable situation, and was in every respect a healthy tree, it is considered that with about two years of such treatment it would in all probability become permanently injured. There seems to be no appreciable difference in the quality of the rubber, whether collected in the dry or in the rainy season. It may be, however, that in the wet season a larger proportion of water is contained in the caoutchouc, while on the other hand a larger quantity of milk flows. The dry season is, in fact, the most suitable for caoutchouc collecting.

Two other methods of tapping, which are chiefly confined to the Upper Amazon and its tributaries are described, the principles of which are similar to those already explained.

With regard to the collection of the milk from the cups when full, it is done by a man running from tree to tree with a large calabash, into which the contents of the cups are emptied. As he pours the milk out of each cup he draws his thumb or forefinger over the bottom to clean out some which would otherwise adhere; a small quantity, in fact, does remain, which is afterwards pulled off and classed as sernamby. The cups, after being emptied, are laid in little heaps at the base of each tree to be ready for use next morning. The time lost in traversing the intricate muddy footpaths beneath the trees is a serious obstacle to expeditious collecting. More than twice the quantity of caoutchouc might be collected in a fourth of the time, and at far less cost and labour, were plantations properly formed.

To prepare the rubber, the milk is put into a large flat earthen vessel; beside this are placed narrow-necked jars about eighteen inches high, and about twelve inches across the broader part; the bottoms are knocked out of these jars, they are raised from the ground on three small stones, fires are lighted in these bottomless jars, and the slight distance they are raised from the ground causes sufficient draft to promote their burning; the fires are fed by dropping pieces of wood and a handful of palm nuts alternately into the mouths of the jars, the aim being to cause a dense smoke to arise from the mouth of the jar. The mould on which the rubber is prepared resembles the paddle of a canoe; in fact, at many places on the Amazon, this is the article most frequently used. If there is much milk, and when the rubber is prepared in bulky masses, a little soft clay is rubbed over the mould to prevent the rubber adhering, and it is afterwards well warmed in the smoke. The operator holds the mould with one hand, while with the other he takes a small cup and pours two or three cups of milk over it. He turns it on edge for a few moments above the dish until the drops fall, then quickly places the flat side two inches above the jar's mouth, and moves it swiftly round so that the current of smoke may be equally distributed. The opposite side of the mould is treated in the same way. The coating of milk upon being held over the smoke immediately assumes a yellowish tinge, and although it appears to be firm, on being touched is found to be soft and juicy, like newly curdled cheese, and throwing off water profusely. When layer after layer has been repeated, and the mass is of sufficient thickness, it is laid down on a board to solidify, and in the morning is cut open along the edge on one side and the mould taken out. Biscuit rubber, when fresh, is often four or five inches thick. After being hung up to dry for a few days it is ready for market. The fact of burning palm seeds (which are said so be those of *Euterpe edulis* and a species of *Attalea*) has given rise to an opinion always stated by travellers that the smoke produced by these burning nuts exercises some peculiar effect upon the milk by which it coagulates almost instantly. After a careful examination of this matter, Mr. Cross expresses it as his conviction that the rapid coagulation of the milk is simply produced by the high temperature of the smoke, and that with a strong current of heated air or a good pressure of steam from a pipe, a similar result would be obtained. He says, "I have no hesitation in giving my opinion that equally as good rubber could be prepared by putting the milk into shallow vessels, and evaporating the watery particles by the heat of boiling water."

With regard to the introduction and propagation of the Para rubber plant into India, the hottest parts and the low-lying, moist tracts, or land subject to inundations are recommended, deep, humid land suitable for cane and coffee planting is quite suited for the tree. The Malay peninsula, Burma, Ceylon and Southern India are said to possess many suitable localities. The green terminal shoots of succulent growth, with the leaves fully matured, make the best cuttings. They should be cut off low enough to take in a joint at the base. When planting in dry firm land, a spadeful of soil should be turned over at each place, and the cutting planted in a sloping position. It should be covered with mould to within three inches of the point. That portion above ground should rest on the earth on one side to its termination so as not to suffer through hot sunshine. Seeds may also be planted and the soil much improved by the addition of a handful of wood ashes with each seed at the time of sowing. In watery places, or in deep mud deposits, seeds are not recommended, as many would mould and rot. Mr. Cross gives a very detailed description of the best modes of propagation, soil, etc., and also his experience in search of the Ceara rubber, about which a good deal of interest has been manifested, the plant producing it not having been accurately known, but suspected by many writers to be identical with the Para tree. Mr. Cross succeeded in bringing home seeds and plants, and the true Ceara rubber is now proved to be the produce of *Manihot glaziovii*, which, though quite distinct from that of Para, neverless belongs to the same natural family, the Euphorbiaceæ. The rubber is collected in a different manner to that of Para. The outer surface of the bark of the trunk is pared off to a height of four or five feet, the milk then exudes and trickles down in an irregular manner, falling, for the most part, on to large leaves that are laid about the base of the trunk to receive it; some, however, drops on to the ground, and so often gathers up with it dust and loose stones. After several days the juice becomes dry and solid, and is then pulled off and rolled up into balls or put into bags in loose masses. The trees are badly used, the tapping being made too deeply into the wood, so that many trees are in a state of decay. From the fact that Ceara rubber occupies a good place in the market, being exported at the rate of about 1000 tons per annum, it is to be hoped that more care may be taken of the trees, and that it may be successfully established in India. Mr Cross suggests that in the districts of Madras, Cochin, Calicut, Cannanore, Mangalore, and Bombay, many localities possessing all the conditions essential for the growth of Ceara rubber may be found, and the plant may also be tried in the deep tropical valleys of Assam; indeed, in all the parched regions of India within the limits of coffee culture.

On the subject of balsam of copaiba, which is yielded

by different species of *Copaifera*, Mr. Cross describes them as having a wide distribution, being abundant in the forests of the Amazon valley, of Guiana and Venezuela, and in the wooded littoral districts of New Grenada, especially in the States of Santa Martha, Carthagena, and Panama. The finest sort known in commerce, and called by the collectors white copaiba, is m with in the province of Para, and is shipped from Para and Maranham. Very large quantities are annually sent to the French market. Formerly, the trees might be seen growing within easy access; but, owing to the method of collection practised, it is now comparatively rare. At present, a collector must make a journey of several weeks in a canoe up some of the Amazon tributaries, or penetrate into the dense forest lying between the rivers, to find any considerable quantity of copaiba. The life of a balsam collector is said to be one of the most wretched description, as he is exposed daily to the drenching rains in the depths of the forest, with often an insufficiency of food, constantly bitten by large, formidable ants, and tormented unceasingly by day and night by swarms of mosquitoes. As if to make amends for all these miseries, a collector can earn, when the trees are abundant, as much as £5 per day. The trees grow to a great height, running up to fifty feet or sixty feet before branching, but no seedlings, or young plants, are to be found in the forests, for so soon as the seeds fall they are greedily devoured by a small animal about the size of a rat. To collect the balsam a hole or chamber, about a foot square, is cut in the trunk, at about two feet from the ground. The wood is white to a depth of four inches or five inches, after which it is of a purplish red colour; indeed, the woods of all the species of copaifera have this peculiar tint. When the centre of the tree is reached by the axe, the balsam flows out in a current full of hundreds of little white pearly bubbles. "At times, the flow stopped for several minutes, when a singular gurgling noise was heard, after which followed a rush of balsam. When coming most abundantly, a pint jug would have been filled in the space of one minute." From the fact that every chip cut out was studded with drops of balsam, it seems conclusive that every particle of the wood is highly charged with it, though the bark appears to possess none. A large tree, in good condition, is estimated to yield about eighty-four English imperial pints. Mr. Cross refutes the stories told by travellers, that the balsam is collected by gashing the bark, and plugging the space with cotton to absorb the juice which exudes, or that of closing cavities, made in the trunk, with clay or wax, to allow the balsam to accumulate, and then opening them and extracting the collected balsam. Both systems, he considers, would be practically useless. Little or no care seems to be taken to preserve the balsam pure. Old jars and barrels, that have previously contained grease or liquors of all descriptions, and old paraffin cans, are very much sought after, and are used without being properly cleaned.

This valuable tree, like those yielding india-rubber, has been proposed for introduction to India. The temperature required for it is similar to that required for the Para rubber tree. Wet or moist land should be avoided, and the plants should be put in the best dry loam such as is suitable for cane or coffee planting; seedlings may be planted tolerably thick so as to shoot up rapidly, when they could be thinned out to proper distances. Mr. Cross concludes his remarks on this interesting tree in the following words:—"I would not recommend the planting of these trees on a large scale with a view to early profit, as the growth would be slower than Panama or Para rubber trees. The return would, I think, be realized in about the same time as is the case with oak plantations. However, a few hundred of copaiba trees growing on a planter's estate ought to enhance the value of it. Apart from the medicinal value of copaiba, it might be well to ascertain if it would not be equal to castor oil for lubricating machinery."

PREPARATION OF COPAL VARNISH. THE COMPOSITION OF COPAL AND ITS ALTERATION BY FUSION.*

BY H. SCHWARZ.

The best kinds of copal varnish are prepared by melting East Indian or East African copal, and dissolving the melted product in linseed oil varnish, and turpentine oil. After being melted, the copal becomes soluble in ether, chloroform, benzene, and carbon bisulphide, but these solvents give a varnish, which dries brittle. A brilliant varnish can be obtained by working up manganese borate and minium with the linseed oil, and then gently heating to decompose the oil.

The author describes the apparatus employed to melt the copal, and the necessary precautions to follow in the melting operations. Galvanized iron melting pots have been employed with advantage instead of copper, which frequently gives a reddish sediment to the melted copal. A good copal varnish can be made by melting 1·5 kilograms of copal for twenty minutes with frequent stirring, then adding 3·5 kilograms of linseed oil varnish, and 1·75 kilograms of French turpentine oil.

An almost colourless specimen of copal, dried over sulphuric acid, gave on analysis C = 78·72, H = 10·24, O = 11·09. The author doubts the possibility of isolating the resins in copal by the alcohol method of Unverdorben, who considered that he had thus separated five resins from African copal.

When copal is successively exhausted with cold dry ether, there remains undissolved a gelatinous swollen mass, which on that account the author terms "schwell-copal." Copal can be thus separated into two portions, one soluble and the other insoluble in ether.

Insoluble in Ether.—Copal contains 66 per cent. of "schwell-copal," hence the reason it is impossible to use crude copal for varnish making. "Schwell-copal" when once melted is rendered soluble in ether. Dried at 170° it gave C = 79·95, H = 10·87, O = 9·18.

Soluble in Ether.—The residue from ether remains liquid at 100°, owing to the presence of ethereal oil, which may be expelled by heating at 130°. Dried at 130° it gave on analysis C = 78·25, H = 10·30, O = 11·70. It is called soluble copal.

Melted Copal or *Pyrocopal.*—Copal when sufficiently melted to be rendered soluble in the usual solvents, loses between 5 and 12 per cent. by weight. The evolved gases were analysed, and gave per cent. CO_2 = 35·6, CO = 32·20, H and CH_4 = 32·20. Pyrocopal is dissolved by ether, benzene, carbon bisulphide, and carbolic acid, but is most soluble in chloroform; it is also dissolved by hot linseed oil and turpentine oil. It contains C = 83·63, H = 10·36, O = 6·01.

When a chloroform solution of pyrocopal is poured into absolute alcohol, a fine yellowish mass is separated, which is quite insoluble in alcohol. It is called "pyro-schwell-copal." Dried at 100° it gave C = 83·01, H = 10·52, O = 6·47. Pyro-soluble copal was obtained from the alcoholic solution as a hard brownish resin. It contained C = 81·02, H = 10·37, O = 8·61.

In all cases, melting the copal causes an increase in the percentage of carbon, and a decrease in oxygen and hydrogen.

The author does not assert that the resins which are separated in this manner are absolutely definite compounds, but it is interesting to construct the formulæ on the above data:—

Crude Copal, $C_{19}H_{30}O_2$.	Pyrocopal, $C_{19}H_{28}O$.
"Schwell-copal," $C_{48}H_{76}O_4$.	Pyroschwell-copal, $C_{48}H_{74}O_3$
Soluble copal, $C_{36}H_{56}O_4$.	Pyro-soluble copal, $C_{36}H_{54}O_3$.

When cautiously distilled, copal gives but little carbonaceous residue; no compounds or products of decomposition have been obtained.

THE MORNING POST ON COUNTER PRACTICE.

"The Medical Bills before Parliament have excited a considerable amount of agitation amongst a numerous body of persons whose relation to the medical profession is not only of the highest utility, but is absolutely indispensable. It is not too much to say that any alteration which the law may be made to undergo ought not to trench upon the interests of the druggists and chemists, and if the law does so as it stands it ought to be amended. At what time this branch of the medical profession first came into existence cannot be clearly determined, but it is certain that the trade existed, and was widely exercised, and had attained a status in the country prior to the passing of the Apothecaries Act of 1815. It is easy to understand how the trade came to be created and gradually spread itself in the country. There was a demand for it, it supplied a public want, and it, therefore, grew in importance until it gradually attained the position which it now holds. So far back as the year already mentioned the chemists and druggists excited the jealousy of the apothecaries, who feared lest the growing importance of what they considered to be a rival body might trench upon their interests. The younger trade, however, had made its utility so felt that when the Apothecaries Act was passed its promoters were obliged to consent to the insertion of a clause saving to the chemists and druggists the exercise of their business 'in such manner and as fully and amply to all intents and purposes' as it was exercised before the passing of the Act. The reasons which weighed with the Legislature in adopting this clause have not been diminished in force by the sixty and odd years which have elapsed since then, nor has anything occurred to disentitle the chemists and druggists to the right which the Legislature thought it just and for the public advantage that they should enjoy. But it is evident that there is a desire on the part of the Apothecaries' Society that a broader line of demarcation should be drawn between them and the chemists and druggists, in order to define more precisely what duties are competent to the latter, and also to put a stop to some of the privileges which they have always possessed, and which were confirmed to them by the Act of 1815.

"There are not many persons living who are able to state what the duties were which chemists and druggists were allowed to exercise before the Apothecaries Act was passed. But we are not altogether without guidance which will lead us to a sufficiently accurate conclusion upon this matter. In a memorandum which the Chemists and Druggists' Trade Association have, at his request, submitted to the Duke of Richmond and Gordon, a statement is made, amongst other things, as to the present manner of carrying on the trade. Its members 'prepare and compound' medicines according to the directions of the Pharmacopœia. They 'dispense and vend' medicines made up according to the prescriptions of physicians or other medical men, and sometimes according to the directions of purchasers. It is in the latter of these cases that a chemist and druggist sometimes offers his advice, or gives it when he is asked to do so, but merely as to the suitableness of some drug which his customer requires for this or that ailment. It is to be observed that he makes no charge for his advice, and that he only receives the value of the medicine which he vends. It is contended with much probability that what is done in this respect by chemists and druggists of to-day was done by their predecessors in the trade prior to the Apothecaries Act, and if this contention is right it is clear that they are acting under the sanction of that measure. We have not, however, to trust solely to probability for the belief that chemists and druggists gave the advice which they give now to such of their customers as asked for it prior to the year 1815. The memorandum cites evidence of a more direct character. Mr. R. D. Upton, who was clerk to the Apothecaries' Society in 1833, wrote in that year to the effect that he was not aware that any law was violated by a chemist and druggist giving advice gratuitously, 'any more than any other private individual. 'If,' he continued, 'he really and *bonâ fide* makes his patient a present of his advice, and only receives a reasonable price for his medicines, I know of no law to prevent him so doing.' In the following year, Mr. John Nussey, Master of the Apothecaries' Society, stated before the Parliamentary Medical Committee that chemists and druggists had exercised the right to prescribe in their own shops since 1815, and that no prosecution had been instituted by the Society against any one of them. The same point is clear from a petition presented to the House of Commons in 1837, by the British Medical Association, in which it is pointed out that chemists and druggists had up to that time assumed the right to 'prescribe and practise' in all minor ailments. We do not suppose that by the word 'practise' it is meant that they visited patients or received fees for their advice, but simply that they gave their advice over the counter gratuitously, and received payment only for their medicines. Once more, there are persons living who were engaged in the trade before 1815, and who at some recent trials gave evidence to the effect that chemists and druggists have always carried on their trade in the same way as they do now.

"But putting these authorities aside, it seems to arise, *ex necessitate rei*, that persons engaged in this trade should do something more than merely vend the drugs which they are asked to sell. There are a variety of minor ailments which only require the use of some simple medicine to remove them. There are thousands of poor people in London and in all our large, yes, and small towns, too, who, when they are out of sorts, only want a little 'doctor's stuff' to set them right. They cannot afford to call in a medical practitioner, they have not always dispensaries in their neighbourhood, and they naturally go to the nearest chemist's shop, and ask what is the best thing to take for a headache, or for toothache, or for some other trifling indisposition. It would be the grossest injustice to forbid the chemist from giving his advice in so simple a matter. It would be placing him in a position different from that of all the rest of Her Majesty's subjects. There is no law to prevent any one from advising another to try such and such a medicine which he has found good in his own case, or which he has heard to be beneficial in such cases. The thing is done constantly, and no law in the world can prevent it. Why, then, should a chemist and druggist, who understands the properties of his drugs and the ailments in which they are usually applied, be debarred from a right which to every one else is as free as air? It is, of course, possible that the medicine he recommends may not always have the desired effect, but that is equally true of the medicines prescribed by qualified practitioners. On the other hand, it is certain that the present practice is an immense convenience to vast numbers of persons. So far as the public are concerned this is the only point to be considered. The various branches of the medical profession do not exist for their own benefit, but for the good of the community at large. We do not for a moment doubt that the Bills before Parliament are in their general aim wisely designed to confine the exercise of the profession to practitioners who have qualified themselves by an arduous course of study, and to raise the standard of proficiency. But that may be done effectually without trenching upon the services which are rendered to the poorer classes, and to some of those who are above them in the social scale, by the chemists and druggists. To say that the latter enter into competition with the regular practitioners is absurd. It follows that the clause of the Act of 1815 under which the Apothecaries' Company claim to have the power to restrain chemists and druggists from giving advice of any description to purchasers of their medicines ought to be abolished. It is contrary to common sense and to public convenience; and if further sanction were given to it a heavy blow would be struck at the interests of the poorer classes."

The Pharmaceutical Journal.

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PROTECTION OF TRADE INTERESTS.

THE accusation to be found in another page that this Journal is "not helping to defend and sustain the common rights and interests of all chemists," in reference to the question of counter practice, is one too serious in its nature to be passed over in silence, however little foundation it may have in fact. For that reason, and out of regard for the principle that if dirt enough is thrown at one some is sure to stick, we again resume the somewhat weary task of refuting the statements made in disparagement of the policy adopted by the Council and its representation in these columns.

Our censorious correspondent refers to an article recently published in the *Morning Post* which is described as having had a refreshing effect upon him as contrasted with the remarks we have made on the action of the Chemists and Druggists' Trade Association, and in order to place our readers in a position to judge for themselves how far there is any ground for the invidious comparisons sought to be established we have printed the article in question on the previous page.

In substance this article is to a great extent a *résumé* of the memorandum lately circulated by the Chemists and Druggists' Trade Association amongst members of Parliament and others, and as it tacitly adopts as representations of facts the statements contained in that memorandum it is not surprising that the general drift and conclusion of the article should be in accordance with the views put forward by the Association.

That we dissent from those views has been sufficiently pointed out already, and we have been at some pains to indicate the reasons for such dissent, deeming it our duty to endeavour thus to check an agitation that we believe to be fraught with danger to the real interests of pharmacy in this country, and calculated to aggravate the uncomfortable relation already existing between a certain class of medical practitioners and chemists and druggists.

In the first place we will call attention to the statement that so far back as 1815, the chemists and druggists had excited the jealousy of the apothecaries, who feared lest the growing importance of what they considered to be a rival body might trench upon their interests. This mode of endeavouring to create a belief that the opposition of the apothecaries of that time to the practice of medicine by chemists and druggists was instigated merely by jealousy of a rival class is, to say the least of it, disingenuous. The truth is that in 1815 the apothecaries acquired for the first time a kind of indirect legitimization as medical practitioners, on the condition that they underwent a test of qualification to practise, in the shape of an examination in the science and practice of medicine. That they should from that time seek to prevent other persons who had not undergone this examination from practising in the same manner as themselves is as natural as the desire on the part of chemists and druggists at the present time to prevent persons from dealing in drugs and dispensing medicine who have not passed the examinations required by the Pharmacy Act. It is unfair to speak of the similar feeling of the apothecaries as being the result of jealousy, and we believe it to be a great mistake to represent the present relations of medical practitioners and chemists and druggists as being in any way the result of such a sentiment.

It appears to us equally a mistake to attempt making capital out of any real or assumed rivalry or jealousy between apothecaries and chemists and druggists. If discussion of this point is to have any value it must refer distinctly to particular epochs and not deal with vague generalities. The apothecaries in the early part of this century were no doubt to some extent the rivals of chemists and druggists, inasmuch as both classes were exercising the functions of pharmacists. The former, having in 1815 acquired a legislative right to practise medicine, virtually abandoned the practice of pharmacy to the chemists and druggists, and in that capacity ceased to be their rivals. But their own experience in the illegitimate practice of medicine prior to 1815 naturally furnished a foundation for the idea that others might also indulge in the transgressions with which they had themselves so long been familiar. Hence the relations between apothecaries and chemists and druggists became of a totally different nature to the rivalry before existing—the chemist and druggist was no longer regarded as the competing pharmacist, but as a possible competitor in medical practice. The fact of the Apothecaries' Society being a trading company engaged in the sale of drugs has really very little to do with the feeling existing between the Society as representing medical men and chemists.

Regarding the nature of the business carried on by the chemist and druggist prior to 1815 as compared with that now generally carried on by this class and with particular features of the business, as carried on by some chemists and druggists, there is of course great difficulty in deciding what differences or similarity obtain. It is admitted by the Apothecaries' Society that there was no objection to chemist

and druggists giving advice and medicine in minor ailments, but inferentially it may be taken that this did not include such medical practice as could be termed acting as an apothecary, since chemists and druggists were not called upon to undergo an examination in the science and practice of medicine like the apothecaries. In dealing with this difficult question the writer of the article in the *Morning Post* merely adopts the definition of the business of a chemist and druggist as now carried on that has been given by the Trade Association, and as we have already pointed out that is more a definition of what ought to be than of what is in some instances.

He is no less misled when he speaks of the evidence of chemists engaged in business before 1815, as having proved that the trade was then carried on in the same way that it is now. So far as their evidence had any relevancy to the point then at issue, it was unmistakable in its tendency and that was to declare the acts complained of by the prosecutors as being such that they would not have done them.

The defence of cases such as this is, we think, not work for the "friends" of chemists and druggists to engage in, and holding that opinion we consider it our duty to express it, however unpalatable it may be in quarters where "trade interest" is the leading idea and its protection is sought to be made a special monopoly.

We cannot regard it as a step in defence of the interests of the trade to ignore in the above-mentioned definition of the chemists and druggists' business the existence of practices that the signataries of the memorandum must know of. Those practices, it is well known, are by no means consistent with the statement made in the *Morning Post*, that it is absurd to say that chemists and druggists enter into competition with regular practitioners. Neither is it a truthful representation to say that it is in dispensing and vending medicines, "according to the direction of purchasers," that chemists and druggists do that which medical men object to as coming within the terms of acting as an apothecary. This statement is so wide of the truth that we cannot regard its propagation, however well intentioned, as being likely to promote or protect the interests of the trade at large.

Looking at the difficulties attending any attempt to define the respective province of the chemist and druggist and the physician, it has always seemed to us that the wisest course is to abstain from it, and rather to strive at the attainment of a more natural partition of functions. This may long be a thing more to be hoped for than expected, but assuredly it is upon this principle that we have most reason to anticipate the improvement of the pharmacist's position. The recent action of the Apothecaries' Society has been of such a nature as to show that there is a disposition on the part of that body to meet the chemist and druggist in a conciliatory and considerate spirit rather than incur the troubles and uncertainty of litigation.

The Trade Association, however, has preferred to raise the cry that the Apothecaries' Society is seeking to harass chemists and druggists, and to attempt a redress of this alleged grievance in a court of law.

So far as the investigation of this question has yet progressed there is no evidence to show that the Apothecaries' Society has instituted oppressive prosecutions against chemists and druggists, either of its own action or at the instance of any Medical Association. There has not been any proof of the assertion that the Apothecaries' Society is harassing the chemist and druggist nor has anything been established to show that the chemist and druggist is at the mercy of that society. And if we turn from these negative results of the attempt to fight this question out by litigation, to the letters written by the Clerk of the Apothecaries' Society to the Solicitor of the Pharmaceutical Society we find not only a distinct disavowal of having sanctioned a prosecution of pure and simple counter practice, but also an expression of opinion that is fully borne out by the action of the Apothecaries' Society, and perfectly consistent with previous utterances on the subject by former officers of the society.

It must not be forgotten also that this expression of opinion in regard to counter practice, having not merely a bearing on the present, but also conveying a pledge as to the future, was made in response to a suggestion by the Solicitor of the Pharmaceutical Society, to the effect that if the Apothecaries' Society really desired to question the legality of counter practice by chemists and druggists, the matter should be openly and fairly tried in a test case, to be arranged for by the respective Societies or the representatives of both parties.

So far as we have dealt with the article in the *Morning Post* there does not appear to be much that is refreshing, and we are unable to agree with it any more than we could with the memorandum issued by the Trade Association. The concluding paragraph of the article, however, is of a different character and it expounds very well the absurdity and injustice of attempting to place chemists and druggists in a worse position than other persons so far as the recommendation of medicine is concerned. Throughout this portion of the article readers of this Journal will readily recognize views that have been over and over again urged in our columns. The writer may be indebted to that source for his inspiration, but in any case we are heartily glad to find that his views are here so thoroughly in accord with our own.

THE COUNCIL REPORTS.

It is with some surprise that we learn Mr. Urwick is still unsatisfied. When once the mind has been possessed with the idea that a house or locality is haunted it is certainly very difficult to

prove the nonentity of what is thus patent to the "mind's eye"; but we hoped that in the Journal of the week before last we had given a sufficiently distinct repudiation of being subject to "control" in regard to the Council reports, or of allowing any "cooking" of them to take place and we also hoped that by so doing we should have left him in future untroubled by such visions. However, this is not the case, and Mr. URWICK has returned to the charge of "control or cooking." In addition he has awarded us a scolding for not inserting the letter upon the matter of which we commented two weeks ago, and we confess to thinking this rather unjust, since he evidently does not rely upon the Journal for publication.

But to avoid further reclamations and on account of the statements and questions contained in Mr. URWICK's latest communication, we have made a point of finding space for it, and must recommend those who are in any way concerned with the circumstances to which it refers to assist in relieving the mental dyspepsia from which Mr. URWICK seems to be suffering.

So far as we have been able to ascertain after numerous inquiries no one knows to whom the allusion in Mr. URWICK's letter refers; all our efforts to discover this "mysterious councillor" merely led to a "non mi ricordo," the sincerity of which we have no reason to question. But here, where all is void to others, Mr. URWICK sees the form and substance of a "leading member of Council"; he is convinced this "leading member" spoke, but speculates in so contradictory a manner as to the character of the speech that we must needs infer he failed—as is indeed often the case in dreams—to catch what was said by the "leading member." This is a pity, for if that were at once stated the whole affair might be cleared up.

[The letter of the official reporter, on p. 98, has a very direct bearing upon this matter.]

THE MEDICAL ACT AMENDMENT BILL.

ON Monday, in the House of Commons, inquiries were made by Dr. PLAYFAIR and Mr. MILLS as to whether the Government intended to persevere in attempting to pass the above Bill during the present session. Lord GEORGE HAMILTON, in reply, said that in consequence of the opposition the Bill met with its chance of passing this session diminished daily, but that he had placed some amendments on the notice paper in hope that they would meet the objections raised, and that until he had ascertained the effect of this step he was unable to give a definite answer as to proceeding with the Bill. The Bill is set down for second reading on Monday next, and amongst the adverse motions with respect to it still on the notice paper are two, in the names of Mr. WELDON and Mr. MCLAREN, that it should be read a second time that day three months; whilst should it be read a second time, Dr. LUSH, Dr. CAMERON, and Mr. ERRINGTON each have given notice of their intention to move that it then be referred to a select committee. So far as we are at present aware none of these amendments affect chemists and druggists.

CHEMISTS' ASSISTANTS' ASSOCIATION.

THE next meeting of the above Association will be held at its rooms, 29, Brewer Street, Regent Street, on Wednesday evening, August 7th, at 8.30, when Mr. MILLAR will read a paper on "Digestion."

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN SCOTLAND.

July 23, 1878.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maelagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Thirteen candidates were examined. *Six* failed. The following *seven* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Adams, Thomas Edwin, jun. ...Liverpool.
Boyd, John .....Durham.
Chislett, Charles .....Edinburgh.
Crowden, Samuel Graham .....Buckie.
Dickson, William .....Kirriemuir.
Duffus, George .....Aberdeen.
Jessup, Robert Markham.....Manchester.

July 24, 1878.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maelagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Twelve candidates were examined. *Three* failed. The following *nine* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Kenny, Thomas .....Boston.
Lea, Frederick James .....Folkestone.
MacEwan, Peter .....Lochee.
McLeish, Stewart Munn.....Uddingstone.
Norval, Thomas Leishman .....Perth.
Pirie, William Rettie .....Aberdeen.
Pollitt, Joseph Moore .....Radcliffe.
Parry, Robert .....Bettws-y-Coed.
Porteous, Arthur Alexander ...Kirkwall.

July 25, 1878.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

MINOR EXAMINATION.

Nine candidates were examined. *Three* failed. The following *six* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Robertson, James Dalgety .....Arbroath.
Sewell, Jonathan Joseph .....Workington.
Taylor, Stephen.....Liverpool.
Walker, William .....Aberdeen.
Watt, James, jun. .....Haddington.
Wyllie, George .....Jedburgh.

MODIFIED EXAMINATION.

Two candidates were examined. *One* failed. The following passed, and was duly qualified to be registered as a Chemist and Druggist:—

Simpson, David.....Liverpool.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN

QUARTZ: AN OLD CHAPTER RE-WRITTEN.*

BY W. SPOTTISWOODE, ESQ., M.A., LL.D., TR.R.S. SEC.R.I.

It is well known that difficult subjects are often made much more intelligible by being presented to the mind in more than one way. Under such a category the operation of rock crystal, or quartz, upon polarized light may

* Lecture delivered at the Royal Institution of Great Britain, Friday, April 5, 1878.

be fairly classed. And although its fundamental laws are well known to students of optics, they are perhaps sufficiently intricate to justify their being brought under a new experimental form before the members of the Royal Institution.

If a Nicol's prism be used as a polarizer and a sphere of Iceland spar as an analyser: then, when the sphere is so placed that its axis coincides with that of the beam of incident light, two images are formed on the screen. If the aperture be a circle, or a circular ring, the two images will be concentric circles; the ordinary image being the larger, and the extraordinary the smaller. The light in both images is polarized, but the polarization in one is radial, in the other tangential. Hence each ring will be broken by two dark intervals opposite to one another, viz., at points where the vibrations would be perpendicular to those transmitted by the polarizer; and as the vibrations at each point of one ring are perpendicular to those at the corresponding point of the other, the dark intervals in one ring are in quadrants at right angles to those in the other. If, however, the sphere be turned round (say about a vertical axis), various results will be noticed; first, the large or ordinary image will remain fixed, and consequently the rays forming it follow the ordinary laws of refraction; secondly, the smaller, or extraordinary, image will shift both its position and form, showing that the rays forming it follow a more complicated law; thirdly, when the angle of turning has reached 90°, the polarization which was radial for the first position of the sphere, will now be plane. The change of figure depends upon the fact that the angle of refraction in the extraordinary image varies with the angle of inclination of the incident ray to the axis of the crystal, and is greatest when that angle is 90°: while the change in the polarization is a result of the general law that the plane of polarization in the ordinary ray passes through, while that of the extraordinary is perpendicular to the axis of the crystal.

Returning to the original position of the sphere, if monochromatic light be used, the same effect is seen as with white light; but if a plate of quartz cut perpendicularly to the axis be inserted between the Nicol and the sphere, the dark interval will be shifted to the right or to the left according as a right-handed or a left-handed quartz is used. The amount of displacement will depend, for light of a given colour, on the thickness of the quartz; and, for a given thickness of quartz, on the colour, or, more strictly speaking, on the wave length. In this way the rotation of the plane of polarization by the quartz plate is brought visibly before the eye.

In this experiment, however, the various stages of rotation for the rays of various colours are brought successively into view; but by the following arrangement they may be all exhibited simultaneously. If, while white light is used, and spectra of the ring images be formed, then, on re-introducing the quartz plate, the spectrum of one ring (the ordinary, or the extraordinary, according to the position of the polarizer) will be seen to be crossed by a spiral band of darkness, sweeping obliquely from red to blue, or *vice versâ*, according as the quartz is right-handed or left-handed. This shows that the various prismatic colours in continuous succession are extinguished at various points of the ring; or, in other words, that the plane of polarization varies continuously in angular position with the wave length. This fact explains the effect seen when the image is formed on the screen without dispersion; viz., the complete image consists of two concentric rings coloured with the residual tints (arising from the extinction of the prismatic colours in succession). These tints run through their cycle once in each semi-circumference; and the tints in each semicircle of one image are complementary to those in the corresponding semicircle of the other. If a biquartz be used, and the line of division between the right-handed and left-handed portions pass through the junction of the red and violet parts of either of the rings, the order of colours in the two semicircles will be reverse to one another.

If with the same arrangement as last described the sphere be turned round through an axis parallel to the line of division of the biquartz, the following results may be observed: first, each of the two images will be tinted by the biquartz in two compartments, the tints of which depend upon the position of the Nicol; secondly, the two images will, as usual, present tints complementary to one another; thirdly, the parts where the complementary tints overlap will, as usual, appear white; fourthly, the parts where the same tints overlap will be more brightly illuminated than the parts which do not so overlap. The interest of the last feature consists in showing, as first noticed by Helmholtz, that the low-tint colours, russet, brown, drab, etc., are really subjective effects due to red, orange, yellow, etc., when feebly illuminated in comparison with some other brighter part of the field.

The effect of right and left-handed quartz in combination is ordinarily shown, and turned to useful account, by a combination of plates, as in Savart's bands, or of wedges, as in Babinet's compensator; but it may also be well illustrated by the following arrangement. A solid cone, having a very obtuse vertical angle, and its axis parallel to that of the crystal, is cut from a right handed quartz; a second cone, in all other respects similar to the first excepting that it is hollow, is cut from a left-handed quartz; and the two are cemented, one inside the other, by balsam, so as to form a compound plate. When the polarizer and analyser are crossed, the following phenomena are observed: The coloured bands are arranged in circles about the centre. Midway between the centre and circumference, where the thicknesses of right-hand and left-hand quartz are equal, a black ring is seen. Inside this the colours are arranged in the order due to right-handed quartz; outside it they are arranged in the order due to left-handed quartz. On turning the analyser round, the middle ring changes from black to white, and the other rings, within and without the middle ring respectively, change their colours in opposite orders. But owing to the fact that the colours are originally ranged in opposite orders, the last-mentioned change gives rise to an optical illusion, in virtue of which the coloured rings seem to flow inwards or outwards throughout, according to the direction in which the analyser is turned.

Another useful combination of quartz may be mentioned. Two series of plates cut perpendicularly to the axis, and in the form of sectors, of various thicknesses, were arranged so as to form circular discs. One of the discs was cut from right-handed, the other from left-handed quartz, and one which was placed in front of the other, was capable of revolving about its centre. When sectors of equal thickness coincided in position, they neutralized one another, and no colour was seen. When, however, by the revolution of the movable disc, plates of different thickness were brought opposite one another, colours were seen due to plates whose thickness was equal to that difference. The vividness of the colours increased to a maximum when the revolution amounted to a right angle, after which it diminished until at two right angles, or half an entire revolution, it again disappeared.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

The Distribution of Ammonia.*

BY DR. R. ANGUS SMITH, F.R.S., ETC.

If organic matter is everywhere, ammonia is everywhere possible, and if that matter is decomposing, ammonia is everywhere. This is the general statement which this paper illustrates. It is now many years since it was observed by me that organic matter could be found on surfaces exposed to exhalations from human beings; but it

* Read April 30, 1878.

is not till now that the full significance of the fact has shone on me, and the practical results that may be drawn from it in hygiene and meteorology. These results are the great extension of the idea that ammonia may be an index of decayed matter; the idea itself has been used partly and to a large extent, as illustrated in my 'Air and Rain.' The facts now to be given enable us to claim for it a still more important place. The application seems to fit well the conditions already examined, and by this means currents from foul places have been readily found. This does not apply to the substances which may be called germs, whether it be possible to see them or not, because these are not bodies which have passed into the ammoniacal stage, although some of them may be passing; those, for example, which are purely chemical and exert what we may call *idiolytic* action. This word may serve to mark this peculiar action, which was left by Liebig unnamed; he used the vague term invented by Berzelius, namely, catalytic. I have elsewhere recognized the two classes of germs, instead of any disputed one, without naming them.

It is now many years since Liebig first surprised me by saying that iron ores and aluminous earths were capable of taking up ammonia, and if they were breathed upon we were able even to smell that substance. He, much about the same time, made numerous experiments in order to find the ammonia of the atmosphere, and to measure its amount in rain. The result for science was great, and Professor Way continued the inquiry for the Royal Agricultural Society. Dr. Gilbert, F.R.S., amongst his many labours in the department of agricultural science, has made this inquiry into ammonia of rain in still later times, but I shall not at present quote his results, as this paper does not intend to go fully into the subject, but rather to indicate its magnitude and importance. The first paper I ever read to this Society was on the ammonia found in peat: I was unable then to see the extent of the subject.

I shall give parts of the fuller paper without the long tables of results.

Ammonia must ever be one of the most interesting of chemical compounds. It comes from all living organisms, and is equally necessary to build them up. To do this it must be wherever plants or animals grow or decay. As it is volatile, some of it is launched into the air on its escape from combination, and in the air it is always found. As it is soluble in water it is found wherever we find water on the surface of the earth or in the air, and probably in all natural waters, even the deepest and most purified. As a part of the atmosphere it touches all substances and can be found on many; it is in reality universally on the surface of the earth, in the presence of men and animals, perhaps attached more or less to all objects, but especially to all found within human habitations, and we might also add, with equal certainty, the habitations of all animals.

If you pick up a stone in a city, and wash off the matter on the surface, you will find the water to contain ammonia. If you wash a chair or a table or anything in a room, you will find ammonia in the washing; and if you wash your hands you will find the same: and your paper, your pen, your table-cloth, and clothes, all show ammonia, and even the glass cover to an ornament has retained some on its surface. You will find it not to be a permanent part of the glass, because you require only to wash with pure water once or twice, and you will obtain a washing which contains no ammonia. It is only superficial.

This ammonia on the surface is partly the result of the decomposition of organic matter continually taking place and adhering to everything in dwellings. The presence of organic matter is easily accounted for, but it is less easily detected than ammonia. It is probable that the chief cause of the presence of ammonia on surfaces in houses and near habitations is the direct decomposition of organic matter on the spot. If so, its presence, being more readily observed than organic matter itself, may be taken as a test, and the amount will be a measure of impurity. A room that has a smell indicating recent residence will, in a certain time, have its objects covered with organic matter, and this will be indicated by ammonia on the surface of objects. After some preliminary trials, seeing this remarkable constancy of comparative results and the beautiful gradations of amount, it occurred to me that the same substance must be found on all objects around us, whether in a town or not: I therefore went a mile from the outskirts of Manchester, and examined the objects on the way. Stones that not twenty hours before had been washed by rain showed ammonia. It is true that the rain of Manchester contains it also, but considering that only a thin layer would be evaporated from these stones it was remarkable that they indicated the existence of any. The surface of wood was examined —palings, railings, branches of trees, grass (not very green at the time), all showed ammonia in no very small quantities. It seemed as if the whole visible surface around had ammonia. I went into the house and examined the surfaces in rooms empty and inhabited, tables, chairs, ornaments, plates, glasses, and drawing-room ornaments. A (Parian) porcelain statuette, under a glass, showed some ammonia; a candlestick of the same material (but uncovered) showed much more; the back of a chair showed ammonia, when rubbed with a common duster, very little. It seemed clear that ammonia stuck to everything.

If, then, ammonia were everywhere, the conclusion seemed to be that it was not at all necessary to do as I had been doing, namely, wash the air so laboriously; it would be quite sufficient to suspend a piece of glass, and allow the ammonia to settle upon it. For this purpose small flasks were hung in various parts of the laboratory, and they were examined daily. The flasks would hold about six ounces of liquid, but they were empty, and the outer surface was washed with pure water by means of a spray bottle; it was done rapidly, and not above 20 c.c. (two-thirds of an ounce) of water was used. This was tested for ammonia at once with the Nessler solution. The second washing produced no appearance of ammonia, done immediately. Ammonia could be observed after an hour and a half's exposure at any rate, but I do not know the shortest period. The results of the washings were as follows; they are the average of 34 experiments for some, and 17 for others; in all 238 experiments:—

	Height from floor: Ft.	In.	Ammonia. M.gms.	Height from floor. Ft.	In.	Ammonia. M.gms.
Front laboratory	7	3	0·013	4	2	0·019
Second landing	6	0	0·032			
Balance room	5	1	0·015	0	8	0·009
First landing	4	10	0·007			
Back laboratory	4	5	0·010	0	6	0·010
Entrance lobby	6	5	0·007			
Office	4	7	0·003			
Back yard	4	8	0·036	0	7	0·042
Back closet	2	3	0·105			
Midden	—		0·572			

The first three belonging to the working laboratory are not very regular, as we might suppose, but they never rise very high, nor do they sink to the lowest. The rest, except the second, keep a remarkable similarity, and the differences are very great. In the second there is a disturbance caused by sweeping the floors. On the other days it was requested that everything should be kept still. This of course brings in a practical difficulty, and limits the use of the test to cases where care can be used and thoughtful observation, since there are many ways by which dust may be made to interfere, even although the act of sweeping should not take place. The house experiments gave similar gradations.

The result seems to be that a piece of glass, of a definite size, hung up in any place, will receive deposits of ammonia, or substances containing ammonia, in a short time; and by washing the ammonia off with pure water, and testing it with a Nessler solution, it may be seen

whether there is too much or not. It is the simplest test for ammonia yet found. Its discoverer deserves great thanks. It must not be forgotten that we may have ammonia in very different conditions ; it may be pure, or it may be connected with organic matter. This mode of inquiry is better suited as a negative test to show that ammonia is absent, than to show what is present. When ammonia is present there may be decomposing matter ; when absent there is not. I am hoping to make this a ready popular test for air—a test for sewer-gases,* for over-crowding, for cleanliness of habitations, and even of furniture, as well as for smoke and all the sources of ammonia. Of course it must be used with consideration and the conclusions must not be drawn by an ignorant person.

How far it may be used as a test of climate is a matter to be considered also.

After this I made another series of trials with air, Nesslerizing the washings at once, and not after laborious distillings, as in former cases ; the results are very valuable, showing that we obtain comparative quantities equally in this way.

The amount of ammonia obtained in this ready way does not give exactly the same results as the more laborious methods which I have used, but it may be taken as the most convenient. It must be observed that the amount rises exactly where you might expect more organic matter to exist. The lowest is from Prince's Road, outside the town, and almost a half a mile from the extreme of the Manchester houses. The next is obtained from an empty yard behind my laboratory, but it is still pure because there was wind and rain ; and any one who observes how unusually pleasant it is to breathe air even of a smoky town during wind and rain will not be surprised. I have not yet, however, had the purest air. I shall require to make a campaign on the moors, hills, and seas before I can give numbers for this. I have not even obtained the best given on land at a distance from manufactures. All this will be done in time.†

In my office the amount is larger than outside, but the air is not so bad as it is in front, and not so good as sometimes in the front where it is open. From the back of the laboratory during fog the ammonia was much higher, but during one day it was excessive, and a special examination of it was made in several streets. The highest amount was obtained at the front of the Cathedral, about midday, on the 8th of February, 1878, when the amount was 1·25, or 14½ times more than it had been found in Prince's Road, showing a considerable range:—

	M.grms. of Ammonia per cubic metre of air.
Prince's Road	0·086
Open yard during rain . . .	0·119 and 0·102
Front of laboratory	0·167 ordinary
Office	0·167
Front and back during fog . .	0·476
Close shut up room	0·413
Closet outside	0·800 to 0·900
Densest part of fog	1·25

* For sewage also to a larger extent than it has yet been used.

† Since the paper was read I examined trees and stones at Skelmorlie and Wemyss Bay, finding very little ammonia.

Parliamentary and Law Proceedings.

Charge of Selling Adulterated Tincture of Jalap.

At the Romsey Borough Bench, Friday, July 19, before the Mayor (Mr. Osborne) and Mr. Godfrey, Mr. William Blissett, dispensary chemist, was summoned, on the information of Superintendent Kellaway, with selling adulterated tincture of jalap. Mr. Glaisyer of Birmingham, solicitor to the Chemists and Druggists' Trade Protection Society, appeared for the defence.

Superintendent Kellaway deposed to having purchased from the defendent three ounces of tincture of jalap, and told him the purpose for which it was bought.

Cross-examined by Mr. Glaisyer : I made no use of it except handing it to the analyst. It was divided in defendant's presence into three parts, and all these parts sealed by me, in the presence of Mr. Blissett, with the county seal. One part I delivered to defendant, one to the analyst, Mr. Angell, the same day, personally, and I produce the third part. I also produce the certificate of the analyst.

The following is a copy of the certificate :—

"To Superintentent E. Kellaway, Romsey.

"I, the undersigned, Public Analyst for the County of Southampton, do hereby certify that I received on the 6th day of June 1878, from self, a sample of Tincture of Jalap for analysis and have analysed the same and declare the result of my analysis to be as follows :—

"I am of opinion that the said sample contained the parts as under, or the percentages of foreign ingredients as under—

"The strength of the spirit equal to 16 per cent. under proof or 40·66 per cent. of alcohol by weight.

"*Observations.*—This Tincture should be made with proof spirit. There is therefore a deficiency of alcohol to the extent of at least 9 per cent. by weight. Three per cent. may fairly be allowed for loss of alcohol during preparation of tincture.

"As witness my hand this 13th day of June 1878.

"Arthur Angell, *Public Analyst.*"

Mr. Glaisyer here asked that the analyst should be put into the witness box by the prosecutor, but this was refused. Mr. Glaisyer said he had given notice for Mr. Angell's appearance and that the case for the prosecution would be incomplete if he were not called.

The magistrates decided that the prosecution could not be compelled to put the analyst in the witness box. Mr. Glaisyer thereupon called for Mr. Arthur Angell, the county analyst, who on entering the box asked the magistrates to whom he was to look for his expenses.

Mr. Glaisyer said under the circumstances he would guarantee the fees, but he protested against the decision.

On being sworn, Mr. Angell gave the following evidence in answer to Mr. Glaisyer : I am public analyst for the county of Southampton. I am a Fellow of the Institute of Chemistry and Fellow of the Royal Microscopical Society. The certificate produced is mine, and the contents are here.—Cross-examined : I had the sample personally from the superintendent. I did not weigh the quantity of tincture I received. Tincture of jalap is made by steeping the jalap bulb in spirits. I am not a pharmacist. I obtained my knowledge from study. I do not remember what proportion of jalap is used in preparing the tincture. The tincture should contain 49 per cent. of alcohol and 51 per cent. of water. This is the liquid portion. I am not prepared to say what proportion of liquid there should be found in 100 parts of tincture of jalap. I cannot tell how much solid matter and how much liquid there should be in 100 parts. I have allowed three per cent. for solid, as stated in my certificate. There would be solid matter in the tincture. I believe the quantities should be 2½ ounces of the bulb to a pint or a *litre* of spirits. I am, however, not certain, but I think it is a pint. I did not weigh the solid matter. I took a weighed quantity of the sample and distilled it. I then took the distillate and made it up to the same bulk as the sample. The temperature of my distillate was about fifteen degrees centigrade. I then took the specific gravity ; the result was that the distillate ranged sixteen under proof. The solid matter is the active principle. I believe the spirit is of use medicinally. I believe there was sufficient pure jalap in the tincture to perform the functions of the medicine. I believe the absence of the alcohol did not at all affect the efficiency of the preparation.

At this stage of the examination the magistrates said they should not require Mr. Glaisyer to reply for the defence, as they had decided to dismiss the information.

An application made by the solicitor for the defence for costs was refused.

Dispensing Memoranda.

[118]. PULV. SCAMMONY.—I was curious to know if any other preparation than the gum was dispensed under above name; the following prescription for a child 18 months old seemed to indicate either that or the prescriber being accustomed to have his prescriptions dispensed with very inferior gum scammon. It was evidently not an error as I saw a similar prescription from the same pen for another child of tender years.

℞ Pulv. Scammony . . . . gr. xij.
Hyd. c Creta. . . . . gr. ij.
Pot. Bitart. . . . . gr. x.
Sod. Bicarb. . . . . gr. v.
Ft. pulv.
G. Cap. Statim.

BORGUE.

[132]. In answer to "Dispenser," I should say: Dissolve the quinæ sulph. in the acid. sulph. dil., add ℥iv. aquæ, then the sp. am. arom., and the tr. aurant. and sp. æther. chlor., aquæ q.s. The appearance, I should think, would be white, opaque, with a tinge of bluish brown derived from the quinine and tr. orange.

W. T. M.

[134]. In answer to No. 134 in "Dispensing Memoranda," lin. saponis is what I have always given as opodeldoc, and what I have always seen used. This I also was taught when studying pharmacy. On turning to Gray's 'Supplement,' I find too that opodeldoc is the synonym given for lin. saponis.

J. F. R.

Stockport.

[136]. DISPENSING OF COPAIBA RESIN.—Having frequently to dispense copaiba resin and experiencing some difficulty in getting a satisfactory mixture, I have adopted the plan of keeping a tincture prepared according to the following formula, which answers very well for hospital dispensing, and when mixed with mucilage of acacia, syrup of tolu and pimento water, makes as palatable a mixture as can be expected. Should you consider this any service to pharmaceutical readers please to insert the following:—

Tincture of Copaiba Resin.

Copaiba Resin . . . . . gr. 480.
Rectified Spirit sufficient to make up ℥iij.

Soften the resin by the aid of a water-bath and then dissolve in rectified spirit previously warmed.

Contains 1 grain in 3 minims.

Formula for Mixture.

℞ Tincturæ Copaibæ Resinæ . . . ℥iv.
Mucilaginis Acaciæ . . . . . ℥i.
Syrupi Tolutani. . . . . ℥i.
Aquæ Pimentæ . . . . . ad ℥viii.
Misce, ft. mistura.

S. R. CHALLIS.

[137]. AQUA GLYCYRRHIZÆ.—I shall be obliged if any reader will furnish me with the strength and preparation of Aq. Glycyrrhizæ. It was ordered to-day in the following prescription:

℞ Tinct. Catechu . . . . . ℥ss.
Spt. Ammon. Arom. . . . . ℥iss.
Spt. Æth. Chlor. . . . . ℥ij.
Tinct. Opii . . . . . ℥ss.
Aq. Glycyrrhizæ (?) . . . . ad ℥vj.
M. ft. mist.

J. W. B.

Notes and Queries.

[511]. G. S. will find that the following recipe forms an excellent tooth-paste, which retains its consistency and depurative qualities unimpaired for any length of time, and in any climate. It is advisable, when potting tooth-paste, to cover with tinfoil, parchment, or oleine tissue before putting on the lids.

℞ Cretæ Præcip. . . . . ℥xvj.
Pulv. Iridis. . . . . ℥iv.
Pulv. Oss. Sepiæ. . . . . ℥j.
Magnesiæ Carbon. . . . . ℥ij.
Moschi. . . . . gr. iv.
Essen. Bergamott. . . . . ℥ij.
Ol. Cinnam. Ver.. . . . . ♏ x.
Cochinill. . . . . ℥ij.
Syrupi Simplicis . . . . . q.s.
Ut fiat pasta dentis.

SUB UMBRA FLORESCO.

[512]. LIQUOR MORPHIÆ BIMECONATIS.—Could any reader furnish me with the formula for making this liquor? Bimeconate of morphia when dissolved in spirit or water forms a perfectly clear solution, but the above preparation, as supplied by Squire or any of the wholesale houses, is of a dark colour, and must therefore contain some colouring agent, or be prepared from the gum opium.

SUB UMBRA FLORESCO.

[513]. PREPARATION OF BLACK BRYONY.—Can any one give me a formula for an infusion or decoction of black bryony root, with the dose, etc.?

T. YOUNG.

EMULSION OF COD LIVER OIL WITH LACTOPHOSPHATE OF CALCIUM.—

℞ Ol. Morrhuæ . . . . . fl. ℥ iv.
Pulv. Sacchari Albi,
„ Acaciæ . . . . . āā ℥ ss.
Ol. Gaultheriæ. . . . . gtt. xxvi.
„ Menth. Piper. . . . . gtt. vi.
Aquæ Destil. . . . . fl. ℥ iv.
Misce; fiat emulsio, cui adde
Syr. calcii lactophosphat. . . . f. ℥ ii.

—L. von Cotzhausen in *Am. Journ. Pharm.*, 1878, 288.

The following formula is recommended by Mr. Shinn:

Cod Liver Oil . . . . . O. i.
Gum Arabic, pd. . . . . ℥ iv.
Sugar, powd. . . . . ℥ vi.
Sol. Lactophosph. Calcium (i. ℥ in fl. ℥ vi. ss) . . . . . fl. ℥ viss.
Lime Water . . . . . fl. ℥ viss.
Add the Cod Liver Oil and essential oils last.

PULVIS CAMPHORÆ COMPOSITUS (Gallop's Powder):—

℞ Camphoræ,
Pulv. Acaciæ,
„ Sacchari . . . . . āā ℥ i.

Mr. C. C. Pingham, of St. Johnsbury, Vt., highly recommends this powder as a convenient form for keeping

and administering powdered camphor. Mr. S. A. D. Sheppard, of Boston, considers it so excellent a preparation as to deserve to be received into the pharmacopœia.

PANCREATIC EMULSION OF COD LIVER OIL.—

R. V. Mattison gives the following formula:

Pancreatin, saccharated	℥ i.
Water	fl. ℥ iv.
White Sugar, powd.	℥ vii.
Cod Liver Oil	O. iss.
Oil Gaultheria	gtt. xx.
„ Bitter Almonds	gtt. v.

(10 grains pancreatin emulsify ℥ ij. of Cod Liver Oil).

COD LIVER OIL WITH CHLORAL.—The following mixture of cod liver oil and chloral is said to effectively stop the night sweats of consumptives, while at the same time producing sleep and improving the appetite:

Cod Liver Oil	19 parts.
Chloral Hydrate, cryst.	1 part.

Mix.

The Council Reports.

Sir,—It has occurred to me more than once, in view of the present discussion with regard to the reporting of the the Council meetings, that a word or two from me, the person principally concerned, might not be out of place, but hitherto I have been waiting for more leisure and a cooler state of the atmosphere. Your note, however, asking me for any explanation I have to make of the statement "that one of the leading members of the Council addressed some remarks he had to make to the Council at their meeting this month, but his speech is not reported for the good of the readers of the Journal" forbids further delay.

My reply to this inquiry will be very brief. 1. I deny that there is any such omission, and therefore cannot explain it. 2. If you wish me to explain how the idea has arisen, I can conjecture simply that it refers either to something which took place in Committee, or to some remarks which the speaker himself wished not to be reported. Candidly I have not the slightest notion what particular remarks are pointed to, and the description given does not at all help me. Probably the names of the "leading members" would be differently given by different individuals, but in my official capacity I consider the remarks of every member of Council entitled to the same attention.

I may be allowed to add that this is the first time that any definite charge of omission has been made, and that not directly, but on hearsay only. In every discussion at the Council table it has been admitted on all hands, as it could not fail to be, that my reports have been fair and faithful; the only complaint has been of their brevity; and I would point out that hitherto no one has ventured to assert that this brevity has been accompanied by the omission of anything—anything material at any rate. The length of the report simply depends on the nature of the business. Whenever there is a regular debate, as there was last month, the report is long; but when a great part of the day is spent either in Committee, or in desultory conversation which leads practically to nothing, or in discussing details of cases under the Benevolent Fund, the report whether furnished by me, or by any one who knows his business, will be brief.

On the question of admission of other reporters, it would not be becoming for me to offer any opinion, even if I had formed one; but I think I may say without impropriety, that so long as I am honoured with the confidence of the Council, I shall report the proceedings *secundum artem*, at my own discretion, and without being affected in any way either by the presence of other reporters, or by any other "influence" of which I am conscious.

Mr. Betty's omitted remarks consisted of a quotation, with comments, of an article in the *Chemist and Druggist*, reflecting on Mr. Carr, a late member of the Council.

THE OFFICIAL REPORTER.

88, *Chancery Lane.*
August 1, 1878.

Sir,—Since my first letter to you this month I have heard that one of the leading members of the Council addressed some remarks he had to make to the Council at their meeting this month, but his speech is not reported for the good of the readers of the Journal. Was that the fault of the reporter? If so the presence of another reporter would be likely to correct such omission. Or was it that his words were "too sweet," or "too acid," or "too bitter," or "too spicy," or that he did not like to see what he had spoken in print, it being "too savoury" for the "report dish."

That the member did speak and is not reported is well known.

In a letter to you in January I called your attention to the "report dish" for December and January, which was "overdone" or "underdone," and no reader, even by the aid of "Pepsina Porci" and "Pil. Rhei Co.," could make them "agree" or "digest."

I trust I have proved that there is a "wee bit of cooking." It is taught at South Kensington, so why not be "acted on" at Bloomsbury Square?

"Control" is patent, see past and present Presidents' speeches this month.

I will not complain of your injustice to me in making comments on a letter you did not publish, when I consider how you have treated the Trade Association, which numbers 4000 or so country chemists (who know better than we in London what affects their trade), attacking their circular, instead of helping to defend and sustain the common rights and interests of all chemists.

On this ground I think I have, as an old member of the Pharmaceutical Society, a just cause of complaint against the action the *Pharmaceutical Journal* has taken.

But it is refreshing to turn from the one-sided petty carping insinuations of the *Pharmaceutical Journal* against their own body to such an article as that published in the *Morning Post* of Saturday last, treating the subject from a public point of view, and founding their argument on the "Trade Association Circular," which the *Pharmaceutical Journal*, controlled by the Council, runs down.

There may be many who do not agree with every word of that circular, but this is not the time to find fault with the work of friends whose calling is identical with our own, and to defend whom is the privilege and duty of all connected with the trade.

W. W. URWICK.

60, *St. George's Road, S.W., July* 23, 1878.

The Admission of Women to the Society.

Sir,—It was not my intention to trespass again on your space in reference to the admission of women, as I should not be a true exponent of their desires if I allowed it to be supposed, as some have insinuated, that they are clamorous to be admitted, or could not wait another year to have their rights accorded to them in a graceful manner by the members at the next annual meeting, and then, not for any personal advantage, but as a right which they claim on principle.

You have inserted a letter from Mr. Fryer, and with due deference to the confidence that writer displays in his superior judgment, I beg respectfully to inform him that he does not "understand the proposition of Messrs. Hampson, Wade and Co.," and I cannot hope after all that has been said and written, that he ever will comprehend it. It is really astonishing that so many intelligent members will continue to harp upon the wrong string. All the fiddle-faddle absurdities about the charms of womankind, woman's mission to stay at home and not to enter into competition with the other sex, have nothing to do with the votes.

Every day life, and the stern necessity for numbers of women to earn their own bread, has long ago settled that nonsense. It is certainly superfluous, however well meant, for some lords of the creation to dictate to women how they are to get their living, and to point out to them that which is indelicate and unseemly for a female to engage in. As if women were not far better judges of that which is suitable for themselves, and had not a keener susceptibility and care for propriety; as if their own sense of modesty was less regarded by themselves than by men.

If Mr. Fryer had grasped the reasons I put forth in favour of the resolution, I should be pleased to reply to his opposition, but as after this length of time he has found nothing more telling than a reproduction of Mr. Vizer's speech, and a few borrowed plumes from Mr. Sandford's "only a woman" argument, I can only strive to make plain to him and others what is the proposition of "Hampson and Co."

The simple fact which we desire every member to understand is, that the law permits both men and women to carry on or assist in the business of chemists and druggists, providing they have shown themselves proficient, and obtained certificates from the examiners of the Society, and are registered as associates or pharmaceutical chemists. The Act of Parliament does not mention sex, or prohibit women from any privileges the men receive.

Three or four ladies have passed through their studies creditably, showing no inferiority to their male competitors, and are indisputably on the register. These lady chemists applied to the Council to be elected, according to their qualifications, members and associates, and a small majority of those gentlemen who manage our affairs had not the courage to fulfil their duty without asking the consent of the annual meeting.

Every one knows the result, and yet the Council refuses to carry out the provisions of the Act, and leaves it open for members at the next annual meeting to express their wishes once more.

As mover of the resolution I am content, but at the same time I protest that it is not a question to be decided by the members one way or the other. It is simply an act of courtesy, because some of the Council cannot overcome their prejudices against females being engaged in pharmacy. I look forward to our next meeting with confidence, because I cannot believe that men who are now contesting apothecaries, and co-operation, and everything which interferes with their rights, can be so inconsistent, so mean, and so churlish, as to refuse to women what they attempt to keep.

Mr. Fryer would by "courtesy allow lady chemists the free use of the library, museum, etc.," but that is all. I think he must have a poor conception of their self-respect if he supposes they would be willing to accept as an indulgence, that which they have as great a right to as himself. As it could scarcely be expected that I should acknowledge each post card sent to me in favour of women's claim, will you permit me to thank collectively those gentlemen who have given me their support. I beg also to thank you, sir, for suggesting that method of obtaining information as to the wishes of members.

JOHN WADE.

EXAMINATION DISCREPANCIES.

Sir,—Having read the correspondence about the discrepancy of the examinations in London and Edinburgh, allow me to call your attention to another case which I think worthy of notice. Any one who has read the result of the examinations in London must be struck with the number of failures for the Minor on the last day of each month's examination compared with those on the previous dates, and also the fact that the percentage increases daily from the first date. For instance, I will refer you to the three last meetings. On April 10th, 18·75 per cent. failed, and the number increased each day until the 17th, when 70·83 per cent. were rejected. June 19th, 43·75 per cent. failed, rising to 85 per cent. on the 21st, and July 10th, commences with 37·5 per cent., finishing on the 25th with 80 per cent.

The question naturally arises, "How can this be accounted for?" It would be impossible to single out the good and bad candidates previous to the examination and so arrange them.

Perhaps some gentlemen with experience in examinations can elucidate what at present seems a mystery to

AN ASSOCIATE.

London,
July 27, 1878.

THE SALE OF PATENT MEDICINES, ETC.

Sir,—Will you kindly allow me a small space for a few remarks relative to the way in which we, as a body of chemists and druggists, advertise patent medicines, etc.? I had a traveller call on me one day of last week, and his announcement was, "Good morning, sir; called again on my usual errand." "What is that?" I asked. "Do you require any counter bills or posters, with your name and address attached?" My answer was, "No; I think you had better call on several of the cutting houses in this city that retail your medicines for the same and, in some cases, less than I can buy them for."

Now, sir, he was very much taken back, and no doubt sorry to hear that a great many chemists and druggists had decided on not having any more bills relative to any patent medicines in their establishments but their own. I think, sir, we have been the means, to a very great extent, of raising the sale of certain patent medicines to their present state, and now what does it mean? Why the public generally go to Mr. Grocer, Draper, Hairdresser, Bookseller, etc., for Cockle's or Holloway's pills, and they are advertised in this city to retail a 1*s.* 1½*d.* box for 10*d.*, 2*s.* 9*d.* box for 2*s.* 2*d.*, Holloway's 1*s.* 1½*d.* box for 9½*d.*, and 2*s.* 9*d.* box for 2*s.* 1½*d.* Who can say but that these prices are such as no chemist can get a living at? I forgot to mention also that Holloway sends a printed form by post, with halfpenny postage attached for an answer, to know if any counter bills, etc., are wanted. Does it not seem a great folly that we should advertise his or any other man's goods for them to be bought at the same price, or less, than I can buy them for? I hope that the chemist and druggist generally will adopt the same plan and not have a single counter bill relative to patent medicines in his establishment, for so advertising the public say, "Oh, I have seen a bill of So and So from Mr. So and So, the chemist; let us try if we cannot get it at Mr. Grocer's for the 9½*d.* or 2*s.* 2*d.*"

W. W. B.

Queen Street, Exeter, July 30, 1878.

A CONTRIBUTION TO THE HISTORY OF COLOCYNTH.

Sir,—I beg to forward you the accompanying cutting from the *World* of July 31:—

"Is there any one thirty years old who has not taken a colocynth pill? Hardly, I suppose. Well, as Cyprus is on the *tapis*, it may interest my readers to know that the colocynth apple is an indigenous Cyprian plant, and largely exported from our new island to this country at a shilling a pound. What one pays for a dozen pills containing a few grains! No wonder chemists make fortunes."

It will probably interest some of your readers who have not chanced to see the original.

JOHN TAYLOR.

13, *Baker Street, Portman Square, W.*

THE PRESENT STATE OF PHARMACY.

Sir,—As an old member of the Pharmaceutical Society, I think that I am entitled to make a few remarks upon the present state of pharmacy.

Mr. Jacob Bell, and the other founders of the Pharmaceutical Society, hoped that the chemist of the future would practise simply pure pharmacy: but up to the present time that has not been the case.

The chemist of the present day deals in as many heterogeneous articles as he did forty years ago, with very few exceptions.

It has ever been the practice of the chemist, in whatever locality he may be situated, to give advice more or less in simple cases; and surely the advice given by the educated chemist is far better than people, who are utterly ignorant of the action of medicines, should doctor themselves, which they surely will do if any restrictions are put upon the time-honoured and legitimate business of the pharmaceutical chemist.

By all means a line should be drawn, and the chemist

should not interfere with the legitimate practice of the surgeon, viz., in visiting or attending dangerous cases.

It is plain the law cannot remain as it is, or the clause as proposed in the Duke of Richmond's Bill be allowed to pass unheeded.

It would be simply ridiculous to think that every pharmacist should have the axe hanging over his head for recommending a simple medicine.

For instance, a gentleman comes into my pharmacy, and says, "I have a slight attack of indigestion, prepare me a tonic for it," or, "what is the best aperient medicine I can take?"

I should like to ask Mr. Urwick whteher he calls these examples treatment of disease?

As the law stands at present we are in this singular position, that we are liable to a prosecution for advising or recommending any medicine, while the makers of patent medicines (many not even chemists) can, with impunity, recommend their preparations for every imaginable disease, by putting a stamp on the bottle, and obtaining a licence.

I believe a remedy for this state of things would be an amended Pharmacy Act (not a clause inserted in the Medical Bill), wherein our duties should be clearly defined "cum justitia publicis et nobis."

It would almost seem that the Society was at present acting for the few *élite*, not for the interests of the whole trade.

Most of us have not yet come into that state in which we can live by simply dispensing prescriptions.

Liverpool, July 29, 1878. J. THOMPSON.

*** We think our correspondent's apprehensions as to the risk of prosecution in such instances as he mentions are not well founded.—ED. PHARM. JOURN.

CAN THE RETAIL DRUG TRADE BE SAVED FROM GOING TO THE DOGS?

Sir,—Many letters have appeared in the Journal on the subject of "cutting" or underselling. I have scanned them all without meeting with one practical suggestion for counteracting the serious and growing evil, which if unchecked, threatens to ruin the prospects of half the druggists in the country. I think I can offer a suggestion which, if acted upon, would at least have a more telling effect than anything that has yet been suggested, and would probably destroy the evil so justly deprecated and denounced. I have in prior letters, which you have done me the honour to insert in the Journal, pointed out and I would again lay all possible stress on the fact that no lowering of the prices of drugs and chemicals can in any appreciable degree increase their consumption. Let Epsom salts be sold at 1*d.* per oz., or 4*d.* per lb., castor oil at 3*d.* or 1*d.* per oz., Cockle's pills a 1*s.* 1½*d.*, or 10½*d.* per box. Give two or six "bilious" pills for 1*d.* Not a single dose more or less will be swallowed. Therefore, unlike the trading in other commodities, lowering the prices of drugs and chemicals simply means a lessening of the income of those who sell them, carrying with it no compensating result arising from increased consumption by those who buy them.

A long experience leads me to believe that a large majority of druggists' assistants consider that their interests are antagonistic to the interests of their employers. This is a grievous error. With artizans employed by large capitalists, to some extent at least, it may be so. It may be to the interest of the workmen to obtain from their masters as much pay as possible for as little work as possible. It may be to the interests of the masters to pay as little as possible for as much work as possible. But the relationship of master-druggists to assistant-druggists is different, and for this reason—the assistants of to-day will be masters to-morrow. Their interests are identical. Assistants so to speak are masters *in embryo*, and whatever affects injuriously the interests of the one, affects injuriously the interests of the other. And in this matter of a disreputable few endeavouring to aggrandize themselves at the expense of the respectable many, it were not difficult to show that the interests of assistants are more seriously assailed than are those of their employers. Many druggists now in business are able, if they please, to retire; others if not in quite such independent circumstances, are at least too firmly established to greatly fear any serious result from the tactics of an unprincipled neighbour who having no confidence in his ability to compete with them in honourable rivalry, endeavours to steal away their legitimate trade by starting "a cutting shop." I will not unnecessarily occupy your space by showing at how much greater disadvantage young men commencing business and desiring to carry on trade in a respectable and honourable manner must be placed, than are their old established contemporaries. That must be patent. But I wish to show that just as the present race of assistants must eventually be the severest sufferers, if these robbers are to proceed in preying on the vitals of the trade, so with them lies the power of successfully waging battle against the accursed thing. These men (if "men" be not a misnomers) are assistants' direst enemies, they threaten to blight their finest prospects and fondest anticipations, to destroy all hope of their succeeding in an honourable career. Then, let every assistant druggist in the three kingdoms require to know, when treating for a situation, the prices that obtain at the establishment in which he is required to serve, and resolutely determine on no account whatever to accept service where the accursed thing is practised, and the occupation of these robbers will very soon be gone, because it is next to impossible for any one single-handed to do a sufficient trade as a druggist if the profits are cut down to those of a grocer; the services of at least one if not two assistants must be required to make the thing pay. Good situations are far more easily to be obtained now-a-days than they were in the days of my assistantship; but had I been asked to take service in a co-operative store (which happily did not then exist), or to serve similar enemies to the profession in which I had cast my lot, I would indignantly have spurned the offer, no matter what remuneration might have been offered me. For I should have felt that in accepting it I should forfeit all claim to be considered a man or a gentleman, and should "write myself down an ass" into the bargain. Those to whom I have not scrupled to point the finger of scorn are, as I have said, the assistants' worst foe, and I hope there is sufficient *esprit de corps* amongst the latter to combine as one man against the common enemy, determined to "cleave him to the teeth," and fight him to the death. It is in their power to save what should be a noble profession and an honourable calling from "going to the dogs." They have only to will it, and they must win. It remains to be seen if they will.

HAMPSHIRE.

DROSERA ROTUNDIFOLIA.

Sir,—With reference to the remarks in "The Month" (a most pleasant feature in your Journal), on the Drosera, I might say I saw last week *D. rotundifolia* in flower plentifully in marshy ground between Brodick and Lamlash, Isle of Arran, at half past two p.m. *D. anglica* and *intermedia* I have seen in flower about midday in Connemara.

Enclosed is a specimen of rotundifolia picked at the time named.

July 28, 1878. G. C. DRUCE.

W. Haydon.—We are obliged to you for forwarding a report of the tincture of jalap case. We had, however, one already in type, which had been obtained from another source.

R. Roberts.—(1) *Hypericum perforatum; H. pulchrum* has ovate leaves (broadest at the base). An entire leaf and fruit will be required. (3) *Stellaria graminea.*

T. Young.—(1) *Bryonia dioica* with flowers; (2) *Tamus communis* with berries.

E. T. G. and "Student."—See before, p. 57, paragraph 36, where it is provided that any person who has been articled as a pupil and paid a premium to a dental practitioner entitled to be registered under the Dental Act, in consideration of receiving from such practitioner a complete dental education, shall, if his articles expire before the 1st of January, 1880, be entitled to be registered under that Act as though he had been in *bonâ fide* practice before its passing.

M. Leigh.—Lindley and Hutton's Fossil Plants (Quantil).

THE PARIS EXHIBITION.

Crude Materials applicable in Medicine and Pharmacy.

ENGLISH COLONIES.

Victoria.

The exhibits from this colony of a pharmaceutical nature consist of a small but neat case of specimens from Mr. G. Bosisto, M.P., of Richmond, Melbourne ; some bottles of essence of eucalyptus, recommended for destroying the phylloxera of the vine, from Messrs. Sanders and Sons, of Sandhurst; and a case of numerous, but very poor specimens of many eucalyptus gums, dyes, etc., from Mr. W. R. Guilfoyle. Mr. Bosisto, who has paid considerable attention for many years past to the native products, more especially to those of the eucalyptus tree, exhibits the astringent gums of *Eucalyptus globulus*, *E. amygdalina*, *E. obliquâ*, *E. sideroxylon*, and other species, the essential oils of *E. amygdalina*, *E. fissilis*, *E. obliqua*, *E. sideroxylon*, and *E. Stuartiana*. The oil of *E. amygdalina* is used in Australian hospitals as a rubefacient for rheumatism, asthma, whooping cough, croup, etc., and in the form of ointment for fetid suppurations. It is also used for copying paper, and as a solvent for resins, etc.

Red gum, from *Eucalyptus rostrata*, is exhibited in the form of thin laminæ, or pseudo-crystalline scales.

Other essential oils exhibited are those of *Eucalyptus oleosa*, used as a solvent for caoutchouc and resins; oil of *Atherosperma moschata*, or Australian sassafras, used as a diuretic, diaphoretic, and sedative, and said to exert a specific lowering influence on the action of the heart in doses of 1 to 2 minims twice a day; oil of peppermint, and oil of *Melaleuca ericifolia*, which resembles in some measure that of cajeput, but affords a very pleasing perfume when much diluted. The perfume from *Acacia pycnantha*, prepared by enfleurage, is said to have a delicious odour; of this, however, it is not possible for the visitor to the Exhibition to judge. Another article worthy of notice is a specimen of opium in small round balls about the size of a green walnut, made from the plant grown in East Victoria, also morphia prepared from it. The official report unfortunately does not mention the percentage of alkaloid present in the opium.

A kind of catechu prepared from the bark of *Acacia decurrens* may probably come into use in the future. The tree is very abundant and widely distributed throughout the colony, and the bark is largely exported to this country under the name of mimosa bark. The tree arrives at maturity in five to eight years. In consequence of its profusion and rapid growth the bark splitters remove only the larger pieces, leaving the rest of the bark on the tree. The catechu is obtained from this waste material, and can be made in large quantities and at a cheap rate. It is rich in tan power, of a red-brown colour, and forms a clear solution.

Mr. Bosisto's interesting essay on the eucalyptus and its properties is appended to the catalogue, and is well worth perusal.

The specimens exhibited by Mr. Guilfoyle include a yellow dye obtained from the bark of *Dais cotinifolia*, a rich brown dye from the bark of *Pipturus argentea*, a blue dye from the bark of *Casuarina stricta*, and a red dye from *Ficus macrophylla*, gum arabic from *Acacia dealbata*, tous les mois from *Canna edulis*, lampblack from *Juncus vaginatus*, and caoutchouc varnish prepared from *Ficus macrophylla*, which mixed with solution of copper is used for coating the bottoms of ships. In this department may also be noticed a collection of dried plants from Victoria, and an album of nature-printed ferns, which, for its beauty, obtained a silver medal in the Melbourne Exhibition of 1872 to 1873.

West Australia.

There is practically nothing of purely pharmaceutical interest in this department. Tanning materials consisting of the barks of various species of eucalyptus and acacia and a few specimens of gums, such as black boy gum, are the only articles that bear any resemblance to crude drugs. From the catalogue we learn that the dugong is found in great abundance upon the north-west coast of this colony and is killed for the oil, which is not only used for medicine, but for general purposes.

Specimens of arrowroot prepared from the roots of a species of *Zamia* deserve a passing notice. At the Exhibition of 1851 in London, the jurors stated that this preparation appeared to rival arrowroot in quality and resembled it in feel and taste. The plant is plentiful in the colony and the root yields 30 per cent. of arrowroot, which is easily prepared. Samples of olive oil are also exhibited from this colony by Mr. T. Jecks and Bishop Salvado, and spermaceti and sperm oil by the Albany Committee. Some nice specimens of the jelly plant of Western Australia are shown. This is a species of seaweed nearly allied to the agar agar (*Eucheuma spinosum*) of the Malayan Archipelago. The jelly plant (*Eucheuma speciosa*) is prepared for use by powdering it, dissolving, straining, and heating to dryness with one-third part of Zamia arrowroot. A teaspoonful of the powder is moistened with cold water, sweetened, flavoured, and filled up with boiling water, and is then ready for use.

Mauritius.

From this island no pharmaceutical exhibit appears to have been sent. This is somewhat surprising, since there is an excellent list of the medicinal plants of the island published by Mons. E. Bouton some years ago. Tapioca starch and tapioca and arrowroot are, however, exhibited, and there are some excellent samples of vanilla, from M. Jules Joly, of Port Louis.

Seychelles.

The objects from this island are arranged close to those from Jamaica. Most conspicuous are the double cocoa-nuts (*Lodoicea Seychellarum*), of which a large number are exhibited in all stages of growth. In olden times important medicinal virtues were attributed to these nuts, water drunk out of vessels made of them being supposed to act like a charm in preserving people from all kinds of complaints. Another curious fruit is the *Carapa Moluccensis*, which has the shape and size of a cannon-ball and contains a number of angular seeds, larger and smoother but of similar shape to Brazil "nuts." The seeds of this fruit are used in Borneo as a bitter tonic and febrifuge.

Among the other objects exhibited from the Seychelles are, cloves, a kind of cinnamon with a fibrous fracture, turmeric, arrowroot, tapioca starch, and a number of unnamed roots and barks, used by the natives for medicinal purposes. The cloves are

of poor quality, which is doubtless owing to the reckless and wasteful manner in which the cloves are gathered. The islanders cut off the branches, although they are aware that several years must elapse before the tree can again reach the bearing stage, and that in fact many of the trees will probably die from such rough treatment. Both cloves and cinnamon grow vigorously in these islands and would probably well repay careful cultivation.

INDIA.

An immense number of specimens of drugs from this portion of the British empire are exhibited in the front transept. These practically consist of two series.

One series, which is arranged alongside of the samples of different kinds of wood, illustrates forestry and the various products, gums, roots, barks, fibres, fruits, etc., derived from the trees and plants. This portion is exceedingly well arranged, all the specimens being carefully labelled and numbered, and grouped according to their natural orders, so that it is easy to find any specimen that one may wish to see. This collection has been sent by Dr. Brandis, and is accompanied by an excellent catalogue. The other series consists of a large number of specimens, in small glazed boxes, badly labelled and badly preserved. Apparently two or three sets of the same article have been sent, for many duplicates are noticeable. Some of the specimens are without labels and have evidently had to be named after their arrival at Paris, and must have entailed an immense amount of unnecessary labour upon the manager of this department. Another collection of indigenous drugs, arranged by Kanny Loll Dey, consists of a number of small specimens of indigenous drugs neatly labelled.

In one of the central cases of the transept may be seen some instructive photographs, illustrating the manufacture of tea, through the various processes of gathering, allowing the leaves to wither in heaps, rolling it while green on mats and when fermented rolling it on tables, drying the leaves in the sun, and firing or drying the leaves in pans by artificial heat, assorting the leaf, and weighing and packing. Some of the dried specimens of Assam tea leaves are of very large dimension, being from 6 to 10 inches long, and from 2½ to 5 inches wide.

Specimens of the cultivated cinchona barks, *Cinchona Calisaya*, *anglica*, and *josephiana*, and illustrations of the plants of *C. javanica* and *C. uritusinga* are exhibited.

CEYLON.

From Ceylon some splendid specimens of plumbago are shown, carved into various figures, such as elephants, etc. A series of photographs illustrating the cultivation of coffee and of cinnamon add considerable interest to the exhibits from this colony. The cutting of the bushes and the peeling of sticks,—the outer bark being scraped off by women, and men forming the bark into pipes and inserting one into another,—the drying, sorting, and packing are all well shown and convey at a glance more than could be described in many sentences. The cinnamon exhibited is packed in bundles four feet long, and varying from four inches to two feet in diameter. That from the plantations of Miquel Pereira and J. F. Duebey is remarkable for the neat manner in which the places where the quills have been joined are hidden by the binding, so that the quills appear to be the whole length of the bundle, and for the pale colour. Vanilla, vetivert, *Hemidesmus indicus*, and cardamoms, orchella weed in great variety, areca nuts, cinnamon chips, castor oil seeds, and a variety of other well known products are also exhibited from this island.

CHINA.

The collection of drugs from China consists of a large number of specimens, well preserved and carefully labelled, but in Chinese only. Many of these presented a familiar appearance and are drugs used either in this country or in India. Some, however, are decidedly peculiar, and by no means likely to meet the wants of Europeans. Such for instance is a drug looking like button shellac. It is obtained by putting frogs in a jar containing flour, and then irritating them with a stick, the secretion which they exude from their skin under these painful circumstances makes the flour sticky and this is made up into the cakes above mentioned, for use in medicine.

JAPAN.

It is impossible to visit the Japanese annex without feelings of admiration and astonishment. The educational department, in which drugs are to be found, would do credit to the most advanced European country. It includes anatomical models, showing veins, muscles, etc., in the surgical department; specimens of drugs and vegetable products used in commerce, and illustrated by drawings or dried specimens of the plants themselves, together with their Japanese name, botanical name and uses; swinging stands, having specimens of products side by side with the plants producing them, and all the most modern improvements in educational appliances.

On two days in the week, at certain hours, a gentleman is present to answer the questions of visitors, on one day speaking in French and on the other in English, so that every arrangement is as complete as could possibly be desired. Some of the drugs exhibited are already well known in English commerce, such as Japanese aconite, and thao, or Japanese isinglass. The *Eucheuma spinosa*, of which the isinglass appears to be chiefly made in Japan, is by no means the only species of alga used by them, specimens of several others being exhibited, among which may be noticed the *Glœopeltis intricata*, *Gymnongrus pinnulatus*, and *G. flabelliformis*, *Kalymenia dentata*, *Halochloa macrantha*, as well as several English species, such as *Laminaria saccharina*, and *L. debilis*, *Codium tomentosum*, *Gelidium corneum* and *Gracilaria confervoides*. Some of the drugs are identical with those used in China and others with Indian drugs. All the specimens are, however, very neatly arranged and labelled.

JAVA AND THE DUTCH COLONIES.

The exhibits here are very numerous. At the time of our visit this department was not quite finished and the labels were in many cases damaged, owing to water having come in upon the specimens before the arrangement of the exhibits was completed. The gentleman in attendance, however, with great courtesy, permitted us every opportunity of examining the specimens although the department was not open to the public. A large number of the

things are such as would be met with in India. Catechu was well represented by the ordinary kinds in cubes, catechu in parallelograms, in circular flat cakes about one inch in diameter and one-third of an inch in thickness, and in lozenges of various shapes. Some fine specimens of benzoin, the variety of aloes wood with resinous stripes, agar-agar (*Eucheuma spinosum*) and edible swallows' nests are well represented. The collection of the nests is illustrated by a model, showing the manner in which they are taken from the rocks. The exhibits from Dutch Guiana are very similar to those from British and French Guiana, but in addition there is an oil obtained from the green turtle (*Chelonia viridis*).

In the annex, a very fine show of vanilla is exhibited by Messrs. De Groot and Co., of Amsterdam; indeed this is the finest exhibit of vanilla in the exhibition, and includes Mexican and Mauritius vanilla, from *V. aromatica*; Bourbon and Java vanilla, from *V. planifolia*; and Guadeloupe vanilla, with the characteristic spiral mark around the pods. Pure vanillin from vanilla, and fine specimens of artificial vanillin in nearly white crystals, are also exhibited by the same firm.

PORTUGAL.

The collection of drugs in the Portuguese annex is remarkably well arranged on stands with shelves, which permit a great number of specimens to be easily seen, while the minimum of space is occupied, each being attached to a wooden foot. The specimens themselves are in inverted glass bottles, are carefully selected and are in sufficient quantity to be representative. Many interesting articles are to be seen here, but unfortunately the bottles are labelled only with the Portuguese names, so that it is only possible to guess at the names of the contents of many of them. In the entrance stands, in a glass case, a fine specimen of that very singular plant, *Welwitschia mirabilis*, showing it in the young state, and also an old specimen of flowers and fruit preserved in liquid. The whole plant consists only of the two cotyledonary leaves, and the stem below and a little above the cotyledons, enormously developed in the course of years, no other leaves ever making their appearance. The cotyledonary leaves, however, in the course of years become as much as six feet long. The specimens of drugs appear to come mostly from the Lisbon Museum, and it is a disgrace to such an establishment that specimens should be sent out without the botanical names of the plants yielding the specimens being given. The specimens are as fine or finer than those of the French colonies, and would be a very valuable collection if properly labelled and described in a good catalogue. Some fine specimens of minerals, including a large mass of magnetic iron ore, titaniferous sand, native copper and selenite are exhibited. Several kinds of indiarubber, a great number of different varieties of copal, gum arabic, soap berries, castor oil seeds, purging nuts (*Jatropha curcas*), and a good series of orchella weed, including *Rocella montagnei*, *R. phycopsis*, *R. tinctoria*, and some species of *Usnea*, *Physcia*, *Parmelea*, etc., which we were unable to identify, and which do not appear in English commerce, and a number of herbs, roots and barks of unfamiliar appearance, are the chief drugs noticeable. Sassy bark, here called "encassa," is also exhibited.

MOROCCO AND TUNIS.

Neither Morocco nor Tunis are well represented as regards drugs. In the Tunis department were observed henna (*Lawsonia inerma*), nigella seed, pomegranate fruit and bark, coriander, cummin, fenugreek, short anise, pistacio nuts, and the peculiar long narrow caraways, which are sometimes imported into this country from Mogador.

In the Morocco department a small stand of drugs is exhibited, consisting of gums, seeds, galls, etc. Among these may be recognized café nègre (*Cassia occidentalis*), senna leaves (*Cassia acutifolia*), colocynth, some fruits of a species of *Datura*, labelled "laudanum," and a small number of other drugs of which only the Arabic name is given.

UNITED STATES.

By far the finest collection of crude drugs in this department is that exhibited by the Philadelphia College of Pharmacy, which appears to include all the crude drugs used in the States, either by allopaths, homœopaths, or eclectics, and is perhaps the most perfect of its kind in the exhibition.

NICARAGUA.

The court devoted to this country contained many interesting articles. Some very fine specimens of cacao beans, liquidambar in reeds, and some india-rubber of excellent quality at once attract attention. A green vegetable wax, resembling bayberry wax (*Myrica cerifera*) a dark thick balsam of copaiba, copalche bark, sarsaparilla, and several tanning barks were also noticeable. It may be noted here as a curious circumstance that cashew nuts (*Anacardium occidentale*) are labelled St. Ignatius's beans.

PERU.

The exhibit of drugs from this country is rather poor and the specimens are of bad quality. They include crude iodine, cochineal, vanilla, coca leaves, borate of lime from Iquique, and a few specimens of cinchona barks of inferior quality. Those of calisaya bark, from Bolivia, are much finer, and with coca and matico are the only exhibits worth notice from that country.

ARGENTINE REPUBLIC.

From this country are exhibited jaborandi from Paraguay, and coca leaves, calaquala root (*Polypodium Calaquala*), and the leaves of *Brosopis ensifolia*.

The name of Sanguinaria is given to the plant of *Polygonum brasiliense*, which possesses astringent properties, although probably not in so high a degree as the Guaycuru (*Statice brasiliensis*). Safflower, aniseed and linseed, red quebracho chips and resin, the fruits of *Schinus molle*, under the name of Pimianta, and several other drugs, are also exhibited by Demarchi, Hermanos y Cie., druggists, at Buenos Ayres.

It will be seen from the foregoing that the present exhibition in Paris is rich in comparatively untried drugs, and that in the collections from the colonies especially there are many probably that would repay investigation by the medical man and the pharmacist. As to the majority of them the conditions under which

they are shown preclude more than the briefest mention; but should the object of the Council be attained in securing some of these collections for the Society's museum there is little doubt that the names of some of the drugs will become more familiar to the readers of this Journal.

KINATE OF QUININE FOR HYPODERMIC INJECTION.

BY HENRY COLLIER.

I have on several occasions been called upon to make a solution of quinine for hypodermic injection, and as the ordinary salts of quinine (the sulphate and hydrochlorate) are not very soluble in water, the subject has always been with me a very unsatisfactory one.

This method of administration is desirable when the patient is so constantly sick that quinine cannot be given by the stomach, and in such cases the principal object in giving the remedy is to reduce temperature; large doses are also required.

Solutions intended for hypodermic use require to be neutral, and of such a strength that a few minims only are needed for injection. I have prepared a solution of ordinary quinine sulphate containing 1 grain in 10 minims, by heating the quinine and water in a beaker and adding just sufficient diluted sulphuric acid to dissolve the quinine, but of course the solution had a very acid reaction. In one case however, in which this was employed, the patient did remarkably well, and no irritation was produced by the punctures. I have made some of the so-called neutral sulphate of quinine, but even after a second crystallization its solution was very acid and it was not more soluble than 1 in 10. Hydrochlorate of quinine is fairly soluble in warm water, and such a solution has been injected warm, but the result was not satisfactory. In Parrish's 'Practical Pharmacy' it is stated that kinate of quinine is soluble in 4 parts of water, and a process is given for its preparation direct from cinchona bark. I, however, procured from Mr. Morson some kinate of calcium which I converted into barium kinate. This salt is freely soluble in water, and upon adding to its solution sulphate of quinine in powder, the whole of the barium is precipitated and kinate of quinine remains in solution. Upon evaporation the kinate comes out in amorphous masses; even when evaporated under the air-pump over H_2SO_4, the same result is obtained. A drop of the same solution spread over a glass slide and evaporated slowly, shows under the microscope very distinct crystalline tufts. The plan I adopt is to reduce the solution of kinate to dryness over a water-bath and then powder the residue. The kinate obtained by slow evaporation at ordinary temperatures contains a large quantity of water, some of which it loses by keeping at 90° F., so that to ensure a definite product it is necessary to dry it.

Kinate of quinine is very soluble in water, and its solution is perfectly neutral. The strength of the solution which is used at this hospital is 1 in 4. I generally prepare ℥j of the solution at a time by putting into a beaker ℥vj aq. destil. and ℥ij kinate of quinine, heating until the salt dissolves, which it does almost immediately, and then making up with aq. destil. to ℥j. It is quite possible to make a permanent solution containing 1 in 3, but I find that 1 in 4 is more convenient for use. Even with this strength the syringe requires constant washing, and the solution great attention, as the stopper and neck of the bottle soon become coated with solid kinate. Kinate of quinine has so far given satisfaction, and as it possesses the two great attributes of solubility and neutrality, I think that perhaps this salt will supply a want which has existed.

M. Yvon, in the *Journal de Pharmacie et de Chimie*, recommends the use of lactate of quinine for hypodermic injection, and in *L'Union Pharmaceutique* of last May, the sulphovinate of quinine is stated to be very suitable for the same purpose. It would be interesting to know what results have followed the use of these salts.

Guy's Hospital.

THE BOILING POINTS OF SULPHURIC ACID OF DIFFERENT CONCENTRATON.*

BY G. LUNGE.

The only table hitherto constructed to show the boiling points of sulphuric acids of different concentration is that of Dalton in his 'New System of Chemistry,' but as his results are to some extent inaccurate, the author has redetermined these constants. About 150 c.c. of the acid were heated to boiling in a flask with a long neck, so that the volatilized acid might flow back into the vessel. A thermometer was suspended in the neck of the flask, so that the bulb was completely under the surface of the liquid, in which a spiral of platinum wire was placed in order to avoid tumultuous boiling. That was taken as the boiling point at which the whole column of mercury became completely immersed in the transparent vapour. The following table represents the results obtained, which, with the exception of the lower ones, are considerably higher than those got by Dalton:—

Observed Volume Weight.	Temperature.	Volume Weight reduced to 15° C.	Corresponding p. c. of H_2SO_4.	Observed b.-p.	Barometer reduced to 0° C.
1·8380	17	1·8400	95·3	297	718·8
1·8325	16·5	1·8334	92·8	280	723·9
1·8240	15·5	1·8245	90·4	264	720·6
1·8130	16	1·8140	88·7	257	726·0
1·7985	15·5	1·7990	86·6	241·5	720·1
1·7800	15	1·7800	84·3	228	720·5
1·7545	16	1·7554	81·8	218	726·0
1·7400	15	1·7400	80·6	209	720·6
1·7185	17	1·7203	78·9	203·5	725·9
1·7010	18	1·7037	77·5	197	725·2
1·6750	19	1·6786	75·3	185·5	725·2
1·6590	16	1·6599	73·9	180	725·2
1·6310	17	1·6328	71·5	173	725·2
1·6055	17	1·6072	69·5	169	730·1
1·5825	15	1·5825	67·2	160	728·8
1·5600	17	1·5617	65·4	158·5	730·1
1·5420	17	1·5437	64·3	151·5	730·1
1·4935	18	1·4960	59·4	143	730·1
1·4620	17	1·4635	56·4	133	730·1
1·4000	17	1·4015	50·3	124	730·1
1·3540	17	1·3554	45·3	118·5	730·1
1·3180	17	1·3194	41·5	115	730·1
1·2620	17	1·2633	34·7	110	732·9
1·2030	17	1·2042	27·6	107	732 9
1·1120	17	1·1128	15·8	103·5	732·9
1·0575	17	1·0580	8·5	101·5	735·0

A curve, differing very little from a parabola, is obtained by taking the percentage amounts of H_2SO_4 as abscissæ and the corresponding boiling points as ordinates.

* *Deut. Chem. Ges. Ber.*, xi., 370—374. From the *Journal of the Chemical Society*, July, 1878.

The Pharmaceutical Journal.

SATURDAY, AUGUST 10, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REPORTS OF THE COUNCIL PROCEEDINGS.

IN order to prevent further misconceptions in reference to the matter of reporting the Council proceedings we think it desirable to mention the fact that Mr. FAIRLIE was entirely wrong in stating "that the Editor of the Journal had asked for per- "mission to attend the meetings and had been refused "by a former Council." No such application was ever made or contemplated, and on reference to the remarks made by Mr. MACKAY at the previous Council meeting it will be seen that they do not bear the construction put upon them by Mr. FAIRLIE. According to the official report those remarks are as follows :—

"It would be in the remembrance of the Council that "more than once this subject had been brought forward, "and it had resulted in this, when the Editor of the "Journal was spoken to he said that if he were allowed "a seat in the Council room during the discussion there "would be more lengthened reports."

To make these remarks clear, and to indicate precisely the position then taken by the Editor, it will be necessary to quote from a previous mention of this subject at the Council meeting of the 4th July, 1877, when Mr. MACKAY is reported to have said—

"It was in his recollection that some time ago it was "remarked by some outsiders that the reports of the "Council meeting were very short, and it was said that "they were so short sometimes as not to give the members "at a distance a fair idea either of the opinions or of the "work done by the Council. He did not share that feel- "ing, but still it became so clamant that a reference was "made to the Editor, whose reply was that he printed "what he received, and that he could neither alter it, "lengthen or shorten it, unless he was allowed a seat in "the room along with the reporter, when he might perhaps "be able to give a longer report, and one which might "give more satisfaction."

From these quotations it will be seen that reference is there made to certain complaints that the work done by the Council was not adequately made known, and to certain suggestions that the Editor should act as the medium by which the opinions and proceedings of the Council should be represented to the pharmaceutical public. The impossibility of that being done under the circumstances is, we think, fairly indicated by the above quotation and it is, we think, made equally clear that the function of the Editor in regard to the report is simply that of faithfully reproducing the record handed to him by the reporter.

Any inadequate representation of the action of the Council by the official report would, of course, be within the cognizance of all the members of Council, and it would be competent for any one of them to make a reclamation to that effect when the minutes were read at a subsequent meeting. We have never sought to assume the responsibility of giving colour to the report, and should indeed be loath to undertake a task so onerous, and perhaps so invidious, as that of controlling the reports of the Council proceedings. Our aim in this respect has been, on the contrary, to maintain a strictly neutra position, and we venture to affirm that no instance can be shown in which there has been the slightest deviation from that course.

Another point upon which Mr. FAIRLIE was in error was his reference to the proceedings in Committee, which he appears to suggest are surreptitiously reported in the editorial columns of this Journal, and in such a manner as to give an unfair predominance to the views of one section of the Council. In reply to this suggestion we have to state that the proceedings of the Council in Committee are never reported in any way except by the authority of the Council. It is indeed naturally probable that the subjects discussed in Committee will be also commented upon editorially, but there is not the least foundation for the charge made by Mr. FAIRLIE that the opinions expressed on such subjects in this Journal are other than those which we consider it our duty to urge in the interests of the pharmaceutical community generally. For the opinions expressed on such cases we are wholly re sponsible, and although we have not always been in accord with the majority of the Council, in no instance has any attempt been made by any member of the Council to interfere with or restrict independent discussion. Mr. FAIRLIE'S reference to our mention of the majority of the Council is really quite out of place.

In regard to the matter of reporting the proceedings of Council, we are beginning to feel much in the same predicament as the unfortunate SINBAD, and we regret to find Mr. URWICK disposed to act the part of the corresponding character. He sends us this week another letter, and we insert it, not so much on account of the value of its contents as for the sake of assuring him we do not fear the severity of its censure, and of controverting the idea that we are unfair to him in replying to a letter that we do not publish.

We have applied to the official reporter for an answer to the question propounded by Mr. URWICK in the first paragraph of his letter, whether it is right "to strike out the remarks of a member, even "at his own request, and when those remarks have "become public property and have been deemed by

'the reporter worth recording." The reporter authorizes us to say that nothing of the kind is ever done by him, and he further denies that there is anything in his letter published last week to justify such an interpretation. We quite concur with the reporter in this, and regard Mr. URWICK's assumption as another illustration of his perversity.

Further reiteration of contradictory statements concerning the July meeting of Council would be useless. The reporter, who was present, is directly at issue with Mr. URWICK, who was not. But as Mr. URWICK appears to have his "own "special reporter" of the Council proceedings, and since he professes, notwithstanding the official reporter's distinct denial of any omission, to be able to name the "leading member" whose remarks at the July meeting he says were unreported, we suggest that the proper course would be to furnish this information, as he says, "for truth's sake," and thus terminate a conflict of statements that can only be prejudicial. Except with this object we must decline further discussion.

In reply to Mr. URWICK'S request that we should explain the passages he quotes from the articles of July the 6th and 20th, we will not be so rude as Dr. JOHNSON was on a similar occasion, but will at least attempt to show that he alone supplies the inconsistency he perceives. Fortunately we can refer to the report of the deputation from the Council to the Duke of RICHMOND for a confirmation of our statement that the original proposal to repeal the 20th section of the Apothecaries Act was an inadvertence. The subsequent correction of that invadvertence was a natural result of its discovery, and that both were brought about by the injudicious course pursued by the Executive of the Chemists and Druggists' Trade Association —were indeed its direct result—is the opinion we hold now as we did before. We cannot perceive that the re-introduction of the 20th section as against chemists and druggists is at all inconsistent with the inadvertent proposal to repeal it with other sections preceding and following it, though it may be inconsistent with the interests of chemists and druggists, and so far we think it unfortunate that attention was directed to the inadvertence.

BRITISH PHARMACEUTICAL CONFERENCE.

THE following list of some of the papers to be read at the meeting of the British Pharmaceutical Conference next week in Dublin has been kindly supplied to us by the Secretary:—

1. Report on the Aconite Alkaloids. C. R. Alder-Wright, D.Sc. Lond., and A. P. Luff.
2. Report on Brucia and the Constituents of Strychnos Bark. W. A. Shenstone, F.I.C.
3. Bismuth Residues. Dr. Letts, F.I.C.
4. Soluble Essence of Ginger. J. G. Thresh, F.C.S.
5. Note on Reichert's Improved Thermo-Regulator. C. Symes, Ph.D.
6. Nitrite of Amyl. Mr. D. B. Dott.
7. Note on Beberia. Mr. D. B. Dott.
8. Notes on the Titration of Hydrocyanic Acid and Cyanides, and its Relation to Alkalimetry. L. Siebold, F.I.C., F.C.S.
9. The Presence or Absence of Sugar as a Normal Constituent in Urine. L. Siebold, F.I.C., F.C.S.

THE REPORT ON KEW GARDENS.

SIR JOSEPH HOOKER'S report on the progress and condition of the Royal Gardens, Kew, during the year 1877, which has only recently been issued, contains a variety of matters, amongst which are several points of pharmaceutical interest. Opening up with the balsam of copaiba plant it seems that out of five seeds brought from the forests of Para which germinated at Kew, only two have been reared, and that these are of extremely slow growth. Upon these two plants at present depends the ultimate hope of propagating a stock from which eventually plants may be sent for experimental cultivation in India.

The cinchona cultivation in Jamaica is touched upon, and it seems of the three species, *C. succirubra*, *C. Calisaya*, and *C. officinalis*, the first grows most rapidly, the second also does well, while the third assumes a shrubby growth, "and will probably have "eventually to be superseded by the other kinds." Mr. THOMSON, Superintendent of the Botanic Gardens, Jamaica, considers that, "it has been "abundantly proved that several species of cinchona "are eminently fitted for cultivation in Jamaica.

"The enterprise has emerged from the purely experi-"mental state, and can now be carried on as an "established agricultural industry." Considering "how long the cinchonas have been established in "the East Indies, we think it is high time the culti-"vation in Jamaica had emerged from the "experi-"mental state."

Regarding the cultivation of ipecacuanha in India, it is anything but satisfactory to find such an authority as Dr. KING, of the Calcutta Botanic Gardens, taking such a despondent view of its prospects, which, as Sir JOSEPH HOOKER says, is the more to be regretted as it affords a drug of such immense importance in Indian medical practice. The cold of the winter season precludes its profitable cultivation at the cinchona plantations and the insignificant appearance and slow growth of the plant prevent its being taken up for extended cultivation by European planters. Sir JOSEPH HOOKER suggests the propriety of the Indian Government establishing a nursery for ipecacuanha in some part of the Indian possessions which enjoy a tropical climate. It seems, moreover, that the Superintendent of the Botanical Gardens, Singapore has taken up the matter with a view of persuading the Government to encourage or foster ipecacuanha cultivation in the native states, believing that both the soil and climate of Perak and the neighbouring States are well suited to its requirements.

Some important facts connected with the botanical determination of one of the varieties of cardamom, known in Indian commerce and described by PEREIRA and HANBURY, are here recorded, the facts of which have been already communicated to the Linnean Society. They may be briefly stated as follows:—The "Buro Elachi," or winged cardamom of the Bengal bazaars, described by PEREIRA as the produce of *Amomum maximum* of Roxb. (which, however, is a native of Java), and by HANBURY, in the 'Pharmacographia' as *Amomum aromaticum*, Roxb., are proved by Dr. KING to be obtained from *Amomum subulatum*, Roxb., a native of the Morung mountains.

The most remarkable paragraph in the report is that referring to Lukrabo seeds which are exported from Siam to China, and used, like the foregoing, in cutaneous affections as well as for a vermifuge. These are now referred, as was formerly supposed, to a species of *Hydnocarpus*. The further suggestion of M. PIERRE, of Saigon, regarding the identity of St. Ignatius's beans with Lukrabo seeds, is a subject which we hope will be further prosecuted, more particularly as Sir JOSEPH HOOKER, while not absolutely endorsing M. PIERRE's views, gives it as his opinion that "there is strong reason, from the "structural characters of St. Ignatius's beans, for "regarding M. PIERRE as so far correct that the plant "producing them must be referred also to some "member of the *Pangieæ*."

Altogether the present Kew report is perhaps the most varied and bulky one that has ever appeared.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 7, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Cracknell, Fairlie, Gostling, Greenish, Hampson, Hills, Robbins, Sandford and Schacht.

The minutes of the previous meeting were read and confirmed.

APPOINTMENT OF LOCAL SECRETARIES.

The members of the Society appointed by the Council at its last meeting to act as Local Secretaries in the following districts having intimated their inability to accept office, the following appointments were made:—

Buckingham .....Sirett, George B.
Cardiff .....Hollway, A. B.
Chatham .....Crofts, H. C.
Gainsborough .....Spouncer, H. T.
Sutton-in-Ashfield .....Buckland, E.
Swansea..... .....Griffiths, W.

DIPLOMAS TO PHARMACEUTICAL CHEMISTS.

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the seal of the Society:—

Abraham, Alfred Clay.
Ashweek, John Sydney.
Eardley, James Furnival
Flemons, Joseph.
Glaisyer, Edmund.
Hogg, Edward Grindle.
Jackson, Alfred Henrick.
Oldham, William.
Phillips, John Edward.
Sangster, John Graham.
Savory, John Field.
Stonham, William Burne.
Thompson, John Hartley.
Ward, John Septibo.

ELECTIONS.

Pharmaceutical Chemists.

Eardley, James Furnival..... .London.
Sangster, John Graham .....Southsea.
Savory, John Field .....London.
Stonham, William Burne .....Maidstone.
Thompson, John Hartley ..... Knaresborough.
Ward, John Septibo .....Holbeach.

Chemist and Druggist.

Stevenson, William .....Todmorden.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Alcock, Henry .....Bath.
Asher, James .....Great Driffield.
Dashwood, James.....Landport.
Jackson, George .....Didsbury.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Bailey, John Harvey .....Winchester.
Crane, William Clifton .....Market Harborough.
Drew, John .....Wednesbury.
Drummond, George .....Edinburgh.
Dunn, William Arthur .....Newark.
Evans, John .....London.
Furness, Joseph Machin.....Liverpool.

Gallienne, Wm. Jas. Norman...Torquay.
Gange, George .....Ludlow.
Gibson, Frederick.....Blackpool.
Hart, Arthur.....London.
Harwood, George Rosamond ...Folkestone.
Holden, John .....Burnley.
Homes, Joseph Peter .....Dudley.
Humfrey, Raphael Charles.....Colchester.
Lewis, Llewelyn .....Neath.
Llewellyn, Thomas .....Pembroke.
Manners, John .....Shildon.
Mawson, Thomas Oliver .....Sheffield.
Middleton, Christopher .....Thirsk.
Mitchell, Joe Charles .....Barnsley.
Monkton, George Joseph .....London.
Pritchard, Edward Thomas ...South Norwood.
Smith, Joseph .....York.
Townsend, Joseph Edward.....Peterborough.
Waites, Richard Foulstone.....Rotherham.
Walker, Robert .....Royston.
Weddell, George .....Kelso.
Williams, Samuel Roskelly.....Devonport.
Yeats, John Williams .....London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society:—

Fry, Edwd. Alfred Augustus ...Taunton.
Harrison, James Hughes.....Sheffield.
Hordley, Edward Ralph .....Stoke-on-Trent.
Howe, John Michael Wheately..Hitchin.
Jackson, William.....Northampton.
Niblett, Frederick John .....Stroud.
Randall, Frank William.....Southampton.

Several individuals were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons were restored to the Register of Chemists and Druggists:—

Archibald Thomas, 35, Great Georges Street, Cork.
Alexander Massie Hendry, Bridge House, Woodside, Aberdeen.

Reports of Committees.

HOUSE.

The report of this Committee recommended that a view front lens for the use of the electric lantern be purchased, and that plate glass be put in the windows fronting Bloomsbury Square, not already so fitted.

Mr. Schacht asked what lens was referred to?

The President said it was a lens which Professor Redwood found necessary for throwing the electric light on to the screen. It had been procured from Mr. Ladd, for the purpose of Professor Redwood's lectures, but it was afterwards stated that it need not be retained by the Society. The Committee, however, considered that it would make the apparatus complete, and that it would be better to purchase it. He must say the Committee were surprised to find that this extra expense was required.

Mr. Bottle said he hoped as the Society had gone to this expense the apparatus would be made good use of.

The President said the lectures referred to were very well attended.

The report and recommendations of the Committee were received and adopted.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid. Among these was the one for the lens above referred to, and in answer to Mr. Schacht—

The President said the lens and whole apparatus were now the property of the Society. He would take care that they were entered in the catalogue of apparatus.

Mr. Atkins hoped the lantern would be frequently used.

Mr. Schacht feared that if the Council were to expect the Professors to keep the members of the Society thoroughly up to the mark with regard to the progress of spectroscopic science, it would be found a very expensive affair, and he did not see that it was really involved in pharmacy.

The President said Professor Redwood put it to the Committee, that this apparatus was necessary for his lectures, and it was agreed to provide it if he would give two or three lectures to the members on optical subjects during the course of the session. He had already given one which had been very successful.

Mr. Hampson asked if the students had yet received any benefit from this apparatus.

The President said that was a question for the Committee to deal with in conference with the Professors.

BENEVOLENT FUND.

The report of this Committee included recommendations of the following grants:—

£20 to the widow of a registered chemist and druggist, sixteen years in business.

£10 to an associate of Society who had been out of employment owing to a long illness.

£20 to a pharmaceutical chemist and member of the Society from 1870 to the present time, but at present in distressed circumstances.

£5 to the widow of a registered chemist and druggist.

A letter had been received from Mr. Owen stating that a child, whose election to an orphan asylum had been entrusted to his care, had been successful, and that he had only spent thirty guineas out of the amount granted.

Mr. Hills said he should move a vote of thanks to Mr. Owen for his kindness.

The President said the Society was indebted to Mr. Owen not only for his services, but for the prudence with which he had acted, thereby saving a considerable sum of money.

The motion was seconded by the Vice-President and supported by Mr. Atkins, and carried unanimously.

The Secretary drew attention to the fact, that nearly eight hundred subscribers to the Benevolent Fund had not up to the present time forwarded their subscriptions for the present year. The Council was giving away large sums every month, and it was important that the subscriptions should not fall off.

The President said the Council would soon have to decide how many annuitants should be elected next year, and he hoped it would be able to see its way to the election of several.

Mr. Bottle wished to observe that the number of annuitants the subscribers would be able to elect would depend to a great extent on the amount of subscriptions received, as the Council no longer relied entirely on the income from the invested funds to pay the annuities. If this were generally known, he hoped it would materially increase the amount subscribed during the next two months. Probably many of the friends of the Fund only wanted reminding that their subscriptions were due.

The report and recommendations of this Committee were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian reported the average attendance in the library during the preceding month to have been, day, 24; evening, 9. Circulation of books, town, 142; country (to 30 places), 48; carriage paid, £1 0*s.* 9½*d.*

The following Donations had been made to the Library:—

'Fluid Extracts by Repercolation.' 1878. 2 copies. From Dr. E. R. Squibb (Author).

Delteill's 'La Vanille à la Réunion.' 1878. From Dr. J. L. Soubeiran.

Holmes' 'Botanical Note Book.' 1878. From E. M. Holmes (Author).

'London University Calendar.' 1871. From Her Majesty's Government.

Wittstein's 'Organic Constituents of Plants, and their Chemical Analysis.' 1878. From Baron F. von Müller (Translator).

Flückiger's 'Otto Brunfels, Fragment zur Geschichte der Botanik und Pharmacie.' 1878.

'Schweizerische Wochenschrift für Pharmacie.' No. 25. 1878. (On Peru Balsams, etc.). From Professor Flückiger.

Cooley's 'Cyclopædia of Practical Receipts.' 6th Edition, Part 4. From Messrs. Churchill.

The following works were recommended for purchase:—

General Fund:—

Tidy's 'Chemistry, Inorganic and Organic.' 1878.

Hooker's 'Student's Flora of the British Islands.' 2nd Edition. 1878.

Ganot's 'Popular Natural Philosophy,' by Atkinson. 3rd Edition. 1878.

Henfrey's 'Botany,' by Masters. 3rd Edition. 1878.

Decaisne, Naudin and Hensley's 'Handbook of Hardy Trees, etc.' 1878.

Kuntze's 'Cinchona Monographische Studien.'

Hanbury Fund:—

'Miers on Apocynaceæ of S. America.' 1878.

The Committee recommended that the Librarian be requested to attend the meeting of the Library Association of the United Kingdom at Oxford, in September, or October, his expenses being provided for.

A letter had been received from Mr. Rice, Chairman of the Library Committee of the College of Pharmacy, New York, promising to complete the set of *New Remedies*, numbers of which he had already sent, as early as possible. He also stated that the College had voted fifty dollars to the Hanbury Fund, and that the College had recently entered upon new premises, where any members of the Pharmaceutical Society would always meet with a hearty welcome.

The Librarian had requested the instructions of the Committee as to whether he should lend a MS. work from the library, and was directed not to do so, as it would be impossible to replace a MS. in case of loss.

Professor Redwood had reported that progress was being made by himself and Mr. Ince with the 'Historical Sketch of Pharmacy.' Also that his class was progressing satisfactorily.

Professor Bentley had reported that his second course of lectures had been better attended than the first, but the students attending his lectures at the Gardens were not so numerous as last year, and that he did not think the numbers so satisfactory as they should be, considering the advantages offered.

The Curator had reported the average attendance in the museum during the previous month to have been, day, 16; evening, 6.

The following Donations to the Museum had been received:—

Specimens of the Juice of *Antiaris Toxicaria*, Inspissated Juice of the same, Aloes Wood from Morocco, Kief and Pipe used in Smoking it, from Tangiers, Opium Pipe from China, from Mr. H. B. Brady, F.R.S. Seeds of *Ptychotis Ajowan*, Small perfect Indian Bael Fruits, from Mr. S. Gale. Seventy-five uncoloured Drawings of Medicinal Plants, from Mr. D. Blair (Artist). Specimens of the Root of *Coptis Teeta*, and *Pæonia Moutan*, and of the Bark of *Pterocarpus flavus*, from Mr. Umney. Specimens of the Root of Guaycuru (*Statice Brasiliensis*), from Dr. Symes. Specimen of Crystals deposited in Sal Volatile, from Mr. West. Specimen of Crystals deposited from Aldehyde, from Messrs. Morson and Son. Specimen of False Calisaya Bark, from Dr. Paul.

The Curator had also laid before the Committee a list of duplicate specimens in the museum, which was directed to be published in the Journal.

A letter had been received from Mr. Fresson, of Demerara, offering to present his collection in the British Guiana department of the Paris Exhibition to the Pharmaceutical Society if acceptable. The Curator having given his opinion that it would be very desirable to obtain this collection, it had been agreed that the necessary steps should be taken to secure it. Also that the Curator should communicate with the Commissioner of the Colonies at the Paris Exhibition, and request him to obtain such additional specimens for the museum as might be available, and if necessary to go to Paris himself for the purpose.

Mr. GREENISH said he thought there would be an opportunity of getting a good number of specimens at the close of the Paris Exhibition.

The PRESIDENT thought it would be well if Mr. Holmes went to Paris for the purpose. He would remark that Mr. Rice had in his letter confounded the Hanbury Fund with the Society, with which, of course, it had no official connection.

Mr. HILLS asked if any other specimens had been offered to the Society.

The PRESIDENT said not yet.

Mr. HILLS suggested that it would be as well to be early in the field, or otherwise many valuable specimens might be lost to the museum.

Mr. GREENISH thought it would be well if this subject received the attention of the Committee. It was known that at previous exhibitions a large number of specimens were lost, because no trouble was taken to acquire them.

Mr. ATKINS said it ought not to be left to chance. Very often valuable specimens might be obtained simply by a small honorarium to the attendants.

The report was received and adopted, and steps ordered to be taken with a view to obtaining specimens at the close of the Paris Exhibition.

THE MEDICAL ACT AMENDMENT BILLS.

The Special Committee appointed on this subject reported that it had met, and after correspondence with the Duke of Richmond, a deputation consisting of the President, Mr. Hills and Mr. Sandford, had waited on his Grace, by appointment, on July 11. The following is the report of the interview agreed to by the Committee:—

"In obedience to resolutions passed by the Council on the 5th of June and 3rd of July, on Thursday July 11th the President, accompanied by Mr. Hills and Mr. Sandford, attended at the Privy Council Office by appointment to confer with His Grace the Duke of Richmond and Gordon, in order to obtain, if possible, such an alteration in the Medical Act Amendment Bill now before Parliament as would restore the repeal of the penal clauses of the Apothecaries Act to the full extent set forth in the third Schedule of that Bill as originally proposed.

"The President on introducing the deputation explained that the memorandum forwarded to His Grace on the 7th ult., contained the basis of the argument which they now wished more especially to bring before him. His attention was at once drawn to certain published opinions expressed by him on introducing the Bill to the House of Lords and since repeated on various occasions, opinions which had led to the hope that difficulties under which chemists now labour in the exercise of their business would be removed. Care was taken to convince His Grace that the Pharmaceutical Society had no desire to legalize "medical practice," properly so called, by unqualified persons; that on the contrary the Society, while doing all in its power to promote the safety of the public by ensuring a thorough education of pharmacists, endeavoured to impress on them the importance of not exceeding the proper scope of their business. That the business of a chemist necessarily included advice to a certain point in the treatment of minor ailments, advice which the public demanded and really insisted on having in all

districts, but more urgently in certain localities where the circumstances of the inhabitants precluded the constant reference to properly qualified practitioners. It was also stated incidentally that now that chemists were compelled to undergo a strict examination and give evidence of certain training prior to being allowed to commence their business, it was felt to be a hardship that medical men who had undergone but a very superficial examination in pharmacy should be allowed to keep open shops, and Glasgow was specially mentioned as affording numerous instances of this practice. Legally these gentlemen were doubtless within their rights, but the circumstance might to some extent account for chemists overstepping thier proper boundary.

"The Duke, who was accompanied by the Parliamentary Draftsman and another gentleman, entered very fully and carefully into the points urged, and repeated his opinion that the public had a right to apply to whom they liked for advice. He stated that the words in the first draft of the Bill went further than was intended: that the clause was in fact inadvertently drawn, and in this he was confirmed by the Draftsman. That, although any man was free to take advice where he chose, it was not intended to legalize unqualified practitioners; that even if it were wise to do so, the Bill now under consideration would not be the proper one in which to do it. If it were desired to enlarge the privileges of chemists it must be done by an addition to the Pharmacy Act, but he saw no chance of Parliament agreeing to such an addition, or even inserting such a provision in the Medical Bill.

"In further conversation, His Grace drew attention to a notice of amendment by Mr. Freshfield, but remarked that it was in no way pertinent to the Bill, inasmuch as the rights of chemists were not affected by the Bill in the smallest degree. The deputation admitting this, still urged the Duke to restore his original full repeal of the 20th section of the Apothecaries Act, the more especially as other sections of that Act being repealed, the obtaining the certificate from the Society of Apothecaries would no longer be possible.

"(That amendment is in effect, if not in actual words, a copy of the 28th section of the Apothecaries Act.)

"Beyond this, His Grace inquired of the deputation if they could instance any cases of oppressive prosecutions by the Society of Apothecaries. The Committee were unable to cite any such cases, but stated that although the society might not voluntarily institute such prosecutions they were urged and sometimes compelled to do so by the "Medical Defence Association." On being informed of the late communication between Mr. Upton and Mr. Flux, the Duke advised that chemists should be satisfied to leave things as they are.

"His Grace, without encouraging any hope that he could make the required alteration, promised to give the matter full consideration, and thanking him for his courteous reception, the deputation withdrew.

"After consideration of the above report,

"Mr. Hampson had moved that the Committee should authorize the President to sign a petition to Parliament in favour of repealing the 20th section of the Apothecaries Act of 1815, he considering such course would be in harmony with the instructions of the Council, and the previous action of this Committee, the petition to be placed in the hands of Mr. Torrens, the member for Finsbury, for presentation.

"On being put the motion was lost."

The PRESIDENT suggested that as the following motion, of which Mr. Hampson had given notice bore, on the same question as that raised by the report of the Committee, it should be discussed at the same time :—

> "That a petition signed on behalf of the Council by the President be sent to the House of Commons in favour of the repeal of the 20th clause of the Apothecaries Act of 1815."

Mr. HAMPSON said he was quite in the hands of the President.

The PRESIDENT said, the Bill having been withdrawn, he presumed Mr. Hampson would withdraw his motion.

Mr. HAMPSON said he should of course withdraw the motion, but he might be allowed to make one or two observations on the report. He regretted that the Committee did not see its way to petition for the repeal of the 20th section of the Apothecaries Act. The action of the Apothecaries' Company had certainly caused considerable anxiety to the trade, and certainly it had instituted oppressive prosecutions. It was not necessary to go into the details of any particular case, which would be unwise, especially as one was likely to come before a court of law shortly; still he could not help thinking that the answer given to the Duke of Richmond by the deputation was scarcely accurate. No doubt it represented the views of the gentlemen then present, but he did not think it was in accord with the facts. Those three gentlemen represented the case very fairly from their own point of view, but it could scarcely be expected that a deputation so composed should realize the condition of the trade as it obtained throughout the country, they being so much more identified with select and high class pharmacy. He did not want to quarrel with what they had done; they had no doubt done their best, and certain parts of their report were very satisfactory, but he scarcely liked the answer they gave to the question addressed to them. One point he should like to mention, that when the Bill was introduced into the House of Lords it was stated that the 3rd schedule repealing the 20th clause of the old Apothecaries Act had been introduced by mistake according to the Duke's statement, and it was not removed in consequence of the opposition of any other body; it was simply an error on the part of the parliamentary draftsman.

The PRESIDENT: An "inadvertence" was the word used.

Mr. HAMPSON: Its removal did not arise from their own opposition or that of any other body.

The PRESIDENT hoped the Council would agree to the report being published.

Mr. GOSTLING thought it most desirable it should be published. He felt some sympathy with the remark made by Mr. Hampson, and although under the present state of circumstances he did not know that any other answer could have been given except that a case was now pending, for although it appeared that the case of Wiggins was a very bad one to defend, yet independently of other cases there was one case still pending which was simply a case of counter practice. At the same time he felt that the Committee's representation of the case was highly satisfactory, and he had no doubt it would be felt so by all the members of the trade.

Mr. GREENISH remarked that when the deputation from the Chemists and Druggists' Trade Association waited on the Duke of Richmond with a reporter, he requested that the reporter should not be present, so that the conversation might be more free, and that it should not be published.

The PRESIDENT said he made no such stipulation with them.

Mr. ATKINS could not but express his sense of pleasure and gratitude in listening to the report. In the main it expressed all he desired to express on that most difficult question. He quite felt with Mr. Schacht in the remark he made at the last Council meeting that it was exceedingly difficult, if not impossible, to frame the exact lines on which they wished to move in this matter, for he thought the expression of opinion which prevailed at the Council, and, as he believed, with the major part of pharmacists throughout the kingdom as given by the deputation, exactly embodied the sentiments of that body, and he did not think it could have been better put. It could not be too emphatically stated that those who claimed what they believed was their ancient and indefeasible right, which no Acts of Parliament could ever

overturn, did not desire in any sense to trench on the medical profession, or to advance beyond those just lines which common sense laid down. He was not quite so sure about the answer given about no oppressive prosecutions being initiated. He did not know where the distinction was drawn between what was being done by the Apothecaries' Company as a corporate institution and what might be done by separate action on the part of other bodies, but he confessed he had not been able entirely to feel that there had been no excessive prosecution or tendency in that direction. He believed it was the fear of such excessive prosecution, and the indications of it, which had aroused on the part of chemists and druggists a feeling that they must defend what they believed to be just. Whether the reason why that clause was removed, which inadvertently was inserted, was the subsequent action which he need not more particularly refer to, was a question on which some might have a very decided opinion. The subject required exceedingly delicate and forbearing action,—a contention for what was believed to be right, but moving with exceeding care and caution,—and his own fear was that what was well intended possibly, although he did not think it was wisely conducted, had considerably prejudiced them in this matter.

Mr. BOTTLE said for his own part he felt extremely grateful to the members of the deputation for the manner in which they had fulfilled the mission confided to them. He believed they had told the Duke of Richmond not only the feeling of the majority on that Council, but of the majority of chemists and druggists. He had no sympathy with the expression of Mr. Hampson, who regretted that they did not see fit to petition for the repeal of the 20th section of the Apothecaries Act. As far as his own views were concerned if chemists and druggists could only be relieved from what they felt to be a little oppression from the operation of that section by the entire repeal of it, it still became a question whether they were interested in seeking relief in that way, because that would immediately throw open medical practice to all sorts of charlatans, and how should they themselves feel if medical men, in any shape or form, were to appeal to Parliament to upset the provisions of the Pharmacy Act? How would they like it if medical practitioners were to memorialize Parliament that all persons should be permitted to sell poisons, on the sale of which the Society had been striving for some years to place restrictions? Yet it seemed to him as if these two matters were entirely on all fours.

Mr. FAIRLIE said there were certain parts of this report which he quite coincided with, and he was particularly pleased that the President had taken up the point he had called attention to with regard to Glasgow. He should not have made any remarks upon this matter at all, but that he thought Mr. Bottle had taken a wrong position. Those who knew anything of the Pharmacy Act knew that medical men had interfered with the Pharmacy Act and got a certain portion of it altered to suit their own convenience, a portion, however, which had done chemists in certain parts of the country a great deal of injury which should not have been submitted to by the Council at the time, and would not he believed, if the Council had then understood the exact position of affairs. He was sorry to see that only one member of the committee had advocated the repeal of the 20th section of the Apothecaries Act. It was a pity that some members of the Council did not look at the matter beyond themselves; they ought to take into consideration the vast number of persons connected with the trade to whom this matter applied personally, for if they did so he was convinced they would take a broader view of it.

Mr. SANDFORD said this question was scarcely pertinent to the matter before them, but in justice to the medical profession he must say that Mr. Fairlie was labouring under a great delusion. When the Pharmacy Act of 1868 was passed the medical men got no provisions inserted which were objectionable to pharmacists, but probably Mr. Fairlie alluded to the Amendment Act of 1869. That was simply passed on account of an insufficient description of medical men in Scotland. The exemptions for all medical men in England were put in the 1868 Act, and were supposed to include all the same class of men in Scotland, but it appeared that the Scotchmen were not sufficiently described in that Act, and therefore it was necessary to have an Amendment Act in 1869. The Council, however, did not object to that at all; on the contrary, it helped to pass the Bill and got certain other provisions inserted.

Mr. FAIRLIE said that was just what he objected to. If the Council had known the exact position of affairs it would have opposed that Amendment Act, or would have got it so framed that chemists and medical men keeping open shop would have been put on an equality, which they were not at present. He thought the Council would be quite justified in asking for a repeal of this section in the same way as medical men went to Parliament and got the Pharmacy Act amended.

The report of the Special Committee was then received, approved, and ordered to be published in the Journal.

GENERAL PURPOSES.

This Committee had received the reports from the Professors as to the prize examinations, and opened the motto envelopes to ascertain the names of the successful candidates.

Botany and Materia Medica.

Professor Bentley had reported that seven candidates had presented themselves for examination for the bronze medal and certificate of merit, and the answers of two were highly meritorious, having obtained respectively, 84 and 75 out of a possible total of 100 marks. With regard to the terminal examination for the silver medal and certificates of honour and merit, for the session 1877-78, thirteen candidates had presented themselves, about the average of ten years, though more than last year. It was to be regretted, however, that several of the most advanced students having creditably passed their Minor and Major examinations had left London before the sessional examination was held. The good conduct, punctuality, and regularity of attendance of the students, both at Bloomsbury Square and at the Botanic Gardens, had been very satisfactory. A list was appended showing the number of marks awarded to each competitor.

Herbarium Prize.

Professor Bentley had reported that three collections had been sent in by Fred. W. E. Shrivell, Hadlow, Kent; David Hooper, Clifton; J. Blackett Foggitt, Thirsk. The first consisted of 650 specimens; the second of 600; and the third of 539, and all three were very meritorious. He therefore recommended that, on this occasion a silver medal and two bronze medals, instead of one as provided by the regulations should be given.

Chemistry and Pharmacy.

Professor Redwood had reported that in this class there had been ten competitors for the silver medal and certificates, the first six having obtained marks ranging from 90 to 72 per cent. In the competition for the bronze medal and certificates, he only had two mottoes to submit, as having obtained the required number of marks.

Practical Chemistry.

Professor Attfield had presented a report showing the number of marks obtained by the first seven out of twelve candidates.

Council Examination Prizes.

Mr. Gilmour, on behalf of himself and Mr. Borland, had presented a report of this examination, giving the mottoes and number of marks of the eleven competitors.

Estimates had been submitted for five new windows on the second floor; also for new fittings in the examina-

tion room, etc., as recommended in the report of the House Committee.

The Committee recommended that the estimate for new fittings in the examination room be accepted, and deferred until the meeting of the Council the consideration of the estimate for new windows.

This portion of the report was received and adopted, and the work referred to ordered to be proceeded with.

Prize Awards.

The following awards were made on the recommendation of the General Purposes Committee:—

Chemistry and Pharmacy.

[Five months' course.]

Bronze Medal ..... Jackson, Alfred Henrick.
Certificate of Merit ..... Furness, Joseph Machin.

[Ten months' course.]

Silver Medal ..... Allen, Henry.
Certificates of Honour ..... Cox, John Goodwin. / Sangster, John Graham. / Warrick, F. Walmsley. / Jackson, Alfred Henrick.
Certificate of Merit ..... Cook, William Richard.

Botany and Materia Medica.

[Five months' course.]

Bronze Medal ..... Jackson, Alfred Henrick.
Certificate of Merit ..... Furness, Joseph Machin.

[Ten months' course.]

Silver Medal ..... Allen, Henry.
Certificates of Honour ..... Sangster, John Graham. / Cox, John Goodwin.
Certificates of Merit ..... Jackson, Alfred Henrick. / Thompson, John Hartley. / Cook, William Richard.

Practical Chemistry.

Silver Medal ..... Allen, Henry.
Bronze Medals ..... Sangster, John Graham. / Jackson, Alfred Henrick.
Certificate of Honour ..... Cox, John Goodwin.
Certificates of Merit ..... Thompson, John Hartley. / Ward, John Septibo. / Smith, James William.

Botanical Prize.

Silver Medal ..... Shrivell, F. W. Edward.
Bronze Medals ..... Hooper, David. / Foggitt, John Blackett.

Council Examination Prizes.

Pereira medal (silver); and Books value £5, presented by Mr. T. H. Hills.

John Graham Sangster.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

Alfred Henrick Jackson.

Pharmaceutical Society's Medal (bronze); and Books value £2, presented by Mr. T. H. Hills.

John Septibo Ward.

The President, in reply to Mr. Atkins, said that Mr. Allen, who had been awarded three silver medals, was a Bell scholar, as also was Mr. Sangster who had obtained the Pereira medal.

Mr. Greenish said two gentlemen in Scotland were appointed to conduct the examination for the Pereira medal, and any student looking at the calendar would see that the subjects of the examination were materia medica, botany, and chemistry; but he noticed that the fifth question in the chemistry paper was one on light and really a question of physics. He wanted to know why a question in physics was included in the questions for the Pereira medal, contrary to what was stated in the calendar.

The President said certain gentlemen were appointed to conduct the examination, and they could hardly now call their proceedings in question.

Mr. Bottle said he was about to answer the question by asking another. Why did questions in physics find a place in all questions on chemistry? There was hardly a treatise on chemistry which did not deal in some way with physics.

Mr. Schacht said there was one thing struck him on looking over the list of prize winners, and that was that it seemed a matter of regret that all these handsome rewards went into the hands of a very few individuals. He did not say that it was wrong, but it was not to him quite a satisfactory condition of things as a result of their efforts to encourage education. He was rather sorry to find that the gentlemen who competed for these three great rewards, about which they had a great deal of discussion some time ago, were pretty well limited to those who happened to have attended last session in the school at Bloomsbury Square, and he was sorry to find that the offer by the Council of these prizes to the trade at large practically came to nothing more or less than rewarding those who had already received a reward in the school. He did not know that he could say this was matter of complaint or objection, but he could not help saying it was a matter of regret, and he drew attention to it in the hope that possibly at some future time a better scheme might flow from a little further consideration of the matter. Of course he meant no disrespect to the young men who had earned the distinctions. They deserved all the honour they had got, but possibly at some future time amended regulations might be framed.

The President said the Council prizes were offered to men who had passed the Major examination during the year, and every one who had passed was at liberty to compete, but it was a singular thing that so few competed. He believed the fact was it was pretty well known who were the best men, and the others did not care about competing with them.

The Vice-President thought there was a good deal in what Mr. Schacht had said, and it did occur to him that it might be desirable that some observation should be made so that the same men should not be allowed to take two prizes of the same kind.

The President asked if he would limit the Council prizes so that those who had gained prizes in the school should not be permitted to compete for them. That would be stultifying the principle of the prizes very much indeed. Whether the Council ought to give such prizes at all was a question, because men who had passed the Major examination might be supposed to be beyond the feelings of prize winning.

The report of the Committee also included a communication from the Solicitor stating that the special case in Mackness's case had been set down, but could not come on for hearing before November.

Mr. John Vaughan, of Audlem, an unregistered person who was ordered by the Council at its last meeting to be prosecuted, had remitted the penalty to the Society's solicitors.

The Secretary had reported that the Dental Practitioners Bill and Weights and Measures Bill had passed, but that the Government Medical Bill had been withdrawn. He had also reported that during the past month he had issued inquiries to Local Secretaries and informants respecting cases of alleged infringement of which he had received information during the first three months of the present year, in order to know if the offences had been continued after receipt of the preliminary letter. A number of replies had been received to the effect that the offences had been discontinued. In two cases the offences were reported as being continued, and these were directed to be placed in the hands of the Solicitor. The same was ordered to be done in another case.

A letter had been read from the Procurator Fiscal of Dunblane asking if it would not be desirable to include

salt of sorrel in the list of poisons, he having held an inquiry into the death of a woman who had been poisoned by this article. It had been recommended that the Secretary should be directed to reply that it was not considered desirable at present to place salt of sorrel on the poison list.

A letter from the coroner for Norwich had been laid before the Committee referring to a sale of syrup of poppies by an unregistered person, through which a death had occurred; and to the sale of the same article by other small shop keepers not on the register. He had also inquired whether the Society could not put a stop to the sale of poisons to unregistered persons by wholesale dealers. In connection with the case referred to by the coroner, the chief constable of Norwich had inquired of the Society's local secretary there whether if he got up a good case the Society would prosecute. The Secretary had been instructed to reply, stating that wholesale druggists were exempt from the operation of the Pharmacy Acts, and also stating that if a case were got up for prosecution it should receive the consideration of the Council.

The PRESIDENT thought it would be hardly desirable to place salt of sorrel in the poison schedule at present, as it was so very much used.

Mr. FAIRLIE was much surprised to find that salt of sorrel was not on the list. It was as dangerous as oxalic acid, and he did not see that any hardship would accrue from placing it on the list.

Mr. HAMPSON remarked that the statement of the President that it was very much used in families was a very good reason for placing it on the list.

Mr. FAIRLIE said he always labelled it poison.

Mr. CRACKNELL said there was very little difference between it and oxalic acid, and if one was on the list he thought the other should be.

Mr. FAIRLIE said he would give notice of motion for a future meeting that salt of sorrel be added to the list of poisons.

Mr. SANDFORD observed that there were many other articles more poisonous which were not put in the schedule, because it was not deemed desirable to interfere with the convenience of the public.

Mr. FAIRLIE said it would not inconvenience the public at all.

Mr. ATKINS said it would certainly inconvenience chemists if it were put on in Part I. of the schedule.

The remaining portion of the report was then received and adopted.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Committee appointed to award these Scholarships, subject to the approval of the Council, reported that the Examination was held on July 1st, when thirteen Candidates competed, viz., London, 6; Bristol, 1; Lincoln, 1; Manchester, 1; Newcastle-on-Tyne, 1; Shrewsbury, 1; Stafford, 1; and York, 1.

The mottoes adopted by the two Candidates who had obtained the highest number of marks, were "*Per angusta ad augusta*" and "*Conatum*," and the Committee recommended that the Scholarships should be awarded to the competitors adopting these mottoes.

The Committee had opened the envelopes bearing these mottoes, and the successful candidates were found to be Francis Harris Alcock, Stoke-on-Trent, and James Henry Allan, Stockton-on-Tees.

The report and recommendation of the Committee were adopted.

The following were declared to be the Scholars for the Session 1878–79:

Francis Harris Alcock.
James Henry Allan.

Mr. GREENISH asked if these young men were from London or the country.

The PRESIDENT said the first was from Stockton-on-Tees, and the other from Burslem, and both seemed well within the meaning of the Bell scholarship provisions. The father of one appeared by the certificate of birth received to have been a seaman in the merchant service and of the other a grocer.

REPORT OF THE BOARD OF EXAMINERS.

July, 1878.

ENGLAND AND WALES.

Preliminary Examination.

Candidates. Examined.	Passed.	Failed
298	134	164

A certificate of the University of Cambridge was received in lieu of this examination.

Mr. SCHACHT asked if there was any possibility of knowing what became of those who failed at the Preliminary, whether they did or did not present themselves again.

Mr. BETTY said this reminded him of a question he had heard, what became of all the old race-horses?

Mr. SCHACHT said his question was passed off with a laugh, but he did not think it deserved to be so treated. The Council had to consider the interests of pharmacy. and those practising it. From figures which had been put before him he found there was an enormous disproportion as regarded the numbers of those who presented themselves at the Preliminary examination, and who presented themselves at the next examination and it was an interesting question to know if those who presented themselves at these Preliminary examinations were really fresh men each time, or whether one half constituted those who were rejected on the previous occasion.

The SECRETARY said the question could easily be answered, because those who came up the second time paid one guinea instead of two. If the Council would like to have the information he could give all the numbers for the last two years.

Mr. BOTTLE said there was one point he should like to draw attention to which perplexed him very much, namely, that the percentage of failures in London appeared to increase with the days on which those examinations were held in sequence. Thus, on the 10th of July, 6 failed; on the 11th, 8 failed; on the 16th, 19 failed; on the 17th, 17; and on the 18th, 20. He could conceive that a probable answer to the question might be that the men were put down seriatim in the order in which they applied, and if so he could understand that men who felt strong in themselves and well up in their subjects would be the early men who would endeavour to secure a place, and

that in the tail of the examination would be a series of men who were very uncertain in their anticipation of the result, but had just gone in to try to see whether they could get through by a fluke. That might be the explanation, but when he came to the examinations in Scotland there he found exactly the opposite. In Scotland on the first day, 6 failed; on the 2nd, 3; and on the 3rd, 3, and that was to his mind very clear evidence that his own theory did not account for this condition of things. If the Council could get from either one or both Boards of Examiners such an explanation as would be satisfactory he should be extremely pleased, for on the face of it it was rather perplexing.

The SECRETARY thought Mr. Bottle's supposition was correct, for if a man failed to present himself after having entered, it was generally on the last day.

Mr. HAMPSON thought it was not wise to draw any conclusion from such recent details without going a little further back. If the subject were worth investigation it should be properly investigated.

The Council then went into Committee to hear a communication from the deputation of the Board of Examiners in Scotland.

This having been read and discussed, the Council resumed, and the following resolution was unanimously passed:

> "That the report of the deputation from the Board of Examiners in Scotland be received and entered on the minutes and reported to the London Board of Examiners. That that portion of the report stating the requirements of the Board in Scotland for the purpose of conducting the examinations be referred to the Library, Museum and Laboratory Committee with a view to supplying such requirements without unnecessary delay."

The following list of superintendents of written examinations for the ensuing year was approved.

SUPERINTENDENTS OF EXAMINATIONS.

Aberdeen	Davidson, Charles.
Birmingham	Southall, William.
Brighton	Gwatkin, J. Thomas.
Bristol	Stoddart, W. Walter.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Hollway, A. B.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, R. M.
Carnarvon	Lloyd, William.
Cheltenham	Smith, Nathaniel.
Darlington	Robinson, A. F.
Douglas, I. of Man	Brearey, William A.
Dundee	Hardie, James.
Edinburgh	Mackay, John.
Exeter	Delves, George.
Glasgow	Kinninmont, Alexander.
Guernsey	Arnold, Adolphus.
Hull	Bell, Charles B.
Inverness	Galloway, George R.
Jersey	Ereaut, J., jun.
Lancaster	Bagnall, William H.
Leeds	Reynolds, Richard.
Lincoln	Maltby, Joseph.
Liverpool	Abraham, John.
London	Taylor, George Spratt.
Manchester	Wilkinson, William.
Newcastle-on-Tyne	East, Rev. W. B.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Fitzhugh, Richard
Oxford	Prior, George T.
Peterborough	Heanley, Marshall.
Sheffield	Ward, William.
Shrewsbury	Cross, William Gowen.
Southampton	Dawson, Oliver R.
Truro	Percy, Thomas B.
Worcester	Virgo, Charles.
York	Davison, Ralph.

DEPUTY-SUPERINTENDENTS OF EXAMINATIONS.

Aberdeen	Kay, James P.
Birmingham	Churchill, Walter John.
Brighton	Savage, William Wallace.
Bristol	Schacht, George F.
Cambridge	Church, H. J.
Canterbury	Amos, D.
Cardiff	Sanders, W. J.
Carlisle	Hallaway, John.
Carmarthen	Davies, R. M. jun.
Carnarvon	Hughes, Richard.
Cheltenham	Barron, William.
Darlington	Hutchinson, Rev. E.
Douglas, I. of Man	Cannell, C.
Dundee	Kerr, Charles.
Edinburgh	Ainslie, William.
Exeter	Lake, John Hinton.
Glasgow	Davison, Thomas.
Guernsey	Collenette, Adolphus.
Hull	Baynes, James.
Inverness	Galloway, George.
Jersey	Ereaut, J.
Lancaster	Hall, William.
Leeds	Smeeton, William.
Lincoln	Battle, John Scoley.
Liverpool	Shaw, John.
London	Bremridge, Richard.
"	Knapman, John William.
"	Holmes, Edward M.
Manchester	Wilkinson, George.
Newcastle-on-Tyne	Proctor, William.
Northampton	Mayger, W. D.
Norwich	Corder, Octavius.
Nottingham	Rayner, John.
Oxford	Thurland, Thomas Henry.
Peterborough	Buckle, F. G.
Sheffield	Maleham, H.
Shrewsbury	Cross, William Gowen, jun.
Southampton	Spearing, James.
Truro	Fiddick, Thomas.
Worcester	Lunn, Thomas.
York	Cooper, Thomas.

THE TRADE ASSOCIATION.

A letter was read from the secretary of the Chemists and Druggists' Trade Association, asking to be informed if the Council refused to grant a sum of money for the defence of Shepperley's case.

The PRESIDENT said the Council had never refused it, because it had never been put to the vote. He supposed Mr. Haydon could read and understand what had taken place.

Mr. SANDFORD said Mr. Haydon might have taken that as the decision of the Council. He should take no further notice of it.

ALTERATION IN THE SCALE OF FEES.

Mr. FAIRLIE next moved the following, of which he had given notice—

> "That considering the increase in the travelling and other expenses to be incurred by candidates for the Preliminary examination, in connection with the reduction in the number of centres now agreed upon for conducting said examination, the fee be reduced to one guinea, on and after the 1st of October of this year."

He said this question had been already discussed, but with reference to a greater reduction than he contemplated. He thought there should be a compromise. As the Council had agreed at the last meeting to limit the number of centres, thereby increasing the travelling expenses of many of the candidates, and obliging many of them to travel the night previous, he thought now was an appropriate time to make a reduction in the fees. He

should be quite in favour of retaining the ten guineas as the total, but still he thought the fee for this examination was far too large. It was known to many throughout the country that it prevented many young men from coming forward. He knew this was the case in Glasgow. In that city they had fully a million of inhabitants and yet only nine or ten came forward each quarter, which was not the proportion which ought to come from a district like the West of Scotland. The question came to be what was the reason so few came forward. It was simply this. There were two bodies in Glasgow, and he believed there were others throughout the country, which had a Preliminary examination at a much cheaper rate. Young men found they could go into other professions where they had better prospects and a higher status by paying a smaller fee. In connection with the Glasgow University and the Faculty of Physicians a young man beginning to serve his apprenticeship in Glasgow could pass the Preliminary examination for ten shillings, and not only so, but he had the privilege of coming forward three different times, and passing in any particular subject for which he got credit, and he might then come forward again and pass in the remainder. He did not ask for such a change as that, but merely that the fee should be reduced. It might be said that if the fee were reduced it would be a loss to the Society, but he thought the increase in the number coming forward would refund, and very likely more than refund, any loss what might be incurred at first. He heard disparaging remarks sometimes made about young men coming forward, and trying their hands at an examination, but that was not to be wondered at, because it was only very recently that in the middle class schools of Scotland the system of examination had been at all in vogue. Formerly young men were not trained at the examination table, but now it was becoming more common, and in a short time young men would go through their first examination much more easily than they did at present, in fact, this attending an examination was a sort of apprenticeship in itself. He had commented before on the large number of medical men keeping open shops in Glasgow for the sale of drugs, and the fact was that young men connected with the drug trade in Glasgow found it as easy to go into the medical profession as to remain connected with the Pharmaceutical Society. If chemist and druggists hoped to get into their own hands the whole dispensing of medicines something must be done to prevent so many young men going into the medical profession, and becoming their opponents in dispensing. The only way this could be done, and more earnestness and intelligence brought into the profession, was to hold out the inducements that other examining bodies did. He believed it was the general opinion throughout the country that the fee was too large, and the modification of the number of centres, which increased the expenses the young men were put to, was an additional reason for now making the concession.

The VICE-PRESIDENT inquired if this motion was in order.

The PRESIDENT asked if any one seconded the motion.

Mr. ATKINS said he wished to make a remark upon it, but he could not second it.

Mr. SCHACHT said he would second it though he thought it might be modified advantageously. He considered this was a very fair opportunity of considering whether the entire examination fee should not be redistributed, for he thought with Mr. Fairlie, that in the last act of the Council a difficulty had been placed in the way of those who wished to pass the examination. He knew the point of law which the Vice-President was going to take, that this formed part of the bye-laws, and that unless the bye-law were altered, the Council had no power to determine at that meeting that the fee should be changed; but he thought that the bye-law went mainly to the effect that the Minor examination should pay a charge of five guineas, and the Major a charge of five guineas also, and that the five guinea fee for the Minor, which included the Preliminary, was divided into two portions, and that that was not a necessary part of the bye-law, but might be regulated by the Council.

The PRESIDENT: No, it is the bye-law.

Mr. SCHACHT said if it were absolutely out of order he supposed Mr. Fairlie would put himself in order at a future time and withdraw the notice for the present.

Mr. FAIRLIE said he was not aware of the point of law, or he should not have put his motion in that form. In the meantime he would withdraw it and would consult with Mr. Schacht with regard to bringing it forward at some future time.

Mr. ATKINS thought if that technical ground were regarded as the only possible ground of defeating the motion there would be some *lâches* in the matter. He himself thought it would be unwise to make a change. Whilst paying a tribute to the way in which Mr. Fairlie stated the case, he wished to express his view that all these examinations ought to pay for themselves. He did not know at all what the theory was with regard to having a balance of profit, which was another matter altogether, but certainly they ought to be self-supporting; and he should strongly object to there being anything like a heavy charge upon the resources of the Society to conduct these examinations which would be unprecedented with regard to other public bodies. It must be known to all present that one guinea would not pay the current cost of the examination, and the reduction in the number of centres would only increase the work of the examiners. He would not say anything more on the general question, but he wished to add that the result of one month's consideration was to convince him that the Council had made a great mistake in abolishing some of the centres.

Mr. SCHACHT asked if the Council was in order in continuing the discussion.

The PRESIDENT said he had read the bye-law bearing on the question. He might tell Mr. Fairlie that the way in which bye-laws had to be altered was somewhat complicated; the matter had to be brought before three successive Council meetings and carried, then a special meeting of the Society had to be summoned, and if that meeting approved the alteration then it was submitted to the Privy Council. If the bye-laws were going to be altered the whole of them should be examined to see if any other alterations were required, which it was quite possible was the case, for he thought he knew of one or two which might be improved. He would remind Mr. Fairlie that the fee for examination was ten guineas, and it was only a question of how it was to be divided. The next motion which Mr. Fairlie had given notice of, was—

> "That as an inducement to chemists and druggists in business prior to the passing of the Pharmacy Act of 1868 to become members of the Society, the entrance fee of two guineas be and is hereby abolished, and that the Secretary be instructed to issue a circular to all chemists and druggists in business previous to 1868, not at present members of the Society, intimating that they may now be enrolled as members on payment of the annual subscription of one guinea, and pointing out the advantages to be derived from membership"—

This would also involve an alteration of the bye-laws, and so he presumed he would not bring it forward.

Mr. FAIRLIE said he was not aware that it involved an alteration of the bye-laws or he should not have given notice in that form. Of course he should not now bring it forward.

Mr. FAIRLIE then moved the third resolution of which he had given notice:—

> "3rd. That the Editor and Sub-Editor of the *Pharmaceutical Journal* be invited to attend the meetings of Council, with a view to obtaining, through the medium of the Journal, more extended and accurate reports of the proceedings of the Council, and also

to enable them to enunciate in their editorial articles and notes the true policy of the Council and the Society."

In bringing it forward he said he was certainly very much surprised at the discussion at the last meeting in connection with Mr. Hampson's motion to hear it stated by Mr. Mackay that the Editor of the Journal had asked for permission to attend the meetings and had been refused by a former Council. Seeing that the Editor was to some extent the servant of the Society and the Journal was the organ of the Society and contained its transactions, those transactions could not be properly reported unless the gentleman who was to control the reports was an eye-witness of those proceedings. He thought it was the least the Council could do, out of courtesy to the Editor if he wished to be present, as well as to do away with any suspicion which had been in the minds of some gentlemen that the reports were to some extent—he did not like to use slang phrases, but certainly there had been one or two slang phrases used in connection with this matter, and they ought as a Council to disabuse the minds of any gentlemen that it was desired to control the reports at all. The Council ought to leave the Editor free, as he had protested that he was free, although some members of the Council had stated distinctly that they wished to control the reports in some way. Still the Council ought to remove any suspicion that it was wished to control the reports; and if it was wished to do so the Editor ought to be present to hear the discussions which took place. Another reason why he ought to be present was this: he observed at the two or three Council meetings he had attended that the Council very often went into Committee and a great many subjects were discussed in Committee which were not reported to the trade at all except through the leading column of the Journal. He observed further that when these subjects were thus reported they were reported only in the spirit of a certain section of the Council.

The PRESIDENT: The majority.

Mr. FAIRLIE said he should contend it was not the majority. The Editor had taken upon himself to speak lately with reference to two or three subjects. He should take first the discussion on the question of the reporters. This was a discussion which was published certainly in the Journal and he had the official report to guide him. He spoke there distinctly about the majority on the Council, but if any one was to look into the matter properly they would see it was the majority that opposed it. If he was informed aright two out of the three gentlemen who were absent when the vote was taken would have voted in favour of the admission of the *Chemist and Druggist's* reporter. Another reason was this. Perhaps he was out of order, but he could not help thinking that the President used two votes against each member's one, and it was a very curious thing that the President of that Society should have two votes.

Mr. BETTY: I must protest, sir, that you do not sit here for your conduct to be criticized by any member of this Council. I have never ventured to do it, and I do not think the youngest member present should interfere in this way with the privilege which the Chairman of this Society enjoys. I protest against it, and I call upon you to uphold the dignity of the Society and your own by checking at once such impertinent observations.

The PRESIDENT: It does seem to me most unusual and unwarranted. There is no doubt the President has the casting vote: it is legal and it is the proper thing.

Mr. ATKINS: I am sure Mr. Fairlie would be the last man to say anything improper. I would remind him that it is the practice of all municipal bodies to give the mayor as chairman a casting vote.

Mr. FAIRLIE was quite aware of that, but he looked to the House of Commons as their model. It was well known that the Speaker did not exercise his privilege of voting except when there was an equality of votes. The speaker in the House of Commons was perfectly impartial.

Mr. BETTY again rose to order. There was no comparison between the Speaker of the House of Commons and their President to the latter's disparagement. He would not sit there as a member of that Council and hear the President maligned even in comparison with the Speaker of the House of Commons. If Mr. Fairlie could not compare the proceedings of the House of Commons with their own in a fair and gentlemanly way, let him cease the comparison altogether and move if he had a right to do so, as a vote of censure, that the President leave the chair. Until it was fairly proved that the President was not worthy to occupy the chair which he then sat upon, such comparisons between what he did and what other people did were derogatory to the dignity of their meeting.

Mr. FAIRLIE said he was in the hands of the chairman not Mr. Betty's.

The PRESIDENT read the bye-law bearing on the matter, which provided distinctly that if on any division the numbers were equal, the chairman should have a second or casting vote. It was therefore distinctly laid down that the chairman for the time being, whether the President or Vice-President or whoever occupied the chair, should have a casting vote, and he must therefore call upon Mr. Fairlie to withdraw any remarks he had made which would reflect upon him for doing his duty.

Mr. FAIRLIE said he was entirely in the hands of the chairman, but he did not think it was fair for a gentleman to stand up and put an impression on his remarks which he did not wish to convey. He did not wish to convey any disparagement of the President.

Mr. BOTTLE: But you did it.

Mr. FAIRLIE said he considered he was entitled to speak against what he considered to be an injustice to the Society, apart altogether from anything individual or personal. He withdrew any remarks that might have been disparaging to the President, but at the same time he held his own opinion the same. He could not help that.

Mr. SCHACHT said that was scarcely a proper withdrawal of words which had offended the majority of the Council. Of course no one intended to imply that Mr. Fairlie wished personally to insult the President, but what Mr. Betty said, and what they felt, was that in calling in question the conduct of the chairman, which conduct was perfectly legal, he had committed a breach of order. That was the *gravamen* of the charge. They did not accuse him of an intention to be rude to an individual, but that his remarks were derogatory to the chairman for doing that which was palpably right for him to do. That being made clear by the reading of the bye-law he should feel that it would better become him if he had made such a mistake, to say that he frankly withdrew the observation.

Mr. FAIRLIE said he frankly withdrew the observation, although he failed to see that the interpretation put upon his remarks by Mr. Betty was correct, but he frankly withdrew any observations that might be considered out of place. What he wished further was to use this as an argument in favour of having the Editor present, so that he might in some way give the reports to the Journal in a thoroughly unbiassed and impartial form. It was well known that the subject of Wiggins's case had been talked of, not discussed, at the Council Board, and remarks had been made by members of the Council with reference to that subject. That case had also been referred to in the Editor's remarks, and the Editor had just taken the position which those gentlemen had assumed. But the subject not having been discussed formally before the Council no opportunity had been given to gentlemen on the opposite side to refute the arguments brought forward, or if that had been attempted, the remarks made on the other side had been taken no notice of by the Editor in discussing the question. Now it was unfair to

the Council that only one side of the question should be discussed, either by the Editor or anybody at all. He was much annoyed to find that the Editor really discussed letters and papers which came before him, and sometimes declined to publish them in the Journal. Now this came under the same category. If the Editor was to report these things that were done in Committee to a large extent, he must be present, and hear for himself the pros and cons of the question, so that he might give a fair and impartial report in the Journal. He knew there were some things which could not be reported, and he should be the last to object to Committee work being done in Committee. At the same time he thought much more ought to be reported to the trade than was, more especially as some things were reported through the editorial remarks only, and it was advisable that both sides should be given. He thought he had made out a fair case with regard to that matter, namely, that the Editor's remarks during the past few weeks had not been representative fairly of the views of the Society. They might be the opinions of the majority of that Council, or even of a pretty large majority of the Society, but as a Society they had other interests than those of the majority to consider, and they ought to look on the Journal as an organ which would take the position of an impartial organ to a very large extent. It ought to be considered there were several parties in the trade other than those who had good businesses. There were those who had businesses in which they must give advice, especially those whose lot was cast amongst the poorer people, and it was unfair to overlook that fact and use arguments which were equivalent to saying that they ought not to be in the trade at all, because it practically came to that. Because if the position of the Society was, as the Editor had taken up recently, that it was not to oppose anything which was advocated by medical men, although it might be against the interests of the trade, that would be unfair to themselves. On the whole he thought it would be to the advantage of the Council that the Editor should be present and listen to the discussions. He did not wish to take up too much time, and he was sorry for the remarks he had made at the commencement, but it was done perhaps in the heat of the moment and without previous consideration.

The PRESIDENT asked if any gentleman seconded the motion. No one having done so, he said it would of course fall to the ground.

Mr. BOTTLE said before passing on to the next business he should like to make an observation with reference to the list of notices of motion which appeared on the agenda paper. He could forgive a new member of Council for, he would not say his ignorance, but his want of knowledge of the bye-laws, but it did appear to him that the officials, when they received a notice of motion that was so palpably in opposition to the bye-laws, should not put it on the agenda paper, and they should not have the time of the Council occupied in discussing it. He thought it should be understood to be the duty either of the Secretary or of the President, or of somebody who received these notices, when it was seen that they were not open to be entertained in the way they were presented, to ignore them, so that the time of the Council might be saved. Then, again, there was on the paper more than half a page of business from Mr. Fairlie. He did not say it was not right to receive half a dozen notices of motion from one individual, but supposing every member of Council chose to send as many, how could the Council get through the business? and would it not be liable to a charge, which had been mentioned at the annual meeting, of putting forward certain things for the purpose of shunting others which were of more importance? He took it that some one or other ought to have some control over the publication of the agenda, so that the time of the Council should not be frittered away.

The PRESIDENT thought it was a very serious responsibility to be thrown either on the Secretary or the President, and it might operate to the great injury of members of Council on some occasions. He thought it was a matter of taste whether one gentleman should send in so many notices of motion, when if he had only made himself master of the bye-laws he would have known they could not be carried; but he did not think it would be right for either himself or the Secretary to interfere with a notice of motion which was given in due form, or they might be held to be acting partially and not with equal justice. He could imagine circumstances under which they might be accused of something of that sort.

Mr. BOTTLE said he would give notice that at the next meeting he would move a resolution that no individual member be permitted to give more than one notice of motion for one meeting of Council.

Mr. BETTY hoped that Mr. Bottle's great desire to preserve the constitutional rights and customs of the Society would not lead him on the spur of the moment to take a step which might be a little unusual, especially as it was only done in view of the action of a gentleman, who after all was a young member. Following Mr. Fairlie's example he begged to join in withdrawing any warm expressions he might have used in checking him. They were uttered *motu proprio* from the bottom of his heart at the time they were made, but still if he had used one word which that gentleman considered too strong, or which was ungentlemanly, he begged in the most unreserved manner to withdraw it. At the same time he could not but think that as this was the first instance in which the Council had had what was called in the West of England, "great cry and little wool,"—he did not say it offensively at all—he hoped Mr. Bottle would think over it before the next meeting, and consider whether, as this was the first case of the kind which had occurred since he had sat on the Council, which was now nine or ten years, he would in consequence of what he might consider the abuse of privilege of a single member, he being but a young member, press the motion of which he had given notice.

Mr. BOTTLE being thus appealed to said he would withdraw the notice.

The PRESIDENT said Mr. Fairlie had given notice of putting several questions to him. To begin with he might just as well have put the questions in the office, where he would have got the answers just as well, but he supposed he wished to have these answers from him, and therefore he would reply to them. The first question was "Are the Boards of Examiners in the habit of informing unsuccessful candidates the subject in which they have failed?" That was a very important question, and one he took great interest in. The practice seemed to have varied at various times. When he first occupied the position of Chairman of the Board of Examiners he was informed that it was not considered quite right to inform candidates of the cause of their failure, because it was supposed that a candidate might entertain some spite against the examiner for what he might consider unfair treatment. He had never held that to be a correct view, and had frequently informed candidates in what subjects they had failed. That had been going on for some time, and on his visit to Edinburgh he learned that there the Board was in the habit of always informing the candidate of what he had failed in, and that appeared to him to be a very proper, reasonable, and right thing to do. He had since made it much more his practice, and had taken every opportunity of informing the candidates in what subjects they had failed; and when they had been very good in one subject and failed in another, he had tried to encourage them by informing them of it. On the last dreadful day of examination, when 25 candidates presented themselves for examination and 20 failed, he had an opportunity of speaking to no less than 17 out of the 20, and of informing them what they failed in. Two had failed so completely that he had to call them up at once and tell them that they could not get a single mark

in anything and were simply wasting their own time and that of the examiners. In many other cases he had been able to tell some gentlemen that they had done very well in some subjects but in others they required further study. With regard to those who went through the whole of their subjects and did not succeed in passing, it used to be the practice that they could apply to the office and obtain information as to the cause of their failure, but some two or three years ago the Board of Examiners agreed that that was a wrong course to adopt, and they did not consider that the officials should have the power of overhauling the books and saying what subjects the examinees failed in. It was therefore not now the practice of the office to inform the candidates in what they failed, but he, as Chairman of the Board, had taken every opportunity of doing so. He would now ask the Vice-President to give his experience on the matter. His own opinion was that the more they let the candidates know how they failed the better.

The VICE-PRESIDENT said it was well known to the whole of the Council that when a man failed in one subject he could not pass, but it was very rarely that he was stopped in the first subject. He was generally allowed to go on to the second and it was generally unnecessary to tell him what he had failed in for he himself knew perfectly well. It had been his custom to tell candidates when they failed and when they had been very successful in particular subjects to give them encouragement in the same way as the President had stated.

Mr. FAIRLIE said he was very much gratified with the answers given by the President. The reason for his putting the question was a report that reached him that some young men had applied to the office to know the subjects in which they had failed and were refused; and they thought it was wrong that they should not receive the same information which others had previously obtained. The plan adopted in the Laws Examinations in Scotland was, he thought, a very good one. On the examination day all the candidates were kept until the close of the examination, and they were then called in individually and the President pointed out to the young men wherein they had failed, and even those who had got through the examination were told to study up certain subjects and to keep themselves ahead in others. He thought it would be a great encouragement to the young men if they were brought before the President and received from him a few words of advice, and if they had failed, to learn in what subjects they had failed.

The PRESIDENT said this plan had been tried and not found practicable in London because there were such large numbers examined, so that it had to be discontinued. The second question Mr. Fairlie had put was this :—"Do candidates obtain credit for subjects in which they have previously secured a high percentage of marks when they present themselves at subsequent examinations?" To that he must answer certainly not. It was a question entirely for the examiners. He considered that each examination should be in itself perfect and complete. If a man be permitted to come up and pass in one subject at one time and then come up and pass in another it would be making the examination a perfect farce. The Board of Examiners was quite clear on that point, and although at one time it was seriously suggested that candidates might have credit for the subjects in which they had succeeded before, it was now the opinion of both Boards without a single exception that it was a wrong thing to do and that each examination must be complete in itself.

The VICE-PRESIDENT said Mr. Fairlie should also know that a young man who had been up at one examination might have to go before different examiners altogether the second time who would not know that he had been up before.

Mr. CRACKNELL said some years ago it was the practice in the office to mark the examination papers of candidates who came up the second or third time, but the examiners felt that this was an improper thing to do, and it was ordered not to be done. It was not desirable for the examiners to know whether a candidate had been up before or not.

The PRESIDENT said the third question put by Mr. Fairlie was :—"When and how are the salaries and allowances of the paid officers of the Society fixed?" In answer he could only say that the salaries were fixed from time to time by the Council as it thought proper, generally on the recommendation of a committee.

Mr. FAIRLIE said the reason he put the question was that he had not heard anything said about salaries or allowances since he had been on the Board. He fancied the new Council must have power if it appointed officers to also fix their salaries at the same time.

Mr. BETTY said it would be a strange thing if every time there were a change of ministry the salary of every subordinate postman throughout the country were altered; to carry out Mr. Fairlie's motion at every new Council, every penny expended on the salaries of the officers, however old, or however low, they might be in the service, would have to come before them.

Mr. SANDFORD said he thought the Council had appointed certain officers at a meeting which Mr. Fairlie attended.

The PRESIDENT said that was so; but nothing was said about salaries.

Mr. SANDFORD said because there was no alteration in the old salaries.

Mr. FAIRLIE said he understood now that each salary was a permanent thing and always went with the office, no matter who the officer was.

Mr. SANDFORD said that was not so. If the Council saw it right at any time to advance the salary of any of the officials it could do so, and did so by resolution. Such alterations had frequently been made.

ALTERATION OF EXAMINATION DAYS.

Mr. SANDFORD moved the following resolution of which he had given notice:—

"That the Preliminary examination be held on the first Tuesdays in January, April, July, and October, instead of on the first Mondays in those months as heretofore."

"That the examination for the Jacob Bell Memorial Scholarships be held on the first Tuesday in July of each year instead of on the first Monday of that month as heretofore."

He said it was remarked at the last meeting, when the Council reduced the number of centres, that some candidates might have to travel on the Sunday night, and therefore he thought it would be only right to change the examination day from Monday to Tuesday. He thought the change would commend itself to the whole Council without any further remarks.

The VICE-PRESIDENT seconded the motion.

The PRESIDENT said Mr. Mackay had written, on behalf of the Board of Examiners in Scotland, a letter making the same suggestion.

Mr. BOTTLE suggested that the alteration should not take place until January, 1879, as the published calendar already contained the arrangements for the current year.

The SECRETARY said he could communicate with each individual.

The PRESIDENT said Monday was originally fixed upon because it was said there were fewer markets on Monday than any other day, but now that the superintendents could appoint deputies that argument was not so important as it was before.

Mr. ATKINS said, if Salisbury had continued a centre and he had continued to hold the office of superintendent he should have been compelled to resign, because Tuesday was a day on which the Salisbury chemists did more business than any other. He thought the change was a

necessary sequence to the previous alteration. It had been said that it did not much matter about the young men coming up and spending Sunday at the examination centre because it was the one great event of their life. It would be fortunate if that were so, but very often the process had to be repeated three or four times, He might also repeat what he had already said that he regretted that such a sweeping alteration had been made at the last meeting, but he hoped that some day the Pharmaceutical Council would have nothing whatever to do with the Preliminary examinations. He was very thankful for the half-way house that had been arrived at in entrusting the elections to the College of Preceptors, and he hoped some day the process would be completed.

Mr. FAIRLIE said that in Scotland, the holidays instead of being at Christmas were on New Year's day, and he therefore suggested that instead of being the first Tuesday in January it should be the first Tuesday in February, because it would be very awkward if it fell on New Year's Day.

The SECRETARY said when that was the case the examination was always put off to the following week.

The motion was then put and carried unanimously.

A letter was read from the Society of Chemists and Druggists at Sheffield, containing a resolution earnestly requesting the Society to aid by a grant of money the defence of Shepperley's case.

THE PHARMACEUTICAL CONFERENCE.

The Secretary of the Conference having written to ask if the Council would appoint delegates to attend the Conference, the President, Vice-President, and the Treasurer were appointed delegates, with any other members of Council who found it convenient to be present.

Parliamentary and Law Proceedings.

THE ARSENICAL POWDER CASE.

At the Central Criminal Court, on Wednesday, before Mr. Justice Field, Henry George King, surrendered to take his trial upon several indictments for manslaughter.

Mr. Poland and Mr. Straight prosecuted for the Treasury; Mr. Warner Sleigh and Mr. Crispe were counsel for the defence.

The case that was taken charged the prisoner with the manslaughter of a child named Ringrose.

On behalf of the prosecution it was stated that the prisoner carried on the business of a wholesale druggist and drysalter at Kingsland Green and had for several years been in the habit of manufacturing the article known as violet powder, which, under ordinary circumstances, appeared to be composed of starch and orris root, or some description of perfume. In 1875 the prisoner commenced the manufacture of some cheaper description of powder, in which terra alba, or sulphate of lime, was substituted for starch, and this article was sold by him to a very large extent in penny packets, which were labelled "For the Nursery, Superior Violet Powder, warranted free from grit." The ordinary article manufactured by the prisoner appeared to be perfectly harmless, but about twelve months ago the violet powder sold by him was found to be largely impregnated with arsenic, and the result was that a great number of children of poor persons residing at Loughton, where the powder was extensively used, lost their lives, that result being undoubtedly attributable to the large quantity of arsenical poison contained in the violet powder sold by the prisoner. The fact of so many children dying in such an extraordinary manner attracted the attention of the local authorities in the first instance, and eventually the Government interfered in the matter, when an inquiry took place at the instance of the Treasury, and in the result the prisoner was committed upon the present charges. The child whose death was now the special subject of inquiry was the daughter of a woman who resided at Shacklewell. It was about ten days old at the time of its death, and it appeared that the powder supplied by the prisoner had been constantly applied to it from its birth. A *post-mortem* examination by Dr. Tidy led to the discovery that the liver and other organs were largely impregnated with arsenic, and the death was clearly proved to be the result of arsenical poisoning. The portion of the penny packet of violet powder which remained was also analysed, and was found to contain arsenic in the proportion of thirty-eight parts out of one hundred, a quantity quite sufficient to account for the results that happened. The prisoner was examined as a witness before the coroner; he appeared anxious to give all the information in his power, and declared that he was entirely ignorant as to the way in which the arsenic had got into the violet powder. It also appeared that when his attention was called to the fact that the violet powder sold by him contained a large quantity of arsenic, he directed his traveller to get back all the packets he had sold to his various customers, and the whole that remained in his possession was destroyed. The case for the prosecution rested entirely upon the assumption that the prisoner had been guilty of criminal negligence in selling such a dangerous ingredient to the public.

A great many witnesses were called for the prosecution, but their evidence merely went to establish the facts as above mentioned.

Dr. Tidy, professor of chemistry at the London Hospital, said arsenic was a very much heavier article than terra alba, and the bulk of the latter would consequently be much greater than that of arsenic. It appeared to him that a person of ordinary skill and caution, while making up packets of this description, ought to have detected the difference between the two articles. He believed that a portion of the arsenic found in the body of the deceased child had been absorbed through the skin and that another portion had passed off into the air while the child was being dusted with the powder, and been taken into the system through the mouth.

In answer to questions put by Mr. Warner Sleigh, in cross-examination, Dr. Tidy said that the body was very much decomposed, and although it had been generally considered that arsenic was a preventive of decomposition, he had heard of cases where it had not had that effect, and he therefore did not regard it as a positive fact that the presence of arsenic would delay or prevent decomposition.

A long statement made by the Prisoner to a detective officer was put in and read. In this statement the prisoner described the articles used by him in the manufacture of the violet powder, the principal ingredients being corn flour, terra alba, orris root, potato starch, and rose perfume. He denied most positively ever having had any arsenic in his possession, and stated that he could not in any way account for the arsenic getting into the violet powder, but he suggested that upon one occasion when he sent to the shop of Mr. Fox, a wholesale chemist and druggist in Bethnal Green Road, for 28lb. of terra alba, arsenic had been sent to him by mistake.

Mr. Henry Fox, jun., was called to disprove the suggestion of the prisoner. He stated that he did not remember the prisoner having been supplied with 28lb. weight of terra alba, and he did not think it possible that such an occurrence as sending arsenic by mistake for terra alba could have taken place.

In reply to Mr. Warner Sleigh, in cross-examination, the Witness said the wholesale price of arsenic was 11*l.* or 12*l.* per ton, whereas terra alba was not worth more than 3*l.* or 4*l.* per ton, so that it was clear that in the sense of cheapness there was no inducement for the prisoner to make use of arsenic instead of terra alba.

Mr. Justice Field, at the close of the case for the prosecution, said he did not know what the jury thought of the case, but he certainly could not see what criminal negligence could be attached to the prisoner.

The Foreman of the Jury said that a majority of them were of opinion that the death was the result of accident.

Mr. Justice Field said that the opinion of a majority of the jury was not sufficient.

Mr. Poland, in the course of a brief summary of the evidence, said that when the jury heard that 28lb. of a deadly poison had been distributed for the purpose of being used upon the bodies of young children, and the fatal results that had attended it, he was sure they would be of opinion that the case was, at all events, one that ought to be fully inquired into.

Mr. Justice Field said it was doubtless a proper case to be fully investigated.

Mr. Poland added that the only question for the jury was, whether the prisoner was guilty of criminal neglect in supplying this poisonous article to the public.

Mr. Warner Sleigh briefly addressed the jury for the prisoner, and contended that the prosecution had utterly failed in establishing any criminal negligence on the part of the prisoner, and that they ought to acquit him.

Mr. Justice Field, in the course of a short summing up, said that, whatever might be the result of the inquiry, he thought there could not be any doubt that from the very first the prisoner had met the charge most fairly, and that he had not only given all the information that he could in reference to the matter, but that the moment he was informed that there was some dangerous ingredient in the violet powder manufactured by him, he took measures to get back all he could of it, and destroyed it. He then explained that before the jury would be justified in convicting the prisoner of this offence they must be satisfied that he had been guilty of some gross and criminal neglect.

The Jury at once returned a verdict of Not Guilty.

Mr. Poland said that, after the full inquiry that had taken place, he did not think it advisable to proceed with any of the other indictments against the prisoner.

Verdicts of Not Guilty were, therefore, taken on all these cases, and the prisoner was ordered to be discharged.

The Council Reports.

Sir,—It appears to me superfluous to add a single word to the letter of "The Official Reporter" in last week's Journal. I should like, however, to say that during the four years I had a seat at the Council table, I do not remember a single instance in which it was attempted to interfere with the free exercise of the professional duties of the reporter; he seemed to be, and I have no doubt was quite untrammeled. No doubt his reports were condensed, but it was most ably done and never, I think, failed to convey the views of the speakers. The chief objection at that time was the constant tendency of the Council to resolve itself into a committee.

Then, as now, I was in favour of admitting other reporters, but frankly I do not believe the work would be better done.

Aug. 5, 1878. James Baynes.

Sir,—I have never complained of the reporter to the *Pharmaceutical Journal*, because I believe him to be a gentleman capable of doing his work most efficiently, and I thank him for his letter denying that there was "any omission" on his part and explaining how "such an omission" might easily occur in the reports of the Journal,—"some remarks which the speaker did not wish to have reported." Is it right thus to strike out the remarks of a member even at his own request, and when those remarks have become public property, and have been deemed by the reporter worth recording? I would humbly ask, are reports thus dealt with (according to your reporter's own letter) fair, honest, and free from all suspicion of "cooking"

I do not wish this subject to become a personal one as I am simply contending for the principle of free and open reporting for the benefit of the Pharmaceutical Society and those who take an interest in its politics, but if you wish the name of the speaker for truth's sake, I can furnish it, provided he has no objection; I have a letter before me dated Aug. 3rd, informing me of the member's unreported remarks in open Council at the last meeting.

By your leading article last week it would appear you consider the censure in my letter too severe on the course you have adopted towards the "Trade Association." I may be perverse, as others appear to have been, in reading your articles wrongly, I shall therefore be glad if you will explain to me and make clear the meaning of the last clause in your article of July the 6th, when placed beside the last clause of the article, July 20.

July 6, 1878.

"We regard the amendment in the Schedule of the Government Medical Bill as being a direct result of the injudicious course pursued by the Executive of the Trade Association, and we regret not only that the possible utility of its career has thus early been marred by this mistake, but also the probability that the efforts of the Council of the Pharmaceutical Society to protect the interests of chemists and druggists may thus have been at the same time rendered more difficult of realization than they otherwise might have been."

July 20, 1878.

"The Duke of Richmond entered very fully into the question and promised to give future consideration to the points urged; but he at once stated frankly that the words in the first draft of his Bill, which had been brought forward as an argument by the deputation, *were inserted inadvertently* and that he could not see his way to restoring them. Beyond that His Grace said the Bill if passed would leave chemists in precisely the same position as that now occupied by them, and he thought under the circumstances the Medical Act would not be the proper channel through which to enlarge their privileges."

To me they appear inconsistent, but perhaps you can reconcile them, and when you have done so there may be a point on which old readers of the Journal can agree with it again. I was pleased to find that you could acquiesce in, and even appreciate, one clause in the article in the *Morning Post*, though it is rather an amusing idea that the editor got that "inspiration" from you while the rest proceeded from another source; but strange things do happen, for from an angry article in the *Pharmaceutical Journal*, July 27, it would appear that you had been trying to kiss the toe of the old medical pope, and in stooping so low had been quite upset; it is hard to be thus misunderstood by friends and opponents, and your devotion might have been better rewarded if it had been offered to old and tried friends. However, I do hope yet to see the *Pharmaceutical Journal* awake to its real duties, and with a bold front contend for chemists' rights, but now especially for those which they possess in common with the old water-cress woman who can recommend her commodity for the cure of any complaint.

W. W. Urwick.

60, *St. George's Road, S.W., August* 7, 1878.

J. R. Birkett.—Your communication has reached us a month too late to be of any service.

F. B. L.—(1) We are not aware that such a society exists; certainly it is not authorized to hold examinations on behalf of the public. (2) The certificate does not authorize the holder to keep open shop for the retailing, dispensing or compounding of poisons. Thanks for the paragraph.

A Country Member.—The reference in your letter to a case that is still undecided is at least untimely. We cannot think that the Council has adopted a course in regard to this case without having sufficient reason for doing so, but as it is not the province either of the Council of the Pharmaceutical Society or of this Journal to prejudice either party interested, it would obviously be improper to make public the grounds upon which they have proceeded.

J. Farmer.—Johnston's 'Elements of Agricultural Chemistry,' published by Blackwood.

The Pharmaceutical Journal.

SATURDAY, AUGUST 17, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH PHARMACEUTICAL CONFERENCE OF 1878.

AT last the whirligig of time, which brings so much that has been impracticable within the bounds of possibility, has brought about a gathering of the British Pharmaceutical Conference in the Emerald Isle, and the meeting of the British and Irish pharmacists, which in 1874 was shunned as possibly containing in it germs that might ripen into misunderstandings that would be detrimental to pharmacy, has now taken place in Dublin, with a promise of a harvest of good feeling among the pharmacists of the three kingdoms and of progress in the art they practise. This result is principally due to the fact that since that year the existence in Ireland of the title of "pharmaceutical chemist," with all that it signifies, has received legislative sanction, and the Pharmaceutical Society of Ireland has become the rallying point of a body of gentlemen having the same aspirations for the advance of pharmacy and its professors as stir in the breasts of the members of the Society in the sister island.

Mr. SCHACHT'S presidential address was devoted to a consideration of what we fain must call the possibilities of pharmacy, though in doing this we assume somewhat a position of antagonism to him, inasmuch as he put forward the picture he drew of the "business life of a pharmacist" as being drawn from facts that lie around us and as a plain unvarnished tale of common-place material to fit the experience of all. In the wish that it were so we could cordially join with Mr. SCHACHT, but we cannot abstain from expressing our belief that it is to the paucity of men who hold to and practically carry out the principles of the ideal mentor sketched by him, that we must ascribe the inferior position of pharmacy, even as a trade, in this country, and the existence of many of the burning questions that now agitate from time to time the whole pharmaceutical community.

But at the same time we think that although neither the pharmacist nor the pupil depicted by Mr. SCHACHT are every day objects, they are not very much better than they ought to be, and the somewhat speculative *résumé* of the business life of a pharmacist may serve by its contrast with reality to awaken in the minds of some a sense of what requires to be done for the promotion of the general interests of the trade.

In this respect there is no principle more worthy of observation now, or more wanting in consideration, than that which represents the pharmacist's shop as the true school of the pharmacist. It is the neglect of this fundamental principle that is the cause of many existing grievances. To that, and not to the obstacles of the Preliminary examination, we ascribe the prevailing difficulty in obtaining apprentices. That this introductory ordeal should in all instances be demanded is an order of things that we can only hope to see prevailing at some future time. And that having been passed through by the pharmaceutical aspirant, as the condition of admittance to the true school of pharmacy, the period of his educational training there should rather be expanded to the utmost than contracted to the narrowest limits. It is only under such conditions that we can hope to see the pharmacist generally appreciative of the fact that while his neighbours the draper and the bookseller are not expected to supply anything but drapery and books, so much more is looked for from the pharmacist as to raise the exercise of his trade far towards the level of a profession.

But there is in the presidential address ample material for reflection, and in the hope that our readers will give it all the attention it deserves, we abstain for the present from further comment.

The business of the meeting was continued by the reading of a report, by Dr. WRIGHT and Mr. LUFF, of some of the latest results they have obtained in the examination of the aconite alkaloids.

These results have already been communicated to the Chemical Society, and partially published in its journal. To a great extent they consist of rectifications of those stated in the report presented last year to the Conference. Thus, for instance, it is now reported that the substance to which the name pseudaconitine was then applied was not a definite base, but, in fact, a mixture of that base with a decomposition product derived from it by removal of water. Consequently the authors now propose the formula $C_{36}H_{49}NO_{12}$ in place of that which they gave last year as indicating the composition of pseudaconitine. This alkaloid is described as crystallizing with one molecule of water which is separable below 100°.

It is now found also that some salts of pseudaconitine are crystallizable; for instance, the nitrate, which is described as being obtainable by rubbing the approximately pure alkaloid in a mortar with dilute nitric acid in slight excess.

Another result is the alteration of the formula of pseudaconine, the product described last year as being formed by the action of acids upon pseudaconitine. The authors now propose to represent this as $C_{27}H_{41}NO_9$ instead of $C_{27}H_{41}NO_8$. This alteration is of course a necessary consequence of the above-mentioned rectification of the formula of pseudaconitine, if the production of pseudaconine from it is

to be represented as consisting in the splitting up of pseudaconitine into pseudaconine and dimethylprotocatechuic acid.

That decomposition of pseudaconitine, however, is now described as being accompanied by another alteration, which consists in mere dehydration of pseudaconitine and furnishes a product which the authors call apopseudaconitine. The composition of this substance is represented by the formula $C_{36}H_{47}NO_{11}$. It is described as a base closely resembling pseudaconitine and easily obtained by heating that substance with dilute hydrochloric acid, or with a large excess of tartaric acid solution for some hours.

The substance described by the authors last year under the name of pseudaconine, as resulting from the splitting up or saponification of pseudaconitine, is now reported to have been in reality a product of another alteration. The production of this substance—now termed apopseudaconine and represented by the formula $C_{27}H_{39}NO_8$—is described as consisting either in the splitting up of apopseudaconitine or in the dehydration of pseudaconine formed by the splitting up of pseudaconitine itself. It is reported not to be formed at all when the temperature is 100°, or rather less, but to be readily formed at 140°.

These are very radical modifications of the results reported last year, and they show that the general conclusions arrived at in these researches must be received with very great caution.

Another report on work done with the aid of a grant from the Conference research fund, was that presented by Mr. W. A. Shenstone on "Brucia and the Constituents of Strychnos Bark." The principal facts in this paper also have already appeared in this Journal, having formed the subject of a paper read at an Evening Meeting of the Pharmaceutical Society of Great Britain during last session. It confirms Mr. Cownley's negation of Professor Sonnenschein's alleged conversion of brucia into strychnia by the action of nitric acid, and states that the yield of strychnia steadily decreases as additional processes of purification are employed, until it completely disappears. It also admits the important fact, previously pointed out by Mr. Cownley, that commercial brucia frequently, if not always, contains an admixture of strychnia, and the reporter gives a method for the purification of brucia from this contamination. Another point in the report is the statement that false angostura bark does contain a small quantity of strychnia.

This concluded the reading of reports, and the next paper read was "On the Volumetric Estimation of Some Official Iron Preparations," by Mr. H. N. Draper. The preparations referred to in the paper were ferrous arseniate, ferrous phosphate, and magnetic oxide, and the point investigated was whether the quantities of bichromate of potash solution ordered in the British Pharmacopœia to be used in the volumetric estimation of these bodies are a fair indication of the products yielded by the Pharmacopœia processes. This the author answered in the negative, and in the discussion that followed Professor Attfield stated that he had always understood that no such indication was intended by the compilers of the Pharmacopœia.

Nitrite of amyl was the subject of the next paper, sent by Mr. Dott, who has been examining specimens of this important medicinal agent, obtained from various sources, with the object of ascertaining whether they presented a fair approach to uniformity. Taking the portion boiling between 90° and 100° C. as a rough indication of the amount of amyl nitrite present,—he having found the portions boiling below 90° and above 100° to be devoid of the physiological action characteristic of that body,—he reports that six specimens yielded respectively 85·0, 65·0, 47·5, 33·3, 11·5, and 6·7 per cent. These results are much the same as those reported some years ago in this Journal by Mr. Umney. In order to throw light upon the question what might be considered to be pure nitrite of amyl, Mr. Dott, using an amylic alcohol boiling between 128° and 129° and nitrous acid, obtained a product the portion of which passing over at a temperature between 90° and 100° had a specific gravity of 0·877, but never amounted to more than 95 per cent. The deficiency was attributed chiefly to decomposition, a portion always remaining with a boiling point above 100°, the distillate at the same time becoming strongly acid. Dr. Tichborne said that this confirmed a statement made by him whilst nitrite of amyl was yet a comparative novelty, that it could not be distilled without undergoing dissociation; he had tried the experiment in a current of carbonic anhydride, but not *in vacuo*.

Some Fragmentary Notes on Opium, by Mr. B. S. Proctor, followed, in which were discussed the variations in morphia strength of opium and some of its preparations, and the importance of using in pharmacy an opium of standard strength.

In calling attention to a soluble essence of ginger, Mr. J. C. Thresh touched upon a theme of considerable interest to the audience. The process adopted by the author is to macerate one pound of finest Jamaica ginger in powder in 8 ounces of rectified spirit for several hours, then pour on more spirit and percolate to 16 ounces. With the product is mixed 2 ounces of heavy carbonate of magnesia; the mixture is agitated and 24 ounces of water added; it is then again agitated and afterwards filtered. The filtrate is said to possess all the aroma of the ginger together with a fair share of its pungency. After keeping a few days it becomes turbid, but if again filtered it remains clear. In a short note from Mr. Proctor it was stated that the milkiness produced when essence of ginger made with strong spirit is diluted with water may be removed by the addition of a little alum or sulphuric acid and allowing it to

stand a little while. The alum or acid can afterwards be removed.

In a second paper, Mr. D. B. Dott announced that he had succeeded in preparing a crystalline hydrochloride of beberine, from the examination of which he hopes to be able to clear up the doubt existing as to the composition of the base.

The Titration of Hydrocyanic Acid and Cyanides and its relation to Alkalimetry was the title of the next paper read, which was by Mr. L. Siebold. The author points out that in using Liebig's process for determining the strength of hydrocyanic acid, it is better to use an excess of alkali than a deficiency, but that if exact results are desired, they may be attained by using an excess, and adding standard normal sulphuric or hydrochloric acid to the mixture at the close of the titration, until the slight opalescence produced by the silver nitrate begins to increase, which will not occur until the excess of alkali has been neutralized. For every cubic centimetre of sulphuric acid required 0·01 c.c. must be deducted from the volume of the silver solution used and the rest calculated as hydrocyanic acid. A modification of the process was also described for analysing mixtures of potassium or sodium cyanide and free hydrocyanic acid, as well as its applicability to alkalimetric operations.

In the discussion that followed the reading of this paper, Mr. Williams made an interesting addendum to his paper read at a former meeting of the Conference on the power of glycerine to prevent the diffusion of hydrocyanic acid. He stated that a solution made three years ago, containing 37½ per cent. of hydrocyanic acid, 37½ per cent. of glycerine and 25 per cent. of water, had been found, on testing it a week ago, still to contain about 37 per cent. of the acid.

The importance of the pharmacist acquiring a knowledge of vegetable histology was then advocated by Mr. T. Greenish, and its value was demonstrated by reference to enlarged drawings of sections of a sample supplied as senega root, which, from its general appearance and the inferior decoction it yielded, was suspected not to be genuine. An histological examination, however, proved it to be a true root of *Polygala Senega*, although immature, and that its inferior pungency was coincident with a deficiency in the cortical layer which Schneider has shown to be the seat of the active principle.

Mr. T. B. Groves then described a miscible copaiba that he had obtained by treating Maranham balsam with a saturated solution of potassium carbonate. It resembled ordinary copaiba in appearance and consistence, but was alkaline, and when shaken with water, instead of floating on the surface, it readily formed a white emulsion, more or less stable according to the degree of dilution.

"Baycuru," the title of a paper by Dr. Symes, is the name of a Brazilian drug, yielded by the *Staticæ Brasiliensis*, which the author thinks is worthy of trial in this country. It is used in Brazil as an astringent and discutient remedy in cases of enlargements and glandular swellings.

Under the cover of a note on "Authoritative Formulæ for Non-Official Preparations," the junior Honorary Secretary of the Conference, Mr. Benger, levelled an attack at the recent magisterial decisions in the north, that the sale of a mineral substance under the name of "violet powder" is an offence against the Sale of Food and Drugs Act. The tone of the paper may be gathered from the fact that the persons convicted were described as men in a highly respectable position, who had suffered pecuniary loss, annoyance and vexation "through failing to recognize as authoritative, formulæ published in Gray's 'Supplement' and similar works." Of course this is a subject upon which there exists a diversity of opinion, and it threatened to lead to a lively discussion. But the time of adjournment had arrived, and there yet remained one more paper on the list.

A perfumed solution of iodoform was the subject of the last paper for the day by Mr. G. A. Keyworth. This is prepared by shaking tincture of iodine with a fragment of fused potash until the colour is removed and covering the odour of the iodoform produced by the addition of eau de cologne or lavender water. The author also speaks of lint that has been dipped in this liquid and afterwards dried as being a very good application to indolent sores.

The proceedings on Wednesday were commenced by the reading of a paper on an "Improved Preparation of Ergot," in which Mr. A. W. Postans recommends one resembling the United States fluid extract in containing glycerine, but without the acetic acid. It is obtained by maceration and percolation of freshly powdered ergot with a mixture consisting of two parts each of rectified spirit and glycerine and one of water, displacing with water, and evaporating the last runnings in a water-bath so that one ounce of the united products shall represent one ounce of ergot.

The next paper entitled a "Comparison of the Strength of Some of the Cinchona Preparations," by Mr. C. Ekin, was perhaps the most important and valuable communication read during the session. It was followed by another on the "Assay of Cinchona," by Mr. J. B. Smith. Mr. Ekin had taken a sample of Calisaya bark of good appearance, treated it by De Vrij's method, so as to obtain the total alkaloids, and then prepared from the same bark for the purposes of comparison, a tincture, infusion, decoction, and fluid extract. From these results the following percentages of total alkaloids were obtained: bark 1·96; tincture, 1·89; infusion, 1·31; decoction, 1·26; and fluid extract only 0·47 per cent. From this it appears that the proof spirit of the tincture had nearly exhausted the bark, the boiling water of the infusion and decoction had taken up about five-eighths, while the cold water of the fluid extract took up, or at any

rate, only retained about one-fourth. In the discussion, Mr. UMNEY made some confirmatory remarks as to the waste involved in making the B.P. liquid extract, and Mr. BRADY mentioned the significant fact that quinine manufacturers are always ready to buy from pharmacists the residues left in the preparation of fluid extracts. Mr. UMNEY also remarked on the inferior quality of Calisaya bark now met with in commerce, and said he looked to India or Java for the barks of the future, whilst Professor MARKOE says that even now the East India barks are preferred in the United States.

The next paper, by Mr. GEORGE BROWNEN, was one of practical pharmaceutical interest, as it dealt with the recovery of the emetia contained in the unsightly deposit that forms in ipecacuanha wine. This may be done, the author says, by making the semi-crystalline mass into a paste with water which is rendered alkaline with calcined magnesia, dried, powdered and exhausted with alcohol. The alcohol is evaporated, and the crude alkaloid purified by dissolving it in dilute acetic acid and precipitating with ammonia. The emetia is thus obtained tolerably pure, as a fawn-coloured powder. Mr. BROWNEN also suggests whether the uncertainty and partial inertness of old ipecacuanha wine may not have another cause in the conversion of the emetia in o the gallo-tannate of the alkaloid, which according to WATTS is "neither emetic nor poisonous."

In a lively paper on the Adulteration of Drugs, Professor TICHBORNE quoted several instances of adulterated drugs that had come under his notice, some of them being substances of such low price as to appear hardly to allow of gain being made by their sophistication. Although the author stated that the gathering of the materials used in the paper had gone on during many years,—and indeed some of them are hardly to be met with now,—a vigorous and well founded protest was uttered by Mr. BOILEAU and succeeding speakers against any inferences being drawn from it, or from some remarks made by Dr. MCSWINEY, adverse to the commercial morality of the drug grinders or druggists of Dublin. The paper gave rise to the most prolonged discussion that took place during the Conference, in the course of which more than one speaker expressed an opinion that the subject had been treated in a somewhat exaggerated and one-sided manner by the author.

A method of distinguishing the presence of carbolic acid or cresylic acid in creasote was then described by Mr. A. H. ALLEN. The necessity of including cresylic acid was explained on the ground that if wood tar creasote were adulterated with coal tar acids, not pure carbolic acid would be used, but a low class product containing a considerable quantity of cresylic acid, which in many respects behaves more like creasote than carbolic acid. The method is based upon the difference in the boiling points of these bodies and the difference of the solubility in glycerine and in collodion.

Two papers by Mr. R. REYNOLDS and Mr. C. H. BOTHAMLEY followed. The first referred to the pink coloration produced in orange flower water by nitric acid, which the authors had found was no longer produced when the essential oil had been removed from the water by ether. The question was started during the discussion as to what ought to be dispensed when orange flower water is ordered in a prescription, the "triple water" as imported or diluted. Some diversity of practice was disclosed, dependent apparently upon the speaker looking upon the water as being ordered simply as a flavouring agent, or possibly for its hypnotic properties. The other paper, by the same author, was a report on the examination of various samples of dialysed iron. Mr. GERRARD communicated the results of an investigation of the New Zealand drug "pituri," and announced that he had succeeded in separating from it an alkaloidal substance, which he thinks will probably prove to be the active principle and proposes to call "pituria." Mr. GERRARD also communicated a method of preparing phosphorus pills, in which he takes advantage of the density of chloroform vapour to preserve the phosphorus from contact with atmospheric air during the manipulation of the pill mass.

In the next communication, Mr. C. W. FLETCHER described an interesting compound which has the composition of a tri-iodide of bismuth and hydriodate of quinine. This was followed by some Laboratory Notes by Mr. H. BARTON, and the reading of papers was brought to a close by a Note on REICHERT'S Improved Thermo-Regulator by Dr. SYMES.

The Conference then turned its attention to the arrangements or its next meeting, and Mr. WARD, on behalf of the pharmacists of Sheffield gave a hearty invitation to the members to meet next year in that town. This it was decided to accept. The election of officers, Mr. SCHACHT being again chosen President, and the passing of various votes of thanks brought the meeting for 1878 to an end.

At an early hour on Thursday morning, which was almost unexpectedly fine, a goodly number of the members and friends of the Conference gathered, by invitation, on the platform of the Dublin and Wicklow Railway, where a special train was waiting, chartered by the Irish members of the Conference, to carry the party to Rathnew, from which point cars conveyed them by way of the Devil's Glen to Glendalough, or the Seven Churches, where luncheon awaited them. The return journey was through the Vale of Clara to Rathdrum and then by rail to Dublin, where they met with fresh proofs of Irish hospitality in a dinner at the Exhibition Palace.

Here our record must for the present close.

It would be wrong, however, to omit speaking in the highest terms of the admirable arrangements which have helped to make the meeting of the Conference this year in Dublin one of the most pleasant and successful in its history. And for the successful

carrying out of those arrangements the vote of thanks to Mr. WILLIAM HAYES (the Local Secretary) Professor TICHBORNE, Messrs. DRAPER, HODGSON, and BOYD, and other members of the Committee, passed by the Conference at its closing meeting, was as well deserved as it was heartily given.

Another pleasant memory that some of the English visitors will carry away with them will be that of the courtesy of Dr. AQUILLA SMITH in rendering personal service as cicerone through the admirable museum of materia medica under his charge in Trinity College. On another occasion we shall refer to this museum more fully.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ON Wednesday evening the opening meeting of the British Association was held in the Exhibition Palace, Dublin, when Dr. ALLEN THOMSON resigned the presidential chair to Mr. WILLIAM SPOTTISWOODE. A very large assembly gathered to hear the new President's address, the merits of which may be judged by the portion appearing in another part of this Journal; but the effect was much marred by the fact that the speaker's words were distinguishable by only a small portion of the audience.

KOROMIKO.

AT page 1042 of the *Pharmaceutical Journal* for June 29 last, in the article on "The Month," it is stated on the authority of Dr. J. A. FRANCIS, in the *British Medical Journal*, that the proper spelling of the newly noticed medicinal plant which has been described as the Roromiko, is Koromiko. The plant has been said to be a native of New Zealand, and if so it would appear to be a species of *Veronica*, perhaps *Veronica elliptica*, Forst., or *V. parviflora*, Vahl., to both of which the name Koromiko is applied. This is given on the authority of Hooker's 'Handbook of the New Zealand Flora.'

CONVERSION OF QUININE INTO QUINIDINE.

M. PERSONNE has been engaged in some researches to ascertain whether, as asserted by M. GUILLOCHIN, quinine is converted into quinidine during its passage through the human system, or undergoes any other important modification. By treating with tannin, the urine from patients under antiperiodic treatment, M. PERSONNE has obtained a considerable quantity of perfectly white crystallized quinine sulphate, but no quinidine. In one case, where 2 grams of the crystallized sulphate were administered, M. YVON, effecting the precipitation with pure tannin, obtained from the urine 0·3 gram.

ACCORDING to the *British Trade Journal*, a cigarette paper is being made in Spain from the water cress. It is said to have a beneficial influence upon the lungs in pulmonary disease and to be less irritating in smoking than ordinary cigarette paper.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The Fifteenth Annual Meeting of the British Pharmaceutical Conference commenced on Tuesday, August 13th, in the Great Hall of the King and Queen's College of Physicians, Kildare Street, Dublin, under the presidency of Mr. G. F. Schacht, F.C.S., of Clifton. The chair was taken at 10.30 a.m.

RECEPTION OF DELEGATES.

The Hon. Sec. read the following list of delegates to the Conference:—

American Pharmaceutical Association and the Massachusetts College of Pharmacy.—Professor Markoe.

Pharmaceutical Society of Great Britain.—The President (Mr. J. Williams), the Vice-President (Mr. W. D. Savage), the Treasurer (Mr. T. Greenish), and Messrs. D. Frazer and Robbins.

Pharmaceutical Society of Ireland.—The President (C. R. C. Tichborne, LL.D., Ph.D.), Messrs. W. Allen, J. G. Boileau, J. E. Brunker, M.A., T. Collins, M.R.C.S., J. Goodwin, W. Hayes, J. T. Holmes, S. Oldham, J. C. C. Payne, R. W. Pring, L.A.H., J. Whitla, L.A.H.

Edinburgh (North British) Branch of Pharmaceutical Society of Great Britain.—Dr. Stevenson Macadam and Messrs. Laird and Winke.

Bristol Pharmaceutical Association.—Messrs. J. Pitman and G. F. Schacht.

Glasgow Chemists and Druggists' Association.—Messrs. E. C. C. Stanford, F.C.S., and D. Frazer.

Leicester Chemists' Association.—Mr. J. W. Clark.

Liverpool Chemists' Association.—Messrs. T. F. Abraham, R. Sumner and A. H. Mason.

Nottingham and Notts Chemists' Association.—Mr. J. Rayner.

Sheffield Pharmaceutical Association.—Mr. Ward, F.C.S., as the bearer of an invitation to the British Pharmaceutical Conference to meet in Sheffield next year.

The report of the Executive Committee was read by Mr. F. Baden Benger, F.C.S., as follows:—

REPORT OF THE EXECUTIVE COMMITTEE.

The period of our annual meeting so nearly comprises the whole of the transactions of the Conference, and these are so fully reported in our published proceedings, that there remains little beyond the record of formal business, and uninteresting details of secretarial work to include in the Committee's report.

The position of the Conference continues satisfactory. Some inevitable loss of members has taken place, but many new names have been enrolled, and the financial statement will show a considerable balance in hand.

The wide interest felt in the Conference and its aims by those connected with pharmacy throughout Ireland has been evidenced in the very hearty efforts put forth to ensure the success of this our first meeting in Ireland by the body of gentlemen forming the Irish Committee, and your Committee regards with pleasant anticipation the prospect of obtaining fresh workers in this new field. At a meeting of your Committee held at Plymouth last year a discussion was raised by Mr. Schacht—then Treasurer—respecting the nature of the securities in which the Bell and Hills Library Fund was invested, and a resolution, proposed by Mr. Ekin and seconded by Mr. E. Smith, was carried—"That the Russian bonds in which the Bell and Hills Fund is invested be sold, and the proceeds re-invested in Consols." It was further resolved, on the motion of Mr. John Williams, seconded by Mr. Umney—"That the Treasurer transfer from the

General Fund to the Bell and Hills Fund, such a sum as may be necessary to allow of that Fund yielding when invested in Consols, a clear ten pounds annually;" and at a subsequent meeting of the Committee held in London on Dec. 5th Mr. Schacht reported that in accordance with the instructions of the Committee conveyed in these resolutions such transfers had been accomplished. It will doubtless afford gratification to members that a sum from the General Fund should have been used to render permanent the Bell and Hills Fund, so generously established by Mr. Hills.

At this meeting of the Committee, Professor Attfield reported that in accordance with the wishes of Mr. Thomas Hanbury, and with the instructions of the Committee, he had sent a copy of 'Pharmacographia' and of the late Daniel Hanbury's 'Science Papers' to the libraries of the Pharmaceutical Associations of Bath, Birmingham, Nottingham, Exeter, Liverpool, Edinburgh, Brighton, Bradford, London, Bristol, Glasgow and Plymouth; and that he had received very hearty acknowledgments from the officers of the respective societies. A printed copy of the following statement had been placed inside the cover of each book:—

"In 1877 Thomas Hanbury, Esq., in memory of his late brother Daniel Hanbury, F.R.S., presented thirty copies of each of these books to the Executive Committee of the British Pharmaceutical Conference, with a request that a copy of the 'Science Papers' and of 'Pharmacographia' should be given to the library of the Pharmaceutical Association of every one of the fifteen towns in which the Conference had already met, or where it would assemble during the succeeding fifteen years."

The senior Secretary, Professor Attfield, was instructed to write to Mr. Siebold as soon as the editorial work of the current year was completed, offering him the editorship for the year 1877–8 on certain conditions as to the date on which the work should be completed. After some correspondence on the subject these terms were accepted by Mr. Siebold.

Dr. Alfred Senier was appointed Assistant-Secretary, at a salary of £40 per annum, to commence from Nov. 1st, 1877.

Professor Attfield submitted a proof of a circular of invitation to membership, proposed to be sent to all persons interested in pharmacy in Ireland, provided such action met with the approbation of the Irish Committee then being formed to promote the success of the meeting in Ireland in 1878. The Committee accepted the proof, and ordered copies to be printed and circulated, subject to the wishes of the Irish Committee.

Accounts of receipts and disbursements since the last meeting of the Committee were submitted by the Secretaries.

Early in the present year a revised edition of the "Blue List" of subjects suggested for investigation was issued to members. This list included only subjects possessing more or less special pharmaceutical interest, it being considered desirable to encourage as much as possible the presentation of papers bearing closely on pharmacy.

It has been found advisable in the past, at intervals of every four or five years, to issue to all registered chemists and druggists not already members of the Conference a circular setting forth prominently the objects of the Conference and the terms of membership. This course invariably results in a large accession of new members, and becomes necessary as from various causes old ones fall away. It is proposed to utilize the balance in the hands of the senior Secretary by the issue of such a circular during the present year, and your Committee trust that this means, combined with the efforts of those members who feel an interest in the subject, will again considerably increase the numerical strength of the Conference.

The financial statement was then read. It is printed on the opposite page.

On the motion of the President, seconded by Professor Tichborne, the report and accounts were received and adopted.

The Donations of Books.

Professor Attfield said he had, according to rule, written to the officers of the Pharmaceutical Society of Ireland, offering on behalf of the Conference to present to the Library of the Society, if it possessed one, books to the value of ten guineas from the Bell and Hills Library Fund. He had received an answer that the Society would gladly accept the books, and that Dr. Tichborne was deputed to select the books which the Society would like to possess. Unfortunately, although he had purchased the books, he had not been able to get them bound in time to lay them on the table. He had also to announce that through the generosity of Mr. Thos. Hanbury, he was able to add a bound copy of the 'Pharmacographia' and of Mr. Daniel Hanbury's 'Science Papers.'

Dr. Tichborne, as President of the Pharmaceutical Society of Ireland, moved that the members of that Society present in the room should pass a vote of thanks to the Trustees of the Fund for this handsome present; this was seconded by Mr. Draper, and carried unanimously.

The President then read the following address:—

The President's Address.

The "Past" of Pharmacy was set before us by our President of last year with so much success that I felt strongly impelled to attempt this year a grasp at its "Future."

My presumption met with its natural reward. Not for the first time in the history of human folly, the effort to penetrate the impenetrable failed. A kind of hope, however, gradually arose that if the effort were directed to a search for the spirit that guides the work of the present and to signs of connection, if any exist, with that of the past, suggestions might arise worthy of acceptance as shadows of things to come. At any rate some beneficial hints might be gathered from a good straight look into things as they are. In a somewhat inconsequent and illogical way, but in the order in which my own mind was swayed, I place before you the grounds upon which this idea was based.

The future, then, is silent and refuses to answer; can we turn for light elsewhere? What says the wisdom of the past? "That which has been will be." What says the wisdom of the present? "To-morrow is the offspring of to-day." Can these words of wisdom help us?

A man becomes what the prevailing habit of his mind impels him to be. Societies become what the prevailing habit of the strongest minds among them impel them to be. Let us call this habit of mind, Tone. Shall we define "tone" to be the name for an unwritten code, self-imposed and acting through the sentiments of honour and shame? So far, well; but what is the impulse that at once determines submission to this code, and declares the line at which honour yields and shame prevails? Sense of duty. Duty! The word has but four letters, but with what infinite variety of significance is it regarded.

For the definition of the scope of a man's duty lies absolutely with himself. To one, the petty concerns of his own being suffice to furnish the limit, and he is content, in a dull way, to work that he may eat. To another, the entire stretch of the visible horizon fails to include all that conscience declares to have a claim upon his life, and even when fainting strength can do no more he weeps himself out "an unprofitable servant." The average man takes his place somewhere between these two extremes: not quite so dull, but he acknowledges vaguely that others have rights as well as himself; not quite so pure, but he has to admit that "ego" still stands to him as of prime importance.

Examined and found correct, { S. B. TURNEY, Plymouth, W. ALLEN, Dublin, } *Auditors.*

But arranged in whatsoever number of groups we will, the individual claims the right to read his own case, to estimate the bearings of all its complex surroundings and to declare the resulting sum of his obligations ;—and who shall presume to gainsay that right ?

Are we not then at the very outset confronted by a great dilemma ?

How mistaken may every conclusion as to the inner life of a community be, which is in any way founded upon a supposed general deference to duty, the word having a different meaning for every individual. And, on the other hand, how hopeless must be the effort to urge upon one's neighbours any other idea of that obligation than the one by which they are already possessed.

Possibly this may be so, but is it not more distinctly true that no man can claim to stand in this world alone? Is not his case of necessity part and parcel of other cases? do not his conditions and surroundings envelop other lives, and his decisions and conduct affect other interests as well as his own? Most surely is this true, and of no portion of his life is it more plainly true than that which is termed his "business avocation," in which perhaps many others are labouring with equal anxiety, and whose interests therein are equally grave. Indeed a man's business avocation may be fairly regarded as the school of his adult life, in which qualities and aspirations for good or evil become developed and confirmed. If the tone of that school be low, the man and his avocation alike become degraded; if it be high, both are in some measure led upward toward honour.

Pharmacy is the school of our adult lives. If the tone of pharmacy be high both we and pharmacy will be led upward.

Our future, then, depends upon our present :—what is our present ?

Let us take up a parable, and call it "The Business Life of a Pharmacist." Let the incidents be gathered, neither from the life of any particular individual nor from our own imaginings, but from the facts that lie around us ; and let us arrange them in the form of a personal narrative, "The Business Life of a Pharmacist."

I left school when between fifteen and sixteen years of age. It was a good average private school. We were there taught English, Latin and Greek, French, mathematics, and the rudiments of physical science. We were trained kindly and with an evident desire to make us good as well as capable lads. It was arranged that I should become a pharmaceutical chemist and that I should be apprenticed to a gentleman in business in a certain provincial town of some size and importance.

My selected master (whom I shall in future call my mentor), having considered all he could gather about me from my friends and from my late school, and being fairly satisfied, required me to pass the Preliminary examination of the Pharmaceutical Society. I remember my guardian speaking of this requirement as a "new-fangled bit of nonsense," and so afterwards did some of the lads who went in with me for the examination ; but my mentor was quite clear upon the point, urging "that if the young gentleman's mental powers were unequal to the moderate requirements of that test it would be wiser to refer him back for a few more terms to his schoolmaster." I came through the trial with fair credit, though, to my surprise, about 50 per cent. of my companions on that occasion were rejected.

One of the first systematic tasks assigned to me was to spend two hours every morning copying from a "prescription book," carrying out in full, by the aid of dictionary and grammar, all the abbreviations and translating them into English. I was also required to refer to books on materia medica and others, and to read about every article named in the prescriptions. Once a fortnight a short examination served to keep my attention alive to the work. But I was chiefly occupied with what I soon began to call, with some pouting, the drudgery of the shop,—wrapping and folding and putting up articles of stock for sale,—until, indeed, I ventured a bit of a grumble.

My mentor listened, with a quiet smile, and assured me that when I could wrap three consecutive ounces of light carbonate of magnesia into three similarly-shaped and equally neat parcels I should be excused wrapping for a whole month.

I am not sure that I ever achieved the task, but I soon ceased to regard such work with any distaste, for I saw that it had to be done, and the growing dexterity of my fingers rendered it day by day less irksome.

My work also soon came to be varied by occasional employment in the laboratory. We there carried on a good deal of drying, grinding, powdering, sifting, infusing, macerating, pressing, straining, extracting, distilling, etc., etc.; for my mentor said, in answer to someone's expression of surprise, that "although doubtless there were many amongst those of whom he could buy the manufactured article who were quite as clever and quite as honest as himself, still his customers confided in him and not in some individual utterly unknown to them, and he thought it right to be able to vouch by personal knowledge for the integrity of, as nearly as possible, every thing he gave them." So there was a good deal of work done (on a small scale) in my mentor's laboratory, and I became familiarized with processes of interest, both scientific and commercial.

In the second year of my apprenticeship—and when my reading and experience had opened my mind in some degree to the qualities and properties of the materials I had to deal with—I was required to attend a course of lectures on systematic chemistry, and in the following year a course upon botany and materia medica ; and my mentor was careful to see the contents of my note book and to have me copy them out in full with the aid of text-books, requiring me in the one case to make drawings of the apparatus used in the experiments and in the other case marginal illustrations of the parts of plants described and graphic descriptions of the technical terms employed by the lecturer. "For," said he, "this will assure both yourself and me that you have understood what you have seen and heard, and it will assist wonderfully in stamping these essential matters into your memory."

That course of lectures on chemistry was for me an important one, for it was during its delivery that I first fell in love. The "smite" occurred in this wise. With more or less effort I had followed the lecturer through perhaps the first half of his course regarding every fact and phenomenon he put before us as so many bits of information to be painfully remembered, till one eventful morning when it became his duty to expound the chemistry of the voltaic pile. As, in the course of that explanation, he proceeded to dilate upon that strange wonder, the parallelism of the phenomena that occur in the generating and in the experimental cells, a screen seemed suddenly to fall from around my senses and I felt for the first time in my life that there was a meaning in the relations of things, the mere cognizance of which was a delight.

Utterly undefinable as that impression then was, it served to give a perfectly new impulse to all that portion of my work. It was the first sweet taste of a spring of wholesome enjoyment that has never since failed, and for whose refreshment I hope I shall never cease to feel grateful. I had fallen in love with the fair Spirit of Science and had reaped the usual result of such a plunge; I had got one step nearer to Heaven.

I was very anxious to dispense long before I was allowed to do so. But my mentor said very gravely, "Remember, if you please, trusting you to dispense is trusting you on the one hand with *my* reputation, and possibly with my very commercial existence, and on the other hand with the safety and existence of the public. It becomes my clear duty, therefore, to withhold that trust until I have full assurance that you deserve it. A dispenser must not only be capable of absolute correctness

himself, but he must also be capable of detecting any error of ignorance or accident on the part of the prescriber; special qualifications of knowledge, training, and even of character, are required in a good dispenser. I admit these qualifications are growing up within you, but they are scarcely yet sufficiently pronounced to justify the trust."

The proper time came in due course, but I have ever felt the responsibility of that portion of my work and have gratefully adopted any aids to safety that have appeared to promise well.

About this time I began to acknowledge the wisdom of one condition of my apprenticeship that had at first appeared a little arbitrary. When its terms were being first discussed I felt unwilling to be bound for so long a period as four years. But my future mentor urged the point with some earnestness, and of course it was yielded. "There is no school for the pharmacist," he said, "equal to that of the pharmacist's shop. Three years is all too short a time in which to master its details; four years is more than 30 per cent better. The healthiest plants are those which are not unduly forced." This, the first argument I ever heard him use was a fair illustration of one of the special qualities of his character. He thought everything that had to be done worthy of the amplest pains. Nothing was allowed to be slurred. Every article purchased was the best that he could select, and many a parcel of goods, once perfect, have I seen him throw into the dust-bin, because it had begun to show signs of change. All suggested new processes were tried and if found to be improvements were adopted. In every case of doubtful prescribing, trouble to any extent was taken to find out the prescriber's intention. To this end I had frequently to spend hours in finding out the doctor and getting him to review his prescripton. Occasionally these efforts were wrongly interpreted and we even received the reverse of thanks for our pains; but the comment and consolation of my chief were invariably the same: "Never mind, it was the right thing to do."

As time went on I had full opportunity of seeing that, though not quite always appreciated as I thought he deserved, my mentor was much trusted and (at times) consulted by his customers and neighbours, and I had frequently to assist him in matters that appeared to lie somewhat outside the usual run of business. He appeared to think these fit opportunities for narrating such bits of experience as he thought might be of use to me. I made memoranda of these as they occurred and as they were told, and find they present a strange mixture of subjects.

I have notes of—

1. *Cases of analysis*, including those of waters, manures, minerals, chemicals, articles of food, samples of healthy and of diseased secretion, etc.

2. *Cases of suspected poisoning*, happily not one case of real poisoning.

3. *Cases of emergencies*, arising from accidents, such as falls, wounds, burns, injuries from machinery, etc.

4. *Cases requiring urgent medical advice*, of all degrees of importance, from toothache to cholera and delirium.

5. *Cases demanding professional sympathy* rather than medical help, and which had for their scenes and times the last moments and the death beds of suffering and distress.

6. *Cases of consultation upon matters commercial, professional, and domestic*, which refuse to be grouped, but which required knowledge, judgment, and secrecy.

I showed my mentor this bundle of memoranda just before I left his house, and he was glad I had preserved them. "More especially," he said, "for this reason. You will see in them how curiously varied is the public demand upon us pharmacists, and how curiously are our labours sometimes valued. The shop on our right is a draper's, and that on our left is a bookseller's, and their proprietors are known to be as good and as worthy men as ourselves, but the public demand nothing from them but drapery and books. Ours is a pharmacist's, and in addition to the supply of drugs, chemicals, and medicines, the same public *looks to us as if by right* for prompt practical help in many of its difficulties and in much of its trouble. We are supposed to be tender of heart, but with nerves drilled as a surgeon's; prompt and self-possessed in emergency, but content to retire and be forgotten when the professor appears upon the scene. Our knowledge must be large and our tempers sweet, but withal we must never forget that we are shopkeepers; what of the battle of life we have to do must be done in the trenches rather than in the arena. Well, let us accept our *rôle*; a campaign may be won as much by the pickaxe and spade as by the sword and rifle."

At the conclusion of my apprenticeship my mentor advised me to devote a year exclusively to scientific study. "Adopt which school you prefer, only let it be one in which your mind and intellect may be trained and drilled as well as informed, strengthened to acquire rather than inflated with knowledge. This is the purpose of all good education. There are Schools of Pharmacy of both kinds, and, as a rule, by their fruits we know them." So I made my selection with what care I could, and spent ten months in the way he advised, and then passed the examinations, Minor and Major, of the Pharmaceutical Society.

Once more deferring to the advice of my old friend and mentor I sought and obtained a situation at one of the "historic houses" of pharmacy. Here I remained nearly three years, gaining much experience and making some valuable friendships.

A favourable opportunity for commencing business on my own account then occurred, and I became an independent pharmacist.

I have had hard work for some years and ultimately have achieved fair success, and I have been lately honoured by an invitation to sit at the Board of Examiners of the Pharmaceutical Society.

I hope some day to be able to accept this crowning honour to my professional career.

There ends our autobiography:—a plain unvarnished tale, of common-place material enough, let us hope, to fit the experience of all.

And I again address you, gentlemen, in my proper person.

It is, I think, an every-day story; yet as I review it I detect a something which when clothed in human form presents a figure of some significance in our present search.

The form is that of a man, charged with an exalted idea of duty, filled with human sympathy, well informed in general knowledge, accurately informed in the special knowledge of his art, with habits drilled to exactitude and care, and fingers trained to dexterity and neatness, and covering all with an imperious determination to do the right thing.

Shall I presume to say that some such summary as this defines the model pharmacist of to-day? I think I may; and, if the definition be fair, then I presume further to assert that he stands the type of a high order of being, and that the sphere of life that provides such a part in the present certainly need not offer a very dreary future.

I think moreover I can detect glimpses of a process by which fit actors may be trained to fill this part with credit. Amongst the points of this process I note the care with which the future pharmacist was selected and his qualifications tested before admission as a pupil, the patience with which his interest in the daily work was watched and fostered, the discretion that marked the gradual infliction of responsibility upon his forming character, the judgment that regulated his introduction to the sciences and encouraged his cultivation of their mysteries until they become to him a joy, the final trust and confidence that made him the depositary of experiences only to be revealed to the initiated, and more or less each and all of these points appear to me of value. But I see that the key of the whole process lay in this, that the man was possessed by a high idea of the duties of his calling,

to which every other consideration connected with it was made to bend; he was jealous of those duties as of a daughter's honour and could not consign them to one that was unworthy. He felt his art to be a living thing, with a past, a present and a future, and though he laboured in it, and lived by it, he refused to regard it as a possession of his own, but only as a trust to be held in common with others for a time, and be transmitted to his successors, if it might be possible, in augmented value. Verily I think this man had his reward. The inheritance committed to his charge he faithfully passed on to hands he had helped to make worthy, and the "future of pharmacy" must, I think, to his eyes have appeared fair and bright.

I forbear to dwell upon the reverse of this picture, though truth compels me to admit that such, alas, may be found; and I feel, therefore, forbidden to interpret as hopefully as I should wish the tenour of the "shadows of things to come" which these considerations have raised.

But I may perhaps venture to say that the gleam of light that casts these shadows bears with it, as I think, a message of high import. I read it thus:—The future of our art rests with ourselves. What we strive to make it, that it will become.

It is a message of severest warning; but it is also one of hope. The warning may reach us all alike, but the comfort of the hope will, I think, be felt in proportion to the consciousness of duty well fulfilled.

Had this address been delivered in England, it would have naturally terminated at this point. But I cannot conclude without saying that the assembling of the Pharmaceutical Conference this year in Ireland (let me gratify myself by saying in the "Sister Island") is, I am sure, a great pleasure to its English members.

That strip of sea which for so many purposes serves to unite the two peoples, and to make them one, has acted, alas, upon some of us as a barrier and has kept us apart.

I fear that pharmacy on both sides of the water may have suffered somewhat by this enforced separation. Let us hope that this gathering will tend to the rectification of any such deficiencies. At any rate I feel assured that this Dublin meeting will not fail in the great object of the Conference, which is the promotion of scientific pharmacy and the cultivation of feelings of mutual respect and cordiality among those that practise it.

Dr. TICHBORNE proposed a vote of thanks to the President for his eloquent address. His first acquaintance with Mr. Schacht arose through the now well-known preparation Liquor Bismuthi, which was introduced by that gentleman. It was at first quite a curiosity, because it was not then generally known that the bismuth salts were not precipitated by ammonia in the presence of citric acid; so that an alkaline solution of bismuth for internal administration was rather a novelty. He having published an analysis of the preparation, Mr. Schacht some time after claimed his acquaintance on that ground. It was evident from the address that Mr. Schacht was a thoroughly practical man and that his education had been one of that typical character which he hoped they would all endeavour to give to their apprentices. One point had been touched on which was perhaps a little dangerous in Ireland. He could hardly say how far the "private notes" referred to would indicate a desire on the part of English pharmacists to trench on medical ground, but happily in Ireland such a thing was unknown. The pharmacist here simply confined himself to his legitimate sphere of duty, and he had no doupt that such was the line of action which the President himself would advocate.

Mr. PRING (Belfast), having seconded the motion, it was put by Mr. BRADY (Vice-President), and carried unanimously.

The PRESIDENT, in response, said he feared from Dr. Tichborne's remarks that his little autobiographical sketch had been taken to be a personal history, but he wished to say most emphatically that such was not the case. He had simply endeavoured to give a sketch of a typical pharmacist's life.

The reading of papers was then proceeded with.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the above Association commenced on Wednesday, August 14, at Dublin, under the presidency of Mr. William Spottiswoode, M.A., D.C.L., LL.D., F.R.S., F.R.A.S., F.R.G.S., who delivered the opening address:—

THE PRESIDENT'S ADDRESS.

On looking back at the long array of distinguished men who both in this and in the sister countries have filled the chair of the British Association, on considering also the increased pains which have been bestowed upon, and the increased importance attaching to, the presidential address, it may well happen when, as on this occasion, your choice has fallen upon one outside the sphere of professional science, that your nominee should feel unusual diffidence in accepting the post. Two considerations have, however, in my own case outweighed all reasons for hesitation; first, the uniform kindness which I received at the hands of the Association throughout the eight years during which I had the honour of holding another office; and, secondly, the conviction that the same goodwill which was accorded to your treasurer would be extended to your President.

These considerations have led me to arrange my observations under two heads, viz., I propose first to offer some remarks upon the purposes and prospects of the Association with which, through your suffrages, I have been so long and so agreeably connected; and, secondly, to indulge in a few reflections, not indeed upon the details or technical progress, but upon the external aspects and tendencies of the science which on this occasion I have the honour to represent. The former of these subjects is, perhaps, trite; but as an old man is allowed to become garrulous on his own hobby, so an old officer may be pardoned for lingering about a favourite theme. And although the latter may appear somewhat unpromising, I have decided to make it one of the topics of my discourse, from the consideration that the holder of this office will generally do better by giving utterance to what has already become part of his own thought than by gathering matter outside of its habitual range for the special occasion. For, as it seems to me, the interest (if any) of an address consists, not so much in the multitude of things therein brought forward as in the individuality of the mode in which they are treated.

The British Association has already entered its fifth decade. It has held its meetings, this the 48th, in twenty-eight different towns. In six cities of note—viz., York, Bristol, Newcastle-on-Tyne, Plymouth, Manchester and Belfast, its curve of progress may be said to have a node, or point through which it has twice passed; in the five Universities of Oxford, Cambridge, Dublin, Edinburgh, and Glasgow, and in the two great commercial centres, Liverpool and Birmingham, it may similarly be said to have a triple point, or one through which it has three times passed. Of our forty-six presidents more than half (twenty-six, in fact) have passed away; while the remainder hold important posts in science and in the public service, or in other avocations not less honourable in themselves, nor less useful to the commonwealth. And whether it be due to the salubrity of the climate or to the calm and dispassionate spirit in which science is pursued by its votaries here, I do not pretend to say; but it is a fact that the earliest of our ex-presidents still living, himself one of the original members of the Association, is a native of and resident in this country.

At both of our former meetings held in Dublin, in 1835 and 1857 respectively, while greatly indebted to the liberal hospitality of the citizens at large, we were, as we

now are, under especial obligations to the authorities of Trinity College for placing at our disposal buildings, not only unusually spacious and convenient in themselves, but full of reminiscences calculated to awake the scientific sympathies of all who may be gathered in them. At both of those former Dublin meetings the venerable name of Lloyd figured at our head ; and if long-established custom had not seemed to preclude it, I could on many accounts have wished that we had met for a third time under the same name. And although other distinguished men, such as Dr. Robinson, Professors Stokes, Tyndall, and Andrews, are similarly disqualified by having already passed the presidential chair, while others again, such as Sir W. R. Hamilton, Dr. M'Cullagh, and Professor Jukes, are permanently lost to our ranks, still we should not have had far to seek, had we looked for a president in this fertile island itself. But as every one connected with the place of meeting partakes of the character of host towards ourselves as guests, it has been thought by our oldest and most experienced members that we should better respond to an invitation by bringing with us a president to speak as our representative than by seeking one on the spot ; and we may always hope on subsequent occasions that some of our present hosts may respond to a similar call.

But leaving our past history, which will form a theme more appropriate to our jubilee meeting in 1881, at the ancient city of York, I will ask your attention to a few particulars of our actual operations.

Time was when the Royal Societies of London and Edinburgh and the Royal Irish Academy were the only representative bodies of British science and the only receptacles of memoirs relating thereto. But latterly, the division of labour, so general in industrial life, has operated in giving rise to special societies, such as the Astronomical, the Linnæan, the Chemical, the Geological, the Geographical, the Statistical, the Mathematical, the Physical, and many others. To both the earlier, or more general, and the later, or more special societies alike, the British Association shows resemblance and affinity. We are general in our comprehensiveness ; we are special in our sectional arrangement ; and in this respect we offer not only a counterpart, but to some extent a counterpoise, to the general tendency to subdivision in science. Further still, while maintaining in their integrity all the elements of a strictly scientific body, we also include, in our character of a microcosm, and under our more social aspect, a certain freedom of treatment, and interaction of our various branches, which is scarcely possible among separate and independent societies.

The general business of our meetings consists, first, in receiving and discussing communications upon scientific subjects at the various sections into which our body is divided, with discussions thereon ; secondly, in distributing under the advice of our Committee of Recommendations the funds arising from the subscriptions of members and associates ; and, thirdly, in electing a council upon whom devolves the conduct of our affairs until the next meeting.

The communications to the sections are of two kinds—viz., papers from individuals and reports from committees.

As to the subject-matter of the papers, nothing which falls within the range of natural knowledge, as partitioned among our sections, can be considered foreign to the purposes of the Association, and even many applications of science, when viewed in reference to their scientific basis, may properly find a place in our proceedings. So numerous, however, are the topics herein comprised, so easy the transition beyond these limits, that it has been thought necessary to confine ourselves strictly within this range, lest the introduction of other matters, however interesting to individual members, should lead to the sacrifice of more important subjects. As to the form of the communications, while it is quite true that every scientific conclusion should be based upon substantial evidence, every theory complete before being submittted for final adoption, it is not the less desirable that even tentative conclusions and hypothetical principles when supported by sufficient *primâ facie* evidence, and enunciated in such a manner as to be clearly apprehended, should find room for discussion at our sectional meetings. Considering, however, our limitations of time, and the varied nature of our audience, it would seem not inappropriate to suspend, mentally if not materially, over the doors of our section rooms, the Frenchman's *dictum*, that no scientific theory "can be considered complete until it is so clear that it can be explained to the first man you meet in the street."

Among the communications to the sections, undoubtedly the most important, as a rule, are the reports ; that is to say, documents issuing from specially appointed committees, some of which have been recipients of the grants mentioned above. These reports are in the main of two kinds—first, accounts of observations carried on for a series of years, and intended as records of information on the special subjects ; such, for instance, have been those made by the Kew Committee, by the committees on luminous meteors, on British rainfall, on the speed of steamships, on underground temperature, on the exploration of certain geological caverns, etc. These investigations, frequently originating in the energy and special qualifications of an individual, but conducted under the control of a committee, have, in many cases, been continued from year to year, until either the object has been fully attained or the matter has passed into the hands of other bodies, which have thus been led to recognize an inquiry into these subjects as part and parcel of their appropriate functions. The second class is one which is, perhaps, even more peculiar to the Association—viz., the reports on the progress and present state of some main topics of science. Among these may be instanced the early reports on astronomy, on optics, on the progress of analysis; and later, those on electrical resistance, and on tides; that of Professor G. G. Stokes on double refraction; that of Professor H. J. Smith on the theory of numbers; that of Mr. Russell on hyperelliptic transcendents, and others. On this head Professor Carey Foster, in his address to the Mathematical and Physical section at our meeting last year, made some excellent recommendations, to which, however, I need not at present more particularly refer, as the result of them will be duly laid before the section in the form of the report from a committee to whom they were referred. It will be sufficient here to add that the wide extension of the sciences in almost every branch and the consequent specialization of the studies of each individual have rendered the need for such reports more than ever pressing ; and if the course of true science should still run smooth it is probable that the need will increase rather than diminish.

If time and space had permitted, I should have further particularized the committees, occasionally appointed, on subjects connected with education. But I must leave this theme for some future president, and content myself with pointing out that the British Association alone among scientific societies concerns itself directly with these questions, and is open to appeals for counsel and support from the great teaching body of the country.

One of the principal methods by which this Association materially promotes the advancement of science, and consequently one of its most important functions, consists in grants of money from its own income in aid of special scientific researches. The total amount so laid out during the forty-seven years of our existence has been no less than £44,000 ; and the average during the last ten years has been £1450 per annum. These sums have not only been in the main wisely voted and usefully expended, but they have been themselves productive of much additional voluntary expenditure of both time and money on the part of those to whom the grants have been entrusted. The results have come back to the Association in the form of papers and reports, many of which have been printed in our volumes. By this appropriation of a large portion of its funds, the Association

has to some extent anticipated, nay, even it may have partly inspired, the ideas now so much discussed, of the endowment of research; and whether the aspirations of those who advocate such endowment be ever fully realized or not, there can, I think, be no doubt whatever that the Association in the matter of these grants has afforded a most powerful stimulus to original research and discovery.

Regarded from another point of view, these grants, together with others to be hereafter mentioned, present a strong similarity to that useful institution, the Professoriate Extraordinary of Germany, to which there are no foundations exactly corresponding in this country. For, beside their more direct educational purpose, these professorships are intended, like our own grants, to afford to special individuals an opportunity of following out the special work for which they have previously proved themselves competent. And in this respect the British Association may be regarded as supplying to the extent of its means an elasticity which is wanting in our own universities.

Besides the funds which, through your support, are at the disposal of the British Association, there are, as is well known to many here present, other funds of more or less similar character at the disposal or subject to the recommendations of the Royal Society. There is the donation fund the property of the society, the Government grant of £1000 per annum, administered by the society, and the Government fund of £4000 per annum (an experiment for five years) to be distributed by the Science and Art Department, both for research itself and for the support of those engaged thereon, according to the recommendations of a committee consisting mainly of fellows of the Royal Society. To these might be added other funds in the hands of different scientific societies.

But, although it must be admitted that the purposes of these various funds are not to be distinguished by any very simple line of demarcation, and that they may therefore occasionally appear to overlap one another, it may still, I think, be fairly maintained that this fact does not furnish any sufficient reason against their coexistence. There are many topics of research too minute in their range, too tentative in their present condition, to come fairly within the scope of the funds administered by the Royal Society. There are others ample enough in their extent and long enough in their necessary duration to claim for their support a national grant, but which need to be actually set on foot or tried before they can fairly expect the recognition either of the public or of the Government. To these categories others might be added, but the above-mentioned instances will perhaps suffice to show that even if larger and more permanent funds were devoted to the promotion of research than is the case at present, there would still be a field of activity open to the British Association as well as to other scientific bodies which may have funds at their disposal.

On the general question it is not difficult to offer strong arguments in favour of permanent national scientific institutions; nor is it difficult to picture to the mind an ideal future when science and art shall walk hand in hand together, led by a willing minister into the green pastures of the endowment of research. But while allowing this to be no impossible a future, we must still admit that there are other and less promising possibilities, which under existing circumstances cannot be altogether left out of our calculations. I am, therefore, on the whole inclined to think that, while not losing sight of larger schemes, the wisest policy, for the present, at all events, and pending the experiment of the Government fund, will be to confine our efforts to a careful selection of definite persons to carry out definite pieces of work, leaving to them the honour (or the *onus* if they so think it) of justifying from time to time a continuation of the confidence which the Government or other supporting body may have once placed in them.

Passing from the proceedings to other features and functions of our body, it should be remembered that the continued existence of the Association must depend largely upon the support which it receives from its members and associates. Stinted in the funds so arising, its scientific effectiveness would be materially impaired; and deprived of them, its existence would be precarious. The amount at our disposal in each year will naturally vary with the population, with the accessibility, and with other circumstances of the place of meeting; there will be financially, as well as scientifically, good years and bad years. But we have in our invested capital a sum sufficient to tide-over all probable fluctuations, and even to carry us efficiently through several years of financial famine, if ever such should occur. This seems to me sufficient; and we have, therefore, I think, no need to increase our reserve, beyond, perhaps, the moderate addition which a prudent treasurer will always try to secure against expenditure which often increases and rarely diminishes.

But however important this material support may be to our existence and wellbeing, it is by no means all that is required. There is another factor which enters into the product—namely, the personal scientific support of our best men. It is, I think, not too much to say, that without their presence our meetings would fail in their chief and most important element, and had best be discontinued altogether. We make, it must be admitted, a demand of sensible magnitude in calling upon men who have been actively engaged during a great portion of the year, at a season when they may fairly look for relaxation, to attend a busy meeting and to contribute to its proceedings; but unless a fair quota at least of our veterans and a good muster of our younger men put in their appearance, our gatherings will be to little purpose. There was a period within my own recollection when it was uncertain whether the then younger members of our scientific growth would cast in their lot with us or not, and when the fate of the Association depended very much upon their decision. They decided in our favour; they have since become presidents, lecturers, and other functionaries of our body, with what result it is for you to judge.

Of the advantages which may possibly accrue to the locality in which our meetings are held it is not for us to speak; but it is always a ground for sincere satisfaction to learn that our presence has been of any use in stimulating an interest or in promoting local efforts in the direction of science.

The functions of the British Association do not, however, terminate with the meeting itself. Besides the special committees already mentioned, there remains a very important body, elected by the general committee, viz., the Council, which assembles at the office in London from time to time as occasion requires. To this body belongs the duty of proposing a president, of preparing for the approval of the general committee the list of vice-presidents and sectional officers, the selection of evening lecturers, and other arrangements for the coming meeting.

At the present time another class of questions occupies a good deal of the attention of the Council. In the first generation of the Association, and during the period of unwritten, but not yet traditional, law, questions relating to our own organization or procedure either "settled themselves" or were wisely left to the discretionary powers of those who had taken part in our proceedings during the early years of our existence. These and other kindred subjects now require more careful formularization and more deliberate sanction. And it is on the shoulders of the council that the weight of these matters in general falls. These facts deserve especial mention on the present occasion, because one part of our business at the close of this meeting will be to bid farewell officially to one who has served us as assistant secretary so long and so assiduously that he has latterly become our main repertory of information and our mentor upon questions of precedent and procedure. The post hitherto held by Mr. Griffith (for it is to him that I allude) will doubtless be well filled

by the able and energetic member who has been nominated in his place; but I doubt not that even he will be glad for some time to come to draw largely upon the knowledge and experience of his predecessor.

But, beside matters of internal arrangement and organization, the duties of the council comprise a variety of scientific subjects referred to them by the general committee, at the instance of the committee of recommendations, for deliberation and occasionally for action. With the increasing activity of our body in general, and more particularly with that of our various officers, these duties have of late years become more varied and onerous than formerly; nor is it to be wished that they should diminish in either variety or extent.

Once more, questions beyond our own constitution, and even beyond the scope of our own immediate action, such as education, legislation affecting either the promotion or the applications of science to industrial and social life, which have suggested themselves at our meetings, and received the preliminary sanction of our committee of recommendations, are frequently referred to our council. These, and others which it is unnecessary to particularize, whether discussed in full council or in committees specially appointed by that body, render the duties of our councillors as onerous as they are important.

While the Government has at all times, but in a more marked manner of late years, recognized the Royal Society of London, with representatives from the sister societies of Dublin and of Edinburgh, as the body to which it should look for counsel and advice upon scientific questions, it has still never shown itself indisposed to receive and entertain any well-considered recommendation from the British Association. Two special causes have in all probability contributed largely to this result. First, the variety of elements comprised by the Association, on account of which its recommendations imply a more general concurrence of scientific opinion than those of any other scientific body; secondly, the peculiar fact that our period of maximum activity coincides with that of minimum activity of other scientific bodies is often of the highest importance. At the very time when the other bodies are least able we are most able to give deliberate consideration and formal sanction to recommendations, whether in the form of applications to Government or otherwise, which may arise. In many of these time is an element so essential that it is not too much to say that without the intervention of the British Association many opportunities for the advancement of science, especially at the seasons in question, might have been lost. The Government has, moreover, formally recognized our scientific existence by appointing our President for the time being a member of the Government Fund Committee; and the public has added its testimony to our importance and utility by imposing upon our President and officers a variety of duties, among which are conspicuous those which arise out of its very liberal exercise of civic and other hospitality.

Of the nature and functions of the Presidential address this is, perhaps, neither the time nor the place to speak; but, if I might for a moment forget the purpose for which we are now assembled, I would take the opportunity of reminding those who have not attended many of our former meetings that our annual volumes contain a long series of addresses on the progress of science from a number of our most eminent men, to which there is, perhaps, no parallel elsewhere. These addresses are, perhaps, as remarkable for their variety in mode of treatment as for the value of their subject-matter. Some of our Presidents, and especially those who officiated in the earlier days of our existence, have passed in review the various branches of science, and have noted the progress made in each during the current year. But, as the various sciences have demanded more and more special treatment on the part of those who seriously pursue them, so have the cases of individuals who can of their own knowledge give anything approaching to a general review become more and more rare. To this may be added the fact that although no year is so barren as to fail in affording sufficient crop for a strictly scientific budget, or for a detailed report of progress in research, yet one year is more fertile than another in growths of sufficient prominence to arrest the attention of the general public and to supply topics suitable for the address. On these accounts apparently such a Presidential survey has ceased to be annual, and has dropped into an intermittence of longer period. Some Presidents have made a scientific principle, such as the time-element in natural phenomena, or continuity, or natural selection, the theme of their discourse, and have gathered illustrations from various branches of knowledge. Others, again, taking their own special subject as a fundamental note, and thence modulating into other kindred keys, have borne testimony to the fact that no subject is so special as to be devoid of bearing or of influence on many others. Some have described the successive stages of even a single but important investigation; and while tracing the growth of that particular item and of the ideas involved in it, have incidentally shown to the outer world what manner of business a serious investigation is. But there is happily no pattern or precedent which the President is bound to follow; both in range of subject-matter and in mode of treatment each has exercised his undoubted right of taking an independent line. And it can hardly be doubted that a judicious exercise of this freedom has contributed more than anything else to sustain the interest of a series of annual discourses extending now over nearly half a century.

The nature of the subjects which may fairly come within the scope of such a discourse has of late been much discussed, and the question is one upon which every one, of course, is entitled to form his own judgment; but lest there should be any misapprehension as to how far it concerns us in our corporate capacity, it will be well to remind my hearers that as, on the one hand, there is no discussion on the Presidential address, and the members as a body express no formal opinion upon it, so, on the other, the Association cannot fairly be considered as in any way committed to its tenour or conclusions. Whether this immunity from comment and reply be really on the whole so advantageous to the President as might be supposed need not here be discussed; but suffice it to say that the case of an audience assembled to listen without discussion finds a parallel elsewhere, and in the parallel case it is not generally considered that the result is altogether either advantageous to the speaker or conducive to excellence in the discourse.

But, apart from this, the question of a limitation of range in the subject-matter for the Presidential address is not quite so simple as may at first sight appear. It must, in fact, be borne in mind that, while on the one hand knowledge is distinct from opinion, from feeling, and from all other modes of subjective impression, still the limits of knowledge are at all times expanding, and the boundaries of the known and the unknown are never rigid or permanently fixed. That which in time past or present has belonged to one category may in time future belong to the other. Our ignorance consists partly in ignorance of actual facts, and partly also in ignorance of the possible range of ascertainable fact. If we could lay down beforehand precise limits of possible knowledge, the problem of physical science would be already half solved, But the question to which the scientific explorer has often to address himself is not merely whether he is able to solve this or that problem, but whether he can so far unravel the tangled threads of the matter with which he has to deal as to weave them into a definite problem at all. He is not like a candidate at an examination with a precise set of questions placed before him; he must first himself act the part of the examiner and select questions from the repertory of nature, and upon them found others, which in some sense are capable of definite solution. If his eye seem dim, he must look steadfastly and with hope into the misty vision, until the very clouds wreath themselves into

definite forms. If his ear seem dull, he must listen patiently and with sympathetic trust to the intricate whisperings of nature—the goddess, as she has been called, of a hundred voices—until here and there he can pick out a few simple notes to which his own powers can resound. If, then, at a moment when he finds himself placed on a pinnacle from which he is called upon to take a perspective survey of the range of science, and to tell us what he can see from his vantage ground; if, at such a moment, after straining his gaze to the very verge of the horizon, and after describing the most distant of well-defined objects, he should give utterance also to some of the subjective impressions which he is conscious of receiving from regions beyond; if he should depict possibilities which seem opening to his view; if he should explain why he thinks this a mere blind alley and that an open path; then the fault and the loss would be alike ours if we refused to listen calmly, and temperately to form our own judgment on what we hear; then assuredly it is we who would be committing the error of confounding matters of fact and matters of opinion if we failed to discriminate between the various elements contained in such a discourse, and assumed that they had all been put on the same footing.

But to whatever decision we may each come on these controverted points, one thing appears clear from a retrospect of past experience, viz., that first or last, either at the outset in his choice of subject or in the conclusions ultimately drawn therefrom, the President, according to his own account at least, finds himself on every occasion in a position of "exceptional or more than usual difficulty." And your present representative, like his predecessors, feels himself this moment in a similar predicament. The reason which he now offers is that the branch of science which he represents is one whose lines of advance, viewed from a mathematician's own point of view, offer so few points of contact with the ordinary experiences of life or modes of thought, that any account of its actual progress which he might have attempted must have failed in the first requisite of an address, namely, that of being intelligible.

Now, if this esoteric view had been the only aspect of the subject which he could present to his hearers, he might well have given up the attempt in despair. But although in its technical character mathematical science suffers the inconveniences, while it enjoys the dignity of its Olympian position, still in a less formal garb, or in disguise, if you are pleased so to call it, it is found present at many an unexpected turn; and although some of us may never have learnt its special language, not a few have, all through our scientific life, and even in almost every accurate utterance, like Molière's well-known character, been talking mathematics without knowing it. It is, moreover, a fact not to be overlooked that the appearance of isolation, so conspicuous in mathematics, appertains in a greater or less degree to all other sciences, and perhaps also to all pursuits in life. In its highest flight each soars to a distance from its fellows. Each is pursued alone for its own sake, and without reference to its connection with, or its application to, any other subject. The pioneer and the advanced guard are of necessity separated from the main body, and in this respect mathematics does not materially differ from its neighbours. And, therefore, as the solitariness of mathematics has been a frequent theme of discourse, it may be not altogether unprofitable to dwell for a short time upon the other side of the question, and to inquire whether there be not points of contact in method or in subject-matter between mathematics and the outer world which have been frequently overlooked; whether its lines do not in some cases run parallel to those of other occupations and purposes of life; and lastly, whether we may not hope for some change in the attitude too often assumed towards it by the representatives of other branches of knowledge and of mental activity.

In his preface to the 'Principia' Newton gives expression to some general ideas which may well serve as the keynote for all future utterances on the relation of mathematics to natural, including also therein what are commonly called artificial, phenomena.

"The ancients divided mechanics into two parts—rational and practical; and since artisans often work inaccurately, it came to pass that mechanics and geometry were distinguished in this way—that everything accurate was referred to geometry, and everything inaccurate to mechanics. But the inaccuracies appertain to the artisan and not to the art, and geometry itself has its foundation in mechanical practice, and is, in fact, nothing else than that part of universal mechanics which accurately lays down and demonstrates the art of measuring." He next explains that rational mechanics is the science of motion resulting from forces, and adds, "The whole difficulty of philosophy seems to me to lie in investigating the forces of nature from the phenomena of motion, and in demonstrating that from these forces other phenomena will ensue." Then, after stating the problems of which he has treated in the work itself, he says, "I would that all other natural phenomena might similarly be deduced from mechanical principles. For many things move me to suspect that everything depends upon certain forces in virtue of which the particles of bodies, through forces not yet understood, are either impelled together so as to cohere in regular figures, or are repelled and recede from one another."

Newton's views, then, are clear. He regards mathematics, not as a method independent of, though applicable to, various subjects, but as itself the higher side or aspect of the subjects themselves; and it would be little more than a translation of his notions into other language, little more than a paraphrase of his own words, if we were to describe the mathematical as one aspect of the material world itself, apart from which all other aspects are but incomplete sketches, and, however accurate after their own kind, are still liable to the imperfections of the inaccurate artificer. Mr. Burrowes, in his preface to the first volume of the 'Transactions of the Royal Irish Academy,' has carried out the same argument, approaching it from the other side. "No one science," he says, "is so little connected with the rest as not to afford many principles whose use may extend considerably beyond the science to which they primarily belong, and no proposition is so purely theoretical as to be incapable of being applied to practical purposes. There is no apparent connection between duration and the cycloidal arch, the properties of which have furnished us with the best method of measuring time; and he who has made himself master of the nature and affections of the logarithmic curve has advanced considerably towards ascertaining the proportionable density of the air at various distances from the earth. The researches of the mathematician are the only sure ground on which we can reason from experiments; and how far experimental science may assist commercial interests is evinced by the success of manufactures in countries where the hand of the artificer has taken its direction from the philosopher. Every manufacture is in reality but a chemical process, and the machinery requisite for carrying it on but the right application of certain propositions in rational mechanics." So far your academician. Every subject, therefore, whether in its usual acceptation, scientific or otherwise, may have a mathematical aspect; as soon, in fact, as it becomes a matter of strict measurement, or of numerical statement, so soon does it enter upon a mathematical phase. This phase may, or it may not, be a prelude to another in which the laws of the subject are expressed in algebraical formulæ or represented by geometrical figures. But the real gist of the business does not always lie in the mode of expression, and the fascination of the formulæ or other mathematical paraphernalia may after all be little more than that of a theatrical transformation scene. The process of reducing to formulæ is really one of abstraction, the results of which are not always wholly on the side of gain; in fact, through the process itself the subject may

lose in one respect even more than it gains in another. But long before such abstraction is completely attained, and even in cases where it is never attained at all, a subject may to all intents and purposes become mathematical. It is not so much elaborate calculations or abstruse processes which characterize this phase as the principles of precision, of exactness, and of proportion. But these are principles with which no true knowledge can entirely dispense. If it be the general scientific spirit which at the outset moves upon the face of the waters, and out of the unknown depth brings forth light and living forms, it is no less the mathematical spirit which breathes the breath of life into what would otherwise have ever remained mere dry bones of fact, which reunites the scattered limbs and re-creates from them a new and organic whole. And as a matter of fact, in the words used by Professor Jellett at our meeting at Belfast, viz., "Not only are we applying our methods to many sciences already recognized as belonging to the legitimate province of mathematics, but we are learning to apply the same instrument to sciences hitherto wholly or partially independent of its authority. Physical science is learning more and more every day to see in the phenomena of nature, modifications of that one phenomenon (namely, motion), which is peculiarly under the power of mathematics." Echoes are these, far off and faint perhaps, but still true echoes, in answer to Newton's wish that all these phenomena may some day "be deduced from mechanical principles."

If, turning from this aspect of the subject, it were my purpose to enumerate how the same tendency has evinced itself in the arts, unconsciously it may be to the artists themselves, I might call as witnesses each one in turn with full reliance on the testimony which they would bear. And, having more special reference to mathematics, I might confidently point to the accuracy of measurement, to the truth of curve, which, according to modern investigation, is the key to the perfection of classic art. I might triumphantly cite not only the architects of all ages, whose art so manifestly rests upon mathematical principles; but I might cite also the literary as well as the artistic remains of the great artists of Cinquecento, both painters and sculptors, in evidence of the geometry and the mechanics which having been laid at the foundation, appear to have found their way upwards through the superstructure of their works. And in a less ambitious sphere, but nearer to ourselves in both time and place, I might point with satisfaction to the great school of English constructors of the eighteenth century in the domestic arts, and remind you that not only the engineer and the architect, but even the cabinet makers devoted half the space of their books to perspective and to the principles whereby solid figures may be delineated on paper, or what is now termed descriptive geometry.

Nor, perhaps, would the sciences which concern themselves with reasoning and speech, nor the kindred art of music, nor even literature itself, if thoroughly probed, offer fewer points of dependence upon the science of which I am speaking. What, in fact, is logic but that part of universal reasoning; grammar but that part of universal speech; harmony and counterpoint but that part of universal music, "which accurately lays down," and demonstrates (so far as demonstration is possible) precise methods appertaining to each of these arts? And I might even appeal to the common consent which speaks of the mathematical as the pattern form of reasoning and model of a precise style.

Taking, then, precision and exactness as the characteristics which distinguish the mathematical phase of a subject, we are naturally led to expect that the approach to such a phase will be indicated by increasing application of the principle of measurement, and by the importance which is attached to numerical results. And this very necessary condition for progress may, I think, be fairly described as one of the main features of scientific advance in the present day.

If it were my purpose, by descending into the arena of special sciences, to show how the most various investigations alike tend to issue in measurement, and to that extent to assume a mathematical phrase, I should be embarrassed by the abundance of instances which might be adduced. I will, therefore, confine myself to a passing notice of a very few, selecting those which exemplify not only the general tendency, but also the special character of the measurements now particularly required, viz., that of minuteness, and the indirect method by which alone we can at present hope to approach them. An object having a diameter of an 80,000th of an inch is, perhaps, the smallest of which the microscope could give any well-defined representation; and it is improbable that one of 120,000th of an inch could be singly discerned with the highest powers at our command. But the solar beams and the electric light reveal to us the presence of bodies far smaller than these. And, in the absence of any means of observing them singly, Professor Tyndall has suggested a scale of these minute objects in terms of the lengths of luminiferous waves. To this he was led, not by any attempt at individual measurement, but by taking account of them in the aggregate, and observing the tints which they scatter laterally when clustered in the form of actinic clouds. These small bodies with which experimental science has recently come into contact are not confined to gaseous molecules, but comprise also complete organisms; and the same philosopher has made a profound study of the momentous influence exerted by these minute organisms in the economy of life. And if, in view of their specific effects, whether deleterious or other, on human life, any qualitative classification, or quantitative estimate be ever possible, it seems that it must be effected by some such method as that indicated above.

Again, to enumerate a few more instances of the measurement of minute quantities, there are the average distances of molecules from one another in various gases and at various pressures, the length of their free path or range open for their motion without coming into collision; there are movements causing the pressures and differences of pressure under which Mr. Crookes's radiometers execute their wonderful revolutions; there are the excursions of the air while transmitting notes of high pitch, which through the researches of Lord Rayleigh appear to be of a diminutiveness altogether unexpected; there are the molecular actions brought into play in the remarkable experiments by Dr. Kerr, who has succeeded, where even Faraday failed, in effecting a visible rotation of the plane of polarization of light in its passage through electrified dielectrics and on its reflection at the surface of a magnet. To take one more instance, which must be present to the minds of us all, there are the infinitesimal ripples of the vibrating plate in Mr. Graham Bell's most marvellous invention. Of the nodes and ventral segments in the plate of the telephone which actually converts sound into electricity and electricity into sound we can at present form no conception. All that can now be said is that the most perfect specimens of Chladni's sand figures on a vibrating plate, or of Kundt's lycopodium heaps in a musical tube, or even Mr. Sedley Taylor's more delicate vortices in the films of the phoneidoscope, are rough and sketchy compared with these. For, notwithstanding the fact that in the movements of the telephone plate we have actually in our hand the solution of that old world problem, the construction of a speaking machine, yet the characters in which that solution is expressed are too small for our powers of decipherment. In movements such as these we seem to lose sight of the distinction, or, perhaps we have unconsciously passed the boundary between massive and molecular motion.

Through the phonograph we have not only a transformation, but a permanent and tangible record of the mechanism of speech. But the differences upon which articulation (apart from loudness, pitch, and quality),

depends appear from the experiments of Fleeming Jenkin and of others to be of microscopic size. The microphone affords another instance of the unexpected value of minute variations, in this case of electric currents; and it is remarkable that the gist of the instrument seems to lie in obtaining and perfecting that which electricians have hitherto most scrupulously avoided, viz., loose contact.

Once more, Mr. De La Rue has brought forward, as one of the results derived from his stupendous battery of 10,000 cells, strong evidence for supposing that a voltaic discharge, even when apparently continuous, may still be an intermittent phenomenon; but all that is known of the period of such intermittence is that it must recur at exceedingly short intervals. And in connection with this subject, it may be added that, whatever be the ultimate explanation of the strange stratification which the voltaic discharge undergoes in rarefied gases, it is clear that the alternate disposition of light and darkness must be dependent on some periodic distribution in space or sequence in time which can at present be dealt with only in a very general way. In the exhausted column we have a vehicle for electricity not constant like an ordinary conductor, but itself modified by the passage of the discharge, and perhaps subject to laws differing materially from those which it obeys at atmospheric pressure. It may also be that some of the features accompanying stratification form a magnified image of phenomena belonging to disruptive discharges in general; and that, consequently, so far from expecting among the known facts of the latter any clue to an explanation of the former, we must hope ultimately to find in the former an elucidation of what is at present obscure in the latter. A prudent philosopher usually avoids hazarding any forecast of the practical application of a purely scientific research. But it would seem that the configuration of these striæ might some day prove a very delicate means of estimating low pressures, and perhaps also for effecting some electrical measurements.

Now, it is a curious fact that almost the only small quantities of which we have as yet any actual measurements are the wave lengths of light; and that all others, excepting so far as they can be deduced from these, await future determination. In the meantime, when unable to approach these small quantities individually, the method to which we are obliged to have recourse is, as indicated above, that of averages, whereby, disregarding the circumstances of each particular case, we calculate the average size, the average velocity, the average direction, etc., of a large number of instances. But although this method is based upon experience and leads to results which may be accepted as substantially true; although it may be applicable to any finite interval of time or over any finite area of space (that is, for all practical purposes of life) there is no evidence to show that it is so when the dimensions of interval or of area are indefinitely diminished. The truth is that the simplicity of nature which we at present grasp is really the result of infinite complexity; and that below the uniformity there underlies a diversity whose depths we have not yet probed, and whose secret places are still beyond our reach.

The present is not an occasion for multiplying illustrations, but I can hardly omit a passing allusion to one all-important instance of the application of the statistical method. Without its aid social life, or the history of life and death, could not be conceived at all, or only in the most superficial manner. Without it we could never attain to any clear ideas of the condition of the poor, we could never hope for any solid amelioration of their condition or prospects. Without its aid, sanitary measures, and even medicine, would be powerless. Without it, the politician and the philanthropist would alike be wandering over a trackless desert.

It is, however, not so much from the side of science at large as from that of mathematics itself that I desire to speak. I wish from the latter point of view to indicate connections between mathematics and other subjects, to prove that hers is not, after all, such a far-off region, nor so undecipherable an alphabet, and to show that even at unlikely spots we may trace under-currents of thought which having issued from a common source fertilize alike the mathematical and the non-mathematical world.

Having this in view, I propose to make the subject of special remark some processes peculiar to modern mathematics; and, partly with the object of incidentaly removing some current misapprehensions, I have selected for examination three methods, in respect of which mathematicians are often thought to have exceeded all reasonable limits of speculation, and to have adopted for unknown purposes an unknown tongue. And it will be my endeavour to show not only that in these very cases our science has not outstepped its own legitimate range, but that even art and literature have unconsciously employed methods similar in principle. The three methods in question are—first, that of imaginary quantities; secondly, that of manifold space; and thirdly, that of geometry not according to Euclid.

First, it is objected that abandoning the more cautious methods of ancient mathematicians, we have admitted into our formulæ quantities which by our own showing, and even in our own nomenclature, are imaginary or impossible; nay, more, that out of them we have formed a variety of new algebras to which there is no counterpart whatever in reality; but from which we claim to arrive at possible and certain results.

On this head it is in Dublin, if anywhere, that I may be permitted to speak. For to the fertile imagination of the late Astronomer Royal for Ireland we are indebted for that marvellous calculus of quaternions, which is only now beginning to be fully understood, and which has not yet received all the applications of which it is doubtless capable. And even although this calculus be not co-extensive with another which almost simultaneously germinated on the Continent, nor with ideas more recently developed in America, yet it must always hold its position as an original discovery and as a representative of one of the two great groups of generalized algebras (viz., those the squares of whose units are respectively negative unity and zero), the common origin of which must still be marked on our intellectual map as an unknown region. Well do I recollect how in its early days we used to handle the method as a magician's page might try to wield his master's wand, trembling as it were between hope and fear, and hardly knowing whether to trust our own results until they had been submitted to the present and ever ready counsel of Sir W. R. Hamilton himself.

To fix our ideas, consider the measurement of a line, or the reckoning of time, or the performance of any mathematical operation. A line may be measured in one direction or in the opposite; time may be reckoned forward or backward; an operation may be performed or be reversed; it may be done or may be undone; and if having once reversed any of these processes we reverse it a second time, we shall find that we have come back to the original direction of measurement or of reckoning, or to the original kind of operation.

Suppose, however, that at some stage of a calculation our formulæ indicate an alteration in the mode of measurement such that, if the alteration be repeated, a condition of things, not the same as, but the reverse of the original, will be produced. Or suppose that, at a certain stage, our transformations indicate that time is to be reckoned in some manner different from future or past, but still in a way having definite algebraical connection with time which is gone and time which is to come. It is clear that in actual experience there is no process to which such measurements correspond. Time has no meaning except as future or past, and the present is but the meeting point of the two. Or, once more, suppose that we are gravely told that all circles pass through the same two imaginary points at an infinite distance, and that every line drawn through one of these

points is perpendicular to itself. On hearing the statement we shall probably whisper, with a smile or a sigh, that we hope it is not true; but that in any case it is a long way off, and perhaps, after all, it does not very much signify. If, however, as mathematicians we are not satisfied to dismiss the question on these terms, we ourselves must admit that we have here reached a definite point of issue. Our science must either give a rational account of the dilemma or yield the position as no longer tenable.

Special modes of explaining this anomalous state of things have occurred to mathematicians. But, omitting details as unsuited to the present occasion, it will, I think, be sufficient to point out in general terms that a solution of the difficulty is to be found in the fact that the formulæ which give rise to these results are more comprehensive than the signification assigned to them, and when we pass out of the condition of things first contemplated they cannot (as it is obvious they ought not) give us any results intelligible on that basis. But it does not, therefore, by any means follow that upon a more enlarged basis the formulæ are incapable of interpretation; on the contrary, the difficulty at which we have arrived indicates that there must be some more comprehensive statement of the problem which will include cases impossible in the more limited but possible in the wider view of the subject.

A very simple instance will illustrate the matter. If from a point outside a circle we draw a straight line to touch the curve, the distance between the starting point and the point of contact has certain geometrical properties. If the starting point be shifted nearer and nearer to the circle, the distance in question becomes shorter and ultimately vanishes. But as soon as the point passes to the interior of the circle the notion of a tangent and distance to the point of contact cease to have any meaning; and the same anomalous condition of things prevails as long as the point remains in the interior. But if the point be shifted still further until it emerges on the other side, the tangent and its properties resume their reality, and are as intelligible as before. Now the process whereby we have passed from the possible to the impossible and again repassed to the possible (namely, the shifting of the starting point) is a perfectly continuous one, while the conditions of the problem as stated above have abruptly changed. If, however, we replace the idea of a line touching by that of a line cutting the circle, and the distance of the point of contact by the distances at which the line is intercepted by the curve, it will easily be seen that the latter includes the former as a limiting case, when the cutting line is turned about the starting point until it coincides with the tangent itself; and further, that the two intercepts have a perfectly distinct and intelligible meaning whether the point be outside or inside the area. The only difference is that in the first case the intercepts are measured in the same direction; in the latter in opposite directions. The foregoing instance has shown one purpose which these imaginaries may serve—viz., as marks indicating a limit to a particular condition of things, to the application of a particular law, or pointing out a stage where a more comprehensive law is required. To attain to such a law we must, as in the instance of the circle and tangent, reconsider our statement of the problem; we must go back to the principle from which we set out, and ascertain whether it may not be modified or enlarged. And even if in any particular investigation wherein imaginaries have occurred the most comprehensive statement of the problem of which we are at present capable fails to give an actual representation of these quantities; if they must for the present be relegated to the category of imaginaries, it still does not follow that we may not at some future time find a law which will endow them with reality, nor that in the meantime we need hesitate to employ them, in accordance with the great principle of continuity, for bringing out correct results. If, moreover, both in geometry and in algebra we occasionally make use of points or of quantities, which from our present outlook have no real existence, which can neither be delineated in space of which we have experience nor measured by scale as we count measurement; if these imaginaries, as they are termed, are called up by legitimate processes of our science; if they serve the purpose, not merely of suggesting ideas, but of actually conducting us to practical conclusions; if all this be true in abstract science, I may perhaps be allowed to point out, in illustration of my argument, that in art unreal forms are frequently used for suggesting ideas, for conveying a meaning for which no others seem to be suitable or adequate. Are not forms unknown to biology, situations incompatible with gravitation, positions which challenge not merely the stability but even the possibility of equilibrium—are not these the very means to which the artist often has recourse in order to convey his meaning and to fulfil his mission? Who that has ever revelled in the ornamentation of the Renaissance, in the extraordinary transitions from the animal to the vegetable, from faunic to floral forms, and from these again to almost purely geometric curves—who has not felt that these imaginaries have a claim to recognition very similar to that of their congeners in mathematics? How is it that the grotesque paintings of the middle ages, the fantastic sculpture of remote nations, and even the rude art of the prehistoric past, still impress us, and have an interest over and above their antiquarian value, unless it be that they are symbols which, although hard of interpretation when taken alone, are yet capable, from a more comprehensive point of view, of leading us mentally to something beyond themselves, and to truths which, although reached through them, have a reality scarcely to be attributed to their outward forms? Again, if we turn from art to letters, truth to nature and to fact is undoubtedly a characteristic of sterling literature; and yet in the delineation of outward nature itself, still more in that of feelings and affections, of the secret parts of character and motives of conduct, it frequently happens that the writer is driven to imagery, to an analogy, or even to a paradox, in order to give utterance to that of which there is no direct counterpart in recognized speech. And yet which of us cannot find a meaning for these literary figures, an inward response to imaginative poetry, to social fiction, or even to those tales of giant and fairyland written, it is supposed, only for the nursery or schoolroom? But in order thus to re-animate these things with a meaning beyond that of the mere words, have we not to reconsider our first position, to enlarge the ideas with which we started; have we not to cast about for some thing which is common to the idea conveyed and to the subject actually described, and to seek for the sympathetic spring which underlies both; have we not, like the mathematician, to go back as it were to some first principles, or, as it is pleasanter to describe it, to become again as a little child?

Passing to the second of the three methods, viz., that of manifold space, it may first be remarked that our whole experience of space is in three dimensions, viz., of that which has length, breadth, and thickness; and if for certain purposes we restrict our ideas to two dimensions as in plane geometry, or to one dimension as in the division of a straight line, we do this only by consciously and of deliberate purpose setting aside, but not annihilating, the remaining one or two dimensions. Negation, as Hegel has justly remarked, implies that which is negatived, or, as he expresses it, affirms the opposite. It is by abstraction from previous experience, by a limitation of its results, and not by any independent process, that we arrive at the idea of space whose dimensions are less than three. It is doubtless on this account that problems in plane geometry, which although capable of solution on their own account, become much more intelligible, more easy of extension, if viewed in connection with solid space, and as special cases of corresponding problems in solid geometry. So eminently is this the case, that the very language of the more general method often leads us

almost intuitively to conclusions which, from the more restricted point of view, require long and laborious proof. Such a change in the base of operations has, in fact, been successfully made in geometry of two dimensions, and although we have not the same experimental data for the further steps, yet neither the modes of reasoning nor the validity of its conclusions are in any way affected by applying an analogous mental process to geometry of three dimensions; and by regarding figures in space of three dimensions as sections of figures in space of four, in the same way that figures in plano are sometimes considered as sections of figures in solid space. The addition of a fourth dimension to space not only extends the actual properties of geometrical figures, but it also adds new properties which are often useful for the purposes of transformation or of proof. Thus it has recently been shown that in four dimensions a closed material shell could be turned inside out by simple flexure, without either stretching or tearing; and that in such a space it is impossible to tie a knot.

Again, the solution of problems in geometry is often effected by means of algebra; and as three measurements, or co-ordinates as they are called, determine the position of a point in space, so do three letters or measureable quantities serve for the same purpose in the language of algebra. Now many algebraical problems involving three unknown or variable quantities admit of being generalized so as to give problems involving many such quantities. And as, on the one hand, to every algebraical problem involving unknown quantities or variables by ones or by twos, or by threes, there corresponds a problem in geometry of one or of two or of three dimensions; so on the other it may be said that to every algebraical problem involving many variables there corresponds a problem in geometry of many dimensions.

There is, however, another aspect under which even ordinary space presents to us a four-fold, or indeed a manifold character. In modern physics, space is regarded not as a vacuum in which bodies are placed and forces have play, but rather as a plenum with which matter is co-extensive. And, from a physical point of view, the properties of space are the properties of matter or of the medium which fills it. Similarly, from a mathematical point of view, space may be regarded as a *locus in quo*, as a plenum filled with those elements of geometrical magnitude which we take as fundamental. These elements need not always be the same. For different purposes different elements may be chosen, and upon the degree of complexity of the subject of our choice will depend the internal structure or manifoldness of space. Thus, beginning with the simplest case, a point may have any singly infinite multitude of positions in a line, which gives a one-fold system of points in a line. The line may revolve in a plane about any one of its points, giving a two-fold system of points in plane; and the plane may revolve about any one of the lines, giving a three-fold system of points in space. Suppose, however, that we take a straight line as our element, and conceive space as filled with such lines. This will be the case if we take two planes, *e.g.*, two parallel planes, and join every point in one with every point in the other. Now, the points in a plane form a two-fold system; and it therefore follows that the system of lines is four-fold; in other words, space regarded as a plenum of lines is four-fold. The same result follows from the consideration that the lines in a plane, and the planes through a point, are each two-fold.

Again, if we take a sphere as our element we can through any point as a centre draw a singly infinite number of spheres, but the number of such centres is triply infinite; hence space as a plenum of spheres is four-fold. And, generally, space as a plenum of surfaces has a manifoldness equal to the number of constants required to determine the surface.

Although it would be beyond our present purpose to attempt to pursue the subject further, it should not pass unnoticed that the identity in the four-fold character of space, as derived on the one hand from a system of straight lines, and on the other from a system of spheres, is intimately connected with the principles established by Sophus Lie in his researches on the correlation of these figures.

If we take a circle as our element, we can around any point in a plane as a centre draw a singly infinite system of circles; but the number of such centres in a plane is doubly infinite; hence the circles in a plane form a three-fold system, and as the planes in space form a three-fold system, it follows that space as a plenum of circles is six-fold.

Again, if we take a circle as our element, we may regard it as a section either of a sphere or of a right cone (given except in position) by a plane perpendicular to the axis. In the former case the position of the centre is three-fold; the directions of the plane, like that of a pencil of lines perpendicular thereto, two-fold; and the radius of the sphere one-fold: six-fold in all. In the latter case, the position of the vertex is three-fold; the direction of the axis two-fold; and the distance of the plane of section one-fold: six-fold in all, as before. Hence space as a plenum of circles is six-fold.

Similarly, if we take a conic as our element we may regard it as a section of a right cone (given except in position) by a plane. If the nature of the conic be defined, the plane of section will be inclined at a fixed angle to the axis, otherwise it will be free to take any inclination whatever. This being so, the position of the vertex will be three-fold, the direction of the axis two-fold, the distance of the plane of section from the vertex one-fold, and the direction of that plane one-fold if the conic be defined, two-fold if it be not defined. Hence, space as a plenum of definite conics will be seven-fold, as a plenum of conics in general eight-fold. And so on for curves of higher degrees. This is, in fact, the whole story and mystery of manifold space. It is not seriously regarded as a reality in the same sense as ordinary space; it is a mode of representation, or a method which, having served its purpose, vanishes from the scene. Like a rainbow, if we try to grasp it, it eludes our very touch; but, like a rainbow, it arises out of real conditions of known and tangible quantities, and if rightly apprehended it is a true and valuable expression of natural laws, and serves a definite purpose in the science of which it forms part.

Again, if we seek a counterpart of this in common life, I might remind you that perspective in drawing is itself a method not altogether dissimilar to that of which I have been speaking; and that the third dimension of space, as represented in a picture, has its origin in the painter's mind, and is due to his skill, but has no real existence upon the canvass which is the groundwork of his art. Or again, turning to literature, when in legendary tales, or in works of fiction, things past and future are pictured as present, has not the poetic fancy correlated time with the three dimensions of space, and brought all alike to a common focus? Or, once more, when space already filled with material substances is mentally peopled with immaterial beings, may not the imagination be regarded as having added a new element to the capacity of space, a fourth dimension of which there is no evidence in experimental fact?

The third method proposed for special remark is that which has been termed non-Euclidean geometry; and the train of reasoning which has led to it may be described in general terms as follows:—Some of the properties of space which on account of their simplicity, theoretical as well as practical, have, in constructing the ordinary system of geometry, been considered as fundamental, are now seen to be particular cases of more general properties. Thus a plane surface and a straight line may be regarded as special instances of surfaces and lines whose curvature is everywhere uniform or constant. And it is perhaps not difficult to see that, when the special notions of flatness

and straightness are abandoned, many properties of geometrical figures which we are in the habit of regarding as fundamental will undergo profound modification. Thus a plane may be considered as a special case of sphere—viz., the limit to which a sphere approaches when its radius is increased without limit. But even this consideration trenches upon an elementary proposition relating to one of the simplest of geometrical figures. In plane triangles the interior angles are together equal to two right angles; but in triangles traced on the surface of a sphere this proposition does not hold good. To this other instances might be added.

Further, these modifications may affect not only our ideas of particular geometrical figures, but the very axioms of the science itself. Thus, the idea, which in fact lies at the foundation of Euclid's method—viz., that a geometrical figure may be moved in space without change of size or alteration of form, entirely falls away, or becomes only approximate in a space wherein dimension and form are dependent upon position. For instance, if we consider merely the case of figures traced on a flattened globe like the earth's surface, or upon an eggshell, such figures cannot be made to slide upon the surface without change of form, as is the case with figures traced upon a plane or even upon a sphere. But, further still, these generalizations are not restricted to the case of figures traced upon a surface; they may apply also to solid figures in a space whose very configuration varies from point to point. We may, for instance, imagine a space in which our rule or scale of measurement varies as it extends or as it moves about in one direction or another; a space, in fact, whose geometric density is not uniformly distributed. Thus we might picture to ourselves such a space as a field having a more or less complicated distribution of temperature, and our scale as a rod instantaneously susceptible of expansion or contraction under the influence of heat; or we might suppose space to be even crystalline in its geometric formation, and our scale and measuring instruments to accept the structure of the locality in which they are applied. These ideas are doubtless difficult of apprehension—at all events at the outset; but Helmholtz has pointed out a very familiar phenomenon which may be regarded as a diagram of such a kind of space. The picture formed by reflection from a plane mirror may be taken as a correct representation of ordinary space, in which, subject to the usual laws of perspective, every object appears in the same form and of the same dimensions whatever be its position. In like manner the picture formed by reflection from a curved mirror may be regarded as the representation of a space wherein dimension and form are dependent upon position. Thus in an ordinary convex mirror, objects appear smaller as they recede laterally from the centre of the picture; straight lines become curved; objects infinitely distant in front of the mirror appear at a distance only equal to the focal length behind. And by suitable modifications in the curvature of the mirror, representations could similarly be obtained of space of various configurations.

The diversity in kind of these spaces is of course infinite; they vary with the mode in which we generalize our conceptions of ordinary space, but upon each as a basis it is possible to construct a consistent system of geometry, whose laws, as a matter of strict reasoning, have a validity and truth not inferior to those with which we are habitually familiar. Such systems having been actually constructed, the question has not unnaturally been asked, whether there is anything in nature or in the outer world to which they correspond; whether, admitting that for our limited experience ordinary geometry amply suffices, we may understand that for powers more extensive in range or more minute in definition some more general scheme would be requisite? Thus, for example, although the one may serve for the solar system, is it legitimate to suppose that it may fail to apply at distances reaching to the fixed stars, or to regions beyond? Or again, if our vision could discern the minute configuration of portions of space, which to our ordinary powers appear infinitesimally small, should we expect to find that all our usual geometry is but a special case, sufficient indeed for daily use, but after all only a rough approximation to a truer, although perhaps more complicated scheme? Traces of these questions are, in fact, to be found in the writings of some of our greatest and most original mathematicians. Gauss, Riemann, and Helmholtz have thrown out suggestions radiating as it were in these directions from a common centre; while Cayley, Sylvester, and Clifford in this country, Klein in Germany, Lobatcheffsky in Russia, Bolyai in Hungary, and Beltrami in Italy, with many others, have reflected kindred ideas with all the modifications due to the chromatic dispersion of their individual minds. But to the main question the answer must be in the negative. And, to use the words of Newton, since "Geometry has its foundation in mechanical practice," the same must be the answer until our experience is different from what it now is. And yet, all this notwithstanding, generalized conceptions of space are not without their practical utility. The principle of representing space of one kind by that of another, and figures belonging to one by their analogues in the other, is not only recognized as legitimate in pure mathematics, but has long ago found its application in cartography. In maps or charts, geographical positions, the contour of coasts, and other features belonging in reality to the earth's surface are represented on the flat; and to each mode of representation, or projection, as it is called, there corresponds a special correlation between the spheroid and the plane. To this might perhaps be added the method of descriptive geometry, and all similar processes in use by engineers, both military and civil.

(*To be concluded.*)

Obituary.

JOHN USHER TAYLOR.

We regret to announce the death, on the 28th ult., of Mr. Taylor, Pharmaceutical Chemist, High St., Bedford.

Mr. John Usher Taylor was born at Potton, April 18, 1824, and was the son of an old naval officer, but very early in life was left an orphan. After the usual school curriculum for a business life, he was at fourteen apprenticed to Mr. Dudley, a chemist at Leicester. His master dying in 1841, he entered the establishment of Mr. Charles F. Palgrave, of Bedford. Here he remained till 1848, when he went to St. Ives and opened new premises in the same line of business. He soon gained confidence and established a large and respectable connection, whilst his activity in many public matters is still in remembrance there. In 1858 an opportunity offering to return to the old premises in Bedford, he, with Mr. Henry Stewardson, carried on business as the firm of Stewardson and Taylor till 1866. Mr. Stewardson then retired and Mr. Cuthbert joined Mr. Taylor. In the summer of that year Mr. Taylor had a serious illness, accompanied by much mental depression, by which he was laid aside for nearly two years. From this he fully recovered, but last winter symptoms of a similar nature again appeared, causing much anxiety to his friends, though not without hope of restoration until within a few hours of his decease.

Mr. Taylor was thirty-seven years associated with the Pharmaceutical Society. Bedford seemed the town of his adoption, and he always showed the strongest concern for its prosperity. He declined municipal duties until 1874, when he was elected for the East Ward. At the end of his term, last November, he was unanimously chosen to fill the important and responsible office of mayor.

Notice has also been received of the death of the following:—

On the 18th of July, 1878, Mr. Thomas James, Chemist and Druggist, Brookend, Woolastone, Gloucestershire. Aged 81 years.

Analysis of Barks brought by Mr. Cross.

Letter from John Eliot Howard, F.R.S.

Sir,—I enclose a careful analysis of the barks recently brought home by Mr. Robert Cross, which has been repeated with like result in the more important trials.

The bark of the Calisaya of Santa Fé was taken "from the shoots, half an inch in diameter, cut away from the plants brought home." "Some of the rods peeled were mere switches." This species "grows in a cool climate like the Pitayo and Loxa Crown."

It seems to me likely to prove of great importance in India; whither I am told two Wardian cases are to be despatched, one to Darjeeling, and the other to the Nilghiris. I hope that they will not be sent too soon: a certain number of the plants are looking healthy, but they were "carried by land for a greater distance than any other description of plants yet brought to Europe, and this too through an unhealthy region, recently devastated by revolution." Under these circumstances I think great credit is due to Mr. Cross for having preserved them at all, and it would be a great pity if they perished (as did the plants brought to India by Mr. Markham), through the results of the hot transit to India. This they certainly would do if sent before winter.

The No. 5, Coralis Inza variety, "grows in a warmish climate, ascending, however, to the cool forests. The tree shoots up rapidly, and is of robust growth. It may be expected to grow in all the cinchona districts of India." To which information, quoted from Mr. Cross, I would add that if it improves as much by cultivation as the *C. officinalis* has done, it will be an acquisition of great importance to the cultivators of cinchona.

The other barks brought home are well known to me, and of no importance. No. 3 is a *Cosmibucna*. Your readers will find further information (not all accurate) respecting these in the pages of the *Gardeners' Chronicle*, March 23. I will take care that the museum of the Pharmaceutical Society is supplied with specimens of the barks.

John Eliot Howard.

(Copy.)

"*Analysis of Cinchona Bark from Columbia.*

"Lord's Meade, Tottenham,

"April 23rd, 1878.

"Sir,

"I beg to transmit, for the information of Her Majesty's Secretary of State for India, an elaborate analysis of the barks brought home by Mr. Cross.

"It will be seen that he has been eminently successful in the chief object of his mission, that of obtaining the Calisaya of Santa Fé; a success which will be complete if the young plants can be safely conveyed to India and established there, when it may, not improbably, prove *second to none*. I am afraid that he was unable to bring seeds. I have explained the advantage to be looked for from this sort in my letter of the 27th June, 1877, and I have only to add that the bark brought by Mr. Cross is of the very best description, and such as indicates the probability of a much larger production of alkaloid in the bark of more mature and developed trees than those from which he has taken the specimen now examined.

"Apart from this, the only kind worthy of cultivation is the No. 5, marked 'Coralis Inza.' This, if a free grower, as I think would be the case, might be well worth naturalizing in India. The bark has met with a ready sale in commerce.

"I subjoin the details of the analysis, and send herewith the botanical description of the species, which is known as the *Cinchona lancifolia Calisaya* (Wedd.).

"I am, etc.,

(Signed) "John Eliot Howard.

"The Under Secretary of State
for India.

"Description of Barks, of which the Analyses are given below.

"A. No. 1. 'Calisaya of Santa Fé.'—Best soft Columbian. Collected October, 1877. Caqueta River; elevation, 7,800 feet. This bark was actually taken from the rejected cane-like shoots cut from the plants brought home.

"B. No. 1. 'Hard Carthagena.'—Paniquita variety, Popayan. Collected October 23, 1877; elevation, 5000 feet, valley of the Cauca.

"No. 2. 'Hard Carthagena.'—Paniquita variety. Collected December 8, 1877, Usenda; elevation, 8500 feet, district of the Cauca.

"No. 3. 'Hard Carthagena.'—Smooth-leaved variety.* Collected December 27, 1877. Pueblo Nuevo; elevation, 8000 feet, district of the Cauca.

"No. 4. 'Hard Carthagena.'—Paniquita variety. Collected January 18, 1878. Silvia; elevation, 7500 feet, district of the Cauca.

"No. 5. 'Hard Carthagena.'—Magdalena variety. Collected January 14, 1878. Coralis Inza; elevation 7000 feet, district of the Magdalena.

"No. 6. 'Hard Carthagena.'—Paniquita variety. Collected January 23, 1878; elevation, 6000 feet, district of the Cauca."

Lord's Meade, Tottenham, July 23, 1878.

"* *Note.*—This smooth-leaved variety is evidently (by the bark) the *Quina blanca* of Carthagena. It does not belong to the cinchona, but to an allied family of plants. It was twice examined, and contains 0·44 of alkaloid of unascertained properties, the quantity being insufficient for examination of probably a new alkaloid.—J. E. H."

Examination Discrepancies.

Sir,—I think that the percentage of failures at the Minor Examinations differing so greatly on the first and last days is very easily to be accounted for. I take it that candidates are placed in order accordingly as they send their fees up to the Square, and as those men who think they are not quite well enough up, as the phrase is, delay sending their money until the last moment, they thus get put on the last day. It is a well-known fact that the best men go up on the first day, and therefore the percentage of failures must be smaller. Another reason may be, is that the Examiners get tired towards the finish and that the candidates get it stiffer; but this last I can hardly believe to be the case.

Hoxton Street, London, N., Aug. 6, 1878. A. P. S.

THE PARIS EXHIBITION.

Pharmaceutical and Medical Preparations.

Galenical and Allied Preparations.

Although the articles falling under this division are probably those in which many of the readers of this Journal feel the most lively interest, they are also unfortunately among those that accommodate themselves least readily to the conditions of exhibition, and this is especially the case with what are known as Galenical preparations. Even when exhibited, as the ordinary visitor has to depend upon the eye alone to form an estimate of their quality, it is needless to say how easily he may be misled by appearances. The consequence is that the number shown by the pharmacists of any country are not nearly so numerous as would accord with their relative importance. Such as are shown, however, in the present exhibition, so far as can be judged by their external characters, appear on the whole to be of a very high order, and many of them give evidence of the considerable advance that is being made in the practice of "elegant pharmacy," or the art of preparing medicines in a form agreeable for administration.

This perfecting of the art of pharmacy would be hailed with unmitigated satisfaction by every lover of his craft were it not for the fact that it entails the withdrawal of the manufacturing processes more and more from the laboratory of the ordinary pharmacist and tends to bring him down to the level of the mere retailer of the preparations made by the wholesale manufacturer. Even in the case of strictly pharmaceutical preparations the possession of superior apparatus, or the practice of some little trick of manipulation, sometimes leads to the production of a more sightly if not a really better and more uniform article, and the result is an increasing tendency to such preparations becoming the specialties of particular houses. It needs only to refer to the price lists of the wholesale druggists to find evidence of such a condition of affairs in this country, whilst in France it is reported that since 1867, the year of the previous exhibition in Paris, the manufacture of pharmaceutical products has decidedly assumed a more industrial character. In fact, whilst the value of the pharmaceutical products manufactured in France annually is estimated at 70,000,000 francs, no less than 9,500,000 francs worth of these, or more than 13 per cent., are exported in the shape of specialties. On the other hand, the imports of compound medicines into France, owing to the difficulties caused by non-reciprocal legal restrictions, only amount to 380,000 francs annually. But it is curious that a considerable quantity of chemical products, including the vegetable alkaloids, are imported into the country which boasts of being the birthplace of modern chemistry and the land where several of the most important alkaloids were first isolated.

Going a little further, it is found that a host of rivals to the products of the dispensing counter also have sprung up in the numberless coated pills, granules, pearls, dragees, capsules, wafers, elixirs, syrups, and other ingenious devices for making the taking of physic a grateful exercise, with which enterprising manufacturers seek now to tempt the eye of the pharmacist, and it is to be feared appeal to the indolence of the medical man.

Recognizing the extent to which this class of business has developed during the last few years the inquiry naturally arises whether the time is not coming when the practice of dispensing by the pharmacist will become exceptional and when his ordinary occupation will be the simple retailing of already compounded medicines. If this be found to accord with the public good and public convenience there will be little use in protesting against it or lamenting over it, and the pharmacist would no doubt show his business skill by accommodating himself to the altered circumstances. But there is one consideration that will have always to be borne in mind,—important alike to medical man, pharmacist and patient,—and that is, the dependence of the reputation of the two former and the health of the latter upon these articles being truly what they are represented to be. There is no intention to suggest any imputation, but simply to record a note of warning, in recalling the fact that four years ago a committee reported to the American Pharmaceutical Association that competition had so far developed the art of elegant pharmacy in the United States that not only the physical characters of taste and smell of powerful drugs, but the actual presence of the drugs themselves in some preparations examined, had defied detection. Such a possibility will always help to make the new system somewhat repugnant to the instincts of the true pharmacist, notwithstanding some undoubted advantages it presents, so that although he may guard himself as much as possible by dealing only with makers of established reputation and bringing his scientific skill to bear in testing the honesty of their preparations, his feeling will still often be expressed by the couplet—

"The reason why I cannot tell,
I do not like you, Dr. Fell."

However the causes may be explained, and whatever may be the consequence, a visit to the pharmaceutical courts of the present exhibition in Paris makes manifest two facts of great importance in relation to the future of pharmacy, and these are, the marked tendency in the present day to the accumulation of the preparation of medicine in the hands of fewer persons, and that of these, unfortunately, taking into consideration the large class of proprietary medicines, a considerable proportion have no pretensions to the name of pharmacist.

Having thus liberated the soul upon this topic there will be no suspicion of undue partiality in the remarks that follow upon this class of exhibits, which may be said to partake many of them more or less of the character of specialties.

As a matter of convenience for the purpose of comparison, and as involving the least amount of repetition, the plan will be followed of dealing with the articles exhibited as nearly as possible in groups as sketched out before on p. 2, so that in many instances the whole of the noticeable articles in a particular case will not be mentioned on the first occasion.

Few pharmacists would pass through the French court without being attracted by the fine appearance of some specimens of dry extracts exhibited by the Société Française (M. Adrian and Co.), M. Grandval, of Rheims, M. Mouysset, of Paris, and Messrs. Darrasse and Co., of Paris; they are beautifully bright in colour, of a light frothy consistence, and do not appear, as exhibited, be hygroscopic. It is probable that this result is obtained by some special manipulation while evaporating *in vacuo*, and the previous careful removal of chlorophyll and other bodies prone to decompose and discolour the products under the

influence of heat. In the British Pharmacopœia dry extracts are the exception, presumably for the sake of avoiding unnecessarily prolonged application of heat, by which a portion of the extract is rendered insoluble, and it is impossible to say without experience how far the beautiful dry crisp appearance of the specimens referred to may be gained at the expense of the solubility and other essential characters of a good extract, though some solutions of the extracts exhibited by the side of them certainly do look very clear. The difficulty is not overcome by the removal and sacrifice of the first quantity of insoluble matter produced, for, as Mr. Proctor has pointed out, the action is renewed with every fresh application of heat, and he reports that he has subjected extract of aloes to successive treatment until only 3½ per cent. of the original extract remained soluble. If these extracts are evaporated to dryness *in vacuo*, in which proceeding there is nothing unusual, then of course the heat can be applied and continued to dryness under conditions least likely to do harm; such products, however, are generally found to be unduly hygroscopic.

The frothy appearance is not an essential character of the above exhibitors' products, for Messrs. Darrasse also exhibit some specimens of aqueous extracts, which by the artifice of laying them on cut glass dishes standing on white earthenware are made to appear quite transparent, and nice looking saccharides of Loxa and Calisaya bark, and of bitter orange, for dilution to form syrups, while M. Grandval shows some fine alcoholic extracts treated with water.

M. Loret, of Sedan, makes a specialty of narcotic extracts prepared from the fresh plant, freed entirely from "inert matters," such as chlorophyll, starch, albumen, and fatty matters, and evaporated in a vacuum, which he claims to be thus rendered more uniform and permanent in their composition. The British Pharmacopœia, differing from the French Codex and the German Pharmacopœia, orders the return of the separated chlorophyll, in making the extracts of aconite, belladonna, conium, and henbane, probably not only because it gives consistency to the extracts, but also because, as separated by simply straining, it contains an admixture of the active principle. To avoid such loss, the process of dialysis has been recently suggested by Mr. Dimock, an American pharmacist, as applicable in removing the inert colloid matters. But this would appear to involve too much dilution and a consequent increase in the amount of water to be eventually evaporated. M. Loret considers that not only does the chlorophyll itself decompose and become darker and insoluble, but it sets up decomposition in the resinoid matter which contains the active principles of the plants, and so diminishes the strength. Deprived completely of these inert matters he finds the extracts are more permanent and contain a uniform quantity of active principle; 1 gram of his extract of stramonium being estimated to contain 0·0068 gram of daturine, and 1 gram of extract of belladonna, 0·0201 gram of atropine, while 1 gram of extract of digitalis contains 0·090 gram of digitalin. From these extracts M. Loret prepares 10 per cent. powders, diluted with sugar of milk, and 1 per cent. alcoholates and syrups. While speaking of the dilution of narcotic extracts it may be remarked that the German Pharmacopœia recommends that for keeping, an equal quantity of dextrin should be gradually mixed with the extract in a warm porcelain capsule, the mass dried at a temperature of 40° to 50° C. until it ceases to lose weight, and sufficient additional dextrin rubbed in to make the weight double that of the extract employed; of this product, in dispensing, twice the weight of the extract prescribed is used.

Saccharated extracts, for dilution to form syrups, 2 parts representing 1 part of the original extract, are shown by M. Grandval, of Rheims, who also exhibits other concentrated preparations. M. Mouysset also shows a collection of saccharated fluid extracts, which when diluted in the proportion of one part to nine parts of simple syrup are said to represent exactly the syrups of the Codex. M. Bougarel, of Paris, exhibits some extracts of ordinary appearance, and some specimens of "onguent de laurier" and "onguent populeum" of a fine green colour.

In the English department, which, although not second in number of exhibits in class 47, undoubtedly is next in importance to France, Messrs. Savory and Moore, of London, exhibit a series of fluid extracts and tinctures, among which, as novelties, may be noticed those of jaborandi, boldo, guarana, coca and coto. They also exhibit preserved juices representing the indigenous materia medica, including succus hyoscyami and succus conii fructus. Some of the other novelties shown by this firm will be noticed further on. Messrs. Southall, Bros., and Barclay, of Birmingham, show in one of their two cases, powdered extracts, described as of constant strength, convenient for dispensers as being easily weighed and diffused in pill masses, etc. They have also some special preparations, such as liquor emetinæ, of the same dose as vinum ipecacuanhæ, said not to deposit and to contain an invariable amount of alkaloid, and a sp. amyl. valer. co., recommended as a substitute for valerian preparations generally. These are accompanied by series intended to illustrate the importance of using analysed drugs.

Amongst the large collection shown in the United States department by Messrs. Tilden, of New York, occupying about one thousand bottles and illustrating all the indigenous crude drugs and their preparations, extracts figure prominently. Here, in the liquid extract, still another variety is met with, containing glycerine, which it will be remembered was introduced as a menstruum in the United States Pharmacopœia for 1873. Although a considerable quantity of these glycerine liquid extracts are now to be met with in this country there are evident signs that in the United States their present form is not altogether regarded as satisfactory, and the attention of the revision committee engaged in preparing the new edition of the United States Pharmacopœia is especially directed to the whole subject of extracts, Professor Diehl, chairman of the sub-committee, having drawn up a scheme for the co-operation of pharmacists generally in carrying out an exhaustive series of experiments. Certain it is that a great deal of work in this direction will have to be done before it will be practicable to include the extracts in an international pharmacopœia.

In the Canadian department, Mr. Saunders, of Montreal, supplements a collection of indigenous drugs in bottles, labelled with botanical names and uses, with a number of liquid extracts, and the case of Messrs. Lyman Bros., of Toronto, also consists principally of liquid extracts. Among them are the extracts of phytolacca, gossypium, serpentaria, cimicifuga, pleurisy root (*Asclepias tuberosa*), chimaphila, leptandra, wild cherry bark (*Prunus Virginiana*), etc.

Coming back to the old world, very little illustrative of this section is found in the Austrian, Spanish, Norwegian or Swedish departments. In the Netherlands department, Messrs. Mouton and Son, of the Hague, exhibit various pharmaceutical extracts, amongst others a dialysed extract of ergot, and various preparations of Java cinchona barks.

As closely allied to the class of extracts may be mentioned guarana, specimens of which are to be seen in several of the French and British cases. Messrs. Rigaud and Dusart also exhibit "cannabine," a preparation from Indian hemp, used in the manufacture of antiasthmatic cigars.

In the case of Messrs. Mawson and Swan, of Newcastle, are to be seen specimens of Swan and Procter's patent preparations of opium, the "Opium Rectificatum" and the "Pulv. Opii Rect.," which, although the subject of a patent, appear to be of great importance pharmaceutically, and will, no doubt, raise considerable interest.

According to the label the above titles have been adopted to indicate that the crude opium, than which scarcely any drug is more variable, has been submitted to treatment having for its object to bring it into the best possible condition for use in medicine, by the removal of narcotine and inert odorous and fatty matters, caoutchouc, etc., that impede the extraction of its active constituent, and the production of a substance containing a uniform proportion of morphine, namely, 9 per cent. in the mass and 10 per cent. in the powder. This is done by treating the opium with such solvents as have the power of dissolving narcotine and other objectionable matters without removing any considerable quantity of meconate of morphia, except in such cases where the morphia is in excess of the desired proportion. The specification of the patent states that the manner in which this is done varies with the nature of the opium, and gives the following as illustrative of the treatment of an average Turkey opium :—

"A convenient quantity of dry opium in fine powder is put into a percolator of a somewhat conical form, provided with a perforated false bottom covered with flannel, and the true bottom fitted with a pipe and tap to regulate the flow of liquid. The tap being closed, a portion of the solvent, hereinafter described, is poured upon the opium and well mixed with it by stirring ; a convenient proportion being one to one and a half gallons for every ten pounds of opium. The mixture is allowed to macerate two or three days, after which the solvent may be drained out, and a further portion poured upon the surface of the opium to displace that which was absorbed. At intervals of a day or two the displacement may be repeated till the percolate comes through almost free from narcotine or other matter desirable to be extracted : the solvent mechanically retained by the opium after draining may be recovered by distillation. The opium then only requires powdering and assaying to fit it for all the purposes to which powdered opium is applied, or working with a certain proportion of water till reduced to a mass to fit it for all the purposes for which lump opium is used.

"The solvent we prefer for operating in this way is a mixture of eight parts by measure of chloroform with one part by measure of ether, but we do not restrict ourselves to this solvent or to the mode of extraction above described.

"In certain circumstances one or more of the following solvents may be used either mixed or separately—namely, ether, chloroform, benzine, light mineral oils, sulphide of carbon, ethylic, methylic or amylic alcohol, oil of turpentine, and, when desirable, their action may be accompanied by that of ammonia or other chemicals.

"Turkey opium, containing but little free acid when treated as above described, will have its narcotine reduced to a small fraction of a unit per cent. Persian opium, frequently containing much free acid, is more difficult to render satisfactorily pure, but the narcotine may be liberated and extracted by the above treatment with the addition of the passage of dry ammonia through the mixture of opium and solvent till an alkaline reaction is permanently established, when the process may be completed as before described. If water be excluded during the presence of the ammonia, the meconate of morphia remains undecomposed in the opium at the end of the process. If the sample of opium under operation contains more than a desirable proportion of morphia, the proportion may be reduced to a desirable standard by adding ethylic or methylic alcohol to the solvent, the meconate of morphia being nearly insoluble in a mixture of chloroform and ether, slightly more soluble in the same with the addition of spirit, and freely soluble in a mixture of chloroform and spirit without the addition of ether."

Another instance in which the eye is pleased, though the drug is not necessarily improved by the special treatment to which it is submitted, is to be found in the fine case of the Pharmacie Centrale de France, of which M. Dorvault is the director, where are to be seen some handsome specimens of scammony and jalap resins that are almost absolutely colourless. In the next case, too, belonging to Messrs. Adrian and Co., of Paris, there is some scammony resin in the form of a snow-white powder. Messrs. T. and H. Smith, of Edinburgh, also exhibit some very nice specimens of these two resins, both brown and white, as well as podophyllin resin.

Powdered drugs do not figure very largely in the present collection, and credit for the best show may be fairly awarded to an English firm, Messrs. Baiss, Bros., of London, who exhibit nice-looking specimens of powdered cinnamon, myrrh, orris, English and Chinese rhubarb, cascarilla, jalap, and the different cinchonas. Messrs. Hélain and Co., of Paris, show a variety of powders for use by pharmacists, grocers, and perfumers, and also some exceedingly thin shavings. Messrs. Mouton of the Hague also show some fine powders.

Of plasters there are several good exhibits, although most of them partake of the nature of specialties of the houses showing them. In the French department may be mentioned those of Messrs. Fourgera and Lancelot (not in catalogue), M. Beslier, of Paris, M. Grorichard and M. Jacques of Besançon, M. Dupont, of Orleans, and M. Cruveiller, of Rouffignac, all of whom exhibit revulsive plasters prepared from the resin of a species of *Thapsia*. It will be remembered that about four years since it was announced that the plant yielding the silphion of the ancients had been rediscovered in one known under the name of "*drias*" in the Cyrenaica;* the claim was however disputed, and ultimately the plant proved to be only a form of the European *Thapsia garganica*. A comparative examination, by M. Yvon,† of the European and African plants, showed

* *Pharm. Journ.* [3], vol. vii., p. 750.
† *Pharm. Journ.* [3], vol. viii., p. 162.

that the composition of the bark of the root was essentially the same, but he noticed that the resin of the African plant had a powerfully irritant action. This observation appears to have been turned to practical account, for the resin from the *Thapsia garganica*, or "bou nafa resin," as prepared for medicinal use, is exhibited as an industrial product in the Algerian house, together with a model of the apparatus used in its preparation. It is rather inefficiently described in the catalogue as being prepared "by distilling a mixture of alcohol and of the powder obtained by trituration of the bark of the root of the *bou nafa*."

In a communication received from M. Lallemand, of L'Arba, near Algiers, respecting this resin, it is stated that the *Thapsia garganica* plant has long been held in honour among the Arabs, who look upon it as a panacea. As a purgative, although a dangerously powerful one, small pieces of the dried root are eaten. But it is chiefly used as a revulsive in rheumatic and other pains, affections of the chest, etc. For this purpose the fresh root is grated and the milky juice that flows from it is rubbed on the skin until a smarting is produced, which is followed by a swelling of the part and a characteristic miliary eruption. The thapsia has also an action approaching that of an emetic and differing from croton oil. The credit of introducing, or reintroducing, this drug into European medicine belongs to two French doctors, MM. Lereboulteau and Berthereaud, who extracted the resin from the root and prepared from it a plaster which in three years has won such favour that Algeria already exports annually for its manufacture, either as pure resin or dried roots, equal to forty tons of the fresh roots.

The pure thapsia resin is of an amber yellow colour, and has a specific gravity rather greater than water. After immersion in water for some time at a temperature of 16° C. it can be worked between the fingers. It is soluble in alcohol, ether, carbon bisulphide, and in most ordinary solvents and in fatty bodies.

For the purpose of obtaining the resin the plant is collected in the spring and the root is cut into slices by a special machine, dried in the sun, and treated with boiling alcohol; the alcohol is then distilled off and the residuary resin is purified by treatment with water. All these operations are dangerous, or at least inconvenient, to the operator, since the alcohol vapour becomes charged with a volatile principle which upon coming into contact with the skin causes a swelling and an erythmatous eruption that prevents the operator from continuing long at the work. In order to overcome this inconvenience M. Lallemand contrived an apparatus, of which a model is exhibited, in which the operation is carried on without the vapours becoming diffused in the atmosphere.

This apparatus consists of (A) a displacement apparatus surrounded by a steam jacket, the opening being closed by a shield or washer and head piece through the centre of which rises a pipe that is bent over and opens into a worm; (B) a reservoir for the tincture produced in (A), and connected by pipes with it and with (C), an ordinary alembic heated by a water-bath or preferably by steam, the worm being connected with (D), the alcohol reservoir. The displacement apparatus being charged with roots, alcohol is run into it from the alcohol reservoir (D), where it is heated and when it has become saturated with resin it passes into the tincture reservoir (B). From thence the alembic (C) is supplied as required with tincture, which is then distilled and the spirit passing off is condensed and returns to the spirit reservoir, whilst the resin is left as a residue. When the charge is exhausted, water is run into the displacement apparatus, and steam heat being again applied any spirit still retained by the roots is recovered. The product is a brown transparent and brittle resin which gives off a peculiar aromatic odour when burnt.

Of the better known vesicants, M. Rigollot shows his "mustard leaves," and mustard papers are also exhibited by M. Esménard and M. Boggio, of Paris. A rubefacient plaster, bearing the indicative name, "l'euphorbium," is shown by Messrs. Desnoix and Co., of Paris.

In the case of Messrs. Foumouze Frères, of Paris, the "vesicatoire d'Albespeyre" is accompanied by a fine specimen of cantharadin and some insects said to have been preserved ten years in carbon bisulphide, probably the vapour. In the case, too, of M. Béguin, besides his "vesicatoire," which has for its basis cantharidin associated with caoutchouc, are to be seen chitin, cantharidin (crystallized, sublimed and precipitated), and the compounds of cantharidin with potash, oxide of copper, ammonia, magnesia, and morphia, together with a series of specimens of vesicating insects used in different parts of the world. Among these may be noted the official cantharides, as well as *Lytta adspersa* (Brazil), *Mylabris Cichorii* (South of Europe, Egypt, India, and China), *M. pustulata* (China), *M. axillaris* (Syria), *M. Thunbergii*, *M. Schœnherri* and *M. Sidæ* (Cape of Good Hope and China), and *Meloe majalis* (South of Europe); there are also specimens of the eggs of various species and the yellow and green fats from cantharides, the yellow from species of *Mylabris* and the black from species of *Meloe*. Turning to the British court, Mr. A. W. Gerrard, of London, exhibits a special adhesive plaster, spread on a strong flexible material, and hence claimed to possess the properties, prized by surgeons, of adhesiveness, strength, and flexibility.

Side by side with these plasters, in the lower part of the case belonging to Messrs. Morson, Mr. Gerrard also has a good display of suppositories, pessaries, and bougies, uniformly arranged in small boxes. In the French department the medicated bougies and suppositories of Messrs. Reynal and Co., of Paris, form the principal, if not the only, exhibit of this class of goods. In the Austrian department the same remark may be made of the exhibit of Herr F. Anton Grohs, of Vienna, who appears to have devoted much attention to the subject of these topical applications. The substance that he uniformly adopts as a basis for his preparations is gelatine, which he considers far better adapted than cacao butter for the purpose, and, as makers are apt to do, he holds a strong opinion as to the superiority of his goods. Herr Grohs has also introduced nasal bougies, made of gelatine, impregnated with various medicaments; they are conical, 3 to 5 inches long, and are said to have been very useful in facilitating a direct and prolonged application of medicines in the treatment of nasal disease. Analogous preparations are his "amygdalæ" and "globuli aurium," for the treatment of aural affections. These are prepared of different sizes and as their names imply, are either almond-shaped or globular. They are "medicated" with varying proportions of sulphate of zinc, tannin, borax, corrosive sublimate, sulphate of copper, nitrate of silver, extract of opium, morphia, etc.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

Continued from Vol. VIII., page 1003.

ALHAGI MAURORUM, *Dec.* (LEGUMINOSÆ). *The plant and manna. Vernacular*: *The plant*, JAWASA (Hind. and Bomb.); *the manna*, TARANJABIN (Pers. and Bomb.).

History, Uses, etc.—The plant, called in Sanskrit, duralabhá and in Arabic, háj, is a native of the deserts of Egypt, Syria, Mesopotamia, Persia and India, as far south as the Concon. In the hot season, when all the smaller plants die, it sends forth leaves and flowers. The generic name is derived from the Arabic, al-haju, the haj plant, which is pronounced by the Egyptian Arabs, al-hagu.

The plant is described in Sanskrit works as laxative, diuretic, and expectorant, the thorny flower stalks and branches being the parts used. An extract obtained by evaporating a decoction of the plant is called yásasukará; it has a bitter sweet taste, and is used as a demulcent in coughs. There is no mention in Sanskrit books of manna being obtained from the plant, indeed none is produced upon it in India. The Hindus use the fresh juice as a diuretic, generally in combination with laxatives and aromatics (*confer*. Sárangadhara and Chakradatta).

In Mahometan works, under the names of háj and khár-i-shutr, or camel thorn, a description of the plant will be found. It is considered to be aperient, attenuant and alexipharmic. A poultice or fumigation with it is recommended to cure piles; the expressed juice is applied to opacities of the cornea, and is directed to be snuffed up the nose as a remedy for megrim. An oil is prepared with the leaves as an external application in rheumatism; the flowers are applied to remove piles. Ainslie notices the plant as one of the sources of manna. In the 'Bengal Dispensatory' and 'Pharmacopœia of India' it is also noticed on this account. Under the name of taranjabin Mahometan writers describe the manna. Meer Muhammad Husain says that it is collected in Khorasán, Mawarunnahr, Kurjistan, and Hamadan, by cutting the plant and shaking it in a cloth to separate the manna; an inferior kind is made by dissolving what still adheres in water, and evaporating it to a suitable consistence. He describes it as aperient and cholagogue, more digestible than ash manna, expectorant, a good purifier of the blood from corrupt humours when given in diet drinks, such as barley water, etc., diuretic, and with milk, fattening and aphrodisiac. In Bombay fine clean white samples of taranjabin are obtainable during the season of import (November to January), but unless very carefully preserved it soon spoils in the moist climate of the western coast, running together and becoming a brown sticky mass. The dried plant is always obtainable under the name of jawasa.

Description.—A low shrub, armed with copious subpatent hard pungent spines, ½—1 inch long. Leaves simple, drooping from the base of the spines or branches, oblong, obtuse, rigidly coriaceous, glabrous Flowers, 1—6, from a spine on short pedicels; calyx glabrous $\frac{1}{12}$ — ⅛ inch; corolla reddish, three times the calyx; pod 1 inch long or less, falcate or straight, constricted between the seeds; seeds kidney shaped, greenish grey, very hard.

Taranjabin occurs in white grains or small agglutinated masses, mixed more or less with the thorns, pods and leaves of the plant, it has hardly any odour; the taste is saccharine and afterwards slightly acrid.

PRUNUS BOKHARIENSIS, *Royle.* (ROSACEÆ). *The fruit. Vernacular*: ALOO BOKHARA (Hind., Bomb. and Pers.); ALPOGADA PAZHAM (Tam.).

Description, Uses, etc.—The Bokhara plum in a dry state is commonly met with in Indian bazaars, being used much as prunes are with us in Europe. It may be considered the officinal prune of India and may be made use of in the preparation of confection of senna and for any other purpose to which prunes are applicable. The author of the 'Makhzan-ul-adwiya,' after noticing several kinds of plum which are common in Persia and the neighbouring countries, goes on to say that for medicinal purposes the amber-coloured Bokhara plum is to be preferred. He describes it as subacid, cold and moist, digestive and aperient, especially when taken on an empty stomach, useful in bilious states of the system and heat of body. The root, he says, is astringent and the gum a substitute for gum arabic, and often called Persian gum. He also notices the wild plum (probably *P. spinosa*), and says that a kind of dry cake is prepared from the pulp and used medicinally on account of its acid and astringent qualities.

The Bokhara plum as met with in commerce is about the size and shape of the dry prune of Europe, but of a lighter colour, showing that in the fresh state it must have been yellow or green, and not purple; it is very acid, but on the addition of a little sugar the taste is agreeable and refreshing. Prunes contain free malic acid, sugar, and albumenoid and pectic substances; what the supposed laxative principle is, has not been determined. I have not met with any chemical examination of the particular kind under notice.

Commerce.—The imports of Aloo Bokhara into Bombay are considerable as it is much used as an article of diet. Value, rupees 8-12 per Surat maund of 37½ lbs. The price varies with the quantity in the market; there is but little difference in quality.

AMMANNIA VESICATORIA, *Roxb.* (LYTHRACEÆ). *The plant. Vernacular*: DAD-MARI (Hind.); AGINBUTI, GUREN. BHAR-JAMBOOL (Bomb.); KALLURIVI, NIRUMEL-NERUPPU (Tam.).

History, Uses, etc.—The properties of this plant and its use by the natives as a blistering agent appear to have been first brought to the notice of Europeans by Roxburgh. Ainslie quotes him, and remarks that the plant has a strong muriatic smell, but not disagreeable; the leaves are extremely acrid, and are used by the natives to raise blisters in rheumatism, fevers, etc.; the fresh leaves, bruised and applied to the part intended to be blistered, perform their office in half-an-hour and most effectually. The authors of the 'Bengal Dispensatory' state that they made a trial of the leaves in eight instances; blisters were not produced in less than twelve hours in any, and in three individuals not for twenty-four hours. The bruised leaves had been removed from from all after half-an-hour. The pain occasioned was absolutely agonizing until the blister rose; they caused more pain than cantharides and are far inferior to the *Plumbago rosea* in celerity and certainty of action. According to Fleming, the leaves are

applied to cure herpetic eruptions. The authors of the 'Pharmacopœia of India' merely notice the unfavourable opinion of the drug expressed in the 'Bengal Dispensatory.' I have made some experiments with an ethereal tincture of the leaves which leads me to form a much more favourable opinion of them; in several instances it blistered rapidly, effectually, and without causing more pain than the liquor epispasticus of the Pharmacopœia, which it resembles in colour; upon evaporation of the ether a dark green resinous extract is left. A spirituous tincture was also tried, but it was not nearly so efficient. I have met with no mention of *A. vesicatoria* in standard native works on materia medica. The plant is common in low moist ground in the neighbourhood of Bombay, and appears in November and December. Its properties are retained after the plant has been dried.

Description.—An herbaceous, erect, much-branched plant, having something the foliage of rosemary; stems four-sided; leaves sessile, opposite, lanceolate, attenuated, about an inch long, and $\frac{1}{8}$ inch broad, much smaller on the upper parts of the plant; calyx, 4-cleft to the middle, lobes acute; accessory teeth very small; flowers very minute, aggregated in the axils of the leaves, almost sessile; tube of the calyx at first narrow and tightened round the ovary, in fruit, cup-shaped petals wanting; capsule longer than the calyx, 1-celled; flowers red. The whole plant has an aromatic and rather agreeable odour which it retains when dry.

TERMINALIA BELLERICA, *Roxb.* (COMBRETACEÆ).
The fruit. Vernacular: BHAIRAH, BAHERA (Hind. and Beng.); BEHARA, YELLA (Bomb.); TANRIK-KAY (Tam.).

History, Uses, etc.—Belleric myrobalans—in Sanskrit, Vibhitaki—are considered by Hindu physicians to be astringent and laxative and are prescribed in affections of the throat and chest. As a constituent of the triphála (three myrobalans) they are employed in a great number of diseases. The kernel of the fruit is narcotic if taken in large quantity, and is sometimes used as an external application to inflamed parts (Sarangadhara). Formulæ for the administration of this myrobalan as a pectoral will be found in Dutt's 'Hindu Materia Medica.' Mahometan writers describe it as astringent, tonic, attenuant, aperient, useful in dyspepsia and bilious headache, also as an astringent application to the eyes. Belleric myrobalans are only briefly noticed by European writers upon Indian drugs. There is no doubt about the narcotic properties of the kernel. The part used in medicine is the pulp. The tree produces a quantity of gum.

Description.—The fresh drupe is obovate, the size of a nutmeg, somewhat pentagonal, fleshy, covered with a grey silky tomentum. When dry it is a little larger than a gall nut, of a dirty brown colour and astringent taste; the stone is hard and encloses a sweet oily kernel.

The gum is in vermicular pieces about the thickness of the finger, of the colour of inferior gum arabic, hardly at all soluble in water, in which it swells up and forms a bulky gelatinous mass; its taste is insipid. Roxburgh's statement that it is perfectly soluble in water, and Drury's, that it burns like a candle, I am unable to confirm.

(*To be continued.*)

PRACTICAL HINTS ON THE PRESERVATION OF ESSENTIAL OILS.*

BY J. B. MOORE.

There are no articles in which the pharmaceutist deals that, as a class, are so unsatisfactory to handle, or so difficult to obtain of really prime quality, or that require such constant vigilance in order to preserve in good condition, as the essential oils, nor is there any part of the pharmaceutist's stock that becomes so utterly valueless when damaged or deteriorated by time and exposure.

There are many articles that, when they become spoiled and unfit for the purposes for which they are especially intended, may often be turned to account for some other use, but an essential oil, when it has lost its flavour, and its aroma is gone, is as worthless as the withered and scentless rose.

To have good essential oils the pharmaceutist must, in the first place, be scrupulously particular in their selection, purchase only those that are of the finest quality, and as fresh as they can be obtained. Then the greatest care must be exercised to keep them in good condition. What is not needed for immediate use should be transferred to small bottles, which should be filled so full that the cork will touch the oil. The cork should be tied down to prevent its expulsion or working out, and then sealed, or, what is preferable, dipped into a melted mixture (not too hot) of two parts of paraffine and one part of yellow wax, or into melted paraffine alone. The corks employed for this purpose should be carefully selected, sound, and accurately adjusted to the neck of the bottle. The oil should then be immediately placed in a dark cool place in the cellar.

Many seem to be under the impression that when the oil is bottled and wrapped up in paper, or otherwise protected from the light, all the conditions necessary for its preservation are complied with, regardless of the influence of the temperature. But my experience has convinced me that the temperature at which essential oils are kept is one of the most important matters to be considered in our efforts for their preservation.

Any essential oil, although carefully bottled and excluded from the light, will spoil much sooner when kept up in the store room than it will in a dark cool cellar. Many of our wholesale dealers observe the commendable practice of bottling their essential oils as soon as they are removed from the original packages, but they afterwards keep them up in their warm store rooms, instead of immediately placing them in a dark cool place. Consequently their oils must suffer very much from such exposure, although every other precaution for their preservation may have been observed.

It is of the greatest importance, too, that the oil should be bottled immediately after the original package containing it has been opened, and not after the oil has been exposed to the air for several days or perhaps weeks, for such oils as orange, lemon, juniper, etc., are very prone to change, and lose their freshness and delicacy of flavour upon the slightest exposure, and especially in hot weather or in a warm situation. Oxidation commences at once, and when once begun, progresses very rapidly. The characteristic rich yellow colour of the oils of lemon and orange also begins to change the moment oxidation commences, and after a short exposure to light and air the altered condition of the oil may be readily detected by the practised eye in the change of colour as well as by the flavour and aroma. Therefore I would recommend that under all circumstances essential oils which are not required for immediate use should be sealed up, as above directed, in bottles holding such quantities as will be most convenient for use, and kept in a cool dark place. When a bottle is opened, and only a portion of the oil is needed, what remains should be immediately transferred to a smaller bottle filled to the cork. But the practice of

* From *the Druggists' Circular and Chemical Gazette*, August, 1878.

keeping essential oils, and especially those most prone to change, in a warm storeroom, as is too often done, is a most reprehensible practice which cannot be too strongly condemned, as the influence of a warm temperature on these oils in conducing to change cannot be overestimated. There are, of course some that are not so sensitive as others to this action, but those that are should claim our most faithful protection.

In retail pharmacies I am aware that there are certain volatile oils which the pharmaceutist must necessarily keep up in his storeroom for the convenience of dispensing, such, for instance, as the oils of cinnamon, cloves, peppermint, and others that might be named, but these oils do not spoil so quickly as some others, and even these should be kept in small bottles, excluded from the light, and containing no more than the actual demands of business require.

The lack of the proper care on the part of dealers in the preservation of essential oils, together with the adulteration that is often practised by manufacturers and dealers, renders it ofttimes next to an impossibility almost to obtain certain of these oils of really unexceptionable quality.

Some essential oils, may even after they have passed into the incipient stage of degeneration, and their natural aroma and flavour have to a considerable extent departed, yet retain sufficient of their characteristic and familiar odour to deceive the inexperienced or indifferent purchaser. Indeed, according to my own observation, a large proportion of the oils of this class as found in the general market are precisely in this condition.

Retail pharmaceutists and perfumers may preserve many essential oils unimpaired for a long period, by mixing them, while fresh, with an equal bulk of alcohol, filling the bottles full, corking tightly, and placing the mixture in a cool dark place. I have kept the oil of orange, one of the most difficult to preserve, in this way, for a long time without the slightest perceptible change, notwithstanding I had opened the bottles frequently and taken oil out of them. But for many purposes the admixture of the alcohol would be objectionable.

A CONTRIBUTION TO OUR KNOWLEDGE OF THE ALKALOIDS OF ERGOT.*

BY T. BLUMBERG.

(*Continued from page* 68.)

II. Picrosclerotine.

In the Appendix† to Dragendorff and Podwissotzky's "Investigations upon the Active and Some Other Constituents of Ergot"‡ it is stated that the sclererythrin, isolated according to the method described in the *Archiv. f. experiment. Pathologie und Pharmacologie*, was contaminated with a bitter alkaloidal substance and a yellow acid. The former was named "picrosclerotine," and the latter "fuscosclerotic acid."

In order to separate the sclererythrin from the fuscosclerotic acid advantage was taken of its property of being precipitated from alcoholic solution by lime water. The picrosclerotine remains in solution with the fuscosclerotate of lime. Upon breaking up the lime salt with dilute sulphuric acid, and shaking with ether, the fuscosclerotic acid is taken up and the picrosclerotine remains partially undissolved. If the fuscosclerotic acid be purified by conversion into the ammonium salt, which is insoluble in ether and soluble in water, a small quantity of picrosclerotine can be recovered, as this is difficultly soluble in water. It is easily soluble in water acidulated with acetic acid or sulphuric acid, and is partially precipitated by ammonia. It is precipitated by the usual tests for alkaloids, and has a toxic action on frogs in very small doses. Doses of one milligram subcutaneously injected quickly produce decrease of sensibility, paralysis of the extremities, followed by death in about ten minutes without cramp or anything of the kind being manifested.

About the same time I had sought to prepare ergotinine according to the method published by Tanret. The product obtained, however, could not be considered to be ergotinine, since it was neither crystalline nor gave a violet solution with sulphuric acid, which according to Tanret were properties of that alkaloid. Professor Dragendorff made some physiological experiments with the preparation and found that on frogs it acted similarly to picrosclerotine, but less energetically.

Sclererythrine was obtained from ergot that had previously been extracted with ether and water. I therefore used in my experiments a residue that had been treated similarly and obtained as a by-product in the preparation of sclerotic acid.

As picrosclerotine is freely soluble in water containing acetic acid it seemed probable that it could be obtained by extraction of this residue with acidulated water, but an experiment gave negative results. The residue was then moistened with aqueous solution of tartaric acid (in the proportion of 30 grams of acid to one pound of ergot), and kept during twenty-four hours at a temperature of about 40°C. It was then exhausted with 85 per cent. alcohol in a percolator. After distilling off the alcohol the residue was mixed with sufficient water to allow the fuscosclerotic and erythrosclerotic acids to be removed by filtration. These were washed with distilled water and the wash water added to the filtrate, which was then concentrated by evaporation. Upon adding ammonia to the concentrated liquor a precipitate was formed, which was filtered off, washed by distilled water and treated with dilute acetic acid; this did not completely dissolve the precipitate, blackish masses remaining suspended in the acidulated liquor, which were removed by filtration.

The filtrate gave precipitates with reagents indicating that it still contained an alkaloidal substance. This was removed, precipitated by ammonia and washed with water. A very small quantity of the precipitate was dissolved in dilute acetic acid and the solution injected under the skin of a frog. The animal acquired a yellow colour (reaction upon the chromatoblast), but no other change was observed.

A somewhat larger quantity was injected subcutaneously into a not fully grown frog. The breathing immediately became irregular, and soon ceased. In seven minutes the animal became convulsed, the head and neck bent backwards, the back becoming strongly arched. It soon relaxed and in twelve minutes became again straight. A third full-grown frog was injected in the right side, here also the breath failed; the right fore leg quickly became paralysed, and the abdomen on the right side hung loose while on the left it was distended; the head and neck were bent back, so that the back was arched inwards; paralysis gradually spread over the whole body, and death followed in an hour after the injection. A fourth frog gave similar results.

These experiments showed that I was dealing with picrosclerotine, although probably not quite pure. It gave precipitates with iodide of potassium and bismuth, mercuric chloride, potassium iodoiodide, phosphomolybdic acid, platinic chloride, gold chloride, potassium bromobromide, tannic acid, picric acid, potassium ferrocyanide and ferridcyanide, iodide of mercury and potassium, iodide of cadmium and potassium, and acid chromate of potassium.

A portion of the precipitate I dissolved in acetic acid, supersaturated the solution with sodium carbonate, and attempted to obtain the picrosclerotine by shaking with different substances. Petroleum spirit removed the least; benzol, chloroform and ether dissolved rather more. The chloroform solution was very dark coloured; the ether solution was lighter. The residues from the evaporation of the ether and chloroform solutions were not crystalline. According to Podwissotzky's experiments picrosclerotine was difficultly soluble in ether. It also appeared to me that it would be difficult to separate it completely by

‡ 'Untersuchungen über die wirksamen und einige andere Bestandtheile des Mutterkornes,'

agitation. I therefore treated the precipitate produced by ammonia with 90 per cent. alcohol. This dissolved the alkaloid, and left a residue which gave an ash containing lime when incinerated upon platinum. The residue after distilling off the alcohol from the alcoholic extract was dark coloured, and not completely soluble in acetic acid. I treated 0·02 gram with dilute acetic acid, filtered, and injected the filtrate under the skin of a frog. The animal died, manifesting all the above-mentioned symptoms of poisoning.

As before stated the distillation residue from the alcoholic extract was not completely soluble in acetic acid, notwithstanding that the precipitate produced by ammonia, as long as it was moist, was entirely dissolved by acetic acid. At that time I could not explain this.

The insoluble portions gave a brown solution with concentrated sulphuric acid, and also with solution of potash. Upon treating a portion of the distillation residue with warm dilute sulphuric acid perfect solution was not obtained. The operation was performed in a porcelain dish and I noticed that the liquid at the edges, where the sulphuric acid had become concentrated through the evaporation of water, was rose coloured. Upon stirring the colour disappeared, but came again upon further heating. To determine whether the alkaloid gave a coloured solution with sulphuric acid a small portion of the distillation residue was heated at the ordinary temperature with dilute sulphuric acid, the insoluble part filtered off, and a few drops of concentrated sulphuric acid added to the solution. Upon heating it, in proportion as the water evaporated, the solution assumed at first a rose and then a violet colour, which remained during thirty-six hours unaltered. Upon treating the alkaloid solution with one or two volumes of concentrated sulphuric acid it became violet coloured at the ordinary temperature.

With Frohde's reagent solution of picrosclerotine was coloured a violet blue at the ordinary temperature; when heated it became first violet, then green. These colorations only took place when a solution of the alkaloid was brought into contact with the respective reagents. They were not observed when a cold mixture of one or two volumes of concentrated sulphuric acid and one volume of water was poured upon the alkaloid.

The distillation residue was further treated with dilute acetic acid, filtered, the solution supersaturated with ammonia, the resulting precipitate washed with water and dissolved in 90 per cent. alcohol, and distilled. It was again found that black flocculent matter insoluble in acids had formed. A second quantity of picrosclerotine was therefore prepared from the ergot residue, but the substance insoluble in acid was always formed.

As the picrosclerotine could not be obtained free from this substance by repeated solution in acetic acid and precipitation with ammonia, I placed the preparation first in a drying closet, and then worked up the fusco-sclerotic acid and the sclererythrin. It was then heated with ether, but complete solution did not take place after standing some time. The whole was then shaken with successive fresh quantities of water acidulated with sulphuric acid as long as any alkaloid was dissolved. The acid liquors were separated from the ethereal solution, filtered, and made alkaline with ammonia, which threw down the picrosclerotine. This was removed by filtration and the filtrate, which I will call A, preserved.

The ethereal solution, which no longer yielded any alkaloid to the acidulated water, was filtered. It left upon the filter a dark-coloured substance, which when extracted with warm dilute sulphuric acid gave up a further small quantity of picrosclerotine. The substance insoluble in acid was again formed. The alkaloid in sulphuric acid solution was coloured violet by strong sulphuric acid. It also behaved similarly towards Frohde's reagent, and was fatal to frogs in doses of 0·02 gram. Attempts to decolorize the picrosclerotine in alcoholic solution with animal charcoal were unsuccessful.

Picrosclerotine is not absolutely insoluble in water, as I obtained some upon evaporating filtrate A and extracting with strong alcohol, which left undissolved the ammonium sulphate. The preparation obtained in this way behaved towards sulphuric acid and Frohde's reagent exactly as picrosclerotine and was fatal to frogs in doses of 0·02 gram.

Whilst picrosclerotine acts thus energetically immediately after its preparation, when it has been kept some time it loses that property almost completely. Moreover the proportion of the substance insoluble in acetic acid and dilute sulphuric acid increases.

The formation of this substance insoluble in acid and the diminished activity find their explanation in the progressive decomposition of the picrosclerotine. The decomposition product of the picrosclerotine formed a hard resin-like mass, which gave with potash ley and with concentrated sulphuric acid dark-brown solutions. Heated upon platinum it burnt with a sooty flame, and when heated with nitric acid it yielded picric acid. It agrees in all its properties with the ergot resin examined by Ganser, who, however, found that neither it nor the ergot oil was inactive. The resin he had obtained from the oil by extraction with absolute alcohol. But from the oil I have isolated a crystalline alkaloid (see under "ergotinine") which acts upon frogs similarly to picrosclerotine and like it decomposed into a resinous mass. Ganser carried out his physiological experiments with this decomposition product, which may have contained a small quantity of undecomposed alkaloid.

NOTE ON THE EFFECT OF INTENSE COLD ON FERRIC HYDRATE.*

BY E. B. SHUTTLEWORTH.

During the winter of 1876, a quantity of moist ferric hydrate, prepared for the manufacture of citrate of iron and quinine, was left to drain on a calico filter, from Saturday until Monday. In the interval the weather became exceedingly cold, and it is probable that the hydrate was exposed to a temperature of about 10° below zero. On Monday morning, the solid mass of ice was examined, and it was found that the hydrate had separated in the form of granular particles. The contents of the filter were thawed, when the water quickly drained away, leaving the hydrate in the form of a dense blackish-brown powder.

On trial, the fact was revealed that this hydrate could not be used for the purpose for which it was intended, as it had lost almost entirely the property of solubility in solution of citric acid. A portion was therefore dried, at a temperature of 90° F., and put aside for further examination. I did not pursue the subject further, until my attention was called to it lately by a paragraph in one of the continental journals, in which was a suggestion to reduce the bulk of ferric hydrate, by freezing, so that it could be washed and separated more easily. In some cases this plan will undoubtedly prove useful, but, as shown by the above fact, is not always applicable.

I have made a few experiments on the powder reserved, and find that it is readily soluble in hydrochloric and nitric acids, but very sparingly in acetic and citric acids. In appearance it closely resembles fine grain gunpowder, but in colour it inclines slightly to brown. On heating to a dull red, it loses 27·2 per cent. of its weight, which would give it a place intermediate between ferric oxyhydrate, Fe_2O_2 2HO, and certain varieties of brown iron ore Fe_2O 4HO. It is, therefore, probably identical with ferric hydrate that has become dry by exposure.

While on this subject, I would mention a fact which is, doubtless, known to many, but which I have not seen noticed in print: when solution of dialysed iron is subjected to a degree of cold sufficient to produce complete congelation, the frozen mass, on thawing, deposits all the oxide in reddish-brown shining scales. The clear, colourless, supernatant liquid tastes decidedly more ferruginous than did the original solution, and with nitrate of silver gives a slight cloudiness. Red prussiate of potash develops a very pale olive coloration. I intend to examine the precipitated oxide when time offers.

THE BRITISH ASSOCIATION.

THE proceedings of the Chemical Section of this body commenced as usual on Thursday morning with the delivery of an address by the president, Dr. MAXWELL SIMPSON, in which he sought to place before his audience the claims of chemistry to a place in general education and the claims of chemical research to a place in the curriculum for the higher degrees in our universities.

The chief grounds upon which Dr. SIMPSON based his argument that the study of chemistry should hold a high place in our schools and colleges were the value of the knowledge acquired from chemistry, the discipline of the intellectual faculties in acquiring that knowledge, and the effect thus produced upon character.

As regards the first point it was shown that our acquaintance with the air we breathe and the food we consume being in itself a portion of chemical science, it is necessary that we should understand the various processes of combustion, fermentation, and other varieties of material change which give rise to the phenomena of daily life. Similar knowledge of the circumstances by which such material changes are modified is also necessary whenever it is required to direct and govern those changes with special objects, as in the various industrial operations by which useful or ornamental articles are produced, food prepared for consumption, or heat produced for facilitating technical operations, etc. A knowledge of the principles of chemical science being thus necessary for understanding the commonest incidents of life, chemistry is for this reason obviously to be regarded as coming among those subjects that should be taught as early as the use of figures and the arts of writing and reading.

In addition to this purely utilitarian reason for the teaching of chemistry the study of that science affords excellent discipline to the mind and is one of the best means of developing the student's reasoning faculties, which are stimulated by the consciousness that he can test the worth of his ideas by experiment, while, at the same time, a spirit of inquiry is created that may lead to the discovery of additional facts useful to science or to art. The habit of mind that leads to a constant demand for proof of opinions, accuracy of observation and careful procedure is also a very valuable result of the study of chemistry.

The influence exerted by chemical training upon the formation of character is not less important, mainly as regards patience, truthfulness, and courage, without which it is almost impossible to carry on chemical research successfully. The chemist must not be discouraged by the slowness of his processes or by fear of accident. BERTHOLET was engaged for months in producing by a series of operations an appreciable quantity of alcohol and demonstrating the possibility of its synthesis from carbon and water; BUNSEN had to evaporate many tons of water from the Dürcheim springs in order to obtain a few grains of cæsium. But one of the most important virtues developed by the study of chemistry is truthfulness. To quote the words of Dr. SIMPSON, the chemist must be above all things *true*. "He must "not allow his wishes to bias his judgment or pre- "vent him from seeing his researches in their true "light. He must not be satisfied that his results "appear true, but he must believe them to be true; "and having faithfully performed his experiments, "he must record them faithfully. He may often be "obliged to chronicle his own failures and describe "operations that tell against his own theories, but "this hard test of his truthfulness he must not "shrink from."

With the views expressed in reference to the necessity and utility of the study of chemistry, we thoroughly agree with Dr. SIMPSON but we are less in accord with him respecting the promotion of scientific research by endowments. In this country the desideratum appears to be more that of developing a sound appreciation of and respect for science, a recognition of its value and importance for purposes of greater moment to the community at large than the mere notoriety of a small number of individuals. Without that regard for science as a prevalent characteristic of public opinion, we fear that the endowment of research would prove, like the distribution of governmental and other grant funds, only another and a larger opportunity for the exercise of unwholesome patronage.

The papers brought before the Chemical Section this year were, with some few exceptions of a more than usually uninteresting character, and the whole of the business of the Section was concluded at an early hour on Tuesday.

One of the chief features of interest to chemists afforded by the Dublin meeting was the lecture given by Professor DEWAR on Dissociation and Modern Ideas of Chemical Action. We hope to be able to give some further account of this lecture on a future occasion.

In point of attendance the Dublin meeting was a great success, the total number of members and associates having been 2578; in fact it waa one of the largest meetings of the Association ever held. Next year Sheffield is to be the place of meeting and in 1880 it is to be Swansea.

BRITISH PHARMACEUTICAL CONFERENCE.

THE excursion of the Conference to Glendalough, on Thursday, to which we just referred in our last number, was a most enjoyable one, everything having been done by Mr. HAYES and his coadjutors that foresight and hospitality could suggest to enable those who took part in it to see the wonders of Wicklow scenery under the most favourable conditions. Even a smart shower, which had to be braved in the open cars, failed to destroy the enjoyment of the riders, who eventually arrived safely in Dublin, gratified beyond measure with the pleasures of the trip.

At the banquet in the evening, which was served in the Exhibition Palace, there was a large number of guests, including many ladies. The chair was taken by Professor TICHBORNE, who, after the dinner was finished and the royal toasts had been honoured, proposed the toast of the evening, "The Pharmaceutical Conference," coupling with it the name of the President, Mr. G. F. SCHACHT. The next toast was that of the Irish Committee, proposed by Professor ATTFIELD, and associated with the names of Mr. H. N. DRAPER and Mr. WILLIAM HAYES. The former gentleman generously attributed to Mr. HAYES all the credit that might be due for the manner in which the plans of the Committee had been carried out, and the rounds of applause that greeted that gentleman proved that the company was by no means wanting in appreciation of his efforts. Mr. SCHACHT next proposed "The Pharmaceutical Society of Ireland," which was responded to by Professor TICHBORNE and Mr. PRING, and Professor TICHBORNE then gave "The Ladies," which brought forth a whirlwind of fun from Professor CAMERON, speaking on their behalf. In the course of his remarks the Chairman alluded to the fact that he had been active in helping to throw open the doors of the Irish Pharmaceutical Society to the ladies, and said that whilst the subject was pending he had received many encouraging letters from sympathizers on both sides of the Channel, but since the decision no ladies had applied for admittance. The moral was obvious. The other toasts drunk were "The Medical Corporations of Ireland," proposed by Mr. W. D. SAVAGE and acknowledged by Dr. GORDON, Dr. MACNAMARA and Dr. COLLINS; "The Pharmaceutical Society of Great Britain," proposed by Mr. J. BOILEAU and acknowledged by Mr. J. WILLIAMS; and "The Press," proposed by Dr. WHITAKER and replied to by Dr. JACOB and Mr. SCOTT. The toasts were interspersed with songs, which were capitally rendered by some of the guests. At a late hour the company broke up, and thus terminated one of the most successful meetings the Conference has yet held.

WE have much pleasure in stating that the name of Mr. ENOCH PALMER, Chemist and Druggist and Local Secretary of the Pharmaceutical Society, has been placed by order of the Lord Chancellor in the Commission of the Peace for the Borough of Great Grimsby.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The first paper on the list was the Report of the Committee on the Aconite Alkaloids, Messrs. C. R. A. Wright, D.Sc. Lond., J. Williams, F.C.S., and T. B. Groves, F.C.S. Before this report was read, however, the following statement was made on behalf of Messrs. Williams and Groves :—

"The previous reports on the subject have been the joint work of the above Committee, appointed September 4, 1876. The work having developed itself into a research of such a character that it could not well be carried on by a committee it was relegated by the committee to the sole care of Dr. Wright, who with his coadjutor, Mr. Luff, is to be credited with the whole of the work recorded in the annexed report."

FOURTH REPORT ON THE ACONITE ALKALOIDS.

BY C. R. ALDER WRIGHT, D.SC. LOND.,
Lecturer on Chemistry,
AND A. P. LUFF,
Demonstrator of Chemistry, in St. Mary's Hospital Medical School.

Since the presentation of the Third Report last year, a large amount of additional work, chiefly of a purely chemical character, has been accomplished; as this has to a large extent been brought before the Chemical Society during the last few months, and has either been published in the journal of that society, or is about to be published therein, it will not be necessary in the present Report to take up space by detailing the results of analyses, etc. The principal results arrived at are as follows :—

§ 1. *Pseudaconitine.*

It has been found that certain salts of pseudaconitine can be obtained in a well crystallized state by special manipulation; thus, if the approximately pure alkaloid, after several crystallizations from alcohol or ether, be rubbed in a mortar with dilute nitric acid till quite dissolved, and a few drops of strong acid be then added and the rubbing continued, the whole quickly becomes a magma of crystallized nitrate, the crystals containing $C_{36}H_{49}NO_{12}$, HNO_3, $3H_2O$. On regenerating the base from the crystals of nitrate, purified by recrystallization, a much purer substance is obtained than the bodies heretofore analysed; several specimens of pure base thus prepared yielded numbers leading to the formula $C_{36}H_{49}NO_{12}$, H_2O, the water of crystallization being lost below 100°. The formula previously deduced, $C_{36}H_{49}NO_{11}$, has been found to be somewhat incorrect accordingly; the substances previously examined were, in point of fact, mixtures of pure pseudaconitine $C_{36}H_{49}NO_{12}$ and a base derived therefrom by the removal of the elements of water thus:

$$C_{36}H_{49}NO_{12} = H_2O + C_{36}H_{47}NO_{11}.$$

To this new derivative we propose to apply the term *apopscudaconitinc* ; it resembles the parent base very closely in all its properties, and is readily obtained in a pure state by heating pseudaconitine to 100° for some hours, dissolved in a large excess of concentrated tartaric acid solution, or dilute hydrochloric acid. In the latter case a small amount of alteration of a different kind is produced, the pseudaconitine being partially split up into *dimethylprotocatechuic* (or *veratric*) acid and *pseudaconine*, the reactions being indicated by the equations

$$C_{36}H_{49}NO_{12} + H_2O = C_9H_{10}O_4 + C_{27}H_{41}NO_9.$$

With tartaric acid, however, only dehydration to apopseudaconitine takes place. By rendering the final product alkaline with soda, shaking with ether, and spontaneous evaporation of the ethereal solution, more or less pure apopseudaco nitine is obtained, easily purified by conversion into crystallized nitrate by stirring with dilute

nitric acid, filter-pumping and washing the crystals, and regenerating the base by means of soda and ether.

The splitting up of pseudaconitine into veratric acid and pseudaconine, shown in the third report to take place when the base is heated with water to 140° in sealed tubes, takes place much more readily on simply boiling for some hours with alcoholic soda, an inverted condenser being attached; perfect conversion thus ensues, although a little of the pseudaconine undergoes a further change and becomes a resinous substance of slightly *acid* characters. The reaction, however, is not indicated by the equation given in last year's report, viz.,

$$C_{36}H_{49}NO_{11}+H_2O=C_9H_{10}O_4+C_{27}H_{41}NO_8$$

but by that given above; the substance regarded last year as pseudaconine and considered to be $C_{27}H_{41}NO_8$ has been found to be really a dehydrated derivative of true pseudaconine, being indicated by the formula $C_{27}H_{39}NO_8$. This substance, which we propose to call *apopseudaconine*, is not formed at all when the reaction takes place at 100° or slightly below, but is readily produced when water at 140° is used as a saponifying agent, its formation being doubtless due to the dehydration of pseudaconitine to apopseudaconitine, and the subsequent saponification of the latter thus:

$$C_{36}H_{47}NO_{11}+H_2O=C_9H_{10}O_4+C_{27}H_{39}NO_8.$$

Pure pseudaconine is readily and completely soluble in water to a strongly alkaline fluid. From ethereal solution it separates as a resinous film on spontaneous evaporation; after standing for a few days the film becomes changed into a mass of crystalline needles; this crystallization, however, does not readily take place with a large mass of base, probably owing to the retention of small quantities of alcohol, ether, etc., preventing the crystallization. Its aqueous solution precipitates silver nitrate, the precipitate being reduced on heating; it does not, however, reduce Fehling's solution, in which respect it differs from aconine.

When pseudaconitine is heated to 100° with a large excess of glacial acetic acid for some hours, it loses the elements of water, the apopseudaconitine first formed being further acted on by the acetic acid forming *acetylapopseudaconitine*, thus

$$C_{36}H_{49}NO_{11}+C_2H_3OOH=H_2O+C_{26}H_{46}(C_2H_3O)NO_{11}.$$

Like pseudaconitine and apopseudaconitine, this base crystallizes with H_2O, in which respect the pseudaconitine derivatives all differ from the analogous aconitine derivatives described below, all of which are anhydrous; it forms a crystallized nitrate and gold salt, and is readily saponified by alkalies, yielding one equivalent of acetic acid and one of veratric (dimethylprotocatechuic) acid. The same acetyl derivative is also formed when pseudaconitine is acted on by acetic anhydride, the reaction being—

$$C_{36}H_{49}NO_{12}+2(C_2H_3O)_2O = 3C_2H_4O_2+C_{36}H_{46}(C_2H_3O)NO_{11}.$$

The corresponding *benzoylapopseudaconitine* is produced when benzoic anhydride is substituted for acetic anhydride, thus—

$$C_{36}H_{49}NO_{12}+2(C_7H_5O)_2O = 3C_7H_6O_2+C_{36}H_{46}(C_7H_5O)NO_{11}.$$

Like the other members of the pseudaconitine series, this forms a crystallized nitrate and gold salt; the free base, however, only crystallizes indistinctly from ether.

On heating pseudaconine with benzoic anhydride *dibenzoylapopseudaconine* is formed in virtue of the reaction—

$$C_{27}H_{41}NO_9+3(C_7H_5O)_2O = 4C_7H_6O_2+C_{27}H_{38}(C_7H_5O)_2NO_8.$$

this base does not dissolve readily in water, nor does it crystallize easily; the corresponding *diacetylapopseudaconine* is formed by substituting acetic for benzoic anhydride.

From the mode of formation of these derivatives, the following "structural" formulæ are arrived at—

$$\text{Pseudaconitine } (C_{27}H_{37}NO_5)\begin{cases}OH\\OH\\OH\\O\cdot CO\cdot C_6H_3\begin{cases}O\cdot CH_3\\O\cdot CH_3\end{cases}\end{cases}=(X)\begin{cases}OH\\OH\\OH\\O\cdot C_9H_9O_3.\end{cases}$$

$$\text{Apopseudaconitine } (C_{27}H_{37}NO_5)\begin{cases}O\\OH\\O\cdot CO\cdot C_6H_3(O\cdot CH_3)_2\end{cases}=(X)\begin{cases}O\\OH\\O\cdot C_9H_9O_3.\end{cases}$$

$$\text{Acetyl-apopseudaconitine } (C_{27}H_{37}NO_5)\begin{cases}O\\O\cdot CO\cdot CH_3\\O\cdot CO\cdot C_6H_3(O\cdot CH_3)_2\end{cases}=(X)\begin{cases}O\\O\cdot C_2H_3O\\O\cdot C_9H_9O_3.\end{cases}$$

$$\text{Benzoyl-apopseudaconitine } (C_{27}H_{37}NO_5)\begin{cases}O\\O\cdot C_6H_5\\O\cdot CO\cdot C_6H_3(O\cdot CH_3)_2\end{cases}=(X)\begin{cases}O\\O\cdot C_7H_5O\\O\cdot C_9H_9O_3.\end{cases}$$

$$\text{Pseudaconine } (C_{27}H_{37}NO_5)\begin{cases}OH\\OH\\OH\\OH\end{cases}=(X)\begin{cases}OH\\OH\\OH\\OH.\end{cases}$$

$$\text{Apopseudaconine } (C_{27}H_{37}NO_5)\begin{cases}O\\OH\\OH\end{cases}=(X)\begin{cases}O\\OH\\OH.\end{cases}$$

$$\text{Dibenzoyl-apopseudaconine } (C_{27}H_{37}NO_5)\begin{cases}O\\O\cdot CO\cdot C_6H_5\\O\cdot CO\cdot C_6H_5\end{cases}=(X)\begin{cases}O\\O\cdot C_7H_5O\\O\cdot C_7H_5O.\end{cases}$$

$$\text{Diacetyl-apopseudaconine } (C_{27}H_{37}NO_5)\begin{cases}O\\O\cdot CO\cdot CH_3\\O\cdot CO\cdot CH_3\end{cases}=(X)\begin{cases}O\\O\cdot C_2H_3O\\O\cdot C_2H_3O.\end{cases}$$

The drug sold under the name of "aconitine (from *A. Ferox*)" contains, as mentioned in Report III., more or less amorphous bases which do not crystallize or yield crystalline salts. These yield veratric acid on saponification, though to a less extent than pseudaconitine. The amorphous mixture from one batch of rough alkaloidal product obtained from Messrs. Hopkin and Williams yielded on analysis somewhat higher percentages of carbon, hydrogen and nitrogen than pseudaconitine, from which circumstance, and the diminished yield of veratric acid therefrom, it appears probable that the amorphous substance was a mixture produced by various alterations of pseudaconitine during extraction, by dehydration, polymerization, saponification, etc., Although not inert, this amorphous mass seemed to be considerably less physiologically active than pure pseudaconitine. It appears, therefore, to be most desirable that the mixture of variable composition now usually sold as "aconitine (from *A. Ferox*)" should be discarded and the pure crystallized base or its nitrate employed instead. As the nitrate is almost insoluble in water containing 8 to 10 per cent. of nitric acid, its preparation and purification is not a matter of any difficulty; it is not necessary that the alkaloid should have been approximately purified by crystallization from ether, alcohol, etc., in order to prepare a well crystallized and almost chemically pure pseudaconitine nitrate. We have succeeded in converting rough alkaloid, containing 25 to 30 per cent. of uncrystallizable bases, into a crystalline magma by simply rubbing in a mortar with dilute nitric acid, and gradually dropping in strong acid with constant rubbing; on draining the magma on a filter-pump, and washing slightly with water containing 8 to 10 per cent. of nitric acid, an almost pure salt is at once obtained; if required this can readily be purified by dissolving in a minimum of hot water, dropping in strong nitric acid when cool, and vigorously stirring, when almost the whole crystallizes out and is obtained pure by filter-pumping and pressing.

§ 2. *Aconitine.*

In addition to the results detailed in Report III. (entirely corroborated by the further work done) we have found that the theoretical amount of benzoic acid is obtainable from aconitine by simply boiling for some hours with alcoholic potash or soda, whereas complete saponification with water at 140° in sealed tubes does not

take place even after twenty-four hours, although about 85 per cent. of the base is thus decomposed.

Aconitine forms a series of derivatives precisely parallel with those of pseudaconitine above described. When heated to 100° for six to eight hours with a strong solution of tartaric acid it becomes dehydrated, forming *apoaconitine*, thus—

$$C_{33}H_{43}NO_{12} = H_2O + C_{33}H_{41}NO_{11}.$$

The same result is brought about by dilute mineral acids, only in this case a considerable amount of saponification takes place as a second reaction. In consequence of this ready dehydration it is difficult to isolate aconitine from *A. napellus* roots, as the crystallized base is apt to be mixed with apoaconitine, which closely resembles the parent alkaloid. Hence many samples of aconitine, analysed as described in former reports, gave numbers not quite accordant with the formula $C_{33}H_{43}NO_{12}$, but agreeing well with a mixture of aconitine, $C_{33}H_{43}NO_{12}$, and apoaconitine, $C_{33}H_{41}NO_{11}$. The hydrobromide of apoaconitine, however, appears to be more soluble in water than that of aconitine, so that by converting the mixture of bases into hydrobromides, as described in Report II., crystallizing and regenerating the alkaloid from the crystals, pure aconitine is obtained, the apoaconitine remaining in the mother liquors.

On treatment with organic anhydrides, aconitine is affected in just the same way as pseudaconitine: thus acetic anhydride forms *acetylapoaconitine* in virtue of the reaction—

$$C_{33}H_{43}NO_{12} + 2(C_2H_3O)_2O = 3C_2H_4O_2 + C_{43}H_{40}(C_2H_3O)NO_{11},$$

whilst benzoic anhydride similarly forms *benzoylapoaconitine*,

$$C_{33}H_{43}NO_{12} + 2(C_7H_5O)_2O = 3C_7H_6O_2 + C_{33}H_{40}(C_7H_5O)NO_{11}.$$

These bases in most respects resemble the corresponding pseudaconitine derivatives.

On treating aconine with benzoic anhydride it forms *dibenzoylapoaconine*, apparently identical with benzoyl apoaconitine from aconitine; heating with dilute mineral acids converts aconine into *apoaconine*, thus—

$$C_{26}H_{39}NO_{11} = H_2O + C_{26}H_{37}NO_{10}.$$

From these data the following "structural" formulæ are arrived at—

Aconitine ($C_{26}H_{25}NO_7$)	OH, OH, OH, O·C_7H_5O	=(Y)	OH, OH, OH, O·C_7H_5O.
Apoaconitine ($C_{26}H_{35}NO_7$)	O, OH, O·C_7H_5O	=(Y)	O, OH, O·C_7H_5O.
Acetyl apoaconitine ($C_{26}H_{35}NO_7$)	O, O·C_2H_3O, O·C_7H_5O	=(Y)	O, O·C_2H_3O, O·C_7H_5O.
Benzoyl apoaconitine, or dibenzoyl apoaconine ($C_{26}H_{35}NO_7$)	O, O·C_7H_5O, O·C_7H_5O	=(Y)	O, O·C_7H_5O, O·C_7H_5O.
Aconine ($C_{26}H_{35}NO_7$)	OH, OH, OH, OH	=(Y)	OH, OH, OH, OH.
Apoaconine $C_{26}H_{35}NO_7$)	O, OH, OH	=(Y)	O, OH, OH.

The remarks made in the previous section as to the great desirability of the substitution in the drug trade and for medicinal purposes of the definite pure aconite alkaloids for the amorphous variable mixtures at present in the market apply with as great force to aconitine as to pseudaconitine. Aconitine is so readily crystallizable from ether that the preparation of the base free from amorphous alkaloids is a matter of great ease; or the process of conversion into crystallized nitrate so as to separate non-crystalline bases might be equally well adopted. So far as we are able to judge apopseudaconitine and apoaconitine are not inferior in activity to the parent bases, so that there would be no necessity to separate the "apo" derivatives, should they be present, crystallizing out with the parent alkaloids. As mentioned in former reports, the use of tartaric acid instead of sulphuric acid to acidulate the alcohol used in percolating is likely to cause an increased yield of pure crystallized alkaloids, the vegetable acid causing no saponification on continued heating with aconitine, whilst dilute mineral acids rapidly bring about more or less saponification and consequent loss of crystallizable base.

§ 3. *Alkaloids from Japanese Aconite Roots.*

At the last meeting of the Conference Dr. Paul and Mr. Kingzett read a paper on this subject, in which they stated that they had isolated from a batch of these roots a crystallizable alkaloid which did not form crystallizable salts, and which gave the following numbers on analysis, from which the identity of their product with pseudaconitine seemed, as pointed out by one of us during the discussion of the paper, to be highly probable:—

Calculated for pseudaconitine $C_{36}H_{49}NO_{12}$		Found (Paul and Kingzett)	
Carbon	62·88	62·926	
Hydrogen . . .	7·13	7·726	7·900
Nitrogen . . .	2·04	2·567 (by volume)	

for nitrogen determinations by volume are usually somewhat in excess of the truth, whilst at the time of their experiments being made it was not known that pseudaconitine formed crystallized salts. The authors, however, assigned to their product the formula,

$$C_{29}H_{43}NO_9,$$

requiring carbon 63·38, hydrogen, 7·83, nitrogen, 2·55, notwithstanding that this formula requires slightly more hydrogen than that found as the mean of their analyses and perceptibly more than that found as the lower value, whilst they wholly neglected to confirm the molecular weight deduced from the nitrogen determination by the analysis of a gold salt or other derivative, such as the hydrochloride or hydrobromide.

We have examined the alkaloids extracted from more than one different batch of roots imported from Japan; whilst our results are as yet incomplete, so that we refrain from details, we have got clear evidence that the crystallizable active alkaloid from different batches of roots is in each case the same body, and that it is different from both aconitine and pseudaconitine. We are doubtful, however, whether the base that we have isolated is the same as that partially examined by Paul and Kingzett, inasmuch as it readily forms well crystallized salts, especially the nitrate, hydrochloride and hydrobromide. The numbers obtained by us lead to a formula considerably different from that assigned on such insufficient grounds by Paul and Kingzett, and lying close to that of aconitine. Moreover, like aconitine, the base from the Japanese roots forms one equivalent of benzoic acid on saponification together with a complementary product closely resembling aconine. Whilst in analytical numbers and general chemical and physical properties the new base is closely connected with aconitine, it differs therefrom in one very remarkable particular, viz., that whilst by the action of benzoic anhydride in excess aconitine and its decomposition product, aconine, form each the same *dibenzoylated* derivative, the base from the Japanese roots and its saponification product form by similar treatment a *tetrabenzoylated* derivative, apparently the same whichever base be benzoylated.

Mr. Groves (Weymouth) said the amount of labour performed by Dr. Wright, in the earlier part of which Mr. Williams and himself had assisted, was enormous, and it was very satisfactory to find that they were at last touching solid ground, and that Dr. Wright's results

were likely to lead to the very practical consequence that they would be able to furnish the medical profession with crystallizable salts of the aconite series of a definite chemical character and equally definite physiological action. Up to the present time the use of aconite in any form had been almost impossible, because no two samples of the aconite root were equal or even similar in effect; whilst the salts or preparations called aconitine varied almost as much, some being almost inert and others of very great activity. The differences he hoped would soon be at an end, and it was a great satisfaction to think that the action of the Conference had been instrumental in producing so desirable a result. There was of course, still much to be done. The Japanese roots seemed to open quite a new field for investigation, which he hoped would be worked as exhaustively as this had been. He was proud of having been the coadjutor of Dr. Wright in the beginning of his researches, but must disclaim any share in the able paper which had just been read.

Mr. WILLIAMS said Dr. Wright had most justly pointed out that it was highly desirable that medical men should have supplied to them, if possible, pure aconitine, not the mixture frequently sold as commercial aconitine. He would remind the Conference that the article Dr. Wright had referred to as having been supplied to him for experiment was the simple crude alkaloid derived from the aconite root, and did not profess to be purified. He quite agreed in the importance of aconitine being purified, and of a definite pure article being always used, but it was after all a question of cost. Competition had so brought down the price of the ordinary commercial aconitine that it could only be made in a simple and somewhat crude manner. It was pretty well known that a much purer article could be supplied, but the cost was very much greater, one reason being, as was admitted by Dr. Wright, that a great deal of that which was lost in the process of purification was as active medicinally as that which remained. That was the only objection he saw to the process, and possibly it might in some respects be modified so as to be more suitable to the production of commercial aconitine, without so increasing the price as to place it almost beyond the reach of ordinary medical practice.

Mr. LONG (London) said Mr. Williams had rather anticipated what he thought on the matter, with regard to the question of cost. At the same time he thought it was time pharmacists took a more manly tone and insisted on having the best articles and making their customers pay a fair price for them. After all, the cost of a chemist's wares was very small compared to what were called medical comforts.

Dr. PAUL asked if any specimens of the definite substances and of the crystallizable salts mentioned in the reports had been forwarded for exhibition.

Professor ATTFIELD said no specimens had been sent.

Dr. PAUL wished to call attention to the fact that on the last occasion the Committee appointed to investigate this subject brought forward a report in which it was stated that the alkaloids of aconite had a certain chemical composition and certain relations which appeared very interesting. He would take, for example, the alkaloid to which Dr. Wright had given the name of pseudaconitine. The formula then given to it was $C_{36}H_{49}NO_{11}$, and it was described as being crystallizable but furnishing uncrystallizable salts. It was described as remarkably prone to change in common with most of the basic products known under the name of aconite alkaloids; when heated with dilute mineral acids it was represented as giving rise to another base which had this composition—$C_{27}H_{41}NO_8$; and this change was represented as consisting in what was termed saponification, *i.e.*, H_2O was added and the base then separated into pseudaconine and dimethylprotocatechuic acid, the composition of which was $C_9H_{10}O_4$. Now in the present paper they were told that the substance then examined and called pseudaconine was now found to be really another substance altogether, and that it was the product of another alteration of pseudaconitine. This product was now called apopseudaconitine and described as having the composition $C_{27}H_{39}NO_8$. There were some other considerations he might have referred to if time permitted, but this instance was enough, he thought, to show that the conclusions brought forward in these reports must be received with a considerable amount of caution. As a general rule, when chemical results were called in question, the revolutionary movement came from outside; but in this case Dr. Wright and Mr. Luff were their own iconoclasts, for the real purport of this report was to state that the results given in the report of last year were not correct, and to supply a rectification of them. On the basis alone of such results as these, however, a column of elaborate structural formulæ had been built up, which he ventured to say had no sufficient foundation in the facts which had been brought forward. Passing on to the alkaloid of the Japanese aconite, that was described by Mr. Kingzett and himself last year, and submitted to the Conference chiefly with the object of showing that the alkaloid obtained from that root was different from that obtained either from *A. Napellus* or *A. Ferox*, he would recall to their minds that Dr. Wright in speaking on the subject did not hesitate to say that, judging from his own experience, the alkaloid they had prepared and described was really nothing but a mixture of some indefinite substance with some other equally indefinite decomposition product, and that he had frequently obtained in the course of his experiments the same product as they had experimented on. Now there were sufficient data given in the two papers then read to show that there was no ground for that statement, but he now saw some reason for the positive way in which Dr. Wright spoke of the possibility of getting mixtures of compounds. That appeared now by his own showing to have been the result of Dr. Wright's experience. So far as the present report went, he now stated that the data upon which he based his opinion last year did not relate to an individual substance, but really to an indefinite mixture of at least two substances. And in the remarks Dr. Wright now made on the Japanese aconite he only repeated in exactly the same words the conclusion which Mr. Kingzett and himself submitted last year, viz., that the alkaloid of Japanese aconite was different both from aconitine and from pseudaconitine. Unfortunately his time was so much occupied with other necessary work that he had very little left to devote to investigations of the kind dealt with in these reports, but their importance in various relations was such that one should be grateful for their being carried out by others who had more leisure, but individually he should have been better pleased if the experiments described in the report had been so far right as to place before the Conference a definite account of the characters and chemical relations of the aconite alkaloids. That they had not done so was sufficiently evident when this year's report was compared with that of last year, and consequently the general impression produced was one of distrust. Therefore he again repeated, that these conclusions, generally, ought in his opinion to be received with very great caution, and they required to be supported by considerably weightier evidence than any they at present possessed.

Professor ATTFIELD regretted that Dr. Wright was not present to answer the remarks of Dr. Paul. He would not attempt to do so, but would draw attention to the fact that the substances which Dr. Wright obtained last year, as he stated himself, were not quite pure; but having still further purified them, he now gave the analysis of the purified article. In his opinion Dr. Wright deserved credit, not discredit, for having done so. At the same time he was inclined to think that Dr. Wright would admit that even now the formulæ he had offered for these purified substances might in some future year turn out to be not quite correct. The results were given last year as far as he could go, and if the Conference enabled him to continue his researches he would

no doubt again have to correct his present results. No chemist probably would be surprised if such proved to be the case, but would be only grateful to Dr. Wright for having corrected his earlier results.

Mr. T. B. GROVES remarked that the whole of these rectifications of the formulæ of pseudaconitine and its decomposition products were based on the accidental discovery of a mode of crystallizing the nitrate of pseudaconitine.

The PRESIDENT in moving a vote of thanks to Dr. Wright, said there was no doubt they were approaching solid ground on this important matter, and he thought the general desire would be that this matter should be further pursued, and he hoped the Executive Committee would be able to make a further grant for that purpose.

The next paper read was a—

REPORT ON BRUCIA AND THE CONSTITUENTS OF STRYCHNOS BARK.

BY W. A. SHENSTONE, F.I.C.

I have to report, as a grantee of the Conference, that papers on these subjects have been read at Evening Meetings of the Pharmaceutical Society in January and December, 1877, in which details were given of the results enumerated below.

I. After many experiments it was found that the yield of strychnia obtained by acting on brucia with nitric acid steadily decreases as additional processes of purification are employed, till finally it completely disappears, thus confirming the results arrived at by Mr. Cownley; and subsequent work has satisfied me that an application of Sonnenschein's process may be made a fairly delicate test for the presence of strychnia in brucia.

II. Several specimens of commercial brucia have been examined. All contained strychnia: the proportion varying from 1·05 to ·25 per cent., which, regarding the activity of the impurity, may be considered as an important quantity.

I have proposed a method of purifying brucia, which depends on the power of strychnia to decompose salts of the former alkaloid. It consists in crystallizing the brucia from boiling water to which some acetic acid has been added (as the residual brucia may be easily recovered, I add enough acid to neutralize half the brucia), then washing, draining and drying the crystals, this operation being repeated if necessary. I find that labour and waste are avoided by stirring the dry brucia with a little water and the acid, and adding them gradually with agitation to the boiling water; this plan prevents the formation of masses of a white solid, difficult of solution, said by Schützenberger to be a variety of igasurine, but which I believe to be wholly or partly dehydrated brucia, though I have not yet made any analysis of the substance.

The statements in the handbooks regarding the solubility of brucia in boiling water are somewhat divergent; I have found that in 'Pharmacographia' to be most accurate.

III. An examination of false Angostura bark has shown that this bark does contain strychnia; the rather small quantity present being probably the reason that its presence was overlooked by Pelletier and Caventou.

IV. Brucia yields decomposition products to the action of weak acid, weak alkali and water. These bodies promise to be chiefly of chemical interest and I am at present engaged upon them, aided, I am happy to say, by a grant from the Chemical Research Fund, as I have been in the above work by the grant kindly afforded to me by the Conference.

On the motion of the PRESIDENT, a vote of thanks was given to Mr. Shenstone for his researches.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE PRESIDENT'S ADDRESS.

(*Concluded from page* 139.)

It has often been asked whether modern research in the field of pure mathematics has not so completely outstripped its physical applications as to be practically useless; whether the analyst and the geometer might not now and for a long time to come, fairly say "hic artem remumque repono," and turn his attention to mechanics and to physics. That the pure has outstripped the applied is largely true; but that the former is on that account useless is far from true. Its utility often crops up at unexpected points; witness the aids to classification of physical quantities, furnished by the ideas (of Scalar and Vector) involved in the calculus of quaternions; or the advantages which have accrued to physical astronomy from Lagrange's equations and from Hamilton's principle of varying action; on the value of complex quantities, and the properties of general integrals, and of general theorems on integration for the theories of electricity and magnetism. The utility of such researches can in no case be discounted or even imagined beforehand. Who, for instance, would have supposed that the calculus of forms or the theory of substitutions would have thrown much light upon ordinary equations, or that Abelian functions and hyperelliptic transcendents would have told us anything about the properties of curves, or that the calculus of operations would have helped us in any way towards the figure of the earth? But upon such technical points I must not now dwell. If, however, as I hope, it has been sufficiently shown that any of these more extended ideas enable us to combine together, and to deal with as one, properties and processes which from the ordinary point of view present marked distinctions, then they will have justified their own existence; and in using them we shall not have been walking in a vain shadow nor disquieting our brains in vain.

These extensions of mathematical ideas would, however, be overwhelming if they were not compensated by some simplifications in the processes actually employed. Of these aids to calculation I will mention only two, viz., symmetry of form and mechanical appliances, or say, mathematics as a fine art, and mathematics as a handicraft. And first, as to symmetry of form. There are many passages of algebra in which long processes of calculation at the outset seem unavoidable. Results are often obtained in the first instance through a tangled maze of formulæ, where at best we can just make sure of our process step by step, without any general survey of the path which we have traversed, and still less of that which we have to pursue. But almost within our own generation a new method has been devised to clear this entanglement. More correctly speaking the method is not new, for it is inherent in the processes of algebra itself, and instances of it, unnoticed perhaps or disregarded, are to be found cropping up throughout nearly all mathematical treatises. By Lagrange, and to some extent also by Gauss, among the older writers, the method of which I am speaking was recognized as a principle; but besides these perhaps no others can be named until a period within our own recollection. The method consists in symmetry of expression. In algebraical formulæ combinations of the quantities entering therein occur and recur; and by a suitable choice of these quantities the various combinations may be rendered symmetrical, and reduced to a few well-known types. This having been done, and one such combination having been calculated, the remainder, together with many of their results, can often be written down at once, without further calculations, by simple permutations of the letters. Symmetrical expressions, moreover, save as much time and trouble in reading as in writing. Instead of wading laboriously through a series of expressions which, although successively dependent, bear no outward resemblance to one another, we may read off symmetrical formulæ of almost any length at a glance. A page of such formula becomes a picture; known forms are seen in definite groupings; their relative positions, or perspective as it may be called, their very light and shadow, convey their meaning almost as much through the artistic faculty as through any conscious ratiocinative process. Few principles have been more suggestive of extended ideas or of new views and

relations than that of which I am now speaking. In order to pass from questions concerning plane figures to those which appertain to space, from conditions having few degrees of freedom to others which have many—in a word, from more restricted to less restricted problems, we have in many cases merely to add lines and columns to our array of letters or symbols already formed and then read off pictorially the extended theorems.

Next as to mechanical appliances. Mr. Babbage, when speaking of the difficulty of insuring accuracy in the long numerical calculations of theoretical astronomy, remarked that the science which in itself is the most accurate and certain of all had, through these difficulties, become inaccurate and uncertain in some of its results. And it was doubtless some such consideration as this, coupled with his dislike of employing skilled labour where unskilled would suffice, which led him to the invention of his calculating machines. The idea of substituting mechanical for intellectual power has not lain dormant; for beside the arithmetical machines whose name is legion (from Napier's Bones, Earl Stanhope's calculator, to Shultz and Thomas's machines now in actual use) an invention has lately been designed for even a more difficult task. Professor James Thomson has in fact recently constructed a machine which, by means of the mere friction of a disk, a cylinder, and a ball, is capable of effecting a variety of the complicated calculations which occur in the highest application of mathematics to physical problems. By its aid it seems that an unskilled labourer may, in a given time, perform the work of ten skilled arithmeticians. The machine is applicable alike to the calculation of tidal, of magnetic, of meteorological, and perhaps also of all other periodic phenomena. It will solve differential equations of the second and perhaps of even higher orders. And through the same invention the problem of finding the free motions of any number of mutually attracting particles, unrestricted by any of the approximate suppositions required in the treatment of the lunar and planetary theories, is reduced to the simple process of turning a handle

When Faraday had completed the experimental part of a physical problem, and desired that it should thenceforward be treated mathematically, he used irreverently to say, "Hand it over to the calculators." But truth is ever stranger than fiction; and if he had lived until our day he might with perfect propriety have said, "Hand it over to the machine."

Had time permitted, the foregoing topics would have led me to point out that the mathematician, although concerned only with abstractions, uses many of the same methods of research as are employed in other sciences, and in the arts, such as observation, experiment, induction, imagination. But this is the less necessary because the subject has been already handled very ably, although with greater brevity than might have been wished, by Professor Sylvester in his address to Section A at our meeting at Exeter.

In an exhaustive treatment of my subject there would still remain a question which in one sense lies at the bottom of all others, and which through almost all time has had an attraction for reflective minds, viz., what was the origin of mathematical ideas? Are they to be regarded as independent of, or dependent upon, experience? The question has been answered sometimes in one way and sometimes in another. But the absence of any satisfactory conclusion may after all be understood as implying that no answer is possible in the sense in which the question is put, or rather that there is no question at all in the matter, except as to the history of actual facts. And even if we distinguish, as we certainly should, between the origin of ideas in the individual and their origin in a nation or mankind, we should still come to the same conclusion. If we take the case of the individual all we can do is to give an account of our own experience; how we played with marbles and apples; how we learnt the multiplication table, fractions, and proportion; how we were afterwards amused to find that common things conformed to the rules of number; and later still how we came to see that the same laws applied to music and to mechanism, to astronomy, to chemistry, and to many other subjects. And then, on trying to analyse our own mental processes, we find that mathematical ideas have been imbibed in precisely the same way as all other ideas, viz., by learning, by experience, and by reflection. The apparent difference in the mode of first apprehending them and in their ultimate cogency arises from the difference of the ideas themselves, from the preponderance of quantitative over qualitative considerations in mathematics, from the notions of absolute equality and identity which they imply.

If we turn to the other question, How did the world at large acquire and improve its idea of number and of figures? How can we scan the interval between the savage who counted only by the help of outward objects, to whom fifteen was "half the hands and both the feet," and Newton or Laplace? The answer is the history of mathematics and its successive developments, arithmetic, geometry, algebra, etc., The first and greatest step in all this was the transition from number in the concrete to number in the abstract. This was the beginning not only of mathematics but of all abstract thought. The reason and mode of it was the same as in the individual. There was the same general influx of evidence, the same unsought for experimental proof, the same recognition of general laws running through all manner of purposes and relations of life. No wonder then if, under such circumstances, mathematics, like some other subjects and perhaps with better excuse, came after a time to be clothed with mysticism; nor that even in modern times, they should have been placed upon an *à priori* basis, as in the philosophy of Kant. Number was so soon found to be a principal common to many branches of knowledge that it was readily assumed to be the key to all. It gave distinctness of expression, if not clearness of thought, to ideas which were floating in the untutored mind, and even suggested to it new conceptions. In "the one," "the all" "the many in one" (terms of purely arithmetic origin), it gave the earliest utterance to men's first crude notions about God and the world. In "the equal," "the solid," "the straight," and "the crooked," which still survive as figures of speech among ourselves, it supplied a vocabulary for the moral notions of mankind, and quickened them by giving them the power of expression. In this lies the great and enduring interest in the fragments which remain to us of the Pythagorean philosophy.

The consecutive processes of mathematics led to the consecutive processes of logic; but it was not until long after mankind had attained to abstract ideas that they attained to any clear notion of their connection with one another. In process of time the leading ideas of mathematics became the leading ideas of logic. The "one" and the "many" passed into the "whole" and its "parts;" and thence into the "universal" and the "particular." The fallacies of logic, such as the well-known puzzle of Achilles and the tortoise, partake of the nature of both sciences. And perhaps the conception of the infinite and infinitesimal, as well as of negation, may have been in early times transferred from logic to mathematics. But the connection of our ideas of number is probably anterior to the connection of any of our other ideas. And as a matter of fact, geometry and arithmetic had already made considerable progress when Aristotle invented the syllogism.

General ideas there were, besides those of mathematics—true flashes of genius which saw that there must be general laws to which the universe conforms, but which saw them only by occasional glimpses, and through the distortion of imperfect knowledge; and although the only records of them now remaining are the inadequate representations of later writers, yet we must still remember that to the existence of such ideas is due not only the conception, but even the possibility of physical science.

But these general ideas were too wide in their grasp, and in early days at least were connected with their subjects of application by links too shadowy to be thoroughly apprehended by most minds ; and so it came to pass that one form of such an idea was taken as its only form, one application of it as the idea itself ; and philosophy, unable to maintain itself at the level of ideas, fell back upon the abstractions of sense, and, by preference, upon those which were most ready to hand—namely, those of mathematics. Plato's ideas relapsed into a doctrine of numbers, mathematics into mysticism, into neo-Platonism, and the like. And so, through many long ages, through good report and evil report, mathematics have always held an unsought-for sway. It has happened to this science as to many other subjects, that its warmest adherents have not always been its best friends. Mathematics have often been brought into matters where their presence has been of doubtful utility. If they have given precision to literary style, that precision has sometimes been carried to excess, as in Spinoza and perhaps Descartes ; if they have tended to clearness of expression in philosophy, that very clearness has sometimes given an appearance of finality not always true; if they have contributed to definition in theology, that definiteness has often been fictitious, and has been attained at the cost of spiritual meaning. And, coming to recent times, although we may admire the ingenuity displayed in the logical machines of Earl Stanhope and of Stanley Jevons, in the "Formal Logic" of De Morgan, and in the "Calculus" of Boole; although as mathematicians we may feel satisfaction that these feats (the possibility of which was clear *à priori*) have been actually accomplished ; yet we must bear in mind that their application is really confined to cases where the subject-matter is perfectly uniform in character, and that beyond this range they are liable to encumber rather than to assist thought.

Not unconnected with this intimate association of ideas and their expression is the fact that, whichever may have been cause, whichever effect, or whether both may not in turn have acted as cause and effect, the culminating age of classic art was contemporaneous with the first great development of mathematical science. In an earlier part of this discourse I have alluded to the importance of mathematical precision recognized in the technique of art during the Cinquecento ; and I have now time only to add that on looking still further back it would seem that sculpture and painting, architecture and music, nay, even poetry itself, received a new, if not their first true, impulse at the period when geometric form appeared fresh chiselled by the hand of the mathematician, and when the first ideas of harmony and proportion rang joyously together in the morning tide of art.

Whether the views on which I have here insisted be in any way novel or whether they be merely such as from habit or from inclination are usually kept out of sight, matters little. But whichever be the case, they may still furnish a solvent of that rigid aversion which both literature and art are too often inclined to maintain towards science of all kinds. It is a very old story that to know one another better, to dwell upon similarities rather than upon diversities, are the first stages towards a better understanding between two parties; but in few cases has it a truer application than in that here discussed. To recognize the common growth of scientific and other instincts until the time of harvest is not only conducive to a rich crop, but it is also a matter of prudence, lest in trying to root up weeds from among the wheat, we should at the same time root up that which is as valuable as wheat. When Pascal's father had shut the door of his son's study to mathematics and closeted him with Latin and Greek, he found on his return that the walls were teeming with formulæ and figures, the more congenial product of the boy's mind. Fortunately for the boy, and fortunately also for science, the mathematics were not torn up, but were suffered to grow together with other subjects. And all said and done, the lad was not the worse scholar or man of letters in the end. But, truth to tell, considering the severance which still subsists in education and during our early years between literature and science, we can hardly wonder if when thrown together in the afterwork of life they should meet as strangers, or if the severe garb, the curious implements, and the strange wares of the latter, should seem little attractive when contrasted with the light companionship of the former. The day is yet young, and in the early dawn many things look weird and fantastic which in fuller light prove to be familiar and useful. The outcomings of science, which at one time have been deemed to be but stumbling-blocks scattered in the way, may ultimately prove stepping stones which have been carefully laid to form a pathway over difficult places for the children of "sweetness and of light."

The instances on which we have dwelt are only a few out of many in which mathematics may be found ruling and governing a variety of subjects. It is as the supreme result of all experience, the framework in which all the varied manifestations of nature have been set, that our science has laid claim to be the arbiter of all knowledge. She does not, indeed, contribute elements of fact, which must be sought elsewhere; but she sifts and regulates them ; she proclaims the laws to which they must conform if those elements are to issue in precise results. From the data of a problem she can infallibly extract all possible consequences, whether they be those first sought, or others not anticipated; but she can introduce nothing which was not latent in the original statement. Mathematics cannot tell us whether there be or be not limits to time or space; but to her they are both of indefinite extent, and this in a sense which neither affirms nor denies that they are either infinite or finite. Mathematics cannot tell us whether matter be continous or discrete in its structure; but to her it is indifferent whether it be one or the other, and her conclusions are independent of either particular hypothesis. Mathematics can tell us nothing of the origin of matter, of its creation or its annihilation ; she deals only with it in a state of existence ; but within that state its modes of existence may vary from our most elementary conception to our most complex experience. Mathematics can tell us nothing beyond the problems which she specifically undertakes; she will carry them to their limit, but there she stops, and upon the great region beyond she is imperturbably silent.

Conterminous with space and coeval with time is the kingdom of mathematics; within this range her dominion is supreme ; otherwise than according to her order nothing can exist ; in contradiction to her laws nothing takes place. On her mysterious scroll is to be found written for those who can read it that which has been, that which is, and that which is to come. Everything material which is the subject of knowledge has number, order, or position ; and these are her first outlines for a sketch of the universe. If our more feeble hands cannot follow out the details, still her part has been drawn with an unerring pen, and her work cannot be gainsayed. So wide is the range of mathematical science, so indefinitely may it extend beyond our actual powers of manipulation, that at some moments we are inclined to fall down with even more than reverence before her majestic presence. But so strictly limited are her promises and powers, about so much that we might wish to know does she offer no information whatever, that at other moments we are fain to call her results but a vain thing, and to reject them as a stone when we had asked for bread. If one aspect of the subject encourages our hopes, so does the other tend to chasten our desires; and he is perhaps the wisest, and in the long run the happiest among his fellows, who has learnt not only this science, but also the larger lesson which it indirectly teaches, namely, to temper our aspirations to that which is possible, to moderate our desires to that which is attainable, to restrict our hopes to that of which accomplishment, if not immediately practicable, is at least distinctly within the range of conception. That

which is at present beyond our ken may, at some period and in some manner as yet unknown to us, fall within our grasp; but our science teaches us, while ever yearning with Goethe for "Light, more light," to concentrate our attention upon that of which our powers are capable, and contentedly to leave for future experience the solution of problems to which we can at present say neither yea nor nay.

It is within the region thus indicated that knowledge in the true sense of the word is to be sought. Other modes of influence there are in society and in individual life, other forms of energy besides that of intellect. There is the potential energy of sympathy, the actual energy of work; there are the vicissitudes of life, the diversity of circumstance, health, and disease, and all the perplexing issues, whether for good or for evil, of impulse and of passion. But although the book of life cannot at present be read by the light of science alone nor the wayfarers be satisfied by the few loaves of knowledge now in our hands, yet it would be difficult to overstate the almost miraculous increase which may be produced by a liberal distribution of what we already have, and by a restriction of our cravings within the limits of possibility.

In proportion as method is better than impulse, deliberate purpose than erratic action, the clear glow of sunshine than irregular reflection, and definite utterances than an uncertain sound; in proportion as knowledge is better than surmise, proof than opinion—in that proportion will the mathematician value a discrimination between the certain and the uncertain, and a just estimate of the issues which depend upon one motive power or the other. While on the one hand he accords to his neighbours full liberty to regard the unknown in whatever way they are led by the noblest powers that they possess; so on the other he claims an equal right to draw a clear line of demarcation between that which is a matter of knowledge and that which is, at all events, something else, and to treat the one category as fairly claiming our assent, the other as open to further evidence. And yet, when he sees around him those whose aspirations are so fair, whose impulses so strong, whose receptive faculties so sensitive, as to give objective reality to what is often but a reflex from themselves, or a projected image of their own experience, he will be willing to admit that there are influences which he cannot as yet either fathom or measure, but whose operation he must recognize among the facts of our existence.

CHEMICAL SECTION.

This Section met on Thursday, August 15th. The proceedings were opened by the delivery of the following

Presidential Address.

BY PROFESSOR MAXWELL SIMPSON, M.D., F.R.S.

My position here is a highly honourable but by no means a comfortable one. Naturally you expect to hear from me something new about the science which occupies the attention of this section, and I have the miserable feeling that I must disappoint you. How can I possibly find a fact in chemistry with which you are not already acquainted? If in order to cater for you I go to France, Germany, Russia, or America, I find the abstractors of the Chemical Society have been there before me and have swept everything of value into their journal. Chemists are now kept perfectly acquainted with the progress of science in every part of the world, and therefore the *raison d'être* of this address, so far as announcing the discoveries of the year is concerned, has passed away. I therefore propose, instead of giving you a concentrated essence of the last twelve numbers of the *Journal of the Chemical Society*, to bring before you the claims of this science to a place in general education, and the claims of original research to a place in the curriculum for higher degrees in our universities.

I have been devoted to chemistry all my life. It has been my business and my pleasure. The longer I live the more deeply am I impressed with the advantages to be derived from its study, and I am anxious that these advantages should be shared by the rising generation.

Whether we take into account the value of the knowledge acquired, the discipline of the intellectual faculties in acquiring that knowledge, or the effect on the character, surely we have a right to give the study of this science a prominent place in our schools and colleges. It would be difficult to over-estimate the value and extent of the knowledge we derive from chemistry. Without it we can know nothing about the air we breathe, the water we drink, or the food we eat; we cannot understand the processes of combustion, respiration, fermentation, putrefaction, or the endless chemical changes which are continually in operation around us, and which affect our lives for good or for evil. In a word, the whole of the phenomena of nature must for ever remain to us more or less an inscrutable mystery.

Again, is it not desirable that we should have some acquaintance with the chemical arts, from which we derive so many of our comforts and luxuries? Should we not know something of the arts of photography, dyeing, metallurgy—something of the manufacture of glass and china, and of the thousand beautiful things that are constantly in our hands? Not only is the knowledge we obtain from chemistry very considerable in itself, but it furnishes us with a key, which enables us to unlock vast stores of knowledge contained in several other sciences; these are, physics, geology, mineralogy, physiology, and I may now add astronomy. Physics and chemistry are so intimately connected that it is difficult to say where the one begins and the other ends. The help that chemistry gives to physics is shown by the numbers of chemists who have distinguished themselves as physicists. I may mention a few belonging to our own time—Andrews, Bunsen, Faraday, Frankland, Graham, Guthrie, and Regnault.

With regard to mental discipline, the mind of the student is exercised in both the inductive and deductive methods of reasoning. His original faculties are stimulated by the consciousness that he can in many cases readily test the worth of his ideas by experiment. With inexpensive apparatus and a good balance the intelligent student can make out for himself some of the laws and many of the facts of the science, and, it may be, also add to them. He glides insensibly from the known to the unknown. Indeed his spirit of inquiry demands in most cases to be curbed rather than spurred. Some students are constantly finding out new methods of analysis or discovering the precious metals in impossible places.

The readiness with which we can cross over into the *terra incognita* of chemistry and make little explorations there, constitutes, in my opinion, the great charm of this science and to a great extent its value as an educational agent. What I wish to insist upon is that the student of chemistry can reach the field of original work sooner than the student of most other sciences. Once he commences original research the development of his intellectual faculties rapidly progresses. His imagination is daily exercised in propounding new theories and devising experiments in order to ascertain their truth or falsehood. And what more valuable intellectual training can there be than the habit of subjecting our ideas to the test of inexorable experiment. In the world outside chemistry we are, alas! too ready to take things for granted. The chemist's motto is, "Prove all things." The ancients adopted a different method: they assumed certain principles and reasoned from them. They therefore did little in science.

Chemistry promotes in a remarkable manner accuracy, thoroughness, and circumspection. An organic analysis requires six weighings: if any one of these is inaccurate the results are worthless. A qualitative test carelessly applied may cause us, in a research, to waste months in the pursuit of a phantom or will-o'-the-wisp which can

have no corporeal existence. If we have to employ absolute alcohol in our experiments we must not be satisfied with going through the ceremony of making it absolute, but we must assure ourselves that it *is* absolute. Unless we are sure of every step in our research our results become doubtful, and therefore of no value.

On the circumspection, also, of the original worker large demands are made. The avenues by which error may creep in and vitiate his results are very numerous. These he must foresee and endeavour to close up. Laboratory work teaches us to use our senses aright, sharpens our powers of observation, and prevents us from reasoning rashly from appearances. It also promotes manual dexterity and trains the hands to work in subordination to the head.

Perhaps in no other science is the student so deeply impressed with the order and economy of nature, the immutability of her laws, and the exactness of her operations. These impressions will no doubt in after life impart seriousness to his character and save him from the adoption of many a wild theory.

I come now to the effect of original work on the character. Many virtues are necessary to the chemist—courage, resolution, truthfulness, and patience. He is often obliged to perform experiments which are attended with great danger, and no man can hope to fight long with the elements without carrying away many a scar. Sometimes fatal accidents occur. Many years ago, Mr. Hennel, of the Apothecaries' Hall, London, lost his life by the explosion of a fulminating powder which he was preparing for the East India Company. And many of us recollect the sad death of young Mr. Chapman, a distinguished chemist whom I had the pleasure of knowing, who was literally blown to atoms while working in the Hartz Mountains on a new dynamite which he had himself discovered. I must tell the ladies, however, that accidents are not always so disastrous, but that often one may escape with merely the loss of an eye. But the chemist must not be discouraged by fear of accident, neither must he be disheartened by the temporary failure of his experiments, nor at the slowness of his processes. Bunsen was obliged to evaporate forty-four tons of the waters of the Dürcheim springs in order to obtain two hundred grains of his new metal, cæsium. It took Bertholet several months to form, by a series of synthetical operations, an appreciable quantity of alcohol from water and carbon, derived from carbonate of baryta. Many years ago, in the laboratory of Wurtz—my honoured master—a poor student, whom I knew, was carrying from one room to another a glass globe, which contained the product of a month's continuous labour, when the bottom of the globe fell out, and the contents were lost. Nothing daunted, he recommenced his month's work, and brought his research to a successful issue.

Above all things, the chemist must be *true*. He must not allow his wishes to bias his judgment or prevent him from seeing his researches in their true light. He must not be satisfied that his results appear true, but he must believe them to be true; and having faithfully performed his experiments he must record them faithfully. He may often be obliged to chronicle his own failures and describe operations that tell against his own theories, but this hard test of his truthfulness he must not shrink from.

But I must not weary you with the virtues of the chemist. If I have succeeded in showing that the pursuit of this science tends largely to develop the intellect and discipline the character, I think I have done something for chemistry. We are told by Bishop Butler that "habits of virtue acquired by discipline are improvement in virtue, and improvement in virtue must be advancement in happiness."

I am glad to see that the importance of original research as a part of higher education is at last beginning to be recognized in this country. The Royal University Commission at Oxford has recently recommended that candidates for the higher degrees in science shall in that university be required in future to work out an original investigation. In Germany, where education has been so long and so well understood, original work has been, for at least the last half century, a *sine quâ non* for a degree. Another admirable rule exists in that country, the adoption of which in Great Britain might go far to wash out the stain from our islands, of not having contributed our fair quota to the advancement of human knowledge. It is this—the Germans make a point of securing invariably that their scientific chairs shall be filled by men who have already distinguished themselves by their discoveries. The professor, on his appointment, naturally desires to continue his investigations and endeavours to secure, and usually succeeds in securing, the assistance of his pupils. This is a mutual advantage. The professor is able to do more work for science and the student on his part learns to conduct for himself an original investigation. Hence there is always a rising generation of original workers in Germany, who turn out papers more or less meritorious with the rapidity of a Walter's press. They are stimulated by the hope of one day arriving themselves at a professor's chair, the path to which they are well assured is only through the toilsome field of original work. But I must not wrong the German student by the implication of a purely selfish motive in his work. His labour is one of love, and his ambition, for the time at least, is bounded by the desire to *do something* for science. And from a multitude of such enthusiasts the great professors come. Great mountains are only found in mountainous countries.

I find myself insensibly led to speak of the encouragement of research in this country; and although it has been very largely discussed in scientific circles I will venture to add a few words. To promote original work here I believe it is indispensable that our professors should be well paid. It would save them from the necessity of supplementing their incomes by commercial analyses, and thus enable them to devote their spare time to original work. And to secure that they shall have spare time I would like to see in every laboratory a competent assistant, who would be able occasionally to take up the professor's lectures, should he be engaged in important work. There are many around me who know how very exacting original investigation is, and how necessary it is at times to be able to work on without interruption, bits and scraps of time being of no value. I am glad to see that the Oxford Commission also recommends the appointment of well paid assistants. Well paid professorships and well paid assistantships would be attractive prizes for our students to work up to; and if it were clearly understood that the only way to these prizes was through original investigation we should very soon have an army of zealous and competent workers.

The plan of appointing a staff of original workers unconnected with teaching has been proposed, but I do not approve of it. The original worker is as a rule the best teacher, and the rising generation of students should not be deprived of the advantage of his instruction. Moreover, as I said before, the professor may be greatly assisted by his pupils.

No doubt the Government Grant Fund does a good deal for science, but the field of its operations is, under present conditions, limited. Professors, as a rule, are so occupied with teaching that they cannot avail themselves of the fund; and of those students who might be competent and willing very few can afford to do so. Instead of trusting to the precarious and insufficient support of the fund they must endeavour to settle themselves permanently in life.

It is much to be regretted that the universities of Oxford and Cambridge, with such splendid revenues at their disposal, should contribute so little to the advancement of physical science. I hope the day is not far distant when the fellowships—or at least a few of them—which now go to reward young men for merely passing a

good examination, shall be given *without examination* to men who shall have advanced human knowledge in any department. At present a fellowship of £250 or £300 a year, lasting ten or twelve years, and in some cases for life, may be obtained on showing proof of a good memory—or, at most, a capacity for assimilating other men's ideas. To make discoveries—to follow out a new train of thought, and establish it by experiments specially devised to that end, has been left not only without reward, but almost without recognition, in our two principal seats of learning. Is it to be so always? The world at large, ignorant as it is, has a sounder instinct on this subject, and the man who makes the humblest addition to the stock of knowledge in the world rarely fails to receive the world's respect and honour.

The suggestions I have ventured to make could not, of course, be well carried out unless the Government take into its own hands the appointment to all scientific chairs. Of this I think I see indications. I believe that sooner or later the Government will assume the supreme direction of education in this country. It has already taken primary education under its control, and quite recently, here in Ireland, intermediate education to a great extent. And does the appointment of so many University Commissions not show a disposition on the part of the Government to assume the direction of higher education also?

Dispensing Memoranda.

[134]. OPODELDOC.—In the list of medicines ordered by the Board of Trade to be supplied to ships leaving any port in Great Britain a mixture of tinct. opii and lin. saponis co. is ordered to be marked "Opodeldoc."

Belfast. R. ECCLES TAYLOR.

[138]. PIL. PODOPHYLLI.—It is very usual for medical men to prescribe these pills, forgetting that they are not a B.P. preparation. What size of pills should be dispensed, and how much podophyllin should they contain?

SUB UMBRA FLORESCO.

[139]. Would some one kindly inform me through the medium of your Journal, how I should dispense the following?—

Empl. Potassii Iodidi
Empl. Belladonnæ p. æ.
Ft. Empl. 5 × 3

as I cannot find a formula for Emp. Pot. Iodid.

Bideford. M. D. J.

[140]. The following formula was handed me a few days since to dispense—

℞ Camphoræ . . . . . gr. iii.
Calomel . . . . . gr. i.
Ft. pil. mitte, xii.

No excipient being ordered I consulted a neighbour, who very strongly suggested ext. hyoscyami. Not liking to add to the doctor's formula, I found mucilage of tragacanth give a splendid result. Will some of our friends tell us who was right or who was wrong?

W. L.

[141]. LIQ. CINCHONÆ. When "Liq. Cinchonæ" is ordered, what preparation is usually dispensed and intended—"Ext. Cinch. Flav.," P. B., or "Ext. Cinch. Cord.," or "Battley's?"

"CINCHONA."

[142]. Can any of our readers kindly inform me how to dispense the following, and what appearance should the mixture have?

Tr. Ferri Mur. . . . . ℥ij.
Tr. Opii . . . . . ℥j.
Tr. Benzoin. Co. . . . . ℥iij.
Pulv. Gum. Camph. . . . . ℥j.
Pulv. Tragacanth. Co. . . . . ℥iv.
Bals. Copaibæ . . . . . ℥j.
Aq. . . . . ad ℥viij.
Ft. Mist. ℥j ter die sum.

F. J. S.

[143]. How should I dispense this mixture to send out clear without any deposit? I had it handed to me to prepare the other day.

℞ Pot. Bicarb. . . . . ℥ij.
Tr. Tinc. Vom. . . . . ℥iij.
Quiniæ Dis. . . . . gr. xij.
Syr. Simpl. . . . . ℥ss.
Sp. Ammon. Co. . . . . ℥ss.
Sp. Chlorof. . . . . ℥ss.
Inf. Aurant. . . . . ad ℥vj.
℥ss ter die ex aqua post cibum.

F. M. M.

I prepared it as stated here: First mixed Spt. Ammon. Co. c̄ Sp. Chlorof. et Tr. Tinc. Vom., then add Quinæ Dis. in measure, put Pot. Bicarb. in bottle with water, and lastly added Inf. Aurant. and syrup; when mixed altogether made a light yellow coloured mixture, but left no deposit.

H. Y.

MEDICAL ACTS AMENDMENT BILL.

Sir,—I have just read the report of the Committee on the Medical Act Amendment Bills, and feel considerable disappointment not only at the report but at the general approbation with which it was received. I hope I may be mistaken in my apprehension of what the committee accomplished in their interview with the Duke of Richmond, for it appears to me, according to their own report, that they have missed two most important points which they should have enforced.

The duke, it appears, was under the impression that we "desire to enlarge the privileges of chemists," and informed the deputation that this would be more appropriately accomplished by "an addition to the Pharmacy Act."

Here I think the deputation ought to have insisted most emphatically that chemists desired no medical privileges.

It will be the first step towards the ruin of the pharmaceutical curriculum when a little bit of medical teaching and a little bit of medical practice creep into our recognized doings. Our only safety is total abstinence from medical privileges. That which is every man's right is no privilege, and the chemist should seek no distinction from the general public as regards his liberty to give and take medical advice. It is no privilege to be allowed to do the same as his neighbours who are in any other calling and give advice, medical or otherwise, without let or hindrance.

The next point in which I think the committee fell short of what they should have attempted is that they should have urged the injustice of any medical corporation having the power of prosecuting chemists or others for medical practice without a clear definition of what constitutes medical practice. If medical practice were clearly defined it would be the duty of chemists as of every one else to avoid infringement, and only when it is clearly defined can it be morally right to prosecute for an infringement, or legally practicable to effect a just and conclusive decision in such a case. The deputation should have impressed upon the Duke of Richmond that the definition which is above all things necessary between the practitioner and the pharmacist belongs exclusively to a medical act amendment bill and not to an amended pharmacy act. The Pharmacy Act defines with considerable clearness what are

the protected privileges of the chemist, and its definition, where it falls short of what is desirable, does so, not in failing to state what a chemist may do, but in failing to be clear enough in stating what a person who is not a chemist may not do. This latter would be an appropriate matter to introduce into an amended Pharmacy Act, but the former subject would be quite out of place in any but a medical bill.

I hope before another opportunity for medical legislation occurs, those who may be in office may see more clearly what are the difficulties of their less favoured brethren, and how these may be lessened.

BARNARD S. PROCTOR.

Grey Street, Newcastle, Aug. 13, 1878.

[*** Our correspondent would perhaps render some service towards the settlement of the subject he refers to, if he were to make known his ideas as to the "definition" which is to most minds a matter of such grave difficulty.—ED. PHARM. JOURN.]

THE REPORTS OF PROCEEDINGS OF COUNCIL.

Sir,—I suspect your leader in the recent issue of the Journal, unless some further explanations are given, will lead to greater misconception rather than prevent it, as you suppose, and I cannot help drawing attention to the fact in the hope that the matter may be cleared up satisfactorily; otherwise the quotations given by you from Mr. Mackay's speech, when placed side by side with your own declarations, will continue to mystify and mislead the majority of country members who have had so little opportunity hitherto of acquiring a knowledge of the ongoings within the "inner circle" of the Society.

Your quotations from Mr. Mackay's remarks distinctly indicate that an application was made to the Editor by some one officially connected with the Council, whether the Secretary, the President, or Mr. Mackay individually, it does not matter; this question was put to you in some official way, "Can you not give the grumblers longer reports?" and the answer given by Mr. Mackay and not contradicted by you is as distinctly official as could be, viz., "Give me a seat with you at the Council and I will guarantee longer and better reports." To this request you have not got any answer and apparently never will, as it appears that the majority on the Council have a most peculiar way of answering inquiries, for instance, the request from the Trade Association for a donation. To the trade generally it does not matter whether a request be made by official letter or through an individual, the matter is all the same. You have indicated a wish to comply with those who wish better reports, on certain conditions; these have not been complied with, and I, for one, think Mr. Fairlie, Glasgow, was quite justified in assuming the position he did at the Council meeting, and the thanks of all interested are due to him for his conduct on that occasion. Personally I have acquired more about the business of the Council from the latest report than I had during my ten years' previous connection with the Society. I hope Mr. Fairlie will retain the courage of his opinions, and in spite of the single handed struggle he is engaged in, do his duty manfully and independently in the Society's interests.

Scotch interests in the Society's Council have been very silently dealt with in the past. It is to be hoped that a new and improved line of conduct is about to be pursued. I am sure were the vote taken of the trade direct on the subject of reports, it would be in favour of admitting a reporter from the Journal office and that of the *Chemist and Druggist* as well.

ST. RULE.

[*** We must refer our correspondent to the articles on this subject for a correction of the views he holds.—ED. PHARM. JOURN.]

EXAMINATION DISCREPANCIES.

Sir,—In the Journal of the 3rd inst. there appeared a letter drawing attention to the large percentage of failures at the Minor examinations on the last days, a fact which I have observed for some time past, and I hoped the letter referred to would have been the means of eliciting some probable solution of the mystery; such, however, has scarcely been the case, for I consider the suggestion of A. P. S., attributing the cause to students delaying forwarding their applications till the last moment, a very insufficient reason for 80 per cent. of failures, as any one may judge by looking at the July Minor examination in Edinburgh, where undoubtedly such a circumstance would hold equally good as in London, but instead of being greater the percentage is less on the last day than on the first.

In my opinion the latter suggestion of A. P. S. that possibly the examiners get tired, and question more stiffly, is better calculated to account for the discrepancy, as I agree with your former correspondent that it is impossible to single out the good and bad candidates previous to examination. Then if for a moment such an occurrence be assumed, can it be considered justice to students?

Whatever its cause it nevertheless presents a disheartening future to those who find their names placed for examination on one of the last days, and may perhaps account for some preferring to go to Edinburgh, where more uniform results seem to prevail.

A subject of such importance to junior members of the profession ought not to remain without some endeavour to solve so perceptible a peculiarity.

JUSTITIA.

Sir,—I also have remarked with curiosity the systematic discrepancies which were the subject of the letter of "An Associate," in the Journal of August 3.

I am unacquainted with the procedure of those who have the marshalling of the candidates for examination, but if the date of a candidate's examination be determined by that of his application (and this I believe is the impression subsisting among students), then I think these discrepancies admit of partial explanation, as follows—

Those candidates who feel themselves deficient, will, in order to gain an extension of time for preparation, delay sending in their names until the last moment, and thus the number of the unsuccessful on the latter days of the examination will be larger than on previous days, when men better prepared present themselves.

The above, to me, appears to be the most probable and satisfactory manner of explaining, in a great measure, the curious facts portrayed by your correspondent. Perhaps, however, the "mystery" is capable of a different elucidation.

A STUDENT.

"Sub Umbra Floresco."—The etymology of the word is not so undisputed as you appear to imagine. The subject has been often discussed, and with very few exceptions of importance uniformity in spelling the word now obtains.

W. G. N. Lance.—Application for registration under the Dental Act will have to be made to a Registrar who is to be appointed by the Medical Council.

H. Cumbers.—See the discussion on this question in the Dispensing Memoranda in the last volume of this Journal (vol. viii.), pp. 19, 38 and 67.

"Superfluous."—We do not know of a good depilatory that will not injure the skin if left in contact with it more that a very short time. A paste made by moistening one part by weight of sulphydrate of sodium and three parts of finely powdered chalk with a little water has been recommended.

N. J. Lewis.—Undoubtedly an action could be brought, but the result would depend presumably upon the amount of evidence as to malpractice that could be produced.

R. F. W.—Everett's 'Text Book of Elementary Physics,' ublished by Blackie and Son.

H. M. D. is recommended to address his inquiry to the egistrar under the Act.

F. B. L.—The certificate authorizes the holder to dispense for a medical man, but we do not know that it has any other value. No regulations have been issued as to the qualifications for such an appointment.

J. Sumner.—We do not think anything can be done except to wait until the smell goes off.

H. Forster.—Baking powders usually have tartaric acid and bicarbonate of soda for a basis. Different methods of preparing them will be found in Cooley's 'Encyclopædia' and other receipt books.

W. W. Urwick.—Your letter does not appear to fulfil the conditions on which alone we could continue a discussion of the report referred to.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Stables, Baker, Birkett, Roberts, Tichborne, Churchill, Thursfield, Forster, Lake, Brown, Raynor, Roberts, Crow, Williams, Young, Abraham, Lloyd, Wade, Williams, Jepson, Thresh, Lewis, Honesty the Best Policy, Junior, Apprentice, Tom, Dispenser of Medicine, Cantab, Cyprus," "Alpha," H., A.P.S., R.A., A.B., G.T.D.

"THE MONTH."

The damp but warm and misty weather of the last few weeks, while it has given "the sere and yellow leaf" to many of our woods and orchards, has also had the curious effect of bringing into blossom several of our spring flowers. Thus, at Kew, the bistort and birthwort are flowering freely, almost side by side with the scammony plant, which is this year blossoming rather earlier than usual. Speaking of scammony, there appears to be no reason why the cultivation of this plant, as well as of some other medicinal plants, such as colocynth, jalap, etc., should not be profitably carried on in the fertile island of Cyprus.

The hop is now arrived at maturity, and the graceful festoons of the hop-gardens will soon be torn down by the rough but willing hands of the hop-pickers. Belladonna, henbane, stramonium, and valerian are now showing fruit instead of flowers, while lavender, peppermint, pennyroyal, chamomile, borage, wormwood, and marshmallow are still in full bloom. The valerian specially is worth noticing when the flower has fallen, for the calyx, which at first seems to have no limb, but to be united to the ovary and to have merely a rim at the top, afterwards develops a bell-shaped feathering pappus. The rim really consists of the inrolled limb of the calyx, which when the flower is over, unrolls and expands. The structure of the fruit, which is one seeded and inferior, as well as the pappus, shows that this family is naturally allied to the Compositæ, although the inflorescence of the two orders appears to be so different.

A few of our native plants possessing medicinal properties, or at least supposed to possess them, may be found in blossom at this time of the year. Among these may be noticed tansy, fleabane, elecampane, mugwort, yarrow, soapwort, mullein, motherwort and vervain. The pretty pink flowers of the soapwort (*Saponaria officinalis*) may be seen in waste places near villages, and occasionally on damp sandy places near the sea, but it is nowhere common and is only doubtfully a wild plant. The flowers are often more or less double, and, according to Mr. Syme, a curious monstrosity of the plant, having the upper leaves connate and the corolla monopetalous, occurs in Northamptonshire, and on sandhills near Liverpool. In France and Germany the decoction has been used as an application for the itch, and the plant has been given internally in gout, rheumatism and syphilis The celebrated Boerhave recommended it for jaundice. It contains saponine, to which its detergent properties are due. When the leaves are bruised in the fingers they do not feel very soapy, but when boiled they readily give a lather which removes grease like soap.

The mullein (*Verbascum Thapsus*), although now scarcely ever used in this country, excepting perhaps the flowers, still finds a place in the materia medica in domestic use in the United States. The leaves and pith of the stalk are used for inflamed swellings, such as mumps, in the form of a poultice, and also as a fomentation. The seeds, which are said to be narcotic, pass rapidly through the bowels, and have been used to remove obstructions in the intestines. The dried leaves are sometimes smoked for asthma. Gerarde gives a long list of the virtues of this plant; amongst other curious statements he quotes one from Pliny and Dioscorides, to the effect that figs wrapped in mullein leaves will not putrefy. In a botanical point of view the mullein is worthy of notice from the fact that it holds a kind of intermediate position between the Scrophulariaceæ and Solanaceæ, having the flowers nearly regular, and the stamens five in number. The woolliness of the leaves is due to branched, somewhat stellate hairs, which form a pretty object under the microscope. The presence of these hairs is sufficient to distinguish even a fragment of the leaf from that of digitalis, with which it is stated to be sometimes mixed. The name "mullein," according to Dr. Prior, is derived from the French *moleine*, which means the scab in cattle. Its old English name of "bullocks' lungwort" has reference to its use in country districts for pulmonary catarrh in animals.

The vervain (*Verbena officinalis*) is the only indigenous British plant belonging to the Verbenaceæ. Although intensely bitter, it does not appear to have been carefully examined for an active principle. Few plants have, however, been regarded with greater respect from the earliest times than this humble herb. In ancient Greece the plant was supposed to possess extraordinary virtues, and it was held by the Druids in almost equal veneration with the mistletoe. Less than a century ago a man made a considerable sum of money by giving the root of this plant as a charm to be worn round the neck in scrofula; he also wrote a book upon its virtues. Gerarde, however, says, "it is reported that the divill did reveale it as a secret and divine medicine."

The Vervain family is nearly allied to the Labiatæ, but may be distinguished by the style being terminal and the fruit not splitting into four parts until ripe, and in some species not even then.

At a recent meeting of the Horticultural Society, Mr. W. G. Smith exhibited a drawing of a Virginian creeper which had acted as veritable "passer of the bottle." A bottle, weighing three ounces, standing on a window sill, had been encircled by a tendril of the creeper, and carried by the downward growth of the creeper several feet, nearly to the level of the window below.

Some capital papers by Mr. W. B. Hemsley, entitled "Garden Botany," have lately been published in the *Garden*, which it may be hoped will be afterwards published in the separate form. The text is very simple, and clearly written, and the illustrations are both good and numerous, and although in some cases taken from rare plants, have the advantage of being appropriate, and of differing from the ordinary illustrations to be met with in botanical works.

In *Nature*, for July 25, a figure is given of an abnormal development of a leaf of the papaw tree, which illustrate in a singular manner the way in which leaf pitchers are formed. A somewhat similar growth may be seen in an ordinary hothouse plant, *Croton appendiculatum*.

The report of the Royal Gardens at Kew recently issued contains much interesting matter. It is, however, not without surprise that we notice that the idea that Lukrabo seeds and St. Ignatius's beans are identical, is entertained even for a moment. Lukrabo seeds have oily albumen and a separate hard testa, while Ignatius's beans are composed of excessively hard horny albumen and present traces of a thin adherent hairy testa and are totally unlike any seeds of the Pangiaceæ with which we are acquainted. The only resemblance between the two is in the shape, which is about as similar as seeds of Malvaceæ are to those of Solanaceæ.

Under the curious name of Tong-pang-Chong, a supposed remedy for certain forms of skin diseases has before been mentioned in these columns. The drug appears in the form of broken pieces of a woody root, and is described in the Kew report as being "produced by a plant which grows in Siam, whence it finds its way to China, where it is stated to have become very generally used" in European and perhaps also in native practice. The chemists of Hong Kong state that an almost unlimited supply can be had, and have suggested obtaining the plant and growing it in Hong Kong. The plant appears to be *Rhinacanthus communis*, regarding which Mr. Hance, the British Vice-Consul at Whampoa writes, "I only know of one plant brought from Siam and used in cutaneous affections, and a specimen of this plant sent to me for determination proved it to be *Rhinacanthus communis*. In conversation with a well-known physician, residing in Hong Kong, some time afterwards, he told me it was exceedingly efficacious in herpes and some allied eruptions, often very intractable under treatment, and that indeed he knew nothing to equal it."

In the *American Journal of Pharmacy*, Mr. F. P. Power, writing on the resin of podophyllum, considers it to be proved that berberina does not occur in the rhizome, and believes that the existence of the colourless alkaloid, mentioned by Professor Mayer, to be improbable, he not having been able to detect any. Mr. Power thinks the fact that Mayer's solution of mercuric-potassic iodide, as well as other alkaloidal reagents, produces precipitates with many other substances beside alkaloids, may possibly have led other investigators astray in assuming the presence of an alkaloid in the rhizome of podophyllum.

A new application for Japanese isinglass has recently been found. Mr. E. Rennard, in the *Pharmaceutische Zeitschrift für Russland*, points out that gelatine is unsuited for suppositories containing tannic acid, but that the jelly produced from Japanese isinglass has the advantage of not forming with it an insoluble compound. For pessaries and suppositories one part of the Japanese isinglass to thirty parts of water may be used, but the product has a milky appearance. If it be desirable to have a perfectly clear suppository, this may be obtained by allowing the isinglass to soak in twenty parts of water overnight, melting the product with a gentle heat, and then adding to it glycerine. If the isinglass be soaked in glycerine alone a sticky instead of a firm product is the result.

In continuation of his valuable investigations of little known Brazilian plants, Dr. Theodor Peckholt, of Rio (*Zeit. d. allgem. österr Apot.-Verein*, xvi., 361) has been examining the *Sparattosperma leucantha*, Mart., a Bignonaceous plant, popularly known as "cynco folhas" (five leaves), and used as a diuretic and remedy in disorders of the liver and spleen. From the leaves he has isolated about 3 per cent. of a non-nitrogenous crystalline body, odourless, but with a faintly alkaline bitter taste, and a composition represented by the formula $C_{19}H_{24}O_{10}$; it thus approaches nearly to phloridzin, but it does not appear to be a glucoside. Therapeutic experiments as to the activity of this body, which Dr. Peckholt has named "sparattospermin," are wanting, except that two grains have been taken without further symptoms than a strong diuresis.

The husks of cacao beans have been examined in the Dorpat laboratory (*Arch. d. Pharm.*, xiii.) by Messrs. Treumann and Donkin, and enough pure crystallized theobromin obtained (0·3 per cent.) to allow of this hitherto waste material being profitably worked at the present price for theobromin. Treumann also gives the solubility of theobromin in water at 100° C. as 1 in 148; in water at 17° C., as 1 in 1600; in boiling absolute alcohol, as 1 in 422—it is much more soluble in boiling 80 per cent. alcohol—the solubility in absolute alcohol at 17° C., is 1 in 4284, and in boiling chloroform, it is 1 in 105.

The result of some investigations upon the constituents of benzoin and vanilla have recently been published by Herr C. Rump (*Studien über Benzoë*, Hanover, 1878). The author is of opinion that benzoic acid does not exist in the free state in benzoin, but is in combination with a second acid. On this account he looks upon the present direct method of obtaining benzoic acid by sublimation as crude and irrational, and inferior to preparing it by the wet way and subsequent sublimation. According to his experience also, the benzoic acid of commerce is not all obtained from benzoin, but is a mixture of the natural and artificially prepared acid. With respect to vanilla he criticizes the methods of estimating its value by the amount of vanillin actually existing in it as such, since good fresh vanilla may be devoid throughout of crystalline matter, though it contains another body from which vanillin is ultimately formed. On this account vanilla is much slower in affecting the organs of taste than pure vanillin.

A new method of preparing artificial vanillin has been patented by Herr Tiemann, the same chemist who discovered that it could be made from coniferin. The present method consists in obtaining eugenol from oil of cloves, forming it into aceto-eugenol by treatment with anhydrous acetic acid, and adding to it a dilute solution of permanganate of potash. When the oxidation has progressed enough, the liquid is filtered, the filtrate made feebly alkaline, concentrated at a low temperature, acidified with sulphuric acid, and the vanillin separated from the liquid by shaking it with ether.

In the *Répertoire de Pharmacie* for May, M. Tanret records that a kilogramme of ergot contains 1·20 gramme of ergotinine, although only 0·60 gramme of it is obtainable in crystals, which are white and needle-like.

The *Lancet* for July 27th, contains a paper upon the effect of nitrite of amyl in sea-sickness. The writer, Mr. J. R. Leeson, states that when it is likely to do good the relief is generally speedy, patients gratefully smiling after a few seconds' inhalation, and the sense of nausea and sinking at the pit of the stomach quickly becoming lessened. He is of opinion that the inhalation of five drops to begin with for men and three for delicate women is safe, except in cases where there is a probability of fatty degeneration of the heart being present.

An addition to the long list of remedies for hydrophobia is mentioned in the same journal. The remedy in question consists of two blistering beetles "*Melve tuccius* (Rossi), and *Mylabris tenebrosa* (Castelnau)." The account of this remedy was communicated to the Société d'Entomologie of France by M. de Chevarrier, of Gabes, near Tunis. It is stated by the Arabs that a piece of the insect, the size of a grain of corn, given in a piece of meat will prevent hydrophobia if given within twenty days of the bite. Even that quantity is said to

occasion frightful colic. We presume the name we have quoted from the *Lancet* should be *Meloe*, there being no genus of beetles called *Melve*.

Professor Robin, of Paris, has recently discovered in the urine of a patient suffering from hydrophobia, the presence of bacteria of a special character. This discovery will probably throw new light upon the cause and consequently on the appropriate treatment of the disease.

A recent case of poisoning by peach kernels in Paris may serve to call attention to the danger of allowing children to eat the kernels of stone fruits, one ounce of the kernels of the peach being stated to contain one grain of pure prussic acid.

Dr. Craig, of Montreal, recommends a twenty grain solution of chloral as a painless but effectual application to warts.

Salicylic acid ointment is a favourite remedy in Sydney in cases of *Porrigo decalvans* and other complaints having a parasitic or paraphytic origin.

A correspondent of the *British Medical Journal* contributes the interesting fact that opium is not any more poisonous to fowls than it is to pigeons. A lady, the wife of a medical man, wishing to kill a favourite hen which was apparently dying from the "gapes," gave it a teaspoonful of laudanum, and this not proving sufficient, another was administered in a few hours, with the result not of killing, but of curing the fowl.

In the *Medical Press and Circular* for July 31, a very valuable series of papers on the physiological action of Sassy Bark is commenced by Dr. T. Lauder Brunton and Mr. W. Pye.

Pilocarpine muriate has lately been used as a remedy for hiccough. In the *Bulletin de Thérapeutique* it is recorded that M. Ortille found an obstinate attack yield at once to 2½ centigrammes, and that it did not afterwards return.

A new source for formic acid has been discovered. The United States Entomological Commission show that the locust is capable of furnishing a very large quantity of formic acid, and a new oil called caloptine. The acid is obtained by the action of sulphuric acid on the juice of the locust.

Mr. W. J. Butler, of the Madras Medical Service, has recently recommended the use of boracic acid in ten grain doses, combined with sodium borate or carbonate, as a remedy for cholera. He represents the treatment as being almost uniformly successful.*

Some of our readers may be glad to know the formula for Dr. Thorburn Paterson's ointment for preventing pitting from small pox. The proportions used are as follows: carbolic acid, twenty minims to half a drachm, glycerine, a drachm and a half, oxide of zinc ointment, six drachms.†

In the *Pacific Medical Journal*, Dr. Q. C. Smith recommends the application of equal proportions of liquor bismuthi and water in nasal catarrh, three times a day, with a spray producer. He describes the results as being very satisfactory. A weak solution of sulpho-carbolate of zinc he also considers to be an efficient remedy in the same complaint.

A new remedy for epilepsy has been recorded by Kunze, in the form of a subcutaneous injection of curare, used at intervals of about a week. The formula he adopts is seven grains of curare dissolved in seventy-five minims of water, mixed with two drops of hydrochloric acid. The quantity injected at one time is eight drops of this solution.

In reference to the recommendation, quoted from a Portuguese source, in "The Month" for July, to use aromatic spirit of ammonia for making tincture of hops, Mr. W. Symons, of Barnstaple, points out that the same suggestion was made some years ago in the pages of this Journal, with the additional suggestion that lupulin should be used instead of the bulky hops, which have the disadvantage of absorbing so much of the menstruum.

The past month has been marked by three important scientific gatherings; the first in order, that of the British Medical Association, was held at Bath on the 6th and three following days, the attendance being estimated at about five hundred. One important feature of the meeting was the adoption of a new bye-law providing that female medical practitioners shall not be henceforth eligible to become members of the Association. It was supposed that this would leave Mrs. Garrett-Anderson and Mrs. Dr. Hoggan members, but some legal informality having invalidated the previous election of a considerable number of persons, their names had to be submitted for proper election at the present meeting, when the opportunity was taken of dropping Mrs. Dr. Hoggan's name out. Mrs. Garrett-Anderson therefore now stands alone as a lady member of the British Medical Association.

The proceedings of the British Pharmaceutical Conference at Dublin are in course of publication in this Journal so fully as to render unnecessary any further mention of them in this place. It will not, however, be out of place to express the hope that the opportunity which has been afforded at this year's meeting for establishing more intimate relations between British and Irish pharmacists may have the effect in future years of inducing many of the latter to attend these meetings.

The Dublin meeting of the British Association, though in many respects more than ordinarily successful, was not marked by the production of any remarkable novelty. The Presidential address, as delivered, seems to have been disappointing to a great number of those who assembled to hear it, but were as little able to do so as they would have been to understand it if they had heard. In some of the local papers, the substance of the address was rather severely criticized, but in a manner that was suggestive of some jealousy that an Irishman had not been selected for the President.

Among the papers read at the Chemical Section there were but few that presented any special interest for pharmacists. Mr. A. S. Wilson, of Glasgow, gave the result of some examinations of the "nectar," or sweet tasting liquid, secreted within the cups of insect fertilized flowers, showing the amount of sugar contained in it and likewise the occurrence of cane sugar in this liquid. In Mr. E. H. Cook's paper on the application of the Food Act to the sale of milk, a suggestion was made to adopt the practice of buying and selling milk according to quality. With this object it was proposed to establish two standards of quality, one to include all milk containing 12 per cent. total solids, and 9 per cent. of solids not fat, the other to include all milk containing less than those amounts. This plan it was suggested would help to do away with injustice in the prosecution of milk sellers that arises from the existence of natural variations

* *Lancet*, August 24, p. 257.
† *Lancet*, August 24, p. 275.

in the quality of milk. It was also urged that th system would tend to stop adulteration. In the discussion of this paper Dr. Cameron, the Dublin city analyst, expressed the opinion that Mr. Cook was correct in assuming that pure milk never contained less than 11·5 of total solids, and that the natural variations in the amount of fat constituted the great difficulty the analyst had to contend with in deciding whether milk was adulterated. He thought, however, that since so few persons charged with that offence took advantage of the power to refer to the Somerset House analysts when convicted it might generally be inferred that they admitted their guilt.

Mr. Edison has now applied the principle of his carbon telephone to a new instrument which is to measure infinitesimal pressure. The instrument depends for its powers upon the fact that by the least pressure upon a button of carbon its conducting power is increased, and when allowed to expand it partly looses it. Mr. Edison expects by-and-by to be able to indicate the heat of the stars and to weigh the light of the sun.

Platinum dishes, if they survive other accidents, succumb at last to mechanical wear and tear. But Mr. T. Garside says (*Chem. News*, Aug. 9) that a slight damage, such as a small hole, may be repaired by placing the dish on an anvil of plaster of paris, moulded to fit the inside, and welding on to the defective place a piece of platinum foil under the influence of the blow-pipe flame and gentle taps with a small hammer. The surfaces to be brought into contact should be previously scrubbed with sand until perfectly clean, and under these conditions the two pieces of platinum unite perfectly and form a neat joint. Platinum wires may be joined in a similar way.

A sad accident has been reported this month from Ireland, Mr. Kearney, the manager of the Limerick National Bank, having been poisoned through taking an overdose of "drops" instead of a corresponding quantity of a "mixture," "owing to some mistake on the part of an attendant." This is rather vague, but it is the only information given in the *Limerick Chronicle*, and it has been sufficient to enable the editor of the *British Medical Journal* to assume,—perhaps correctly,—that the accident might have been prevented by the use of a fluted bottle. It is rather racy of the *locale* of the accident, however, to learn that this case of poisoning in *Ireland* is due to the Council of the Pharmaceutical Society of *Great Britain* having deserted its public duty of regulating such matters. What would Professor Tichborne and his colleagues of the Irish Pharmaceutical Society say to an attempt to carry out this suggestion? If our contemporary had such an excess of indignation on hand it might have used up a little of it more appropriately and perhaps more profitably in denouncing the mischievous practice of preseribing medicines for internal administration in so concentrated a form as to require their being dispensed in poison bottles.

After troubling the feet in the shape of magenta-coloured socks, and paying a flying visit to the trimmings of gentlemen's hats, arsenic, which has recently almost rivalled lead in its ubiquity, has settled in the coverings for the hands. The *Allgemein medicinische Central-Zeitung* reports that a military gentleman, after wearing a pair of marine-blue gloves purchased in Hamburg, suffered from *malaise*, whilst his hands became covered with a peculiar eruption. "Suspicion naturally fell upon the gloves, and upon examination a considerable quantity of arsenic was detected in them.

Some cases of suspected poison by calomel powders containing corrosive sublimate, that have occurred in Italy, induced Herr Slop to make some experiments as to the conditions under which the mercurous is converted into the mercuric chloride, and its probable behavour towards the juices of the stomach. He reports (*Schweiz. Wochenschrift f. Pharm.*) that he found this change to have taken place after digesting calomel during six hours in a dilute solution in (1 1000) of hydrochloric acid, and that a solution (1 in 5000) of sodium chloride behaved similarly. The general conclusion arrived at was that mercuric chloride was formed in the presence of hydrochloric acid, organic acids, chlorides of the alkalies, and carbonates of the alkaline earths, the last being specially important considering the frequency with which calomel is dispensed with magnesia. Turning his attention to sugar, Herr Slop examined several specimens of calomel pastilles, having sugar for their basis, that had been made more than a month. Some of these contained a considerable quantityof mercuric chloride, whilst others did not contain a trace. This difference he attributes to the latter having been prepared from a neutral refined sugar, while for the former, probably, a first crystallization of beet sugar, still contaminated with the calcium hydrate introduced in the neutralization and clearing of the juice, or a raw colonial sugar, which as a rule would be acid, had been used.

In a note on this subject in number 421 of this Journal, Mr. H. W. Langbeck expressed a doubt whether sugar perfectly dried and mixed with well washed calomel, kept in a stoppered, coloured bottle would change into glucose, and thus act reductively. He now writes: "I have kept well washed calomel mixed with loaf-sugar, with milk-sugar and with loaf-sugar containing 1 per cent. of glucose for about ten weeks, and in analysing the three samples found that no perchloride had been formed in either of them, but that the first sample (loaf-sugar) contained glucose, viz., 0·4 per cent., grape-sugar (soluble in rectified spirit), and 1·1 per cent. fruit-sugar (soluble only in water). A mixture is kept in some pharmacies under the name of children's cooling powder, which consists of calomel, sugar, nitrate of potash, and antimonial powder. I analysed a sample of it two months old but could not find any traces of perchloride of mercury."

The first Dispensing Memorandum that requires comment this month, is one on which remarks have been postponed somewhat, in the hope that some opinions upon it would have been expressed by correspondents.

Such a prescription as that of No. 127 places a dispenser in a very difficult position. It orders an unusual quantity of powdered cantharides in each dose, and if dispensed as written, each pill would contain one grain and a third, which, taken three times a day, would amount to four grains of powdered cantharides each day for as many days as these pills may be regularly taken, presumably at least six days. A dispenser is expected to recognize unusual doses, and when he does so, and more especially when he considers the dose a poisonous one, his first duty is to refer the prescription to the writer, at the same time taking care to ascertain

that he is a properly qualified medical practitioner. In this instance the unusual dose was recognized and the prescriber was communicated with on the subject, the result being that the author of the prescription, evidently quite aware of what he had written, endorsed the unusual doses, and further emphatically states that "the doses are *not* poisonous. The prescription has certainly my professional sanction."

Now comes the difficulty. An apothecary is legally bound to make up the prescription of a physician, but the dispensing chemist is not; he may use his own discretion and, if he chooses, decline the responsibility, and, as in the case of the chemist at Ramsgate, he may be censured by a coroner's jury. His own reputation being at stake, as well as having before him the possibility of ulterior proceedings, he should act with caution, but yet with intelligence. Having referred the prescription to the writer and obtained his sanction to its being dispensed as written, the dispenser should take the greatest care that any further objections are well founded. What quantity constitutes a poisonous dose of cantharides? Having received no special medical education he must be guided in the formation of his opinion by medical literature. Christison quotes several cases of poisoning by powdered cantharides, but each the result of the administration of the powder in single large doses, and states that "the quantity of the powder or tincture which is required to prove fatal or dangerous has not been accurately settled." He also states the medicinal dose to be from half a grain to two grains of the powder, and that the experiments made on animals do not furnish satisfactory proof of the absorption of the poison, but rather tend to show that it does not enter the blood; death resulting apparently from the local irritation produced by the cantharides. It is stated in Bentley and Redwood's edition of Pereira's 'Materia Medica' that "powdered cantharides are not unfrequently employed internally. The dose is one or two grains in the form of pill."

The 'United States Dispensatory' says "The dose of Spanish flies is one or two grains of the powder, which may be given twice a day in the form of pill."

Taylor states in his 'Medical Jurisprudence' that "the quantity of this poison required to produce serious symptoms or destroy life has been a frequent subject of medico-legal inquiry. Dr. Thompson represents the medicinal dose of the powder to be from one to three grains. In a late criminal investigation a medical witness stated that one grain was its maximum dose, but this is an under statement; according to Thompson it is three gains."

In the foreign pharmacopœias there is usually a table of the maximum doses of potent medicines, and the quantity to be taken during the day that may be dispensed by the chemist without being specially marked thus (!) by the prescriber. In the 'German Pharmacopœia' the maximum quantity of powdered cantharides that may be taken during the day is two and a third grains, and in the 'Austrian Pharmacopœia' two and four-fifth grains, so that in the latter pharmacopœia the quantity of powdered cantharides that may be dispensed for consumption during one day in the ordinary course of business and without the special note of the prescriber is just three grains.

The quantity of powdered cantharides in each pill of the prescription in question is not in excess of that stated in Bentley and Redwood's 'Pereira' as a medicinal dose, neither is it so large as the maximum dose quoted by Taylor, and it is only the same quantity during the day as that given by the United States Dispensatory as the dose of Spanish flies, and if those cases which have resulted in death from the administration of large doses of the powder point rather to its action as a local irritant than to its absorption, the resinous extract of nux vomica in this prescription would probably somewhat diminish its local activity.

Having obtained the professional sanction of the writer of this prescription, and with the authorities just quoted before him, the dispenser would have been justified in making up this prescription, and he would have acted prudently if he had also sent to the patient a copy of the letter he wrote to the prescriber on the subject, and also a copy of the answer he had received, retaining the original for future reference if required. The dispenser would have placed himself in a false position if, after requiring the sanction of the prescriber to what he considered an unusual dose, he had declined without any apparent further reason to dispense the prescription, and supply the medicine ordered by the physician, that is to say, the eighteen pills. This, however, would not have met the requirements of the customer, and the demand for so large a number as one hundred of such pills might fairly be regarded as a sufficient reason for declining—out of consideration for the responsibility that might be incurred—to dispense the prescription in this multiple manner. It is, however, a case of difficulty, one on which opinions will probably differ, and it is eminently one which should be ventilated in the medical journals.

There are no official formulæ for syrups from essential oils, as required in No. 131, but probably a solution of the oil in a little spirit, mixed with the previously made syrup may accomplish the object; or recourse may be had to a method which has been recommended, viz., that of dropping the oil into boiling distilled water and subsequently making into syrup. Experiments in these directions would be very likely to lead to something satisfactory.

The result of a combination such as that in prescription No. 132, has on previous occasions been adverted to, and it has been pointed out that the quinine will separate from the liquid and adhere to the sides of the bottle in a more or less agglomerated form. The mixture is not elegant or even in such a condition that the proper quantity of quinine can be taken in each dose; a little mucilage added previously to the sp. am. arom. will to a great extent obviate this inconvienence. The particular mode in which this mixture may be dispensed will not materially affect the result, so that any remarks on this part of the subject are unnecessary. The dispenser should avail himself of every opportunity that may present itself to bring combinations of this description under the notice of the prescriber and at the same time show him the condition of the mixture after being made up exactly as ordered in the prescription.

It is not unusual to meet with prescriptions in which the "Dil." after the acid is omitted, as in the mixture No. 133, where it is quite evident that the dilute acid was intended by the writer. In the present case, and in that of others involving more difficulty, the dispenser should for his guidance

refer to the Pharmacopœia for the dose of the acid; that of the acid. nit. hydroch. dil. is from 5 to 20 minims, and one drachm in an eight ounce mixture is quite usual in prescriptions. In the second prescription where the nit. mur. acid. is prescribed alone, it must be assumed that the dilute acid is intended, in fact the strong acid is never prescribed, neither is it official in the B.P. So corrosive an acid should not, undiluted, be placed in the hands of a patient for internal adminstration.

Opodeldoc, the subject of the inquiry in No. 134, was in use as a nostrum previously to its finding a place in the Pharamacopœia; it is now represented there by lin. saponis, a fluid preparation, and one suitable for dispensing purposes. At the present time opodeldocs are known of a solid character, their consistence being mainly due to the soap employed in their preparation; these are sold as proprietary preparations, but with them the dispenser has nothing to do as regards a prescription. Opodeldoc to him is represented by lin. saponis. B.P.; on no account should a lin. sapon. c. opio be used. That is a preparation represented in the B.P. by lin. opii. of later date than lin. sapon., and to which the name of opodeldoc does not apply. The statement that some chemists use lin. sapon., whilst others that preparation with opium, is open to doubt; their reasons for the use of the latter preparation would be interesting. The fact stated in the *Pharmaceutical Journal* of August 21, that the Board of Trade orders a mixture of tr. opii. and lin. sapon. to be marked opodeldoc does not affect the question.

A formula is required, No. 135, for ung. glyceroli plumbi subacet. There is no definite form for this ointment. The formula for glyc. plumbi subacet. was first published in the Journal, May 6, 1876, by Mr. Balmanno Squire, and in June of the same year, in a further communication from the same writer, he mentions a suggestion of Mr. Peter Squire, that the glycerole should be used in the preparation of the official ointment instead of the liq. plumb. subacet., B. P.; ℥j, therefore, of the glycerole with ℥j ung. simp. would be suitable for an ointment, and as in the last "Month's" remark on No. 130 it was pointed out that the ointment would become yellow, the greater or less intensity of the colour would very likely be due to the relative proportions of the glycerole to simple ointment and also to its age. The combination and the exact proportions may have been the result of much thought and experiment on the part of the firm supplying the ointment, and a similar result can only be obtained by conjoint action of brain and muscle.

An inquiry was made in the Dispensing Memoranda with regard to pulv. scammony, with the view of ascertaining what would be used when thus ordered; the reply in the following "Month" was to the effect that the gum resin scammonium only could be used. From the same correspondent it now appears that 12 grains with other ingredients were ordered in a powder for a child. Such a dose attracted the attention of the dispenser, and it was one that may very properly have been referred to the writer but in practice it is not unusual to find a large dose of scammony to be prescribed for a child under special circumstances, and as scammony is said to have its action corrected by the addition of sulphate of potash it is quite reasonable to suppose that the bitartrate which was combined with it would have some effect n the same direction. Some better reason should be given before it is assumed that the prescriber had been accustomed to have his prescriptions dispensed with very inferior gum. scammon.

Copaiba resin being now occasionally prescribed, the suggestion of Mr. Challis is a very practical one and in principle closely corresponds with a note on the subject of this resin in mixtures read at an evening meeting of the Pharmaceutical Society, and which will be found in the *Pharmaceutical Journal*, November 4, 1876.

There is no official form for aq. glycyrrh., ordered in prescription No. 137, and as it is only a vehicle for the administration of other medicines it may be made by infusing 1 oz. of bruised liquorice root in one pint of water, or by a decoction of the liquorice root; perhaps the former would in this instance be more suitable.

If a prescriber orders pil. podoph. in a prescription, as in No. 138, without at the same time appending a formula, where possible he should be referred to. When that is not practicable, ¼ gr. podophyllin may be combined with 4 grs. compound rhubarb pill. The dose of podophyllin would be a very ordinary one and the combination not unusual. The habit of ordering a pill as in this prescription is very likely the result of prescribing from hospital or dispensary formulæ, where approved combinations of every kind required are kept ready for the dispenser's use. It is probable that to this source may be traced much of the difficulty that arises from unknown formulæ, for although those of hospitals are published, yet there are many dispensaries and other institutions, each having its own formulæ, which the medical men in attendance use, and which occasionally and inadvertently creep into the prescriptions of their private practice.

A formula is required in No. 139 for emp. pot. iodid. It will be found in the London Pharmacopœia, 1851, as follows:—

Iodide of Potassium	1 ounce.
Prepared Frankincense	6 ounces.
Wax	6 drachms.
Olive Oil	2 fluid drachms.

To the frankincense and wax melted together add the iodide first triturated with the oil and stir constantly until they cool. This plaster is to be spread on linen rather than leather.

As a general rule a dispenser in making an external preparation for which there is no authorized formula, may very properly be guided in the proportion of the active ingredient by an official formula having the same ingredient with a different basis.

In prescription No. 140, camphor and calomel are prescribed in the form of a pill, but without an excipient. It was suggested to the writer to use ext. hyoscy., but he very properly used glycerine and tragacanth; this excipient is the most suitable for such a purpose, and is one very generally applicable when powders have to be made into pills. The use of a medicinal extract for making camphor and colomel into pills is not admissible, and the employment of ext. hyoscy. for this purpose is to be strongly condemned. The suggestion indicates a want of judgment. The pills made with ext. hyoscy. would be dark coloured, to which there may very properly be an objection on the part of the patient, and the peculiar odour of henbane would be equally objectionable. Should the pills have been properly dispensed on a previous occasion, such an error as the

addition of henbane would tell strongly against the establishment where it occurred.

When liq. cinchon. is ordered, as in No. 141, and no special name attached to it, the ext. cinch. flav. liq., B.P., is dispensed, a fluid extract and a liquor being considered in this, and perhaps in other instances, equivalent terms. It is difficult to say what is intended, but there can be no difficulty as regards the preparation to be used when liq. cinch. is ordered in a prescription.

No. 142 is a prescription involving a little manipulatory skill, but a very good emulsion may be made by the following method of procedure. First make the p. tragac. co. into a thick mucilage, using the mortar for this purpose; then add gradually, with constant stirring, the bals. copaibæ. It will be necessary at intervals to add also a little water, whilst the balsam is being emulsified. Put the camphor into the three tinctures mixed together; when dissolved add to it as much water as the solution will take up without precipitation, then gradually pour this with constant stirring into the previously made emulsion of copaiba. If the tinctures be added without dilution to the emulsion a separation will take place in the mixture, and the previously made emulsion of copaiba will be spoilt. And equally satisfactory will be result if the method, so kindly furnished by W. H. R. in this day's Dispensing Memoranda, be adopted. The mixture should be of a light brown colour, a perfect emulsion, and showing no sign of separation.

The mixture, No. 143, cannot be made clear and without deposit. Probably the best method would be to dissolve the quinine in the tinctures, and to it to add the sp. am. arom.; then to dissolve the bicarb. of potash in the inf. aurant., and gradually to mix them with continual shaking. It does not make an elegant mixture and the quinine separates after standing some time. The combination of quinine in a mixture with sp. am. arom. has on several occasions been referred to; a separation of the quinine will to a greater or less extent take place. This is in some cases prevented, and in others much modified, by the previous addition of a little mucilage. From the statement of the writer that he put the potass. bicarb. into water, it is presumed that he used a concentrated infusion, and it may be well here to remark that conc. infus. of orange peel has no place in the British Pharmacopœia.

FLUID EXTRACTS BY REPERCOLATION.*

BY EDWARD R. SQUIBB, OF BROOKLYN.

As the time approaches for a revision of the U. S. Pharmacopœia those parts of it which require the most time and labour should be recognized, that due consideration may be given to them; and there is certainly no department of the work where more time and labour is needed than upon the fluid extracts and extracts. Should the Committee of Final Revision fail to find and adopt the best plan of making this important class of preparations the Pharmacopœia instead of being the model and standard of the nation will be surely disregarded and left behind by the practice and the results of the large manufacturer and the evil of the present will be confirmed and fastened upon the future.

It will not do for the Committee to disregard any plan because it is laborious, or troublesome, or expensive, or complicated, or because it is not adapted to the knowledge and capacity of the large majority of physicians and pharmacists. These, though very important, are still secondary considerations. The thing to be accomplished in the Pharmacopœia is to have practically perfect preparations in every respect. That is, preparations what they really profess to be. They should contain all the active and useful parts of the drug in their natural conditions and associations; should reject as far as practicable the inert and useless portions of the drug; and should bear the established relation to the drug, of minim for grain;—or, weight for weight, if this can be accomplished without materially disturbing the established relation. To effect this object a general scheme, plan or process can be adopted, and then every drug must be studied carefully and laboriously.

The original process of Professor Procter accomplished the exhaustion of the drug insufficiently, but that difficulty can be easily remedied by carrying the percolation further. But the concentration of the weaker percolate to obtain the established relation between the drug and the fluid extract presents difficulties which are probably insurmountable by that process. It is not simply by the heat and oxidation of the evaporation process that all the harm is done to that portion of the preparation, but the active principles are so dissociated and split up by the concentration that they are no longer in their natural condition, but form new relations and combinations which change their solubilities, and bring a new set of reactions into play, making the preparation something else than what it professes to be. The evidence of this is found in the fact that a resinous or oleaginous drug can be thoroughly exhausted by a menstruum which will permanently hold all its constituents in solution. But if such menstruum be evaporated off, the same menstruum will not dissolve and hold the extract again. Nor will any other menstruum ever again reconstruct the extract or restore it to its original condition. For example, a diluted alcohol will exhaust buchu and will hold the oil, while in its natural relations with other constituents of the leaf, in the same kind of combination or emulsion that exists in the leaf before extraction, and in such a solution, though very dense, the oil does not change in odour, much, if at all, more rapidly than the leaf does. But if such a solution being evaporated until the oil is precipitated and shows itself as a fully formed oil, the same strength of alcohol will not redissolve it. Nor will any strength of alcohol redissolve the whole of the extract, or recombine its once separated elements into their natural condition. And, moreover, the oil when separated changes its physical properties more rapidly than when in its natural condition in the leaf, or than when separated with its natural associations unbroken. These circumstances constitute the chief objection to the original process, and to many of the original menstrua of Professor Procter, and led the present writer to try to make improvements both in the process and the menstrua.

This effort at improvement by the writer was begun in a paper published in the 'Proceedings of the Amer. Pharm. Assoc.' for 1865, p. 201. To diminish the proportion of alcohol in the menstrua, and to economize its use, were the principal objects of this paper, and it is cited here for reference in regard to the importance of the points there insisted upon, because these points have not attracted the attention they deserve.

The effort at improvement was continued in 1866 by a paper published in the Proceedings of that year, p. 81. In this paper the method by repercolation was first proposed and described as overcoming the principal objections to the previous methods.

This method of repercolation has now been exclusively used by the writer for nearly twelve years in the production of many thousands of pounds of all the principal fluid extracts, and the object of this paper is to sum up this experience, and publish the modifications of the process, as they have been suggested and successfully applied during this prolonged experience, with a view of bringing the process more prominently into notice in

* *American Journal of Pharmacy.*

order to be critically examined and tested. The general results of the application of repercolation, in the writer's hands, are, that no other process yet proposed accomplishes the main objects so well; and, therefore, that unless some new process can be devised that may attain the objects better and more accurately than this, it should be the process adopted for the Pharmacopœia.

In 1867 papers by the writer upon this same subject, as applied to the cinchonas, may be found in the *Amer. Journ. of Pharm.* for July, August, and September, and in the 'Proceedings of the Amer. Pharm. Assoc.' for 1867, p. 391. All the principles involved in percolation and repercolation were fully discussed and illustrated in those several papers, but they seemed to attract little attention, and they are cited here to avoid recapitulation, since they cover nearly every point which the writer has now to bring forward. But the papers also contain many details which accumulating experience has improved and materially modified.

About 1870 a new form and arrangement of percolator was devised by the writer, and was put into practice so successfully that two years later in the 'Proceedings of the Amer. Pharm. Assoc.' for 1872, p. 182, an account of it, with a cut, were given in detail. This contrivance has now been in use continuously for about eight years, upon every scale from 4 ounces to about 400 pounds, and by pretty thoroughly carrying out the principles involved in percolation, it has contributed very largely to the success and uniformity of the process in the writer's hands. But the apparent complication of this device, and the details of repercolation, seem to have operated against any general understanding of the process, so that it has probably been generally condemned without sufficient trial; while the physical laws which govern the relations between liquids and solids in the direction of discriminative solubilities have been still too much overlooked, in favour of the earlier and more simple processes.

Whatever may be said of the older processes in regard to simplicity and facility of application, by which they are adapted to any capacity, and thus go into general use, it may also be said with great certainty that under the ordinary conditions of their general use, they do not accomplish their object to a reasonable extent, or as well as other processes now known: and that although the resulting preparations are put forth in the Pharmacopœia as representing the drugs minim for grain, they do not really come near to this relation. The variations in the quality of the drugs used, and the variations in the moisture which they contain, are elements of so much uncertainty and want of uniformity in the liquid preparations made from them, that it becomes very important to reduce all other sources of variability to a minimum.

Repercolation, well applied, leaves little to be desired in making a liquid preparation that will fully represent the drug in almost any desired relation of strength; and if indifferently applied, the inaccuracies of one operation are so made up and controlled by those which follow that when the results of the different operations or percolations of the process are mixed together the general results must be practically good and uniform.

Indeed, so satisfactory has this process been in the writer's hands for the last eight or ten years, that the difficulties of making good fluid extracts have been entirely confined to the getting of good materials to make them from, and in controlling the hygrometric moisture in such materials when used. And in view of the satisfactory results, the inconveniences of the process and the disadvantage of having to carry a large stock of the weak percolate from each drug, seem now to be of very much less consequence than at first.

Upon finding out how much more serious these inherent objections to repercolation appeared to others than to himself, and how little credit the process obtained for its results in the way of counterbalancing these objections, the writer set himself to the task of trying to simplify the apparatus and the process to the utmost extent that could be done without sacrificing the principles upon which the success depends: so that by doing away with the machinery and apparent complication of a special percolator, and as many details as possible, the process might appear less objectionable beside the older methods, and thus induce pharmacists to learn it and try it long enough to become expert at it, and to be able to judge wisely in regard to its practicability and its appropriateness to pharmacopœial use.

These efforts at simplification are now to be set forth for whatever they may be worth, and they may be best introduced here by a model process.

For this model process it may be well here, again, to take the most difficult substance known to the fluid extract maker, namely, cinchona bark. This was one of the substances investigated in the papers of 1867 above referred to, and they may be usefully read as including some points of investigation omitted here, and especially in regard to testing the alkaloid value of different portions of the percolates.

The cinchona used in the model processes to be given is of exceptionally good quality, and therefore exceptionally difficult to exhaust. It is a yellow cinchona from the *C. officinalis* cultivated in Java, and contains about 9 per cent. of total alkaloids, of which about 7 per cent. is quinia. It is therefore more than three times the value of officinal yellow cinchona, and when such barks are used for making the fluid extract, this should be reduced to some standard of strength. That is, the Pharmacopœia should direct that its fluid extract should have a definite alkaloid strength. In these model processes, however, this cinchona is used as if it was of the ordinary quality.

As the preparation of this paper for publication was undertaken by the special request of the committee of the American Pharmaceutical Association on the Pharmacopœia for use in connection with their work of finding out the best way of making fluid extracts, the details of the processes must be given with a minuteness that may seem useless and tedious. Beside, it is a prominent object of the writer to show how, in his judgment every individual fluid extract must be studied before it is adopted by the Pharmacopœia, if the utility and character of the Pharmacopœia as a standard for the nation is to be restored to it. Who is to do this work, and who is to pay for the time, skill, and labour necessary to do it well, are problems for the future.

(*To be continued.*)

A REMEDY FOR TAPEWORM.*

Dr. Bröking, of San Remo, calls attention to an anthelmintic in common use among the people of Northern Italy. It appears that the fresh seeds of the *Cucurbita maxima*, or pumpkin, are sold in large quantities at the herb shops, both as an article of food and as a domestic remedy for tapeworm. Their purgative action is but slight and they produce neither nausea nor pain in the abdomen, but they appear to destroy the worm. If the patient has fairly good teeth, he may be directed to eat an ounce and a half of the seeds, or the same quantity may be beaten up into a paste, with sugar and water. The seeds should be taken early in the morning, the patient having fasted from food from the noon of the previous day, and should be followed by a dose of castor-oil at an interval of three or four hours. It is asserted that the head and cervical segments seldom fail to appear in the stools. It is worthy of notice that the seeds of pumpkins grown in cooler latitudes do not possess vermicide properties; some seeds obtained in Paris and Germany did not produce the desired effect. There is, however, no difficulty in obtaining them from San Remo, for Signor Vacchieri of the Farmacia Internazionale has been good enough to undertake to forward a supply gratis to any hospital or infirmary. The seeds have a sweet and pleasant taste, and when beaten up with a little sugar are freely taken by children.

PROCEDURE FOR OBTAINING REGISTRATION UNDER THE DENTISTS ACT.

THE recent amendment of the law relating to dental practitioners having now come into force, provision has been made by the General Medical Council for the registration of dental practitioners. A circular has been issued by the Registrar appointed under the Act, setting forth the grounds upon which registration as a dentist can be claimed, and stating the manner in which application is to be made. Forms of application have also been prepared suitable for various cases.

By the courtesy of the Registrar we have been furnished with copies of these documents, and as some of our readers are doubtless interested in learning how application is to be made for entry upon the Dentists' Register we take this opportunity of placing the information before them, and thus replying to many inquiries that have been addressed to us upon this subject.

In the first place, the Registrar is W. C. J. MILLER, B.A., and the office for Registration is the Medical Council Office, 315, Oxford Street, London, W.

The amount of the fee to be paid for registration depends upon upon the date of application; those who apply before the 1st of January, 1879, will have to pay two pounds, and those who apply on and after that date will have to pay five pounds.

There are three classes of persons who are entitled to be registered under this Act, and as specified in section VI. they are as follows:—

A. Licentiates in dental surgery or dentistry of any of the medical authorities.

B. Persons entitled to be registered as foreign or colonial dentists.

C. Persons who on July 22nd, 1878, were *bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy.

In regard to pharmacists seeking registration it is important to note that no registration under clause C. can be effected after the 1st August, 1879.

The printed form of application, copies of which may be obtained from the Registrar, to be filled up with particulars and signed by the applicant, is as follows:—

DENTAL REGISTRATION.

Particulars to be Supplied by Applicants.

Under Clause (C) of Section VI. of the Dentists Act (1878).

I request to be registered as a Dentist, under Clause (C) of Section VI. of the Dentists Act (1878), for which purpose I submit the following particulars:—

Whether practising Dentistry separately, or in conjunction with the Practice of Medicine, Surgery, or Pharmacy.....

DECLARATION required to be made by a person who claims to be registered under the Dentists Act (1878), on the ground that he was *bonâ fide* engaged in the practice of Dentistry at the date of the passing of the Dentists Act (1878).

I,

residing at , hereby declare that I was *bonâ fide* engaged in the practice of dentistry at , at the date of the passing of the Dentists Act (1878).

(*Signed*)

(*Witness*)

Dated this day of , 18 .

NOTE.—Any person who wilfully procures or attempts to procure himself to be registered under this Act, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, and any person aiding and assisting him therein, is liable, under the Dentists Act (1878), to imprisonment for twelve months.

Provided the foregoing details are satisfactory, applicants may be registered on transmitting this paper, duly filled up and signed, together with the registration fee, to the Registrar of the General Medical Council,

W. C. J. MILLER,
Medical Council Office,
315, Oxford Street, London, W.

Any person who claims to be registered under the clause of Section VI. must state in the above form, his name and address, and whether he has practised dentistry or dental surgery separately or in conjunction with the practice of medicine, surgery or pharmacy; he must also sign the declaration in the schedule annexed to the Dentistry Act (1878), and the Registrar may, if he sees fit, require that declaration to be affirmed in the manner provided by chapter 62 of the Act of the 5th and 6th years of the reign of King William the Fourth.

This document is to be sent, together with the registration fee, to the Registrar.

We understand that the Medical Council is expected to meet early in October, for the purpose of taking measures for carrying the Act into execution, and that meanwhile the registration is in progress. The *Lancet*, in giving this information, seems to suggest that the work of registration will be attended with considerable difficulty, and in a somewhat supercilious tone commiserates the Registrar in having to decide, among other things, what constitutes the practice of dentistry *bonâ fide* in connection with pharmacy. At the same time it volunteers a mitigation of the assumed difficulty by adding the

remark, "Surely it will not be held to consist in the mere act of extracting teeth." We must, however, ask why that should not be the case, notwithstanding the obvious conviction of the *Lancet* that its view of the matter admits of no question. It is not the intention of the Act to preclude pharmacists from practising dentistry as they have hitherto done, but on the contrary to recognize their right to do so subject to registration. The act of "extracting teeth" comes within the scope of the term "practising dentistry," and it requires that the practitioner should be registered as a dentist. With many chemists and druggists the extraction of teeth constitutes the extent to which they practise dentistry and why they should on that account not be entitled to registration we confess our inability to perceive.

A REPUBLICAN PHARMACIST IN LONDON.

That travellers see strange sights is proverbial. Prof. Garrison, of the Chicago College of Pharmacy, has been spending six weeks in London, and has communicated his experiences in a lively style to the *Pharmacist*. Notwithstanding the large number of United States nostrums that he says he recognized on the shelves, and the patriotic way in which he accounts for the fact, he found that in London everything smells of royalty, and that like all other London traders, the chemists and druggists revel in this kind of glamour. Judging by the number appointed by Her Majesty and other members of the royal family, he has formed the opinion that royal stomachs require an immense amount of physic. The great number of educational institutions indulging in the adjective "Royal" also attracted his attention, and among these he has discovered a Royal Pharmaceutical Society. From this the respected professor appears to have been not quite free from the glamour himself.

PROBABLE POSTPONEMENT OF THE MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

We are sorry to learn that there is a probability of the meeting of the American Pharmaceutical Association, which was to have commenced next week in Atlanta, having to be postponed in consequence of the dreadful epidemic of yellow fever which has broken out in the Southern States. A circular has been issued by the Executive Committee of the Association, asking the opinion of the members as to the propriety of omitting the meeting altogether this year, or of holding it in some Western city instead of Atlanta, or of postponing it until some time in November, when it will be possible to hold it in Atlanta with safety. Our contemporary, *New Remedies*, in making the announcement, favours the last mentioned of the three courses, one of the reasons given being that it is desirable that the next meeting shall be held in the South, and that it cannot be guaranteed that yellow fever may not be as prevalent next year as it is this.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of this Association will be held at 29, Brewer Street, Regent Street, on Wednesday evening next, September 4, at half past eight o'clock.

Provincial Transactions.

DOVER CHEMISTS' ASSOCIATION.

The usual quarterly meeting was held at the Apollonicon Hall on the 14th inst. Mr. H. Peake presided in the absence of the Chairman. A report was presented by the Secretary, from which it appeared that during the past quarter an attempt had been made to form an Assistants' Association, which failed, mainly through the apathy of those whom it was proposed to benefit. Early in July a petition, emanating from the Trade Association, had been duly signed and forwarded, and the following letter, amongst others, was read to show the result of the efforts which had been made—

"House of Commons Library,
"10th July, 1878.

"W. H. Cotterell, Esq.

"My dear Sir—I have this day presented your petition against the Medical Act Amendment Bill which has come from the House of Lords. I have also given notice to insert the substance of clause 28 in the Act of 1815 in the Bill, as a new and additional clause. I am afraid that the Government will not accept the amendment, but they ought, and I will do what I can towards it.

"I am, my dear Sir,
"Yours faithfully,
"C. K. Freshfield."

The report concluded by recommending full deliberation on the matter so that appropriate action may be zealously and unanimously taken at a fitting opportunity.

After the report had been unanimously adopted, the Secretary, Mr. Brown, said there were two points on which he felt somewhat strongly, the first being the denial given to the Duke of Richmond by the Pharmaceutical deputation that any instances of oppressive prosecution existed. Viewed in the light of the verdict given in Wiggins's case, viz., "That the defendant acted as an apothecary in taking cases that were dangerous," it was fair to assume that Mr. Shepperly in prescribing for a paid informer, who feigned an ailment for the purpose of getting up a case, was wrongfully convicted. It was unfair and unjust to allow this view to be overborne by secret and informal accusations against the defendant of having otherwise transgressed the limits commonly observed, and he regretted that the deputation was apparently biased to the extent of giving an obviously inaccurate reply. Again, the original total repeal of the 20th section of the Apothecaries Act met apparently with the tacit approval of the Council, and the Editor of the Journal had suggested that the Trade Association had brought about a correction of this "inadvertence." So that seemingly an alteration of the law would, if attained by inadvertence, have been welcomed by the same body who yet refused openly to ask for it. This was conduct hardly worthy of an ancient, dignified, and wealthy corporation.

The Chairman (Mr. Peake) said that the Pharmaceutical Society was hardly to blame for not undertaking the defence of Mr. Shepperley, since it appeared that he had made a practice of visiting, which he considered unjustifiable.

It was resolved that a donation of a guinea from the funds in hand should be sent to the Special Defence Fund of the Trade Association, and the proceedings terminated.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of this Association was held at the Rooms, Halford Street, Leicester, on Thursday, the 1st instant. A report was presented and adopted, in which one of the most important facts mentioned was that in the earlier part of the session

some of the classes had been discontinued in consequence of the attendance being small. This was attributed to some of the members having joined the Science and Art classes in the town. The Treasurer's report showed a balance in hand of £3 12*s.* 10*d.*, against £9 3*s.* 9*d.* in hand at the end of the previous half-year. A programme of lectures and classes extending to the end of January, 1879, has also been issued.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 154.)

The next paper read was on—

The Volumetric Estimation of some Iron Compounds of the Pharmacopœia.

BY HARRY NAPIER DRAPER, F.C.S., M.R.I.A.

The paper which I present to the Conference is scarcely worthy of the name. It is somewhat of a note, but much more of a query, and is the result of a doubt which was a few weeks since expressed to me by Professor Tichborne as to the correctness of the figures given by the Pharmacopœia in the volumetric estimation of arseniate of iron. Professor Tichborne thought the quantity of bichromate solution stated as necessary for the conversion of two grammes of ferrous arseniate far too small to effect that object, and this led to my making some experiments not only with the arseniate but also with the phosphate and the magnetic oxide.

These are, from the short time at my disposal, somewhat incomplete, but I bring them forward in the hope that some member who has worked at the subject may be able to explain the discrepancies which have presented themselves to me.

The Pharmacopœia volumetric solution of potassium bichromate is, as is well known, viginti-normal, that is, it contains in a litre 14·75 grammes of the salt. And, as correctly stated by the Pharmacopœia, 100 c.c. are capable of converting from the state of proto- to that of persalt 1·68 grammes of iron. This statement is obviously in accordance with the equation—

$$6\,FeO + Cr_2O_6 = 3\,Fe_2O_3 + Cr_2O_3.$$

Thus 0·168 grammes of pure iron would require 10 c.c. of volumetric solution, and in actual practice the mean of three carefully conducted experiments made with piano wire was found to be 9·7 c.c.

Ferrous Arseniate was the first compound experimented upon. Its composition is given by the Pharmacopœia as $Fe_3As_2O_8$ "partially oxidized," and it is stated that two grammes require 17 c.c. of the volumetric solution of bichromate. Now if it were possible to prepare the arseniate so that it should not be "partially oxidized," but that all its iron was in the ferrous condition, it would be oxidized by the bichromate as represented by the equation—

$$2\,Fe_3As_2O_8 + Cr_2O_6 = 3\,Fe_2O_3 + 2\,AsO_5 + Cr_2O_3,$$

which gives 892 grams of the arseniate as requiring 295 grammes of bichromate. Therefore $\frac{1}{100}$th of this quantity (8·92 grammes) will require 2·95 grammes, that is 200 c.c. of volumetric solution, and necessarily the two grammes of the B.P. 44·84 c.c.

But the Pharmacopœia says that two grammes require but 17 c.c., and if this be correct the arseniate as prepared by its instructions can contain but 37·9 per cent. of absolute ferrous arseniate. This represents a constitution which is certainly but inadequately expressed by the phrase, "partially oxidized."

Nor does experiment make the matter clearer. Ferrous arseniate was prepared in strict accordance with the instructions of the Pharmacopœia, and three separate quantities of two grammes gave the following results:—

Two grammes of arseniate required—

(*a*) 10·8 c.c. volumetric bichromate.
(*b*) 10·7 „ „ „
(*c*) 10·7 „ „ „

Giving a mean of 10·73 c.c. and representing but 21·7 per cent. of ferrous arseniate.

It is thus apparent that while the Pharmacopœia estimate of the percentage of ferrous arseniate in its preparation falls far short of what theory may reasonably demand, an actual experiment carefully made, falls short even of this.

According to Gmelin, ferrous arseniate contains six atoms of water, but no notice of this is taken by the Pharmacopœia.

The specimen of arseniate prepared by myself contained as stated 21·7 per cent. of $Fe_3As_2O_8$. I have, however, examined four other specimens purchased in Dublin, with the following results:—

(*a*)	Two grammes	required	3·0	c.c.	= 6·64	per cent.
(*b*)	„	„	1·5	„	= 3·34	„
(*c*)	„	„	2·3	„	= 5·2	„
(*d*)	„	„	6·0	„	=13·6	„

An attempt made to diminish the oxidation by using hot solutions, washing rapidly with hot water, and drying at 212° instead of at 100°, was unsuccessful, the product in this case containing only 21·1 per cent. of actual ferrous arseniate.

Ferrous Phosphate.—The reaction of this compound with the bichromate is obviously similar to that of the arseniate

$$2\,Fe_3P_2O_8 + Cr_2O_6 = 3\,Fe_2O_3 \times 2\,P_2O_5 + Cr_2O_3$$

and two grammes will require 55·8 c.c. But the Pharmacopœia demands only 25 c.c., that is a degree of purity corresponding to 44·8 per cent. of actual ferrous phosphate.

In this case experiment gave results directly opposed to those obtained in that of the arseniate, for instead of not being able to attain to the Pharmacopœia standard, a specimen of phosphate prepared according to its instructions required 34 c.c. so that it contained 60·9 per cent. of real phosphate against the 44·8 per cent. of the Pharmacopœia.

Four purchased specimens gave the following results:—

(*a*)	Two grammes	required	17·5	c.c.	=31·3	per cent.
(*b*)	„	„	27·5	„	=49·2	„
(*c*)	„	„	13·5	„	=24·1	„
(*d*)	„	„	16·0	„	=29·6	„

It would seem that here again the expression "partially oxidized" but very imperfectly signifies a degree of oxidation which is stated by Wittstein to vary between one atom in nine of persalt to one atom in four, and which from the experiments now detailed may possibly exceed this latter proportion. Both Gmelin and Wittstein, it must be observed, agree in assigning to the phosphate eight atoms of water.

Magnetic Oxide.—The results obtained with this compound have been still more unexpected. If it were absolute ferroso-ferric oxide, having the formula assigned to it by the Pharmacopœia, two grammes would require according to the equation—

$$6\,Fe_3O_4 + Cr_2O_6 = 9\,Fe_2O_3 + Cr_2O_3$$

28·7 c.c. of volumetric solution. But the Pharmacopœia, though admitting the presence of 20 per cent. of water of hydration and "some peroxide of iron," requires only that two grammes shall be oxidized by 8·3 c.c., which would indicate but 28·8 per cent. of magnetic oxide, and a specimen prepared according to its direction has not even reached this standard, requiring only 5·6 c.c. of bichromate.

Professor Tichborne asked if Mr. Draper had calculated the actual percentage of arsenic represented by the

variation he had noticed. It struck him that this was an important point in connection with the dose of an article like arseniate of iron.

Professor ATTFIELD said he had himself never regarded the number of cubic centimetres and volumetric solution of red chromate required by a given weight of either phosphate or arseniate of iron as indicating the percentage which the compilers of the Pharmacopœia expected these articles to possess. He had always considered that the figures given only showed what was the composition of the particular sample analysed by the compiler, and had looked to the text generally for the standard of purity of these two substances. The two words which expressed the degree of purity, viz., "partially oxidized," he regarded as being extremely vague, and as therefore most properly showing the very vague character of the strength of these two substances when made in conformity with the Pharmacopœia.

Dr. SYMES said he had always contended that if the process given in the Pharmacopœia would not yield a salt of absolute purity it ought to give one which would bear the test there given; but according to Mr. Draper this was not so, and the results did not correspond with the test given. On a previous occasion he had pointed out that the addition of a little sugar to the water in which the ferrous salts were precipitated assisted in preventing peroxidation, and this fact might have an interest in connection with the present paper.

Mr. WILLIAMS said it had been well known for a long time that the salts mentioned by Mr. Draper were very liable indeed to vary in their composition. With regard to phosphate of iron it was the practice of the makers to rather encourage oxidation, because their customers much preferred a nice looking blue phosphate of iron to a slate-coloured grey article, and the blue colour could only be obtained by allowing a little more oxidation to take place. It was fortunate, however, that the use of the dry phosphate of iron was now hardly necessary, and probably it would be struck out of future editions of the Pharmacopœia. Phosphate of iron was now mainly used in the form of syrup and in solutions, and in that form it was used before it had time to oxidize; in fact, the fresher it was the better. Arseniate of iron was so very little used that there had not perhaps been so much attention paid to it as might have been desired; but phosphates and arseniates were so analogous that it might be expected the results would be very similar. As for the magnetic oxide, he could quite endorse what Mr. Draper said, that it was most liable to vary in its composition and very difficult to keep in a perfect condition; it was almost certain to have a considerable quantity of peroxide mixed with it.

Mr. DRAPER in reply said he had not made any calculation of the quantity of arsenic present. The arseniate of iron was rather an arsenic than an iron preparation, and he did not think it important whether the salt were in the ferrous or ferric condition; of that, however, he was not sure, not having directed his attention to that subject. He would add that the whole gist of his paper was to show that the Pharmacopœia gave a process for the preparation of the arseniate which would not come up to the standard it laid down and could not be made to do so. With the phosphates the case was exactly the reverse, the process furnishing a product which gave a far higher percentage than was required. He thanked Dr. Symes for his observations with regard to sugar, and he had seen it observed that in examining saccharated carbonate of iron more bichromate of potassium was required than if there were no sugar present. He might inform Mr. Williams that he had seen the Pharmacopœia process strictly carried out, and a very good phosphate obtained of a nice blue colour.

On the motion of the PRESIDENT the thanks of the Conference were accorded to Mr. Draper.

The next paper read was on—

NITRITE OF AMYL.

BY D. B. DOTT.

Nitrite of amyl is now admitted to be an important remedial agent, having taken its place in the national Pharmacopœia. Being a substance of great physiological activity, it is highly important that it should be obtained pure, or if that is impracticable that the preparation should be of constant strength. With the view of ascertaining whether either of these conditions holds good with the article in the market, I procured several samples from such sources that they may be regarded as fairly representative and submitted them to examination along with a quantity (*a*) prepared by ourselves. As there is considerable divergence in the boiling-point of amylic nitrite as given by different authorities, the fraction 90°-100° C. was collected as correct. This portion had invariably the proper sp. gr. of ·877. The results of the examinatio are embodied in the table annexed.

Sample.	A	B	C	D	E	F
Specific Gravity.	·877	·876	·864	·875	·875	·875
Below 90° . .	5·0	3·0	34·6	2·6	0·0	52·0
90°–100° . . .	85·0	65·0	6·7	47·5	11·5	33·3
Above 100° . .	8·0	28·0	51·7	45·7	83·9	11·4
Water	0·0	0·0	1·8	0·0	2·2	0·0
Loss	2·0	4·0	5·2	4·2	2·4	3·3
	100·0	100·0	100·0	100·0	100·0	100·0

These figures give the results of a single rectification. Of course, on again rectifying the lower and higher fractions an additional quantity of nitrite of amyl would be obtained; but the numbers are sufficient for the purpose of comparison. The samples C and E are of very poor quality, E being probably the inferior, because although it apparently contains a larger percentage of amylic nitrite than C, it yields a large proportion boiling above 100°, the temperature rising to 230° before the distillation was stopped, leaving a black oily residue in the flask. The odour of this sample was quite different from that of genuine nitrite of amyl. It will thus be seen that out of five specimens examined, two were of very inferior quality. That it is difficult completely to separate the nitrite of amyl by rectification from the accompanying substances, is shown by the numbers here given. The fractions boiling below 90° and above 100° from the sample F were rectified together in the same way as before, the process being repeated twice.

I. 59·0 c.c. gave 13·0 c.c. = 22·0 per cent 90°—100°
II. 43·0 „ „ 8·0 „ = 18·6 „ „ „
III. 33·5 „ „ 5·0 „ = 14·9 „ „ „

In passing judgment, however, on such a substance as nitrite of amyl, the question meets us at the very outset, What degree of purity have we a right to expect in this body? In the case of amylic nitrite the question is one of considerable difficulty, requiring for its elucidation the consideration of a number of facts. In the first place, have ascertained that the fractions boiling below 90° and above 100° are for the most part either physiologically inert or have an action distinct from that of nitrite of amyl. There may, however, be several isomeric or metameric nitrites, whose boiling points differ and yet whose physiological action is the same. That this is the case seems probable from the varying boiling points given for amylic nitrite and amylic alcohol. Indeed two isomeric alcohols are known to exist. According to the authorities cited in Watts's 'Dictionary' the boiling point of the nitrite varies from 91° to 96°. Tanner ('Year-Book of Pharmacy,' 1872, 186), gives 95°-100°, and Umney (*Pharmaceutical Journal* [3], i., 422) 98°-100°, as the temperatures at which nitrite of amyl should distil. For

amylic alcohol Gmelin gives boiling points varying from 127° to 134°, and even the more recent researches record apparently conflicting accounts. Schorlemmer found ('Proceedings of the Royal Society,' xv., 131) that amyl alcohol whether prepared from fusel oil or from American petroleum, boiled at 132°. On the other hand, Pedler (*Chemical Society's Journal* [2], vi., 74) gives 128° and 129° as the boiling points of the dextrogyrate and optically inactive alcohols, respectively. Without going further into the matter at present, I may say with certainty that there is an amylic alcohol or mixture of alcohols boiling at 128°-129°. This I have proved by rectifying a fraction repeatedly until it distilled entirely at 128°-129°, and then oxidizing the same with potassic anhydrochromate and sulphuric acid. It gave a yield of valerianic acid equal to 14 per cent. Other matters that have to be taken into account are the possible inapplicability on the large scale of a process of preparation or purification that may work well in the laboratory, also that a sample honestly prepared by one method may contain impurities not existing in a sample prepared by another process. Not much importance need be attached to the sp. gr., as on account of the lower fractions having a higher, and the higher fractions a lower sp. gr. than amylic nitrite, it is easy by a judicious blending to produce the desired density.

For the preparation of the nitrite, two processes are given in the Pharmacopœia, "by the action of nitric acid or nitrous acid (N_2O_3) on amylic alcohol." Of these two I have no hesitation in pronouncing the latter to be the better. Whether it is the more economical may be open to question. The objection of Hunge, quoted in the 'Year-Book of Pharmacy,' 1871, 225, that by this process a black non-volatile substance and a number of other impurities are formed, is unfounded. After passing the gas through for a sufficient length of time, the liquid is agitated with water, decanted therefrom and shaken up with sodic carbonate. The nitrite is now rectified, the portion passing over between 90° and 100° being retained. The amylic nitrite thus obtained has a sp. gr. of ·877. By repeated rectification, however, I have never been able to get more than 95 per cent of distillate. This arises partly from loss in the distillation, but chiefly from decomposition which then occurs, there invariably remaining a residue boiling above 100°. The fact that decomposition does take place is proved by observing that while the liquid before distilling is quite neutral to test-paper, the distillate is strongly acid.

The results of one experiment are here given—

60·0	c.c. gave	52·5	c.c. = 87·5	per cent,	boiling at	90°-100°
52·5	,, ,,	49·5	,, = 94·2	,,	,,	,, ,,
49·0	,, ,,	46·5	,, = 94·8	,,	,,	,, ,,
6·5	,, ,,	44·0	,, = 94·6	,,	,,	,, ,,

Considering all the circumstances of the case it will readily be allowed that the fixing of a standard of purity for nitrite of amyl is, in the present state of our knowledge, a matter of difficulty and that it must be to a certain extent arbitrary. The British Pharmacopœia describes the liquid in question as boiling at 205° F. or 96° C. I can only say that no sample we have ever examined, whether purchased or prepared by ourselves, boiled constantly at that or at any other temperature, nor have I any reason to believe that such a perfect preparation has been produced. It is not, of course, for me to decide what tests medicinal amyl nitrite ought to answer; but I think it will be generally agreed that such products as those marked C and E are not altogether creditable to the profession of pharmacy.

Mr. UMNEY expressed his regret that nitrite of amyl was not to be found in a purer state now than it was seven years ago, when he went over precisely the same ground as that covered by the present paper. The physiological action of the nitrites of methyl, ethyl, and amyl had been thoroughly worked out by Dr. Richardson. He believed that the *sine quâ non* in the manufacture of pure nitrite of amyl was a definite body, amylic alcohol, to start with, not ordinary fusel oil.

Professor TICHBORNE was very glad to find that Mr. Dott had confirmed a fact which he noticed many years ago in a work called the 'Laboratory,' which was afterwards denied by Mr. Chapman, one of the main authorities on nitrites. He then pointed out that nitrite of amyl was dissociated in the act of boiling into amylic hydrate and nitrous oxide gas; this was denied, as he had stated, by Mr. Chapman, and he was glad to find that recent experiments confirmed his observations.

Mr. T. B. GROVES asked if Professor Tichborne had tried distillation *in vacuo* or in carbonic acid, so as to be out of contact with air.

Professor TICHBORNE said that at the time he performed the experiment he tried carbonic acid, and that had no effect; but he was not prepared to say what would be the result of distillation *in vacuo*. He fancied that the dissociation of the molecules was really a matter of temperature, and as distillation *in vacuo* could be carried on at a much lower temperature, that dissociation might be brought to *nil* or almost so.

A vote of thanks having been passed to Mr. Dott, the Conference adjourned for luncheon, which was provided in an adjoining room by the Local Committee.

Upon reassembling the Secretary read a paper entitled—

FRAGMENTARY NOTES ON OPIUM.

BY B. S. PROCTOR.

Called upon by your worthy Secretary to contribute a paper to this meeting of the Conference, I venture to return to the subject of my recent communications, namely, opium. On this I propose to make one or two short observations, which I trust may not be without interest to practical pharmacists.

Crude Drug.—Excluding exceptional specimens, commercial Turkey opium varies in its strength from 4 per cent. to 12 per cent. of morphia. The importance of standardizing is too obvious to require enforcement. No one could prudently use his opium from either extremity of this scale, and the science of therapeutics can never progress satisfactorily while its agents remain of this uncertain force. It is the duty of pharmacy to supply instruments of precision with which the science of medicine can perform its work.

Impurities.—It has been sufficiently pointed out that the appearance of Turkey opium as it occurs in commerce is but little guide to its morphia value, but it is perhaps not sufficiently acknowledged that no hard-and-fast line can be drawn between genuine and adulterated samples. The only satisfactory definition must lie in general characteristics well known as belonging to the common run of samples, together with an official strength as regards morphia, defined between certain narrow limits, which should fix a maximum as well as a minimum. If we attempt to define what opium should be, say the residue obtained by the evaporation of poppy juice, every commercial sample might be regarded as impure, from the presence of vegetable tissue quite unavoidably there. The smooth extract-like appearance presented by most samples of Persian, and by occasional samples of Turkey and Egyptian opium, should be the rule and not the exception if opium were pure evaporated poppy juice. Nor are we any nearer to a satisfactory definition of genuineness if we say that it should contain no tissue or foreign matter but what is unavoidably present, for the adhering leaf and chaff, which are common and convenient, are not unavoidable, and yet could not be reasonably objected to. On the other hand, the descriptions of the collecting and manufacture of opium tells us of fruit pulps and gum being worked up with the scraps, and made into presentable looking lumps. These additions we would without hesitation declare to be adulterations, though the official

standard of strength might readily pass some specimens so made up if the scraps were rich, and the excipient not used extravagantly. Probably this custom of "making up" very much influences the character of the opium as regards its tendency to absorb moisture, or to lose it, to become mouldy, etc., though it is not unlikely that these qualities may vary in great degree with the soil, climate, season, or mode of collecting the opium, for I have found rich samples hard and mouldy, and others soft and hygroscopic.

Hygroscopic Quality.—Samples of opium vary very much in their hygroscopic qualities, though all I have examined have considerable affinity for water. Some when exposed to a damp atmosphere absorb water with avidity till they are reduced to the condition of a sticky extract. Others which did not under the same circumstances absorb nearly so much, yet retained the last few percentages of water with obstinacy when heated in the drying closet to 150° F., and I have noticed 100 grains, which had been dried at 212° F., reabsorb three grains of water in a few hours while exposed on the top shelf in my office, where the thermometer stood at 90° F., with the gas burning near it. Constancy in the degree of hydration of the powder, which of course affects constancy in its morphia value, will no doubt be best attained by desiccation being carried only to a moderate degree.

Gummy Samples.—Samples of crude opium, which were by analysis palpably sophisticated and unfit for medical use, have presented appearances varying no less than those of the better qualities. One character, which I have repeatedly observed, is a smooth pilular texture, suggestive of apple or fig pulp, an external covering of a bright green leaf, and a morphia percentage sinking down to the small numbers or to fractions of a unit. All ordinary opiums when reduced to a syrupy magma with water undergo curdling on the addition of spirit, but in these pulpy specimens the curdling is so great as to cause the separation of a sticky clot of gum or mucilaginous matter. I am told that a green leaf variety is much esteemed by smokers; probably the samples which have come under my notice may have been imitations of this favourite article, for their appearance was such as to lead to hesitation, if not rejection, had they been offered to a druggist for pharmaceutical use.

Mouldy Samples.—Mouldy samples have varied from 6 to 12 per cent. Perhaps a want of odorous matter may be characteristic of them; it certainly was so in several cases; and not improbably the odorous principle may have an antiseptic action upon some of the constituents of the drug. From the richness of some of these samples it would not appear likely that the moulding has any injurious action upon the morphia. This supposition is further supported by the following observation: In March 1875, I prepared a solution of opium in water to test the relative merits of sundry modes of analysis, and obtained results varying from 6·6 to 7·0 per cent. of morphia. This solution was beginning to turn mouldy in June 1876; the stopper was occasionally removed to encourage the moulding to do its worst; and in November 1877, the analysis was repeated with results closely agreeing with those first obtained, the percentage being between 6·6 and 7·0.

Extract, and Liquid Extract.—Bearing in mind that the Pharmacopœia admits opium varying from 6 per cent. up to the richest found in commerce, it becomes important to consider how far the therapeutic value of the extract and liquid extract corresponds with the value of the crude drug from which they were prepared. Turning to Mulder's analysis as quoted by Pereira, it gives the percentage of morphia in Smyrna opium as varying between 2·8 and 10·8, and the gummy extractive as varying from 21 to 31, but the percentage of morphia has no constant relation to the proportion of gummy extractive. The sample yielding 31 of gummy extractive contained only 4·1 of morphia, while another sample yielding 21 of gummy extractive contained 9·8 of morphia; so that while, of the crude opiums one was little more than twice the strength of the other, the extracts prepared from the same would probably vary in about the proportion of 3 to 1.

Again, turning to the paper by Mr. Dott, presented to our meeting at Glasgow, where he gives particulars of twelve samples of Turkey opium, all within the Pharmacopœia standard—that is, varying between 6·76 and 12·30 per cent.,—the dry extract yielded by the same varied between 13·7 and 34·4 per cent. of morphia; this exceptionally rich extract being yielded by a poor opium, containing only 6·93 per cent. of morphia. Comparing No. 4 in Mr. Dott's table with No. 10, there is a difference in morphia value of the crude drugs amounting to only about 2 per cent., the difference in the extracts from the same is nearly 11 per cent. of morphia. The relation among the samples of commercial extract he examined was, by some happy accident, more satisfactory. I say by accident, as the relation does not correspond as it naturally should do with the relation among the samples of liquid extract. In this latter preparation he found the grains of morphia per fluid ounce varied from 1·66 to 4·51, that is omitting one very bad sample which it is stated yielded only 0·61, but which he seems to admit requires confirmation.

Solid Extract.—These observations point emphatically to the importance of making a change in the formulæ for these two preparations. According to my experience the solid extract is but little used except for the preparation of the liquid, and it might probably be discontinued without much disadvantage; but if it is to be retained, it should be prepared from opium of defined value and the product should be made up to a definite quantity by the addition, if necessary, of sugar, gum, starch or other inert matter.

Liquid Extract.—The liquid extract should be made from a standard opium direct, and after the requisite solution, evaporation and resolution to separate the narcotine, resinous matter, etc., the product should be made up to such a quantity that a fluid ounce would contain 3 grains of morphia. This would correspond pretty closely with the average of the liquid extracts of opium as found in use, and very closely with the strength of the official liquors of morphia.*

Analysis, etc.—In a former communication I had occasion to point out the solubility of narcotine in neutral or alkaline solutions of morphia in water, I have now to record an observation of the solubility of morphia in benzine in the presence of a considerable proportion of narcotine. This, however, applies to morphia in its free state and not as it exists in opium. Working upon opium in considerable quantity, as I have had occasion to do in connection with Swan and Proctor's patent for the purification of opium, I have failed to detect any morphia or codeia in the benzine percolates. This would rather confirm the propriety of the order of proceeding in Mr. Cleaver's mode of analysis; the benzine percolation being finished before the addition of lime which accompanies the action of water in the second percolation. The observation also exemplifies the difficulty there is in sharply separating these two alkaloids, and the necessity there is for vigilant circumspection in dealing with samples differing from the common run.

If, however, it be desirable in any case to free a sample of opium entirely from narcotine before treating it for morphia, an observation which I have recorded in the specification of patent, but which, it may not be out of place to repeat here, will bear upon the point, namely, that some samples of opium containing excess of acid cannot be freed from their narcotine by treatment with benzine or ether unless the acid be neutralized and the narcotine thus set free. A sample of acid opium in dry powder, suspended in dry ether and dry ammonia passed

* Three grains of morphia being about equal to four grains of the hydrochlorate or acetate.

through it till all was strongly alkaline, yielded up its narcotine readily on subsequently percolating more of the solvent.

Ammonia was not discovered in the latter portions of the percolate, but was freely evolved from the powdered opium during the subsequent drying (or more correctly during the warming to rid it of the absorbed ether, for water had been excluded all the time); and what is equally remarkable the natural morphia salt of opium, presumably the meconate, appeared to have undergone no decomposition, for the morphia was still readily extracted by spirit or water.

Possibly the presence of excess of acid would account for the difficulty experienced by Professor Flückiger in removing narcotine, etc., by ether. See 'Pharmacographia,' p. 59—60, and *Pharmaceutical Journal*, April 24, 1875, in which latter article the learned professor speaks of treating opium with boiling ether twenty or thirty times for the extraction of its narcotine, and then does not quote any evidence of the absence of this alkaloid in the opium so treated, nor does he state whether the latter decoctions continued to extract appreciable quantities.

Numerous experiments have shown the power which ether possesses of detracting from the solvent power of spirit or chloroform in relation to the morphia in its state of combination in the opium, the meconate of morphia being nearly insoluble in a mixture of chloroform and ether, slightly more soluble in the same with the addition of spirit, and freely soluble in a mixture of chloroform and spirit without the addition of ether.

No discussion followed the reading of this paper.
A vote of thanks was passed to the author.

The next paper was on—

Soluble Essence of Ginger.

BY J. C. THRESH,
Pharmaceutical Chemist.

Requiring some time ago a strong solution of the active principles of ginger, which would mix with water or syrup without causing turbidity, I was led to make a number of inquiries and experiments, some of the results of which it is the purpose of this paper to communicate.

I found that most wholesale drug houses made and kept in stock a so-called soluble ginger essence, but in many cases the pungency was due to cayenne, and (with one exception) the pleasing aroma of ginger was wofully deficient.

I also obtained several receipts for this essence, but none of them gave satisfactory results. One ordered the powdered root to be percolated with a dilute alcohol, another with a mixture of spirit and glycerine, a third ordered a strong decoction of the ginger to be fortified and preserved by the addition of a weak tincture of cayenne, etc.; but not one of them yielded a result possessing the full flavour and odour of the ginger from which it had been prepared.

I then began to investigate for myself, and ultimately succeeded in making an essence which answered my requirements; but before giving the form for its preparation, allow me to say a few words about the varieties of ginger and of the essence, of rather B.P. strong tinctures, found in the market. On making the soluble essence from the B.P. strong tincture obtained from different houses, I was much struck by the varying qualities (judged by the odour) of the essences made therefrom. Most of the strong tinctures were of a deep red brown colour, and contained a large percentage of resinous matter in solution, and invariably the darker the tincture the more inferior the essence. These I have no doubt were made with Jamaica ginger of inferior quality, for I find that the cheaper kinds are much richer in resins, whilst they are equally poor with regard to the volatile aromatic principle. In the strong tincture the spirit conceals the aroma; hence it is difficult to compare two specimens by their odour without diluting them. Let them be diluted, however, and then compare the essence prepared from fine Jamaica ginger and that made from an inferior variety. The difference is so surprising that I have heard an experienced chemist doubt whether the fragrant odour of the former was solely due to the ginger used.

To return to my subject. After finding a method of making the soluble tincture, and trying the effects of varying the proportions of the ingredients, the following form was fixed upon as yielding upon the whole the best results.

Take of finest Jamaica ginger in powder 1 pound; pour upon this 8 ounces of rectified spirit, and after allowing to stand for several hours add more spirit; percolate to 16 ounces. To this add 2 ounces of heavy carbonate of magnesia, agitate and add 24 ounces of water. Shake well, and filter. If the filtrate is turbid the whole must be shaken with a little more magnesia and again filtered. The filtrate possesses all the aroma of the ginger, and a fair share of its pungency, and is of a pleasing yellow brown colour. After keeping a few days it becomes turbid and deposits slightly, but if again filtered appears to continue clear.

The action of the magnesia probably is partly mechanical, partly chemical, for the peculiar tint of the essence is undoubtedly due to the action of the hydrate of magnesia upon the ginger resin, and the precipitate which forms soon after the essence is first made is a compound of resin and magnesia. I had suspected that the resin left in solution differed from that removed, but upon evaporating the soluble essence and examining the resinous residue I could detect no difference between them; moreover when dissolved in spirit, diluted and shaken with magnesia, most of it was removed from solution, and the magnesia compound resembled that first separated.

I have since found that calcium sulphate, calcium carbonate, and charcoal powder, are equally efficacious in removing the excess of resin, but the resulting solution is in all cases much paler in colour, and probably when charcoal is used the odour may not be so strong. These no doubt act mechanically causing the aggregation of the resin precipitated by the water; hence it is probable that any fine inert powder will answer as well as the magnesia.

A syrup made by mixing equal quantities of strong simple syrup and soluble essence is very suitable for using with gazogenes, and a weaker syrup might with advantage replace the unsightly preparation of the Pharmacopœia.

The belief that this subject would be of interest to many pharmacists, and that the results of my imperfect investigation would be of value to others, must be my apology for troubling the Conference with this paper.

Specimens of soluble essence and of syrup made therefrom are upon the table, at the service of any member who would like to examine them.

The following note on the same subject was also read:—

Soluble Essence of Ginger.

BY B. S. PROCTOR.

Commercial samples have no great alcoholic strength.

Essence of ginger made with strong spirit and diluted with water continues milky for a long time.

The same mixed with a little alum or sulphuric acid becomes clear after standing some time (a week or two ?). The quantity of alum or acid requisite is not sufficient to impart any taste to the essence produced, and may be got rid of (the acid most completely) by mixing with pure carbonate of lime and filtering. A clear, pungent, aromatic essence is thus produced, which turns slightly opalescent when mixed with water.

Mr. UMNEY thought that for this paper the Conference was much indebted to Mr. Thresh, especially the Irish members, for in no place of an equal population was the manufacture of aerated waters so extensively carried on. A good essence of ginger was still a desideratum. He had for some time been trying to make a good soluble essence. He had made considerable quantities by a process similar to that now indicated, but with the omission of the spirit, using dilute glycerine only. He found that this did not take up the resinous principle, but the essential oil only, and as far as he could judge, this essence was merely a solution of the essential oil. He was glad to find that Mr. Thresh was investigating this matter, as he had previously investigated capsicine very successfully, and he felt sure that if he carried on his experiments much benefit would result. There was no doubt the different varieties of ginger had a great effect on the resulting essence. He had tried all kinds, and had found some specimens of Jamaica ginger so mucilaginous that there was no doing anything with them. This process of exhaustion by spirits of wine and precipitation of resinous matter by means of some mechanical body, such as carbonate of magnesia, seemed a good one, but he was not prepared to say that the process was wholly mechanical. If crude animal charcoal were used he presumed it would have some chemical effect.

Mr. SAVAGE said this was one of those practical papers which were always appreciated by the trade. Some time ago a ginger beer maker called upon him, and said that he was in the habit of using essence of ginger, but he always found the beer became opaque. He found the remedy was, instead of using strong spirit, to use it in the proportion now given, two of spirit to three of water. This did not dissolve the resin, and the compound was satisfactory.

Dr. SYMES had found, in examining samples of ginger with regard to their suitability for preparing essence, that a good method was to prepare a small quantity by treating it with a small quantity of spirit and adding a few drops of the essence so obtained to a large quantity of water, say ten minims to an ounce of water. The water seemed to have the property of throwing up the flavour and making it apparent, and strong essences of ginger, which while they contained strong spirit were not readily distinguishable could in this way be easily distinguished. The deep coloured specimens referred to might have been prepared from African ginger, which was very dark, but not of good flavour. His experience confirmed that of Mr. Savage, that if ginger were treated with dilute spirit in the first instance the same result was obtained as by dissolving in strong spirit and then precipitating the resin. But percolation was then apt to fail, because there would be a precipitation of a layer of resin on the surface of the marc which prevented the further percolation. Agitation with dilute spirit and lengthened maceration so as to allow the resin to subside appeared to be the most practical and efficient mode of working.

Mr. HATCH thought it probable that the darker fluid had been prepared from African ginger.

Mr. GROVES asked if any one knew the nature of the resin which was rejected by the proof spirit.

Dr. SYMES said he had never examined it.

Mr. GROVES said he should imagine that the essence of ginger as made by Mr. Thresh was not quite so pungent as that made by maceration, which would contain the whole of the resin.

Professor ATTFIELD said it had been affirmed that the flavour of the ginger resided in the oil, and the pungency in the resin. If that were so it would follow that if the resin were removed the pungency would be reduced to a similar extent; but then, as Mr. Thresh hinted, there might be two resins, one of which was pungent and the other not. He should suggest that Mr. Thresh examine the matter further, for he was evidently well fitted to carry out an investigation of this kind.

Mr. DRAPER referring to the remark of Mr. Umney that oil of ginger was quite a different preparation, said essence prepared from it did not give the same results as that obtained from ginger itself. The oil of ginger came from Germany, and was said to be distilled from the ginger root. No varieties were given, but neither essence nor syrup of ginger could be made from it. Why this should be if the whole flavouring resided in the volatile oil was not quite clear. On the other hand, it did not seem to reside in the resin, because with this formula 16 ounces of tincture were taken and added to 24 ounces of water, therefore necessarily precipitating the whole resin. What was left was certainly of considerable interest to pharmacists to determine. He took rather an exceptional interest in the subject, and should be glad if it were further investigated.

Mr. ABRAHAM said the specimen of syrup furnished seemed to him very deficient in aroma although not in pungency.

Mr. SUMNER said there was room for a great deal more research with regard to extracting the properties of ginger. One of his sons had given a great deal of attention to the subject, and his experience up to the present time had been that the pungency was in the resin, and the aroma in the soft part. Ginger might be separated into two distinct kinds, the soft floury ginger and the resinous, and his son had found that he got the aroma in the soft ginger, and the pungency in the resinous. With regard to the flavour no ginger would give the same flavour or anything approaching it as the Jamaica.

The PRESIDENT, in moving a vote of thanks to Mr. Thresh, said it seemed to him that the subject might be divided into two portions. If the object of the investigator was to get a preparation which was perfectly soluble in water that was one thing; but if it were to produce a mixture which should dissolve all the characteristic properties of the drug and produce them in a fluid form, that was another question altogether, the latter being by far the most interesting as it came into the category of inquiries which he rather thought in the future would attain more interest than they had up to the present time. Many present would be familiar with some work of Dr. Squibb, in which he had been endeavouring to show that almost every drug should be treated with a different menstruum. That seemed to be the tendency of Dr. Squibb's investigation, and already some curious results bearing upon it had been brought out. He should be disposed to think the ultimate analysis of ginger was still to be made. As far as obtaining simply a preparation soluble in water the problem was not a very difficult one, and Mr. Thresh seemed to have pretty well worked it out.

The next paper read was a—

NOTE ON BEBERIA.

BY D. B. DOTT.

Beberine was discovered in 1834, by Dr. Rodie, of Demerara, and has since been investigated by several eminent chemists. The formula $C_{19}H_{21}NO_3$ was ascribed to it by Von Planta, but $C_{18}H_{21}NO_3$ was found by Bödeker to be the formula of pelosine, and that alkaloid Flückiger considers to be identical with beberine. Considerable uncertainty, however, has always existed as to whether the alkaloid analysed was perfectly pure, owing to the fact that hitherto no crystalline salt thereof had been obtained.

I have succeeded in preparing a crystalline hydrochloride, from the examination of which I hope to be able to ascertain the composition of the base. This crystalline muriate may be prepared in a variety of ways, amongst others by the process now described. The ammonia precipitate of the British Pharmacopœia process is extracted with ether, the ether distilled off, and the residue dissolved in water with hydrochloric acid. From this solution by fractional precipitation the base is obtained of a greyish-white colour. When this is dissolved in excess

of dilute hydrochloric acid, and the solution allowed to evaporate at the ordinary temperature, crystals will gradually make their appearance, generally after some days. The solution ought not to be neutral, as in that case it is apt to form a gelatinous mass. The largest crystals I have obtained, however, were from an almost neutral solution. Even with these the form was only discernible under the microscope, when they were seen to consist of very long four-sided prisms. The crystalline magma, formed as above described, should be freed from mother-waters by pressure, and the remaining muriate by recrystallization may be obtained perfectly white. This salt possesses in a marked degree the sweet bitter taste, formerly noticed by Dr. Maclagan. The alkaloid precipitated from it is free from colour and may be assumed to be pure.

The paper gave rise to no discussion.

A vote of thanks was passed to Mr. Dott.

Parliamentary and Law Proceedings.

Poisoning by Carbolic Acid.

An inquest has been held at Tollesbury, near Maldon, upon a boy of thirteen, named Hume. He and a companion were playing in the yard of the Plough and Sail Inn, when they entered a shed in which there was a stone bottle containing carbolic acid, which had been left there by a carrier for the inspector to the local sanitary authority, for use in fever cases. The cork was not sealed or tied down, and the poison label was unobservable. The two boys, supposing that the bottle contained beer, drew the cork, and Hume drank of the contents. He was immediately taken ill, and after some hours of extreme suffering, died. A verdict of Accidental Death was returned, with the addition that more caution ought to be taken by the sanitary authority, and that the chemist who supplied the acid should be severely censured.

Dispensing Memoranda.

[117]. Tinct. Cardamomi.—Not having read the last few numbers of the Journal I had not seen the remarks upon tinct. card. which appeared under the head of "Dispensing Memoranda," or I should certainly have solicited the favour of an insertion earlier.

In the first place I must say that I entirely concur in the opinions of Messrs. Barnes and Stephens, that when tinct. card. is prescribed, it is the duty of the dispenser to use the simple tincture of the P. L. 1851, unless otherwise directed by the physician.

I do not understand why your correspondent who subscribes himself as one "Heavy at Heart" should ignore as he does the old, or as he is pleased to name them, *antiquated pharmacopœias*. I admit that as a rule the B.P. should be the chemist's guide-book, but that does not necessitate an entire renouncing of the others, because there are many medical men of the old school who will never conform to the new dispensation, and they are the persons generally who prescribe preparations in past pharmacopœias.

That being so, I contend it is necessary for the careful and accurate dispenser, in cases of doubt, to consult such books as Phillips's 'Translation,' and the Dublin and London Pharmacopœias; also in some cases even Beasley of which Οχθαι spoke so scornfully.

It appears to me that if this plan is adhered to, not so many of those egregious mistakes referred to will occur. Intelligent discretion on the part of a dispenser is one thing, and contemptuous disregard for every other authority but the B.P. another.

Those gentlemen who follow the latter course should consider whether they are justified in placing on their dispensing envelopes, "Prescriptions accurately and faithfully dispensed."

A. P. S.

[134]. Opodeldoc.—It is rather difficult to say what Paracelsus used for his opodeldoc. The word is also obscure as to its derivation, but the first syllable is evidently from ὀπός, juice.

I find a very old formula was given in the Edinburgh Pharmacopœia, viz.:—

Balsamum Saponaceum Opodeldoc.

Spanish Soap	1 lb.
Camphor	2 oz.
Essential Oil of Rosemary,	
,, Origanum . .	each ½ oz.
Rectified Spirit of Wine	4 pints.

The soap was to be digested in the spirit of wine with a gentle heat till it was dissolved, and the camphor and the essential oils were afterwards added. The liniment was thick, and not fluid and transparent, as in the lin. saponis of the B. P. It is said Mindererus invented a kind of plaster for external injuries, which he called opodeldoc.

I think that a dispenser would be justified in sending out the lin. saponis of the B. P. for opodeldoc, unless the old and thick liniment was specially ordered.

Henry Brown.

[138]. Pil. Podophylli.—As the dose of resina podophylli is from one-sixth grain to one-half grain, or sometimes more, according to the peculiar idiosyncracy of some individuals, it is impossible to say what should be dispensed when simply "pil. podophylli" is written on a prescription. I think the safest mode in dispensing would be to use one of Cox's formulæ, say 172, 173, or 174. In these formulæ podophyllin is combined with opium, calomel, and compound colocynth pill mass, or with rhubarb, capsicum and extract of belladonna, or, as in 175 and 176, with extract of colocynth (compound), and extract of henbane, or extract of henbane and rhubarb pill mass.

It is hardly necessary to say that whatever formula is adopted the pills should not be larger than three or four grains, and, as I have known most violent purging from a single dose of one fourth grain combined with extract of henbane, it is well to bear this in mind in dispensing an agent so variable in its action that I have known two grains cause little disturbance of the bowels in other cases.

Henry Brown.

[139]. M. D. J. might have saved himself the trouble of writing if he had referred to "Pereira," or "Beasley."

Rodenburg's formula is: ℥ss of iodine (or ℥j of iodide of potassium), rubbed up with a few drops of spirit and olive oil, and then mixed with ℥j of simple plaster, previously melted. The emplastrum iodinii comp. is thus made: ℥ij iodine, ℥iij iodide of potassium, 1 lb. lead plaster, 6 oz. opium plaster. Melt the plasters, and then add the iodine and iodide of potassium reduced to a very fine powder.

In another formula iodine only, and Venice turpentine with olive oil, are mixed with belladonna plaster. I think in making a plaster, such as M. D. J. describes, I should use Rodenburg's formula, and add ℥j of iodide of potassium to the simple plaster, as described, and then add the empl. belladonnæ sec. art.

Henry Brown.

[140]. W. L. was perfectly right in using the mucilage of tragacanth. The extract of hyoscyamus, as a rule, is a bad excipient.

Henry Brown.

[141]. Where liquor cinchonæ is ordered without the name (Battley), or not otherwise specified, the extractum cinchonæ liquidum of the B. P., made from yellow bark, should be used. One part equal to 4 of bark.

Northallerton. HENRY BROWN.

---

[141]. If liq. cinch. was ordered, the dispenser would be justified in using the B. P. preparation. When ext. cinch. cord. is meant, the doctor generally puts ext. cinch. cord., P. L. If Battley's was meant, he would put liq. cinch., Battley's. FRANK C. GOLDING.

---

[142] The only difficulty in this mixture is the incompatibility of the tr. ferri mur. with the gum acacia of the pulv. tragac. co. I have succeeded, however, in making a satisfactory mixture, of a light brown colour, and the consistence of a thickish emulsion, by the following method.

First, powder the camphor with the aid of a few drops of spirit, mix the pulv. tragac. co. with this and then add 1½ oz. aq. to form a mucilage. With this incorporate first the tr. benzoin. co., and then the bals. copaibæ, gradually, in small quantities at a time, stirring well between each addition and adding a little water as it thickens. Next add tr. opii, previously diluted with a little aq. and lastly tr. ferri mur. diluted with 2 oz. aq. The addition of the last ingredient causes the mixture to become like a jelly, but after standing some hours, with occasional stirring, this gets sufficiently liquid to pour into the bottle. The mortar can then be cleaned with the remaining aq. and a mixture as above is the result. Label it, "Shake the bottle." This takes rather long, but, I believe it is the only method that can be adopted where the prescriber is not known, and cannot be consulted respecting the above incompatiblty.

Mevagissey. J. KEMBLE.

---

[142]. This may be satisfactorily dispensed in the following manner:—Mix the pulv. camph. with the pulv. tragac. co. in a mortar, add sufficient water to make a thin paste, then gradually add the bals. copaibæ and the remainder of the water in the usual manner; lastly, add the tinctures, and shake. The result is a light brown emulsion, which after standing three days has shown no apparent separation. PHILIP PRINCEPS.

---

[142]. Mix the tinctures, and dissolve the camphor in the mixture, to this add the balsam, and mix thoroughly. Put the pulv. tragac. co. into a mortar with the above mixture, and rub them well together; then add the water gradually, triturating well after each addition.

The result will be a light brown emulsion.

W. H. R.

---

[144]. When "Aqua Menthæ" is ordered should "Menth. Pip." or "Menth. Vir." be used?

KAPPA.

---

[145]. How should "Cochlearia duo" be translated when occurring in a prescription for a mixture; should it be "two spoonfuls" or "two tablespoonfuls"?

KAPPA.

---

[146]. A mixture containing

Sodæ Salicylas.
Sp. Æth. Nit.
Sp. Ammon. Comp.
Aq. Dest.

turns a deep orange colour after being mixed some hours. Can any one kindly suggest the reason? KAPPA.

---

[147]. LIQUOR SECALIS AMMON.—When this preparation is prescribed what should be dispensed? I give ext. ergotæ liquid., 3 parts; spirit. ammon. aromat., 1 part. M. Is there any recognized formula for it?

SUB UMBRA FLORESCO.

---

[148]. What is the best excipient for the following pills?—

℞ Acidi Carbolici
Ferri Sulphatis . . . . . āā gr. i.
Ext. Nucis Vomicæ . . . . . „ ¼.
Pulvis Rhei . . . . . „ ij.

M. ft. pil. j., mitte tales xij.

SUB UMBRA FLORESCO.

---

[149]. How should the following be dispensed, and what appearance will the mixture have?

℞ Sol. Donovani. . . . . ℥iss.
Tr. Opii. . . . . ℥iii.
Æther. Chloric . . . . . ℥ij.
Ferri et Quin. Cit. . . . . ℥j.
Aq. Cinnam. . . . . ad ℥viij.

M. ft. mist. et capiat cochlear. magnam unam ter in die post cibum. ALKALOID.

Notes and Queries.

[512]. LIQUOR MORPHIÆ BIMECONATIS.—In reply to the query of "Sub Umbra Floresco" in a recent Journal I beg to say that some few years since I was inconvenienced by the difference between the bimeconate of Morphia of one maker and that supplied by my wholesale house, the latter being perfectly white, and the former a light yellow or fawn colour. On inquiring the cause of the difference I was informed by the firm (certainly one of the first in London) that the article supplied by them was pure, and that the other contained pulv. rad. glycyrrhizæ.

A. P. B.

---

[514]. AMMON. MONOCARB. ODORIF.—Will any reader kindly give a good formula for "Ammon. Monocarb. Odoroif?"

"TOM."

---

[515]. NON-POISONOUS FLY PAPER.—Could any fellow chemist give me a good and effectual receipt for making non-poisonous fly papers? I have tried infusum quassiæ conc. but find it not sufficiently effectual.

Obituary.

Notice has been received of the deaths of the following:—

On the 20th of July, 1878, Mr. Thomas Fletcher, Chemist and Druggist, Lytham, Lancashire. Aged 52 years.

On the 29th of July, 1878, Mr. Thomas Bowers, Pharmaceutical Chemist, Eastgate Street, Chester. Aged 58 years. Mr. Bowers had been a Member of the Pharmaceutical Society since 1843.

On the 12th of August, 1878, Mr. Richard Rogers Foott, Pharmaceutical Chemist, Stockbridge Terrace, Pimlico. Aged 66 years. Mr. Foott had been a Member of the Pharmaceutical Society since 1864.

On the 21st of August, Mr. Thomas Alison Darling, Chemist and Druggist, High Street, Dalkeith. Aged 33 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Boundaries of Medical Practice.

Sir,—I note the challenge which you append to my letter in the Journal of 24th. I do not feel that it is any part of my province to define the boundaries of medical practice. My opinion is that the deputation fell short of what we had a right to expect from them, in not showing to the Duke of Richmond that it was the duty of the promoters of the Medical Act Amendment Bill to define what constituted medical practice, and not place power in the hands of any corporation to prosecute chemists for a trespass unless they could show a clear definition which should be a sufficient guide to those who wish, in the conduct of their business, to meet the reasonable requirements of their customers and not break the law.

Had it been desired to draw up a delimitation in public interest only, I might have felt tempted with the task, but as it must be a boundary sufficiently wide to satisfy medical practitioners of all grades, and as the pure question of public convenience may possibly not satisfy all grades of the profession, I think it is probably better that chemists should be satisfied with holding a position of criticism and defence till such time as the promoters of the Bill are alive to the necessity of sinking the wishes of the lower grades of the profession in favour of that which will satisfy at once the higher grades of the profession and the public good. When the question of pecuniary interests as between medical practitioners and chemists is subordinated to the question of public safety and convenience, the difficulties of the definition will be in great measure removed.

Grey Street, Newcastle. Barnard Proctor.

A "Nostrum" Repudiated.

Sir,—A handbill, pictorial and highly tinted, lies before me. It is mine simply by chance. Its existence is to myself a great surprise, and I believe it to be compatible with my interest in the public morality, did I place an abstract with comments before your readers. The central object [handbill enclosed] is, you observe, an acre or more of meadow in full blow. In the foreground is presented to us *a grey-bearded physicist*, so to name him, ideally, the mysterious "old soldier," of course, in fanciful costume; the scene enclosed within an ornamental border. The figure gathers "herbs" in mid meadow, dandelion, scurvy-grass, ranunculus acris, helleborus fœtidus, "all herbs;" giving therefore to the analyst no room "for finding any trace of any substance *but what is purely vegetable*." Tablets of letterpress, each also in a border, variegate the page. But most notable, perhaps, of all, is a copy, coarsely coloured, and on a reduced scale, of the emblem or armorial bearings, assumed by the President and Council of a not inconsiderable body in the State, the Pharmaceutical Society of Great Britain.

Now the handbill, Sir, so pretentious, sets forth the praises of a commodity styled, "Celebrated Herb Pills, prepared by one who describes himself as a Patent Medicine Vendor, at the Post Office, 93, Gooch Street, Birmingham." A remedy this, of wide-extending virtue, "that," continues the letterpress account, "may be taken at any season and under any circumstances, by either young children or the aged, or by the most delicate of females; and *during travail in the various periods of change, they may be resorted to freely with the greatest benefit.* Gravel, asthma, and upwards of a score of other *affecting* [*sic*] maladies, for curing which, by removing the original cause, the faculty have been generally unsuccessful in finding a remedy which answered the purpose without causing mischief otherwise. One trial will convince all. And are to be had in boxes at one penny upwards."

But, Sir, in consideration of the corporate privileges which the author of this handbill enjoys, and of the confidence which as a trader he seeks for himself from the public, several questions crop up in demand of satisfactory answer.

1. Is it competent of an *attaché* of the Pharmaceutical Society (be he associate, member, or designate otherwise, as the case may be), that he may use for purposes of mere individual trading the insignia which of right is the badge of the Society incorporated? 2. Is it reputed consistent with the *status* of the Pharmaceutical Society, also with the felt necessities of its institution under Royal Charter, that a person receiving registration thereby, should (if so minded) formulate an impossible panacea, and proceed to advertise said nostrum for sale in terms depreciatory of modern medical science and practice, of which presumably he knows nothing whatever? 3. In exhibiting by handbill a coloured sketch of a man culling herbs in open field, is it just in us to credit the advertiser with intending thereby to induce in us the notion that with powder and extract, reduced in his own laboratory from such aforesaid herbal materials, are prepared the "Celebrated Herb Pills" as advertised? 4. Finally, assuming the facts to have been accurately brought under your notice, would a physician or a surgeon be acting prudently who knowingly committed to such an one, so variously occupied, and perhaps with one occupation more, a prescription wherein quality, quantity, time, and method in the preparation of it were elements of vital importance to the patient?

August 24, 1878. Honesty, The Best Policy.

Within the Trade or Business of a Chemist and Druggist.

Sir,—Such of us as have carefully considered the present position and probable future of our trade will, I think, have come to this conclusion, that the suppression of counter practice is an utter impossibility.

Legislation may cause it to assume, as regards ourselves, a more negative aspect, with the blessed certainty of less responsibility; and further, unless members of the medical profession cease through the medium of the press to give us the benefit of their experiments and lucubrations, there is every likelihood of its assuming much larger proportions than hitherto.

Allow me to relate the following conversation (a myth, perhaps), as it might, could, would, should, did, or did not occur, in a pharmacy of the first, second, third, fourth, or fifth magnitude; time, once upon a time, shortly after the recent prosecutions in the matter of Unicorn *versus* Phœnix and others.

"Dose you gave me for toothache the other day—marvellous! better in five minutes. Worm powders for my brother's children—first class! Wish you could cure my wife—doctor, you say?—she's had a doctor—she don't want a doctor—she wants some right good medicine; hav'n't you quinine or anything else I could try for her?"

"You might try quinine and nux vomica with or without a little steel: it just depends, it might answer or it might not."

"If you think there's any chance, mix up a bottle. We have thought about buying Dr. Coffin's book and going to a herbalist, you are so shy."

"Sir, I speak through a muzzle. 'Fully and amply' in the Apothecaries Act means a trap to catch £20. You must prescribe medicines for yourself, and, according to the now newly shrunk and attenuated meaning of the active verb dispense, I'll passively dispense them for you.

Here's Hooper's 'Vade-Mecum,' or 'Neligan,' or 'Atthill;' on this page you'll find your wife's symptoms as you state them detailed word for word. The medicines indicated will be one shilling; but if you prefer it, here's Vampire's mixture at 2*s.* 9*d.*, or Carionbeak's balm of Cyprus, highly corroborated, at 4*s.* 6*d.* and 11*s.*; only please know this, I'm permitted to chisel you, for the benefit of such persons and that of the Revenue, to any extent."

Need I say more, for it cannot be concealed that the most repulsive feature in the late counter practice trial consists in this, that had the defendant only foisted some stamped nostrums, 13½*d.* fever curers, or lung-healers, on the poor people who applied to him for advice and medicine, no matter how worthless or dear such nostrums might have been to them for the purposes required; had he only condescended to blacken himself by such a safe but unscrupulous course towards his customers, any adverse action on the part of the Apothecaries' Society would have been, there is good reason to believe, amongst the things that are not.

The retail drug trade has many sides, potencies, and developments; those amongst us who discountenance counter practice appear to me to view it in the contracted aspect and interest of their own particular high class businesses. Is it not this which causes them to overlook the fact that we have at the very least equal rights with stamped nostrum makers? How are we, I ask, to convince ourselves and the public that it is unlawful to dispense and to sell medicines of our own compounding for all purposes for which stamped medicines are advertised?

The unquestioned liberty of a stamped nostrum maker is, I take it, most surely within, properly belongs to, and is derived from, the trade or business of a chemist and druggist.

York, August 5, 1878. ICTUS EQUI.

NEWSPAPER SCIENCE.

Sir,—In these days of universal education it is instructive and amusing to note the growing acquaintance of newspaper writers with science and scientific terms, and the delightful way in which these terms are used to illustrate their ideas. The following appeared on Wednesday last in one of the leading articles of a periodical boasting the largest circulation in the world. The writer is tracing the influence of Heine's writings on German Socialism. In the course of his remarks, he says:—

"His writings, acting upon the socialist tendencies of modern Germany, have proved not the wholesome barm that leavens the mass, but the burning acid that bites and corrupts, which in contact with the alkaloid base of imperfect understanding has caused that effervescence and ebullition of the seething atoms which take the form of socialist communism."

After this it may be truly said, "The population of the globe is more than ——— millions—mostly fools," and the *D. T.* has naturally the largest circulation in the world.

London, August 23, 1878. J. H. P.

[*** A large circulation does not always justify our correspondent's inference, but it certainly is no guarantee of infallibility. The "most popular scientific paper in the world," the *Scientific American*, devotes a special leaded paragraph in its issue for the 24th inst., to informing its readers that:—"Nine ounces—a little more than half a pint—of water may be decomposed into eight ounces of hydrogen gas and one ounce of oxygen gas."—ED. P. J.].

COUNTER PRESCRIBING.

Sir,—In the few remarks I am about to make I do not wish to touch on the question of counter prescribing by chemists, but on the other side of the picture at present presented to the Pharmaceutical Society, to the Royal College of Surgeons, and to the public. The keeping of shops by M.D.'s, surgeons, and other members of the medical profession who have so poor an opinion of their own ability that they think it requires the aid of one penny cakes of scented soap, threepenny tooth brushes, one pennyworth of precipitate powder, combined with the general stock of a chandler's shop, to introduce them to their patients, and to carry on which they must employ a lad or any young man they can get, who has no qualification to carry on business for himself as a chemist. "The doctor" not being able to see his patients, and at the same time sell his penny cakes of soap, threepenny tooth brushes, and one pennyworth of precipitate, and not being able to afford to have a qualified man to attend to his, what ought to be, chemist's business, the consequence is that London and other large towns are favoured with the pitiable sight of a professional shopkeeper, a disgrace both to the Royal College of Surgeons and the Pharmaceutical Society. When the medical profession prevent their members from keeping their shops in such a disgraceful manner, and conducted, as they are, by unqualified persons, then the Pharmaceutical Society will be able to take into consideration the question of counter prescribing. JAMES DUNKERLY, M.P.S.

50, *Southgate Road, Kingsland.*

H.—Have you not misread the words "Aq. Fœniculi."

"*Cyprus.*"—(1). A widow of a chemist and druggist is in the same position as any other person with regard to the carrying on of his business, and can only do so with the aid of a qualified assistant, if, and so long as, she continues to be *bonâ fide* an executor, administrator, or trustee of the estate. (2). We presume that an action for damages would lie against the person in whose name the business was carried on.

"*Alpha.*"—Several formulæ for Syrup of Lactophosphate of Lime have already appeared in this Journal. That adopted by the Paris Society of Pharmacy will be found in vol. vii., p. 1041. It is too long for reinsertion.

R. G. Mumbray.—The specimen is a piece of the inner bark of *Geissospermum læve* (Pao-pereiro). See *Pharm. Journal* [3], vol. viii., pp. 182 and 648.

P. B.—*Epilobium montanum* and *Lysimachia nemorum*.

J. Crow.—*Cannabis sativa* (Cannabinaceæ).

"*Cantab.*"—(1) *Lycopus Europæus*; (2) *Pastinaca sativa*; (3) No leaves sent; (4) No flower sent, probably *Agrimonia Eupatoria*; (5) *Pulicaria dysenterica*; (6) *Malva sylvestris*; (5) *Malva moschata*; (6) *Matricaria Parthenium*; (7) *Vicia cracca*.

R. Roberts.—(1) *Achillea Millefolium*; (2) *Tanacetum vulgare*; (3) *Pulicaria dysenterica*.

"*Cyprus.*"—(1) *Prunella vulgaris*; (2) *Pulicaria dysenterica*; (3) *Mentha aquatica*; (4) *Centaurea Scabiosa*, probably (no leaves sent); (5) *Knautia arvensis*; (6) *Campanula rotundifolia*.

W. J. Williams.—(1) *Matricaria inodora*; (2) *Artemisia vulgaris*; (3) *Eupatorium cannabinum*.

G. A. H.—(1) *Œnanthe Lachenalii*, probably (neither root, root-leaves, nor fruit sent); (2) *Viola lutea*; (3) *Statice occidentalis*; (4) *Statice Limonium*; (5) *Viola lutea*; (6) *Erythræa latifolia*.

F. P. Balkwill.—Several species of *Boletus* present the character you mention, and all of them, are, we believe, poisonous.

P. Princep.—We recognize the force of your objection, but think as a rule any evil effect will be prevented by the preponderating evidence elicited that the practice of pharmacists is sound in such cases. See p. 166.

W. J. Harris.—A knowledge of the general principles of classification and of the Linnean and De Candolle's system is required in the *Major* examination.

"*Quæro.*"—The use of methylated spirit is illegal in preparing any article *capable* of being used as a beverage or internally as a medicine.

M. P. S.—We see no reason why mastic varnish should not answer, if properly made.

W. Willis.—Dichloracetic acid ($C_2H_2Cl_2O_2$) may be prepared, according to Maumené, by leaving 5 at. of dry chlorine to act upon 3 molecules of pure monochloracetic acid in a large flask for twenty-four hours, boiling the product in a water-bath to remove hydrochloric acid, and distilling. It is very corrosive. See Watts's Dict., 1st Suppl., p. 19.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Masson, Nicholson, Miller, Puntau, Johnson, Golding, Bumstead, Siebold, MacSwiney, Long, Quinlan, Sumner, Symes, Connyngham, Frazer, Holmes, Harris, Benger, F. A., W. B., M. P. S., G. A. H., A. H. J., H. B., A. P. S., Inquirer, Pax, Associate.

THE DETECTION OF ALUM IN BREAD AND FLOUR.

BY G. WELBORN.

For several months past I have been carrying on experiments for the purpose of discovering a better process than any hitherto in use for detecting the presence and determining the quantity of alum in bread or flour, both which there is reason to believe are more frequently adulterated with that most undesirable substance than is commonly supposed.

It may, perhaps, be warrantable to infer from the following details of analyses that alumina is frequently not present as one of the constituents of wheat, and that too much allowance has been made on that account by the old processes of incineration, inasmuch as it has hitherto been quite impossible to determine in what form the alumina existed in the sample submitted to analysis; hence, in disputed cases of adulteration, the conflicting testimony of public analysts and analytical chemists has tended in no small degree to shake the faith of the public as to their capabilities and truthfulness.

It may be accepted as a fact that, in the great majority of flour-mills, efficient means are taken for depriving wheat of all foreign matters, such as small lumps of clay, or other kinds of earth, as well as the seeds of wild plants growing amongst corn, so that wheat when submitted to the process of grinding is generally exceedingly clean. It is evident, then, that but very little alumina can be derived from extraneous sources when wheat is thus treated; but there yet remains another channel by which an infinitesimal quantity might possibly find its way into flour, that is by the attrition and detachment of small particles of the mill-stones; but this must be so small that it may safely be dismissed from further notice.

The experiments described below were performed with a 5¼ inch gutta-percha dialyser, having a parchment paper diaphragm. When in use, the dialyser was simply placed inside a white glazed stoneware basin, provided with a suitable spout and affording sufficient capacity beneath the dialyser for about ½ pint of water when the lower edge of the dialyser rested upon the curved inside surface of the basin, thus forming a firm and convenient support and rendering any arrangement for suspension unnecessary. The whole may be covered with a glass plate while in use.

The following is an outline of the processes finally adopted, which embrace the separation of alum, "as alum," from its admixture with bread or flour and subsequent precipitation and weighing, or otherwise, of the alumina as aluminic phosphate; and also the determination of the amount of sulphuric acid. There are at least three different methods of estimating the amount of alumina:—

(1) By washing, drying, and igniting the precipitated aluminic phosphate.

(2) By measuring the volume of the precipitate in a tall, narrow, glass cylinder, and comparing it with that from a known quantity of alum.

(3) By comparison and imitation of the degree of opacity with aluminic phosphate, in a similar cylinder and volume of water, obtained from a known measure of a standard solution of alum, as in ammonia estimation by means of Nessler reagent. By the two latter methods a difference of much less than a ¼-grain of alum is easily perceptible.

Experiment I.—A piece of crumb of bread, commonly known as "bakers'," was taken for analysis; its weight was 1¾ ounce. In order to prepare it for dialysis it was simply rubbed between the palms of the hands into a granular condition, the powder transferred to the dialyser, and sufficient distilled water, to which fl℥iss of dilute hydrochloric acid had been added to cover the bread, always taking care that the depth of the contents of the dialyser does not exceed ½ an inch. The dialyser being placed in position in the basin, containing about ½ pint of distilled water it was then set aside for twenty-four hours, when the dialysate was poured into a conical glass precipitating jar and "nearly neutralized" with ammonic hydrate. An excess of pure sodic phosphate was next added and then rendered "slightly alkaline" with ammonic hydrate. This gave a very copious white cloudy precipitate of aluminic phosphate, which showed no disposition to subside in a reasonable time. This difficulty may be overcome by placing the jar and contents on a sand-bath and boiling for a few seconds, when the precipitate speedily aggregates into larger or smaller flakes, the size depending very much on the quantity of precipitate present. On removing the jar from the sand-bath the aluminic phosphate rapidly subsides, leaving the supernatant liquid very clear. About two-thirds of the clear liquid may be decanted, and the remainder containing the precipitate transferred to a narrow glass cylinder for measurement of precipitate. On subsidence, its volume was found to be about equal to that obtained from 0·7 gr. of alum similarly treated.

The contents of the dialyser, after the above process, were again submitted to dialysis with a fresh quantity of distilled water, for twenty-four hours, when it was found the alum had been completely removed, since subsequent treatment of the dialysate with sodic phosphate, ammonic chloride, and ammonic hydrate, failed to produce a precipitate on boiling. The addition of a small fraction of a grain of alum to the boiling liquid at once gave a white cloudiness which immediately broke up into flocculi, floating in a clear ammonia liquid.

Two grains of ammonia-alum were next projected into the contents of the dialyser, and the dialysis again repeated; in less than two hours its presence in the dialysate was easily shown by treating with baric chloride.

Experiment II.—1½ oz. of wheat meal was mixed with sufficient cold distilled water to form a thin creamy liquid to which was added fl ℥j of strong, pure hydrochloric acid; the mixture was then poured into the dialyser. At the expiration of twelve hours from the time of starting the process there was no indication of the presence of a sulphate when a small quantity of the dialysate was treated with baric chloride. 4 grs. of alum, in powder, were next accurately weighed and scattered over the above contents of the dialyser; in an hour and a-half baric chloride gave abundant evidence of the presence of sulphuric acid in a small portion of the dialysate which had been removed with a pipette for the application of the test. The dialysis was continued for about twenty-four hours, when the dialysate was transferred to a glass precipitating jar, as in the previous experiment, and similarly treated, the precipitated aluminic phosphate being collected on a filter. The filtrate was acidified with hydrochloric acid, brought to the boiling point, then an excess of

baric chloride added and the ebullition continued until, by the subsidence of the baric sulphate, the liquid became clear upon standing aside for a short time. Most of the clear liquid was decanted off the baric sulphate, which was collected on a tared filter, washed, dryed in a current of hot air, and weighed. It was found to weigh 2·25 grs., this being 1·86 less than the theoretical yield of baric sulphate from the quantity of alum taken. The process of dialysis was repeated with fresh water on the residue in the dialyser, the result being a further yield of baric sulphate, weighing when dry 1·75 grs., making with the former quantity 4 grs. instead of 4·11 grs. of baric sulphate, the calculated product. There was also a further amount of aluminic phosphate obtained, making up the total, after igniting the washed precipitate, to 1·12 gr., or 0·04 gr. too much. I believe this may be regarded as a crucial test of the capabilities of the process, inasmuch as the conditions for rapid diffusion of the salt were decidedly unfavourable, since it would necessarily be some hours before the whole of the alum could possibly be dissolved and diffused throughout the contents of the dialyser.

Experiment III.—To 1 oz. of pure wheat meal I added 1 gr. of alum and dialysed into ½ pint (10 fl. oz.) of water for twenty-four hours, poured dialysate into a precipitating jar and brought to the boil. The very clear dialysate became cloudy and eventually formed the characteristic small white flakes of aluminic phosphate, the source of the P_2O_5 doubtless being the natural phosphates present in wheat.

Experiment IV.—To 1 oz. of wheat meal and 1 gr. of alum I added f℥j. of dilute hydrochloric acid and dialysed for twenty-two hours. Divided dialysate into two portions. Boiled one, no change, *i.e.*, no precipitate was produced; added an excess of ammonic hydrate, then acidified with acetic acid, boiled, and added an excess of sodic phosphate; there was an immediate precipitate of aluminic hydrate.

To the second portion I added an excess of ammonic hydrate in the cold—no change; acidified with acetic acid and added sodic phosphate—no change; boiled—a white precipitate of aluminic phosphate, which together with that from the former portion about equalled in volume, and quite so in depth of colour, when the diffused precipitate was viewed vertically through the column of liquid contained in a glass cylinder against that from 1 gr. of alum in a similar cylinder.

The latter process, No. 4, I believe deserves preference over the preceding in which no acetic acid is used, inasmuch as silica, magnesia, and lime are not affected and consequently are not precipitated along with the aluminic phosphate.

It may, perhaps, be useful to mention a few facts observed during these investigations, of which the following are most prominent:—

a. Hydrochloric acid appears to facilitate the process of dialysis, keeps the bread or flour from fermentation, and also prevents the formation of mould.

b. A large excess of free ammonia, or ammonic compounds, prevents the ready subsidence of the aluminic phosphate, and is, therefore, to be avoided.

c. The addition of ammonic chloride up to a certain point causes the rapid separation and subsidence of the precipitate.

d. Acetic acid does not succeed when used in place of hydrochloric acid.

e. Alum is not decomposed, so as to render the alumina insoluble, during the process of baking.

f. A small correction should be made in the amount of baric sulphate obtained when bread contains much common salt, which is always contaminated with some sulphates.

g. Bread or flour may possibly be adulterated with calcic sulphate; it is, therefore, advisable to test a small portion of the dialysate for lime with ammonic oxalate, ammonic hydrate, and acetic acid.

I wish to say here that I first used the process of dialysis for detecting alum in bread, etc., more than four years ago, and that even now I do not claim to have hit upon the best method the process is capable of, *e.g.*, I am of opinion that it would be very desirable to use a much larger dialyser, which would of course materially shorten the time hitherto necessary for a complete separation of the alum.

Grantham, July 20, 1878.

THE PARIS EXHIBITION.

Pharmaceutical and Medical Preparations.

Galenical and Allied Preparations.

(*Continued from page* 144.)

Gelatine, appears to find wide and increasing applications in pharmacy. Deferring at present any remarks upon its sources and manufacture, some other of the preparations in which it plays an important part may be referred to here. Besides the previously-mentioned preparations, Herr Grohs also exhibits "amygdalæ" containing definite doses of such unpleasant tasting substances as fresh kousso flowers and sulphate of quinine for internal use, and "folia gelatini," consisting of gelatine containing sulphate of zinc, sulphate of copper, etc., cast in thin sheets, for external application to wounds; one advantage claimed for the latter is that their non-adhesiveness renders the changing of the dressings a comparatively painless operation.

Gelatine capsules have long been known as a French specality, and naturally they are not wanting in the French court. Messrs. Barberon, of Chatillon-sur-Loire, exhibit their tar capsules, which are spherical, about the size of a pill, and contain pure Norwegian tar. M. Fleurent, of Rheims, shows his "capsule hydrofuge," which he claims to be suitable for holding instable saline compounds, aqueous and alcoholic solutions, and other compounds for which capsules have not hitherto been available. Among the medicinal substances that he thus encloses are the gelatinous protocarbonate of iron, laudanum, black drop, the official (Codex) solution of protoiodide of iron, rendered unalterable by suspending reduced iron in it, dialysed iron, etc. In the exhibit of Messrs. Rigaud and Co. (formerly Grimault), of Paris, the capsules and perles are noticeable for their transparency, which speaks well at least for the purity and thinness of the envelope. The latter is a character not without importance in this class of preparations, as it is evident that the thinness of the covering, provided that it is strong and soluble, has the advantage of decreasing the bulk of the capsule and allows it to be more quickly dissolved. There are also in this department exhibits of capsules by M. Foucher and M. Quentin and others.

But the most varied exhibit of gelatine preparations is to be found in the British court, in the centre of the case of Messrs. Savory and Moore, of London.

This comprises a complete series of the ophthalmic and hypodermic discs of this firm, and among them may be seen not only old established remedies, as morphia and atropine, but also such recent introductions as colchicia, pilocarpine, curara, and duboisia. Then there is a series of "lamels," consisting of small sheets of gelatine divided by raised lines into squares, each containing a dose of the medicine with which the material is impregnated, which may be cut off and either taken dissolved or as a lozenge. A considerable number of medicines are thus illustrated, and the series would probably be extended by the firm to any substance compatible with gelatine and non-volatile. The list is completed with sheets of blistering gelatine ("lamellæ cantharidis"), and soluble gelatinous suppositories. Selections of these gelatine preparations are exhibited packed together in small cases, and form a very portable medicine chest.

Although not quite in place it may be mentioned here, as medicine chests have been alluded to, that they form a not unimportant or uninteresting portion of Messrs. Savory and Moore's exhibit. There is, for instance, a "Field Companion," similar to those supplied to the British army. It is light, and could be easily carried by a soldier on the march, and yet contains a good selection of lint, bandages, plasters, splints, tourniquets, and the medicines most important for emergencies in field operations. Then in connection with this "Companion" there is a "Chemical Cabinet," designed by the late Professor Parkes, of Netley Hospital, and supplied by this firm to the Government for use in expeditionary services, such as those to Ashantee and Abysinia. But the most interesting of all is a dingy looking case, bearing the marks of travel and rough usage. This is the medicine chest of Mr. H. M. Stanley, the celebrated explorer, which after a few years' knocking about in the wilds of tropical Africa, still stout and strong, finds here a peaceful rest.

In the English court, too, are to be found the medicated glycecolls of Messrs. Kirby, of London. These are transparent, like gelatine lozenges, and, judging from their name, are made from a mixture of gelatine and glycerine. Each glycecoll is said to contain a definite quantity of some medical ingredient, such as those of tannin (1 grain), or those of ipecacuanha and morphia, $\frac{1}{2}$ grain of the former and $\frac{1}{3\frac{1}{6}}$th grain of the latter.

As having some affinity with these preparations, mention may be made here of the beautiful fresh-looking slabs of jujubes prepared by Hawker's process, and exhibited by Messrs. Allen and Hanbury, of London.

Many of the preparations already referred to owe much of their perfection of manufacture to advantages involved in the large scale upon which they are produced by their respective exhibitors. But none of them perhaps owe more to this condition than the non-metallic coated pills that have gained so much popularity during the last few years. Coated pills of good appearance are of course prepared on the small scale, but the operation does not always accord conveniently with the arrangements of the dispensing counter, and it requires considerable dexterity of manipulation to obtain a creditable result. Were it possible, or desirable, however, that the ordinary pharmacist should abdicate this portion of his duties, he would find it most difficult to decide between rival competitors ready to perform it for him. Nor would an inspection of the cases of the different coated pill manufacturers in the present exhibition help him much. So far as outward appearance of the pills goes, there seems to be nothing to desire, and each maker might claim to be *primus inter pares*. Any further judgment must be based upon the maker's statement or actual experience, and the best proof that the one has generally confirmed the other is to be found in the present enormous consumption of physic in this form.

By a few makers coated pills are exhibited in enormous variety of official and non-official formulæ. From the United States, where these preparations have been long in use, Messrs. Warner and Co, of New York, show a case full of handsome looking "sugar coated" pills. Messrs. Schieffelin and Co., of New York, also show a large variety of pills enveloped in a "soluble coating" of good appearance, though some of them, such as the five-grain cinchonidine, and five-grain salicin pills, seem rather large. Then there are the "compressed pills" of Messrs. Wyeth, which are said to be formed by simply pressing the powdered drug, without any admixture, into a kind of flattened pill.

But in the British department the show is quite equal. Messrs. Richardson and Co., of Leicester, who claim to be the largest makers of tasteless pills in the world, exhibit upwards of six hundred varieties of their "pearl coated" pills, there being no less than thirty varieties of phosphorus pills. These "pearl coated" pills are said to be perfectly soluble in cold water, and to keep unaltered and uncracked in any climate. Another case, containing coated pills, is that of Messrs. Kirby and Co., of Hatton Garden. Both of these firms also exhibit a variety of portable medicine cases.

In the French department the non-metallic coated pills do not, perhaps, take quite so prominent a position, though the granules and perles could not be easily surpassed. But the brilliant burnished appearance of the silver-coated pills is very noticeable. Printed pills are exhibited by M. Torchon, of Paris. Here too is to be seen M. Limousin's ingenious invention for the administration of nauseous powders, which has now obtained wide acceptance, the "cachets médicamenteux," together with the press and wafers used in their formation.

Infusions and decoctions are almost necessarily absent; and of official syrups, tinctures, and wines very few are seen. In the French court M. Baron-Barthélemy, of Béziers, exhibits some cinchona wines, and others made with the white muscat wine of Frontignan are shown by M. Barral, of Paris. Of the scale preparations there is an exhibit of those of the British Pharmacopœia in the fine case of Messrs. Burgoyne, Burbidges and Co., and another is in that of Messrs. Bush and Co., of London; but not many others are noticeable. The same firm shows a number of good looking granular preparations, as do also Messrs. Savory and Moore, including those of salicin and salicylic acid. In the French court a good collection of granulated effervescing salts is exhibited by M. Le Perdriel, of Paris, including the salts of lithia, the citrate, carbonate and pyrophosphate of iron, and seidlitz and vichy salts; whilst close by M. Torchon, of Paris, exhibits a granular preparation of rhubarb and magnesia.

Pepsine is a substance which might itself be included in this division, but it is so closely allied

with a large number of proprietary preparations that it will be more conveniently dealt with under that head.

The medicinal varieties of cod liver oil are extremely well represented in the present exhibition; in fact they form by far the most important part of the class of chemical and pharmaceutical products sent from Norway, constituting no less than eighteen out of the twenty-eight exhibits from that country. As it would be presumptuous to allot the palm for excellence upon a mere inspection of the numerous specimens, it will be sufficient to say that a pale good-looking oil is shown by Mr. Jordan, of Tronheim, and a similar remark applies to the oils shown by Mr. Bovthen, of Trondhjem, and by the well-known house of Möller, of Christiania, the latter being accompanied by a model of the apparatus used in its preparation. There is also an extremely pale and limpid oil shown by Messrs. Meyer and Co. of Christiania. Of course, in singling out these light oils there is no intention of suggesting that the medicinal efficacy is in inverse proportion to the depth of colour.

In the French department, Mr. Hogg, of Paris, exhibits a "natural" golden yellow oil in triangular bottles, and a covered spoon for administering it. Shark and ray liver oils are also to be seen in this department.

In the Austrian court a very limpid cod liver oil, "purified from stearine," is shown by Herr Fumagalli, of Monfalcone.

In the English court the way in which the "A" cod liver oil, manufactured by Messrs. Southall, Bros. and Barclay, in Norway, is shown, demonstrates how much more instructive and interesting such exhibitions might be made by the expenditure of a little more trouble on the part of the exhibitors. Besides tall jars of the oil of their own make, this firm, in order to illustrate the chemistry of the oil, exhibits analysed samples of the various kinds to be met with in the market, together with a series of the organic constituents of the oil, comprising the solid fatty matters (consisting of cetylic and stearic glycerides), stearic acid, cetylic acid, oleic acid, volatile fatty acids, glycerine, "biliary matter," and gaduine. The case also contains water colour paintings of species of fish, allied to *Gadus morrhua*, sometimes used in the manufacture of "cod liver oil." The following, as representing the composition of different varieties, is copied from a tabular statement suspended in this case:—

	Oleic Acid.	Cetylic and Stearic Acids.	Volatile Acids, Glycerine, Iodine, Bromine, Phosphorus, etc.
Pale Oil . . .	83·4	12·6	4·0
Newfoundland Oil	83·6	13·2	3·2
"A 1" Oil . .	86·3	9·1	4·6
Pale Brown Oil	85·0	11·3	3·7
Ditto (reddish) .	84·5	11·7	3·8

Messrs. Allen and Hanbury also show specimens of cod liver oil bearing their punning trade mark.

From the islands of St. Pierre and Miquelon, lying off the entrance to Fortune Bay, Newfoundland, are sent some specimens of cod liver oil which are very white, as well as some of a pale yellow and brown colours. In those islands the oil prepared in the month of May from lean livers is reckoned the best; but it then requires sixteen parts by measure of liver to obtain one of oil, whilst in July the same quantity will yield six parts, and in September eight. The pale yellow oils are here prepared by the heat of a water-bath from the residuary livers from the first product; and the brown, used for oiling machinery, etc., are obtained after the livers have undergone a kind of putrid fermentation.

Before closing this section mention may be made of the beautiful specimens of almond oil expressed from blanched almonds, both sweet and bitter, exhibited by M. Cauchois, of Paris. Some of them appear to be absolutely colourless, and the manufacture is a specialty for use in the preparation of cold cream, etc. In the same case are samples of very white almond paste and powder, and some of varying shades of colour.

(To be continued.)

FLUID EXTRACTS BY REPERCOLATION.*

BY EDWARD R. SQUIBB, OF BROOKLYN.

(*Continued from page* 168.)

The first most important question is that of a proper menstruum. The present U.S. officinal menstruum having proved objectionable soon after the Pharmacopœia was issued, a menstruum was adopted by the writer containing 109 parts alcohol, 16 parts water, and 41 parts glycerin. This menstruum has now been in successful use for many years, and affords good exhaustion, and a fluid extract which weighs 7685 grains to the pint. This is almost exactly minim for grain and weight for weight. But as the drug never is quite exhausted, even under the very best management, the measure never should have been made minim for grain if the drug was to be fairly and fully represented by the fluid extract. As a rule of actual practice, the drug will not often be exhausted within 5 or 10 per cent., and by the officinal management, will fall greatly below this. A more accurate proportion would have been 90 to 95 minims to each 100 grains of drug or about 8000 grains of drug to make a pint of fluid extract, each minim of which should represent a grain of the drug. Even by repercolation some such excess is needed to make the therapeutic relation what it professes to be. Beside this objection of being too close in theoretical relation to be true in practical value, this menstruum has long been believed to be unnecessarily strong in alcohol, and containing too much glycerin. The glycerin in many cases has a secondary use in menstrua which is hardly less important than its primary use as a solvent. It has the property of wetting substances, and permeating them to the exclusion of air, to a much greater degree than water or alcohol, and, when mixed with water or alcohol imparts this property to the mixture. When used at all, therefore, it must be used with both these functions in view, and one step beyond this is objectionable. After a preliminary set of percolations with this old menstruum to observe how it would work on the small scale of 4 troy ounces of powder to each percolation, a new menstruum was tried consisting of 2 parts stronger alcohol, 2 parts water, and 1 part glycerin, and a preliminary set of percolations upon the same scale of 4 troy ounces gave good results, but proved that the scale was so small as to need especial skill and care in order to attain the desired accuracy.

Another tentative trial was then made with this new menstruum on a scale of 8 avoirdupois ounces at each percolation, and this proved to be a much less troublesome scale. And, for cinchona it is about as small a scale as can be worked to advantage. An avoirdupois pound would be better and easier still. The details of these trials need not be given, and it is sufficient to say that they indicated, and gave a part of the necessary

* *American Journal of Pharmacy.*

experience needed for another careful trial, in which two very important points were still to be settled, namely, the proportion of menstruum and weak percolate that was best to moisten the powder, and the length of time that was best to macerate each portion, the trials having shown that great variation was produced by both these elements. It was at first believed that 4 parts of liquid was sufficient to moisten 8 parts of powder, and that twenty-four hours was long enough to macerate, and the first two percolations of the following series were made with these conditions. In the third percolation the liquid was increased to 5½ parts, and the maceration kept at twenty-four hours. In the fourth the liquid was increased to 6 parts. In the fifth it was kept at 6 parts, and the time of maceration was extended to forty-eight hours. In the sixth percolation it was increased to 7 parts, and the moistened powder, covered closely, was allowed to stand eight hours to absorb the liquid more thoroughly. Then the powder was passed through a No. 8 sieve, packed pretty firmly, filled with weak percolate, and then macerated for forty-eight hours, making a total maceration of fifty-six hours.

The first percolation of the series, made with fresh menstruum throughout, is of course a simple percolation, and was carried to practical exhaustion. And this practical exhaustion was doubtless to within 5 or 10 per cent. of absolute exhaustion of all matters soluble in the menstruum. The residue was quite tasteless for more than half way down the percolator, and then began to be very slightly bitter. This bitterness increased until at the bottom of the percolator it was quite distinctly bitter, after percolation under very favourable circumstances with nearly four times its weight of menstruum.

It is quite certain that the extract obtained from a drug by percolation is not uniform throughout the percolation in its medicinal value. If the menstruum be well adjusted as a solvent of the active principles of the drug it will dissolve and carry out the most soluble portions first and in largest proportion, so that although doubtless some of the useful part continues to be present in all parts of the percolate and its extract, yet the proportion must diminish much more rapidly than the proportion of extract. This point is well shown, so far as cinchona is concerned, in a table given by the writer in the *American Journal of Pharmacy*, for 1867, p. 402, where each portion of percolate and its extract were assayed for the total alkaloids they contained. Hence, though the quantity of dry extract yielded by different portions of the percolate be not a measure of the medicinal value of the percolate it is still the best guide that is easily accessible. Bearing in mind then, that medicinal exhaustion by percolation is more rapid than absolute exhaustion, and that the dry extract which measures absolute exhaustion becomes poorer in medicinal efficacy and richer in inert extractive matter, and that this divergence in value is greater near the end of the process, the quantity of dry extract yielded by each fraction of the percolate is adopted as the most convenient measure of the rate and the extent of the exhaustion.

The want of uniformity introduced into this series of percolations by the variation in the quantity of liquid used to moisten the several portions of the powder, and the variation in the time of maceration, diminishes the value of the series as illustrative of the best results of repercolation, and made it advisable to add a fifth and a sixth percolation to show the true character of the process when fairly established in actual practice, and thus these two percolations become by far the most valuable of the series as results of repercolation in actual practice, whilst the formula and process merely show how to begin to use repercolation.

The formula and process now to be given embrace the experience obtained in making the series which it represents, and is offered as a model by which other trials should be made by other hands, with other varieties of cinchona :—

Take of—

Yellow Cinchona, in powder No. 50 . .	32 parts.	
Stronger Alcohol,* s. g. ·819 at 15·6° C. = 60° F., ...		For a sufficient quantity of menstruum.
or s. g. ·811 at 25 ° C. = 77° F.	2 parts.	
Glycerin s. g. 1·250 at 15·6° C. = 60° F.		
or s. g. 1·244 at 25° C. = 77° F.	1 part.	
Water	2 parts.	

Weigh the stronger alcohol, glycerin, and water in succession, in any convenient quantity at a time, into a tared bottle, and mix them thoroughly for a menstruum.

Moisten 8 parts of the cinchona with 8 parts of the menstruum, by thoroughly mixing them, and allow the mixture to stand eight hours in a closely covered vessel. Then pass the moist powder through a No. 8 sieve, and pack it firmly in a percolator. Pour menstruum on top until the mass is filled with liquid and a stratum remains on top unabsorbed; cover the percolator closely, and macerate for forty-eight hours. Then arrange the percolator for an automatic supply of menstruum, and start the percolation at such a rate as to give 1 part of percolate in about four hours. Reserve the first six parts of percolate, and continue the percolation until the cinchona is exhausted, separating the percolate received after the reserved portion into fractions of about 8 parts each.

Moisten a second portion of 8 parts of the cinchona with 8 parts of the weak percolate,—the portion that was obtained next after the reserved percolate,—and allow the moist powder to stand for eight hours in a vessel closely covered. Then pack it moderately in a percolator and supply the percolator automatically with the remaining fractions of the weak percolate in th order in which they were received, and finally with freh menstruum until the cinchona is exhausted, Percolate in the same manner and at the same rate as with the first portion of cinchona, and reserving 8 parts of the first percolate, separate the weaker percolate into fractions of about 8 parts each.

Percolate the third and fourth portions of 8 parts each of the cinchona in the same way as the second portion.

Finally mix the four reserved percolates together to make 30 parts of finished fluid extract, and having corked, labelled and numbered the bottles containing the fractions of weak percolate, set them away until the process for cinchona is to be resumed.

When this fluid extract is to be again made, repeat the process as with the second portion, and reserve 8 parts of the first percolate as finished fluid extract from each 8 parts of cinchona from that time forward so long as the fractions of weak percolate are carried forward with which to commence each operation.

In applying this formula and process each part was taken as an avoirdupois ounce, and therefore each percolation was made with a half-pound avoirdupois of the cinchona, and the menstruum was made in a tared bottle from time to time as required.

As before stated, the series was made to consist of six percolations, and therefore the last two are in addition to the four of the formula, as if the process had been twice resumed, and the results of these two are entitled to most attention as showing the true practical character of the process of repercolation. And every percolation which might follow these can be demonstrated mathematically to approach nearer and nearer to accurate results the

* It is hoped that in the next revision of the U. S. Pharmacopœia the "alcohol" (s. g. ·835) may be dropped, and the simple name, alcohol, be applied to a clean spirit, of about the s. g. here given.

further the series is extended, since every successive percolation tends to correct the errors and improve the accuracy of those which have preceded it.

(*To be continued.*)

THE SUGAR MAPLE.*

BY GEORGE MAW.

Acer saccharinum is a much larger tree than the red maple, and is at once distinguishable from it by the roundness of the notch between the lobes of the leaves. It is one of the largest trees of the genus, often attaining a diameter of from three to four feet, and out-topping the other deciduous trees, sometimes reaching a height of over 100 feet. For fuel and charcoal its wood is especially valuable; it also produces the well-known bird's-eye maple used in cabinet work, supposed by Emerson to be a distinct variety of the sugar maple, but from information given me in Upper Canada, it seems probable that it is only of mere casual occurrence in individual trees. This species is pre-eminently the source of maple sugar and was known to the Indians before the settlement of the country by Europeans.

I had the advantage of inspecting on the farm of a Dutch gentleman, near Haysville, a section of the forest in which the maples are tubbed, and the collected sap boiled down for sugar, the particulars of which I record.

A very interesting physiological point connected with the production of maple sugar is the variability of the flow of the sap dependent on diurnal changes of weather, the whole life-force of the big old trees being apparently ruled by trifling changes of temperature and alternations of heat and frost. Changes of life-action occur which are unappreciable to the eye in the daily development of the spring growth, but which the flow of sap records with precision.

The rising of the sweet sap commences immediately after the the first break up of the long frost from the middle to the end of February, continuing through March and into the early days of April, but varying in different localities and at different seasons. A cold north-west wind with frosty nights and sunny days in alternation, tends to incite the flow, which is more abundant in the day than the night. It is, however, most sensitive to unfavourable changes, and from a flow of 3 gallons a day from one tree may almost cease in a few hours, and then gradually recover itself. From this it will be seen that the flow given from day to day is uncertain, and that reliable statistics of produce are difficult to record. A continuous course of favourable weather tends to the largest production, a rising and falling supply reducing the total produce of the season.

The time at which the flow commences varies, not only with the season, but with the exposure and elevation of the ground, being earliest in warm and low situations. A thawing night is said to promote its flow, and it ceases during a south wind and at the approach of a storm, and so sensitive are the trees to aspect and climatal variations that the flow of sap on the south and east side has been noticed to be earlier than on the north and west side of the same tree.

There are generally from ten to fifteen good "sap-days" in the sap season, which continues on and off for about six weeks, after which, as the foliage develops, the saccharine matter is reduced, and the sap is said to be "sour" though a restricted flow still continues. Emerson, in his work on the 'Trees of Massachusetts,' referring to Michaux's observations, considers that the product of sugar depends also on the character of the previous summer, and that a season of plentiful rain and sunshine prepares the tree for an abundant harvest of sugar in the succeeding spring. Open winters are thought to cause the sap to be sweetest, and much freezing and thawing to make it most abundant and of the best quality. The sap of isolated trees is richer in sugar than that of those which are massed together in the forest.

In the Maple Bush at Haysville the produce of sugar was at the rate of 1 lb. to each 6 gallons of sap, and the average may be 1 lb. to 4½ or 5 gallons, but Emerson records instances in which 1 lb. of sugar has been produced from 3 gallons of sap. With reference to the produce of individual trees, in a good sap season an average tree will run as much as 3 gallons of sap in a day, occasionally more, and produce about 4 lb. of sugar in the season, but Emerson records instances of the production of 10, 20, 33, and 43 lb. of sugar from single trees. Such weights are, however, altogether exceptional. The highest weight was produced from a draught of 175 gallons of sap from a single tree. The average quantity per tree would be from 12 to 24 gallons in a season.

Young trees under twenty-five years old are seldom tapped, the smaller trees scarcely paying for the trouble, apart from the debility it produces in the young growing tree. Repeated tapping of the matured trees produces no apparent injury or effect on their vigour. Emerson records instances of trees that have been tapped for forty consecutive years without injury, and it is said that both the quality and quantity of the sap are visibly improved after the first tapping.

The trees are usually tapped at a height of 3 or 4 feet from the ground with a ¾ inch auger to a depth of from 2 to 6 inches, into which a perforated plug is driven to lead the sap into the collecting vessels, or a simple notch 1½ inch deep is cut with the axe. From one to three taps are inserted in each tree, and these have to be renewed in succeeding years in fresh places, generally alternated on opposite sides of the tree. The sap is evaporated either in iron chaldrons or in shallow boilers, 6 feet long, 2½ feet wide, and about 8 inches deep. Those of copper are preferred to iron, as they are said to yield a whiter sugar.

Care is taken to keep the boilers filled up with fresh additions of sap during evaporation till the syrup attains a sufficient consistency, which is ascertained by its "breaking" or crystallizing when dropped into cold water. The syrup is strained during evaporation, a small quantity of lime or soda added to neutralize any free acids that may be present, and a little white of egg or milk to clear it. After straining and skimming, the syrup is poured into pans or moulds to crystallize, and it may be further clarified by gently boiling in tapering cans with a tap at the bottom towards which the molasses gravitates, and is drawn off as the crystallized sugar sets.

Maple sugar is made not so much as an article of commerce as for the home use of the producers, and the great bulk being consumed where it is made, it is difficult to arrive at anything like an accurate estimate of the total production. Emerson states that in Massachusetts alone between 500,000 and 600,000 lb. weight of sugar are annually produced from the maple, and he values it at 8 cents. a lb. In 1874 the price rose to from 10 to 22 cents. a lb. In Canada at the beginning of April last, new maple sugar was selling at from 10 to 11 cents. a lb., about the price of the best cane sugar.

A considerable proportion of the maple sap product is also preserved as syrup without crystallization, and in this state it is used as sweet sauce and for various culinary purposes.

The maple sugar production is said to be a growing industry, and if the preparation could be centred in well-ordered factories, on the plan of the cheese and butter factories, there is little doubt that carefully prepared maple sugar would closely compete in price with cane sugar. As it is, with the simple and almost rude appliance for preparation, there is little to choose between the purchase of cane sugar and the cost of producing the local home-made sugar from the sap of the maple.

* From the *Gardeners' Chronicle*, August 3, 1878.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 7, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EXAMINATION DISCREPANCIES.

WHEN the question was first propounded by "An Associate," how to account for the greater number of failures on the last day of each month's examination for the Minor, we confess that we were disposed to regard the alleged discrepancy as being somewhat questionable, and to think, so far as the instances given by our correspondent were concerned, that they merely pointed to an accidental coincidence. Under this impression we were inclined to answer our correspondent's question by another, viz., Is it a fact that there really is any such discrepancy as that alleged?

The correspondence that has since taken place on the subject has not done anything towards clearing up this difficulty in any way, and though all the writers have taken for granted that there is a general difference between the proportion of rejected candidates on the first and last days of examination, they have not in any instance been fortunate in suggesting modes of explaining how this comes to pass.

Taking first the letter of "An Associate," in which attention was first directed to this matter, it must be admitted that this is done with great fairness, and that in asking for some elucidation of what seemed to him a mystery, he then very reasonably expressed the opinion that it would be impossible to single out the good and bad candidates previous to the examination, and so arrange them. That, of course, is out of the question, and at first sight we think this remark will seem to apply almost as fully to the assumption involved in one of the explanations first offered by A.P.S., that the candidates are themselves able to arrange themselves in such a manner. This correspondent thinks that the percentage of failures at the Minor examination, differing so greatly on the first and last days, is very easily to be accounted for, since candidates are placed in order, according as they send their fees up to the Registrar, and since those who think they are not quite well enough up delay sending to the last moment: they are consequently last on the list, and come up for examination on the last day.

This explanation is not altogether a satisfactory one, for it is difficult to conceive any such connection between the readiness of candidates to enter their names for the examination and their fitness for passing it, as would classify them apart from those who were unable to pass the examination. Eagerness to enter for the examination is, moreover, by no means a trustworthy indication of the candidate's qualification for undergoing that ordeal.

The statement made by this correspondent that it is a well-known fact that the best men go up on the first day is one that will surprise many persons as much as the alleged discrepancy in the proportion of failures on the first and last days, though if the one be true the other must be likewise, and, in fact, they are but different ways of stating the same thing. As our correspondent, "An Associate," remarked, there is no possible way of determining before the examinations who are the best men; and though students may accord among themselves the repute of superiority to some of their number, this circumstance cannot have much influence in the examinations among a number of candidates from various places, many of whom are not known to each other.

Again, if the result of the examinations is taken as affording the indication which are the best men, we are still in almost the same difficulty in offering an explanation how it is that these men come to be examined on the first day.

The other reason suggested by A.P.S. appears to us a remarkably unreasonable one. He thinks the examiners get tired towards the finish, and that consequently, as he expresses himself, the candidates "get it stiffer;" that is to say, they are asked questions which are more difficult to answer. We must, however, do our correspondent the justice to mention that he adds he can hardly believe this to be the case, and it is a wonder that he did not bestow sufficient reflection upon the probability of such a course to have abandoned the idea altogether.

Surely if the fatigue of the examiners could be regarded as a reason for their tendency to hurry over the latter part of an examination, such a result would be more certainly attained by asking the candidates questions so easy and simple that they could not have any difficulty in answering them. The only result we can imagine to follow from putting more difficult questions would be the prolonging of the examiners' labour in consequence of the greater difficulty experienced by the candidates in answering.

However, the suggestion of a possible injustice being the cause of the difference between the number of rejections on the first and last days of an examination, though evidently based on the weakest foundation, has been accepted by another correspondent signing himself "Justitia," who, without any sufficient reason, adopts the idea that the difference is due to the examiners getting tired, and he then proceeds to lament the disheartening effect that will in future be produced upon those who find their names placed for examination on one of the last days.

"Justitia" discards the explanation offered by A. P. S., as being a very insufficient reason for the disproportion in the failures on different days and in

support of this opinion refers to the Scotch examinations as not being marked by this peculiarity.

The letter of "A Student" in the same number of the Journal is better calculated to elucidate this apparently strange discrepancy and, with some apparent knowledge of the circumstances by which candidates are influenced in entering their names, he ascribes it to the deferred entry of the least prepared students. At any rate his may be regarded as a more common sense view of the matter, and without accepting it at once as sufficient to explain the difference, we cannot but admit that the explanation he offers is reasonably consistent with the circumstances of the case. What can be more natural than that those who feel themselves deficient should delay sending their names until the last moment?

The letter signed C. H. which appears in the present number of this Journal is chiefly noticeable for a misstatement in connection with the practice followed in the office. According to the writer of this letter it is customary to send up first of all those candidates who present themselves a second time and have already proved themselves efficient in most of the subjects, while those who have before made a bad failure, or have not before presented themselves, are called up last. It is only necessary, in regard to this statement, to say that it is founded merely upon imagination; and as no such system is carried out at Bloomsbury Square it is unnecessary to say more in order to show that this cannot be the cause of greater proportion of failures at the end of the examinations in London.

Hitherto we have, like our correspondents, taken this difference as a fact without going into the details of the examination returns, but it is not surprising that this task should have been undertaken by some of the officers of the Society. As will be seen by the report of the Council proceedings, Mr. BOTTLE has, in accordance with a suggestion of Mr. HAMPSON'S, gone through the returns for the current year, and he has established the fact that throughout this period there has been a very notable difference in the relative proportion of passed and rejected candidates between the commencement and the end of the examination.

In reference to this the Secretary described the ordinary course of procedure in arranging for the examination of candidates, and according to his statement the general rule is for candidates to be summoned in the order in which they enter their names. But he added that very frequently inquiry is made by the candidates whether they cannot come up on the last day because they required as much time as they could to prepare themselves. So much stress appears in some instances to be laid upon the possibility of thus deferring examination till the latest moment that candidates will often defer making application until the end of the time allowed for receiving entries. By so doing they obviously are almost sure to come up at the end of the examination, and it is neither an unfair inference that those who adopt this course do so from a sense of their own weakness, nor is it surprising under these circumstances that the greater proportion of failures to pass should be met with at the end of the examination among these candidates.

Some further elucidation of this supposed mystery is afforded by the comparison of the results of examination in England with those in Scotland. Generally speaking, the Scotch Board gets through with the examination in one day, but when it extends over two days there is no such discrepancy between the failures on the two days as is observed in London. If the fatigue of the examiners induced greater severity in their examination of candidates we should scarcely find that to be a special peculiarity of the London Board.

A much more important circumstance, however, is the fact that the Scotch candidates have no idea whether there will be more than one day's examination, and the inducement to hold back so as to come last does not exist at all, while in London, owing to the larger number of candidates, those who are in this position may sometimes gain a week or more before being called upon to come up.

It will be satisfactory to many who are interested in this matter to know that it is now referred to the Board of Examiners for consideration and inquiry, and that it is thus in a fair way of being thoroughly explained.

FRENCH PHARMACEUTICAL STATISTICS.

FROM a statement published in the last number of *L'Union Pharmaceutique* it appears that in the year 1877 there were in France 6232 pharmaciens, that being an increase of 471 since 1866. The average relative proportion of the pharmacists to the whole population is about 1 to 11,500, but the proportion varies very much in the different departments, as will be seen from the following table:—

Seine department,	1 pharmacien to	2,958	inhabitants.
Bouches du Rhone	„	3,161	„
Alpes Maritimes .	„	3,337	„
Eure	„	3,696	„
Deux Sèvres. . .	„	10,859	„
Hautes Alpes . .	„	13,233	„
Haute Loire . .	„	14,939	„
Morbihan . . .	„	18,798	„

The 87 departments of France are subdivided into 36,056 communes, in only 2453 of which is there a pharmacy; consequently there are 33,603 communes in which there are none. The number of communes in which there are neither doctors nor officers of health is 29,697.

THE FORGERY OF TRADE MARKS IN TURKEY.

ACCORDING to a recent report made by Mr. Vice-Consul WRENCH, Constantinople, in addition to her other troubles, is plagued with a local trade in spurious articles bearing forged trade marks. An imitation of HENRY'S Magnesia, for instance, is sold in bottles bearing the name of Messrs. HENRY in relief, covered with a forged British patent medicine stamp; whilst, with a smack of irony, an ill-spelt printed notice wrapped round the bottle informs all whom it may concern, that "in the British dominions the forgery of the Government stamp is highly penal." Sometimes an imitation of STEPHENS'S "Blue Black Ink" is met with, bearing a label closely resembling the original one, but with the word "Steelpens," in capital letters, substituted for the name "STEPHENS." Other articles similarly treated are GUINNESS'S stout and BRYANT and MAY'S matches.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, September 4, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Gostling, Grecnish, Hampson, Hills, Robbins, Shaw and Woolley.

The minutes of the previous meeting were read and confirmed.

The Pharmaceutical Conference.

The President said as one of the delegates who were appointed to attend the Conference in Dublin, he had to report that it had proved a very successful meeting in every way, and had been certainly a very pleasurable one to those who were present. He would take this opportunity of moving that the *Pharmaceutical Journal* should be sent regularly to the Pharmaceutical Society of Ireland. He thought it was rather an oversight that this had not been done before, and he thought a complete set might be sent for, say, the last three years.

The Vice-President seconded the motion.

Mr. Gostling suggested that the Calendar also should be sent, and

Mr. Hampson added that the Catalogue of the Library and Museum might be included.

The President said the better way would be to instruct the Secretary to send all official publications of the Society.

As thus amended the motion was passed unanimously.

The Examinations.

Mr. Bottle said he might take this opportunity of referring to a matter which he mentioned at the last meeting, viz., the large number of failures which occurred on the last day of the July examinations as compared with the previous days. In accordance with a suggestion then made by Mr. Hampson, he had gone through the examinations for the year because he felt that this matter was of importance, and that the examinations ought to be like Cæsar's wife, above even suspicion. The result of his investigations was as follows:—On July 12, 1877, 19 were examined of whom 7 were rejected; on the 20th, being the concluding day of that examination, 26 were examined, of whom 18 were rejected. On the 17th October, 20 were examined and 10 failed; on the following day 21 were examined and 14 rejected. On the 12th December, 18 were examined and 6 rejected; on the concluding day of that month, 26 were examined and 15 rejected. On the 13th February the Board began by passing 7 out of 10, and finished by passing 12 and rejecting 9. On the 10th April, 16 were examined and only 3 rejected; on the concluding day, 17 were rejected out of 24. On the 19th June, 7 were rejected out of 16; on the concluding day, 17 were rejected out of 20. It was evident, therefore, that throughout the year there had been a very notable difference in the returns as to the passing and rejecting of candidates between the beginning and the end of an examination, and if either the Office, the Board of Examiners or the President could furnish any explanation how this discrepancy arose, he was sure it would be very satisfactory to the members at large.

The President said the question raised was certainly most important. It could not be answered off-hand, but it would no doubt receive the careful attention of the Board of Examiners.

The Secretary stated that as a general rule candidates were summoned in the order in which they entered, but they very frequently inquired when entering for examination whether they could come up on the last day, as they wanted as much time as they could get to prepare themselves for examination. If they could not be assured that they would be summoned on the last day, they would frequently defer making application until the very last moment on which entries could be received, in order to be summoned for the last day's examination. The inference he drew was, that the majority of the candidates who were summoned for the latter portion of an examination were men who intentionally placed themselves in that position from a knowledge of their own weakness.

The Vice-President thought the Secretary was quite correct in his view. The worst prepared men came up last, leaving it to the eleventh hour, hoping to get through.

The President said it was curious that this did not appear to happen in Scotland.

Mr. Bottle said that as a rule the Scotch Board got through the examination in one day, but where it did happen to run into a second day, the opposite effect to that which took place in England seemed to result. On the 12th July, 1877, the Scotch Board examined 9 and rejected 2; on the 13th they examined 10 and rejected 3. On the 17th October, 2 failed out of 11; on the 18th 1 failed out of 10. On the 19th December, 3 failed out of 12; on the 20th, 2 out of 9. In March there was only one day's examination. There could hardly be a parallel between the English and Scotch examinations, because a Scotch candidate had no idea that there would be a second day, and therefore, would not hold himself back under the impression that he would be able to come up on the last day.

Mr. Hampson thought this was a most important matter, and one which the Examiners ought most seriously to consider. He hardly thought the explanation offered by the Secretary was adequate to the solution of the mystery which seemed to attach to it.

Mr. Shaw said he had read the remarks made by Mr. Bottle at the last meeting, and had taken the opportunity of making inquiries of some of the young men who had been examined, and all with whom he had communicated explained the matter in the same way as the Secretary had done.

Mr. Woolley suggested that the question be laid before the Board of Examiners. It might also be well to ascertain what was the result in the examinations conducted by other bodies, such as the College of Surgeons.

The Secretary explained that in Scotland the practice was to place the whole of the candidates for examination in one alphabetical list which was then divided, according to the number of days the Board would require to sit; so that the same considerations did not apply.

The President thought this question deserved the attention of every one who could throw any light upon it, especially the Examiners. It would be sure to come before them and he had no doubt they would deal with it.

Mr. Atkins was glad that this subject had been brought forward, it being of considerable importance; but he was disposed to think from all he could learn that the Secretary's statement went a very long way to explain the matter, though he was not prepared to assert that other causes also might not be in operation. He feared that many of those who came up last did so in order to secure every inch of time for the purpose of "cramming," and with the natural result of failure.

Mr. Hills said the Examiners might be able to throw some light on the matter, and he thought it would be well to have their opinion on the subject.

The President remarked that the Examiners were the only persons who could afford trustworthy information. It was impossible to get it from the candidates themselves.

Mr. Gostling thought the main reason of the results described was that given by the Secretary. But would it not be desirable to request the Examiners to consider the propriety of adopting the Scotch method of taking the candidates alphabetically to see whether the results would be the same?

Mr. Robbins suggested that the matter should be

officially brought before the Examiners, so that they might give their opinion upon it to the Council.

The PRESIDENT said the matter would no doubt come before the Board of Examiners in connection with the report of the deputation from the Scotch Board. If he were in the chair he should certainly bring it forward.

Mr. BOTTLE thought it was due to the Board of Examiners that the Council should formally ask it to take the matter into consideration. He had an idea that some of the candidates who came up last might confuse themselves by getting hold of candidates who had been examined on the previous days, and trying to ascertain what questions had been asked.

It was resolved accordingly to request the opinion of the Board of Examiners on the matter.

Mr. GREENISH said he was requested by Professor Markoe to ask if the Council would send the Journal regularly to the Massachusetts College of Pharmacy, and he also hoped that a complete set of the third series might be sent. He might mention that some time ago he asked the Council to allow the Journal to be sent to the Botanic Gardens at Natal, and he had lately received from thence a parcel of articles connected with materia medica, which would find their way to the museum, accompanied by a letter thanking the Council for sending the Journal.

ELECTIONS.

Chemist and Druggist.

Saffery, John .....Sheerness.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Good, George Arthur .....Bridgwater.
Parry, Robert .....Bettws-y-Coed.

ASSOCIATES.

The following, having passed their respective examinations and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Cooper, Albert Henry.....Walmer.
Dickson, William.....Kirriemuir.
Gibson, John Chambers .....Manchester.
Lea, Frederick James .....Folkestone.
Pain, Edwin .....Dover.
Paterson, James Smith .....Castle Douglas.
Stevenson, John Joseph .....London.
Thomas, Archibald .....Northamption.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Bowman, Edward James.....Douglas.
Escreet, Williams Myers.....Hull.
Hamer, Joseph Armitstead.....Southport.
Heynes, Thomas Edward .....Maidenhead.
Puntan, Herbert Harding C. ...Turriff.
Westwater, George .....Lochgelly.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The name of the following person was restored to the Register of Chemists and Druggists:—

George John Blennerhasset Woolley, 3, St. Michael's Terrace, Maidstone.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£5 to a registered chemist and druggist, aged 60. Applicant had a grant of £10 in March last.

£10 to the widow of a member, aged 60, who had a grant of a similar amount in July, 1877.

£15 to the widow of a pharmaceutical chemist and late member of the Society, who was in business for thirty-eight years.

£5 to a registered chemist and druggist.

Another case was considered, but no grant was recommended.

The report and recommendations were unanimously adopted.

GENERAL PURPOSES.

This Committee's report included a statement of sundry correspondence which had taken place relating to alleged breaches of the Pharmacy Act. Amongst others a letter had been received from a coroner saying that he feared the supply of poisons to unregistered persons by wholesale dealers could not be prevented except by fresh legislation.

The SECRETARY reported that he had made inquiries of local secretaries and informants respecting cases of infringements of the law, which had been reported in May, asking whether the offences had been continued since the premonitory letters had been sent. A number of replies had been received, stating that the offences had been discontinued.

The report was unanimously adopted.

Mr. ATKINS inquired if any information had been sent with regard to the non-registration of the sale of poisons at Penzance, which was mentioned some time ago.

The PRESIDENT said he recollected one or two letters having appeared in the Journal upon the subject.

The VICE-PRESIDENT said he believed there had been no official communication of any kind from the Penzance chemists.

A letter was read from the Leicester Chemists' Association regretting that the Council had removed that town from the list of local centres for the Preliminary examination.

AMENDMENTS IN THE PHARMACY ACT.

Mr. BOTTLE, referring to the Committee which was appointed last year to consider any amendments which might be desirable in the Pharmacy Act, which Committee he believed had been re-appointed, wished to know if it had held any meetings, and considered the subject relegated to it. It appeared to him that the coming session of Parliament might possibly be a fitting one for the Council to submit some amendments in the Pharmacy Act.

Mr. GREENISH said the Committee had been re-appointed, but had not held any meeting. There had been no occasion for so doing.

The fact of the re-appointment of the Committee having been questioned by the President, and no minute of it having been found,

Mr. BOTTLE gave notice that next month he would move the appointment of a special committee to attend to this matter.

WEIGHTS AND MEASURES.

The SECRETARY reported that apothecaries' measures were now for the first time legal, as appeared by the following extract from the *London Gazette* of August 30th.

"*Apothecaries' Measures.*

"At the Court at Osborne House, Isle of Wight, the 14th day of August, 1878; present the Queen's Most Excellent Majesty in Council. Whereas the following apothecaries' and ounce measures are already legalized as imperial standard measures of capacity, viz.:—Quart,

equal to 40 fluid ounces; pint, equal to 20; half-pint, equal to 10; gill, equal to 5; half-gill, equal to 2½; quarter-gill, equal to 1¼ fluid ounces; four fluid ounces, two fluid ounces, one fluid ounce, half a fluid ounce.

"And whereas the Board of Trade have represented to Her Majesty that the following apothecaries' measures of capacity, which have been constructed and duly verified and authenticated in the Standards Department of the Board of Trade, and their capacity accurately determined in relation to the Imperial standard measure of capacity established under the provisions of section 6 of the Act 5 George IV., cap. 74, should be declared to be legal secondary standards of capacity, in pursuance of sections 6 and 8 of the Standards of Weights, Measures, and Coinage Act, 1866, viz.:—

"Imperial Standard Measures of Capacity to be used in the Sale of Drugs.—4 fluid drachms, weighing 218·75000 grains; 3 fluid drachms, weighing 164·06250 grains; 2 fluid drachms, weighing 109·37500 grains; 1 fluid drachm, weighing 54·68750 grains; 30 fluid minims, weighing 27·34375 grains; 20 fluid minims, weighing 18·22917 grains; 10 fluid minims, weighing 9·11458 grains; 5 fluid minims, weighing 4·55729 grains; 4 fluid minims, weighing 3·64583 grains; 3 fluid minims, weighing 2·73438 grains; 2 fluid minims, weighing 1·82292 grains; 1 fluid minim, weighing 0·91146 grain; also 3 fluid ounces, weighing 1312·50000 grains. Now, therefore, in pursuance and by virtue of the said recited sections of the Standards of Weights, Measures, and Coinage Act, 1866, Her Majesty, by and with the advice of her Privy Council, is pleased to order, and it is hereby declared that the said measures of capacity shall be legal secondary standards of capacity from and after the time when this order shall have been duly published in the *London Gazette*, pursuant to the said Act.

"C. L. Peel."

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 177.)

The next paper read was on—

The Titration of Hydrocyanic Acid and Cyanides, and its Relation to Alkalimetry.

BY LOUIS SIEBOLD.

Liebig's method for estimating the strength of hydrocyanic acid by means of decinormal solution of silver nitrate gives perfectly accurate results if the following precautions be observed:—

(1) The solution of sodium or potassium hydrate should be placed in the beaker first, and the hydrocyanic acid added to it from the pipette. If, instead of this, the acid is placed in the beaker first, and the alkaline hydrate added afterwards, there may be a slight loss by evaporation, which becomes appreciable whenever there is any delay in the addition of the alkali.

(2) The mixture of hydrocyanic acid and alkali should be largely diluted with water before the silver nitrate is added. The most suitable proportion of water, according to my experience, is from ten to twenty times the volume of the officinal or of Scheele's acid, which is more than twice the quantity recommended by Fresenius and other authorities. With such a degree of dilution the final point of the reaction can be observed with greater precision.

(3) The amount of alkali used should be as exactly as possible that required for the conversion of the hydrocyanic acid into alkaline cyanide, as an insufficiency or an excess both affect the accuracy of the result. With an excess the results are too high; with an insufficient quantity they are too low. The error due to the first named cause is but small and is pointed out in some of the standard analytical works, which therefore recommend the use of sufficient alkali to produce a distinct alkaline reaction and the avoidance of an undue excess. But it is just this direction which may lead a conscientious yet inexperienced manipulator to the far more serious mistake of using too little alkali, because litmus entirely fails to mark the point at which the hydrocyanic acid has been completely converted into sodium or potassium cyanide. These cyanides are so strongly alkaline to test paper, and hydrocyanic acid is so weak an acid, that a mixture of the two may have a distinct or even a very strong alkaline reaction and yet contain a considerable amount of free hydrocyanic acid. Hence it follows that the use of a quantity of sodium hydrate quite sufficient to produce a strong alkaline reaction may only ensure the conversion of a portion, and perhaps of the smaller portion, of the hydrocyanic acid actually present into sodium cyanide. The inevitable result will be a serious error in the estimation, as the quantity of silver nitrate solution required to produce a permanent precipitate will only indicate that portion of the hydrocyanic acid which has entered into combination with the alkali; and this error may possibly amount to as much as 75 per cent.

I have alluded to this source of error at one of our previous meetings, in connection with a paper on the preservation of hydrocyanic acid, and I pointed out on that occasion that the alkalinity of the mixture at the end of the reaction, *e.g.*, after the addition of sufficient silver nitrate to produce a slight permanent precipitate, may be regarded as a sure indication that a sufficient quantity or rather an excess of alkali has been used, and that the result of the determination will be fairly correct, or in the presence of an undue excess of alkali a little too high. The alkalinity of the mixture of hydrocyanic acid and sodium hydrate completely ceases after the addition of the required amount of silver nitrate, unless some excess of alkali was used, and if it does cease, the result of the analysis will almost certainly be too low. My reason for again touching upon these points is that the neutrality of the double cyanide of sodium and silver (the product of this reaction), on which these conclusions were based, also forms the basis of my present communication.

From what I have already stated it is clear that the titration of hydrocyanic acid with silver nitrate cannot give results of scientific accuracy unless the quantity of alkali used is exactly that required to combine with the acid, or unless a correction can be made for the excess of alkali employed. It is true that a slight excess of the latter does not appreciably affect the result, but then the question arises how to make certain that the excess used is but a slight one. It will not do to start with just sufficient soda to render the mixture alkaline and then to add gradually more as the alkalinity ceases during the titration, because in that case free hydrocyanic acid would be present in the mixture during nearly the whole of the process, and under the influence of the exposure and the continual stirring a portion would inevitably be lost by evaporation, thus causing an error which, though perhaps not considerable, is certainly greater than that which would result from the use of even an immoderate excess of soda to start with. I find, however, that the following *modus operandi* will meet the difficulty and ensure results agreeing perfectly with those of gravimetric determinations:—The acid is allowed to run from the pipette into an excess of solution of sodium hydrate; decinormal solution of silver nitrate is then added drop by drop until a slight opalescence is produced, and this point being attained, standard normal hydrochloric or sulphuric acid is added until the opalescence begins to increase, which does not take place until the whole of the free alkali is neutralized. From experience I find that for each c.c. of standard mineral acid thus required 0·01 c.c. should be deducted from the volume of the silver solution used, and the remainder calculated for HCy. It will be seen that in this process the cyanide of sodium and silver acts as an acidimetric indicator, and indeed, it answers well for the

purpose, for a single drop of free acid produces with it a very distinct precipitation of silver cyanide.

The fact, that in the absence of a sufficient quantity of soda the volume of silver solution required to produce a permanent precipitate only indicates that portion of the hydrocyanic acid which has been used up in the formation of sodium cyanide, and that this determination of NaCy is in no wise affected by the presence of free hydrocyanic acid, renders this method applicable for the analysis of mixtures of the free acid and alkaline cyanides. Supposing the solution to be analysed contained free hydrocyanic acid and potassium cyanide, the volume of silver solution required to produce a permanent opalescence would show at once the quantity of KCy present. On now adding NaHO in slight excess and continuing the titration until the opalescence is again produced we find the quantity of free HCy. The results thus obtained are quite exact.

Before quitting this subject I wish to refer to a very handy process for the estimation of cyanides recently communicated to the Chemical Society by Mr. J. B. Hannay. It consists in the addition of decinormal solution of mercuric chloride to the hydrocyanic acid or cyanide rendered previously alkaline with ammonium hydrate, until a permanent precipitate is formed, which does not occur until the whole of the cyanogen has been used up in the formation of mercuric cyanide, as alkalies have no action on the latter. I have tried the process repeatedly with most satisfactory results, and believe that it will find much favour with pharmacists in the testing of hydrocyanic acid, especially as an excess of alkali does not affect its accuracy. But it cannot be used like the other for the analysis of mixtures of free HCy and cyanides.

I now come to the second part of my report, viz., the relation of the titration of cyanides to alkalimetry. It stands to reason that if an alkaline cyanide can be correctly estimated in the presence of free hydrocyanic acid by silver nitrate, this titration must answer as well for the estimation of a caustic alkali as for that of hydrocyanic acid. For that purpose the quantity of KCy or NaCy found, or the volume of silver solution used, is simply calculated for KHO or NaHO instead of HCy. Now if the applicability of this test for alkalimetric purposes were confined to the determination of caustic alkalies, I feel certain that nobody would think of using prussic acid and silver nitrate in preference to the customary sulphuric acid and litmus; but I find that it answers equally well with the alkaline carbonates, and here I consider it decidedly preferable to the process in general use, for the following reasons:—

(1). The solution of alkaline carbonate does not require boiling, as the carbonic acid does not interfere.

(2). The change from perfect clearness to an unmistakable turbidity, as produced by a single drop of the silver solution, is more striking than that of the colour of litmus brought about by one drop of standard sulphuric acid.

(3). As a decinormal solution is used the results are more accurate than those obtained by normal H_2SO_4 or HCl.

(4). The result may be readily checked, without the necessity of operating on a fresh portion of the sample.

(5). The chloride present in commercial alkaline carbonates can be estimated by the same process with but little additional trouble.

It is well known that hydrocyanic acid does not decompose alkaline carbonates at an ordinary temperature. But in the presence of silver nitrate the decomposition takes place in accordance with the following equation—

$$K_2CO_3 + 2HCy + AgNO_3 = KAgCy_2 + KNO_3 + CO_2$$

The first drop of silver solution added in excess precipitates silver cyanide.

$$KAgCy_2 + AgNO_3 = 2AgCy_2 + KNO_3$$

The weak solution of the carbonate to be tested (about 0·5 to 1 gram in 100 c.c. of water) is mixed with 10 to 20 c.c. of hydrocyanic acid of Scheele's strength (a decided excess), and the decinormal solution of silver nitrate added drop by drop, stirring well all the time until a permanent turbidity is produced. Each c.c. of the silver solution required corresponds to 0·138 gram K_2CO_3 and to 0·0106 Na_2CO_3. I quote the results of a few determinations to show the accuracy of the process.

Pure K_2CO_3 used.	Found.
0·5850	0·5851
0·1670	0·1672
0·8775	0·8779
0·2088	0·2085

If after the addition of the required quantity of silver nitrate the mixture is boiled down to less than half its volume or until the excess of free HCy has been completely expelled, then mixed with a few drops of solution of potassium chromate and the addition of silver nitrate now proceeded with until the colour of the mixture changes to red, the volume of the test thus used will be found equal to that used in the first titration. This may serve to check the previous result. In the presence of chloride, however, the number of c.c. used in the second titration will be greater than that used in the first. The difference between the two exactly indicates the chloride.

If 40 c.c. were used in the first and 45 c.c. in the second experiment the difference of 5 c.c. must be calculated for chloride.

A few of my results will show the value of the method.

Used.	Found.
(1). Pure K_2CO_3 0·2000	K_2CO_3 0·2005.
Pure NaCl 0·0680	NaCl 0·0683.
(2). Pure K_2CO_3 0·9750	K_2CO_3 0·9750.
Pure NaCl 0·1825	NaCl 0·1830.

Hence I believe, that this method merits the attention of those who are much engaged in alkalimetric estimations.

I have also employed silver nitrate with success in the analysis of mixtures of hydrocyanic acid and mineral acids, and indeed I find that these processes may be advantageously extended to other applications, but my experiments in this direction are not yet completed.

The PRESIDENT said this appeared to be a most valuable paper. He had reaped considerable benefit from previous papers by the same author, and he should have the greatest pleasure in applying the present one to practical use.

Mr. WILLIAMS thought Mr. Siebold's suggestions were likely to be of great practical value, though, of course, many of the points he had mentioned were of more importance to those who were not constantly in the habit of testing hydrocyanic acid and cyanides, than to those who were frequently so engaged. Many of the points mentioned were familiar to him, but some, in which Mr. Siebold by a reverse action checked his first results, were very valuable, and likely to be of great service. He might here mention a subject to which he had alluded a few years ago—the preservation of hydrocyanic acid by means of glycerine. At that time he had a quantity of very concentrated hydrocyanic acid put on one side, and to it he added pure (Price's) glycerine. The strength of the mixture was taken very accurately three years ago, and it was found to contain 37½ per cent. of real hydrocyanic acid, 37½ per cent. of water, and 25 per cent. of glycerine. It had been standing ever since, not tied over, in diffused daylight, in an ordinary blue glass bottle, and purposely without any special precautions for preservation, and on the Thursday previous he had it tested again. It then contained 37 per cent. of real hydrocyanic acid, only ½ per cent. difference; in fact, it might be said not to have varied, for he should be sorry to say with hydrocyanic acid of that strength that he could test it to ½ per cent. This was an extraordinary fact, and quite confirmed what he suspected from his original experiments that

glycerine had the power of preserving hydrocyanic acid, especially when concentrated, in the most extraordinary manner. It even prevented its diffusion.

Dr. SENIER said the plan he had adopted in order to obviate the very great error which arose from following the direction of the ordinary text-books for the estimation of hydrocyanic acid was this. He added to the dilute hydrocyanic acid soda solution to a strong alkaline reaction, which was conveniently determined by means of tincture of litmus, then adding the silver solution drop by drop from a burette, when in most cases the mixture would become acid. When it did so he added more soda solution, and went on until the final reading. The great point was to see that the solution was alkaline at the final reading. In this way the addition of too much soda at the commencement was avoided.

Mr. SAVAGE asked if Mr. Siebold had had any experience in keeping hydrocyanic acid, whether in the stronger or diluted form. They all knew that when the bottle had been opened for dispensing purposes, it became sometimes almost inert when not used rapidly.

Mr. SIEBOLD said he had an objection to the process mentioned by Dr. Senier, for the reason stated in the paper. If sufficient caustic soda were used in the determination of the hydrocyanic acid to produce a strong alkaline reaction, yet not sufficient to convert the whole hydrocyanic acid into cyanide, there was free hydrocyanic acid present during the whole process, and as the titration required continuous stirring, a slight loss of hydrocyanic acid by evaporation could not possibly be avoided. If a measured quantity of hydrocyanic acid of known strength were poured into a beaker, stirred for five minutes, and then determined again, a very appreciable difference between the two results would be found. The point raised by Mr. Savage had been discussed a few years ago, when it was recommended in two papers out of four which were read that the acid should be largely diluted with water, as an exceedingly weak acid kept much better than a stronger one. In his own experience he found that an acid only one-twentieth the strength of that of the Pharmacopœia kept on the whole very well, certainly much better than the strong acid. Mr. Williams at the time threw out the suggestion that glycerine might be advantageously employed, and having tried the experiment he was convinced of the excellent properties of glycerine, so that he should now recommend its use rather than the addition of so large a quantity of water. Scheele's acid kept very well with the addition of glycerine. His main object in bringing forward his paper was to show the applicability of this process to the determination of pearl ash and soda ash; because without any boiling, in two or three minutes, the result was obtained. The operator had only to add the hydrocyanic acid, run in the solution of nitrate of silver, and he got a very accurate result. He (Mr. Siebold) thought whoever gave this method a fair trial would adopt it for general use.

A vote of thanks was passed to Mr. Siebold.

The next paper read was on—

THE MICROSCOPE IN MATERIA MEDICA.

BY THOMAS GREENISH, F.C.S.

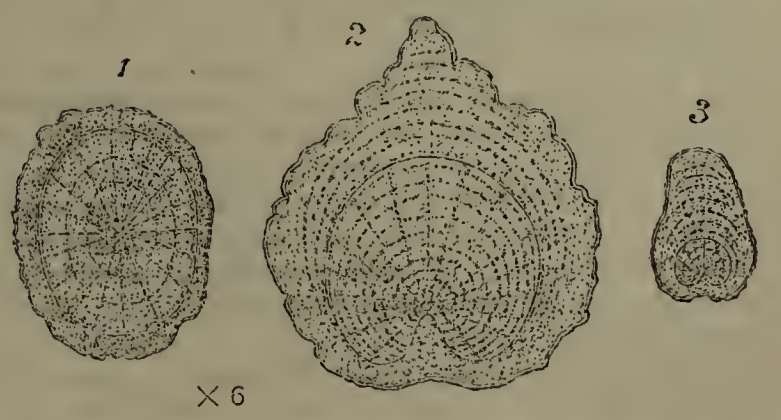
Vegetable histology is a subject which merits more attention from the pharmacist than it usually receives. The necessity of a general knowledge of botany or the natural history of the vegetable kingdom is fully recognized, but the pharmacist in dealing with the vegetable materia medica requires something beyond and more special than this general knowledge. He should know the organographic locality of the active constituents of the different plants used in medicine and also something of the histological localization or the particular tissue or tissues in which those active principles reside. The anatomy of these elementary parts of which the organs of plants are composed constitutes vegetable histology, and the several cells are distinctly visible and capable of being examined and identified only with the aid of the microscope.

As one instance in point, cinchona bark may be mentioned. Wigand investigated this bark with the view of determining the question which had occasioned some controversy, which of the cell tissues was the seat of the alkaloid? Chiefly through the employment of reagents he came to the conclusion that the alkaloid resided mainly in the bast or liber cells; but the more careful experiments conducted by Carl Müller have settled this question and have placed beyond doubt the fact that the parenchymatous tissue is the seat of the alkaloid in the cinchona bark, and this opinion has, I believe, never since been called into question. The relative proportions, therefore, of bast or liber to parenchymatous tissue in a given sample of cinchona bark, which to a certain extent may be indicated by its short or otherwise fibrous fracture, is an element of some practical value prior to a chemical analysis.

Cultivation, with reference to particular soils, has the property of determining the development of one tissue at the expense of another; for instance, holly cultivated in a rich soil loses the spiny character of its leaves due to prosenchymatous tissue in the excessive development of its parenchymatous tissue. Some medicinal plants by garden cultivation lose much of their medicinal activity. Schroff states that this is the case with the aconites, and Hanbury mentions that the variation in quantity of volatile oil yielded by valerian is influenced by locality, a dry and stony soil yielding a root richer in oil than one that is moist and fertile, and I have but little doubt that this influence of soil is accompanied by a corresponding alteration in the histological elements of the valerian root.

Facts such as these are very suggestive to the pharmacist, and they may on a little reflection be much extended; but they are sufficient to show the value of a study of vegetable histology, without which the influence of soil, climate and cultivation on the development of particular elementary tissues cannot be accurately determined.

A parcel, supplied as senega root in the usual course of business to a pharmacist, was forwarded to me for microscopical examination. Its being a senega root at all was called in question. It will be observed from the sample that the roots are thinner, of a lighter colour, and have fewer rootlets than the senega usually met with in commerce. Also the dark concentric rings are not present and there is an absence of keel, with other characters of lesser importance. A decoction of it as compared with one from an ordinary sample is much lighter in colour and in taste much less pungent. The histological examination proved it to be a true root of *Polygala senega*; a transverse section of it is represented by No. 1 drawing,



No. 2 is a section of a root of a senega of commerce taken across a keel, and showing the general structure to be similar to the preceding; No. 3 is a section of one of the rootlets.

I shall now proceed to describe the tissues histologically. For this purpose No. 2, a section of the senega of commerce, may be taken. The cortical portion or bark of the root is divided into three parts, an outer layer or periderm composed of a series of two or three tabular

cells of a yellowish brown colour; next, a middle layer of thin-walled parenchymatous tissue, the outer cells stretched for the most part in a tangential direction. This layer is very unequally developed, when there is a keel o the root, as is the case in this section; on that side it is smallest; from there it increases gradually till it reaches the opposite side where it displaces more or less completely the inner layer which is the most fully developed on the keel side, where also may be seen the bast or liber cells, and passing through this tissue the medullary rays.

Although the histological elements of these three sections are identical, yet in their relative proportions the three roots differ materially and to the result of these differences, bearing immediately on the greater or less activity of the root, attention will next be directed.

Senega has probably not received so much attention as other substances of the vegetable materia medica, but Schneider, in 1875,* undertook the determination of the following points, the active principle of the senega root, and what part of the root contained it in the greatest quantity; but with the latter part only we shall have to do on the present occasion. Trommsdorf had in 1832 stated that the active principle resided in the bark of the root only, and not at all in the woody tissue of the centre, and Schneider confirmed the correctness of his conclusions by analyses of different roots and different parts of the same root. The conclusions he arrived at may be summed up as follows, giving to the active principle of the root the name of senegin:—

Rootlets . . .	9·26	per cent	senegin.
Middle-sized Roots	3·28	,,	,,
Thick Roots . .	3·02	,,	,,
Crown of the Root	2·6	,,	,,

The central woody portion being inert, I shall pass over that part, and not further allude to it, excepting in reference to the space it occupies relative to the parenchymatous tissue, the seat of the active principle. From the conclusions of Trommsdorf and Schneider that the bark only yields the active principle, it will be seen that these sections have an immediate practical bearing on the value of senega root. No. 1, the root in question, has little bark relative to its woody and inert centre. No. 2, a section from a fair sample of the senega of commerce with a keel, has much more bark in proportion to its woody portion, and No. 3, a section of a rootlet is nearly all bark. Calculating now the superficial area of the parenchymatous tissue of the bark which contains the senegin, and comparing it with the prosenchymatous or woody tissue, which is inert, the relative proportions in the three roots will, approximately of course, stand thus:—

Rootlet, 8·5 to 1 . .	(or relatively)	17
Middle-sized Senega, 3 to 1		6
The Senega in question, 1 to 2 . . .		2

It will be observed how closely the superficial area of parenchymatous tissue, in which alone the active principle resides, corresponds with the relative proportions of senegin in the roots and rootlets analysed by Schneider.

These enlarged drawings are to scale and the relative proportions exactly those of the microscopic sections from which they were drawn. It will now be seen why the rootlets yield so much more active principle than either of these roots, and it will at the same time be evident why the sample in question yields a decoction so deficient in strength. Schneider remarks that it would be impossible to obtain rootlets in sufficient quantity to meet the demand for senega, and recommends the use of roots of medium thickness, in accordance with the results of his analyses, and probably if these are well furnished with rootlets, so much the better.

The keel, generally considered an important feature of good senega root, is due to a peculiar development of bast or liber tissue on one side, and the same root may be quite round in one part, and have a development of keel in another; this keel is shown in section No. 2. Having isolated the elementary organs of a section across this particular part of the root, separated the tabular cells of the epidermis, the cells of the parenchymatous tissue, and also the liber cells represented by these waves in cellular tissue, and examined the individual cells so separated, I have always found that those of the parenchymatous tissue contained granular and oily matter, whilst the liber cells were free from it; and reasoning from analogous instances I am led to conclude that the liber tissue does not equally with the parenchymatous contain the active principle, and this may probably be the reason why middle sized roots, with less liber tissue, yield more senegin than those of larger size.

There is no doubt in my mind but that this root which has been called in question is that of *Polygala senega*, but it is deficient in cortical portion, the seat of the active principle, and is, I believe, a young and immature root, and consequently one that does not fairly represent the senega of our materia medica from which the preparations of the British Pharmacopœia are directed to be made. I think from what I have stated, and demonstrated by drawings from microscopical sections of different roots of senega, it will be seen how important it is that the senega employed in pharmacy should have its cortical portion fully developed, and the same process of anatomical analysis is applicable to almost every drug with which the pharmacist has to deal.

May I indulge a hope that the time is not far distant when vegetable histology, embracing the isolation and microscopical examination of the tissues so isolated, together with the microchemical analysis of the vegetable cell, will takes its place by the side of botany in the practical course of study for the pharmacist; when an intimate knowledge of the seat of the active principles of the plants with which he has to deal, and the relative proportions of the special tissues containing those active principles, will exercise its due influence in the pharmacy, be felt in the drug markets, and react on the sources of supply, so that more judgment as to the time of collecting, and more care as to the mode of harvesting, may furnish us with the several drugs of the materia medica in the best possible condition for pharmaceutical preparations?

Mr. Long remarked that this paper showed the great advantage of education to pharmacists, but they must become more united and get better paid for their labour. If they were to go on at a bare pittance there would be no possibility of devoting any leisure to these important subjects. His experience was that the assistants of the present day were lamentably deficient in the qualities of men of business, though they might have passed a good examination. They would, he thought, have to insist on a higher education, and raise themselves so as to stand better both with the profession and the public.

Mr. Sumner had anticipated that Mr. Greenish would have made some reference to the large roots which had been on the market lately, which contained almost all woody substance with very little bark. He was glad to have heard such an elaborate paper on so important a matter as senega root. Much of that lately offered had been almost exclusively large chumpy roots, so much so that it scarcely looked like senega at all. He was hardly prepared to hear from Mr. Greenish that in the young root he found so great a yield of wood.

Mr. Umney said if the specimen now brought forward had been put before him on a broker's show-room board, he should have rejected it, not so much from the appearance as from the entire absence of aroma, and of any action on the fauces when chewed. In fact, he believed he had seen this root in the London drug market, and declined purchasing it. Still he had so often appealed to Mr. Greenish for his opinions as a microscopist, and placed so much confidence in his judgment, that but for

* *Archiv der Pharmacie.*

the observations of Mr. Summer he should have remained silent.

Mr. GREENISH said he believed the specimen to be a young immature root of senega. It had the characters of the root, and on turning to Göbel and Kunze's drawings he found there three roots: one an old root, one a young one, and the third one of medium age. The young root was almost entirely devoid of rootlets, whilst the medium root had many of them, and the old root had the appearance usually found, showing the concentric rings, and the keel. Frequently on the upper portion there would be no keel, but on the lower there would be one, due to the excessive development of the inner layer of the bark, which contained the bast and liber cells. In this root neither concentric rings nor keel were found, but there were furrows in a longitudinal direction, and they so entirely corresponded with the drawing in that work that he believed the root to be that of *Polygala senega*.

A vote of thanks was passed to Mr. Grecnish.

The next paper read was—

MISCIBLE COPAIBA.

BY T. B. GROVES.

Some years ago my brother, Henry Groves (now of Florence), discovered the interesting fact that when a mixture of balsam of copaiba and oil of tartar (a saturated solution of carbonate of potassium) are shaken together and thereby emulsified, the creamy fluid after standing a few days deposits a white crystalline substance, leaving supernatant a clear stratum of apparently unaltered copaiba. It was, however, more or less completely saponified and rendered miscible with water, forming with it a white emulsion. It, therefore, differs essentially from that which is known as soluble copaiba.

Since that time the preparation has occasionally been employed here, but as its applications were limited it did not, until the recent papers on copaiba by Mr. Siebold and others appeared, occur to me to examine the reaction.

As it is I have but made a superficial examination of the question, which, in order to do it justice, would require the expenditure upon it of far more time than I have at my disposal.

A sample some six or eight years old of this miscible copaiba (Bals. Copaibæ, Oj.; Ol. Tartari, ℥ij fl.) presented the following characters:—

It was, as I have already said, similar in appearance and consistence to ordinary copaiba, but instead of having an acid it had an alkaline reaction, and when shaken with water instead of floating on its surface as ordinarily it readily formed with it a white emulsion, more or less stable according to the degree of dilution. This emulsion was of course readily destroyed by acids. As regards its behaviour towards solvents it differed little from ordinary balsam of copaiba. The only point worth remarking on in this connection was the fact that alcohol did not affect a perfectly clear solution and caused after a few days a minute whitish deposit to collect at the bottom of the bottle. The removal of this substance (probably a resin-salt of potassium) did not, however, affect the emulsibility of the balsam.

So much for the fluid balsam which had been carefully drained off from the underlying white saline deposit. This was found to be imbedded in a pasty resinous substance on the surface of which were planted numerous crystals, slender needles of from one quarter to half an inch long. The mass having been well washed with benzol these crystals disappeared and up to now they have refused on the evaporation of the solvent to put in a second appearance. The white substance left after the washing above referred to proved to be entirely composed of minute crystals of bicarbonate of potassium.

The action, therefore, of the acid resins of the copaiba had been this, to deprive two molecules of the carbonate of half their potassium, leaving the second atom to combine with both atoms of carbonic acid and one atom of water to form the acid carbonate of potassium and water known as bicarbonate of potassium. No evolution of gas, therefore, attends the operation. It seems moreover, that balsam of copaiba in the cold exerts no action on bicarbonate of potassium. The balsam of copaiba used in making the preparation above referred to was presumably the Maranham variety; it was obvious, however, that as the copaiba balsams of commerce differ as widely in their characters as in their botanical sources it would be desirable to experiment on well defined samples of known origin. I accordingly obtained from Messrs. Barron and Co., of Giltspur Street, London, authentic samples of Maranham and Para balsams of copaiba and of Gurgun balsam and treated them as follows:—

In bottle No. 1 were placed 2½ fluid ounces of Maranham balsam of copaiba and ¼ fluid ounce of oil of tartar. A fluid drachm of this yielded on evaporation 34 grains of solid saline residue.

Bottle No. 2 contained Para balsam of copaiba and oil of tartar in the same proportions.

Bottle No. 3 contained Gurgun balsam and oil of tartar in the same proportions.

Bottles No. 4 and 5 contained Maranham balsam of copaiba, adulterated to the extent of 10 per cent. in one case with linseed oil, in the other with Gurgun balsam. It was thought probable that these admixtures would be at once detected when the oil of tartar should be added; but as such was not the case and an opinion on the subject could not be certainly formed before the lapse of several days, I will not further refer to them.

Each of the mixtures well shaken over night showed signs the next morning of depositing. It was not, however, until five days had elapsed that the operation seemed complete.

No. 1 had by that time deposited a whitish layer of bicarbonate; over that lay a thin stratum of viscid resin, on the surface of which floated numerous small needle-shaped crystals; above that came the clear balsam, through which could be seen numerous crystals attached to the sides of the bottle. Neither layer was emulsible, although the lower one showed some tendency that way.

No. 2 differed altogether from the preceding. There was indeed the stratum of bicarbonate, but it was less in volume; the viscid resin was absent; the space occupied in the other case by clear balsam was here cleanly divided into two equal parts, the upper portion containing a pale coloured essential oil not miscible with water, the lower portion a saponified balsam of the usual character, except that it had a little more colour.

No. 3 took a considerable time to settle down into three tolerably distinct layers, the lowest portion dark and dense, occupying about one-fourth of the space, the middle of darker colour still but less abundant, the upper fluid but both paler and thinner than the original Gurgun balsam. It was not emulsible.

A sixth mixture was now prepared with 2½ fluid ounces of Maranham balsam of copaiba and ½ fluid ounce of oil of tartar. This comported itself very differently from No. 1. It took much longer time to settle, and during the operation deposited neither crystals nor viscid resin. In fact the whole of the fluid portion was saponified and rendered readily emulsible.

It seems then that in order to prepare a perfectly miscible copaiba, the oil of tartar must be added in proportion to the acid resins present in the balsam and that experiment only can reveal what that proportion should be.

The peculiar behaviour of the Para balsam in contact with the oil of tartar points to the existence of radical difference between it and the Maranham variety. Whether it be anything more than this, that it contains a larger quantity of essential oil than the saponified resin is capable of dissolving, further experiment must decide. I think it must be something more, as I find the essential oil of the Para balsam is not miscible with the completely saponified Maranham balsam, or with the saponifiable

portion of the Para balsam, and it is in my opinion quite a moot point whether the essential oil of copaiba is in any proportion soluble in the saponified balsam. In fact I am inclined to regard the Maranham variety as a balsam, the Para variety as a balsam *plus* essential oil.

There are, I am aware, other varieties of balsam of copaiba known to commerce to which it might be interesting to apply this test, but it would be necessary to be quite sure about the identity and purity of the samples. Balsams of varied origin and also resinified essential oils might also be subjected to experiment.

For administration in capsules this miscible copaiba would seem to offer some advantages over the ordinary balsam. It would mix more evenly with the contents of the stomach and not float on the surface, causing pain and nausea. Moreover, the alkali present would be beneficial in the class of cases for which balsam of copaiba is usually administered. I have filled a few capsules of gelatine in order to see whether that material would be acted on injuriously by the saponified balsam. I will only add (*miseris succurrere disco*) that they are at the disposal of the members of the Conference, and that any report on their action that I may be favoured with shall be treated confidentially.

Mr. DRAPER asked the strength of the solution of carbonate of potassium.

Mr. GROVES said it was saturated; a fluid ounce contained 34 grains.

A vote of thanks was accorded to Mr. Groves.

The next paper read was on—

BAYCURU.

BY CHARLES SYMES, PH.D.

Baycuru or biacuru is the vernacular name given to a plant growing on the shores of Rio Grande. It imbeds itself more or less in the sand, a number of radical leaves rising above, and being some five to seven inches in length by one and a half or two inches in breadth. The flower resembles that of London Pride (*Saxifraga serratifolia*). The whole plant is sometimes covered by the sea for days and even weeks together, dependent on the direction of the wind, there being no tides in this locality. I am indebted to Mr. Thomas Hallawell for a specimen of the root, and also to Dr. Landell (both residents in Brazil) for reliable information as to its medicinal properties, and uses to which it is applied. I do not find mention of the plant in Chernoviz's 'Formulario ou Guia Medica,' which is practically the Pharmacopœia of Brazil, or in any botanical work at my command. Mr. Holmes has also kindly searched in the Pharmaceutical and British Museum libraries, but has found no satisfactory information concerning it. From a sample, however, with the foregoing description he believes it to be a *Statice*, probably *Statice Brasiliensis*, and although the Plumbaceæ are not generally inhabitants of tropical climates, some do exist there, and from the marked resemblance of the chemical and medicinal properties of these and baycuru it seems very probable that the above conclusion is correct. Further specimens are promised, including a flower, which will of course be more satisfactory for its identification.

The root is the part used medicinally, both fresh and dry. In the latter state the pieces are six or seven inches in length, from one-third to one inch in thickness, and tortuous in shape. The cortical portion is thin, of a dark chocolate colour, contrasting markedly with the central portion, which is of a flesh colour in some pieces, in others darker; the former has an acrid astringent, the latter a purely astringent taste, which suggest the probability that the acrid resin exists in the cortical portion only. The natives have an unlimited amount of faith in its virtues as an astringent and discutient remedy in all kinds of enlargements and glandular swellings, externally as a fomentation, and frequently as a vapour. It is also prescribed by the medical men, not as a specific, for Dr. Landell tells me he has sometimes found it to fail utterly, but as a rule it is reliable both externally and internally, and forms a valuable astringent gargle. The sample which arrived quite recently was only small, and therefore for want of both time and material, I have been unable to make as complete a chemical examination of its constituents as could have been wished; nevertheless I will submit the principal results obtained. The process followed was that recommended by M. Fleury for proximate organic analysis (*Journal de Pharmacie et de Chemie*, 1872), which with some modifications is that of Dr. G. C. Wittstein (*Anleitung zur chemischen Analyse von Pflanzen*).

The substance to be examined is dried to ascertain the amount of moisture present, powdered, and percolated to exhaustion with anhydrous ether, absolute alcohol, cold and hot water, dilute chlorhydric acid, and solution of potassa respectively, the residue being dried and weighed between each operation. Fresh portions are then distilled with water, dilute acid (preferably phosphoric), and milk of lime.

The ethereal solution first obtained might contain all substances soluble in that menstruum, such as fats, resin, wax, volatile oil, alkaloids, glucosides, etc.; it is concentrated and agitated with a little water, allowed to repose, and the different layers are examined for these substances.

The alcoholic percolate is evaporated to dryness, agitated with water, etc., and the other solutions are examined for such constituents as they may contain, starch, gum, dextrine, albumen, salts, sugar, etc., each being tested by the usual reagents for alkaloids, and although I obtained reactions, and even a minute quantity of crystals, which possessed the characteristics of an alkaloid, I cannot regard its existence as actually proved, and must await the arrival of further supplies for its verification. The activity of the root, partly, if not chiefly depends on tannin, of which it contains about 12·5 per cent., and its greenish coloured reaction with iron salts indicates that it belongs to that variety known as mimotannic acid. It also contains 1·3 per cent. of acrid pungent resin, soluble in ether and alcohol; a small quantity of volatile oil; a resinous substance, insoluble in ether, soluble in alcohol; proteic and pectinaceous bodies, starch, colouring matter, chloride and sulphate of sodium, potassium, a soluble silicate, and 14 per cent. moisture. The ash, 4·5 per cent., consists chiefly of soda and silica.

Pharmaceutically the infusion (℥ss to the pint) and proof spirit tincture (1 to 10) appear to be the best preparations, the dose of the former being one ounce, of the latter one to two drachms. An aqueous extract, of which it yields one-third its weight, contains all the astringent properties, but an alcoholic extract contains the acrid resin on which I presume its discutient properties more or less depend.

In conclusion, I would call attention to the apparatus recommended by M. Fleury for the exhaustion by ether and alcohol. It is not new, and is usually mentioned as an apparatus for continuous distillation; but this is really a misnomer, inasmuch as the percolate, and not the distillate is the object for which the process is conducted. I have here a rough sketch of it, my object being partly to point out that it is not altogether the most convenient form, but with some slight modifications it answers the purpose admirably, economising both time and menstruum. An apparatus differing somewhat in form, but of the same character, for manufacturing purposes is illustrated, described, and recommended in Dorvault's 'L'Officine,' p. 1265.

Mr. DRAPER said this paper certainly required no apology. If it had only contained a description of the beautiful process of Fleury, by which the results were obtained, it would not in the slightest degree matter what was the substance he had examined. Inasmuch as Dr. Symes had indicated a process, which was certainly pretty

generally known, but far too little carried out, he had rendered real service. That a systematic method of proximate organic analysis was very much wanted would be readily admitted. This method could not be made too well known, so that when any substance turned up with which they were not acquainted it might be thoroughly examined.

A vote of thanks was passed to Dr. Symes.

Parliamentary and Law Proceedings.

Poisoning by Oxalic Acid.

A inquest was held on Wednesday, August 21, at Luton, before the deputy coroner, Mr. J. P. Piper, concerning the death of a young woman named Game. It appeared from the evidence that the deceased was seen by a boy to put something in a cup, add water to it, stir it with a knife and drink it. She was shortly afterwards seized with vomiting and died before medical assistance arrived. Close by where she had been sitting at work was found an envelope, addressed to "Mr. C. Chambers, The Market Hill, Luton," containing some white powder.

Mr. G. H. Chambers, oilman and drysalter, Market Hill, recognized the envelope produced, as that of an invoice received by him, from the date, on Monday evening. It was his custom to cut open envelopes and put them on the counter for use as waste paper. On Monday he sold about 3 cwt. of oxalic acid, and 1½ to 2 cwt. on Tuesday. Did not recollect selling any in a paper like that, but it might be done by one of his men. Observed white grains in the paper. Saw in it an oxalic acid crystal. After tasting a grain he said it was undoubtedly that acid. They sold on an average 30 or 40 pennyworths a day. The envelope would hold a pennyworth. He always used a red label with "poison" printed on it.

Mr. J. J. Chambers, brother to the last witness, said he did not sell any acid in the envelope produced. When asked for a pennyworth of oxalic acid, they put it into any paper at hand suitable for the purpose. As a rule they labelled or wrote poison on the paper, but not invariably. Large parcels they did not generally label poison.

David Bodsworth, shopman at Mr. Chambers's, said he did not remember seeing the envelope before, and he did not sell any acid on Monday night or Tuesday morning, for he was mostly out of the shop. When selling oxalic acid in pennyworths, he always used a label marked "poison," but if the quantity were 14 lbs. or so, they might not put a label, but would write "oxalic acid."

Dr. S. T. Lewis, surgeon, said he was called to see the deceased about 20 minutes to 1 p.m., and went directly. He found her quite dead, lying on a bed dressed. Did not observe any vomit. The body was warm. He made an external examination. The pupils of the eyes were largely dilated. Did not observe traces of poison in the mouth. He noticed stains on her dress. Subsequently he made a *post-mortem* examination, in conjunction with Dr. Rankin. There were no external marks of violence The body was well nourished. The stomach was unusually red on both the front and posterior aspects, and the lining of it was completely charred. It contained four or five ounces of thick black fluid. All the other organs were healthy. The appearances of the stomach were such as would be caused by an irritant poison—he should hardly like to say oxalic acid. It would take from half an ounce to an ounce to account for her death so suddenly.

Dr. M. A. Rankin spoke to assisting at the *post-mortem*, and concurred in the evidence of Dr. Lewis. They had tried a solution of oxalic acid, obtained from Mr. Chambers, on her dress, and it made corresponding stains to those caused by the vomit of the deceased.

The coroner said that was all the evidence. It was clear that deceased had died from oxalic acid, and probably the jury would think the account the boy gave of what had happened was correct. He thought they would conclude from the evidence that the oxalic acid was purchased at Mr. Chambers's, and that though it was his rule to label it he did not invariably do so, and might not have done so on that occasion. There was nothing to point to the poison being administered by anybody but deceased herself. As to the state of her mind they had slight evidence that she was rather strange at times. If they thought anything further was likely to be found out by an adjournment they might do so, but he did not see much likelihood of it.

The jury discussed the matter in private, and arrived at a verdict that deceased committed suicide by poison, but that as to the state of her mind there was not sufficient evidence to show. They recommended that all packets of oxalic acid sold should be labelled "poison."—*Luton Times.*

Poisoning by Laudanum.

On Friday, August 30, Mr. W. Carter held an inquest at St. Thomas's Hospital, on the body of a gentleman who had been found lying in a state of coma in his bed, having it is supposed been poisoned, a bottle containing laudanum having been found in the room. The jury returned a verdict "That the deceased died from poisoning, but whether taken intentionally or not there was no evidence to show."

Poisoning by Bichromate of Potash.

On Friday, August 30, Mr. G. Collier held an inquiry at Dalston, as to the death of Mr. Carl Walberg, 49. Mr. Neal said that on Wednesday morning he was in Victoria Park, when he saw Mr. Walberg sitting on a seat apparently unconscious. By his side was a bottle containing poison. A doctor was then sent for, who ordered his removal to the Royal Hotel, where an emetic was administered and he became conscious, but refused to give his name and address. He was afterwards removed to the German Hospital, and died the same afternoon. A *post-mortem* examination had been made, and traces found of bichromate of potash, which had caused death. The jury returned a verdict of "Suicide while in a state of unsound mind."

The Sale of Soda Water.

Two more mineral water manufacturers have been charged at Manchester for selling soda water which was not of the nature of the article demanded. Samples had been analysed, and they were declared to be simply water with carbonic acid gas passed through it. The public analyst stated that soda water proper should contain, according to a rule in the Pharmacopœia, thirty grains of bicarbonate of soda to the pint, and be aerated, as the samples in question were, with carbonic acid gas. It was contended for the defence that the provisions of the Act had not been complied with, the defendants not having been informed that the article was for analysis by a public analyst. Both cases were adjourned for a week.

Dispensing Memoranda.

[117]. Tinct. Cardamomi.—I was surprised to find on taking up the Journal of last week a note bearing the above heading. In the first place, I think the fittest and most proper thing for A.P.S. to have done would have been to attempt an answer to the question I put to Mr. Stephens, respecting t. gentian. and rhei and pil. rhei, and afterwards to have given us his opinion on the subject.

As far as I can see, he has done nothing whatever towards clearing up the matter simply contradicting

statements. He has not advanced one single argument in favour of his theory. He commences with an anachronism: the P. L., 1851, contained no tr. card. simp., as a reference to Phillips's 'Translation,' which he quotes, and which book lies before me at the present time, will show. Thanks to A.P.S. for his information respecting the meaning of Οχθαί. It is now fifteen years since I was initiated in the mystery of the Greek language, but I never before knew the word to signify "heavy at heart." Perhaps if he lived in this quarter he would find out the real meaning of it. He states that he has not read the last few numbers of the Journal; I would advise him to see the remarks on the subject by the Editor, in the article entitled "The Month," June 29th. I will make no comment on his statement respecting my scornful reference to Beasley and other authorities, further than this, that I use them judiciously when occasion requires, without pinning my faith to any one in particular, judging discreetly. Again, men of the old school are not the only ones who omit the affix "co.," as witness the examples cited, which are from prescriptions of a young and rising medical practitioner in the West-End.

In conclusion, I will remark that the final paragraph of Mr. A.P.S. requires modification, and will meet with the treatment it deserves at the hands of those whose opinion is synonomous with that of

Οχθαί.

[*** We would remind our correspondents that this department of the Journal was established simply for the interchange of opinion upon subjects connected with the dispensing counter. The expression of such opinions in a censorious manner is not necessary or advisable, as it would import a personal element into the columns that would be very injurious, and out of place.—Ed. Ph. J.]

---

[137]. Aq. Glycyrrhizæ is usually prepared from the Guy's Hospital form, and consists of—

Ext. Glycyrrh.	¼ oz.
Aquæ	℥x

G. J. K.

---

[144]. When "Aqua Menthæ" is ordered, "Menth. Vir." should be used.

Inquirer.

---

[144]. Menth. vir. is always intended to be used when mentha is simply ordered, as the spearmint is commonly known to the profession as "mint."

Hamilton.

---

[145]. When "Cochlearia duo" occurs in a prescription for a mixture, it should be translated "two tablespoonfuls," unless such a dose would be extreme or poisonous.

Inquirer.

---

[145]. "Cochlearia duo" affixed to a prescription ought not to puzzle a dispenser as to whether tea, dessert, or tablespoonfuls are intended to be used in the measuring of the medicine. If it were a small mixture, say, a ℥ii or ℥iii, cochl. parv. would certainly be intended, but if it were a six or an eight ounce mixture, cochl. mag. would be intended. Such is the general manner of meeting such difficulties, but if rather undecided, should the mixture contain rather potent doses, the prescriber should, if possible, be communicated with.

Hamilton.

---

[147]. Liquor Secalis Ammon.—In answer to the question of "Sub Umbra Floresco," which appeared in last week's Journal, I beg to say that there is a preparation called liq. secalis ammon., which is (to the best of my knowledge) exclusively manufactured by Messrs. Richardson, chemists, Leicester, and which therefore should have been dispensed instead of ext. ergotæ liquid. and sp. ammon. co.

H. H.

[147]. Liq. seccalis ammon. is a preparation introduced by Mr. Colchester, and is recommended by Dr. Waller in his book on Midwifery, as a very effective combination. One drachm contains the virtues of half a drachm of the powder.

G. J. K.

---

[147]. Several manufacturing chemists make a specialty of liq. secalis ammon., and this specialty is intended when liq. secalis ammon. is ordered in a prescription. The liq. secalis ammon. which is best known amongst the profession, is that sent out by Messrs. Richardson and Co., Leicester.

Holloway. S. S.

---

[148]. "Sub Umbra Floresco" will find that the best excipient for the pills named in the last number of this Journal would be "hard soap."

Inquirer.

---

[148]. Three grains of glycerine of tragacanth.

G. J. K.

---

[148]. I find the following method to be very satisfactory.

Having mixed the ingredients well together, add 3 grains powdered tragacanth, and 1 small drop of glycerine and work them thoroughly. The above quantity is for 12 pills. This excipient answers far better than the ordinary tragacanth paste.

Southport. W. H. R.

---

[150]. Will some one kindly tell me how to dispense the following mixture so that it may be sent out perfectly clear?—

℞	Potass. Brom.	100 gr.
	„ Bicarb.	80 „
	Quinæ Disulph.	20 „
	Syrup. Zingib.	℥vi.
	Aquæ Menth. Pip.	ad ℥viij.

M. ft. mist.

A. V. O.

---

[151]. A prescription was brought to me to-day, can any of your readers oblige me with the formula for it?—

℞ Ung. Sulph. Perchlor. Co. (E. W.) ℥ss.

E. A. T.

---

[152]. Tinct. Quinæ Co.—If tinct. quinæ comp. is prescribed, as in annexed prescription, what should be dispensed, as there is no such preparation in the B.P.?

℞	Acid. Sulph. Dil.	℥iij
	Tinct. Quinæ Co.	℥ss
	Tinct Aurantii	ad ℥iij

M.

Veritas, M.P.S.

---

[153]. Lin. Æruginis.—Should old linimentum æruginis containing a deposit be shaken up before using for dispensing, or the clear liquor poured off?

[517]. ULTRAMARINE INK.—B. Y. would feel obliged by a receipt for Ultramarine Blue Ink that would stand washing on parchment.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Report of the Meeting of the Dover Chemists' Association.

Sir,—My attention has been called to a report of the quarterly meeting of the Dover Chemists' Association, appearing in the last issue of your Journal, in which I am stated, as chairman, to have said, that "the Pharmaceutical Society was hardly to blame for not undertaking the defence of Mr. Shepperley, since it appeared that he had made a practice of visiting, which I considered unjustifiable."

I am not responsible for the conversation having found its way into public print, nor had I the least idea that it would do so, more especially as the case alluded to is still *sub judice*; I therefore withdraw the assertion attributed to me that Mr. Shepperley had "made a practice of visiting;" and I would further say in explanation of the remarks I am reported to have made that having in mind the letters of Mr. Upton, the solicitor to the Society of Apothecaries, addressed to Mr. Flux on the 1st of January and the 5th of February last, and published in your Journal of the 9th of February, I felt the inference was, that Mr. Shepperley "visited," but had I known that my remarks, made in a conversational way, would have been published, I should have abstained from taking any part in the discussion.

Henry Peake.

1, *New Bridge, Dover, September* 5, 1878.

Physicians and Surgeons *versus* Chemists and Druggists.

Sir,—The vexed question of counter prescribing could be easily and quickly remedied and eventually settled in an amicable manner, satisfactory alike to the profession and the trade if medical men would give up the practice of supplying their patients with medicines from either closed or open surgeries, and if chemists and druggists would refrain, *in toto*, from giving advice or rendering medical or surgical aid to their customers upon any pretext or any circumstances whatever.

Chemists themselves are not so much to blame for the habit of prescribing and advising that prevails amongst them as are the public; persons of all grades, those of the upper and middle classes quite as much as those in the lower ranks of society, frequently consult their chemist in cases of minor illness, and I can assure my professional brethren that, in ninety-nine cases of a hundred, it is simply impossible for a chemist to refuse to prescribe for his customer without the risk of offending and perhaps losing him altogether as a customer for the future. Suppose a chemist refuse to prescribe, telling his would-be patient that it was not his province or duty to do so: in most cases the individual would go elsewhere, and a less conscientious chemist would do all he required for him, supplying medicines and prescribing, and probably in some cases doing him good. Now, what conclusion does such an one come to from such a proceeding? Why, that the first chemist he honoured with his patronage was not capable of prescribing or was too independent to do so; and furthermore, the slighted (in his own opinion) member of society makes up his mind never again to give the first chemist a chance of refusing to prescribe or anything else for him; thus the poor fellow, for conscience sake, loses what his more obliging and less scrupulous fellow trader gains. I feel persuaded that as long as medical men have any interest in the sale of medicines or rather in supplying their patients with medicines, either directly or indirectly, so long will a certain portion of the public, and that not a small one, make but a slight difference between the profession and the trade; in fact many poor people, especially in towns, call the chemist a doctor and regard him as a person both legally and practically able to treat their illnesses and complaints, and more particularly so in infantile ailments.

Another custom, too, prevails amongst the public, especially those of the wealthier classes, and an astonishing one it is, so much so that I am afraid if any medical man should read this he might think I was not adhering strictly to the truth; but I can assure such an one that it is no uncommon thing for persons, when they bring prescriptions to the chemist to be dispensed, to enter more or less into their ailments and detail symptoms in a minor degree, which some time previously they had given in full to their physician or surgeon, and at the same time ask the said chemist whether he thinks the prescription good for them, and some even go further and ask if the chemist thinks such and such a doctor understands their complaint. This one fact points out how many there are who believe the chemist to be more or less of a doctor, or in other words to possess some amount of medical knowledge, which, to a certain extent is true. I grant that chemists know full well the action of all drugs, but how scientifically to combine and prescribe the same is quite beyond their capacity; at any rate, it is beyond their functions, and moreover, they should never be tempted to exercise that function, though there are some who from study, observation, and innate skill, seem to be able to prescribe for trivial ailments better than most of their brethren; but all chemists do so alike, and as we know full well that minor ailments are but the preludes to more serious disease, and that the want of recognizing such by the prescribing chemist in the first instance has frequently led to disastrous consequences, it is foolish of the public themselves to consult the chemist, and much more so in the latter to attempt to do the doctor's work without having had the doctor's training. Such being the state of afiairs, how are the evils of counter prescribing to be done away with?

I can only see one solution for the difficulty, *i.e.*, for the profession to give up trading and for the trade to give up advising, and if general practitioners wrote their prescriptions only, I believe chemists could supply, at a fair profit, medicines at one-half their present prices. Let Act of Parliament forbid the physician or surgeon to supply medicines and the chemist to give advice, and I venture to predict happier times in store for both parties; each would occupy his proper station in life—the practitioner of medicine as the professional man, in the truest acceptation of the term, and the chemist as a tradesman. As they are now, the surgeon in general practice is neither one nor the other; he is a compound of professional and trader, in fact his legal status in society would be difficult to define.

In submitting the following tariff for medicines I exclude the price of bottles, and I take it for granted that prescriptions will not be copied and numbered as the present custom is, thus necessitating the patient sending his prescription to the chemist each time he or she may require the medicine renewed; that would save the chemist an immensity of time and trouble and a needless excess of labour to the dispenser. Each time the prescription was dispensed the date of such should be endorsed on the prescription by the dispenser together with his initials, and no bottle of medicine should be dispensed a third time without the prescription being endorsed "Rept." by the medical attendant, unless special instructions were given in writing to the contrary in the first instance. With the reduced price of medicines I should hope that practitioners of all grades would give the chemist a turn whenever they could, by prescribing the larger sized mixtures and avoid ordering expensive remedies in a concentrated form, thus keeping the chemist from reaping any or next to nothing of a profit for his labour and outlay, as is the custom with many physicians and surgeons of the present day. In addition to the prices marked below, an extra charge would have to be made in cases of doses of quinine of over one grain, when other costly drugs are prescribed, such charges not to exceed a small profit on the cost price of such drug or remedy prescribed in extra large doses.

When medical men prescribe only, another evil would be done away with; I allude to the "Advice Gratis" system, when it means, "Shan't let you off without a bottle of physic," for which payment is of course expected and readily obtained. Under the new *régime* if a doctor gave his advice gratis it would be so and nothing else, as he could not recoup himself, and I presume that few surgeons would see people for nothing; but what they could do would be this, give, say, one hour per day to see poorer patients whom they would charge one shilling, with or without a prescription. Once more, the charges below to be cash prices; if it is advisable to give credit, 5 or 10 per cent extra would be charged, according to circumstances, to pay the chemist for trouble in booking, making out accounts, and having to wait for his money. Then again, when one is fetched out of bed to dispense medicines extra would be charged for so

doing. The prescriber charges extra for night work; why should not the dispenser do so too? Cheap medicine tumblers, to sell for 3*d.* each and give a profit, could be manufactured to enable the practitioner to prescribe a four-ounce mixture of double strength for the very poor with safety, so that the patient could take one tablespoonful or less, and thus allowing such an one to get the medicine for eight pence instead of a shilling.

Charges for Mixtures, Gargles, and Lotions, per bottle.

Bottles 1*d.*	℥ss . . . 3*d.*	Bottles 2*d.*	℥x . . 1*s.* 4*d.*
	℥j . . . . 4*d.*		℥xij . . 1*s.* 8*d.*
	℥iss and ℥ij . 6*d.*		℥xvj . . 2*s.* 0*d.*
	℥iij and ℥iv . 8*d.*	Bottles 3*d.*	℥xx . . 2*s.* 6*d.*
Bottles 1½*d.*	℥vj . . . 10*d.*		℥xxx . . 3*s.* 6*d.*
	℥viij . . . 1*s.*		

Draughts, 3*d.*, 4*d.*, and 6*d.* each, 1*d.* extra for bottle.
Embrocations, 4*d.*, 6*d.*, and 9*d.* each ,,

One or two pills . . . 1*d.*	Ointments 2*d.* per oz. .
Ordinary powders . . 1*d.*	Special ointments and electuaries at about half the present prices, extra being charged for pot or jar.
Packets of six powders. 4*d.*	
Larger single powders for lotions and injections, 2*d.* and upwards each.	

If chemists could supply medicines at these rates and doctors see their patients at the same moderate remuneration, both profession, trade, and the public would understand each other better and the latter would know whom they had to repay for goods supplied and whom for brains.

Some may say this idea is too far-fetched, but I feel confident that the above scheme may in course of time (with alterations I grant) be brought into play, and should only a hint as to how to remedy the present disordered state of affairs existing between the profession and the trade be arrived at from a perusal of this paper, I shall be more than satisfied.

HENRY W. WILLIAMS, M.D.

168, *Fulham Road, S.W.*

WHAT IS "VIOLET POWDER?"

Sir,—Having a strong antipathy to shams, I should like to see some of the mist of obscurity that at present hangs over this useful and very respectable cosmetic dispelled by the light of truth and honesty. In order to answer the question at the head of this letter, it is necessary to carry the mind back about a century, or more perhaps; and to remind your readers that it was formerly the correct thing for the "fine old English gentleman" to use "hair powder" for his own hair, or for his peruke if he wore one. This hair powder was simply finely sifted starch powder. In process of time some individuals thought a little perfume would be an agreeable improvement, and hence arose "violet hair powder." Now, Sir, although I am not an octogenarian, I am old enough and I remember that in the days of my youth this article was labelled "violet hair powder." The use of hair powder having now become almost a matter of history, what so natural as that the word "hair" should be dropped out of the name, and its title become plain, simple violet powder? May I, therefore, be permitted by your courtesy to ask any of the brave defenders of terra alba, French chalk, and gypsum, whether any of these earthy compounds were ever used by any gentleman or peruquier for the purpose of hair powder? The answer to this question will be very interesting to the readers and especially to the writer.

Another question may interest some members of the trade and medical profession. Can it be possible that hydrated bisulphate of lime, with its angular prismatic crystals, can be as soft and soothing an application to inflamed and abraded surfaces as the round and smooth granules of wheat starch? Would kaolin or terra alba be as comforting and beneficial an application to inflamed or erysipelatous swellings as pure starch? If these questions can be answered in the affirmative then all objection to the use of these agents may cease.

My interest in this matter has led me to search all the literature in my possession, and my conviction is that "violet powder" should contain nothing but starch and a little perfume; all other substances when sold under this title are shams and delusions.

ROSICRUCIAN.

EXAMINATION DISCREPANCIES.

Sir,—In the Journal of August 24, two correspondents ask the question, why so many failures occur on the later examination days; one suggests that the examiners get tired and give more difficult questions, the other that those who are not well up in their subjects delay forwarding their names, and therefore are called up last, but I think the principal cause is that those candidates who, although they have failed, have nevertheless proved themselves efficient in most of the subjects, are, upon sending in their names at a subsequent examination, called up before those who have made a bad failure, or those who have never presented themselves before.

C. H.

2, *Clement's Inn Passage, W.C.*

"WHAT'S IN A NAME?"

Sir,—Newspaper invective seems to be quite on a par with newspaper "science" as set forth by J. H. P. in your last issue. A few weeks ago it was made public that Madame Rachel had given to a certain lady a lead lotion (in reality perfectly harmless) for application to the skin. This was bad enough, according to the journalists, but the robbery and deceit she practised, could not, it seems, be sufficiently condemned in writing without recourse to some thesaurus of English (un-English!) words and phrases. Accordingly, in one single article, in the *D. T.*, of April 12, 1878, "Madame" received the following appellations:—

"Criminal of advanced years," "wretched old woman," "incorrigible cheat," "fraudulent quacksalver," "most astute old women," "the harridan," marvellous charlatan," "inveterate impostor," "crafty old woman," "female Katterfelto," "artful tempter," "terrible old witch," "brazen beldame," "old daughter of the horseleech," "unconscionable crone," "incorrigible harpy," "hardened and dangerous offender."

Can we wonder at such writers, who, of a truth, seem to be "inebriated with the exuberance of their own verbosity," talking of "the burning acid that in contact with the alkaloid base of imperfect understanding causes effervescence and ebullition of the seething atoms of socialistic communism?"

F. G.—The publication of the address was due to an oversight. As regards the authorship of the letter and the motive with which it was written, we have good reason to believe that you are in error.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Chipperfield, Cottrill, Smith, Ekin, Payne, Barton, Reynolds, Jackson, Hawthorne, Laurie, Gerrard, Stables, Masson, Allen, Tichborne, Postans, Thresh, Griffin, Spes, Veritas, B.P.

NOTES ON AN ABNORMAL SPECIMEN OF GLYCERINUM ACIDI TANNICI.

BY GEORGE MASSON, PH.C.

During the early part of May in the present year a sample of the above was met with possessing some unusual characteristics, a few notes on which may be of some interest. Attention was drawn to the subject by the circumstance of a mixture which had been made with this and distilled water becoming opaque after standing a quarter of an hour and in half an hour opaque and gelatinous. The appearance of the glycerole presented no unusual features, and when first mixed the solution, but for a faint pinkish tint, was all that could be desired. No perceptible difference was observable whether distilled or tap water was employed for dilution, decomposition appearing to occur in either case with equal facility and completeness. The attention of the writer being otherwise occupied, no further observations were made until the second week in August, when on attempting to renew the preceding experiments some difficulty was experienced, the solution, made precisely as in the previous case, showing but little inclination to decompose even after the lapse of a few days. Various assignable causes suggested themselves as explanatory, each of which in turn received careful attention; ultimately, however, it was found that the altered behaviour of the liquid was entirely due to the change of temperature which had occurred since the time of the previous experiment, the temperature during the second week in May probably being less and certainly not having exceeded 64° F., whilst at the period referred to it had attained 72° F.* That this supposition was correct the following experiment amply demonstrated:—A solution having been prepared as in the previous instances, consisting of glyc. acidi tannici, 1 part, aq. destill. 15 parts, it was divided into two portions, half being allowed to remain at the ordinary temperature and the remainder transferred to a beaker of thin glass containing a thermometer. The temperature of this latter was then slowly reduced to 64° F. and so maintained for about two hours. At the end of the first half hour the solution had become gelatinous, acquiring a consistency about equal to thin mucilage, only lumpy, and before the expiration of an hour it had completely broken down, presenting an appearance in every respect similar to that obtained at the ordinary temperature during the earlier observations. It might reasonably have been expected that the solution so decomposed would redissolve the precipitate when it had regained the temperature of the surrounding atmosphere; in fact, that it would become like that portion which had been set aside and continued unchanged. Such, however, was found not to be the case; on the contrary, decomposition when once set up appeared to go on to a given stage, for on filtering and again exposing the clear filtrate to a temperature some degrees lower no further change could be induced. It was observed that on the formation of the precipitate the mixture quite lost its gummy consistency and became fluid. On heating a portion of the opaque solution it readily dissolved the precipitate and became clear, but on cooling again resumed its former condition. Between the first and second series of experiments, however, there was this appreciable difference, viz., that whilst in the former the vessel containing the cooled solution could be inverted without disturbing its contents, in the latter, although otherwise similar, the mixture remained liquid. A solution of the former strength having been freshly prepared, different portions were successively treated with NH_4HS, $Ba2NO_3$, $(NH_4)_2C_2O_4$, H_2O, in every case with negative results. A little of the solution was now diluted with twice its bulk of distilled water, and a second solution of corresponding strength prepared, made with some recently manufactured glycerole. To each a drop of a 4 per cent. solution of $AgNO_3$ was added, with the result that in the former case decomposition ensued with a much greater rapidity and vigour. The gelatinous precipitate having been removed from the decomposed solution, it was freely washed on a filter with distilled water and afterwards subjected to microscopical examination; it was then found to be amorphous. Subsequently it was dried at a heat of about 190° F. and weighed, the product representing nearly one-fifth of the tannin present in the original solution. The colour of the moist precipitate was greyish-white; this on drying changed to a lightish brown. Of the dried precipitate 0·5 gram was dissolved by the aid of heat in 250 c.c. of distilled water and 50 c.c. of the solution carefully titrated with standard gelatine, the strength of which had been previously ascertained. It was then found that the quantity of gelatine required to effect complete decomposition exactly represented 0·1 gram of tannin, *i.e.*, the weight of the dried precipitate present in the 50 c.c. of liquid under examination. This experiment was repeated for confirmation. A few grains of the substance were next dissolved in a sufficient volume of ether and the solution filtered to remove a trace of extraneous impurity; it was then exposed for spontaneous evaporation. On drying, the residue had acquired the yellowish colour of ordinary tannin; its solution, however, still displayed the increased power of reducing a solution of argentic nitrate which has been previously described. Lastly, a small quantity incinerated in a platinum dish left no residue. A full consideration of the foregoing leads irresistibly to the conclusion that the proximate cause of decomposition in the mixture was oxidation of the tannin contained in the glycerole employed, and that the precipitate itself was nothing but that substance thrown out of solution in consequence of having by this means been rendered partially insoluble. When or how this change was produced it is difficult to determine, and unfortunately the age of the sample is involved in some obscurity. I have some reason, however, to believe that it is old, and should such be the case it would doubtless go far towards furnishing a key to the whole matter. Whether such is the true explanation or not, the importance of keeping this and the sister preparation of gallic acid in bottles well closed will be sufficiently obvious to require more than a passing remark.

* According to the Royal Observatory tables the mean daily increase for the relative period during August was 7·6° F.

THE PARIS EXHIBITION.

(*Continued from page* 184.)

Chemical Preparations: Alkaloids, Salts, etc.

Many of the bodies that belong to this class are, in virtue of their crystalline form and brilliant colours, so favourable to the purposes of exhibition

that it is not surprising to find that they form a very prominent feature in some of the most handsome of the exhibitions of chemical and pharmaceutical products. It is true that in one or two cases very interesting series of bodies are shown in a fashion not at all likely to attract to them the attention they deserve, but in most cases, and especially in the French court, the finer chemicals are shown in such perfection, profusion and beauty of arrangement as to become attractive even to the most untechnical eye. The large and handsome case of chemical products exhibited by Messrs. Billault and Billaudot, of Paris, for instance, is quite a masterpiece of effective arrangement, whilst the substances shown are many of them so rare and beautiful that no chemist visiting the Champ de Mars should miss seeing them. The bed of the case is covered with crystallized bismuth, the splendid iridescence of which demonstrates that the secret of preparing this form has not become a lost art, as has been reported. Grouped above this are a large number of beautifully manufactured chemicals, among which may be mentioned crystallized glucose, crystallized dambonite or caoutchouc sugar, and crystallized mannite; leucine from albumen, tyrosine from fibroine, and alanine from fibroine in white crystalline flakes. Then there is a specimen of erythrite, or erythromannite, in transparent crystals, sparkling like so many diamonds, and another in crystals nearly as large as a man's fist; also sublimed alizarine in needles nearly an inch long, and sublimed indigotine in fine crystals, resembling those of permanganate of potash. Sulphate of cadmium appears in wonderfully perfect large white rhombic prisms, and is accompanied by some very fine iodide of cadmium; silicon is also there in steel-grey crystals. But one of the most striking features in the case is a group of platinocyanides, not only because of their beautiful appearance, but for the interesting illustration they afford of the polymorphism of these compounds. Thus the yttrium platinocyanide is in dichroic red and green crystals; whilst the potassium platinocyanide forms crystals of a rich copper-bronze colour, to which the double platinocyanide of potassium and sodium affords a vivid contrast, its crystals being of bright yellow with a purplish tinge.

Another very interesting case, and more closely associated with pharmacy, is that of M. C. Hoffmann, of Paris. It contains specimens of eserine and its sulphate, menispermine, elaterine, kamaline as a brown powder, and paracotoin. Cicutine and nicotine, two liquid alkaloids similar in colour, stand side by side. Atropine and digitalin are shown in globular crystalline masses. Two large white cylinders, each nearly two feet in diameter, represent caffeine, and above these there is a large sample of morphia hydrochlorate, which is supplemented by specimens of meconin, thebaine, codeine, and a very fine specimen of white crystallized hyoscyamine. Œnanthylic ether is shown as a green and as a white liquid. There is also in this case a good collection of the rarer metals. The whole is surmounted by a splendid specimen of phthalic acid, which must excite the admiration of every observer. It consists of long white lamellar crystals, at least a foot long, that droop gracefully over the edge of the vessel in which they are contained. Phthalic acid is a derivative from coal tar, and has been prepared industrially since 1865, but not to a very great extent. It has, however, assumed importance during the past year, in consequence of its application in the preparation of the beautiful new fluorescent coal tar colours, eosine, aureosine, fluorescine, etc., which are the products of the reaction of phthalic acid upon tetrabromated resorcin. Phthalic acid itself is prepared by the slow oxidation, effected by nitric acid at the heat of a water-bath, of a mixture of tetrachloride of naphthaline α and tetrachloride of chloronaphthaline, yielded by the action of potassium chloride and hydrochloric acid upon naphthaline. The tetrachloride α is transformed into phthalic acid, whilst the tetrachloride of chloronaphthalene is converted into chlorinated naphthoquinone, $C_{10}H_4Cl_{12}O_2$. From the complex mass the phthalic acid is extracted by treatment with boiling water.

It may be also mentioned here that M. Hoffmann has been compelled by want of space to divide his collection and that a very remarkable series of physiological products obtained from the urine, blood, and other animal secretions are to be found in Group V., class 45, among the non-alimentary agricultural products.

Two other cases worthy of special mention are those of the Pharmacie Centrale (M. Dorvault, director) and of Messrs. Adrian and Co. In the former, which is perhaps rather too crowded, there is a large glass jar containing probably nearly a hundredweight of fine crystals of strychnine. It contains further a large globe of chloral hydrate, a dish of racemic acid, and some fine looking herapathite, atropine, igazurine (from St. Ignatius's bean), emetine, nitrate of pilocarpine, quinine salts, benzoate of ammonia, and also some good specimens of lithium and cobalt, the latter in a cake about three-and-a-half inches in diameter. In the case of Messrs. Adrian there is a dish of crystallized digitalin, about nine inches in diameter; also crystallized daturine, atropine, and other alkaloids and their salts.

Crystallized digitalin is also exhibited by M. Nativelle, who was the first chemist that produced this body in the crystalline form. It will be remembered that when crystallized digitalin was first obtained by direct treatment of the plant by M. Nativelle,* it was affirmed by him that the crystalline constituent of the plant was rejected with the residue in the processes previously practised. M. Blaquart, however, the present representative of the house of Homolle and Quevenne, which has long been engaged in the manufacture, has found that Nativelle's statement is not correct, for that it is possible to crystallize the digitalin of the Codex, and this he now demonstrates by exhibiting a specimen of that preparation in the crystalline state, and one in course of transformation from the amorphous to the crystalline form, radiating feathery crystals being quite perceptible on the sides of the containing vessel. M. Blaquart appears therefore inclined to think that the difference between the Codex preparation and crystallized digitalin is merely one of isomerism; but it must not be forgotten that experiments have shown that there is a vast difference between the two in physiological and therapeutic action.

Some good crystals of atropine and its salts, of daturine and the hydrobromate of concine, are to be seen in the case of M. Moreaux, of Ainzy-le-Chateau. Close by, in the case of Messrs. Montreuil Frères, of Clichy-la-Garenne is an original calabash of curare, together with a specimen of curarine, and also some

* See *Pharm. Journ.* [3], vol. iii., p. 865.

wonderfully fine crystals of iodide of cadmium, filling a dish 9 inches in diameter. M. Gigon, of Paris, shows specimens of narceine and a syrup prepared from it.

The case of Messrs. De Laire and Co., of Paris, claims attention by a direct appeal to the sense of smell. It contains samples of vanillin obtained from vanilla, lying side by side with its rival prepared synthetically according to Tiemann's process from coniferin,* specimens of which, in the crude state and purified, are also shown. Messrs. De Laire also illustrate the practical application of artificial vanillin in making such preparations as "sucre" and "dragées à la vanilline." Of course there was no opportunity given of tasting these specimens, but it may be mentioned that in a recent communication, received from Messrs. Haas and Rosenfeld, manufacturers of essential oils and flavouring essences, in Gaya, Moravia, they state that experiments have led them to the conclusion that although artificial vanillin may possibly find an application in the manufacture of perfumery, it is perfectly useless in the flavouring of liqueurs, etc.

In the French court there are also some very fine exhibits of the cinchona alkaloids and their salts. Messrs. Armet de Lisle and Co., of Paris, who on the strength of having had Pelletier, Delondre, and Levaillant as their predecessors, have adopted the trade sign of "Sulfate de quinine des trois cachets," show a large number of good specimens. The consumption of cinchona bark by this firm at its manufactory, established in 1829 at Nogent-sur-Marne, is stated to amount annually to about 1,000,000 kilograms, or nearly 1000 tons. The quantity of quinine sulphate produced for home use every year is about 2000 kilograms, and for exportation about 10,000 kilograms. In this case the specimens are as a rule of considerable size (the sulphate of quinine, for instance, weighing probably three or four pounds), and are contained in large vases. Among them are quinine (the alkaloid) and its sulphate, bisulphate, hydrobromate, valerianate, and hydrochlorate, cinchonine (crystallized), and its sulphate and hydrochlorate, and the sulphates of quinidine and cinchonidine. M. Taillandier, of Argenteuil, also has a case devoted to the cinchona alkaloids and salts. Another good show is that of Messrs. Dubosc and Co., of Paris, which includes the lactate of quinine as a white crystalline crust, the salicylate as a powder and the valerianate, together with various salts of cinchonine and cinchonidine. Here also is quinoidine in the form of a black cake, divided into squares like chocolate. Crude quinium from Loxa bark is shown by M. Perret, of Paris, in brown soap-like tablets, while the "quinium Labarraque," a preparation of amorphous quinine, occurs in the case of M. Limousin. In the Dutch department a preparation consisting of the mixed alkaloids of *Cinchona succirubra* is shown by Messrs. Mouton and Sons, of the Hague, under the name of "chinetum de Dr. de Vrij."

Reference to the cinchona alkaloids would not be complete without mentioning the extensive series of compounds exhibited in the Italian department by the Fabricia Lombarda di Prodotti Chimici, of Milan. Besides the more familar salts of quinine there are the anisate, antimoniate, arseniate, benzoate, dithionate, ferrocyanhydrate, phloretate, meta- and oxybenzoate, salicylate, tartrate, and valerianate prepared with valerianic acid from five different sources. In addition there are various methyl, ethyl, and phenol compounds, and a bibromated hydrochlorate of quinine. The salts of cinchonidine, cinchonine and quinidine are also fully represented.

It will be seen from the foregoing that the display of definite principles of vegetable origin fully sustains the reputation of the French chemical manufacturers. In the absence of German competitors, through an unfortunate misunderstanding, their only serious rivals are the manufacturers of this country. In fact, the more important exhibits of these substances from other countries have already been mentioned, if we except an exhibit including jervia and ammoniacal glycyrrhizin from Messrs. Miller and Rittenhouse, of Philadelphia, United States, and one from Messrs. Hance, of the same city, showing hydrochlorate of berberine, and a collection of the resinous "eclectic" remedies in use in that country, such as gelsemin, caulophyllin, myricin, leptandrin, geranin, frazerin, etc.

Turning to the British court, however, some of the cases containing substances in this class will be found of a high order and very interesting, though in some instances they cannot be said to enjoy much factitious advantage from the manner in which the articles are displayed. This may be fairly said of the case of Messrs. Macfarlan and Co., of Edinburgh, in which are exhibited a series of specimens, principally illustrating the educts of opium and their products of decomposition. There are no less than ninety specimens, which comprise the principal opium alkaloids with their salts and derivatives. The collection is specially interesting to the chemist as showing the progress made within the last few years in obtaining new compounds from the opium bases, by which much light has been thrown on the constitution of these bodies. A large specimen of morphia is surrounded by basins containing the hydrochloride, hydriodide, hydrobromide, sulphate, nitrate, meconate, acetate, and tartrate. The codeine is in large well-defined crystals, and the salts exhibited are the muriate, sulphate and acetate. Narcotine and narceine with their salts form good specimens, showing beautiful crystalline arrangement. The other alkaloids are thebaine, papaverine, oxynarcotine and hydrocotarnine, which are shown in the crystalline form. Among the derivatives of morphia the one of most general interest is the powerful emetic, apomorphia, formed by the action of hydrochloric acid or chloride of zinc on morphia. The facility with which morphia and codeine assume polymeric modifications is well illustrated by specimens of the hydrochlorides of trimorphia and tetramorphia, dicodeia, tricodeia, and tetracodeia. The acetyl, butyryl and benzoyl substitution products of morphia and codeine are shown, in which the acid radicle takes the place of hydrogen in the base. It is narcotine, however, which of all the opium bases gives rise to the greatest number of derivatives. Perhaps the most noteworthy of these are opianic acid and the base cotarnine, produced by the oxidation of narcotine. From opianic acid vanillin has been obtained by Dr. Wright, while cotarnine, by the action of nascent hydrogen, is converted into hydrocotarnine. Opianic acid, again, when heated with excess of potash, splits up into meconin and hemipinic acid. Dimethyl-nor-narcotine, methyl-nor-narcotine and nor-narcotine are formed from narcotine by the elimination of methyl, ordinary

* *Pharm. Journ.* [3], vol. iv., p. 996.

narcotine having the composition of tri-methyl-nor-narcotine. Meconic acid (with which the bases are at least partly combined in the opium) is interesting as a tribasic acid, from which a bibasic and a monobasic acid are formed by the removal first of one molecule and then of a second molecule of carbonic anhydride, the resultants being named comenic and pyromeconic acid respectively. Meconin is obtained directly from opium, but is likewise formed from opianic acid as before mentioned, and also from narcotine immediately by the action of water. Of all the products above described, and many others, good specimens are displayed. The other exhibits in this case are—samples of pure chloroform of which the firm, as is well known, are extensive makers; acetic acid, which was discovered in opium by Mr. Brown,* and lactic acid, which was obtained from willow bark, by Mr. Dott;† beberia and its hydrochloride, with the well-known B. P. sulphate, and lastly a fine sample of salicin will also attract attention.

From the same city, Edinburgh, Messrs. T. and H. Smith send a collection of chemical products derived from opium and other vegetable substances, nearly, if not quite equal in interest and having the advantage of being well displayed. It includes morphia in large white crystals, and its hydrochlorate, sulphate and bimeconate; hydrochlorate of apomorphine; a fine crystallization of codeine, weighing eight or ten pounds; narceine, narcotine, papaverine and its hydrochlorate, meconin, thebaine, a crystalline mass of thebaine hydrochlorate weighing about twenty pounds, and meconic acid. Then there are several bodies shown with which the name of Messrs. T. and H. Smith is associated as discoverers. First in order of the opium educts stands thebolactic acid, discovered in 1861. Cryptopine was discovered three years later, and of this alkaloid more than a pound is shown, although it occurs in opium in the proportion of only about 0·01 per cent.; its hydrochlorate, which from strong aqueous solutions forms transparent gelatinous crystals, is also exhibited. These are accompanied by gnoscopine and meconoisine, the two alkaloids which have been lately described for the first time in this Journal.‡ Aloin, which Messrs. Smith consider to be the purgative principle of aloes, and which was first isolated by them in 1851, also occurs in the case, together with nitrate of furfurine (an artificial alkaloid), strychnine and its salts, caffeine, santonin, salicin, and some fine crystals of monobromated camphor. The opium products are appropriately accompanied by specimens of Smyrna, Persian, Egyptian and Chinese opium.

Mr. A. W. Gerrard, of London, also exhibits in this department compounds towards the history of which he has contributed, in crystalline specimens of the nitrate, phosphate and hydrochlorate of pilocarpine. He also shows some amorphous looking, but really crystalline masses of chryosphanic acid; the bromides of conia, quinine and strychnine, and other alkaloids; monobromated camphor in crystals 2½ inches long; gelseminic acid, thymol, and the three varieties of aloin (barbaloin, socaloin and nataloin). In the same case, which bears the name of Messrs. Morson, is a specimen of capsaicin, the active principle of cayenne pepper, in snow-white crystals, exhibited by its discoverer Mr. Thresh, of Buxton, who has promised to present this, the first specimen shown in public, to the museum of the Pharmaceutical Society.

Valerianic acid and several of its compounds, such as the valeriantes of iron, zinc, ammonium, potassium and amyl, are well illustrated by Messrs. Foster and Gregory, of London, who also show specimens of the hypophosphites, large specimens of binitrobenzine and other coal derivatives. In one of the best displayed cases in the section, Messrs. Burgoyne, Burbidges and Co., exhibit a collection of "pure chemicals for research, analytical purposes, photography and the arts;" and among other things chrysophanic acid and the salicylates of quinine, ammonia, potash, soda and lithia. Messrs. Southall and Barclay also exhibit a good looking collection of chemicals said to be specially prepared with regard to purity for the purposes of analysis and research. Another fine lot of chemicals, especially of the iodides and bromides and mercurial and antimony compounds, is that of Messrs. Atkinson and Co., of London. This case contains as well a handsome specimen of cinnabar and a bell of camphor weighing upwards of twenty pounds. Also, but in class 46, the house of Raspail illustrates camphor, which is so closely associated with its reputation, by several fine bells and in the granular and pulverulent forms. Refined camphor is also shown by M. Roques, of Paris, together with the subliming dishes used in its preparation. Some fine camphor is exhibited in the Austrian court from the works of Herr Rossler, of Aussig-on-the-Elbe, in Bohemia. In this manufactory, which is the only camphor refinery in Austro-Hungary, crude camphor from Japan is principally used, which is brought up the Elbe from Rotterdam.

Different varieties of chloral,—methylic, amylic, and ethylic,—are to be observed in the case of Messrs. Rigaud and Dusart, of Paris. The ethylic chloral has been made a specialty by this house, under the name of "Leconte's alcoholate of chloral," and it is claimed that it offers many advantages over the ordinary chloral hydrate. Metachloral, which is a nonhygroscopic isomeric modification of ordinary chloral obtained by treating it with strong sulphuric acid,* and propylate of chloral, are shown by M. Torchon, of Paris; the former is said to have been employed with good results in the place of iodoform, whilst it is free from the disgusting odour of that compound. The antiseptic properties of chloral hydrate are amusingly illustrated in M. Torchon's case by a rat and a cock which were killed and mummified in 1871 by the injection of a 10 per cent. solution. Xylol, the hydrocarbon which a few years since attracted temporary attention as an alleged remedy for small pox, is to be seen here also, together with some of its homologues.

Considering the important position in contemporary medicine that has been attained by salicylic acid and its compounds, they hardly appear so frequently in the present exhibition as might be expected. The only exhibit noticed in the French court is that of Messrs. Schlumberger and Cerckel. This includes salicylic acid, amorphous, crystallized and sublimed, sodium salicylate in powder and crystallized and also prepared in wafers, and the salicylates of potassium, ammonium, zinc, magnesium, lithium, quinine, morphine, copper and lead. The salicylate of zinc is used in the preparation of an

* *Pharm. Journ.* [3], vol. vii., p. 246.
† *Pharm. Journ.* [3], vol. viii., p. 221.
‡ *Pharm. Journ.* [3], vol. viii., p. 981, and vol. ix., p. 82.

* *Pharm. Journ.* [3], vol. iv., p. 684.

astringent injection, and the salicylate of lithium is said to be useful in gout and calcareous affections of the bladder. A salicylated starch powder is also recommended as a substitute for ordinary violet powder. The allied paraoxybenzoic acid, and cresotinic acid, are shown by this firm. There is also an exhibit of salicylic acid in the Belgian court from Ghent, and salicylated wool is shown by Messrs. Savory and Moore, of London, and a salicylated preparation of charpie by the Schaffhausen bandage factory.

Of carbolic acid the best specimens are to be found in the British court; though there is one otherwise fine specimen in the French court, but its surface has become reddened by a coating of rosolic acid. In the case of Messrs. Bowdler and Bickerdike, of Church, near Accrington, the specimens are quite colourless and very fine. One large specie jar contains about a quarter of a hundredweight of pure carbolic acid, or "absolute phenol" as it is designated by this firm, in the granular form. The fact of its being in this form is claimed to be a guarantee of its purity, on the ground that although phenol itself is not deliquescent,* the presence of a small quantity of cresol would, through the avidity with which it absorbs water, cause the whole mass to become damp too rapidly to allow of it being reduced to powder. Besides the convenience of the granular form it is free from the inconvenience of cracking the bottle upon change of temperature which sometimes attends the solid glacial acid. Professor Lister has expressed an opinion that the "absolute phenol" is less irritating than the ordinary qualities; nevertheless the firm appears to somewhat ignore this dictum by preparing a second quality, with the special name of "medical carbolic acid," which may be fairly presumed to contain some cresylic acid. A still cheaper commercial quality is shown, which is used in manufacturing the coloured derivatives, such as picric acid and rosolic acid (aurin), and also salicylic acid. Sulphocarbolic acid is shown in pure crystals from alcohol, and the sulphocarbolate of zinc, crystallized from water. To these may be added two large cylinders of commercial cresol. In the case of Messrs Lowe and Co., of Manchester, there is another well displayed collection of carbolic acid and its derivations, naphthaline and its tetrachloride, and other products from coal tar.

Close by these is a very interesting case belonging to Mr. J. B. Readman, of Glasgow, in which the stages in the manufacture of citric acid are illustrated, beginning with the crude juice and the citrate of lime and ending with the finished product. The manufacture of sodium phosphate is similarly illustrated. The crude material used by the firm for preparing this salt is a native phosphate of alumina. This, after being furnaced with the proper proportion of soda ash of high strength, is lixiviated, and to the alkaline sodium phosphate thus produced, phosphoric acid is added in sufficient quantity to convert the basic into the ordinary neutral phosphate. The liquor is then boiled down to crystallization and the product purified by recrystallization. The firm also exhibits the stannate and sulphite of sodium and phosphorus. The phosphates of lime and of iron, and syrups, wines, pastilles, etc., prepared from them are exhibited in several cases. M. Chassaing, Guénon and Co., of Paris, show specimens of the soluble calcium triphospate described by M. Falières in 1875.*

In the case of Messrs. Poulene and Wittman, of Paris, are some long narrow flat transparent scales, labelled "crême tartre paillettes;" also very handsome crystals of potassium permanganate, some nearly as big as the little finger, various lactates and formates, monobromated camphor and fine sodium nitroprussiate and potassium fluotitanate.

Many other substances that are used in pharmacy, such as iodine, some of the alkaline salts, glycerine, etc., might be included under this head, but they will be more conveniently dealt with under "Chemical Manufactures."

But this section must not be concluded without mention of the iron preparations, as they are of considerable interest. Ferrum redactum, which was first introduced by M. Quevenne, under the name of "fer réduit," is shown by his successor, M. Blaquart, of Paris, as an exceedingly light powder of a magnificent slate-grey colour. Besides these important external characteristics of colour and impalpability, evidence is given of its possession of another, that of freedom from sulphur. This is ingeniously done by means of a small apparatus, consisting of two flasks connected by a tube. In one the reduced iron has been treated with hydrochloric acid,—and, by the way, apparently completely dissolved by it,—in the other is a solution of lead acetate which has not been in the least darkened by the action of the evolved hydrogen. In several respects therefore this product seems to mark a considerable advance. Dragées and pastilles of Quevenne's iron are also shown.

Another iron preparation which, introduced as a specialty by a French house under the name of "fer Bravais," has won such wide favour that there is at least a probability of it some day acquiring Pharmacopœial honours, is dialysed iron. This is shown by M. Bravais, of Paris, together with syrups, pills and lozenges, prepared from it. The house of Rigaud and Dusart exhibit the dialysed iron of Lebaigue, who it is claimed was the first in France to introduce this preparation to the notice of medical men; in their case, too, are very fine scales of phosphate of iron prepared by Levas. Dialysed iron is also exhibited by Messrs. Wyeth, of Philadelphia.

The case of M. Jolly, of Paris, is one that reflects honour on pharmacy, the pamphlets and products it contains furnishing evidence of that combination of systematic scientific physiological and pharmaceutical work which, unfortunately it must be owned, is more frequently done by the continental than the British pharmacist. The products exposed will be best explained by a brief *résumé* of the pamphlets by which they are accompanied.

In a memoir presented to the Academy of Sciences, entiled 'Recherches sur la constitution chimique des globules sanguins,' M. Jolly claims to have demonstrated by analysis that iron exists in the blood globules in the state of tribasic phosphate. In a second memoir, after attributing the varying results obtained by different chemists in the analysis of blood to the defective method of calcination, which should be carried on in closed vessels at as low a temperature as possible, he states that iron does not, as is generally affirmed, form an integral part of the colouring matter of blood, and this he now demonstrates by exhibiting a chloroform solution of the

* See a paper by Mr. Bickerdike in the *Pharmaceutical Journal* [3], vol. v., p. 661.

* *Pharm. Journ.* [3], vol. vi., p. 882.

hematic pigment, free from iron. In a later memoir he indicates a process for extracting the phosphate of iron from blood, and among the exhibits is a quantity of phosphate of iron obtained from bullocks' blood by this method. During his investigation M. Jolly came to the conclusion that phosphate of sodium has a physiological importance approaching that of phosphate of iron, and in a preparation now exhibited under the name of "Fer hématique Michel" he has sought to imitate the supposed combination. It consists of a mixture of equal parts of tri-metallic phosphate of iron and phosphate of sodium dissolved in an alkaline (sodic) liquid. In two other pamphlets M. Jolly gives the inferences he has drawn from some investigations he has made into the physiological history of phosphate of lime. He is of opinion that (1) the phosphate of lime eliminated is nearly entirely an "intra-vesical product of formation"; (2) that phosphate of lime, administered under whatever form (whether as simple phosphate, biphosphate, lactophosphate, or chlorhydrophosphate), is only absorbed in extremely small quantities; and (3) that the organism forms its phosphate of lime from all quarters. Further, he considers that the pyrophosphates cannot be considered to be phosphates from a physiological point of view, and that they are neither assimilable nor reconstituant. Besides the preparations mentioned, M. Jolly exhibits the blue phosphate of iron (ferroso-ferric phosphate), the green phosphate, and the white phosphate (ferric phosphate).

Messrs. Desnoix and Co., of Paris, exhibit some specimens of hematosine and a cross weighing 1·25 grams made of iron obtained from blood. According to a memorandum lying in the case, 100 grams of hematosine when incinerated yield 10·75 grams of ash; according to Boussingault, the percentage composition of this ash is Fe_2O_3 84·121—equal to Fe 58·884—and phosphoric acid, 13·51.

Preparations of a saccharate of iron are exhibited by M. Coquet, of Paris, whilst Herr Kral, of Olmutz in Moravia, exhibits specimens of metallic saccharates and liquid metallic soaps. Finally, a series of alkaloidal oleates, intended as substitutes for ointments and liniments, are to be seen in the case of Messrs. Savory and Moore.

(To be continued.)

MORPHIA REACTIONS.*

BY DAVID LINDO.

During the analysis of a complex mixture it was noticed that the aqueous solution exhibited an intense green colour. This solution was found to contain ammonia and copper salts with organic matter, which proved to be morphia. I have not seen this colour reaction mentioned before, and as it might sometimes prove useful as a confirmatory test for morphia, I have endeavoured to ascertain the conditions most favourable to its development. These appear to be as follows:—

Dissolve one part crystallized sulphate of copper in ten parts of water; add solution of ammonia cautiously and with active stirring until the precipitate is just dissolved.

To ascertain if this solution is fit for the intended purpose, dissolve two grains muriate morphia in one ounce of distilled water: place some of this in a test tube, add a few drops of the test fluid, and shake the vessel slightly. If a precipitate or permanent turbidity is observed, the test fluid requires a little more ammonia, which should be added in small quantity at a time, and the mixture well shaken after each addition, as a notable excess prevents the test from acting. Adding ammonia to the morphia mixture that is being tested to rectify deficiency in the test fluid will not be found to answer.

When a few drops of a properly prepared test fluid are added to a neutral solution of morphia salt of the above strength, and the tube is slightly shaken, no cloudiness will be observed, but the fluid assumes a magnificent emerald-green colour either immediately or after a short time. Weaker solutions may require to be gently heated, but the mixture must not be boiled or the reaction is destroyed, suboxide of copper being precipitated.

Of a stronger solution of morphia salt one drop is sufficient to give a good reaction on a white porcelain surface. The test fluid should be applied on a slender glass rod, and stirred in as soon as it is taken from the bottle.

If the copper solution has not been added in sufficient quantity the colour obtained will be yellowish green. Large excess of the reagent destroys the reaction, and so does the addition of a few drops of liquor ammonia.

Phenol is the only other colourless organic compound I have met with as yet which affords a similar colour reaction with the test, but further experience on this point is desirable.

* From the *Chemical News*, August, 9, 1878.

QUININE TANNATES.*

BY J. JOBST.

Contrary to what is usually stated, tannic acid does not combine with quinine to form a quinine tannate of definite composition, but a compound in which tannic acid may vary indefinitely, and to an extent depending on the method of preparation.

The following analyses of several so-called quinine tannates show that the alkaloid varies not only in quantity, but also in character.

No. 1 had been prepared by precipitating a neutral solution of quinine hydrochloride with a solution of ammonium tannate.

Nos. 6 and 7, which the author obtained by adding tannic acid to an acid solution of quinine sulphate, show that quinine tannates can contain tannic acid in very large proportion.

	Water at 120°.	Quinine.	Quinidine.	Cinchonidine.	Cinchonine.	Total alkaloid.
	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.
No. 1...	7·2	31·37	—	—	—	31·37
No. 2...	9·7	22·72	—	—	—	22·72
No. 3...	9·1	4·46	11·97	7·33	—	23·76
No. 4...	9·8	4·93	2·43	13·10	3·35	23·82
No. 5...	10·2	6·23	trace	23·80	trace	27·03
No. 6...	10·7	10·00	—	—	—	10·00
No. 7...	11·4	7·40	—	—	—	7·40

The amount of quinine in No. 1 corresponds nearly with that required by the formula,

$$C_{20}H_{24}N_2O_2.2C_{14}H_{10}O_9 + 4H_2O,$$

and in No. 2 with $C_{20}H_{24}N_5O_2,3C_{14}H_{10}O_9 + 8H_2O$.

The bitter taste in these tannates decreases as the proportion of tannic acid in them is increased.

The author gives the following method as the best to follow in the analysis of quinine tannate.

One gram is finely powdered, and mixed with milk of lime, then dried, and the dried residue exhausted with chloroform. The residue, after distilling off the chloroform, is dried at 120°, and weighed; then dissolved in dilute sulphuric acid, and tested with ether and ammonia in the usual manner, in order to ascertain whether the alkaloid is pure quinine or contains any alkaloid insoluble in ether, such as quinidine, cinchonidine, or cinchonine.

THE WEIGHTS AND MEASURES ACT.

THE Order in Council relating to apothecaries' weights, which appeared in the *London Gazette* on the 30th inst., and was brought under the notice of the Council at its last meeting,* by the Secretary, brings to a close a passage in the history of legislation affecting weights and measures in this country, which threatened at one time to be productive of considerable inconvenience to pharmacists.

It will be remembered that in a Bill introduced early in the past session, with the object of including in one Act all the existing laws upon the subject of weights and measures, there was a special permission for the use of apothecaries' weight in the retail sale of drugs, although standards for the drachm, scruple, fluid ounce, fluid drachm, and minim were not included in the schedule to the Bill as being in existence. During the passage of the Bill through the House of Lords the inconsistency was removed by striking out the permission to use apothecaries' weights. Had the Bill passed in this form, since it made it penal to be in possession of weights or measures not of the denomination of some Board of Trade standard, the position of pharmacists called upon to dispense according to the weights and measures even of the British Pharmacopœia would have been an awkward one. Attention was at once called to this fact in these columns, and shortly afterwards a deputation from the Council of the Pharmaceutical Society of Great Britain waited upon Mr. FARRER, at the office of the Board of Trade, and laid the subject before him. The result of that interview was that the permission to use apothecaries' weight when selling drugs by retail was restored to the Bill, and the fluid ounce, fluid drachm, and minim, and multiples of them were included in the schedule of Board of Trade Standards appended to it. The Bill passed in this form, and has now become law, and suitable specimens of the above measures having been prepared and verified in the Standards Department, they were by the Order in Council referred to declared to be legal secondary standards of capacity. The new standards thus created are those for 1, 2, 3, 4, 5, 10, 20, and 30 minims; 1, 2, 3, and 4 fluid drachms. Standards for 1, 2, 3, and 4 fluid ounces had been previously prepared.

* See before, p. 190.

It will perhaps be as well to remind our readers that the above measures, being thus legalized, now come within the terms of the Act as to inspection of weights, measures, and scales, and that authorized inspectors may at all reasonable times demand to inspect them, and compare them with the local standards.

THE REPORT OF THE NOXIOUS VAPOURS COMMISSION.

Two years ago, in compliance with the terms of an address presented to Her Majesty by the House of Lords, a Royal Commission was appointed to inquire into the working and management of works from which sulphurous, ammoniacal and other noxious vapours are given off and as to the effect produced by such vapours upon animal and vegetable life; also to report upon the means to be adopted for the prevention of injury by them. The issue of the Commission raised some little demur, on the ground that sufficient time had not yet elapsed since the passing of the Alkali Act, 1874, to allow of its effects being properly estimated; but the wisdom of the step is quite established by a report that has just appeared, which shows that great as has been the improvement effected under the influence of past legislation, the problem of carrying on manufactures of vast importance with a minimum tax upon the health and wealth of the community has not yet been completely solved, and extends to many industries not affected by the present state of the law.

It is satisfactory to learn, however, that the effects of legislation on this subject up to the present time "appear, by general consent, to have been on the "whole beneficial to the public, and not unduly "onerous to the manufacturer;" nevertheless, through the multiplication of works in some districts the benefit realized takes the form of prevention of increased injury rather than absolute improvement in the atmosphere.

As in former similar inquiries, many of the statements of the witnesses are contradictory and irreconcilable. Thus Dr. B. W. RICHARDSON, speaking of Halton and Norton, which lie south-east of Widnes, says the destruction caused by the vapours from the alkali works is very complete and extends over several miles. Sir RICHARD BROOK says that his woods and park, situated about three miles from Widnes and Runcorn, are hourly deteriorating; many thousands of trees have had to be cut down, and about three thousand at the time of his giving evidence were only fit for the axe, while the bark from the oak trees had become, in consequence of the action of the vapours; utterly unsaleable and valueless. The growth of grass is suddenly arrested by a visitation of vapour, cattle grazing on such grass become "hide-bound" or die, and when cut for hay horses will not eat it, and no person knowing where it comes from will buy it. Corn, potatoes, and even turnips, "the most gas-proof" of all crops, suffer in a like manner, and hedges refuse to grow

At St. Helens and Tyneside, where "copper smoke" comes into play, the complaint is similar. On an estate of one thousand acres, at Hebburn, once famous for its wheat and fruit, the fruit trees are entirely destroyed, the hedges have disappeared; there is not a single thorn on the estate, nor a bush of gorse or bramble, and the only plants that survive in the struggle for existence are the elder and the deadly nightshade. At Whitehouse, even the wire-rope fences that have been put up as the natural fences failed have been eaten through in the course of two or three years.

As to the effect produced upon the health of human beings the medical witnesses were agreed that the vapours from alkali works have a tendency to produce or aggravate chest affections. It would appear probable, too, that the sulphuretted hydrogen acts as a depressant, and retards recovery from illness. But the workmen engaged in the manufactories do not seem to suffer much, and Dr. RICHARDSON has been "unable to discover any "evidence which showed to him proof of special "deterioration of health" in the neighbourhood of Widnes and St. Helens. The theory, however, that epidemics are prevented by the presence of these vapours must, in his opinion, be abandoned. If this be correct it would narrow the question very much to one in which damage to property only is principally involved.

On the other hand, the case of the manufacturers may be stated thus. They argue that there has been a great improvement in the vegetation since the passing of the Act of 1863, and especially since that of 1874, and that most, if not all, the damage complained of,—except so far as it is due to the acid vapour resulting from the burning of coal or to vapours from works not coming within the operation of these Acts,—was done before 1875. As a proof it is stated that the value of land in the vicinity of the works is rising, and instances are quoted of gardens flourishing almost under their shadow. Damage caused by accidental escapes is admitted, but this, it is urged, could generally be traced to its source and compensation enforced. It is also alleged that a principal source of complaint is the sulphuretted hydrogen evolved through the contact of acid liquors with the waste heaps from alkali works, which is not injurious to vegetation and, moreover, might be prevented.

Taking the evidence on both sides into consideration, the Commissioners appear to be of opinion that the Act of 1874 is working well, but that the time has now arrived for enforcing it more stringently and with an increased staff of capable inspectors. Turning their attention to other sources of noxious vapours than those coming within the operation of the Alkali Acts, they have listened to complaints as to damage done by the "dry" process of copper smelting, coke ovens, glass works, salt works, cement, chemical manure, sulphate of ammonia, and other manufactures. Although looking upon them as a prolific source of damage, they do not seem to think the time ripe for further legislation beyond the extension of the power of the inspectors so as to visit some of these places and to report upon what they see, presumably with a view to obtaining information that will be useful at some future time; whilst they also think the Local Government Board should have the power in certain cases to fix a standard of escape (subject to the approval of Parliament) and to require the adoption of the best practicable means for preventing escapes. These recommendations extend to chemical manure works, sulphate of ammonia works, tar distilleries, gas liquor works, coke ovens, arsenic works, cement works, cobalt works, dry copper works, wet copper works (so far as regards the operations which correspond to those of dry copper works), galvanizing works, glass works, lead works, nickel works, potteries where the salt-glazing process is carried on, salt works, spelter works, tin plate works, and works for the manufacture of dyes from coal tar derivatives.

The Commissioners also recommend that the escape from works under the Alkali Acts of more than half a grain of nitrogen or one grain of sulphur, in the form of any of their acids (except of sulphuric acid produced from sulphur gases that otherwise would escape uncondensed), in one cubic foot of exit gas at 60° F., and under a barometric pressure of 30 inches, shall be made an offence under the Act. Also, that the deposit of alkali waste so as to be a nuisance, or permitting acid drainage to come into contact with alkali waste or the drainage from alkali waste, should be made an offence. Lastly, they recommend that all works in which sulphuric acid is manufactured for sale or use should be brought within the action of the Alkali Acts.

POSTPONEMENT OF THE MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

IN accordance with the expectation expressed in a recent number, the annual meeting of the above Association has been postponed until some time in November. In the notice to this effect, a copy of which has been courteously forwarded to us, it is stated that the Executive Committee is still of opinion that at the time originally fixed for the meeting Atlanta would have been as safe a place as could have been selected; but it was feared that the spread of yellow fever in the Mississippi Valley would keep many pharmacists at their posts in the infected districts, and also tend to diminish the number of visitors from the Northern States.

EXEMPTION FROM JURY SERVICE.

WE are reminded by the Registrar that the lists of persons liable to serve as jurymen during the year 1879 are now being exhibited at the doors of all churches and places of public worship. It would therefore be advisable that all pharmaceutical chemists who desire to secure exemption from jury service should ascertain by examination whether their names have been erroneously included, so that any such mistakes may be discovered before the time has past during which their removal may be effected.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 197.)

The next paper read was entitled :—

Authoritative Formulæ for Non-Official Preparations.

BY F. BADEN BENGER, F.C.S.

Some recent proceedings instituted against chemists for selling as "violet powder" a compound consisting mainly of hydrated calcium sulphate, have resulted in convictions, it being held by the magistrates that starch, or a mixture of starch and powdered orris root. can alone be legally termed violet powder. It was not proved that calcium sulphate is in any way injurious as an absorbent application to the infantine cuticle; indeed, what most persons would consider very conclusive evidence to the contrary was freely adduced. Nevertheless newspaper accounts of the prosecutions were headed, "poisonous violet powder," and the defendants, men in a highly respectable position, have doubtless suffered some pecuniary loss, and much annoyance and vexation, through failing to recognize as authoritative, formulæ published in Gray's 'Supplement' and similar works. Had it been contended that violet powder should consist of powdered violets we need not have been surprised.

The question which has presented itself to my mind as one of possible interest to this Conference is, then, to what extent are we, as pharmacists, at liberty to apply our acquired knowledge and accumulated experience to the improved manufacture of such articles as violet powder, cold cream, and the like? Are we bound to follow blindly for ever Gray, Cooley, and other "early English" authorities, never questioning the wisdom of the ancients; or is the other alternative to apply to a magistrate for a formula when it is not to be found in the British Pharmacopœia?

As violet powder forms the text of this communication, a more special reference to the now authoritative formula may be desirable. Is starch the most suitable substance that can be selected as the basis of an absorbent application to moist and irritable surfaces? I believe not. It is occasionally acid, frequently alkaline to begin with, and invariably and rapidly becomes acid when moistened and maintained at the temperature of the human body. I find by experiment that pure starch moistened with water and maintained at a temperature of 98° Fah. for four hours, reddened litmus paper; in eight hours it was distinctly sour to the taste, and a few hours later had acquired an offensive odour. It is probable that moist violet powder is often left in contact with the skins of children for a much longer period than this, and decomposition would be further advanced. Such a compound of decomposing vegetable matter can scarcely be regarded as soothing. It is within my knowledge that for many years a violet powder has been largely manufactured and sold, consisting entirely of French chalk, silicate of magnesia, in impalpable powder, and this substance I regard as the best basis for a dusting powder. It is quite as absorbent as starch, is unalterable by combined heat and moisture, and possesses exactly the physical properties required in an application intended to absorb moisture, reduce friction, and prevent abrasions. In my own experience this powder has very satisfactorily replaced its ancient prototype, and a recent attempt (made from prudential motives on my part) to return to the formula of my forefathers has met with serious opposition, nursing mothers insisting on being supplied with the silicate, even if shorn of its familar floral designation.

The Conference has already at its Liverpool meeting expressed a very decided opinion against the employment of misnomers by those who introduce popular remedies, and there is not a word to be said in its favour. Amongst perfumery stock we still have, however, "bear's greases," "taurus marrows," "marrow oils," "lime juice and glycerine," etc., etc. Public analysts will no doubt thank me for directing their attention to these. If we turn to the so-called patent medicines, I fear that in many cases the ingredients indicated by the labels as at least prominent constituents, would be the last the makers would think of employing. But there is another class of preparations in common use, the nomenclature of which though often incorrect does not seriously mislead the public, and the alteration of which either by assimilating the composition to the name or by the adoption of new designations, would be attended by inconvenience to both buyers and sellers.

"Spirit of hartshorn" is not a spirit, nor is it now obtained from hartshorn.

"Essential salt of lemons" could hardly be obtained from that fruit by the most skilful chemist.

Ferric oxide is very commonly known as "carbonate of iron;" carbonate of soda as "soda." "Cold cream" is not a product of the dairy, nor does the manufacture of catgut ligatures any longer necessitate the destruction of the feline race.

It would be interesting to know what Mr. Erasmus Wilson thinks he is prescribing when he writes "Aqua Mellis." Gray gives the following formula--

"Aqua Mellis—Honey water for the hair. Honey 4 lbs.; very dry sand, 2 lbs. Put into a retort or body that will hold five times as much. Distil with a very gentle heat. A yellowish acid water, used to encourage the growth of the hair."

So far as I am aware the honey water of high-class pharmacy resembles this only in name, colour, and the use to which it is applied.

Many other instances might be cited, but enough has been said to illustrate what appears to me to be the somewhat difficult position in which pharmacists are placed with regard to the composition and nomenclature of some non-official preparations.

Mr. Tanner said he had always considered starch powder one of the worst thing that could be used as an application to the skin. It had been his practice to use French chalk, or silicate of magnesia, and with every satisfaction to his customers.

Professor Quinlan had listened to the paper with great pleasure, but he could not agree with the writer in his remarks with reference to the prosecutions for selling adulterated violet powder. He followed them in the *Times*, and as far as he could judge the adulteration frequently consisted of white arsenic. Starch was not the best application as a drying powder; starch and orris root was better; but the powder mentioned in the paper was the best of all. With regard to authoritative formulæ of all these things, it was a difficult thing to ask people to tell all the secrets of their business. There were a great many persons who put out patent medicines who would not like exactly to say what was in them. But would it not be well if when a thing was being sold a short analysis should be attached to it in order that people might see what they were getting? It would be a great advantage even in the case of cold cream to see on the label what it exactly contained.

Mr. Umney thought the last speaker had not followed the whole of the cases, as the one he referred to was not, properly speaking, an adulteration, but a mishap. There was arsenic present in the powder, unquestionably, but he had no hesitation in saying that the case was almost parallel to one he remembered some twenty years ago, when "daft" was being used at Bradford in making cheap peppermint lozenges, and arsenic was put in by mistake. That it was a pure accident there could be no question.

Professor Quinlan said he never meant to imply that it was anything but a pure misadventure. He believed the arsenic was put in by mistake for another mineral powder, terra alba. White arsenic, they all knew, was largely used in commerce, and he remembered at one time

seeing it lying about on the quay at Falmouth to the quantity of many tons.

Professor ATTFIELD said there had been several prosecutions for what had been termed adulterated violet powder. The one to which reference had just been made, in which arsenic by some mistake got mixed with starch, stood quite alone; but there had been others where the question of arsenic had not cropped up at all, and where the question had simply been, what was violet powder? and it had been held by some magistrates, curiously enough, that violet powder ought always to be starch. Mr. Benger was alluding to some prosecutions which had occurred in Manchester not in London.

Mr. GROVES said a respectable tradesman in Birmingham had also been fined 20*s*. for selling violet powder not made of starch. Mr. Benger had alluded to improper names being given to articles, and he might mention that in his neighbourhood a great nuisance was growing up by the public calling the compound generally known as citrate of magnesia simply "magnesia." It was bad enough to call it "citrate of magnesia" because it contained no magnesia and very little citric acid, but when it came to "magnesia" simply it was altogether too bad.

Dr. MACSWINEY took the liberty of saying that the point of most interest to a practical physician in connection with the discussion which had arisen, growing out of the prosecutions about violet powder, was that it would be most desirable if physicians could have a knowledge of the composition of proprietary remedies as they were called. It was within his personal knowledge that these proprietary remedies did not exercise by any means the same effect at all times when obtained from different sources. Violet powder was an example, and having himself to treat the diseases of children very frequently, he was bound to say he had been often alarmed at the apparent injuries effected by violet powder applied on the surface of the body. He was not an analytical chemist, but he had no doubt that the violet powder on those occasions contained some very irritating ingredient, and that showed how desirable it was that those like himself should know the actual composition of the powder so that they might use their own discretion in directing it to be applied or not. It was admitted that violet powder varied very much in its composition. They were all familiar with the nature of the prosecution which had recently taken place, but the point to which the writer of the paper under discussion alluded, of the arbitary decision of the magistrates might be regarded from a different point of view. What was the magistrate to do? He had to inquire of the persons best competent to give him an opinion as to what was understood in the trade by violet powder, and in that particular instance it was explained by a gentleman, whom he regarded as an expert, that violet powder should consist solely of a coloured or perfumed starch. Whether starch was or was not the best ingredient to use as a dusting powder for excoriated or irritated skin, was another question, but the magistrate was not to be supposed to know more about the matter than chemists and druggists knew, and there was evidently a difference of opinion amongst chemists as to what should be the constitution of violet powder. His own impression was strongly against the statement that a vegetable was inferior to a mineral dust to apply on these occasions. He was inclined to think that a vegetable dust, properly applied, was more likely to be beneficial and less likely to be irritating than a mineral one. Calcium sulphate was an irritant to the stomach, and consequently he thought it would be a dangerous substance in a particular class of delicate skins, to apply constantly, as they knew ladies were now in the habit of doing, when dusting their faces before going out. His desire, however, was to state his opinion that it would be for the benefit of medical practitioners if they knew the precise constitution of various remedies now subject to great discrepancy in composition. Magnesia or citrate of magnesia had been mentioned, and in conversation with Mr. Williams he had been told what, as a practical physician, he had no reason to expect would be the case, that the less magnesia the preparation contained the better it was. That was a very undesirable condition in any pharmaceutical preparation, that it should have a name which was calculated to mislead. He also wished to say, with great respect to pharmaceutical chemists, that he thought they were slightly travelling out of their domain in determining what was or what was not a desirable application to the interior or exterior of the body; that duty, he apprehended, appertained to the calling of the physician. It had been stated by the writer of the paper that such and such results might be expected to follow from the application of these powders, and he should wish to ask him how he derived his knowledge on the subject. Was it by mere theoretical reasoning, or was it from the practice of the medical art? Because in order to the writer having a knowledge of what was good for the exterior or interior of the body, merely high scientific acquirements and acquaintance with the chemical, pharmaceutical, or physical properties of bodies, were not sufficient; he would require to be a physician.

Professor ATTFIELD quite agreed with Dr. MacSwiney that it was not the province of chemists to interfere with questions of physiology. They were anxious to know from medical men what was the effect of these vegetable or mineral powders on the skin, and guide themselves accordingly. Perhaps Dr. MacSwiney would enlighten the meeting on this point.

Mr. HOLMES had heard that day for the first time that sulphate of lime had been always used as violet powder. He had been in the trade for twenty years, and always considered that what was known as violet powder was powdered starch, perfumed, and nothing else.

Professor TICHBORNE said the term violet powder probably arose from that fact of the original violet powder being a mixture of starch and orris root; at any rate, what was known for many years before as violet powder was starch, though latterly a great number of things had crept into the market. It was quite true that from a chemical point of view starch was liable to change, and a solution would become acid; but many of the better kinds of violet powder were chiefly formed of perfumed starch, with the addition of a little carbonate of magnesia which perfectly remedied this defect. As to the irritating effects of sulphate of calcium, that might be explained in this way. There were some sulphates of calcium which would unquestionably irritate mechanically; he had seen sulphate of lime crystallized in very fine crystals, and he could not imagine that it would be desirable to apply such a powder to an irritated surface. He would conclude by suggesting that violet powder was a preparation of sufficient importance to be introduced into the Pharmacopœia, or a powder to be used in its place, and he hoped in a future edition a formula would be introduced.

Mr. CHIPPERFIELD said things formed on theory were not always borne out by experiment. Mr. Benger according to his theory, had to a certain extent proved that violet powder made of starch would be rather injurious than otherwise. He had been perfectly astounded to learn from the different prosecutions that had taken place that anything but starch had ever been used. In all the situations he had ever held he never learned that anything else was used; and although Mr. Benger had apparently established that starch would be attended with injurious results because of its tendency to turn acid, he had never heard of any violet powder he had supplied having any injurious effect, though it was used for dusting babies, and ladies' faces. He should be sorry to see calcium sulphate introduced, and should hesitate very much about using French chalk. He believed whenever these things had been used, with very few exceptions, it was because they were cheaper than starch powder.

Mr. SIEBOLD agreed with Mr. Benger as to the suita-

bility of French chalk, and could see nothing objectionable in very finely powdered sulphate of lime. He also agreed with the statement that starch in a moist state at the temperature of the human body turned acid very soon, and it was at least possible, if not proved, that it might in that way irritate. But the question before them was not whether starch powder was irritating or not, but whether these mineral powders which had been objected to were really objectionable. They were not compelled to use starch, only compelled by law not to use mineral powders. Now he demanded proof that they had ever done harm. No doubt they might meet with medical men here and there who would say, "I can conceive that a mineral powder showing a crystalline formation under the microscope might possibly do harm." But what did that come to? It was merely a personal opinion or conjecture, entirely unsupported by actual observation, and was opposed to the positive knowledge which they had to the contrary. Several manufacturers had sold mineral powders for this purpose, and sold them at the rate of one ton per week for upwards of twenty years, and if such powders had been so used day after day in hundreds and thousands of families and there had never been any complaint, that was overwhelming evidence as compared with the personal impression of one or two or half a dozen medical men. It had been said that the original violet powder was a mixture of starch and orris root. All he knew about it was that the original violet powder was orris root powder pure and simple, and that it had long since been found out that orris root was not by any means suitable for a dusting powder. If they must have a vegetable powder lycopodium was a very good thing, and that was used in many parts of the continent. They had nothing to do with the origin of the term. If they found they could improve on a preparation, especially one not in the Pharmacopœia, they were entitled to make use of their knowledge; and it seemed very hard that chemists and druggists, with their life-long experience, should be taught by magistrates, who know nothing at all about the subject, what the composition of a toilet article ought to be. No doubt there was a certain excuse for them, because they relied to a great extent on the statements of public analysts; but the mere fact that a public analyst had obtained an appointment was not in all cases a sufficient guarantee that he knew his subject. He considered that chemists and druggists were a little to blame for some of the ridiculous decisions on the part of magistrates. They should take care by united action to put such pressure on the Local Government Board that no appointment of a public analyst under the Food and Drugs Act would be sanctioned unless it were proved that he had acquired a proper knowledge of drugs as well as of food. It became, in his opinion, the duty, not of individual chemists and druggists, but of local associations, to insist that men appointed under the Adulteration Act were not ignorant of the chemistry of drugs, as some unquestionably had proved to be. He was far from wishing to cast the slightest imputation on public analysts, as a body, knowing that many of them possessed in a high degree the knowledge and skill required for the efficient performance of their duties, but it could not be denied that in some instances honest traders had suffered great annoyance and loss of reputation through the blunders of incompetent analysts.

Mr. GREENISH said he had examined a great many of these powders, and it was impossible to look at them with a tolerably high power without being convinced that the angular character of the crystals must be irritating to tender surfaces as compared to granules of starch. He was quite satisfied on that point. Dr. MacSwiney had alluded to the ignorance of medical men on the composition of certain articles, but he considered they had the remedy in their own hands; they should not order any article for medical use the composition of which had not been published.

Mr. WILLIAMS wished to correct Dr. MacSwiney on one point. When speaking to him on the subject of citrate of magnesia he did not say that it was better without any magnesia, but simply that the public liked it better. With regard to violet powder, he had had no suspicion all his life that anything but starch and orris root was used until this case of arsenic poisoning had arisen. He then found to his great astonishment that he was perfectly ignorant of his business, or that portion of it, and that there were substances used which he was informed by some gentleman from Manchester were much superior to starch, but he could not see it at all. Hydrated sulphate of lime, or *terra alba*, the basis of the so-called violet powder now used, was not only crystalline but soluble, and if you took a dose of it it would act as a purgative. Now it appeared to him that what acted in the interior on the mucous membrane was probably irritable also, to say the least of it, on the exterior portion of the skin. He could not agree that violet powder ought to be anything but starch and orris root, and those who changed the violet powder to something else, although they made a large fortune by it, he thought took a responsibility in retaining the name for another preparation which was not justifiable.

Mr. LONG said that although there had been prosecutions in many parts of the country in reference to violet powder, the source from which the agitation arose was one and the same, but fortunately no other occurrence of the same kind had taken place. It was made by Mr. King, his object being undoubtedly to produce a cheap article, though no doubt the evil results were accidental. They were much obliged to Dr. MacSwiney for his remarks, and whilst maintaining their own independence they always paid great deference to what physicians said, but in such a matter as that they were not originating or devising anything for medicinal purposes, but were only competing with the barber. The barber made vast quantities of this violet powder, and, in fact, chemists really ought not to have anything to do with it. If physicians would only place confidence in pharmacists, and if they wanted to know what their patients had been purchasing, would simply come and ask, he was sure that any respectable tradesman would give the information.

Dr. SYMES said Mr. Benger's argument was that French chalk was superior to starch powder, but the discussion had gone entirely away from French chalk to sulphate of lime. It was by no means a new thing that violet powder did not consist of starch, for ten years ago a very old chemist, who had retired from business, advised him to use powdered French chalk, saying, if he did so once he would never use starch again. He introduced it at first very cautiously, and the first thing that struck him was that his violet powder was getting more like that of a celebrated maker, which fetched a much higher price. He then increased the quantity, when it became still more like this celebrated violet powder which fetched double the price paid for the ordinary article, and for the last few years he had used nothing but French chalk with as little perfume as possible. In some cases where irritation was produced he believed it arose from the large amount of essential oil used to perfume it. The gentleman he referred to told him he had been using French chalk for twenty-five years and that was ten years ago.

A vote of thanks was then passed to Mr. Benger.

The next paper read was entitled:—

SOLUTION OF IODOFORM AND IODOFORMED LINT.

BY G. A. KEYWORTH, F.C.S., HASTINGS.

When iodine tincture is shaken with a fragment of fused potash so as to remove the colour, the essential step in the preparation of iodoform, the characteristic odour of that substance appears. In this simple form the fluid possesses great energy as a therapeutic agent, more especially in the healing of indolent sores for which purpose iodoform is so highly valued by some medical practitioners. Iodine ointment of various strengths,

alone or combined with a small quantity of carbolic acid, has long been known to have great power in producing cicatrization and granulation with obstinate ulcers, sores and wounds. The odour of iodoform, which is to many persons very repulsive, may be readily concealed by the addition of eau de cologne or lavender water.

The alcoholic solution above described, when so treated, furnishes an elegant substitute for iodine tincture, with its dark colour, strong chlorine-like odour, and staining property. Lint soaked in this colourless perfumed liquid and allowed to dry, is a singularly useful application for various sores, promoting the healing process with much energy. Equal parts of this fluid and glycerine form a very useful combination for many purposes.

A vote of thanks was passed to Mr. Keyworth, and the Conference then adjourned.

Wednesday, August 14, 1878.

The Conference resumed this morning at 10·30 a.m., when the reading of papers was proceeded with. The first paper read was a

Note on an Improved Preparation of Ergot.

BY A. W. POSTANS, F.C.S.

It is only right to preface my remarks on this subject with a statement to the effect that the liquid extract I desire to bring before the Conference is what I have considered to be an improvement on the process given in the Pharmacopœia of the United States of America, and the resulting preparation is possessed of stability, activity, and good keeping power.

It is at once obvious that however highly esteemed by some medical men the freshly powdered ergot may be, yet a fluid extract, on which reliance can be placed, has such manifest advantages in convenience of exhibition, accuracy of dosage, etc., that to find one even equal to the freshly powdered ergot is a gain.

In the following observations I do not propose to analyse the different samples of ergot, although that is a most important starting point. I do not propose to suggest any new method for the preservation of ergot itself, nor to assert positively to what it owes its activity, and the general history of the drug, as well as its adulterations and occasional admixture with ergot of wheat, ergot of oat, and various other inferior ergots is so exhaustively dealt with in 'Pharmacographia' that I may fairly pass on; with the intimation, however, that I shall hope on a future occasion to give an account of the value of liquors obtained from ergot of oat and ergot of wheat.

The process I have adopted is as follows:

To 20 ounces of freshly powdered ergot packed in a percolator, the extremity of which had been closed, was added a mixture containing 10 ounces each of rectified spirit and glycerine, and 5 ounces of water; the whole was then allowed to macerate for a week, at the expiration of which time the percolation was proceeded with, and the subsequent displacement continued with distilled water until the drippings almost ceased to have any taste or colour. Eighteen ounces having been collected of the first liquid, the remainder was evaporated gently in a water-bath to 2 ounces, and then mixed with the previous quantity, so that 20 ounces of this fluid extract exactly represents 20 ounces of freshly powdered ergot; and I am told by several obstetricians of eminence that it is highly satisfactory.

In conclusion, I desire to point out that the main difference between the above process and the American consists in the addition, by the United States Pharmacopœia, of half an ounce of acetic acid to each 16 ounces of liquor, thus rendering, in my opinion, an otherwise good preparation nauseous and unpalatable, as well as presenting a difficulty as to the desirability and wisdom of introducing acid into the stomachs of patients. These are points which, at certain times, it is most necessary for the physician to consider and the pharmacist to determine.

Mr. Williams said he supposed this preparation contained the oil, as well as the other ingredients.

The President said he was glad to know that Mr. Stoddart was working rather closely on this subject, and would have prepared a paper for that meeting, but unfortunately the season was a little backward in the West, and he had not been able to obtain the ergot in good condition. Before their next meeting, however, he had no doubt he would have investigated the subject, and he would not therefore make any remarks on this paper.

Mr. Greenish remarked that this process of Mr. Postans was as nearly as possible that of the United States Pharmacopœia, and he should have liked to hear some scientific reason given for his slight deviation from that process. According to that, there was a small quantity of acetic acid added, and there was a reason given for this addition, the object being to prevent volatilization of the active principle while the process of evaporation was going on. He should like therefore to hear from Mr. Postans some equally valid reason for leaving the acetic acid out of the process. One of the latest treatises on ergot was that of Blumberg, which appeared in the Journal about a month ago, and the subject was treated in the most exhaustive manner. He stated most distinctly that he was able to obtain all the active principles merely by percolation with water, and that there was no necessity for using any other menstruum. From the researches of Dragendorff on this subject it would appear that great care was required in the introduction of spirit, because one of the active principles, sclerotic acid, was very liable to be thrown down by alcohol beyond a certain strength.

Mr. Umney thought he could see one disadvantage in this process. He imagined that alcohols, whether 56 o.p. or even in the more dilute form, would take up the fixed oil. The use of ether had for years been recognized, after a full discussion, to be a mistake, and Professor Redwood had acknowledged that it involved a waste both of time and money. He had manufactured fluid extract of ergot on a large scale by the use of water only. Water would not touch the fixed oil, but it would take up the whole of the active principle, and if a fluid extract thus prepared were preserved with the proper proportion of alcohol 56 o.p., there was no difficulty in keeping it in excellent condition.

Mr. Groves was rather surprised that the tincture of ergot was not more frequently used. It was a very simple preparation made with weak spirit. He believed it contained all the active principles; it was made entirely without heat, and seemed a better representative than any of those which required more manipulation. He knew it was active, because he supplied it constantly to a gentleman in his neighbourhood in large practice. With regard to the keeping of ergot he would make a suggestion. They all knew how prone it was to decay from atmospheric causes, the attacks of insects, mildew, etc., and that was no doubt due in great measure to its form as well as to its constitution. He would suggest that it should be ground and subjected to great pressure in a hydraulic press, so as to bring it into the form of cubes. By this means the fixed oil, which had no action, would be got rid of, and it would be less exposed to the attacks of insects, and might probably be preserved for many years. He had no means himself of trying the experiment, but he hoped some one who possessed a hydraulic press would do so. The pressure would break up the cells, and render it more easily exhaustible when powdered.

Mr. Gerrard said he had had some experience in the manufacture of the official preparation, and he should like to ask Mr. Postans what special advantage he claimed for this over the liquid extract of the Pharmacopœia. When a novelty of this kind was introduced it ought to possess some advantage over the preparations already in use. The B.P. preparation was very efficient, and the only fault was the use of ether, which was now generally omitted because practical pharmacists knew that it could be made equally well without. According to the official

formula also, water of a certain temperature was directed to be used, but he had pointed out in the Journal some time ago, that he could make a better liquid extract by using cold water, simply because water at a higher temderature decomposed the ergot and caused changes which might affect the activity of the extract.

Professor ATTFIELD said the pharmacy of ergot, like that of every drug, must be founded on their knowledge of its therapeutics, or of its chemistry, or on both. Mr. Postans said he founded his knowledge of the efficacy of this preparation on therapeutics, having placed it in the hands of those who found it active. Undoubtedly it was desirable that they should found their pharmacy of it on its chemistry, but having lately read the researches to which Mr. Greenish alluded, he was not convinced that they yet knew what the active principle or principles were; and therefore they were not yet in a position to depend on its chemistry for their treatment of it. He was satisfied, however, from the eminence of two or three of the men who were working at the subject, that in the course of two or three years the chemistry of ergot would be opened up, and they would then be able to found their pharmacy upon sounder knowledge than they now possessed.

Dr. SYMES thought Professor Attfield had scarcely answered Mr. Gerrard's question. He said that when a new preparation was introduced, it should be shown that it had some superiority over the one already existing. The mere fact that this preparation answered its purpose was no reason why it should replace that of the B.P. Both the liquid extract and the tincture, prepared according to the Pharmacopœia (with the omission of the ethereal extraction), were efficient preparations, and it did not strike him that this was any improvement, though possibly it might have advantages of its own.

Mr. BOILEAU asked if the age of the ergot had anything to do with the efficacy of the preparation. It was a most important article, especially to the obstetrician, and he had seen great difference in different specimens, some being almost inert, while others were very good. The young ergot was very different generally to that which had been kept for any length of time.

Mr. GREENISH said that whatever might be the active principle of ergot, it was admitted by every writer on the subject that the active principle could be extracted by water. With regard to the therapeutic efficacy of these preparations, ergot was given in nineteen cases out of twenty as a matter of course, and the confinement would take place quite naturally, and would have done so without any ergot being administered. It was in case of hæmorrhage afterwards that the real efficacy of the ergot was put to the test.

Mr. LONG said ergot was now being used largely in spitting of blood from the lungs.

Mr. POSTANS said he should have been disappointed if at such a meeting some gentleman had not shown that loyalty and conservation for official preparations which was indeed the natural order of pharmacists. The idea of bringing this forward was suggested to him by the "blue list" issued prior to the meeting at Plymouth, in which there was a line "Ergot, new preparation required." With regard to a hot water infusion, there could be no doubt that the active properties were taken up, but the difficulty with such a preparation was that it would not keep unless spirit was added. His experiments were not sufficiently conclusive to enable him to state whether the oil was taken up, although that was considered to be inert. It was believed that in the evaporation of the subsequent liquor, the heat used was more than the active principles of ergot would allow without producing some change, and therefore the acetic acid was added with a view to preservation by forming salts with the bases. His experience, however, had led him to the conclusion that this addition was unnecessary. His object was not to supersede the British Pharmacopœia preparation in any way, but he believed this process to be an improvement upon it.

The PRESIDENT said they were much obliged to Mr Postans for giving the results of his experience, for with Professor Attfield's authority for the opinion that the chemistry of the matter was still somewhat vague, all that could be done was to experiment empirically. There was no doubt that a large amount of the mystery which attended the chemistry of this subject consisted in the fact that ergot was not the same at all periods of its development. Up to that time all experiments had been made on the ergot obtained in the market, about which nothing was known as to its growth, condition of development or season of gathering; but on this point they must look for some information next year, because Mr. Stoddart was paying great attention to the individual granule, and was having them gathered in a period of development which he would be able to speak to positively when he came to experiment upon them.

The thanks of the Conference were accorded to Mr. Postans.

The next paper read was on:—

A COMPARISON OF THE STRENGTH OF SOME OF THE CINCHONA PREPARATIONS.

BY CHARLES EKIN.

(1). Two hundred and fifty grains of apparently a good sample of calisaya bark were reduced to a fine powder and mixed with milk of lime, made of 100 grains of dry slaked lime and 600 grains of water. This mixture was dried thoroughly at a low temperature (in the sun) and treated with 6000 grains of alcohol in successive portions after Dr. de Vrij's method (*Pharm. Journ.*, 3rd series, vol. iv., p. 241).

The alcoholic solution was slightly acidulated with sulphuric acid, filtered and the filter well washed. The greater part of the spirit was recovered by distillation and the residue poured into a capsule to which were added the spirit and the water with which the retort was subsequently washed. The capsule was heated on a water-batht ill all the spirit was expelled, and the remaining liquor after cooling was filtered and the filter and its contents washed repeatedly with water slightly acidulated with sulphuric acid until caustic soda ceased to produce any turbidity in the passing liquid. The greatest care was used in this and in the previous washing to guard against the slightest loss. The liquid was reduced in bulk on the water-bath, transferred to a stoppered bottle into which the washings of the capsule were also placed, rendered alkaline with ammonia, and agitated with sufficient chloroform in three successive portions. The chloroform solution was separated by a funnel and evaporated to dryness on a water-bath until it ceased to lose weight. The dry residue, which may be taken to represent the total alkaloids of the bark, weighed 4·9 grains or 1·96 per cent.

(2). Two and half ounces of tincture made from the same bark were slightly acidulated with sulphuric acid, evaporated to expel spirit, cooled, filtered, and the filter and its contents washed as in the bark assay with water, acidulated with sulphuric acid. The filtrate was transferred to a quart bottle, rendered alkaline by ammonia, and thoroughly shaken with a pint of chloroform in two successive portions. The chloroform solution was separated by a funnel, the bulk of it recovered by distillation and the residue with the chloroform washings of the retort evaporated to dryness, yielding 4·15 grains total alkaloids.

(3). Eight ounces of infusion of the same bark were concentrated and treated as No. 2, giving a residue of 2·3 grains.

(4). Ten ounces of decoction of the same bark, treated in the same way, gave 3·45 grains.

(5). One fluid drachm of fluid extract of the same bark, having a specific gravity of 1·1, gave 1·05 grains.

(6). One fluid drachm of Battley's liquor cinch. cord., taken from a bottle freshly opened for the purpose, and

equal according to the label to one ounce of the finest bark, after the same treatment gave 2·05 grains.

These results tabulated according to their percentages are as follows:—

	Total alkaloids.
100 grains of bark yield	1·96 grs.
500 min. tincture (made from 100 gr. bark) yield (About ℥ix.)	1·89 „
2000 min. infusion „ „ (About 4½ ounce.)	1·31 „
1600 min. decoction „ „ (About 3½ ounce.)	1·26 „
25 min. fluid extract „ „	0·47 „
13 min. Battley's liq. cinch. cord. (equal according to the label to 100 grains bark) yield .	0·46 „

The proof spirit tincture therefore nearly exhausts the bark. Boiling water, as in the case of the infusion and decoction, takes up about five-eighths of the alkaloids, and cold water, as in the case of the fluid extract, takes up, or at all events only retains, about one-fourth.

As manufacturers well know many yellow cinchona barks, even though rich in alkaloids, are not suitable for the preparation of the liquid extract. I therefore applied to one of the first West-End London houses, who kindly supplied me from their own stock with a suitable sample, from which they themselves prepared the liquid extract.

It will be seen the sample, provided Dr. de Vrij's method of assay entirely exhausts the bark, barely comes up to the Pharmacopœia standard, even if the total alkaloids consisted for the most part of quinine, which from their almost entire solubility in ether is not improbable.

The yield from the tincture seemed to me very high. I therefore after the tincture was made continued the exhaustion of the bark by percolation with proof spirit until colour and taste were almost entirely absent.

This last product yielded a residue equal to 0·23 grs. of alkaloids to 100 grains of bark, bringing up the total alkaloids to 2·12 or 0·16 in excess of the quantity obtained from the bark itself. This excess may be due to a small quantity of quinovin being dissolved by the chloroform.

The quantity of chloroform used to take up the alkaloids seems large, but no less a quantity would break up the gelatinous fluid first formed (and which was due probably to a large excess of quinovic acid), and so insure complete separation.

The bark yielding to all appearance an excellent preparation of liquid extract, I was curious to compare it with Battley's, hence my examination of the latter.

The results show that Battley's liquor, although by no means representing the finest bark in the proportion claimed, is twice the strength of the B.P. preparation. The latter, however, if made from a richer bark might have been richer in alkaloids, though judging from my own limited experience, I should say this by no means follows as a matter of course.

Exception may be taken to the residue from the chloroform solution being given as necessarily consisting entirely of alkaloids. I am fully alive to the doubts that may exist on this head. In this case, however, I am inclined to think the evidence is decidedly in favour of the alkaloids being as I have given them. At any rate an error would affect all the results alike and in the same proportion, and so not vitiate them for the purposes of comparison.

Before discussing Mr. Ekin's communication the following paper was also read:—

Assay of Cinchona.

BY JOHN BARKER SMITH.

Cinchona bark, cinchona preparations and alkaloids, and nearly all the important preparations of vegetable substances contained in our Pharmacopœia, may be estimated with the greatest facility and approximate accuracy by means of a weak solution of permanganate of potassium.

A stronger solution of permanganate may be made, which will keep several days, by adding one gram of permanganate to one hundred cubic centimetres of distilled water.

The solution used in the actual examination is made by diluting ten cubic centimetres of the stronger solution to a litre with water.

Fifty cubic centimetres of the dilute solution, acidulated with sulphuric acid, and corresponding to five milligrammes of potassium permanganate is the standard quantity invariably used. The preparation to be estimated should be diluted, regularly admitted from the burette, and the point of decolorization selected for the termination of the experiment.

Exhaustion of Bark and Estimation of the same.

(1). *Rectified Spirit Extraction.*—By careful percolation, after maceration, to ten parts, the bark is practically exhausted. Less than one per cent. of oxidizable matters (cinchotannic acid, alkaloid, etc.) in fact was found in the last quarter of the percolate to ten, and of this only a quarter was alkaloid.

Experiments.

Maceration and percolation to ten volumes, each quarter separately examined.

Percolates.	1st.	2nd.	3rd.	4th.
Percentage. Oxidizable Matters . .	14·0	3·5	1·5	·9
Percentage. Alkaloid . .	3·1	·8	·4	·2

Total oxidizable matters nearly 20 per cent., of which a quarter might be alkaloid.

The data for these experiments consist of twenty milligrammes being selected as the quantity both of alkaloid and other oxidizable matters in bark required to decolorize the standard quantity of permanganate solution.

Alcoholic tinctures of bark may be estimated by first diluting and verifying total oxidizable matters, and afterwards the alkaloids, by precipitating another portion of the tincture with lime, filtering when cold, diluting, and estimating as before.

As regards the official tincture of yellow bark, and those prepared by the same process with other commercial bark (red and East Indian), my experiments have indicated that they should, when submitted to this process, show a possible percentage of alkaloid in the preparation of ·6 or 3. for the bark used, and at least three times as much total oxidizable matters as of alkaloid.

I think an approximation may also be made to the quantities of cinchonine in such tinctures by suitable dilution. An example will best illustrate.

5 c.c. of a tincture of red bark, diluted to 100 c.c., form a solution, of which 20 c.c. decolorize the standard acid permanganate. Another portion of the tincture treated with acetate of lead and ammonia, and diluted with water to ten volumes, forms a solution, of which 28 c.c. decolorized before filtration, and 34 c.c. afterwards. Or when calculated, our tincture may be said to contain 2 per cent. of oxidizable matters, ·7 per cent. of alkaloid, of which one-fifth may be cinchonine.

So far as my experiments extend an approximation of the percentage of alkaloid in a bark may be rapidly made by first washing the powdered bark with ten volumes of a 1 per cent. caustic soda solution by percolation, and afterwards exhausting the bark by percolation with rectified spirit to twenty volumes. Estimating the tincture as before.

Experiments.

1. Gravimetric 2·7 per cent. impure alkaloid.
2. Permanganate 2·8 „ „

(2). *Cold Aqueous Extraction.*—Scarcely more than a fourth of total oxidizable matters extracted by twenty volumes of water, half the alkaloid also remaining in marc.

Experiments.

Maceration and percolation to twenty volumes, each quarter separately examined:—

Percolates.		1st.	2nd	3rd.	4th.
Percentage.	Oxidizable Matters. .	3·5	1·	·57	·36
	Alkaloid . .	2·4	·4	·3	—

The alkaloid in the first quarter was determined again by the lead and ammonia method, and was found 1·8 per cent.

(3). *Hot Aqueous Extraction.*—These experiments show that the official infusion will compare very favourably with decoction, and that both methods are effectual in extracting the greater part of the alkaloids. Lead seems better than lime as the precipitant when water is the menstruum.

Experiments.

	Percentage Results.		
	Oxidizable Matters.	Alkaloids.	
		Lime.	Lead.
Infusion, one hour, paper filtration .	8·7	4·7	2·7
„ two hours „ .	7·9	4·7	2·5
Decoction, official	7·7	—	2·4
„ „ strained hot . . .	8·7	4·7	- -
„ repetition with marc . .	4·3	1·5	—
„ official, acidulated . . .	11·2	—	3·1

The above are the records of actual experiments by the permanganate process, and the author therefore hopes that they will be accepted and found useful. Percentage results of course refer to the bark itself.

Professor ATTFIELD had gathered from a previous memorandum he had received from Mr. Smith, giving only his results, and also from some letters, that he proposed to estimate the value of any drug, the active principle of which was precipitated from its solution by lime, in this way. He took an aqueous decoction or infusion of the drug, and added permanganate of potassium until all the oxidizable matter had been oxidized. Then he took a similar portion of the aqueous decoction, and precipitated the alkaloid from it by lime, filtered it, and then estimated the amount of oxidizable matter in the filtrate, which would now contain no alkaloid, and the difference between the two quantities of permanganate of potassium added he considered indicated the amount of alkaloid. The foundation of that statment was that he had examined a third portion of his infusion or decoction in the ordinary way, and obtained by that means a certain quantity of alkaloid which as he said corresponded with the amount obtained by his own method, and inasmuch as this was much more rapid than the ordinary gravimetric method, the author claimed advantage for it.

The PRESIDENT said it would seem to be implied that the addition of the lime separated nothing but the alkaloid.

Professor ATTFIELD said that apparently the author did not altogether take into account that something else besides alkaloid might be precipitated, and that the total quantity of alkaloid might not all be precipitated. A great deal would have to be done evidently before a method of this kind could be relied upon for the assay either of cinchona bark or of drugs generally.

Mr. WILLIAMS said there was one point in Mr. Ekin's paper which he should like to have cleared up. Did he understand correctly that the liquid extract from a certain known bark yielded much less alkaloid than a tincture from the same bark?

Mr. EKIN said, Yes, the same sample of bark was used in all the experiments.

Mr. UMNEY said Mr. Ekin's paper was a most valuable one. For some time past they had been looking for a table showing the relative values of the official preparations of bark. Mr. Smith's paper he did not feel competent to discuss as he could hardly follow it, and it seemed to contain something quite novel. Mr. Ekin's paper brought out very strongly the imperfections of the fluid extract of the B. P., and showed how wasteful it was, as had been long known. Manufacturers knew that according to the natural acids contained in the bark, so would only 40 to 60 per cent. of the alkaloid be removed, and on an average they did not get out more than half, varying according to the amount of quinovic acid present. The fluid extract of the B. P., as now made from calisaya bark, varied considerably, and the calisaya bark had deteriorated to a fearful extent of late; so that in a few years he believed it would be altogether a thing of the past, and they would have to depend on East India bark containing 5 or 6 per cent. of quinia for fine fluid extract.

Professor MARKOE said the subject of Mr. Ekin's paper had excited a good deal of attention in the United States. The preparations of calisaya and red bark had been much studied by some of the best men, and they long ago came to the conclusion that all efforts to get a satisfactory preparation of bark by the present modes of treatment were entirely wrong in principle and total failures in practice. This was recognized in the United States Pharmacopœia, which directed that even in making an infusion aromatic sulphuric acid should be added to make the alkaloids more soluble and prevent the loss of a large portion of the active principle. Following on that principle they had a fluid extract which fairly represented the bark in the proportion of a minim to a grain. They used three volumes of officinal alcohol, sp. gr. ·835, and one volume of glycerine, and with this menstruum there was no difficulty whatever in totally exhausting the bark; but it was a question with them whether that had any advantage over a purely alcoholic menstruum. Dr. Squibb had demonstrated that it was easy to make a preparation which should be fluid enough to drop easily, containing as much as two grains in each minim, and which would not precipitate. He agreed with the remarks of Mr. Umney that calisaya bark was getting to be a very unsatisfactory drug, and in the States they had perhaps even greater difficulty in getting it of good quality than in England, and the East India barks were now being preferred. With regard to solid preparations of cinchona, the present officinal formula of the United States Pharmacopœia directed a double treatment. The bark was first percolated with a certain proportion of alcohol, and afterwards this was continued with water. The alcoholic percolate was evaporated to a syrupy consistence, the aqueous percolate was then evaporated, and the two mixed together. Carefully conducted experiments, however, made by a number of investigators had shown that the alcoholic treatment was quite sufficient to thoroughly extract the whole of the bark, and that the addition of the aqueous extract simply served to swell the bulk of the preparation without adding any value to it. They were, therefore, now using, instead of the officinal preparation, the alcoholic extract. In the next pharmacopœia if glycerine were used at all it would only be to a small extent; in fact its wholesale use in the U. S. Pharmacopœia was in spite of the protest of the best pharmaceutical workers in that country, and owing to the unfortunate circumstance that that work was issued practically by three or four men, instead of representing the whole profession throughout the States. That was an error which would be corrected next time.

Mr. SUMNER was glad to find that this paper treated of the waste at present incurred in making the liquid extract. As had been remarked, it was almost impossible to get good calisaya bark. Those whose recollection went back some years could remember when what was called the monopoly bark was the one used generally, but now they could neither get that nor anything corresponding in quality to it. It was just possible that if they went further into the South American territory, they might be able to get bark of a similar character, but if that were not so there was no hope of getting quilled bark from South America, inasmuch as the trees had been totally destroyed

in order to get at the bark in former years. At the present time it was next to impossible for any one to know how to go into the market to buy and get value received, except by analysis. The definitions seemed all altered, for what was called crown bark now was very different to what went by that name twenty years ago; that was the finest quality of the pale description, whereas now crown bark was understood to be the fine description of yellow bark. He wished that Mr. Ekin, instead of working on one description only, had treated various kinds, as he would then have given them information of what they were much in need. Large quinine makers might be able to analyse a bark before buying, but indiscriminate purchasers had not the same advantage of judging of what they were buying, and he hoped this point would not be lost sight of in the future treatment of the subject.

Mr. F. W. Fletcher wished to ask Mr. Ekin, as the object of his process seemed to be the extraction of the total alkaloid, and especially as calisaya bark preparations were under examination, why he preferred to use spirit as a solvent, instead of chloroform, ether, or amylic alcohol. The process of treating the bark with lime and so decomposing the kinate of quinine was first proposed by Carles, and he recommended chloroform. If percolation was used, the chloroform came through as a nearly colourless liquid, and if this were agitated with dilute acid the whole of the alkaloid passed into the acid solution. On separating the acid solution, and treating it with an excess of ammonia, the alkaloids could be extracted by Allen's ether process, and thus the long process of distillation to recover the spirit was avoided. Of course this method would not answer if it were desired to separate the cinchonidine, the cinchonine, and the amorphous alkaloid; but where the object seemed to be to get the total alkaloid in a comparatively rough way, he should certainly think that chloroform or ether would be a preferable solvent.

Mr. Williams said the most important point brought out was the difference in the yield of alkaloid from the same bark when treated in different ways. In the fluid extract form in which the smallest quantity was produced a considerable amount of evaporation was required, and possibly the alkaloid was decomposed by oxidation or in some other way, and probably in the subsequent concentration three-quarters of the alkaloid was lost.

Mr. Brady said there was a practical confirmation of the thoroughly unsatisfactory nature of the Pharmacopœia process, in the fact that quinine makers were very ready to buy the residues from pharmacists after they had treated the bark for the fluid extract.

Mr. Mason said the Pharmacopœia process was a most wasteful one if the residues were not employed. He knew an instance where two serons of bark were purchased, and the residue sold for two-thirds of the original cost.

Mr. Ekin said in reply to Mr. Sumner that he could not have used different samples of bark, or the whole purpose of his examination would have been frustrated, and he could not have instituted a comparison between the solvent powers of water and spirit. He had no doubt that chloroform would be an equally good menstruum, but alcohol was certainly more convenient, adopting Dr. de Vrij's method. No doubt a small proportion of the lime was taken up by the alcohol, but it was got rid of afterwards by adding a sufficient quantity of very dilute sulphuric acid. He was surprised at the small quantity of alkaloids contained in the fluid extract, and it was gratifying to find that men of such large practical experience as Mr. Umney could corroborate his conclusions. He did not think the alkaloids were precipitated in evaporation, but that the true reason why more alkaloids were not obtained in the fluid extract had been pointed out by Mr. Umney, and this was borne out by other experiments which he had not mentioned in the paper. The richer the bark was in quinovic acid, the less alkaloids were obtained. After examining this sample of liquid extract he made another sample, or tried to do so, exhausting the bark with a good deal more water, but he found in concentrating it, that it was impossible to reduce it to the proper bulk, the sp. gr. being altogether too high. The quantity of quinovic acid in solution prevented the concentration going beyond a certain point.

Mr. Groves asked how Mr. Ekin explained the fact that while an infusion yielded 1·3 per cent. of alkaloids, that same infusion when evaporated into a fluid extract was reduced to ·47. The loss must be occasioned by the evaporation.

Mr. Ekin said that the infusion could not be concentrated beyond a certain point if the bark were rich in quinovic acid. A quantity of infusion representing 100 grs. could not be concentrated into 27 minims. If the exhaustion of the bark were continued according to the directions of the Pharmacopœia, "until the water ceases to dissolve anything more," long before the desired point of concentration could be arrived at, a gelatinous semi-solid extract would be formed to which the name of *fluid* extract would be inappropriate, and if the concentration were stopped when the sp. gr. was 1·2, the liquid instead of measuring three fluid ounces to a pound of bark, would measure at least four times that quantity, and consequently three fluid ounces would only contain a fourth of the total quantity of alkaloids.

Mr. Umney asked if the explanation was not rather that boiling water was used in the one case and cold water in the other. Ether would not do as a solvent of the total alkaloids; it dissolved the quinine only, with a very small quantity of cinchonidine, but would not act upon the cinchonine.

Votes of thanks were passed to Mr. Ekin and Mr. Smith.

The next paper read was on—

The Extraction of Emetia from the Deposit in Vinum Ipecacuanhæ.

BY GEORGE BROWNEN, F.C.S.

It is not my intention to direct the attention of this Conference to the chemistry of ipecacuanha, that has been done by our secretary, Professor Attfield and others. At the Birmingham meeting in 1865, a paper was read by Mr. Johnson, in which some of the causes at least of the instability of ipecac wine were noticed and suggestions made; yet in the revision of the Pharmacopœia after that date these suggestions were either set aside or forgotten and the same objectionable and unsatisfactory formula is preserved by authority in the Pharmacopœia of 1867.

I do not intend to dilate on the turbid solution and unsightly deposit which continuously forms as long perhaps as there is anything in the form of alkaloid to deposit from this wine; neither do I ask you to decide which course should be followed by the dispenser, filtration and consequent weakening of the wine or the use of a turbid inelegant mixture. Ipecacuanha wine will deposit, if made according to the official formula, and that deposit will contain the most valuable and perhaps the *only* valuable constituent of ipecac root, and being mixed with the crystalline tartar adheres to the sides and bottoms of the vessels containing the wine; even if it becomes detached is is not readily or easily diffused by agitation, but is often rejected and thrown away.

Quite recently a considerable quantity of these deposits and incrustations came under my notice and I determined to try and see if some use could not be made of this waste product.

The semi-crystalline mass was therefore made into a paste with water, and then mixed with calcined magnesia until a marked alkaline reaction was obtained. Calcic hydrate was tried, but the evolution of ammonia and other changes led me to suppose that the emetia might be affected by the lime. After standing for twenty-four hours, the mixture was slightly warmed to complete the reaction, and the resultant mixture spread in thin layers

and dried as rapidly as pos-ible at a low temperature. The mass was next reduced to powder and percolated with spirit of wine. The alkaloid associated with some impurities was thus abstracted from the other salts, and it was possibly pure enough to fortify a "weakened" ipecac wine if the necessary proportions were known. Such, however, was not my purpose. The alcohol was therefore removed by evaporation and the emetia dissolved in dilute acetic acid and then precipitated by ammonia; the emetia obtained was fawn-coloured and tolerably pure, completely soluble in acids, and precipitated by Sonnenschein's and the other alkaloidal tests.

The process I have described is an adaptation of the process of MM. Pelletier and Dumas, and by this method a considerable proportion of alkaloid may be obtained from the brown-coloured crystals and slime, which the pharmacist in his disgust is sorely tempted to throw away as a nuisance and loss.

In Watts's Dictionary, vol. ii., page 485, under the heading "emetine," I find the following:—"The gallotannate is a white flocculent precipitate soluble in alkalies, it is *neither emetic nor poisonous.*" May not this compound be formed in old ipecacuanha wine and be the cause of its uncertainty and partial inertness even when the wine was "well shaken before taken?"

No discussion followed the reading of this paper.

A vote of thanks was passed to Mr. Brownen.

(*To be continued.*)

CHEMISTS' ASSISTANTS' ASSOCIATION.

On Wednesday, August 7, Mr. A. Wallis, President, in the chair, Mr. Miller read a paper on "Digestion." This included besides a concise description of the alimentary canal, a very complete exposition of the various classes of food, their economic and physical values, and the changes they undergo in the system. After a short discussion, a hearty vote of thanks was awarded to Mr. Miller for his paper.

At the meeting on September 4, the President announced the following donations towards the expenses attending the projected removal of the Association to new and permanent rooms:—Messrs. S. Maw, Son and Thompson, £5 5*s.*; Burgoyne, Burbidges and Co., £2 2*s.*; A. S. Hill and Son, £1 1*s.*; Evans, Lescher and Evans, £1 1*s.*; Allen and Hanburys, £1 1*s.*, and some others promised.

Obituary.

Notice has been received of the deaths of the following:—

On Tuesday, September 10, at his residence, 15, Hanover Street, Leicester, Mr. Thomas Cooper, one of the founders of the Pharmaceutical Society, and Local Secretary for Leicester since its formation. Deceased had carried on business in the Market Place since 1833, and recently retired through ill health in favour of his son, Mr. Henry Cooper, and Mr. Wm. Sturges. At the time of his decease he had completed his seventy-third year within two days. Mr. Cooper was useful to his fellow townsmen in several public offices.

On the 27th of August, 1878, Mr. Thomas Almond, Chemist and Druggist, Sussex Street, Leeds. Aged 54 years.

On the 28th of August, 1878, Mr. John Cock, Chemist and Druggist, Penzance. Aged 36 years. Mr. Cock had been an Associate of the Society since 1869.

Dispensing Memoranda.

[117]. I am glad you added to the memorandum of Οχθαί (117) the wholesome reminder that "interchange of opinion" is the object of the department solely, and no personal element should be introduced. A. P. S. is slightly in error in translating Οχθαί "heavy at heart;" but Οχθαί should be civil in his critiques. Οχθη is a height or bank, and Οχθαί is used to represent the banks of a river, or crags, and is mostly used in the plural for such purpose. Οχθεω, the verb, means "heavy at heart," and hence the mistake.

H. Brown.

[138]. The following is a good formula for podophyllin pills:—

℞	Resin. Podoph.	3 gr.
	Sacch. Lactis	3 „
	Saponis Duri	3 „
	Ext. Aloes Soc.	12 „
	„ Nuc. Vom.	3 „
	„ Hyoscyam.	18 „

Triturate together the podoph. and sugar of milk, mix with soap and ext. aloes, add extracts of nux vom. and hyoscy., and make into twelve pills. Each pill contains one quarter grain podoph. in minute state of division, which obviates the liability to gripe. When "pil. podoph." is ordered in a prescription, without any indication of the quantity of podophyllin which each pill is to contain, I should think a dispenser would not be justified in sending out a pill containing more than a quarter of a grain, since half a grain is too large a dose for many people. Podophyllin is, I believe, generally given when there is an objection to mercurials, so that to dispense a pill containing podophyllin in combination with calomel, as suggested by a correspondent in last week's Journal, seems to me scarcely the right thing to do.

Belfast. P. B.

[147]. Liquor Secalis Ammon.—As H. H. says in reply to "Sub Umbra Floresco" that the above preparation is, he believes, made exclusively by Messrs. Richardson and Co. of Leicester, I hope I may be allowed to say that it has been made by me, for the last twenty years at all events.

Henry Ayscough Thompson.

[147].—Liq. Secalis Ammoniata has for many years been manufactured by Messrs. Ferris and Co., of Bristol. The dose of their preparation is thirty drops.

Felix Stevens.

[150]. If dispensed as written (which in my opinion it ought to be) this cannot be made into a clear mixture, but may be made so by the addition of a small quantity of acid. sulph. dil., though at the expense of decomposing part of the potas. bicarb.

C. E. P.

[151]. I presume the initials E. W. are intended for Erasmus Wilson, who gives in his select remedies in his work on diseases of the skin the following formula:—

℞	Sulphuris Hyperchlorid.	℥ij.
	Potass. Sub-Carb. (now P. Carb. B.P.)	gr. x.
	Adipis Purificat.	℥j.
	Ol. Amygd. Ess.	gtt. x.

M. ft. Unguent.

I know of no other formula.

W. Stott.

(151).—Ung. sulph. perchlor. co., E. W., is most likely that ordered by Mr. Erasmus Wilson; the formula may be found in Beasley's 'Pocket Formulary.'

F. Stevens.

[151]. The formula for ung. sulph. perchlor. co. (E. W.) Erasmus Wilson, is—

℞	Sulphuris Hypochlor.	℥ij
	Potassæ Subcarb.	gr. x
	Adipis Purif.	℥j
	Olei Amygd. Essent.	♏x

M. ft. Unguentum.

C. E. P.

[151.] E. A. T.'s question as to the formula of ungt. sulph. perchlor. co. (E. W.) can be best answered by saying that the writer meant hypochlor. The formula of Mr. Erasmus Wilson (E. W.) is, hypochloride (hypochlorite) of sulphur, ℥ij; subcarbonate of potash, gr. x; lard, ℥i; oil of bitter almonds, gtt. x. M. Useful in acne. I may state that the hypochlorite is very prone to explode, and in opening a fresh bottle great care should be exercised.

Henry Brown.

[152]. Tinct. quinæ co. was officinal in the London Pharmacopœia, and the B. P. tincture is exactly the same, the "co." being dropped. The strength, 1 gr. of disulphate of quinine in ♏ 60 of tincture of orange peel, being the old formula as well as that of the B. P.

Henry Brown.

[152]. I should dispense tinct. quinæ, B.P., as it is made of the same ingredients, in the same way, and of the same strength as the tinct. quinæ co. of the P.L. 1851.

C. E. P.

Scarborough.

[152].—Here tinct. quinæ B.P. is undoubtedly meant; it was introduced as tinct. quinæ co. in the P. L., and in the B. P., 1864.

Felix Stevens.

[153]. Lin. æruginis was officinal in the London Pharmacopœia, and was a difficult preparation to make satisfactorily. Where practicable it should be made fresh; but, if long kept, the deposit should be shaken up, as it consists of the acetate of copper with probably some other compound owing to the honey used in the preparation of the liniment.

Henry Brown, L.R.C.P., etc.

Northallerton.

[154]. Ung. Acidi Carbolici.—This ointment being often prescribed, what strength should it be dispensed?

Sub Umbra Floresco.

[155]. Ol. Morrhuæ c. Ætheris Sulph.—I have had occasion to dispense this. The prescription was for ℥vj (tablespoonful dose) and I gave ætheris sulph. ℥ss., ol. morrhuæ ad ℥vj. Is there any recognized formula for this preparation?

Sub Umbra Floresco.

[156]. Liq. Plumbi Subacet,—When this is ordered in lotions with aq. puræ ad —— should pure or distilled water be used?

Sub Umbra Floresco.

Notes and Queries.

[515]. NON-POISONOUS FLY PAPER.—"Associate" will find paper saturated with a sweetened infusion of quassia and dried, will answer this purpose. Pepper, with milk, is also used; and also some adhesive compounds by which these domestic pests are fatally entangled.

Sub Umbra Floresco.

[518]. LIQUOR COPAIBÆ COMP., COMPOSITION BALSAM OF COPAIBA, CONCENTRATED ESSENCE OF CUBEBS AND BUCHU.—This preparation, when diluted with water in any proportions forms a perfectly clear and bright solution. Dose ℥j. ad ℥ij. Could any reader kindly oblige with the formula for preparing the above?

Sub Umbra Floresco.

TINCT. TONKÆ.—It will be found that tinct. or ess. tonkæ is best prepared by digesting one pound of bruised beans with one gallon of rectified spirit for fourteen days—strain, press, and make up to a gallon with spirit.

Sub Umbra Floresco.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Dangerous Doses and Difficult Problems.

Sir,—In the *Pharmaceutical Journal* of July 13, page 39, and No. 127 in the "Dispensing Memoranda," will be found particulars of a prescription left at the shop of a pharmacist to be dispensed. The following is a copy:—

℞	Sesquibromid. Ferri.	gr. xxxvj.
	Ext. Nucis Vomicæ.	gr. iij.
	Ext. Ergotæ Aquos.	gr. xxiv.
	Pulv. Cantharidis	gr. xxiv.

M. ut fiat massa et divid. in pil. xviij.

One pill to be taken three times daily.

On reading the prescription the quantity of cantharides, the drug alone being unusual in a prescription, attracted the dispenser's attention, and the peculiar nature of the combination, with other points of lesser importance, induced him to hesitate before he prepared the prescription, and to request the name of the writer. This was furnished, and the prescription being referred to him, was in due course returned with the following observations: "The doses are not poisonous; the prescription has certainly my professional sanction; the patient might be put on his guard so far as irritation of the bladder might occur, but this is not likely. I note the doses again and return your note that you may see."

Quoting the words of the writer in the Journal, "It was thus plainly apparent that the chemist was required to dispense and order to be taken four grains of powdered cantharides in a day, and that this quantity was to be repeated for six days;" and more than this, the prescription orders eighteen pills only, but the person leaving the prescription wanted the number increased to one hundred, as the patient was going abroad. The question implied in the letter is, What was the dispenser's duty under these circumstances? A very important question and one that should not be left in a state of uncertainty.

It will be recollected that in 1873, Mr. Fisher, of Ramsgate, was censured by a coroner's jury, for declining to dispense a prescription which, taking the Pharmacopœia as his guide, contained a poisonous dose of tincture of digitalis; on that occasion I wrote a letter to the Journal on the subject, calling attention to the difficulties which surround a dispenser, and I would here quote the same observations under somewhat different circumstances: "It would be well therefore while the facts are fresh in the memory, that some attempt should be made to define the relative responsibility of medical man and chemist when an unusual dose of an active medicine is ordered in a prescription." On reading the facts of this case two questions suggest themselves. 1st This being the prescription of a medical man in practice, consequently a legitimate prescription and one stamped with the emphatic sanction of the writer, should it, notwithstanding the large dose of cantharides, have been dispensed? 2nd. If it was right to dispense it as a prescription ordering eighteen pills, sufficient for six days, should it have been dispensed when the conditions were altered by the patient's requiring one hundred pills, or

sufficient for five weeks, on the plea that he was going abroad?

The object of this communication is to direct attention to the prescription alluded to, which has been apparently overlooked. Had it been a trade question the very mention of it would have sufficed to have filled the pages of the Journal with correspondence; but it is nevertheless one of immediate interest to every dispenser, and a legitimate subject for discussion in the pages of the *Pharmaceutical Journal*.

THOMAS GREENISH.

20, *New Street, Dorset Square.*

THE LUTON OXALIC ACID POISONING CASE.

Sir,—The trading in oxalic acid seems to be carried on in a rather loose irregular fashion at Luton, and the report of the above case very plainly shows that the regulations of the Sale of Poisons Pharmacy Act, 1868, have been altogether ignored.

Part 2 of the Schedule of Poisons within the meaning of the Act which is now before me, sets forth oxalic acid, red precipitate, white precipitate, corrosive sublimate, etc., as requiring in their sale by retail to be labelled as follows, namely—

1. Name of the article.
2. The word "Poison."
3. Name and address of seller.

The report of the inquest in the Journal states that the coroner "thought they (the jury) would conclude from the evidence that the oxalic acid was purchased at Mr. Chambers's, and that though it was his rule to label it he did not invariably do so, and might not have done so on that occasion."

I apprehend the selling of oxalic acid is unlawful excepting by registered chemists and druggists, wholesale or retail, and I infer Mr. Chambers is not one of the above, and, moreover, it is an established fact that he has not complied with the law in respect to labelling in the retail department. I think it would have been as well if the jury had, whilst recommending all packets in future to be labelled "Poison," coupled with it the name and address of the seller, or that oxalic acid should be sold in accordance with the law.

104, *Freeman Street, Grimsby.* J. M. JEPSON.

[*** We understood that this case, like all other cases of infringement of the Pharmacy Act brought under the notice of the Registrar, has had full consideration, and that Mr. Chambers, who apparently has erred in ignorance of the law, has promised to obey in future the provisions of the Pharmacy Act.—ED. PH. J.].

EXAMINATION DISCREPANCIES.

Sir,—To my mind the "mysterious" examination discrepancies are very easily explained, especially if other schools of pharmacy have a system similar to that which obtains in the "recognized school" in which I studied before passing the Minor.

A *vivâ voce* examination is held daily, and this must give a teacher an intimate knowledge as to who are his "best men," his "weaker men," and his "worst men." Therefore, about a fortnight before the time expires for receiving notices of examination, instructions are given by the teacher to the "best men" to send their notices and fees at once, so as to be entered for the first day of examination. A week after the "weaker men" send in their fees and notices, so as to be put down for the second or third day, while the "worst men" are told not to send in their notices until the very last day.

The supposed advantages of this system are (1) the "best men" pass well, and so encourage and stimulate the weaker and the nervous men; (2) it allows the backward men an extra week to work themselves up; (3) it allows the school to advertise that "ten or eleven out of twelve sent up from this school have passed."

My respect for the gentlemen composing the Board of Examiners is my apology for troubling you with this long rambling letter. I do not wish them to be branded with unfairness, for that would be unfairness itself.

One thing I would like to mention while the examinations are being discussed. I am told that refreshments used to be served out to candidates before examination, but that has ceased to be done. I was summoned to attend at Bloomsbury Square at 10.30 a.m., and, as candidates are called into the examination room in alphabetical order, my turn came last, at 3.15. Now, sir, judge of my fitness for examination after six hours' fasting and five hours' momentary suspense. I certainly should have been "plucked" had not one of the examiners noticed my condition and taken me to their luncheon table and told the housekeeper to supply me with a glass of wine and other refreshments.

September 9, 1878. G. W. W.

EXAMINATION DISCREPANCIES.

Sir,—I read with interest in last week's Journal the editorial article on "Examination Discrepancies," in which it is remarked that the correspondence which has taken place on the subject has done nothing towards solving the mystery. How, I ask, could it be otherwise, since others, like myself, wrote not so much with a view of stating the cause of the peculiarity—which none but those officially connected could do with certainty—as to draw attention to the occurrence and thereby hope to obtain from examination statisticians a satisfactory elucidation? I may add, my previous remarks being simply conjectural, and not intended to imply firm convictions, are therefore open to modification, notwithstanding several assistants having expressed to me similar surmises.

I was also glad to find the matter discussed at the Council meeting; also, the statement by the Secretary as to the order in which candidates are placed for examination, together with the fact that many desire to be examined on the later days for the sake of a few hours' extra preparation, a circumstance with which many, like myself, were unacquainted, and one, I admit, capable of accounting for an increase in the number of failures. A complete official investigation, as now contemplated, will, I trust, be the means of giving general and entire satisfaction, and I shall certainly without hesitation discard my previous supposition on its proving erroneous, at the same time fairly accepting the resulting explanation, which I doubt not will prove gratifying to others besides

JUSTITIA.

"REVISED PRICE LIST FOR PHARMACISTS."

Sir,—As every week brings new ideas into the pharmaceutical world, I think many of our rank must have felt somewhat amused at the suggestion of a South Western "Æsculapius" (whether young or an old veteran is at present unknown), that drugs should be dispensed by pharmacists at prices about equal, I suppose, to what they are worth in shop bottles, to say nothing about paying assistants' salaries for dispensing them. Of course we know there are some medical practitioners (I don't say all) who frequently (I won't say always) employ an errand boy to dispense, or otherwise mix in a bottle, a compound called physic; but the pharmacist would perhaps consider his professional skill brought into requirement to produce a result as intended by theprescriber.

Islington, London. W. N. G. L.

COUNTER PRESCRIBING.

Sir,—The letter in the Journal of the 7th inst. from H. W. Williams, M.D. is a first rate contribution towards the settlement of this vexed question, and is as near as possible the "whole truth." I have long held the opinion that the public are to blame in asking advice from chemists. On a close view of the matter, however, it more frequently turns out that they merely call on the chemist for a confirmation of their own opinion as to what may be wrong, and of course what remains to be done is the selection of a remedy for their ailment. I am convinced that a persistent yet unoffending disinclination to prescribe on the part of chemists would go far to stamp out the evil. In my own experience in the town and provinces, I have generally succeeded in satisfying such demands by supplying a simple article, plainly labelled and giving verbal instructions for its use, or by a little conversation in the course of which the existence and proper functions of the medical practioner are brought up, when the interview usually ends in a deter-

mination on the part of my customer to see his own medical man and get his advice.

No reasonable member of the medical profession could object to the first of these methods I follow in preference to compounding a mysterious looking mixture, etc., and of course the second one is the proper and always preferable, monetarily and otherwise.

It is to be hoped that the time is not far distant when the relative positions of the prescriber and dispenser will be better understood and that in all communities there will exist between doctors and druggists the greatest possible confidence and forbearance and that no offence will be deliberately given, or readily taken. A mutual understanding between doctors and druggists, to the exclusion of the public always, whilst strictly avoiding anything like prejudice to brethren in profession or trade, is much to be desired.

St. Andrews, Fife. W. R. KERMATH.

PHYSICIANS AND SURGEONS *versus* CHEMISTS AND DRUGGISTS.

Sir,—I was much surprised on looking at the *Pharmaceutical Journal*, September 7, in the Correspondence column to find the letter, headed "Physicians and Surgeons *versus* Chemists and Druggists." I think the writer's opinion in some instances good, but not on all points. For instance if a person has got headache or feels rather bilious, could not the chemist give him relief and so save him the trouble of going to consult his medical adviser? If the person were seriously ill the chemist would naturally say, you had better have medical aid. Then the writer of that article draws up a price list as to what chemists should charge for dispensing medicines, which I consider absurd; for instance 8 oz. bottle 1*s.*, 20 oz. bottle 2*s.* 6*d.* If the bottle contained expensive preparations I think the poor pharmacist would not be able to live, especially if he had one or two assistants to pay out of the profits.

Wood Green, N. A. F.

VIOLET POWDER AND HAIR POWDER.

Sir,—I may, perhaps, add a little to the information given by your correspondent at page 200. Like him, I am not an octogenarian, yet I am "old enough," and I have reason to know that the hair powder of the last century was prepared from wheat starch, and that it was not always perfumed, simple white starch powder being often preferred, but it was liable to be adulterated with wheat flour, and a delicate skin could detect this adulteration.

I have heard an anecdote related by an old gentleman of a barber using flour for hair powder, and assuring his customer that it was not mixed.

If wheat flour was so objectionable, surely an earthy or metallic preparation must be more so, although no doubt the effects on a tender skin of this latter would be very different to flour.

Downside, Chilcompton, Bath, September 9, 1878. JOSEPH LEAY.

WHAT IS "VIOLET POWDER."

Sir,—In your issue of 7th inst., your correspondent "Rosicrucian" asks the question whether terra alba, French chalk or gypsum was ever used for the purpose of hair powder. If Smiles is to be credited, it would appear that terra alba was used as hair powder before being applied to the potter's art.

At page 84 of 'Self-Help,' edition 1876, in the article on Böttgher the potter, Mr. Smiles states as follows:—"One day, in the year 1707, he found his *perruque* unusually heavy, and asked of his valet the reason. The answer was, that it was owing to the powder with which the wig was dressed, which consisted of a kind of earth then much used for hair powder. Böttgher's quick imagination immediately seized upon the idea. This white earthy powder might possibly be the very earth of which he was in search; at all events the opportunity must not be let slip of ascertaining what it really was. He was rewarded for his painstaking care and watchfulness, for he found on experiment that the principal ingredient of the hair powder consisted of kaolin, the want of which had so long formed an insuperable difficulty in the way of his inquiries."

I am not a defender of terra alba, etc., but write this reply to your correspondent "Rosicrucian's" question, as he states an answer will be very interesting to your readers and especially to himself.

Inverary, N.B. JOHN RODGER.

Errata.—In the paper on 'The Detection of Alum in Bread and Flour,' printed in the *Pharmaceutical Journal* on the 7th inst., on p. 181 column 1, line 12 from bottom, read "drying, igniting, and weighing" for "drying, and igniting," etc. In column 2, p. 181, line 6 above the paragraph commencing with "Experiment II," omit "ammonia," and read, "in a clear liquid." On p. 182, column 1, line 7 from top, for "1·86," read "1·86 gr." and in the last line of the paragraph begining with "Experiment IV," for "aluminic hydrate," read "aluminic phosphate."

W. F. Haydon.—Mr. Peake's letter in explanation was printed in the Journal for last week, p. 199.

"*Spes.*"—We should always be happy to comply with your wishes so far as they are consistent with the interests of the Journal, but even editors are entitled to civility from their correspondents. This we consider to be wanting in your last communication, and for that reason no notice can be taken of it beyond acknowledging its receipt.

E. H. S.—Assuming that such a display of what you consider bigotry has occurred,—though you yourself profess to disbelieve it,—the republication of such a vague accusation would annoy many who have had nothing to do with it. Moreover, it is not desirable to attempt to establish in these columns a censorship in such matters.

W. Wade.—No opinion of any value could be expressed without a proper examination of the water. The presence of a considerable quantity of iron in the water would certainly render it unfit for some domestic purposes, such as washing linen, making tea, etc.

A. B. C.—In Thomson's process the silver is precipitated from a neutral solution of the nitrate by means of grape sugar. See Cooley's 'Cyclopædia,' under "Silvering."

J. R. C.—(1). Yes, he is liable to a penalty, if unqualified. (2). We cannot say; the question should be addressed to the Secretary of the Royal College of Veterinary Surgeons. (3). No; he may not.

"*Sub Umbra Floresco.*"—(1). "Essence of Ylang-ylang" may be made by dissolving the imported otto of ylang-ylang in rectified spirit (160 minims to a pint) and filtering, if necessary. (2). The question as to "chloric ether" was discussed in this Journal last year. See vol. viii., pp. 19, 38 and 67.

R. S. Caudell.—Hypericum perforatum. Specimens to be named in these columns should be addressed to the Editor.

"*Fides.*"—The examination will probably be held about the middle of the month; certainly not before the 9th.

C. B.—We have applied for the information, but up to the present time have received no reply.

W. J. Williams.—Nos. 1 and 3 are correctly named. (2). *Lychnis diurna.* (4). *Odontites rubra.* (7). *Senecio Jacobœa.* (8). *Polygonum Hydropiper.* (10). *Epilobium montanum.* Nos. 5, 6, 9, and 11 are too fragmentary to name.

R Roberts.—Nos. 1, 2, 4, 6, 7, 9, are correctly named. (3). *Centaurea nigra*, radiant form. (5). *Anthemis Cotula.* (8). *Stachys sylvatica.* (10). *Erica cinerea.* (11). *Calluna vulgaris.* Our correspondents are reminded that not more than six specimens should be sent at one time.

E. T. Pritchard.—Among the stations given by Sowerby as places where *Aconitum Napellus* grows apparently wild is one near Leominster.

H. C. Putnam.—In the 'Pharmacographia' sand is mentioned as one of the alleged adulterants of Turkey opium, but so large a proportion as that found by you certainly ought not to be present in a good specimen.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Balkwill and Eliott, Mr. Hayes, Dr. Tichborne, Mr. Stott, Mr. Jackson, Mr. R. G. Mumbray, "Ipse," and A. Z.

POTASSIC PERMANGANATE IN WATER ANALYSIS.

BY WILLIAM CORDUKES STABLES.

Much has been said, and very justly too, on the fallacy of the permanganate test in detecting organic matter in potable waters, and it requires but very little practice to prove that potassic permanganate does not possess the power of oxidizing albuminoid matter.

In the early days of chemistry, chemists endeavoured to estimate the amount of organic matter in water by incinerating the total solids contained in a given volume, calculating that whatever was lost or dispersed by heat must necessarily be "organic" matter.

In course of time, however, they became aware that not only was "organic" matter dispersed by heat, but carbonate of lime lost its carbonic acid, hydrated salts became anhydrous, etc., and thus the amount of organic matter was very greatly overestimated.

Then followed the permanganate process, the principle of which was that the nitrogenous matter would become oxidized on the addition of the permanganate solution, which would then necessarily lose its colour. Theoretically this system was "perfection," but when it came to practice these anticipations were blighted by the discovery, as I have already mentioned, that potassic permanganate does not possess the power of oxidizing albuminoid matter. Free ammonia is infallibly detected, while the all important "albuminoid" matter escapes untouched.

The next method is the one now in general use, that is by converting the albuminoid matter into ammonia by means of a strong solution of hydrate and permanganate of potash, and then estimating the amount of ammonia by a solution known as "Nessler's."

This process, however, is a very complicated one, and one that can only be undertaken by those who have had considerable experience in water analysis, and have the necessary time and apparatus at their disposal.

What is particularly wanted at the present day, and what has not yet been discovered, is a qualitative test which will at once determine whether or not a water is fit for dietetic purposes, and the introduction of such a reagent is the object of the present paper.

Potassic permanganate is undoubtedly the base of a very sensitive and reliable test, and only requires a little modification to develop it.

Convinced of this fact, I commenced experiments by endeavouring to find a reagent which would act upon the nitrogenous matter, bringing it under the influence of the potassic permanganate.

For this purpose I found that the potassic hydrate could not be excelled. Having therefore taken a small quantity of the water to be examined in a test tube, I added a few drops of the hydrate solution, and to this a minute particle of the permanganate, just sufficient to give a pink tinge. I then placed the test tube in a proper position over a white surface and in a good light; this I allowed to remain for a few hours. As I was operating on a sample of water which I had just submitted to a minute quantitative analysis I could anticipate the result. I knew it to contain an excess of albuminoid matter, upon which the simple permanganate would have no effect. I therefore anticipated a brownish precipitate with loss of colour, and my anticipation proved correct.

I then proceeded to make a solution exactly similar to that we use in estimating the albuminoid ammonia by the "Nessler" process, only in different proportions.

I found that 1 part of potassic permanganate, 4 parts of potassic hydrate, and 160 parts of freshly distilled water made the best solution.

With this solution I have made various comparative experiments. One minim, placed in a test tube of pure distilled water, will remain a beautiful pink hue for several days, but the minutest trace of egg albumen in the same quantity of distilled water will infallibly be detected.

I have now used this test for some time with most constant results, that is; that if on the addition of a minim of this solution, the water in a few hours gives a brownish precipitate with loss of colour, I have invariably found such water to contain an abnormal proportion of organic matter, so much so as to be injurious to health.

There will always be a very slight precipitate produced by the lime contained in the water, but so long as the colour remains perfect, such water will be perfectly good and in every way suitable for dietetic purposes.

I am now continuing a series of experiments, with the hope, in a short time, to arrive at such results as will enable an ordinary inexperienced person to estimate, approximately, the amount of organic matter contained in a sample of water, and so be enabled to arrive at the conclusion whether or not a water is fit for human consumption.

In the meantime I should be glad to receive any information or suggestions on the subject.

THE PARIS EXHIBITION.

(*Continued from page* 206.)

Miscellaneous and Proprietary Preparations.

This class of preparations is, as might be expected, abundantly represented in the Paris Exhibition. Many of them bear labels that disclose little more than the name and the virtues that they are alleged to possess; concerning these no comment is needed here, as proprietors have every opportunity of making those details known in the advertising sheets, to which in our opinion such matters should be confined. But it is a fact not without significance, as throwing light upon the genesis of the laudatory "criticisms" frequently met with, that applications to exhibitors for information for the purposes of this report have sometimes been met on the one hand by a preliminary inquiry as to the terms for advertisements, or on the other by a cautionary notice that the writer in furnishing the information does not commit himself to the payment of any charge for its publication. Such precaution is suggestive of a regard for the homely proverb, "Once bitten, twice shy," which was, in this instance, specially inappropriate.

There is a considerable number of preparations exhibited, however, the proprietors of which give indications as to their composition, or the principles followed in their manufacture, which may not be without interest to the readers of this Journal. A very important group of these is that which includes such as are intended to meet the wants of weakly

and dyspeptic stomachs, either by presenting the food in a readily digestible form, or by giving extraneous help to the stomach for its digestion.

Commencing with extract of meat, precedence ought perhaps to be given to the Liebig's Extract of Meat Company, Limited, who exhibit in the Uruguay court. There may be seen a large number of well-executed photograghs of the works at Fray Bentos, illustrating not only the operations in the preparation of the extract, but others involved in the utilization of the hides, offal, refuse, etc. But, as is well known, the preparations that are sent out into the market by various makers under the name of "Liebig's extract" are practically aqueous extracts of beef, containing only the portions of the meat soluble in water, and hence lacking some of its most important food constituents. From these preparations Messrs. Southall and Barclay claim that their "soluble meat," shown in the British court, differs in containing also all the fibrin, gelatine, and albumen contained in lean beef, but in "a state similar to partially digested meat," as well as mineral matters, chiefly phosphates, usually left in the imperfectly exhausted beef.

This principle of saving fatigue to the digestive organs by administering an already digested food is further carried out in the "peptones" of various exhibitors. It may be thus explained in the words of Dr. Sanders, of Amsterdam, in whose case, in the Netherlands court, are specimens of the peptones of meat, fibrin, milk, peptonized vegetable albuminoid substances, peptonized bread, peptone chocolate, solution of peptone and raspberries and peptone capsules:—"Peptone, known in physiology and in chemistry as the product of the digestion of the albuminoid bodies in the intestines, by means of the pancreatic and gastric juices, is distinguished from the albuminoid bodies (1) by the facility with which it passes through the dialysing membranes and the walls of the intestines, and its rapid absorption by the blood and the lymph; (2) by certain chemical properties, among which may be noted its great solubility in water and its not being precipitated by heat, acetic, hydrochloric, sulphuric, or nitric acids, by alkaline hydrates or salts, or by sulphate of iron. Albuminoid bodies after their digestion,—*i.e.* their transformation into peptone,—are upon being absorbed by the blood reconstituted there as albuminoids. Thus the peptone introduced into the stomach, or into the large intestines, requires no previous digestion, and the entire nutritive effect is produced without fatigue or delay. Consequently, since peptone represents the principal elements of nourishment, the albuminoids, it recommends itself whenever there is need of rapid and vigorous reparation, or in the cases where digestion is defective or insufficient, as in abdominal typhus, dysentery and other intestinal maladies." Dr. Sanders prepares peptone by exposing beef to artificial digestion by a bullock's pancreas; it is sold in a rather concentrated aqueous solution, one part of which is said to represent three parts of the digestible portion of the beef. As a complement to the beef peptone a peptone of bread is prepared which is sold as a nearly dry mass. The recent great development of this business is shown by the fact that although Dr. Sanders's manufactory was only founded in 1875 he now turns out twenty-five tons of peptone annually. Peptone from different sources, in scales and powder, is also shown in the cases of Messrs. Hottot and Co., and M. Perret, of Paris.

It may be remarked that though the subject of the peptones remains still incompletely investigated, the preparations exhibited are creditably abreast of our present knowledge. Dr. Henninger, who has recently published the result of some researches,* has found that the peptones derived from fibrin, albumen, or casein, when purified from mineral matter, all appear as white amorphous infusible powders, very soluble in water and in glacial acetic acid. They react slightly acid and behave like feebly acid amides. When an acetic solution of a peptone is treated with sulphuric, hydrochloric or nitric acid, a plentiful white precipitate is immediately formed that collects into a nearly colourless viscous mass, soluble in water. This Dr. Henninger looks upon as a salt of peptone corresponding to the acid employed. No difference could be detected in the behaviour of peptones from various sources towards reagents, all having certain characters in common with albuminoid matters, but less tendency to coagulation and precipitation. They approach closely to gelatine, but their hot solutions do not gelatinize on cooling. Yet the peptones, although apparently identical in their chemical properties, differ, like the albuminoid matters from which they are derived, in their effect upon polarized light, the rotatory power of albumen peptone being the weakest and that of casein peptone the strongest.

Of the substances which are prepared for introduction into the stomach to assist the digestive organs in the performance of their functions, pepsine, pancreatine, and diastase are shown in various forms. In the French court "Boudault's pepsine" is exhibited by Messrs. Hottot in pills, lozenges, dragées, wine and elixir. Messrs. Chassaing and Co., and M. Perret show pepsine and diastase separately, and the latter adds a compound of the two, called "pepsine-diastase." In the case of M. Catillon, among various glycerine preparations, including one of cinchona, wine and iron, in which the glycerine appears to prevent the discoloration of the compound, there is one of pepsine. This exhibitor claims that his pepsine is capable of digesting two hundred times its weight of fibrin, but under what conditions this result is obtained he does not state. Messrs. Rigaud and Dusart, with more moderation, only claim half this digestive power for their pepsine. Another compound shown is the "Elixir eupeptique" of M. Tisy, which is described as containing 0·10 gram of pancreatine, 0·30 gram of diastase, and 0·10 gram of pepsine per spoonful. Turning to the English court, Messrs. Morson exhibit their "pepsina porci," and Messrs. Savory and Moore their pepsine pancreatine, "peptodyne," and "pancreatic emulsion;" but perhaps the most famous maker of pepsine on this side the Channel, Mr. Lloyd Bullock, is not represented. A "pepsine wine," which we have had an opportunity of tasting and found very palatable, is shown by Mr. Broomhead, of Aberdeen, as well as an emulsion, said to contain pepsine and hypophosphite of lime and 75 per cent. of cod-liver oil. Messrs. Richardson, of Leicester, also exhibit a compound pepsine wine under the name of "peptocolos." It will be noted that in the foregoing the alcoholic preparations of pepsine still retain a place, notwithstanding the fact that it has been asserted that in the presence of alcohol pepsine ceases to exert a digestive action. It may be, however, as

* 'De la Nature et du Rôle Physiologique des Peptones.' Paris: Savy. 1878.

has been suggested, that the digestive power of the pepsine is only rendered latent, and that when the alcohol has become diluted by the fluids of the stomach, the pepsine resumes its activity.

It is due, however, to M. Defresne to make special mention of his pancreatine, which is shown in the case of Messrs. Ringaud and Dusart, of Paris. M. Defresne has been making a thorough investigation of this substance, and has recently communicated his results to the French Academy.* He finds that pancreatine as prepared by him contains three distinct ferments, which he has isolated and named. These are (1) myopsine, obtained in brilliant garnet scales, capable of digesting 104 times its weight of dry albumen, but without action on fat or starch; (2) steapsine, obtained in shining translucid scales, capable of breaking up twenty-four times its weight of fat, but without action upon starch; and (3) amylopsine, obtained in brilliant lemon-coloured scales, not affecting fat, but saccharifying twenty-five times its weight of starch. Another observation, important in its bearing upon the preparation of pancreatine, but only what might be expected, is that the pancreatic juice is not identical in different species of animals, but attains its maximum power upon albumen—*i.e*, contains most myopsine—in omnivoræ, whilst in the ruminants, the ox, for example, it is almost without action upon albumen.

In order to give an idea of the power of M. Defresne's product, a turkey, weighing eight kilograms (between seventeen and eighteen pounds) has been placed in warm water with some pancreatine, and the result is exhibited. There remains only the skeleton of the bird floating in a yellowish liquid, which contains what was once the flesh, but has now become converted into "peptone." There are also specimens of starch that has been converted into sugar; and cod-liver oil that has been emulsified, in fact, undergone artificial digestion by treatment with pancreatine.

Closely allied with the foregoing are the extracts of malt, which probably owe any medicinal or nutritive virtue they possess to the diastase they contain. This theory of their action is by no means novel,† although it has recently undergone the honour of rediscovery in an experience that has been recounted to a learned society, and gone the rounds of the journals.‡ A "chemically pure" extract of malt is exhibited by Dr. G. Wander, of Berne; it is of the consistence of honey, and is claimed to be free from alcohol, carbonic acid, albumen, and all other indigestible matters. Dr. Wander prepares a compound of phosphate of lime with his malt extract, containing 0·3 gram of the phosphate in a spoonful (35 grams). Various other combinations with extract of malt are shown in this case, such as those with quinine, santonin, iodide, pyrophosphate, and lactophosphate of iron, a "Liebig's food for infants," and an emulsion with cod-liver oil. M. Gerbay, of Roanne, shows some pastilles and other preparations of "maltine." There are also a number of "foods for infants" shown by various exhibitors.

Medicated preserved milks are to be found in the case of Dr. Bouyer, of Saint-Pierre-de-Fursac (Creuse). Here the inventor professes to follow nature in introducing into the system substances, that would otherwise be irritating, under the protection of a liquid rendered mucilaginous by the casein and butyrin it contains. Iodine, arsenic, and mercury are the principal bodies employed, and these are prepared as syrups, powders, and chocolates. It is said to be necessary, in order to obtain a good result, to use a milk of a particular composition, rich in casein to favour preservation, and containing in the serum a suitable and uniform proportion of salts. From the udder to the heel is not far, and this perhaps is the best place to mention an exhibit of preserved vaccine, shown by Mdme. Subra, "sage femme d'Algiers."

Snails are no longer an article of materia medica in this country, though they are occasionally used, boiled in milk, as a popular remedy in diseases of the chest, simply, perhaps, for the reason that their mucilaginous properties are looked upon as likely to be beneficial. But although snail soup is usually suggestive of the ludicrous to the insular English mind, M. Baron-Barthélemy maintains that snails are capable of rendering valuable service in most chest complaints, bronchitis, asthma, etc., because, in his words, they contain "animalized sulphur, a little phosphate of lime, and especially carbonate, animalized, in solution, and in the nascent state, in their mucilage." The preparations he exhibits are snail syrup, snail bonbons, and "helicine" as mucilage and powder. For these the edible snail (*Helix pomatia*) is used, collected in the vineyards in the south of France, preferably in the months of August and September, and carefully fed and preserved during the winter. M. Barthélemy lays stress upon this point of food, and attributes the fact that these snails are not more generally used as an article of diet to their flavour only being properly developed where they get suitable food, as in the vineyards in the south of France and Italy. However this may be, and whatever may be thought of the chemistry of the subject, it certainly is the case that when this very mollusc was a tit-bit of the Roman epicure it was, before being cooked, fattened in the *cochlearia* by feeding upon a paste made with meal and wine.

Another preparation that has been the subject of ridicule in this country is to be seen in the case of M. Meynet, of Paris, in his dragées prepared from the aqueous liquor obtained from the liver of the cod. It is only fair, however, to say that this preparation has obtained the approval of the committee of the Academy of Medicine necessary to its being sold in France as a proprietary medicine, and that some of the statements made on its behalf seem sufficiently reasonable to require more tangible refutation than can be conveyed by a note of exclamation. According to M. Meynet the value of cod-liver oil does not depend altogether or chiefly on its oleaginous properties, since it cannot be replaced by any other oil, nor upon the quantities of the metalloids it contains, since these are present in homœopathic proportions, but also upon other substances present in the oil, such as trimethylamine, gaduine, etc. To their presence in larger proportion in the unpurified brown oil is attributed the superior activity with which that variety is credited by some practitioners. These substances, being soluble in water, are also found in the aqueous liquor from the livers, and, when this has been concentrated by M. Meynet's process, the extract is alleged to contain half its weight of gaduine, 3 per cent. of trimethylamine, besides other am-

* *Répertoire de Pharmacie*, vol. vi., p. 244.

† *Pharmaceutical Journal* [3], vol. vii., pp. 312 and 542.

‡ *British Medical Journal*, July 13, 1878, p. 64.

moniacal and nitrogenous bodies, 2 per cent. of phosphoric acid, a relatively enormous proportion of chlorine, iodine, and bromine, and the soluble principles of the bile, etc. It is admitted that the odour and taste of this extract are more detestable than those of cod-liver oil itself, but it is claimed that the difficulty is overcome by administering it in the form of dragées. There is nothing more startling in this than to find the oil of boa constrictor exhibited in the French Guiana court as a pain-killer! Perhaps a little faith would be a useful admixture with both.

A large number of phosphated syrups of different kinds are exhibited by various makers, but concerning these nothing more can be said than that they mark the enormous popularity which these "chemical foods" have attained during the last few years. M. Declat's iodophenic syrup is said to contain $\frac{1}{1000}$ of free iodine, $\frac{1}{500}$ of potassium iodide, and $\frac{1}{10}$ of carbolic acid. M. Demesse, of Villemeux, exhibits in the French Guiana court a syrup of *Cissampelos Caapeba*, described as a powerful diuretic and possessing tonic and sedative properties. Here also are some preparations of "conguérécou" (*Xylopia frutescens*), which are said to have the property of modifying exaggerated mucous secretions.

It is not surprising, considering the attention that has been paid to the tree during recent years, to find numerous preparations of *Eucalyptus globulus* claiming a place in the medical arsenal. Victoria, of course, takes the lead in this respect, and several preparations of this kind are to be found in the case of Mr. Bosisto, of Melbourne. The essential oil is recommended as a tonic, stimulant and antiseptic, and for promoting the appetite in small doses; in larger doses, 10 to 20 minims, it accelerates the pulse and produces a pleasant general excitement; and in very large doses it causes intoxication, followed by soothing sleep. Any unpleasantness arising from an overdose is said to be removable by strong coffee. "Eucalyptol" is used as an antiseptic, stimulant and disinfectant, and for inhalation in bronchial affections, half to one teaspoonful being placed in the inhaler with a pint of hot water. "Liquor eucalypti globuli" is said to contain the bitter principle of the leaves, and to possess valuable antiperiodic and antimalarial properties, without the disadvantages of quinine. "Eucalyptic acid" is another antiseptic, with a powerful and persistent odour, so that it has been necessary to exhibit it diluted to avoid flavouring the other preparations shown. It is obtained sparingly by fractional distillation from the *E. globulus*, but abundantly from *E. rostrata*, and is supposed to be the principle that protects the timber of this tree from the attacks of the *Teredo navalis*. Australian kino, from *E. globulus*, is also shown in this case, together with laminæ of the astringent gum from *E. rostrata*, obtained by tapping the trees in autumn, a syrup of which is said to be an efficient remedy in affections of the mucous membrane of the stomach and bowels, and especially in chronic dysentery and diarrhœa; for throat affections it is used in the form of a lozenge. Further, there are some cigarettes of *E. globulus*, with and without tobacco, recommended for use in bronchial and asthmatic affections, and for their antiseptic and disinfecting properties. In this court, also, Messrs. Sander and Sons, of Sandhurst, show some eucalyptus preparations, and Dr. Day, of Geelong, exhibits a disinfectant consisting of rectified oil of turpentine 1 part; benzine 7 parts; and oil of verbena, five drops to each pint. In the French court, M. Delpech, of Paris, exhibits several preparations of *Eucalyptus globulus* including an "essence," a powder of the leaves, a "balsam," a liniment and a bath preparation for rheumatism, a wine as a tonic febrifuge, capsules, an alcoholate for internal use and as an application to wounds, a syrup and pills. From the abbey monastery of Saint Paolo a la trè Fontana, near Rome,* the Trappist fathers send an elixir and other preparations of eucalyptus. From Algeria, too, "essence of eucalyptus" is sent by M. Cournier, of El Kantoun, Algiers.

France is the home of the tar preparations, and they are well represented in several cases in the present exhibition. M. Manche, of Paris, shows a "goudron Manche," described as a non-alkaline solution of tar; Messrs. Barberon and Co., of Chatillon-sur-Loire, exhibit their "goudron-Barberon," said to contain all the medical principles of Norwegian tar, and to represent the tar water of the Codex in its maximum degree of concentration; also tar capsules, spherical and about the size of a pea; and an elixir of tar containing chlorhydrophosphate of lime. Then M. Roussin has a 4 per cent. "saccharole of tar" and a "soluble vegetable tar." M. Le Beuf, of Bayonne, has a 20 per cent. emulsion of coal tar with saponin, which body he also uses to emulsify balsam of tolu, copaiba resin, and oil of cade; while M. Gerandel shows pastilles of Norwegian tar for inhalations; and M. Pol le Mettais a solution of tar from the Norwegian pine, which he calls "elaline." Besides these, Dr. Fournier exhibits a wine and cod-liver oil, both containing beech creasote, which are recommended for phthisis and catarrhal affections.

In the Queensland department there are a number of specimens that cannot fairly be described as specialties, having been prepared by Mr. L. Carmichael from plants growing in the Brisbane Botanic Gardens. Among these are "oil of blue gum" (*Eucalyptus botryoides*, Sm.), said to be antiseptic and useful in putrid fevers and fetid suppurations; "tincture of red gum" (*E. tereticornis*, Sm.); tincture of gelsemium; "tincture of bitter bark" (*Alstonia constricta* F. Muell.), and "tincture of crab tree" (*Petalostigma quadriloculare*, F. Muell.), both reputed to possess properties similar to quinine. "Ayapana bitters," a preparation described as containing eupatorin and a peculiar essential oil, is said to be used as a stimulant, tonic and diaphoretic, whilst an infusion is used in dyspepsia and bowel affections. There are also orange bitters, as well as "bitter cups," made from the "crab tree" and the "bitter bark tree."

Lastly, there is the class of preparations in which medicines are disguised under the form of sweetmeats, or some other attractive form, such for instance as M. Crinon's chocolate, wafers and lozenges of "hemoglobine" (soluble dried blood); and M. Dardel's medicated chocolates, containing purgative, emetic, ferruginous and other ingredients. In the British court Messrs. Wyndham show a "spirit of eggs," which is said to have something of the character of the B.P. mistura spiritus vini gallici, but to contain the whole of the egg,—shell and all,—though what difference this makes, of course no opportunity is given of testing. But it would be useless to continue the enumeration further. Enough has been said to show that in the French and British courts at least, and

* *Pharm. Journ.* [3], vol. vi., p. 625.

especially in the former, proprietary preparations muster strongly. A large number of them have an unmistakable flavour of quackery about them; others at least bear evidence of the expenditure of a considerable amount of practical skill and ingenuity; whilst there are some that undoubtedly reflect high credit upon the pharmaceutical calling.

(To be continued.)

THE AMOUNTS OF SUGAR CONTAINED IN THE NECTAR OF VARIOUS FLOWERS.*

BY ALEX. S. WILSON, M.A., B.SC.,

Fellow in Natural Science, Glasgow University.

Nectar is the term applied by botanists to the sweet-tasted fluid which is secreted within the cups of insect-fertilized flowers; and the object gained to the plant by its presence is that insects, induced to visit flowers for its sake, are useful to the plants by effecting a cross-fertilization. Mr. Darwin has shown what an amount of additional vigour is thus conferred on the seeds which subsequently result in contrast with the evil effects produced by continuous inbreeding. In many instances this sweet liquid is exuded from special glands, but in other cases from portions of the flower that do not seem to have been specially adapted for this purpose. Morphologically, nectaries may represent very different structures, but not unfrequently they are of the nature of an aborted organ, such as a petal or stamen. It is a point in dispute among biologists whether this saccharine matter is a true secretion or simply an excretion of effete matter from the vegetable cells, a by-product of the chemical changes taking place within these cells. The latter view seems to be favoured by the fact that a similar sweet-tasted fluid, much sought after by insects, is exuded on different parts of some plants quite unconnected with the flower, as in the laurel, brake fern, lime tree, acacia, etc. As to the use of such exudation of sweet fluid, various suggestions have been made by those who are disposed to regard it as a true secretion; as for instance, that it serves as an attraction to certain insects to frequent the plant, these insects rendering service by keeping off animals to whose attacks the plant may be subject. Probably this is to some extent true, but it cannot be said to hold universally. Nectar is of course the source whence the bee derives honey, but it also affords food to many kinds of insects which do not possess the habit of storing up. A division of the humming birds is named Melliphagi on account of living on this substance; but it is probable that in some cases the small insects seeking the nectar, and not the nectar itself, may be the objects of the visits of these birds to nectar-producing flowers. The bright colours, as shown by Sir John Lubbock's experiments, serve to guide insects to the flowers, and the odours which they emit fulfil the same end. The markings on a flower's petals, it is to be noted, always converge towards the nectar, as in the violet. The importance of these guides to insects will be apparent from the following estimations, which show how indispensable it is that as little time as possible should be lost by an insect collecting honey. It must also be remembered that the nectar is usually contained in the most secure and best covered part of the flower, the object being to prevent the access of rain, which owing to the extreme solubility and diffusibility of sugar, would speedily cause it to be transferred to parts of the plants where insects could reach it without being of any service in the way of cross-fertilization. The chief purpose of the flower would in this way be frustrated. The formation of nectar is observed to take place most freely in hot weather, and to be prevented by cold or wet. So great economy is exercised by the plant that it is only formed at the time when insects' visits would be beneficial, *i.e.*, when the anthers are ripe and shedding their pollen, or when the stigma is mature and ready to receive pollen. By biologists the visits of bees, butterflies, and other insects are believed to have exercised in past time an important influence in modifying the size, shape, colour, etc., of flowers, and the following experiments, in spite of their incompleteness, are of interest as showing to what an extent this action takes place in nature, and as helping to determine the value of this factor. These estimations are only the first of a series, and the writer regrets that he has been unable to give them the desirable completeness, but hopes to continue them.

The nectar was extracted with water, and the sugar determined before and after inversion by means of Fehling's copper solution. Many of the estimations were done in duplicate, and gave results that agreed perfectly. In the case of fuchsia, which is not deprived of its nectar by any insects in this country, the nectary being inaccessible to native species, we have probably the whole of the amount formed, but in other cases the visits of bees, etc., may have reduced the amounts considerably. In this case it is a clear colourless liquid, having an acid reaction and an intensely sweet taste; that of many others has the strong characteristic odour of honey:—

Sugar in Flowers.

	Total. Mmg.	Fruit	Cane? (as Fruit.)
1. Fuchsia, per flower . .	7·59	1·69	5·9
2. *Claytonia Alsinoides*, do.	0·413	0·175	0·238
3. Everlasting pea, ditto .	9·93	8·33	1·60
4. Vetch (*Vicia Cracca*) per raceme	3·16	3·15	0·01
5. Ditto, per single flower .	0·158	0·158	—
6. Red clover, per head .	7·93	5·95	1·98
7. Ditto per floret . . .	0·132	0·099	0·033
8. Monkshead, per flower .	6·41	4·63	1·78

Approximately, then, 100 heads of clover yield 0·8 grm. sugar, or 125 give 1 gram, or 125,000 1 kilo. of sugar; and as each head contains about 60 florets (125,000 × 60), that is, 7,500,000 distinct flower tubes must be sucked in order to obtain 1 kilo. sugar. Now as honey, roughly, may be said to contain 75 per cent. sugar, we have 1 kilogram equivalent to 5,600,000 flowers in round numbers, or, say, two and a half millions of visits for one pound of honey. This shows what an amazing amount of labour the bees must perform, for their industry would thus appear to be indispensable to their very existence. Another point worth notice in these results is the occurrence of what appears to be cane-sugar, and that in the case of fuchsia in the proportion of nearly three-fourths of the whole. This is remarkable, as honey is usually supposed to contain no cane-sugar, its presence being usually regarded as certain evidence of adulteration. The question therefore arises whether this change, which takes place while the sugar is in the possession of the bee, is due to the action of juices with which it comes in contact while in the honey-bag or expanded œsophagus of the insect, or whether the process of inversion goes on spontaneously, as may perhaps be the case.

THE TELEGASTROGRAPH.*

In this big gooseberry season we scarcely expect the enclosed extract to be received with anything but incredulity. Nevertheless there seems to us nothing absolutely impossible from a scientific point of view, and the extract, which must be taken *cum grano* having as a basis of

* *The Melbourne Age.* Reprinted from *The Gardeners' Chronicle*, September 7, 1878.

truth, has been sent to us from one of the leading scientific men in Melbourne, who, with the Governor, Sir George Bowen, and others, himself took part in the proceedings. When this machine gets perfected one pine or one bunch of grapes will suffice for a large party.

"The telegastrograph is a machine by which, through the aid of electric currents, the flavour of any food or liquor can be transmitted by wire to any distance, and the sensation of eating or drinking conveyed by merely placing the end of the wire between the teeth. The inventor never pretended that any actual nourishment was conveyed by his process. He merely claimed that the sensation of partaking of rich viands and costly wines could be imparted to people a hundred miles away from the operator, written on their palates, in fact; and that the number who could receive this sensation from a small quantity of food, and the length of time that it be could be made to last, were practically unlimited.

"There were five points of observation fixed upon, viz., the *Age* office, Government House, the Minister of Education's office at the top of Collins Street, and the post-offices in Geelong and Castlemaine. At each of these places a number of persons were assembled to watch the proceedings and take part in them. Telephonic communication was established with every station, and at a few minutes past eight o'clock every gentlemen was at his post.

"At the urgent request of the inventor all the observers had refrained from having dinner, but before operations commenced they partook, according to direction, of brown bread and butter, with two or three glasses of cold water. Precisely at a quarter past eight, and when it was ascertained by a preliminary trial that the wires were in working order, a bottle of the best sherry, flavoured with half a wineglassful of orange-bitters, was poured into the receiver of the machine, and the electro-magnetic battery was turned on by Messrs. Ellery and M'Gowan. This was hardly fair to the inventor. He had directed that no more should be placed in the receiver for each sensation than an ordinary diner was in the habit of consuming at a meal; but Dr. Bleasdale, unused to the control of the telegastrograph, considered that one wineglassful would be quite inadequate to supply the wants of the numerous observers, and he therefore gave sixteen times more than he should have done. The evil effect of this mistake was speedily apparent. The observers at the different stations having taken the wires between their teeth, and the battery being turned full on, the alcoholic essence of the large quantity of sherry placed in the receiver was sent along the wires in full force to the five points of observation, and the thirty-six persons in gastrographic connection with the machine received the impression of having each consumed an entire bottle of sherry and bitters. Some of the observers stood this very well, and showed little signs of having received too heavy a sensation; but others, especially some gentlemen who are prominently connected with the cause of total abstinence, were very strongly affected, and in response to an urgent appeal by telephone from the editor of this paper (*Melbourne Age*), the battery by which the wine was discharged was turned off. From first to last five minutes had elapsed from the time when the sherry was put into the receiver till our message caused the supply to be discontinued. In that brief space five-sixths of the bottle was dissipated, and some of the observers were temporarily disabled from taking notes, Every sign of incipient intoxication was produced. Instantaneously, however, upon the electric current being stopped the ill effects ceased. The pleasurable sensation of having lately partaken of wine remained, but that, and an exhilaration of spirits that lasted throughout the experiment, was the only result of Dr. Bleasdale's ill-judged zeal.

"Half-a-dozen exceedingly fine Sydney oysters were next exposed to the action of the battery, each having squeezed upon it a few drops of lemon juice. The effect of this was very fine, and proves that the telegastrograph is peculiarly well qualified to transmit the flavours of the most delicate foods. Intentionally *menus* had not been forwarded to the various posts of observation, as the inventor wished to have a perfectly unbiassed opinion from the gentlemen who took part in the experiment. A scientific objector had endeavoured, in anticipation, to account for the sensations by declaring that they were produced by the action of imagination. But the fallacy of this argument, on which a great deal of stress was laid, was shown through the whole course of last night's proceedings. Several of those who felt the effects of the wine most would not have had a sensation of the kind if they knew what was coming. And so with the oysters. The general impression among the observers was that soup would have been the next thing supplied, and it came as rather a surprise when the delicious sensation of slowly swallowing the freshest and plumpest oysters came upon them. His Excellency, Sir George Bowen, sent a message himself by telephone congratulating the inventor on the marked success that had up to this time attended the experiments; and Professor Pearson and Mr. Berry simultaneously informed him from Castlemaine and Geelong that they could almost smell the sea, so fresh were the oysters. A glass of Chablis closed this part of the performance, after which there was an interval of about five minutes, that was employed by the observers in comparing notes on what they had felt.

"There were five soups prepared under the special management of Mr. Sayers, and a different kind was sent to each place. Clear turtle was sent to the office of this paper (*Age*), and it was of a nature to make every one regret when the supply ran out. Rather an amusing accident happened with that supplied to Government House. When it was announced that everything was ready. His Excellency and his friends put the wires into their mouths, but no sooner was the soup (clear oxtail) turned on than as one man, and with various exclamations, they withdrew the wires, and so cut off the connection. It turned out that the soup had been put into the receiver scalding hot, and the gentlemen each received the sensation of having burned his mouth. Nothing can prove more plainly than this that the theory of imagination is utterly at fault. It is worthy of note, however, that the unpleasant feeling of scalding disappeared as soon as the wire was withdrawn; while, on the contrary, the pleasurable sensations imparted by the telegastrograph to the palate and stomach were felt for several hours after. A glass of East India sherry succeeded the soup, and a feeling of a convivial and social nature became apparent at all the posts.

"In every case the food looked as tempting after being subjected to the action of the gastrographic battery as when first brought in from the kitchen; but it was found to be utterly devoid of taste, and some analytical experiments conducted on the spot by Baron Von Mueller and Messrs. C. Newberry and W. Johnson proved it to be utterly valueless for human sustenance.

"The sparkling wines were those that obtained the largest share of approbation. Every bubble on every glass of champagne poured into the receiver was faithfully imprinted on the palates of the observers at every one of the stations, and the only departure from the carefully prepared *menu* was in response to urgent appeals for 'more champagne.' The dissipation of the viands and liquors with their elementary parts, and their distribution along the lines, was protracted or hastened according to the strength to which the battery was adjusted. A slice of the breast of a turkey, weighing four ounces, was distributed by way of experiment in forty-five seconds, while the flesh on a chicken's wing was made to last for nearly fifteen minutes.

"The warmest congratulations poured in upon the inventor (a member of the staff of the *Age*), at the close of the proceedings, and Sir George Bowen stated his intention of recommending him to Her Majesty for some mark of her favour."

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 21, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACIST IN GERMANY.

To see ourselves as others see us is frequently a wholesome thing since it affords perhaps the best opportunity of detecting our own errors, and at the same time gives us some chance of correcting them. In a somewhat similar manner it is useful for men engaged in any pursuit or business to have an opportunity of observing the proceedings of those occupied in the same manner in other countries, and under different conditions. If this is done without the odious comparison of the Pharisee, and in the hope of gaining instruction, it may often give rise to profitable suggestions, and lead to beneficial results.

It is therefore with some considerable satisfaction that we have been able this year, almost by an accident, to carry out a long conceived project of attending a general meeting of the Deutscher Apotheker Verein. This society partakes in some respects at once of the character of the Pharmaceutical Society and of the Pharmaceutical Conference, inasmuch as it is an incorporated body, recognized by the state, and in this capacity deals with various matters relating to the regulation of the practice of pharmacy, while at the same time it holds an annual meeting in one or other part of the country, to afford an opportunity to pharmacists to meet in a social manner or discuss scientific as well as other topics of interest to them.

This year the general meeting has been held at Coblentz, under the Presidency of Herr WOLFRUM, of Augsburg, and the number of visitors amounted to somewhere about three hundred, besides a very considerable number of ladies—either the wives or daughters of the members. The proceedings were commenced on Wednesday, the 11th inst, with the delivery of an address by the President, reviewing the various work of the Association during the past year. This was followed by an admirable address by Professor MOHR, upon the relations of Chemistry to Pharmacy, of which we shall shortly publish a translation in full. At the second meeting in the afternoon another address was delivered by Herr SCHLICKUM, upon the Education and Training of Pharmaceutical Apprentices. In the course of the day the members of the Association were presented to the Empress, who happened to be staying at the time in Coblentz.

A very good exhibition of drugs, apparatus, pharmaceutical preparations and sundries was held in a building near the place of meeting, and several objects of interest were shown, to some of which we shall refer subsequently.

The second day's proceedings comprised the transaction of some official business and the delivery of another address by Professor REICHART, of Jena, in which he dwelt upon the fitness of the German *apotheker* to carry out the chemical work required in connection with questions of public health, etc. Both this address and that of Herr SCHLICKUM, we purpose giving translations of, since they contain much that is of interest to pharmacists at home.

The conditions under which the pharmaceutic art is exercised in Germany are very different from those obtaining in this country: the *apotheker* does not carry on counter practice, but he is the only person permitted to dispense medicines; the number of businesses is limited, and any addition is made to depend upon a proved want for public convenience. The training of apprentices in German pharmacies has always been considered better, both in scientific and practical bearings, than in most other countries, since every establishment was in itself a school of pharmacy. There is, however, abundant reason to infer that this favourable condition is rapidly becoming a mere ideal one, for the preparations of the wholesale druggist are displacing the home manufactures, as could be observed from the nature of the articles shown in the exhibition. The sale of proprietary articles and the so-called "patent medicines" is also gradually becoming a more considerable part of the pharmacist's business.

One of the most striking impressions produced by the proceedings at the meeting was the somewhat unexpected one that the pharmaceutists of Germany are at present mainly occupied with the consideration of "trade interests." This was manifested to some extent in a manner that has no possible analogy in this country, for instance in reference to the questions of concessions and of the tariff for dispensed medicines; but at the same time there are other questions under discussion quite the same as those to which attention is now directed at home. Thus, for instance, the training of apprentices, the dispensing of homœopathic medicines, and the sale of drugs by persons who are not pharmacists. In the course of the discussion that took place on these topics some of the difficulties and grievances referred to were identical with those experienced here.

The social aspect of this gathering was also especially noteworthy. A very large proportion of the members brought with them their wives or daughters and sometimes both. At the dinner given on Thursday ladies formed nearly one half of the number present. To provide for them more agreeable entertainment than attending the daily meetings, special arrangements were made for visiting some of the points of interest in the locality, and in

the evenings there were concerts and dancing. On Friday an excursion was made to the old town of St. Goar in a special steamer, which conveyed between four and five hundred persons to the landing place, whence they walked up to the ruined abbey of Rheinfels, and there found abundance of Rhenish wine and other refreshment awaiting them. On the return journey, when the evening had closed in, several of the old ruins on the banks of the Rhine were illuminated as the steamer passed, and on reaching Coblentz a shower of rockets lighted up the town and the opposite heights of Ehrenbreitstein. The whole of the arrangements for the meetings and excursions were carried out in a manner that showed the local committee entrusted with this work had spared no trouble or labour.

QUICKSILVER MINING IN CALIFORNIA.

According to the report of Mr. Booker, Her Majesty's Consul at San Francisco, the production of quicksilver in the state of California during the year 1877 slightly exceeded that of the previous year, having been 78,600 flasks against 75,074. Of this the mining industry of the Pacific coast of the United States is estimated to have absorbed 18,000 flasks, whilst no less than 31,200 flasks were exported to China.

Nearly one-third of the whole quicksilver obtained in California during the year, or upwards of 24,000 flasks, was yielded by the New Almaden mines, which are the most productive quicksilver mines, except the Spanish Almaden mines, in the world. They are situated, together with the reduction works, in the Santa Cruz mountains, at an elevation of 1700 feet above the level of the sea, fifteen miles south of the city of San José, Santa Clara County, California. These mines were first worked in 1845, but the operations were then on a small scale. The records of the extent of the operations only date back to 1850, but these show that in the twenty-three and a quarter years following the production amounted to 595,882 flasks, or 406,457,255 lbs. of quicksilver.

The New Almaden mines are now developed to a depth of 1300 feet, and the workings extend horizontally somewhat in the shape of a letter Y. The work is actively prosecuted during the year and between five and six hundred men find steady employment. During the twelve years between the beginning of 1864 and the end of 1875, the drifting and sinking in the mines of the Company, independent of the excavations made in extracting the ore, exceeded twenty-six miles, at a cost of one million dollars. The rock in most places requires to be drilled and blasted, and in 1875 there were used in the mines 2361 kegs (25 lbs. each) of black powder and 9350 lbs. of "giant" and "hercules" powder. At the close of the same year about five miles of underground railroad and over two thousand drills were in active use in the mine.

The reduction works at New Almaden consist of nine furnaces, and include the most approved methods of working quicksilver ores.

Provincial Transactions.

COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

The sixth monthly meeting of the Students' Section of the above society was held on the 22nd ult. in the Library of "The Square" (at the Provident Dispensary), the President, Mr. Axford, occupying the chair. After the transaction of the ordinary business, the chairman announced that the Hon. Sec. (Mr. Horace Sainsbury) had from illness been compelled to resign his office. A vote of thanks was passed to that gentleman for the interest he had taken in the affairs of the section, and cordial wishes were expressed for his speedy recovery. Mr. Holdcroft was then unanimously elected to fill the vacant office.

A paper, by Mr. Hulme, was next read on "A New Liquid Extract of Ergot." In this paper, chloroform water was recommended to be used as an exhaustive by slow percolation, the chloroform acting as a preservative, and glycerine being subsequently added to the concentrated liquor. The author proved by a table of specific gravities he had drawn out showing the solvent powers of various menstrua, that water was unquestionably the best medium to use. An interesting discussion followed the reading of this paper, and the remarks of the author were somewhat severely criticized.

Mr. Holdcroft followed with an interesting essay on "Pepsine." After explaining the supposed composition and action on food of pepsine, he criticized the various processes used for its manufacture, and stated that the process recommended by the Pharmacopœia was the only one that could be satisfactorily adopted. He then fully explained the composition and mode of manufacture of the various pepsine preparations, and concluded by exhibiting some very elegant compounds of pepsine, kindly lent by Messrs. Wyleys and Company of Coventry.

In proposing a vote of thanks, Mr. Barrett, F.C.S., related practical experience of the manufacture of pepsine, and gave the results of his experiments on a number of "medicinal pepsines" he had met with in the market. He warmly criticized the vaunted superiority of many extensively advertised nostrums called "medicinal," "lactopeptine," "saccharated pepsine," etc., and said that many of these were composed chiefly of starch, sugar, etc.

The President (Mr. Axford) followed, and questioned some of the remarks of the reader of the paper regarding the solvent action of the ptyalin contained in the saliva, and further discussion ensued.

After a vote of thanks to the President and the readers of the papers, the meeting came to a conclusion.

It was announced that the next monthly meeting would be held on the 19th proximo, when a lecture, accompanied with experiments, would be delivered by Mr. Fred. Barrett, on "Milk Analysis." The laboratory was also stated to be complete and ready for the immediate use of students.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 217.)

The Adulteration of Drugs.

BY CHARLES R. C. TICHBORNE, LL.D., PH.D., F.C.S.

In considering the adulteration of drugs, three points naturally present themselves for consideration, namely, the bearing of the Adulteration Act upon this question; secondly, the bearing of the question itself upon

the practice of medicine; and, lastly, the moral responsibility of the pharmacien in connection therewith.

In discussing of the first of these points I wish to confine myself to very few remarks, as it is impossible to go into the merits of that Act, or Acts, in the time at my disposal. Any unprejudiced observer, however, must be alive to the fact that as regards drugs and chemicals, the Adulteration Act is a failure (particularly the first), and also to the fact that in two cases out of three the analyst appointed under that Act has never received the peculiar education necessary for such a post. It requires not only considerable ordinary analytical experience but also that rare practical training in connection with the apothecary or pharmaceutical chemist, which is generally wanting. There are exceptions to the rule as regards my remarks about competency, and Dublin and London may be instanced as notable examples of these exceptions.

There is a general notion that it is the most expensive drugs and chemicals, such as saffron, scammony, quinia, nitrate of silver, etc., that are commonly adulterated. There are, no doubt, many such cases, but as details of these examples would be more than twice told tales, it is not my intention to weary you by repeating them.

In the following examples, however, I wish to bring before you a few adulterations which I have picked up lately in the course of my experience. They are in a degree typical and also illustrate the fact that adulteration is perhaps even more extensively carried on amongst cheap drugs than dear ones. I have been informed on good authority that powdered hematite (red iron ore) is frequently sold as the peroxide of iron. It is still a favourite remedy, particularly among amateur doctors, and as the pharmacopœial article is only worth a few pence per lb., a variable rock with various proportions of oxide of iron (10 to 70 per cent.) should not be substituted for it; I am not, however, prepared to vouch for the correctness of this statement from actual observation, but the instances I am now about to mention are some that have come under my own immediate notice, and which I am now in a position to put before you.

Phosphorus and nitric acid are not very dear substances, and therefore we would suppose that a preparation like phosphoric acid would always be made as directed from those chemicals, particularly when sold as the British Pharmacopœial acid. But I place before you a specimen of the so-called B.P. acid, which is made from bone ash and oil of vitriol. On reference to Watts's 'Dictionary of Chemistry,' vol. 4, pp. 500 to 544, it is therein stated that a very pure acid may be obtained by treating bone ash with oil of vitriol; that it is say, by repeatedly treating with H_2SO_4, evaporating and other details of manipulation, not necessary to specify in this paper. The writer says, after describing the process, "the filtrate when boiled constitutes a solution of orthophosphoric acid contaminated with a trace of sodium, but otherwise pure." Now, whether it is possible to remove the whole of the lime and magnesia by easy and cheap means, I am not prepared to say. It is evident that by treating the bone phosphate directly by sulphuric acid the first stage is to remove only two-thirds of the calcium, as is evidenced by the following equation—

$$Ca_3(PO_4)_2 + 2\,H_2SO_4 = CaH_4(PO_4)_2 + 2\,CaSO_4$$

As far as I can see the sample of so-called phosphoric acid under examination, is very little removed from the acid solution represented by the above equation, and more exactly represents the biphosphate of lime of the manure makers than the pharmacopœial acid. It gave a voluminous precipitate on adding chloride of ammonium and carbonate of ammonia, and also contained appreciable quantities of magnesium. Here we have a chemical product, cheap in itself, cheap as regards the sources from which it is procured, and yet, "it shall not escape calumny." The doctor's dose, thirty drops, is not much, but for the sake of commercial greed it must be cheapened.

Linseed is a very cheap commodity, owing partially to the extensive cultivation of the plant for flax and other purposes, and also because as regards the seeds, we utilize the whole of the residue after expressing the oil. After getting the latter valuable product, we have the linseed cake, which is valuable as a cattle feeder. This again, when ground, is prized by the medical man for its emollient properties. Well may the plant be called *Linum usitatissimum*. Of such universal application is this substance that it becomes important that we should have it extremely pure and free from extraneous matter. Yet even the cheapness of this commodity has not saved it from the adulterator's hands. Extensively as the linseed is pressed for oil, grapes are much more extensively pressed for wine, and unfortunately the vinegrower cannot utilize the residue of his winepress except for manuring his vineyard, therefore the winepress residue may be practically considered as a dead loss, but some ingenious winepresser bethought himself that as he had a press it was only necessary to add a little linseed farina to grape residues to produce a very presentable linseed cake, as far as the eye went. I show you now specimens of linseed cake, manufactured abroad, in which the residue of the grape stones and stalks can be easily recognized by using a low power on the microscope.

I was rather amused by a late number of the *Pharmaceutical Journal* calling attention to a paragraph in the *World* of July 31. The writer in the *World* points out that the well-known drug colocynth is an indigenous Cyprian plant and imported at a shilling a pound. "No wonder," he says, "apothecaries and chemists make fortunes, when we see what we have to pay for a few pills, containing a few grains of it." Now, like all gentlemen who go out of their sphere, he makes a miss of it. He is evidently innocent of the fact that of the five ingredients of the pill he has pitched upon one of the cheapest, whilst it contains double the quantity of scammony, a very expensive drug. The writer having been so successful in finding the word colocynth in some encylopædia, comes to grief in the Pharmacopœia. He has got from the shoe-latchet to Appelles' legs. *Ne sutor ultra crepidam.*

How much more surprised would he be to hear that the wonderful drug that costs so little is extremely difficult to procure in commerce in a state of purity, if we are to take the Pharmacopœia as a standard. The official part of the colocynth is, as expressed in the Pharmacopœia, "the dried decorticated fruit, freed from seeds."

Now we have in commerce three articles, none of which represent the colocynth of the Pharmacopœia. The colocynth apple may be anatomized into the rind, pulp, and seeds. Although Pereira says, "that the seeds are bitter as found in commerce, and that a scruple will act upon a dog," this bitterness is only skin deep and is more strikingly observed in the dry pulp than in the fresh fruit, the seeds of which are stated to be an article of food in North Africa. The albumen of the seed is perfectly tasteless; if we wash the seed for some time and then try it, we shall find that the seed is nearly free from bitterness, and *ergo*, the seed contains no colocynthin. These remarks also apply to the rind, although in a somewhat less degree. Therefore, I maintain that as these parts are inert, it is as much an adulteration to sell such an article for the medicinal powder as a direct adulteration with starch would be. It is another method of lowering the price at the expense of quality, and constitutes a system adopted in more drugs than *pulv. colocynthidis.*

I have carefully anatomized a colocynth apple, and find that it consists of—

Seeds (inert)	47·19 per cent.
Rind (nearly inert)	33·78 „
Pulp	19·03 „
	100·00.

So that if we take Meissner's analysis, which states that colocynth pulp only contains 14 per cent. of colocynthin,

we shall be astonished at the small amount of colocynthin in some commercial samples.

	Per cent. of active principle.
Pure sample	14·3
Turkey pulp ground without removing the seeds	4·2
Colocynth ground with rind and seeds. . .	2·6

In a substance in which the medical man depends upon a dose of 2 to 8 grains, this presents a wonderful range of active principle, from 14 per cent. to 2½ per cent.

The samples exhibited to this meeting were all in commerce, one is a sample of the very best average quality, but still containing a very large proportion of seed; in fact, it is very seldom without indications of the presence of that substance, and I believe it is generally the practice to powder the colocynth pulp with the seeds remaining in it.

The second sample is one which is much darker in colour and consists of the whole colocynth apple ground.

The third sample is not only the whole colocynth ground up, but a sufficient quantity of potato starch added to make the colour right, a very profitable transaction. A medical man prescribing 8 grains of such a powder would be disappointed in the results.

The second point of the adulteration question, viz., its bearing upon the practice of medicine has been indirectly touched upon, and is perhaps more strikingly viewed from the consideration of the adulteration of very active drugs, such as opium, chloral hydrate, etc. We all know the acknowledged superiority of the English made alkaloids over the foreign. Some time since, I had to perform experiments pathologically and otherwise with atropia. The English specimen (specially manufactured by Messrs. Hopkin and Williams) proved itself at the lowest computation six times as strong as the German. How is the physician to regulate his dose in such a case where one-fiftieth part of a grain will produce a marked result?

As regards the moral responsibility, I wish emphatically to express my conviction that the control of drug adulteration must come from the pharmaceutical chemist himself. In time, the public analysts must be selected from this body, and if he once realizes his great responsibility, and it is a very great responsibility, he will be able to control the manufacturer. He is much more than an ordinary trader. He has been declared to have an education outside the "three Rs," and outside his buying and selling. This in itself is a responsibility. If he says I must have a colocynth which represents 14 per cent. of active matter, get it how you like, the manufacturer or powderer will supply it. He, the pharmacien, will satisfy the doctor, the public in years to come will learn to appreciate him, and, above all, he will satisfy his own conscience.

"Nought's had, all's spent,
Where our desire is got without content."

The PRESIDENT said this paper was very valuable, especially as it showed how adulterations occurred in articles of low commercial value. Pharmacists were apt to imagine that it was only the more valuable and rare products which need be examined, but this paper showed that they must look a little more widely for contaminations.

Mr. SIEBOLD, referring to the instance mentioned, in which phosphoric acid sold as the officinal article was found to contain so large an amount of lime, said from his own experience he could not but regard such a case as quite an exceptional one. It was not, however, a rare occurrence to find a minute trace of lime in commercial specimens of the B.P. acid, and its presence showed that a good deal of that acid was still made from bone ash or some other form of calcium phosphate. But it by no means followed that phosphoric acid made in that way must contain much lime, or indeed, any appreciable quantity of it. It was true enough that if the bone ash and sulphuric acid were used in the relative proportions indicated by Dr. Tichborne's equation, the resulting preparation would contain one third of the lime present in the bone ash operated upon; but such a preparation was not phosphoric acid at all, but acid calcium phosphate. Manufacturers of phosphoric acid used a larger proportion of sulphuric acid, in fact, just sufficient to decompose the acid calcium phosphate; and the precipitation of the calcium as sulphate was rendered complete by the addition of alcohol which was subsequently expelled again by evaporation. This acid thus prepared was practically free from lime, and if pure sulphuric acid was used in the process, it would also be free from arsenic, an impurity which nearly always occurred in the acid prepared from phosphorus, from which it was difficult to remove. In the case of most of the officinal chemicals, he thought, it did not matter by what process they were obtained, so long as they stood the tests of the Pharmacopœia. With regard to the adulteration of drugs, he did not believe that such cases as those just brought before the meeting were at all frequent. No one willing to pay a fair price for his goods would have the slightest difficulty in obtaining good and pure drugs. He could at once call to mind more than a dozen wholesale firms from whom he could purchase drugs of unexceptionable quality, but he should not know where to apply for adulterated articles such as had just been described. He should find it much easier to obtain pure than to procure adulterated drugs. He made these remarks because he was anxious that those present who were not chemists, and especially medical men, should understand that the instances of adulteration brought under their notice by Dr. Tichborne did not represent the rule, but were rare and isolated exceptions, against which any chemist and druggist with a knowledge of his business would know how to guard. He cordially agreed with Dr. Tichborne as to the necessity of public analysts possessing a proper knowledge of drugs.

Mr. MASON said Professor Tichborne seemed to be of opinion that the Adulteration Act had not at all affected drugs or chemicals, but his own opinion was that it had had a most salutary effect, because it had obliged the wholesale manufacturers to label all their articles correctly, and thus prevented business competition going too far. As far as the adulteration of drugs was concerned, he must say he rather agreed with Mr. Siebold. If people wanted pure colocynth they could have it, but if chemists and druggists would have an article not pure, it must be provided.

Mr. LONG thought the paper was very valuable in putting chemists and druggists on their guard. He feared they had fallen on degenerate days, when falling prices were recouped by adulteration of the article sold. A short time ago there was a most determined effort to have the very best things, but he was sorry to say that on account of the present state of the drug trade there were a lot of inferior, pettifogging men come into it, who, he was afraid, would sell anything, and they brought a most injurious competition to bear on more respectable tradesmen.

Mr. WILLIAMS could not agree with the remarks of Mr. Siebold, respecting the phosphoric acid made from bones. He did not think it was possible to so purify the acid made from bones by any means with which he was acquainted, as to bring it up to the point he should consider suited for medicinal purposes, especially for the preparation of the various syrups. The difference was soon discovered between an acid containing only what Mr. Siebold called a trace of lime, and a pure acid. He believed it was perfectly possible to get phosphoric acid without any trace of lime at all. But not so easy to separate a more injurious ingredient, namely, magnesia. Lime was frequently employed in syrups, but magnesia appeared to be fatal to the keeping properties of any syrups. He was not before aware that hematite was ever sold as the medicinal hydrated oxide of iron of the Pharmacopœia, though he knew that iron forge scales were sometimes ground and sold as magnetic oxide of iron, which was a very improper thing to

do, because they were not so soluble. With respect to atropine, the German makers said the English did not know how to make atropine, but only made belladonine, whilst they made real atropine. It was, therefore, according to them, a question whether English manufacturers made atropine at all, but as the article of English manufacture seemed to have satisfied Professor Tichborne, he (Mr. Williams) thought they might be contented.

Mr. UMNEY said reference had been made to an article published in some of the daily papers since the annexation of Cyprus that colocynth was sold here at 1*s.* per lb. That was an error, it should have been 1*s.* 9*d.* In the London market the drug known as Turkey colocynth came invariably in a peeled and not in an unpeeled state; for years, indeed, he had not seen unpeeled Turkey colocynth. Occasionally they saw unpeeled Mogador colocynth; but it was rare. He ventured to say if the majority of the wholesale drug lists were searched colocynth would be found quoted first of all as colocynth itself, then as colocynth powder, and finally as colocynth pulp. There was no mystery about the matter. As to the manufacture of the extract, Professor Tichborne had spoken of the seeds being used with the colocynth in making extract. But colocynth seeds contained about 50 per cent. of fixed oil, and the manufacturer would avoid these as much as possible. In making an extract with an alcoholic menstruum no one could succeed properly (unless he wanted to get oil in his residue), without he rejected the seeds almost entirely. He had seen instances where a few seeds were left behind in which the small portion of oil thus remaining would contaminate the simple extract, and in endeavouring to make a compound extract a satisfactory powder could not be obtained from it. Then again with regard to potato starch. They did not know very much about potato starch on the other side of the Channel, but he must uphold the honour and integrity of drug grinding on the other side of the Channel by saying that as far as his experience went potato starch was not used or even dreamed of. As for phosphoric acid his own idea was that 90 per cent., probably, was neither made from bone ash nor yet by the Pharmacopœia process, but by a combustion of phosphorus under bell jars. And if there were any additional amount of oxygen required it was finished off with nitric acid. He knew of factories where serious mishaps had occurred whilst this combustion of phosphorus was being carried on under large earthenware vessels. One could not dispute the occasional adulteration of saffron. The late Daniel Hanbury pointed out that saffron was adulterated. They dressed it abroad, and it could be obtained at any price. The dressing consisted in treating it with some adhesive body, such as glycerine, containing carbonate of baryta or lime. If a small quantity were taken, and infused, a white powder was thrown down, and on removing the infusion, and treating the residue with hydrochloric acid effervescence took place, and the alkaline base could be most easily identified. One could understand that even 5 per cent. of such adulteration would very materially cheapen the price, but these things were few and far between with fine Valencia saffron. Scammony was adulterated, but it was done on the other side; scarcely a single parcel could be found which did not contain starch in some degree. He had found 2, 3, and 4 per cent. of starch in the finest scammony, which would assay over 80 per cent. of resin, and when found, it was very difficult to convince any one that it was genuine scammony. It was a fact that scammony resin is made here, and sent abroad to be mixed with low quality natural scammony to come back to this country as fine scammony.

Dr. SYMES could not think that pharmaceutical or public morality had fallen to the low ebb attempted to be proven by Professor Tichborne's paper, and the discussion which followed from it. His opinion was that drugs and chemicals were never to be obtained in so great a state of purity as in the present day. He was quite convinced that if Professor Tichborne sought for adulterated articles he could find them, but he did not believe the sample of dilute phosphoric acid was a fair specimen of the article as usually found. He was quite satisfied that bringing forward these articles did good, but this sample had, in his opinion, been sought for as a bad sample, as an article which was to be found rather than the average article in the market. He had found in dilute phosphoric acid traces of dilute nitric acid as if the final heating had not been sufficient to drive off the nitric acid. With regard to linseed there had been within the last few years a competition amongst manufacturers as to which could produce the best, not the worst, linseed meal, and he could now obtain linseed flour in which a large proportion of the husk was removed at a considerable cost to the manufacturer. He scarcely thought any of this cake would be found in the linseed meal of commerce; no doubt it might be imported for feeding cattle, but as pharmacists they had little to do with that matter. In making extract of colocynth no one having regard for the product would attempt to use a powder containing seeds.

Dr. MACSWINEY was anxious to express his opinion of the great value of the paper read by Professor Tichborne. The discussion which had taken place testified unmistakably to the importance of this subject to the gentlemen who composed the Conference, and he would venture to call attention to its serious bearing from the point of view of a practising physician. He need scarcely point out how essential it was that the physician should have at his command pure drugs. It would be waste of time to expend any argument to show how important it was on the one hand that the drugs should not be deficient in their characteristic energy and activity; and on the other hand that there should not be such a disparity between one sample and another of what purported to be the same substance that a dose of one being useful, the same dose of another should be disastrous or even fatal. While it was highly interesting to pharmaceutical chemists to ascertain how it was and why it was that drugs were more or less adulterated, the medical man had not much to say to that particular inquiry. He required pure drugs for the treatment and cure of his patients, and it was in the highest degree desirable that means should be taken by such an important body as the present that the practitioner should be able to depend on the purity of the drugs he prescribed. They had listened with interest to the explanation of how it happened that contaminations crept in, and from a pharmacist's point of view that was of great importance and interest, but as he would remark again, from a medical practitioner's point of view, that was entirely outside the question. He wanted pure drugs, and when he prescribed them, he certainly was greatly disappointed, and his patients were frequently the sufferers, from the presence of these adulterations, or contaminations, in whatever way their presence might be explained. It was within the cognizance of every practising physician that several drugs often did not produce the effects which were to be expected; neither astringents, nor hypnotics, nor purgatives, nor sedatives would always act invariably as they might be expected to do. He of course excepted idiosyncracies with which the physician would know how to deal. Thus in the matter of opium or chloral hydrate, or iodide of potassium, or various purgatives, or that class of remedies to which citrate of iron and quinine belonged, the physician concluded, often with very good grounds, that he could not rely on the drug being pure. He had listened with great interest to the views the Conference entertained with regard to analysts. He was not competent to offer an opinion whether the ordinary analyst elected under the Adulteration Act did or did not perform his duty effectively. But one thing appeared certain that there should be in every large drug establishment a careful, constant and reliable analysis of each sample of drugs sent out, to be ultimately used by the physician for administration to human beings. How much more important

was it that the powerful drugs administered to human beings should be pure than that they should have an explanation of the mode in which the impurity happened to creep in. In private practice, they often saw what he had pointed out, and in hospital practice, speaking generally, he believed it was also very noticeable. He had the advantage of being an hospital physician, and he must say he had not much confidence in a number of the drugs which may sometimes be met with as supplied to this class of public institutions. He was not competent, and if he were he had not the time, to analyse the drugs, but that these drugs should be analysed and their purity guaranteed every right-minded man would admit. An inspection of the list of prices of the drugs sent to the hospitals he thought clearly explained why they could not be of such a quality of purity as would be desirable. First of all, he found the drugs were quoted at prices very much under those which respectable druggists would sell them at; and next, there was the greatest variety in some articles, one, two, and three varieties at very different prices; he must naturally conclude from that that all the specimens were not pure, and he might perhaps, be permitted to doubt whether any were.

Professor MARKOE said that one very common source of inorganic impurities, such as calcium and magnesium salts in phosphoric acid, was the vessels in which the analyses were made. It was impossible to get the best porcelain dishes that would not have the enamel and even some of the ware taken in solution when the syrup of phosphoric acid was heated to 400° F. So that it was impossible to follow the process of the United States or British Pharmacopœia without getting a trace of some of these contaminations unless platinum were used. The removal of arsenic was exceedingly difficult, and he was sorry to say he had never been able to get a sample of English phosphorus but what contained an enormous quantity of arsenic. In fact it was often more difficult to get rid of all the arsenic than to make the phosphorus in the first place. He had worked up several hundred pounds of phosphorus into acid, and the removal of the arsenic was the most troublesome part of the process. Allusion had been made to making extract of colocynth from the whole colocynth, and he noticed that the B.P. did not include the simple extract. The United States Pharmacopœia did, and it was his practice to make that simple extract from the whole apple, taking care not to powder it, but simply crushing it without breaking the seed. Acting in this way none of the fixed oil went into the solution because it was insoluble in dilute alcohol. If, however, the drug was ground, then the fixed oil would be more or less removed. He might back up that statement by the authority of Dr. Squibb. He thought it would be a better practice to make simple extract of colocynth, and then dry the powder and pound it with aloes and scammony, thus doing away with the necessity of powdering the drug and simplifying the operation in every way.

Mr. BOILEAU said the paper was a valuable one as it would incite young pharmacists to keep only pure drugs. But, as a partner in one of the oldest houses in that city, he could not sit quiet when he heard such terrible aspersions made on the Dublin drug grinders. He had seen drugs supplied by a great many Dublin houses, and had never seen them adulterated. There might be one drug superior to another, as in the case of powdered rhubarb, where there were three or four qualities, but the cheaper were not adulterated. With regard to colocynth, he quite agreed with Mr. Umney. With regard to saffron, the article imported from Alicante was invariably adulterated and could not be sold in this country owing to the Adulteration Act, but that from Valencia was not adulterated. It had lately been attempted to adulterate it with the stamens of the *Calendula arvensis*, but he had not seen any specimens. Dr. MacSwiney drew his conclusions from the matter of price. But there was no proof, because the price was lowered through competition, that an adulterated article was sold; it might be that the seller was content with less profit. As Dr. MacSwiney had said he had not the time and might not be competent to test drugs, and it was not often that medical men in that country were competent, because they really had not the time; the testing of drugs was a science in itself. It was the medical men throughout the country who cut up prices; not gentlemen in Dr. MacSwiney's position, but the general practitioners; they would buy a cheap article and the men who wished to supply only the best article had very little chance. With regard to scammony, he was not aware that he had ever seen pure scammony yet. He had seen it analyse 80 per cent of resin, but he had never seen pure virgin scammony. The price varied from 20*s.* a lb. to 48*s.* and 50*s.*, but price should not be a consideration in drugs. If people did not want a cheap thing it would not be produced, and it was the public who were to blame, not the druggists.

The discussion was here adjourned until after luncheon. Upon it being resumed—

Mr. GREENISH said it would be recollected by those who attended the Conference in Edinburgh in 1871, that he there read a paper on "Pulvis Lini," where he pointed out that much of the linseed meal found in druggists' shops was made from the linseed cake, and that in that cake there was a great quantity of cruciferous seeds, and that it was not at all suitable as a representative of the linseed meal of the Pharmacopœia. Since that he had occasionally examined samples from different parts of England, and at the present time there was no difficulty whatever in getting linseed meal corresponding with that of the B.P. and without cruciferous seeds. Another article mentioned by Dr. Tichborne was colocynth. He had spent some time over this article and found that of a great many samples examined very few indeed contained starch, and the quantity in those was very small, in fact he could scarcely say that it should be considered an adulteration. There was no difficulty whatever, if it were examined under the microscope, in determining whether the outer rind were present or not. If a small quantity were placed in a solution of potash and gently warmed there would be found the flattened cells peculiar to the outer rind. With regard to the seed, they contained no starch, and, however small the proportion of seed in the pulp—and it was a most difficult thing to deprive the pulp of all its seed—their presence could be determined under the microscope by a solution of potash used in the same manner, because on the surface of the seed would be found a peculiar and beautiful stellate cell. With regard to saffron, it was sometimes met with very much broken up, but he had found the pollen grains differed so essentially from those of calendula that there was no difficulty in detecting the latter under the microscope. He thought the subject as brought forward had been somewhat exaggerated; and so far as Great Britain was concerned was a thing of the past; but while every pharmacist should avoid the least appearance of evil, it was also his duty to preserve his fellow members from any undue aspersions, and the public from exaggerated ideas of the adulteration of drugs.

Mr. PAYNE said there was one point very important to clear up in this interesting paper. It had taken him by surprise that there should be so many adulterated articles obtainable, and he should like to know whether Professor Tichborne had used any special means to obtain these substances he had analysed, or whether they were offered to him in the ordinary course of business.

Mr. COTTRILL said he was about to put the very same question. He should like to know, without mentioning names, the source whence these things came. He did not think it was possible to get drugs to any extent impure in any pharmacy in the kingdom. He could name numberless London houses where, if they sent out a parcel of drugs, the ticket upon it was a guarantee of their genuineness. Possibly Professor Tichborne had been searching for impure drugs, as Diogenes with his lantern for an

honest man, but he did not think in any respectable establishment he would find them. The fault lay in another direction. There were many persons throughout the country, particularly in the West of England, who had no legal and consequently no educational qualification, and did not know good drugs from bad. They sold things wholesale and retail, and dispensed physicians' prescriptions, but the only test they had of drugs was the price list. He also considered the Government was very much to blame. In the way contracts were taken for prisons, for instance, a list was sent out like a wholesale druggist's price list containing innumerable drugs, the prices being all fixed, and a lower price than he thought he could find any house in London would supply them at. You were informed that you could tender either net, at a percentage premium, or discount. He tendered for one prison, as he thought the supply would not be very great, and was informed that the contract was accepted by a London house at 10 per cent. discount. The imperial powers in London allowed and countenanced that which ought not to be. Again he was told that in that country contracts were taken by the guardians for drugs at prices that made him think that the drugs could not be fit for pigs to take. It was not so much, therefore, the pharmacists, but the public and the imperial powers who were to blame. On the one hand the druggists were tied down by analysts, and on the other forced to sell at prices that pure drugs could not be obtained for.

Mr. CONYNGHAM remarked that Dr. MacSwiney had said he could not find pure drugs in the public institutions he visited. If such was the case he considered, it was the fault of those having charge of the institutions who would not give the price of the best articles. But he could corroborate Mr. Boileau who said they were not supplied with impure drugs, but inferior drugs. In the north of Ireland there was a union supplied with drugs, and a gentleman belonging to the board complained of the very second and third class quality. He produced the list and asked a gentleman if he could supply pure drugs at those prices. He said no, but if he would give him a wholesale list from a London house with 10 per cent. upon it, he would supply them with pure drugs. They acted on that suggestion, and there had not been a single complaint since.

The PRESIDENT said he had been very glad to hear the remarks which had been made, but he would suggest that the discussion should not take the direction of pharmaceutical ethics or politics.

Mr. HOLMES said he held the office of dispenser to one of the dispensaries in Dublin, and the drugs could not be better than those used there.

Mr. FRAZER remarked in reference to Professor Tichborne's suggestion that public analysts should be trained druggists, that it would be very difficult to get men competent for the purpose who would give up their present positions. He could see many gentlemen around him thoroughly competent, but it would not be worth their while to become public analysts. They had had a few gentlemen connected with the Pharmaceutical Society who were appointed public analysts, and some of them had retired from business in order to give their undivided attention to their new and responsible duties. By and by the Government would have a larger field from which to make a selection, and then perhaps they would see a better state of things. With regard to the purity of articles, Mr. Mason said the public were to blame, because they would have a cheap article. His reply was, do not give the public a cheap article. If they did not keep impure articles the public could not get them; and with regard to competition he would say, compete on a high level and not on a low level. He would insist on every man selling a good article, and getting a fair price for it.

Professor TICHBORNE, in reply, said it was not necessary to contradict the indefinite trade statements which had been introduced into the discussion. He had nothing to do with them. His object was merely to bring before the Conference some facts, and how he got hold of them he would explain. He was rather surprised and sorry to see the tone that a great number of gentlemen who were connected with manufactures had taken in this discussion. They knew perfectly well that there were good drugs in the market and bad drugs, but every gentleman who got up indignantly repudiated these matters, and ended by acknowledging that every one of them was correct. Thus Dr. Siebold described a process by which this phosphoric acid was made from bone ash. He maintained that when phosphoric acid was supplied labelled B.P. it ought to have been made from phosphorus and nitric acid. Except in one case, and that was to confirm an experiment of his own, he had not bought a single sample; they were transmitted to him in the ordinary course of business and offered on the market. There were many other cases he had not mentioned. For instance, it was not long ago he got one of these ordinary samples, which were sent out as an inducement to buy, in a little wooden box, by a house in London, marked "pure pepsine," containing 80 per cent. of sugar of milk. With regard to the excuses that the public craving for cheapness had induced this adulteration, it was true that might have done something, but how about the competition of traders? If you told the persons you were selling it to that linseed meal is half of it grape refuse, would they buy it, however cheap it might be? He was rather surprised to find from a remark of Mr. Williams that magnetic oxide was frequently sold made from the refuse of blacksmiths' shops, and that showed the advantage of bringing forward this subject, as it elicited further information which could be used with discretion by pharmacists. This was another striking instance of what he had tried to prove, that adulteration was not confined to the dearer articles. Some time ago he examined a sample of capsicum which contained only twenty-five parts of red pepper, the other being common salt. That was an article which was cheap enough to be sold fairly, and the consumption was not very heavy. One gentleman said it could not be the fact that colocynth was adulterated; the next said it was a very well known fact that whole colocynth powder was always on the wholesale lists. His only object in touching on this subject was to show that that colocynth so marked on the drug list was not the proper colocynth to use, inasmuch as it only contained 2 per cent. of the active principle, while the real thing contained 14. If it appeared fifty times on a list it would not make it right or increase the percentage of colocynthin. He did not suppose that one in twenty who used it were aware of the difference in the quality. One gentleman made a remark that all the potato starch was made in Ireland, but it so happened there was not a particle of potato starch made there; the only starches made in Ireland were wheat and rice; the whole of the potato starch was manufactured in England, the two made there being potato and rice, but chiefly the latter. Somehow or other the question of the extract of colocynth had crept into the discussion, but he never said anything about the extract. What he dwelt upon was the fact that when a man sent colocynth to the drug mill he did not remove the seed. With regard to druggists as analysts, he merely introduced that question to point out that public analysts required an experience, and there were some excellent men amongst their number; but they required, besides actual reading and school education, an experience which was better got, in his opinion, under the tuition of an apothecary or a pharmacist than anywhere else. He did not believe that an intimate knowledge of drugs was to be got in a public chemical school In conclusion, he might remark that if they were to try to find excuses for this adulteration, which seemed to have been the tendency of the discussion, it was rather an acknowledgment of a leaning to immorality. If the laws of the country were wrong that was another matter, and if they were wrong they should get them altered.

The PRESIDENT, in proposing a vote of thanks to Pro-

fessor Tichborne, said he thought he had slightly misapprehended the tone of some of the remarks. The course of events was somewhat in this way. Certain charges of adulteration were thrown out, and a medical gentleman seemed to infer that those adulterations were general, and upon that assumption founded an argument that pharmacists were to be blamed in the matter. On the other hand it was contended that these cases of adulteration were more exceptional than general, and that as a rule, pharmacists were open to but little blame in such matters. During the adjournment he had explained to Dr. MacSwiney that however the case stood with regard to adulteration or contamination in some of the materials they employed, one thing was indisputable, that the whole history of the British Pharmaceutical Conference went to show that their efforts had been mainly directed to the discovery and prevention of these contaminations, and this he was happy to say Dr. MacSwiney freely admitted.

A vote of thanks was passed to Professor Tichborne.

The next paper read was entitled—

The Distinctive Tests for Carbolic Acid, Cresylic Acid, and Creasote.

BY ALFRED H. ALLEN.

Several previous observers have devised methods of distinguishing carbolic acid from wood-tar creasote, and have described tests which when applied to the pure substances leave little to be desired.

It appears, however, not to have been observed that cresylic acid, so largely present in the commoner kinds of carbolic acid, resembles creasote more closely than pure carbolic acid does, and fails altogether to respond to some of the tests which have been proposed to distinguish carbolic acid from creasote. As the substitution of coal-tar acids for wood-tar creasote is pretty certain to be made by the employment of a crude variety of carbolic acid, the presence in it of cresylic acid cannot rightly be ignored.

With a view to clearing up the discrepancies between the results recorded by other observers, and of ascertaining the most reliable tests for distinguishing carbolic and cresylic acids from wood-tar creasote, I have instituted a series of special experiments.

As the origin of some of the statements made by other observers cannot be traced, owing to imperfect descriptions of the substances on which they worked, I think it well to define carefully the exact substances on which my own experiments were made.

The *Carbolic Acid* was a sample of Calvert's No. 1. for internal use; boiling point 182° C.

The *Cresylic Acid* I prepared by fractional distillation of Calvert's No. 5 carbolic acid. The portion coming over between 125° and 205° C. was collected separately and again distilled, the first and last portions being rejected. The cresylic acid thus obtained boiled chiefly at about 197° C., but another smaller fraction boiled at 203° C.

I believe this difference is due to the presence of two isomeric cresols in coal-tar, having slightly different boiling points. Many of the experiments were made separately on both fractions, but without the least further difference in their properties becoming apparent. The distillations were conducted in an atmosphere of coal-gas.

The *Creasote* was a sample of Morson's wood-tar creasote. It boiled at 217° C, and so probably consisted chiefly of creasol, as guaiacol boils at 200° C.*

It was pointed out by Calvert many years ago that carbolic acid formed a crystalline hydrate, of the composition C_6H_6O, H_2O, which fused at 17° C. This fact is usually ignored by the bookmakers though well known to carbolic acid manufacturers. This hydrate would contain 16·07 per cent. of water. When water is gradually added to carbolic acid with repeated shaking, the crystals become liquefied, and at length a portion remains at the surface.

In order to ascertain how much water carbolic acid would take up, about 13 grams of the crystallized acid were melted and boiled for a minute or two in a small weighed test-tube to drive off traces of water. After cooling the whole was weighed. Cold water was then added gradually with repeated shaking until about ·2 c.c. remained as a layer on the surface of the liquefied acid. This was then removed by cautious use of wet blotting paper, and the residual carbolic acid weighed. 9·190 grams were found to have increased to 12·527, which gives 26·6 per cent. as the proportion of water in the liquid acid. On repeating the experiment a liquid acid containing 27·0 per cent. of water was obtained. This fact is of importance as showing that carbolic acid will take up far more water than is commonly supposed. The proportion is also of interest, as it corresponds pretty closely to the formula C_6H_6O, $2H_2O$.*

Hence the liquid acid may be regarded as a definite hydrate of phenol, but the fact that warm carbolic acid will take up a larger proportion of water than the above, and that the water is entirely separated by agitation with benzol is against this supposition.

On trying a similar experiment with cresylic acid I found that the water absorbed amounted to 13 per cent. of the hydrated acid. On repetition the product contained 14 per cent.

C_7H_8O, H_2O requires 12·7 per cent. of water.

In the subsequent experiments, when mention is made of hydrous carbolic or cresylic acid, the products obtained as above are to be understood,

1. *Action of Cold.*—Absolute carbolic acid is solid at ordinary temperatures, and the hydrous substance solidifies in a freezing mixture of hydrochloric acid and crystallized sulphate of sodium. Neither absolute nor hydrous cresylic acid, nor creasote, shows any signs of freezing on exposure to the same degree of cold.

2. *Solubility in Water.*—Twenty c.c. of water at about 170° C., dissolved 1·8 c.c. of hydrous carbolic acid. This corresponds to a solubility of 1 volume in 11·1 of water. Hence the saturated aqueous solution contains 8·56 per cent. by weight of the absolute acid, corresponding to a solubility of one part by weight of absolute acid in 10·7 parts of water. This is a far greater solubility than is generally attributed to carbolic acid, the discrepancy being probably due to an impure acid being generally used. In hot water carbolic acid is still more soluble.

Hydrous cresylic acid dissolves in about 29 measures of water at about 20° C., which represents a solubility of 1 part by weight of absolute cresylic acid in about 31 parts of water.

3. *Solubility at* 15·5° *C.* (=60° *F.*) *in solution of Caustic Soda containing* 6† *per cent. of* NaHO.—Absolute carbolic acid is completely soluble in an equal volume of soda solution containing 6 per cent. of pure NaHO (free from alumina). Addition of more of the alkaline solution up to 6 volumes causes no change, the liquid remaining clear. Absolute cresylic acid is insoluble in small proportions of 6 per cent. soda solution. When a large excess (9 volumes) is added, it disappears and forms distinct crystals.

Creasote is practically insoluble in 6 per cent. solution of soda.

4. *Solubility at* 15·5° *C. in solution of Caustic Soda containing* 9† *per cent. of* NaHO.—Absolute carbolic acid is soluble in an equal measure of 9 per cent. soda. On addition of any proportion of water up to 7 volumes the liquid remains clear, but is precipitated by 8 volumes of water. Carbolic acid is also soluble in 2 measures of 9 per cent. soda, and is not precipitated by less excess of the reagent than 5 or 6 measures. Absolute cresylic acid

* According to some observers, at 210° C.

* The theoretical proportion of water in this compound would be 27·69 per cent.

† These solutions contained respectively 94 and 91 grams. of water to each 6 and 9 grams. of pure caustic soda.

is soluble in an equal measure of 9 per cent. soda, but is precipitated when the proportion of the reagent is increased to $3\frac{1}{2}$ volumes. If to a clear mixture of equal volumes of cresylic acid and 9 per cent. soda, a few drops of water be added, precipitation occurs, and when the proportion of water is increased to one volume, the orginal bulk of cresylic acid separates out. Hence, cresylic acid is insoluble in two measures of $4\frac{1}{2}$ per cent. soda solution.

Creasote is insoluble in any smaller quantity than two volumes of 9 per cent. soda. It is partially reprecipitated when the proportion of the solvent is increased to more than three and half measures.

5. *Solubility at* 15·5° *C. in solution of Ammonia* (*sp. gr.* ·880).—Carbolic acid is completely and readily soluble in an equal volume of strong ammonia. The solution is not precipitated by addition of less than one and half volumes of water. A mixture of one part of carbolic acid and three of cresylic acid is soluble in an equal measure of ammonia, but the solution is precipitated on adding even a few drops of water.

6. *Behaviour with Benzol.*—Absolute carbolic and cresylic acid and creasote are miscible with benzol in all proportions.

The hydrous substances dissolve in five volumes of benzol with complete separation of the water. Hence benzol may be used for the determination of the proportion of water present in samples of carbolic and cresylic acid.

7. *With Chloroform, Carbon Disulphide, or Ether.*—Carbolic acid, cresylic acid, and creasote react in much the same manner as with benzol. Agitation with 9 per cent. soda removes them from their solutions in the above solvents.

8. *Behaviour with Petroleum Spirit of sp. gr.* ·669 (*Commercial "Benzoline"*).—Absolute carbolic acid dissolves half its volume of petroleum spirit, forming a clear liquid. On addition of a larger proportion of petroleum spirit precipitation occcurs.

With one volume of carbolic acid and three of petroleum spirit the layers have about the same measures as the original liquid. Each layer, however, contains both liquids, as may be proved by cooling the tube with a freezing mixture (or by wrapping filter paper round it and dropping ether on the outside), when carbolic acid crystallizes out.

Absolute carbolic acid is permanently soluble in about ten measures of petroleum spirit at 15·5° C. (=60° F.). The solubility is enormously increased by rise of temperature. Hence carbolic acid and *hot* petroleum spirit are miscible in all proportions. On the other hand, by cooling with a freezing mixture the carbolic acid is almost wholly deposited.

If the cooling occurs slowly, it forms a heavy liquid layer with a portion of the petroleum spirit, but by rapid cooling the carbolic acid is deposited in long crystalline needles which render the liquid semi-solid.*

Hydrous carbolic acid is almost insoluble in moderate quantities of cold petroleum spirit, which liquid does not separate the contained water from it. (Another difference between benzol and petroleum spirit.) Absolute cresylic acid appears to be miscible with petroleum spirit in all proportions.

No separation, either of crystals or liquid, occurs by exposing a solution of one measure of the acid in three of petroleum spirit to a freezing mixture.

When hydrous cresylic acid is treated with cold petroleum spirit the volume of the former increases somewhat by dissolving a little of the spirit, but on addition of a greater volume of petroleum spirit it undergoes slight solution. It is only very sparingly soluble in petroleum spirit, requiring upwards of twenty volumes for complete solution, when the water separates. Creasote is miscible with petroleum spirit in all proportions.

9. *Behaviour with Glycerin of* 1·258 *sp. gr.*—Absolute carbolic acid is miscible with Price's glycerin in all proportions. A mixture of one volume of carbolic acid with one of glycerin is not precipitated on addition of three volumes of water. In presence of 25 per cent. of cresylic acid precipitation occurs on adding more than two volumes of water.

Absolute cresylic acid is miscible with Price's glycerin in all proportions. A mixture of one volume of glycerin and one of cresylic acid is completely precipitated by one volume of water.

Creasote is insoluble in Price's glycerin, whether it be added in the proportion of one, two, or three volumes for one of creasote. The sample of Price's glycerin used for the above experiments was found to have a density of 1·258.

10. *Behaviour with Collodion.*—Absolute carbolic or cresylic acid, when shaken with half its measure of *Collodium, B.P.*, precipitates the nitrocellulose in a transparent gelatinous form, very difficult to see. It is best observed by inclining the tube and causing the liquid to flow gently from one end to the other. Creasote does not precipitate the nitro-cellulose from collodion, but mixes perfectly with its ethereal solution. Addition of much creasote to a mixture of collodion and carbolic or cresylic acid causes the re-solution of the precipitated nitrocellulose.

11. *Reaction with Ferric Chloride.*—The addition of one drop of a 10 per cent. aqueous solution of ferric chloride to 15 c.c. of an aqueous solution of cresylic or carbolic acid causes a permanent violet-blue coloration. When creasote is similarly tested a blue colour results which almost instantly changes to green and brownish-yellow.

Other distinctive tests for creasote and carbolic acid are to be found in the books, but are almost worthless in practice. Thus the reactions with bromine, sulphuric acid, and nitric acid are far too much alike to be of service for distinguishing between these bodies. It has been stated that creasote differed from carbolic acid in its power of rotating a ray of polarized light. I redistilled a sample of Morson's creasote to obtain it colourless, and carefully tried this test, expecting to find in it a possible means of determining the creasote in a mixture, but the rotating powers of creasote proved so exceedingly weak as to be quite worthless for the intended purpose, or even as a qualitative test. It is, however, quite possible that different samples of creasote may exhibit considerable differences in this respect, but if so the test is valueless for qualitative purposes, and the problem is not so much to detect wood-creasote as to recognize an admixture of the coal-tar acids. I am also unable to confirm the statement that creasote gives a solid deposit when kept for some hours at the temperature of boiling water.

I have not obtained satisfactory results by the reaction of an alkaline solution of the substances with hydrochloric acid and pine-wood, or with a solution of iodine in iodide of potassium. Sulphomolybdic acid, also, gives a blue colour alike with creasote and carbolic acid, even when the test is applied to an aqueous solution of the sample.

From the foregoing details it will be seen that in various manners carbolic acid, cresylic acid, and wood-tar creasote can be readily distinguished from each other. The case, however, is very different when we have to deal with a mixture of the three substances, such as occurs in the case of a sample of creasote adulterated with crude carbolic acid. In such a case many of the tests are greatly reduced in value or rendered absolutely worthless. As the problem is to detect the coal-tar acids in presence of wood creasote, rather than the reverse,

* Crystallized carbolic acid may be used for distinguishing between coal-tar benzol and petroleum spirit. In the latter it is sparingly soluble, and is re-deposited in a crystalline state by rapid cooling. With benzol it is miscible in all proportions, the crystals of carbolic acid rapidly melting. A solution of one in three deposits no crystals by rapid cooling.

only affirmative tests for the former bodies are of service, and in many cases these are seriously modified by the simultaneous presence of creasote. Thus, as has been pointed out by Mr. J. Williams, the ferric chloride test entirely fails to detect the presence of carbolic acid in a mixture of equal parts of that substance and creasote.

The only marked differences I have been able to observe between Morson's creasote and a mixture of equal measures of that liquid and Calvert's No. 5 carbolic acid are the following:—

When shaken with twice its bulk of 9 per cent. soda solution, pure creasote is dissolved, and remains in solution when the solvent is increased to three volumes. The *mixture* was insoluble either in two, three, or four times its volume of 9 per cent. soda. This anomalous result proved to be due to the presence of water, which reduced the strength of the soda solution. When the water was previously expelled by boiling from the mixture of crude carbolic acid and creasote, solution took place with two volumes of soda.

When shaken with Price's glycerin (sp. gr. 1·258) pure creasote remained undissolved, though the proportion of glycerin was varied from one to three volumes. The mixed creasote dissolved completely and readily in an equal measure of glycerin. The liquid was not affected by a drop or two of water, but a further addition caused precipitation A mixture containing 25 per cent of creasote, when shaken with an equal measure of glycerin, was not precipitated by less than 1¼ volumes of water.

Shaken with half its volume of collodium (B.P.), pure creasote dissolved to a clear liquid. The mixed creasote showed decided signs of precipitation when the liquid was allowed to run gently from one end of the tube to the other. With a mixture of two volumes of Calvert's No. 5 acid to one of creasote, the precipitation of the nitrocellulose was very marked.

As carbolic acid, cresylic acid and creasote boil at temperatures tolerably widely apart, I thought it might be possible to effect a sufficient separation by fractional distillation to enable the tests for the coal tar acids to be more readily applied. For this purpose I introduced a mixture of No. 5 carbolic acid and Morson's creasote into a small retort and distilled the liquid. The water, which first came over, was collected separately. The next portion of the distillate (amounting to about one-fifth of the whole bulk of the liquid) was boiled to free it from a little water, and was then tested with glycerin and with collodion. It dissolved readily in the glycerin, and precipitated half its volume of the collodion. Hence the carbolic acid of the mixed creasote was fairly detected, and there seems no reason why fractional distillation should not serve for the detection of smaller proportions of carbolic acid, as it will certainly be most abundant in the first portions of the distillate. The ferric chloride test was not found of service for testing the distillate, sufficient creasote being present to produce a decided brown coloration.

As the tests with glycerin and collodion are the only reactions of service with mixtures of carbolic acid and creasote, I did not think it necessary to apply the other tests to the distillate.

It will be seen from my experiments that the high value usually attached to the glycerin test is amply justified. It has been stated that pure creasote was soluble in anhydrous glycerin. This is certainly not my experience; but if it be true that some varieties of creasote dissolve in absolute glycerin, they will doubtless be precipitated by the least dilution, and can thus be distinguished from mixtures containing considerable proportions of the coal-tar acids.

Mr. J. Williams examined a sample of German creasote which was supposed to be pure, and which dissolved in glycerin; but the fact that 40 per cent of the sample distilled at 200 to 203, together with other characters, renders it very probable that it contained an unacknowledged mixture of the coal-tar acids. It must not be forgotten that cresylic acid is much cheaper than carbolic, and is far more difficult to distinguish from creasote, even when unmixed with it.

I have thought it best to place my results on record in the fullest possible detail, as it is just the omission to do this that has caused so many confusing and incorrect statements to appear in our text-books. The tests described are remarkably liable to failure when the conditions are slightly varied. This is notably the case with the reactions with solutions of soda, a change of temperature or strength of the solvent causing extraordinary variations in the results.

Mr. Williams said Mr. Allen did not seem to have read or remembered his paper quite accurately, and he must remind him that he made some pure guaiacol (or creasote) from guaiacum itself, so as to be quite certain that it was free from carbolic acid. He found it was perfectly insoluble in Price's glycerine, but when he mixed 30 per cent. of carbolic acid with it that mixture was perfectly soluble. He also found Morson's creasote insoluble in glycerine, and therefore concluded that it had all the characteristics of true creasote. Still when this was mixed with 30 per cent. of ordinary crystallized carbolic acid, the mixture was perfectly soluble. What he attempted to do in his former paper was to find a test, if possible, to distinguish carbolic acid when mixed with creasote, but, although he could easily find a test which would distinguish carbolic acid from creasote when separate, the conclusion he came to was that he was quite unable to determine the admixture of the two. The assumption he arrived at was, that as the German creasote dissolved in glycerine, it must be like the guaiacol or Morson's creasote when mixed with carbolic acid.

Mr. Allen said he did not understand that that was the result of Mr. Williams's paper. He understood him to believe that the sample he examined was pure. It appeared from what Mr. Williams now said that they were quite agreed as to the mixed character of that creasote.

Mr. Groves asked if Mr. Allen was quite sure that Morson's preparation was always identical and uniform.

Mr. Allen said he was not sure at all; he did not know anything about it. He had experimented on a sample of Morson's creasote, and described it as nearly as he could. Messrs. Morson would no doubt be able to say whether their preparation was always the same.

A vote of thanks was given to Mr. Allen.

(*To be continued.*)

Parliamentary and Law Proceedings.

Suicide of a Chemist and Druggist by Prussic Acid.

Mr. C. J. Carttar, coroner for West Kent, held an inquest on Tuesday, at Lewisham, on the body of Thomas Sturton, aged 62, a chemist and druggist, of 102, Douglas Street, High Street, Deptford, who had been found dead on the previous Friday morning by a coachman named Latham Brown, in a gravel-pit on Blackheath.

Dr. Prior Purvis said he was called in to see the deceased, who had been dead about half an hour. In his breastcoat pocket was a bottle which had contained Scheele's prussic acid, a poison about five times as strong as the prussic acid used for ordinary purposes of dispensing. Death must have been almost instantaneous, and it was a remarkable circumstance that deceased, after swallowing the poison, could have put the stopper in the bottle and the bottle in his pocket. The bottle would hold 480 drops of the poison, 20 or 30 of which would have been enough to produce death.

Julia Sturton, daughter of the deceased, said that about half-past seven on the morning in question her father went out, saying he was going to be shaved. She

heard in a few hours after of his having been found dead. Of late he had been seriously depressed in mind. Some time ago he lost the sight of one eye, and he seemed to have an idea that he would eventually lose the other, and thus become a burden to his relations. He had also suffered much mental anxiety through having been bitten by a dog. A short time ago he was at a person's house, and left a letter addressed to his home, requesting the lady to post it for him. She opened it directly he was gone, and found it was a farewell letter. Her husband went after deceased, and found him on the bank of the canal. It was with great difficulty he was got home. He had frequently expressed a dread that he would come by an unnatural end. He kept the prussic acid for poisoning dogs.

The jury returned a verdict of "Suicide whilst of unsound mind."

Dispensing Memoranda.

[117]. Tinct. Cardamom.—Two or three weeks ago there appeared in the *Pharmaceutical Journal* a question bearing on the subject of tinct. card. I should have imagined, with the Editor's remarks thereon, the subject would have dropped. However, as your correspondent who subscribes himself A. P. S., has thought fit to renew the subject, I may be excused if I add my quota. Each answer to the question bears a certain amount of plausability.

The plan I adopt in such cases is to endeavour (if possible) to communicate with the prescriber, that failing, to question the patient as to the general appearance of the mixture, etc., or in case of failure from both sources, to dispense the recognized B.P. preparation. This I think is the general rule in first class dispensing establishments.

I think A. P. S. has made an error in quoting tinct. card. as in the 1851 P.L. I find that (to use the Editor's words) it occupied a place in the 1836 P.L.

J. T. Griffin.

23, *St. Nicholas Cliff, Scarborough.*

---

[147]. Liquor Secalis Ammon.—In addition to the notes published last week, letters have been received from Messrs. Ferris, of Bristol, and Mr. Colchester, of Hoxton Square, who both claim to have introduced the preparation referred to, and others stating that it has been made many years by Messrs. Curtis, of London, and Messrs. Harris and Co., of Birmingham. Any further discussion as to priority must be excluded as unsuited to these columns, but they will be open to remarks upon the original question, as to what a dispenser is justified in using when such an ingredient is ordered in a prescription.—Ed. Ph. J.

---

[154]. In answer to "Sub Umbra Floresco," ung. acidi carbolici is prepared according to the formula of the Royal Bristol Infirmary, and consists of:—

℞ Glycerini Acidi Carbolici . . . . . ℥ss
Ung. Simplicis . . . . . ad ℥j
Misce.

F. J. K.

---

[154]. The following is the formula of St. George's Hospital:—

℞ Acidi Carbolici . . . . . gr. x.
Hydrargyri Ammonia-Chlorid. . . . gr. x.
Axungiæ . . . . . ℥j
Misce.

F. J. Kilner.

---

[154]. Ung. Acidi Carbolici.—Might I, as a medical man, but one who is a constant reader of the Journal, suggest to your correspondents the propriety of either using initials, or appending their names, to the communications sent to you. It would be so much easier for those who, like myself, desire to impart a little information, to reply to "James So-and-so," than to such an one as "Sub Umbra Floresco," or such cognomens as Oχθαί. I verily dislike anonymous appendages such as I have mentioned.

The formula for carbolic acid ointment, according to that given in the United States Pharmacopœia, is carbolic acid, 60 grains, and ointment, 420 grains. Benzoated lard should be used, or any simple ointment. Squire gives 30 to 60 grains to 1 oz. of benzoated lard.

If applied to an abraded skin, it may give much trouble, and even induce poisonous symptoms. H. Brown.

---

[155]. Ol. Morrhuæ c̄ Æth. Sulph.—In ordering this combination it should be borne in mind by the prescriber that ether may be given with cod-liver oil in all proportions, so that to leave the dose of ether to "Sub Umbra Floresco," or any other person, is, to say the least, injudicious. Twenty drops of ether, with a tablespoonful of cod-liver oil, three times a day, shall we say, is a good dose, and one which the great majority of stomachs will soon sicken at. If a person can take the tablespoonful of cod-liver oil, I should not recommend more than five or ten drops of ether to each dose. If a dessertspoonful is ordered, the same dose—five to ten drops—of ether is sufficient. The doses, however, should be settled by the medical attendant, not by the pharmacist.

H. Brown.

---

[155]. Ol. morrhuæ c̄. ætheris sulph. is dispensed at the Bristol Royal Infirmary as follows:—

℞ Ætheris Sulph. . . . . ♏xx.
Ol. Morrhuæ . . . . . ad ℥j
Ter die.

F. J. Kilner.

---

[156]. When liq. plumbi subacetatis is prescribed with aq. pura, distilled water should be used, otherwise carbonate of lead would be precipitated, due to the carbonic acid gas contained in ordinary water.

F. J. Kilner.

---

[156]. Liq. Plumbi Subacet.—Distilled water should be used in making lotions containing liq. plumb. subacet.

The term aq. pura may, or may not, mean distilled water. For example, aqua was introduced into the Edinburgh Pharmacopœia, and was used for making some preparations instead of distilled water. We are told the College was censured for this innovation, but Sir Robert Christison remarks "that no one would have made this criticism who was acquainted with the hydrography of the country for which chiefly the Edinburgh Pharmacopœia is intended."

But even this aqua is not altogether pure, although the Scotch boast, and justly too, of the quality of it.

Rain water also contains ammonia, some salts, and organic matter, according to the mode of collecting it and its storage. It thus follows that the only water which should be used in making lotions of subacetate of lead is distilled water, and although aqua, or aqua pura, may be good enough for some pharmaceutical purposes, in the case above, only distilled water is admissible, and it should also be free from carbonic acid.

Northallerton. H. Brown.

---

[157]. Liq. Copaib. Alk.—Can any correspondent inform me what should be used for the first item in the following prescription and what the general appearance of the mixture should be when dispensed?—

℞ Liq. Copaib. Alk. . . . . ℥iij
Liq. Potassæ . . . . . ℥j
Syrup. Aurant. . . . . ℥j
Inf. Buchu . . . . . ad ℥xii
Sign. ℥ss ex aquâ ter die.

Nuncio.

[158]. Will some reader kindly inform me the best method of dispensing the following prescription?—

℞	Ol. Pini Sylvest. (Laritz)	℥i
	Tinct. Benzoin. Co.	℥i
	Magnes. Carb.	gr xxx.
	Aq. Puræ	℥iij

M. ft. vapor.

M. A. T.

[159]. EXPLOSIVE MIXTURE.—This morning I dispensed the following prescription:—

℞	Sodæ Bicarb.	℥ij.
	Bismuth. Alb.	℥ij.
	Sp. Ammon. Ar.	℥ij.
	Sp. Chloroformi	℥j.
	Aquæ	ad ℥viij.

The bottle was laid on the counter awaiting to be sent out. After it had lain about an hour it burst. What could be the cause of it? I may say the same prescription has been dispensed for the same customer before, and such a thing had not occurred.

AN ASSISTANT.

[160]. I had the enclosed prescription to dispense lately. Should it be sent out with a "shake the bottle" label on or not?—

℞	Sodæ Bicarb.	℥j.
	Vin. Opii	℥ss.
	Liq. Bismuthi	℥j.
	Sp. Am. Arom.	℥jss.
	Sp. Chlorof.	℥jss.
	Aq. Calcis	ad ℥vj.

M. ft. mist.

J. W. SAVAGE.

[161]. Will some one kindly tell me how to dispense the following mixture so that it may be sent out perfectly clear?—

℞	Ferri et Quinæ Citratis.	℥iij.
	Tr. Valer. Co.	℥vj.
	Aquæ Puræ	ad ℥xij.

M. ft. mist.

W. W. B.

[162]. The following is a copy of a prescription received some time ago. I should be glad to know if it can be dispensed without a separation taking place of one of the principal ingredients:—

℞	Potassæ Acetatis	℥ij.
	„ Chlorat.	℥ij.
	Tinct. Calumbæ	℥ss.
	Aq. Camph.	ad ℥iij.

Ft. mist. Coch. magn. duo t. d. s.

I may add that the result I obtained was the separation of a white crystalline precipitate, which I found to be potassium chlorate.

INQUIRER.

Notes and Queries.

[519]. LIME JUICE CORDIAL.—"Ipse" would feel much obliged by a recipe for lime juice cordial that will not ferment.

[520]. TEREBINE HAIR WASH.—Can you oblige us with a form for "terebine hair wash."

BALKWILL AND ELIOTT.

[521]. ARQUEBUSADE.—Will any reader kindly oblige with good formula for "Arquebusade"?

CHEMIST AND DRUGGIST.

Correspondence.

VIOLET POWDER.

Sir,—I observe that the question, "What is violet powder?" continues to call forth the expression of opinions, the existence of which among the intelligent class of dealers in this article, represented by your readers, seems to indicate a radical defect in the conditions under which the article is supplied to the public. It has been clearly shown that there are two varieties of violet powder commonly sold, one of which consists principally of starch, while the other consists principally of finely powdered selenite. Each of these varieties of the article has its advocates, who have assigned reasons for their preference, and I believe there are substantial grounds for preferring, and also for objecting to, each of the two varieties in particular cases. If I find that powdered selenite answers the purpose I require it for better than starch, why should I not be allowed to use it? Yet the next time I ask for violet powder I may perhaps not be supplied with the sort I require. The mistake has been in applying the same name to two essentially different articles, and for this it appears to me that there is a simple and effectual remedy, which the makers of violet powder may easily adopt, without injury or inconvenience to themselves or the public. I would suggest that without reference to minor differences, which may still exist, all violet powder which consists principally of starch should be labelled "amylaceous violet powder," or "violet powder (amylaceous)," while that which consists principally of selenite should be labelled "selenitic violet powder," or "violet powder (selenitic)." Other names might be similarly constructed to suit particular manufactures, such as amylo-selenitic or amylo-steatitic. The public often like long names, especially if they cannot easily interpret them. It might then be left to those who use these articles to decide which they prefer to have. In such a case the old woman whose opinion has been formed from direct observation and daily experience is quite as capable of judging as the professional man whose knowledge is obtained second-hand and whose judgment may be chiefly based on theoretic considerations.

17, *Bloomsbury Square.* T. REDWOOD.

WHAT IS VIOLET POWDER?

Sir,—This question may now I think be allowed to disappear from your pages. The discussion on the subject at the Conference, as reported in the present issue of the Journal, has fully answered the questions raised in my letter of the 7th inst. After reviewing all that has been said the weight of evidence largely preponderates in favour of starch pure and simple. It may be all very well to say that the different earthy matters have never done any harm, but the harm may have in a great many instances existed and been attributed to other causes. This was the case with the arsenical compounds at first. Mr. Umney did well to instance the Bradford lozenge case. Once begin these substitutions and there is no telling in what sort of catastrophe the practice will end. Steatite or French chalk is not always of the same nature or composition. Hydrated sulphate of lime I apprehend is only a waste product, and if it can be procured so cheaply as has been stated, no great care can be bestowed on its purity. Free acid may happen to be present in a sample now and then, or some metallic contaminations. Why have these earthy substitutes been introduced? It has not appeared during the controversy that any body has thought them better for the purpose, with one exception only. The only reason which I have been able to gather is that they have enabled certain wholesale dealers to sell an article at a less price, and in a case of this kind it is a questionable benefit. Foolish as the public analysts may sometimes appear, it must be admitted that it is not quite so easy to poison the public as it once was. The law is a terror to evil doers.

ROSICRUCIAN.

"Violet Powder."

Sir,—Mr. Groves is mistaken in saying at the Conference that a respectable chemist in Birmingham had been fined 20*s.* for selling violet powder not made of starch. I can assure you that no such prosecution has taken place here.

Birmingham. W. J. Churchill.

Dangerous Doses and Difficult Problems.

Sir,—The subject of Mr. Thomas Greenish's letter in the Journal of to-day is one of great importance and interest, not only to the medical profession but to pharmacists in general.

In treating such a subject, one requires to avoid anything which savours of dogmatism, and the best mode of procedure is to adduce facts and quote authorities. This I intend doing.

The question is this: Is a chemist justified in compounding a prescription for eighteen pills, ordering one and a third grains of powdered cantharides in each pill, said dose to be taken three times a day for six consecutive days? To this I answer, Yes. Why? Because it is not a poisonous dose, and the whole twenty-four grains of cantharides, if taken at once (a thing not likely), would only be the smallest quantity known to destroy life. This quantity (twenty-four grains) was given to a young woman in two doses and she died in four days, abortion having taken place, but twenty grains have been taken and recovery has followed, as also after a dose of two drachms. A boy died after taking one ounce of the tincture, in fourteen days, and Dr. Taylor says, "this is the smallest dose of the tincture which has proved fatal." One ounce of tincture is equal to five and a half grains.

Beck and Pereira quote a case in which six ounces of tincture were swallowed, but the authority, Dr. Hosack, from whom they derived the information, fails to say what the strength of the tincture was. Dr. Pereira adds, "in contrast with this I may instance a case that came within my own knowledge where one ounce of the tincture produced serious symptoms." Amoreux says, in one case a pinch of the powder caused death! Be this as it may, the dose of one to two grains has been given frequently to patients without poisonous symptoms supervening after administration, and I have myself given in the form of pill, in a case of obstinate gleet, freshly powdered cantharides for three weeks, with good effect, in grain doses three times a day. I say, therefore, if I were a chemist I should have no hesitation in compounding a prescription for eighteen pills, each pill containing a grain and a third of powdered cantharides.

I think this is a complete and satisfactory answer to Mr. Thomas Greenish's question, "This being the prescription of a medical man in practice, consequently a legitimate prescription and one stamped with the emphatic sanction of the writer, should it, notwithstanding the large dose of cantharides, have been dispensed?" I say again, it should have been dispensed because the dose is not large, but within that which has often been given with benefit.

The second question is only one of pharmaceutical or apothecaries' ethics.

Mr. Greenish asks, "If it was right to dispense it as a prescription ordering eighteen pills, sufficient for six days, should it have been dispensed when the conditions were altered by the patient's requiring one hundred pills, or sufficient for five weeks, on the plea that he was going abroad?" Decidedly it should. Why should "Beta" scruple when he had the sanction of the medical man by letter? Does "Beta" always tell the folk who favour him with their patronage what each prescription contains? Surely not. Who would not condemn a chemist for refusing to give, say, one ounce of Fowler's Solution to a customer who presented a prescription for the same? Yet in the case of the arsenical solution or strychnia solution, when ordered to be taken in drops, if we medical men so order these potent poisonous solutions, and give into the hands of our patients quantities sufficient to produce death in several persons,—why, I ask, should "Beta" hesitate, and at last absolutely refuse, to compound a prescription which was sufficient to last for six days, seeing that twenty-four grains of cantharides have only caused death when swallowed in four days, in one case. Also I say, with all due regard, "Beta" should have given the one hundred pills. He need not have been afraid, because, if irritation of the bladder was produced, or if strangury followed after the pills had been taken for some days, be assured the patient would soon leave off of his own accord, and it would not require much persuasion to induce him, nor the application of the straight jacket either. There are other points which I might touch upon and which bear upon the subject brought forward by Mr. Greenish, but I leave them for the present, as I am unwilling to occupy too much space now, and conclude by hoping that some others may express their sentiments upon the same subject, as it well deserves attention.

Henry Brown, L.R.C.P., and L.R.C.S., etc.

Northallerton, 14th September, 1878.

Dangerous Doses and Difficult Problems.

Sir,—That over-dose prescriptions have been attended with great anxiety to dispensers cannot, I think, be denied, and why this unnecessary burden should be borne by them is a question which must need some answering.

I think it is quite time that some definite understanding be come to between prescriber and dispenser as to some mark of attestation against all over-dose ingredients, which are for some special object of the prescriber intended for administration, and this might easily be done by the medical man affixing his initial to any ingredient whose dose exceeded that of the Pharmacopœia; this done, the dispenser would be free from all anxiety and the responsibility would rest with the medical man alone.

If some such method be not adopted how are we to decide whether the over-dose be intentional or mishap? That some prescribers are oftentimes exceeding the Pharmacopœia dose there can be no denying; indeed, I have been informed by more than one medical man, that most of the doses of the Pharmacopœia might be exceeded by 50 per cent., without causing any ill effect! Well, this may be so; whether it is so or not is not for me to decide. I, as dispenser, am to answer by the text laid down in my official guide, and any departure from that I am responsible for, unless said departure be distinctly authorized by the special initial of the prescriber to the particular ingredient.

In the case which Mr. Greenish calls attention to in last week's Journal, I quite think the dispenser was justified in acting as he did, and in reply to the first of Mr. Greenish's queries, viz., "This being the prescription of a medical man in practice, consequently a legitimate prescription, and one stamped with the emphatic sanction of the writer, should it notwithstanding the large dose of cantharides have been dispensed?" I should say certainly not, unless the cantharides itself had been specially initialed. Without this I should have considered it my duty to either see or communicate with the medical man.

The second question suggested by Mr. Greenish is, "If it was right to dispense it as a prescription ordering eighteen pills, sufficient for six days, should it have been dispensed when the conditions were altered by the patient's requiring one hundred pills, or sufficient for five weeks, on the plea that he was going abroad?"

I think where so active a medicine as cantharides is prescribed in a large dose, we are certainly not justified in repeating the prescription unless so directed by the prescriber. The eighteen pills may have been necessary to obtain some special result, but the one hundred as demanded by the patient would probably cause much injury.

It is all very well to say we should or ought to use individual discretion in such matters; we have to do this and very often too, but in these days when our actions are so much surrounded by the law, it becomes necessary for us to look at doubts in their legal bearings and so keep clear of the rough handling of the coroner, and, by no means profitable, censure of the jury.

September 16, 1878. Wm. Lane.

Counter Prescribing.

Sir,—The somewhat elaborate plan suggested by Dr. Williams for putting a stop to counter prescribing which is hailed with such satisfaction by two or three of your correspondents is a scheme which looks well enough in theory, but I fail to see how the profession and trade are to be induced to adopt and carry out such a compact, or how any restriction is to be applied to prevent departure from it should it be once adopted.

We are by no means sure either that the public whose co-operation would be needful would assent to such a plan.

In cases of sudden illness would it not be annoying to have to go first to the doctor for his attendance or prescription, then perhaps a considerable distance to a chemist to have the medicine put up. I fear those in the country who often have to send miles to the doctor, would think it intolerable to have (in the night perhaps) to call up the chemist also.

The doctor has suggested a very moderate scale of charges for dispensing medicines; nevertheless I do not think the trade would object to the terms, provided dispensing were handed over entirely to them. In many districts the poor are already prescribed for by the chemist on a scale quite as low as that proposed by the doctor, but to compel them to pay the professional fee in addition, will I think be a difficulty.

I have not yet been able to see that the prescribing chemist is a nuisance that must be put down. On the contrary one would naturally think that next to the professional man he is, from the nature of his calling, well fitted to be consulted in simple cases. Instead of which he is to be the only one legally restricted from giving advice.

A Country Chemist.

Sir,—I have been carefully scanning the columns of your Journal for some time, in the hope of seeing some such suggestion as I am about to make. As no abler hand has taken the matter up, I venture to lay my suggestion before the members of the Pharmaceutical Society, that they may consider the matter seriously, and I trust put such pressure upon the members of their Council as will bring them to realize the real wants and necessities of the trade. As a member of the Pharmaceutical Society I have always felt that it would be a pity and somewhat anomalous if the Council, through its law agent, were to be drawn into court in defence of any case of prosecution by the Apothecaries' Society. The two bodies are so identical in their operations as examining and licensing bodies, that I think nothing should have been done on either side to bring them into open antagonism. Circumstances change, however, and so do our opinions; I have to confess that my opinions on the above point have changed, and I am very glad to say that this has not been produced by any direct action on the part of the Pharmaceutical Council. I think the Court of Apothecaries have had no cause for complaint of the conduct of our Council. It becomes a serious matter, however, for the trade in general and for very grave consideration on the part of our representatives at Bloomsbury Square, when we find that the Court of Apothecaries are giving their influence toward the prosecution of chemists and druggists for legitimately advising their customers over their counters, just as one friend would advise another, but are also subscribing liberally of their funds to assist such unjust and unnecessary prosecutions. When we hear of such bodies as the British Medical Association subscribing for such a purpose, it behoves us to look at the matter fairly and see what we can do. I think the trade cannot be too grateful to the gentlemen who took upon themselves the formation of the Trade Defence Association, and also to yourself, Mr. Editor, for having enabled that association to be launched without any unjust or harsh criticism. I therefore trust that the appeal made by the executive of that body to raise a guarantee fund of £2000 shall not be in vain, and that those who appreciate the noble stand, taken in the interests of the trade, will subscribe liberally towards it. In connection with this matter (and this is the point I wish specially to refer to), the question arises, Is the Pharmaceutical Council not bound to do something directly for the trade in this matter? I think the correspondence you published some time age, between Mr. Flux and Mr. Upton, taken in connection with previous and still more recent action, to be most unsatisfactory; and there seems to be nothing left for the Council but to buckle on its armour and do its very utmost to defend the trade. The Trade Association is prepared to do the necessary work, and the very least the Council can do is to vote a sum of money in aid of that association's guarantee fund. I think £500 not too much, and therefore hope that Mr. Fairlie or some other member will bring the matter up at the Council board again.

Now, when danger threatens us, let us be united in resisting such aggressive claims as are put forward on the strength of an Act of Parliament, which for two generations has been a dead letter. Let there be no half-hearted action, and we shall then learn who are the real representatives of our trade.

Edinburgh. Siegel.

Morphia Reactions.

Sir,—In your issue of September 14, p. 206, will be found a paper on "Morphia Reactions," by Mr. David Lindo, in which the author proposes the use of a solution of ammonio-sulphate of copper as a reagent for the detection of morphia, a bright green colour being produced when this liquid, under certain conditions, acts upon a solution containing morphia. Mr. Lindo states, "I have not seen this colour reaction mentioned before, and, as it might sometimes prove useful as a confirmatory test for morphia, I have endeavoured to ascertain the conditions most favourable to its development."

Allow me to direct Mr. Lindo's attention to the fact that this reaction was first noticed and thoroughly investigated by Nadler, whose results are published in a paper in the *Swiss Journal of Pharmacy* for 1873, p. 5, abstracts of which appeared in the *Jahresbericht*, 1873, p. 328, in the *Pharmaceutical Journal* [3], v., p. 47, and in the *Journal of the Chemical Society*, 1874, p. 589. The test is also to be found in Professor Attfield's 'Manual of Chemistry,' in the chart facing p. 550 (6th ed.).

The reagent which Nadler employs is made by dissolving well washed hydrate of copper in solution of ammonia. The liquid thus obtained does not deposit on boiling, and is consequently preferable to Mr. Lindo's solution of ammonio-sulphate of copper. The investigation of the origin of the green colour resulted in the discovery of an alkaloid probably identical with Schützenberger's oxymorphin.

Henry G. Greenish.

20, *New Street, Dorset Square.*

Pharmacopœia Query.

Sir,—My attention was recently directed to the Pharmacopœia, page 279, where I find resina scammoniæ placed under the head of "Preparations of Scammony."

Surely this is an error, as the resin is ordered to be prepared from the dried root, see page 278. The remarks that have appeared under "Dispensing Queries" respecting the dose of scammony, and a visit of our local inspector for half an ounce powdered scammony for analysis caused me to refer to the Pharmacopœia for information.

Sandown, I. W. George Brown.

"*Ferrum.*"—An amber liquor can be prepared by digesting dragon's blood (1 part) with sulphuric acid (4 parts) and diluting the solution obtained to the required shade with distilled water.

"*David.*"—See before, p. 169, for the procedure for obtaining registration under the Dental Act.

W. B. O.—The exemption of chemists and druggists from jury service has not been lost sight of. A Government Bill, dealing with the laws relating to juries, has been before Parliament more than once, but has been crowded out by other legislation. In this bill, which no doubt will be brought forward again when there is an opportunity, the Council of the Pharmaceutical Society has secured the insertion of a clause extending the exemption to all chemists and druggists.

A. Z.—Very much would depend upon the nature of the fluids, and altogether the subject is one for experiment. See, however, 'Taylor on Poisons.'

The Dental Bill.—We have received, with a request for publication, from Mr. Westlake, of Windsor, a statement of the receipts and expenditure connected with the presentation of a petition to Parliament for the amendment of the Dental Bill, by the insertion of the word "pharmacy," necessary to remove the ambiguity that characterized the Bill upon its first introduction with respect to the right of pharmacists practising dentistry to registration. The subscriptions received by Messrs. Westlake and G. J. Gostling amounted to £11 2*s.* 9*d.*; the expenditure to £9 17*s.* 9*d.*; and the balance of £1 5*s.* has by request been handed over to the Chemists' Trade Association.

"*Subscriber since* 1870."—As your question involves considerations of considerable importance, we think that a legal adviser would be your best guide at least so far as the law is concerned.

Communications, Letters, etc., have been received from Messrs. Jackson, Leigh, Manning and Co., Young, Griffin, Swinn, Boothing, Turner, Corder, Jackson, Moss, Smith, Davy, Watson, Major, Machaon, Pharmacist, Chemicus, David, Gita, Sub Umbra Floresco, Tenens, R. W. W., A. E. C., A. E. R.

"THE MONTH."

The brown tints of autumn are now everywhere visible, and the "sere and yellow leaf" forms a common although pretty feature in the landscape. In gardens, too, the flowers are beginning to show a withered and stricken appearance. But the recent warm and moist weather succeeded by rain and wind, while it has stripped the trees and scattered the dead leaves far and wide, has given life in abundance to another form of vegetation; and the woods are now decorated with the bright red, green, amethyst, yellow, orange, brown, and pure white tints of innumerable fungi, which this year are unusually abundant. The amount of ignorance which prevails with regard to these plants is greatly to be deplored, since it frequently results in loss of life.

Only a few days ago two Swiss nurses, visiting Hampton Court, ate some fungi on the Sunday and were dead on the Monday. Although there are many fungi which form excellent food, yet most of them have, so to speak, poisonous twin brothers, so like them that only the practised eye can distinguish them. Thus the delicious *Lactarius deliciosus*, the taste of which has been likened to lamb chops, has a poisonous counterpart in the *Lactarius torminosus*, which is only distinguishable by the downy or hairy margin of the cap and the white milky juice. The pretty yellow chanterelle (*Cantharellus cilarius*), which possesses an odour of apricots, is parodied by the *Cantharellus aurantiacus*, differing only in its smaller size and in having the gills of darker colour than the cap, and the *Boletus edulis* is mimicked by several other species of *Boletus*, in most of which, however, the flesh of the cap turns blue when broken. Respecting this plant, a correspondent Mr. R. Goodwin Mumbray, of Richmond, writes that having found a fine specimen, about 9 inches across and weighing 8½ ounces, he consumed it for his evening meal, and that it smelt and tasted like a very fine mutton chop, while his cat whose refined taste refuses aerated bread, although fond of ordinary bread, signified its belief in the wholesomeness of the fungus by eating a portion and asking for more! Perhaps the instinct of animals might furnish a guide as to the properties of fungi, for a celebrated authority on agarics states that, after having been all but poisoned by a fungus he had eaten, he offered a portion of it to a tame rabbit which would eat mushrooms without hesitation, and the rabbit would not eat the fungus. The exhibitions of fungi which have been the fashion for the last few years have probably done some good in spreading a knowledge of these plants. The annual exhibition of fungi collected by the Woolhope Club, one of the earliest established of the fungus clubs, takes place at Hereford on the 3rd of October, and that of the Cryptogamic Society of Scotland, on October 11, at the Royal Botanical Gardens, Edinburgh. From the abundance of fungi this season a large show of curious and rare species, as well as good illustrations of the common ones, may be expected.

There is one fungus only, however, that in this country at least has any medicinal value. The properties of *Agaricus muscarius* are known and the muscarine will probably ere long come into use in medicine, although the ignorance of the botanical characters of this species, and consequent difficulty in obtaining the alkaloid, as well as the long and tedious process of extraction (detailed in Watt's 'Dictionary of Chemistry,' 2nd Supp.), will probably tend to render muscarine a very expensive article for some time to come. The physiological action of some of the more important fungi, and the antidotes most likely to prove successful, would form a subject well worthy of investigation by medical men, for scarcely a year passes without some lives being sacrificed to the dangerous practice of eating fungi indiscriminately. Our readers will do well before experimenting to consult Dr. M. C. Cooke's excellent little work on the 'Characters of the Edible and Poisonous Fungi.'

The study of fungi and an inquiry into their properties, especially of the more minute, would probably lead to exceedingly valuable results. Some interesting experiments, made by Fritz not long ago, led him to believe that extract of malt fermented by means of *Mucor racemosus* yields three times the quantity of alcohol that is produced when *Mucor mucedo* is used for the same purpose.

Although the trees in the London squares and streets are beginning to look bare, there are still many plants to be seen in the Botanical Gardens. The Convolvulaceæ, Polemoniaceæ, Compositæ, Malvaceæ, Violaceæ, and Onagraceæ beds are still gay with autumn flowers, while the Solanaceæ present the curious prickly capsules of the thorn apple, the singular pyxis of the henbane, the scarlet "berries" of the woody nightshade, and the black shining ones of the belladonna. The handsome tobacco plant, with its large pinkish funnel-shaped flowers, is now in its prime. The Lobeliaceæ can be well studied at this season of the year. The deep crimson blossoms of the old favourite cardinal flower, *Lobelia cardinalis*, form a conspicuous object and quite cast into the shade the dull blue flowers of *Lobelia syphilitica*, a native of Virginia, whose name indicates its use. The syngenesious anthers in these flowers demonstrate why the order is placed near the Compositæ. In the Royal Botanical Gardens at Regent's Park a white variety of the common periwinkle is now in full blossom. Like the violet, this plant occasionally flowers in the autumn.

The squirting cucumber is now in excellent condition for examining the fruit; the force with which the juice is ejected when the fruit is pulled off is prodigious for so small a fruit, the liquid being spurted, in several instances in which the distance was observed, as far as twenty feet. Fortunately the juice does not appear to have such an irritating effect upon the eye as it does upon the internal mucous membrane of the body.

Among rare British plants the *Cyperus longus* and *Chrysocoma Linosyris* may be seen in blossom. The latter, although sometimes called *Linosyris vulgaris*, is by no means common in this country, there being only two well known localities for it in Britain, and the former, the root of which was formerly used as a perfume and as an aromatic tonic in this country, is said never to ripen its fruit here, an indication that it is not a native of British soil.

In the Economic House at Kew there are few flowers to be seen. The jute plant (*Corchorus olitorius*) shows a few small yellow flowers. The leaves have two curious auricles, or elongated hair-like teeth, one at each basal angle, the use of which is not very obvious. It is said to be much cultivated as a potherb in Egypt and Syria, and so to have acquired the name of the Jews' mallow. The papaw tree (*Carica Papaya*) has now well formed fruit. This is rather interesting, since, there being

no male plant in the gardens, the flowers were fertilized by the pollen from two other species of the same genus, *C. cauliflora* and *C. cundamarcensis*, the former of which is a dicœcious and the latter a monœcious plant, fertilizing its own fruit. The Canada rice (*Zizania aquatica*) is now coming into blossom for the first time in these gardens.

A number of young plants of the orange cinchona of Santa Fé, one of the most valuable of the cinchonas, are now being propagated at these gardens, and will doubtless, some of them, when of sufficient size, find their way to the Government plantations in India. Considerable interest also is being taken in indiarubber plants, and there are now under cultivation two very valuable kinds of indiarubber from Madagascar, *Vahea gummifera* and *V. Madagascariensis*. There is also in healthy condition a specimen of the ficus which is said to yield the best kind of indiarubber in West Africa, *Ficus Vogelii*, a plant for the first time brought alive to this country, and presented, we believe, by Mr. Thomas Christy, a gentleman who takes much interest in West African products.

The number of 'Medicinal Plants' issued this month, contains figures of the coffee plant, dandelion, elm, and the slippery elm, garlic, *Salix alba*, and a double plate of the sugar cane. The slippery elm, *Ulmus fulva*, is an American remedy, used as a demulcent. According to the authors the tree is very like our common wych elm, but may be recognized by the large, hairy, reddish leaf buds, and by the rough upper surface of the leaves. The artist seems to have made up his mind that the public shall not recognize the plant by the leaves he has depicted, for were it not for the uncoloured leaf in outline behind the coloured figure, it would be scarcely possible for such of the public as are not conversant with the mysteries of perspective to tell either the shape or the appearance of the leaf. The dandelion, *Salix alba* and garlic are, however, well represented, and the text is as usual full of interesting matter. Under "Coffee," the new Liberian and other coffees are alluded to, and under *Salix alba*, salicin and salicylic acid find mention as popular remedies.

In the country a few flowers only are coming into blossom at this time of year. In the localities in which it deigns to grow the *Colchicum* is now decking the damp meadows with its pale purple blossoms, and the pretty little ladies'-tresses, *Spiranthes autumnalis*, may be found by the careful observer on grassy slopes on chalky or limestome hills. Although not a medicinal plant, its tubercular roots, which are remarkably large for the small size of the plant, would make excellent salep. The small white flowers are spirally arranged on the flowerstalk (scape), and once seen the plant is easily recognized although otherwise very likely to be overlooked. The structure of this little flower is extremely interesting, several pages being devoted to its description in Darwin's 'Fertilization of Orchids.' That admirable observer points out that humble bees always commence at the base of the inflorescence and make their way spirally up the spike from flower to flower. The spike opens in a centripetal manner, so that the youngest flowers are at the top; hence the bee carries the pollen masses from the uppermost flowers to the basal and more mature flowers at the base of the next spike of flowers that it visits. If the bee commenced to search for honey at the top of the spike, and worked its way downward, the peculiar structure of the flower in an early stage would cause the pollen masses to be torn off from the bee's proboscis and the pollen would thus be wasted.

The Chenopodiaceæ are in full force this month. The wild beet, *Beta maritima*, may be found on almost any rocky or pebbly shore, with its leaves and stems often tinged with the brilliant colour which is better seen in the cultivated root. Some specimens, however, present rather a yellowish green tint. It is from these two varieties, under the power of cultivation, that the garden beet and the mangold wurzel are believed to have been derived. In ripening, the five-parted calyx (perigone) becomes hardened at the base, while the segments shrivel up and the stamens are attached to a fleshy ring, so that the one-seeded small ovary is not readily noticed. Like many other plants of this family the fruit affords an example of the utricle. Several species of Chenopodium possess medicinal properties. In the United States, the volatile oil of *Chenopodium anthelminticum* is used as a popular but exceedingly nauseous remedy for worms in children. On the Continent *Chenopodium ambrosioides* has been used as a remedy for chorea with some success, and *C. botrys* has been used in France in catarrh and asthma. The two latter species may be seen in most botanical gardens. The red variety of *Chenopodium Quinoa*, which is largely cultivated in Peru and Chili, contains a bitter principle in its seed husks, and is used as an emetic and antiperiodic. One little British species, *Chenopodium olidum*, which grows in waste places under walls, etc., may be easily recognized by its whitish ovate entire leaves and prostrate habit, and is remarkable for its exceedingly powerful and persistent odour of stale fish, which after touching the plant can hardly be got rid of without washing. The odour appears to reside in the glandular scales on the leaf, and has been found by Dessaignes to be due to trimethylamine.*

Another British species, *Chenopodium Bonus-Henricus*, called also "Good King Henry" and "Fat Hen," possesses slightly purgative properties. It is often to be found in waste places near villages, and as it was formerly much used as a potherb, it is only doubtfully a native. The origin of its singular name of Good King Henry appears to be lost in obscurity and is identical in both English and German. The plants of this genus are often confounded with those of the genus *Atriplex* by young botanists, the flowers being very small and not easy to examine, even with a lens, on account of being crowded together. These plants should always be collected if possible in fruit, when the triangular calyx of two sepals (perigone) of *Atriplex* has become enlarged and readily distinguishes the plants of this genus from those of *Chenopodium;* the latter moreover has hermaphrodite flowers, while those of *Atriplex* are unisexual, but monœcious.

The number of vegetable substances used as remedies against disease in different parts of the world that yet require to be properly examined is enormous. This sort of work is, however, being done to some extent in the University at Dorpat, and Dr. Dragendorff communicates the results of a recent pharmacological investigation of three Abyssinian remedies (*Archiv d. Pharm.*, xii., 97 and 193). The drug named "add-add" consists of the leaves of the *Celastrus obscurus*, Rich., a plant growing in the

* *Comptes Rendus*, vol. xxxiii., p. 358.

Abyssinian highlands at from 8000 to 10,000 feet above the sea-level, and used as a remedy against "kolla," a peculiar malarial disease that infects the locality. The only constituents found in the dry leaves that were likely to have a therapeutic action were tannic acid, an essential oil, and a glucosidal bitter substance, resembling menyanthin, which he has named "celastrin." Neither the oil nor the bitter substance seemed to have any property to justify the reputation of the plant as a febrifuge, though Dr. Dragendorff thinks it might have a tonic action similar to *Menyanthes trifoliata*. The chemical similarity between celastrin and menyanthin, occurring in plants standing, botanically speaking, so far apart, is notable.

The second drug consisted of the leaves, flowers, and fruit of a composite plant, supposed to be the *Ubiæa Schimperi*, Gay, and called by the Abyssinians "tschuking" or "zerechtit." This plant also grows between 5000 and 10,000 feet above the sea-level in Abyssinia. The flowers resemble in appearance and odour those of the yarrow. The powdered drug, made with water and grated soap into a paste, is applied in the form of a poultice to allay painful cramps in the limbs that accompany convalescence from "kolla;" administered internally it is said to be an active antispasmodic; and a concentrated decoction is said to be a good stomachic, to increase the secretion of saliva, and to replace sarsaparilla in the treatment of syphilis. Here again the only probably therapeutically active constituents found were an essential oil, tannic acid, and traces of a bitter substance, and Dr. Dragendorff thinks that the drug may be compared to chamomile flowers. No constituent that could explain its substitution for sarsaparilla was detected.

The third drug examined was called "kossala" or "sangala," and is said to have an increasing reputation as an anthelmintic. It consists of small dark brown kidney-shaped seeds, compressed at the sides, striated longitudinally with fine dottings on the striæ, exalbuminous, and having a yellowish raphe. Six grams of the finely powdered seeds administered to a dog weighing about twenty-five kilos, resulted in the expulsion of a worm of considerable length on the following day; but doses of one to two grams, administered to smaller dogs and cats, produced vomiting, loss of appetite, and considerable disturbance of the digestive organs.

Baron von Mueller points out in the *Australian Medical Journal* that the Australian bitter bark contains no quinine. This was ascertained twelve years ago by Dr. Wittstein, of Munich, and Dr. Palm, who determined the existence of an indifferent resinous bitter principle (not alkaloid) allied to cailcedrin, a volatile oil, tannic acid and other ingredients. The tree affording this bark, *Alstonia constricta*, belongs to the order *Apocynaceæ*, and to a genus of which one species (*A. scholaris*, R. Br.) affords a well known tonic bark (dita bark) in India and the Philippines (see Bentley and Trimen, 'Med. Plants,' tab. 173). This apparently contains in small quantity an alkaloid, ditamine; and it is possible that further investigation may find the same or a similar substance in *A. constricta*. But it would clearly be misspent energy to plant bitter bark trees in Australia as has been recently proposed.

M. A. Petit has also recently re-examined the bark of *Alstonia constricta*, and finds that when treated with alcohol of 80°, and the extract treated with water, a liquid is obtained which gives all the reactions of an alkaloid. He has also determined the rotary power of duboisine, and finds it equal to +15·5 for sodium light, that of sulphate of eserine being 103°. He finds that mahwa flowers (*Bassia latifolia*) contain 40 to 50 per cent. of a sugar which is capable of reducing Fehling's solution.

In the London drug market lately there have appeared some remarkably fine samples of Sumatra benzoin in the tear, *Eucalyptus globulus* leaves, the old thick cinnamon bark, described in the 'Pharmacographia,' Celyon cardamom, and some very fine senega, which is almost entirely without the keel so frequently present on the root of *Polygala Senega*. From the appearance of the root it is probably derived from another species, but it has the taste and odour of true senega in perfection.

In some samples of senega root, a foreign root has been detected, which upon comparison with specimens in the Society's Museum proves to be that of *Asclepias Vincetoxicum*.

A yellow *Pareira Brava*, which, from the description given in the *American Journal of Pharmacy*, appears to be identical with the yellow *Pareira Brava* of the 'Pharmacographia,' has recently been examined by Mr. C. Morrison. He finds the root to contain two alkaloids, both of a yellow colour and one of them very similar to berberine, but differing in several particulars. The author, however, appears to have compared the sulphate of the new alkaloid with the hydrochlorate of berberine. The two alkaloids differ from each other in the one being soluble in ammonia and the other not.

In a recent number of the *Archiv der Pharmacie*, Leonhardi has a paper on the adulteration of essential oils, in which he states that fennel oil stearoptene is imported from Russia for adulterating oil of anise, often to the extent of 90 per cent., a sophistication which is easily detected by heating the oil, when the fennel odour becomes apparent. He also finds oil of coriander and essence of bergamot adulterated with rectified oil of orange (essence de portugal), an admixture which may be discovered by the insolubility of oil of orange in alcohol of 90 per cent. Oil of caraway he finds to be adulterated with oil of turpentine, in which case it forms a turbid mixture with alcohol of 90 per cent. He considers that the best test for the presence of alcohol in essential oils is the red coloration which is produced (if alcohol be present) when a little of the suspected oil is dropped on a crystal of aniline red.

Dr. J. A. G. Clowes, writing in the *Medical and Surgical Reporter*, recommends the use of *Polymnia Uvedalia* (bear's foot) in chronic rheumatism. He finds that in the form of ointment it relieves the pain and gives better use to the joints than any other application he has used. He also recommends its use locally as an ointment in enlargement of the spleen, pepsine and dilute muriatic acid being administered at the same time.

From the *Doctor* we learn that *Œnothera biennis*, or evening primrose, has been used for some years as a mild sedative and alterative in many diseased conditions of mucous surfaces by Dr. J. F. Sullivan, who has also found it of especial value in typhoid fever. The dose of the fluid extract is fifteen to thirty drops every three hours, but a tablespoonful dose has not proved harmful.

In a paper published in the *Journal de Pharmacie*

et de Chimie, M. Bourband recommends the cultivation in Algeria of the *Acacia pycnantha*. The bark is largely used for tanning purposes, it containing from 40 to 45 per cent. of tannin; the flowers exhale a delicious perfume, and the stem yields a gum similar to gum arabic.

In the *Druggists' Circular*, Dr. J. H. Bundy, of California, who introduced *Berberis Aquifolium* (Oregon grape) into notice some two years ago as a tonic and alterative in syphilis, states that he believes the three species, *B. repens*, *B. nervosa*, and *B. pinnata* are confused with the *B. Aquifolium*, *Berberis Aquifolium* is known by its dentate leaves having a shining upper surface. It is the little shrub commonly cultivated in gardens and shrubberies in this country, with prickly holly-like leaves, yellow flowers, and racemes of purplish berries, with a grey bloom on them.

Dr. Planat, of Nice, recommends arnica as a remedy for cutting short eruptions of boils, applied externally, as well as internally in the form of tincture taken in doses of three or four drops every two hours.

An important discovery comes from Munich and is one of which it is impossible to estimate the future value. Professor Baeyer has discovered a means of making isatin artificially, and thus the chain is complete, for the re-conversion of isatin to indigo is now a well known process. Professor Baeyer obtains isatin by the oxidation of amido-oxindol by means of either ferric chloride, cupric chloride or nitric acid. Although at present the process is too expensive to produce indigo on a paying scale, yet it will doubtless be possible ere long to obtain indigo artificially at a price which will probably have a disastrous effect upon the markets of indigo-producing countries.

Dr. Méhu, in a paper recently read before the French National Academy of Medicine (*Journ. Pharm. Chim.*, xxviii., 159), announces that the use of lead salts for the removal of the pigmentary matter from urine, bile, fæces, and other animal and vegetable secretions may be advantageously replaced by that of sulphate of ammonia. Usually it is necessary to first acidify the liquid to be treated with sulphuric acid; the sulphate of ammonia then being added to saturation precipitates the whole of the colouring matter, which can be separated by filtration. In like manner, sulphate of ammonia added to milk causes the complete separation of the albumen and butter, leaving the whey limpid and colourless and suited for a saccharimetric examination. In the case of milk the previous addition of sulphuric acid is not necessary, but a slight acidification renders the coagulum more compact and facilitates the filtration. Sulphate of ammonia does not precipitate gum, sugar or tannin; in fact Dr. Méhu has used it to separate the chlorophyll from a solution of commercial tannin.

A writer in an American contemporary suggests the use of fluorescin as a show colour for druggists' windows. Certainly there is room for novelty in this direction, and the beauty of some of the new fluorescent substances renders them peculiarly suitable for such a purpose. The proportion to be used is one grain of fluorescin dissolved in a drachm of water of ammonia, and added to a gallon of water.

Those who are interested in microscopical work will be glad to hear of a green stain for vegetable tissues. An Italian, named Tafani, has found that a mixture of a saturated solution of four parts of aniline blue to one hundred of a similar solution of picric acid answers admirably for this purpose.

The subject of the preservation of food has recently acquired a new development from Dr. Campbell Morfit's new gelatine process, the object of which is to use if possible a preservative agent which shall itself be useful as food. Some idea of the process may be obtained from the following method of preserving milk:—One pound of gelatine is dissolved in a gallon of milk at a temperature of 130° to 140° F., the solution is allowed to gelatinize and the jelly cut in slices and dried; these slices are then dissolved in another gallon of milk and the process repeated until the original pound of gelatine is combined with the solids of ten gallons of milk. One theoretically excellent application of this process is the dissolving of gelatine in lime juice and incorporating the dried lime juice and gelatine with the powder of navy biscuits, so as to provide lime juice in a portable form. The biscuits, however, are naturally very sour, and the acidity has to be somewhat masked by the use of a quantity of sugar. Few things are more liable than gelatinous preparations to become mouldy in a damp atmosphere. The food preparations, however, made by this process, not containing more than 10 to 12 per cent. of water, do not become mouldy even when exposed to warmth and moisture. The thao, or seaweed jelly, is well known to possess remarkable keeping properties, and might in some cases probably replace animal gelatine.

The report on the adulteration of food, lately issued from the Department of Inland Revenue of Canada, contains a number of beautifully engraved figures of starches and vegetable tissues from photographs furnished by the Inland Revenue authorities at Somerset House, which will be very valuable to microscopists. Amongst these are an instructive series of the sections of the midrib of leaves, which indicate a surprising variation both in the form of the midrib and of the arrangement of the vascular bundles in it, and seem to point out a field of investigation which might be worth while following out, plants of the same family, so far as may be gathered from the plates, having a similar, but slightly varied, arrangement of the vascular bundles.

Many correspondents who have to wait for information on their several questions for the month's summary would find those questions answered if they only took the trouble to refer to preceding prescriptions which have been already commented on.

The question No. 144, respecting aq. menthæ has been asked on a previous occasion, and the answer to it will be found in "The Month" of April 27 last.

Prescriptions are frequently met with, as that of No. 145, where "coch." is written without mag., med. or parv. being added. Pereira, in his 'Selecta e Prescriptis,' renders "cochlear" a spoonful, and adds, "Where no qualification is added to it, it is generally understood to mean a tablespoonful, but some discretion must be exercised by the dispenser; he must be guided by the size of the mixture, the dose, and whether the medicine be for a child or for an adult." The remarks of "Inquirer" and "Hamilton" on this subject are very much to the purpose.

The mixture of No. 146 changes colour or other-

wise, according to the acidity of the mixture. "Kappa," gives only the ingredients, omitting the proportions; these should have accompanied the prescription. The change of colour is due to the action of the acid, more or less present in the sp. æth. nit., on the salicylate of soda. If the acid be first neutralized with the sp. am. arom., and then added to the salicylate of soda, no change of colour will take place.

For liq. secalis ammon., No. 147, there is no recognized formula. From the correspondence which has taken place in the Journal on the subject it would appear that the preparation has been recommended by a writer on midwifery as a very effective combination, and that it is prepared by several wholesale houses. It may be a valuable preparation, or a valuable property, and as there are several makers and no published formula it can hardly be expected that the preparation should be alike from each of the sources. It would be better perhaps to use the preparation of one of the recognized makers; at the same time it is just possible that the extemporaneous one adopted by "Sub Umbra Floresco" may possess equal merit with any one of those mentioned. If members of the medical profession were guided by some sound principle in the use of preparations other than those of the British Pharmacopœia it would be better, and would materially contribute to the advance of true pharmacy.

The best excipient is required in No. 148 to form acid. carbol. with ferri sulph., ext. nuc. vom. and pulv. rhei into a pill mass. Glycerine of tragacanth has been so often alluded to as an excellent excipient, and specially adapted for pills containing ferri sulph., that its repetition here should not be required. W. H. R. recommends powdered tragacanth with a drop of glycerine as being better than tragacanth paste. It may be so, but the difference between that and tragacanth paste tolerably stiff is not very clear. The two excipients should be tried, and the experience acquired preserved for future guidance.

The mixture, No. 149, containing sol. Donovan. with tr. opii and quinine will throw down a deposit of the alkaloids. A composition of this kind has been commented on in the month's summary, Dec., 1877, p. 506. The precipitate in this instance is due to morphia and other proximate principles of opium, which with the quinine have been thrown down by the iodide of mercury in Donovan's solution.

The mixture, No. 150, contains quinine and bicarbonate of potash. The quinine in this instance must be reduced to fine powder by rubbing it with the bicarbonate of potash, and consequently the mixture will not be clear, the quinine being diffused, but not dissolved. The suggestion of C. E. P., p. 217, is inadmissible. If the quinine be dissolved by a little dilute sulphuric acid it will be again thrown out of solution on the addition of an excess of alkali.

It is probable that the "perchlor." of prescription No. 151 is an error on the part of the writer. Most likely the hypochlorite was intended. The remarks of Mr. Scott and others, p. 217 and 218, are quite to the purpose, and the formula given in all probability is the one intended by the writer of the prescription.

If tr. quinæ co. be prescribed, as in No. 152, the tinct. quinæ of the B. P. should of course be used, as the preparation is identical in composition with that of the tinct. quinæ co., P.L., the latter being named tr. quinæ co., whilst in the B. P. the "co." has been dropped. The subject is fully treated in the observations of Mr. Henry Brown and others on p. 217.

Lin. æruginis, No. 153, is a preparation formerly more used than is the case at the present time. It always presented some difficulties, and could not be kept in a satisfactory condition. Mr. Brown, p. 218, states that the deposit is acetate of copper, but this does not seem to be the case. From a letter from Mr. Quekett on the subject in the *Pharm. Journ.* for February, 1845, it would appear that a microscopical examination to which he had subjected the deposit from lin. æruginis revealed the presence of "very finely divided copper, which had been reduced from the subacetate by the saccharine principles of the honey employed in its preparation," and to which the deposit is due.

In last month's summary, p. 166, a suggestion is made that $\frac{1}{4}$ gr. podophyllin and 4 grs. of compound rhubarb pill may be used when "pil. podoph." without a formula is ordered in a prescription and the writer cannot be referred to. P. B., of Belfast, now sends a formula for podophyllin pills, in reply to the same inquiry, but he must be reminded that an elaborate formula such as the one forwarded, and containing ext. nuc. vom., however good it may be, cannot be adopted by a dispenser under the circumstances mentioned. The addition of nux vomica involves a medical opinion, which the pharmacist is not competent to give, and which is, besides, quite beyond his province.

A formula for ung. acid. carbol. is required (No. 154). In the casual notices of carbolic acid ointment widely different proportions are given, ranging from 1 to 5 per cent. 60 grains of carbolic acid made up with simple cerate to 480 grains is the form adopted in the United States Pharmacopœia.

There is no formula recognized for ol. morrhuæ c. æth. sulph., and the proportion of ether to the tablespoonful of cod-liver oil dispensed by the inquirer shows that care was exercised in giving the minimum Pharmacopœia dose of ether; but the remarks of Mr. Brown, page 237, deserve consideration, and tend to show that a question of this kind coming before a dispenser must be viewed in all its bearings.

In No. 156 the question is asked, When liq. plumbi subacet. is prescribed with aq. pura, should pure or distilled water be used? Pure water should, where possible, certainly be used. But then the question occurs, What is pure water? Is any water, or even that which has been distilled, pure? The object presumably aimed at in the inquiry is to make the lotion as free as possible from milkiness. If the water be distilled there will, from the carbonic acid absorbed by it, result a little milkiness when liq. plumbi subacet. is mixed with it. In freshly distilled water the carbonic acid is best removed by boiling previous to its being used for lead lotions.

The question is asked by "Nuncio," in No. 157, as to what is meant by "liq. copaibæ alk." The following formula in Beasley's 'Pocket Formulary' is probably referred to:—"Solutio Copaibæ Alkalina: Copaiva, ℥ij; solution of potash, f℥iv; distilled water, ℥x; boil together, and when cooled to 140° F. add spirit of nitric ether, f℥j. Separate the clear solution from the sediment and what floats on the surface." The mixture made with this sol. copaibæ is of a dark amber colour, and quite transparent.

The combination of ol. pini sylvestris cannot be

made miscible, but if the oil be rubbed with the magnesia and to it be added two drachms of mucilage previous to the addition of the tr. benz. co., a satisfactory product will be obtained which will continue in the same condition.

Explosive mixtures, as that of No. 159, have on a previous occasion been under notice, and to the remarks on this subject in the month's summary of July, page 66, nothing now need be added. If these two mixtures were made with the same bismuth a sample of it on examination may throw some light on the subject of these obscure decompositions.

The prescription No. 160 results in a deposit, and the question is asked, Should a label to shake the bottle be placed on it? If the sodæ bicarb. be dissolved in the lime water there is an immediate precipitate of carbonate of calcium, but if all the liquids be added to the sodæ bicarb. previous to the addition of the lime water, the mixture may be made without an immediate precipitate. Precipitation will, however, take place on the mixture standing an hour or so; in whatever order the ingredients are put together there will result from the combination of carbonate of soda with the lime water a precipitate of carbonate of calcium. When a deposit forms as the necessary result of the combination properly put together there should always be placed on the bottle a printed slip to shake the bottle. The patient is thus informed that the precipitate is a necessary result of the combination, and that it is not a consequence of imperfect manipulation nor a result unexpected by the dispenser, but one for which he is in a position to offer a satisfactory explanation.

The quinine mixture No. 161 is typical of those combinations of quinine and ammonia which have on several occasions been commented on in "The Month," and to these comments the writer must in this instance be referred. One such mixture will be found alluded to in June, page 1045, and several others in the preceding "Months."

In conclusion, the remarks of Mr. Brown with reference to appending to communications either initials or names (p. 237) may be commended to the consideration of correspondents. When the suggestions of a correspondent have to be referred to in "The Month" it is more convenient to quote a simple initial letter or letters, than those combinations of a more complex character to which he has referred.

PRODUCTION OF OPIUM IN CHINA.

A series of reports on the opium trade in China have been recently gathered together from the various British Consuls residing in the celestial empire. Though opium cultivation is ostensibly prohibited in China, it is, nevertheless, not only carried out on a large scale, but is increasing rapidly, the cultivation being much more profitable than than that of wheat and other food crops. Thus it is asserted that if the Chinese government were really and sincerely desirous to stop its growth it would be quite unable to do so. From Newchwang the reporter says—"Though the growth of the poppy is prohibited by the Imperial government, this prohibition is regarded as a dead letter in many districts, and the cultivation is encouraged by the local authorities, as the inland dues levied on native opium, though lighter than those on the imported drug, are much heavier than on any other description of native produce and their receipts proportionally greater." The chief opium producing provinces are Yunnan, Kweichow, Szechuen, Shensi, Shansi, and also Eastern Mongolia and Manchuria. In all these provinces poppy cultivation has made rapid progress, and in some parts the opium has improved in quality. In the opium producing districts the smokers are estimated at five-tenths of the native male population, and the proportion throughout China is computed at three-tenths of the native male population. The consumers of native Chinese opium consider it to be less deleterious in its effects than the foreign produce. It is stated, however, that some authorities hold a contrary opinion. An authority of some importance gives it as a fact that a much larger quantity of native than foreign opium is required to produce a like state of stupor; and in the case of the Manchurian produce, in addition to this inferiority of quality the effects of indulgence in its use are more deleterious. The native opium is said to be coarser and more fiery and the flavour inferior to the Indian.

Regarding its capabilities for smoking, Mr. Adkins, reporting from Newchwang, says,—"There can be no doubt that the residue, after smoking the native drug, is much more available for again passing through the pipe than the residue of the foreign drug. It is said, indeed, that good native drug can be passed four or five times through the pipe. Against this must be set the fact that the foreign drug is more satisfying than the native. A pipe of native opium at 6 a.m. will require a second at 10 a.m., whereas the craving would not return after the foreign drug sooner than noon."

In the northern provinces, Shansi, Shensi and Kansuh, poppy cultivation requires very great care on the part of the grower, together with the richest possible soil. It is grown with the utmost success on the terrace slopes or on the most fertile bottom land, which allows of thorough irrigation and which would be devoted to the cultivation of wheat and vegetables were it not for the very large profits derived from the prepared opium. In the provinces just referred to "there is a limit beyond which the poppy cannot be raised with remuneration to the grower, and the production is never likely to be much in excess of the demand for consumption. In the southern and central provinces, on the other hand, the poppy cultivation does not interfere to any considerable extent with that of grain, especially in Szechuen where the difficulties of transport in supplying a deficiency in the local crops from the neighbouring provinces renders necessary the retention of large tracts of land for the raising of grain. The soil here is so rich and fertile that the most suitable ground for the poppy is the terraced hill sides where the effects of the heavy rains frequent at certain seasons of the year, and which would render the low lying fields too damp, are, comparatively speaking, unfelt. Sown during November the poppy blossoms early in April, and comes to maturity within a month, thus leaving the fields free for a summer crop. Before the poppy has seeded, an intermediate crop of maize, wheat, cotton, or tobacco is growr, the poppy stalks being cleared away in time to prevent interference with the young shoots." The opium yield is very uncertain, being much affected by the state of the weather during the growth of the plant; thus bad weather may ruin a whole year's crop, but on the contrary one good season may recoup the losses of several bad ones.

In Shantung, it appears that native grown opium is seldom or never used alone, owing to its hot and unpleasant flavour. It is usually mixed with an equal quantity of Indian opium. The increasing consumption of opium here is stated to be clearly caused by its cheapness, added to the belief that it is less injurious in its effects than the Indian drug. Though Bengal opium is chiefly used in the Suchow and Chang-Chow prefectures, the native opium is largely used for mixing purposes, and in the districts north of the Yangtze, where Malwa is chiefly consumed, the native product, although smokers of Malwa are said to take to it less easily than smokers of Bengal opium, has already affected the consumption of the foreign article. The Indian product is almost exclusively used in Shanghae.

The Pharmaceutical Journal.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE TRAINING OF APPRENTICES.

OF late we have not heard so much of the subject of provincial education as we used to some few years ago, and there is room to hope that many of those who were then clamorous for external aid have since learned to appreciate the value of self-help and to avail themselves of its advantages. The conditions under which embryo pharmacists are commonly placed in this country are not indeed such as to afford very great facilities for acquiring a knowledge of those sciences which must constitute an important part of the trade capital of the accomplished pharmacist, nor are they always such as to satisfy the very moderate desideratum of making a young man passably conversant with his business. It is no disparagement to say that the shop of the ordinary chemist and druggist is rarely a school of pharmacy, nor can we reasonably entertain a hope that it ever will be raised to that position; for on the one hand we find that it is gradually ceasing to be the case in other countries where greater attention is given to educational requirements, and on the other it does not need much penetration to recognize the fact that such a position is inconsistent with the tendencies of the age.

At the same time it is becoming more essential to consider how the apprentices to the trade are to be educated, because the possession of competent scientific knowledge no less than practical skill is now recognized to be indispensable. In regard to this subject the address delivered by Herr SCHLICKUM at the late meeting of the German Pharmaceutical Association presented several features of interest to British pharmacists, and we think it will not be without utility to place his opinions in an English form before our readers, especially as we are often asked what methods of instruction and study are to be adopted for the training of apprentices.

The preference is given by Herr SCHLICKUM to the gymnasium schools for acquiring qualification for passing the Preliminary examination which every intended apprentice must pass before being received into an *apotheke*. He admits that the "real" schools give a better training in mathematics, physics, and chemistry than the gymnasium, but nevertheless he considers that the advantages of such a training in science are, to a great extent, illusory, since he holds that the full comprehension of these subjects is dependent upon the pupil having attained a certain age, in other words, a maturity of intellect that boys of fifteen or sixteen seldom possess. The advantage of the gymnasium training is due to the prominence given to the study of the classics, and it cannot be denied that a knowledge of the Greek and Latin languages is at least a great help towards understanding many of the names met with in scientific works.

Even at schools where science is taught the duration of the school training should not be prolonged beyond the age of fifteen or sixteen, since the result would be to divert the apprentice from the practical experiences of the pharmacy.

After entering upon the apprenticeship, Herr SCHLICKUM suggests that the period should be divided into two portions. During the first half it should be the business of the apprentice to become acquainted with the names of preparations and their nature in reference to dispensing, to learn how drugs, etc., are prepared for pharmaceutical and medicinal use by grinding, powdering, etc., for even if these operations are not to be carried out in future practice, it is necessary to have a practical acquaintance with them. During this period of the apprenticeship it should be the endeavour of the master to give his pupils instruction in physics, general chemistry, and botany, indicating, also, the means of acquiring a knowledge of these sciences. Necessary time for study, experiment and botanizing must also be allowed, the master at the same time aiding with advice. It cannot be expected that every one will undertake to teach his apprentice science, even if he be able to do so, but a certain amount of aid and advice should always be given, since there are so many things in regard to which questions may arise upon which manuals or other books will not give information.

Laboratory experience is also a thing which the apprentice should always have an opportunity of gaining, both in the preparation of chemicals, etc., and in analysis. The pecuniary advantage of purchasing preparations should not be allowed to stand in the way of this essential branch of pharmaceutical training, for it is to be remembered that the apprentice is there on his own account for his improvement, and not merely for the good of the business he is attached to.

The kind of scientific instruction recommended by Herr SCHLICKUM is that which tends to convey a knowledge of broad principles rather than mere details, and with the object of facilitating the labour of instructors and students he has lately published a work containing a suitable *résumé* of the sciences connected with pharmacy. When in this way it has been possible for the student to build up a skeleton he can afterwards easily extend his knowledge by the study of larger works.

In the second portion of the apprenticeship period attention should be more particularly directed to

special pharmacy, to the study of chemical and pharmaceutical preparations, as well as pharmacognosy. Here the Pharmacopœia is to be the guide in operating, and the general scientific knowledge acquired during the earlier part of the period will enable the apprentice to make use of more extended sources of information, such as the commentaries upon the various pharmacopœias, etc.

It is recommended by Herr SCHLICKUM that both the Linnean and the natural systems of botany should mastered by the student, commencing with the Linnean, and learning to determine according to that system the plants growing in the neighbourhood; then going on to the natural system.

As regards chemistry the use of the modern molecular system cannot now be avoided; it has the advantage of being simple and easy to learn. But for those who are not acquainted with it, system or theory may be dispensed with altogether, and the mere facts of chemistry dealt with by both teacher and pupil. These are the same, however expressed by the aid of systems, and it is these facts that the student requires to know.

Lastly, while insisting upon the necessity of giving the apprentice not only a sound practical training, but also scientific instruction, Herr SCHLICKUM urges that principals should always have regard to the efficient education of their pupils, and take a pleasure in initiating them into the various sciences connected with the art. By so doing the association of master and apprentice is made the most potent means for securing the advancement of pharmacy, the master looks upon his pupil as to some extent the work of his own hand, and the labour bestowed by the one upon the development of the other creates a mutual interest conducive to the well-being of their calling.

But in order to realize fully such a desirable relation the labours of the pharmacist as the instructor of his apprentices must be adequately remunerated. Since it is not merely for the sake of the business that the apprentice is taken it is but just that the work of training him should be properly paid for, and on the propriety of demanding such payment for the labour of training apprentices, Herr SCHLICKUM very properly insists.

THE OPENING OF THE NEW SESSION.

ON Wednesday next, the 2nd of October, an Evening Meeting of the Pharmaceutical Society will be held at which the prizes and certificates gained by the students of the Session 1877-78 will be distributed by the President, Mr. JOHN WILLIAMS. An address will also be delivered to the students who have entered for the coming session, by Mr. OCTAVIUS CORDER. The students and their friends, ladies and gentlemen, are invited to be present.

CHEMISTS' ASSISTANTS' ASSOCIATION.

THE next meeting of the above Association will be held at its new rooms, 32A, George Street, Hanover Square, on Thursday, October 3, at 8.30 p.m., when Mr. WALLIS, President, will deliver an address. A list of meetings to the end of April will shortly be issued.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page* 236.)

The next paper read was—

A REACTION OF ORANGE FLOWER WATER.

BY R. REYNOLDS, F.C.S., AND C. H. BOTHAMLEY.

A few months since, the following prescription was presented and was duly dispensed:—

℞.	Bismuth. Alb.	℥iss.
	Acid. Nitro-mur. Dil.	℥iss.
	Tinct. Gentian. Co.	℥ss.
	Sp. Chloroformi.	℥iss.
	Aqua Aurantii . . . . . ad	℥viij.

Misce.

The patient complained that the mixture, including the deposit, had a pinkish hue, which was not the case to such a degree when the same medicine had been dispensed elsewhere.

Some experiments showed that the coloration was due to a reaction between the orange flower water and nitro-hydrochloric acid. Although we believe that few pharmacists have had this reaction brought under their notice the fact is already recorded in Hanbury and Flückiger's 'Pharmacographia,' where it is said of orange flower water, "Acidulated with nitric acid, it acquires a pinkish hue more or less intense, which disappears on saturation by an alkali."

The literature of the question is contained in its most complete form in Gmelin's 'Handbook of Chemistry,' vol. xiv., page 386. Here we find the following statements under the head of oil of neroli, viz., When orange flowers are distilled with water, "the oil which passes over is a mixture of two oils, one easily soluble in water and fragrant; the other sparingly soluble, of less agreeable odour; the latter floats upon the watery distillate and is easily separated (Soubeiran). Orange flower water treated with nitric acid acquires in a few minutes a rose-red colour (Ader and others). With oil of vitriol it becomes rose coloured (Le Roy), but Ader insists that this is only the case when the oil of vitriol contains nitric acid, and he adds that it is not coloured by hydrochloric acid. Ether, almond oil, and castor oil abstract from orange flower water the whole of the volatile oil; the ether solution, mixed with nitric acid, immediately assumes a rose-colour, and leaves on evaporation a fragrant volatile oil (Ader, 1830, *Journal de Pharmacie*; also Soubeiran)."

Our experiments may be divided into two sections; firstly, the isolation of the soluble oil; secondly, its reactions.

I. In order to separate the soluble oil, 300 c.c. of orange flower water were introduced into a glass tube about one metre in length and twenty mm. diameter, having its lower extremity drawn out and closed by a pinch-cock and india-rubber tube as in Mohr's burette, whilst the upper end was drawn out and fitted to receive a small cork; sixty c.c. of absolute ether were added and thorough agitation effected. After separation the operation was repeated with 30 c.c. of fresh ether. The mixed portions of ether were placed in a small distilling flask, and the ether was evaporated in a current of air. Some of the volatile oil may have passed off with the ether, and a slight odour favoured this supposition, but as the flask was constantly coated with ice owing to the refrigeration caused by the rapid volatilization of the ether, the process of evaporation could hardly have been effected more favourably as regards the avoidance of loss. The oil obtained weighed 2·126 grams = 0·71 per cent. upon the orange flower water used. It had solidified towards the close of the process, but rapidly liquefied when evaporation ceased. It possessed a deliciously fragrant odour.

II. The reactions of the oil with nitric acid (normal strength, 63 grams per litre) are those stated for orange

flower water by previous observers, but intensified in degree. The colour may be described as crimson red; that with orange flower water is faint red. We have to differ from Ader on two points: viz.: we find that pure sulphuric acid produces the rose colour with orange flower water, and that hydrochloric acid does the same; both reactions being much less marked than with nitric acid.

The orange flower water after exhaustion by ether gave no trace of coloration with nitric acid. It was not, however, absolutely deprived of odour, but had lost its characteristic scent, and now possessed an odour suggestive of rose water.

We may add that if strong nitric acid be added drop by drop to orange flower water, the rose colour at first produced is destroyed when the quantities of the two liquids are about equal.

If the orange flower water be agitated with nitrous fumes and dilute nitric acid then added, no colour is produced, or if acid largely charged with such fumes be added to orange flower water the colour appears for an instant but is almost instantly destroyed.

Before leaving the subject of orange flower water, it may not be inappropriate to its bearings on pharmacy to quote from Parrish's 'Pharmacy' (ed. 1859) the following statement: "Its sedative effects, which are not generally known in this country, and not noticed in our works on materia medica, adapt it especially to use in nervous affections. In doses of a tablespoonful it is found to allay nervous irritability and produce refreshing sleep." If orange flower water has valuable hypnotic qualities, it should be welcomed as a desirable rival to various less innocent substances now used for the purpose.

Mr. GREENISH said he had worked a little on this subject, and had noticed that if orange flower water were brought up from the laboratory into the shop, in the course of a little time it seemed to deposit yellow particles, and finally entirely lost its odour of orange. He had examined this deposit microscopically, and under a tolerably high power he found these yellow spots were quite circular, and had all the characters of a ferment. More than that, mixed up with these particles, which appeared to be cellular and organized, he found bacteria. Thinking it possible that the orange flower water in the laboratory might be in a different condition, he poured off a little into a measure, and found it perfectly free from the deposit, but at the bottom of the same stock vessel there was a large quantity of yellow deposit. He had noticed the action of nitric acid on orange flower water in turning it pink, and that it turned that with a deposit pink also. He had distilled a portion, and that also with nitric acid became pink. His idea was that the oil had become oxidized, and gradually lost its odour by being exposed to the light and air. About four years ago a paper appeared in the *Archiv der Pharmacie*, on this subject, by Dr. Hoffmann, who had endeavoured to ascertain the cause of the coloured particles, and came to the conclusion that they were due to portions of coniferous wood, as he found such portions in orange flower water. He (Mr. Greenish), however, had never been able to find any coniferous wood whatever, nothing but these little circular apparently organized particles. Dr. Hoffmann then examined the colour spectroscopically, and found the absorption bands were precisely the same as those of the phytolacca, which was used in the south of France for colouring wines, and thought that possibly a little of this colouring matter might have got into the orange flower water. About eight years ago Gobley, in the *Journal de Pharmacie* wrote a paper on this subject, and stated that there were two waters made in the south of France, one from the leaves, and the other from the flowers, and that the water from the leaves did not, on the addition of acid, turn pink, while that from the flowers did. He then gave a formula, two parts of nitric acid, one of sulphuric acid, and three of water, as a test solution for determining whether the water came from the flowers or the leaves, but unfortunately it turned out that if the water was 90 per cent. from the leaves, and only 10 per cent. from the flowers, it yet gave this pink colour. He finished by stating that he found that after a time the orange flower water lost the property of becoming pink on the addition of nitric acid. He (Mr. Greenish) therefore concluded that this was due to the loss of the oil, aud to determine what really gave the colour to this water he dissolved a drop of oil of neroli in spirit, and poured it into water, and on adding a drop of nitric acid, he found the same pink colour as was observed in orange flower water.

Mr. GROVES said he should like to elicit what was the general practice in dispensing orange flower water. They knew it was an officinal substance, but the mode of preparation was not stated. He observed in the opening of the paper that there were complaints of the pink colour as being greater in the case of the medicine then dispensed than in previous cases, and the question occurred to him whether they ought not to regard the water so imported as a triple water, and dilute it. When used for syrup of orange flower, it must be used as imported, or the syrup would not be sufficiently flavoured, but he doubted whether it would be agreeable to the patient, or would be expected by the prescriber, that in dispensing ordinary medicines, where the excipient was simply orange flower water, that the water of the full strength should be used. His practice was to dilute the orange flower water as imported with two parts of water from a desire to make it agreeable.

Mr. EKIN said the usual practice certainly was to dilute in the proportion Mr. Groves named. He did not think physicians would mean the concentrated water to be given. He understood Mr. Greenish to say that it deteriorated when brought from the laboratory into the shop. He had always understood that it improved immensely by keeping; the French houses who supplied it recommended that it should be kept for some time in order that the flavour might mature.

Professor MARKOE said the orange flower water was always used in the States in a dilute form. There was no doubt that if orange flower water were kept in an open vessel, or exposed to the light, it very rapidly spoiled, and this was forced on their attention by the more intense sunshine in the States. If the package were opened, and kept in a dark place, stopped with a plug of cotton, it improved.

Mr. GREENISH said he had several times put orange-flower water on the shop shelf and allowed it to remain there for some time, and the aroma entirely disappeared. He did not think there was a single preparation which did not change by being exposed in the shop to the influence of light.

Professor MARKOE said he had tried the experiment and found the orange flower water completely spoiled by a fortnight's exposure on the shop shelf.

Mr. PAYNE thought Mr. Groves's inquiry was a very necessary one. The medical men in his part of the country very rarely ordered orange flower water in any great quantities, but generally from half ounce to two ounces in an eight ounce mixture; and his custom was to use it as imported.

Mr. COSTER said his practice always was to dilute the triple orange flower water as imported, with two parts of water.

Mr. CONYNGHAM thought when a mixture was ordered to be made up with orange flower water it was invariably used diluted.

Dr. MACSWINEY said he had always understood that orange flower water, which was a very favourite medium for the exhibition of other remedies, was a rather concentrated article, and accordingly it was his practice to order two ounces with an eight ounce mixture, believing that quantity would fully flavour it. He might be wrong, but he was not aware of the fact that there was any difference

in the strength of the water ; at any rate there was but one preparation included in the British Pharmacopœia, and he confessed he was astonished to hear of *two*, of different strength, being kept in stock for dispensing. Was it right that it should be so? He thought this was another instance of a most objectionable practice which prevailed, of departing from some one uniform standard of strength and composition of substances liable to be prescribed by the physician. He took leave to say that pharmaceutical chemists, instead of favouring each one a different composition and mode of preparation of articles in general use amongst medical men, as remedies, should all supply the substance of exactly the same stable composition, and with a name which, as far as possible, would convey an intimation of its true nature.

Mr. BENGER asked if there were any stronger reason why orange flower water should be used of a greater strength than rose water. He believed it was the general custom in dispensing to dilute it with two parts of water, and so reduce what was described as *triple* to normal strength.

Mr. FRAZER said that in Scotland it was the universal practice to dilute it. When he first became a druggist there was no triple water, and since it came into use they had diluted it two to one, for dispensing purposes. They kept a stock in a cellar in stone jars, and always found it richer as it got old.

The PRESIDENT said it seemed to him that the usage in this respect must a great deal depend on what they understood to be the purpose of the prescriber. They had heard from one gentleman practising in that city, who was probably a fair representative of the profession, that orange flower water was mainly used for flavouring purposes, and in that case it was perfectly clear, that so long as a respectable amount of flavour was produced it did not much matter whether the concentrated or the dilute preparation were used. It happened, however, in his neighbourhood that prescribing physicians were aware of the fact that this water had considerable sleep producing power, and he had frequently known it given alone for this purpose, and answer extremely well. That, perhaps was not a subject for him to discuss, but, as the opinion appeared to prevail to some extent, it had been his invariable practice for many years to employ the strong orange flower water, thinking he had no right to an opinion as to whether this or that prescribing physician meant it to be used simply as a flavour or on account of its medicinal value. There was this difference between orange flower water and rose water, that there was an officinal preparation for aq. rosæ, but no official strength given for orange flower water. If there were any great medicinal value in the preparation it was unfortunate that it should be open to such variations that in one case it might be three times the potency of another.

Professor MARKOE asked what was understood in England by the terms, single, double, triple, or quadruple. Was the latter four times the strength of the single ? it certainly was not four times the price. In the United States they obtained all their supplies from France, except a little which now came from Florida.

Mr. SUMNER thought the origin of triple water was twofold. The main object was in order to meet the duty on perfumed waters from France, so as to get three times the strength for the same amount of duty; it was found also that the stronger water kept better.

Mr. LONG said this was one of those unfortunate questions which much troubled pharmacists, because there was no legitimate strength, It was no use being over anxious about what other people did, nor must they always think it was their duty to give a higher strength, or that the stronger a thing was the better. He hoped in the nextedition of the Pharmacopœia an official strength would be laid down.

A vote of thanks was passed to Messrs. Reynolds and Bothamley.

The next paper read was entitled—

NOTES ON VARIOUS SAMPLES OF DIALYSED IRON.

BY R. REYNOLDS, F.C.S., AND C. H. BOTHAMLEY.

Amongst those members of the British Pharmaceutical Conference who can carry back their recollections to the meeting at Nottingham in 1866, there are doubtless some who have not forgotten the specimen described in the following extract from the annual report for that year:—"Exhibition of Objects relating to Pharmacy. Dr. Wagner, Pesth, Hungary. Ferrum dialysatum (oxydatum solutum in aqua). A reddish-brown fluid of pure astringent taste. Dose in case of diarrhœa or dysentery, one scruple to a drachm." After this introduction, rather to British pharmacists than to British pharmacy, dialysed iron relapsed into a Rip Van Winkle sleep, and appropriately enough turned up in about ten years time in the United States. The *Pharmaceutical Journal* has no further notice of the new remedy until the volume for 1877–78, where we find eight articles on dialysed iron, the whole being quoted from American writers.

During this period, however, the new remedy was certainly becoming better known in France and Germany, and was more slowly, perhaps, taking its place in the pharmacy of Great Britain. Squire's 'Companion to the British Pharmacopœia,' eleventh edition, 1877, contains the following notice:—

"Liquor Ferri Dialysatus.—This preparation is an improvement upon the liquor ferri chloroxydi, as it is dialysed almost free from acid, and has no unpleasant taste. Each fluid drachm contains two grains of oxide of iron."

The Paris Pharmaceutical Society has included dialysed iron in its formulæ for new medicaments (*Pharm. Journ.*, July 14, 1877), and has given its quasi-official sanction to a standard of strength and purity, whilst the new remedy is waiting for the more important authority of acceptance by the framers of any legal pharmacopœia. It is not necessary to quote details of the process given. The result is said to be "a 10 per cent. solution." The solution of ammonia is directed to be used of "sp. gr. 1·169." Have not misprints crept into both these directions, or is the residue left on evaporation to be weighed and calculated in an undefined condition of dryness?* The properties of the product are thus described:—"The highly coloured solution is no longer precipitated by silver nitrate, and gives no acid reaction. It is then absolutely free from the disagreeable taste of certain ferruginous preparations."

Professor J. M. Maisch has published an interesting "Note on Dialysed Iron" in the *American Journal of Pharmacy* for July, 1877 (reprinted in *Pharm. Journ.*, August 4, 1877). Professor Maisch refers to the strength adopted by the Pharmaceutical Society of Paris as being 5 per cent., which is a close approach to the maximum amount found to be possible by Graham in his researches on the diffusion of liquids (1861). Professor Maisch says "As to the advantage of the dialysed over the oxychloride made by saturation with hydrate of iron, that is best ascertained by comparing their taste, which in the former is scarcely astringent, whilst that of the latter is distinctly ferruginous. A preparation now before me, imported from Germany, called ferrum oxydatum dialysatum, I do not hesitate to say has been made by saturation alone, or by incomplete dialysis, for its reaction is distinctly acid, and its taste quite styptic."

The determinations given below were made by the following method.—The solution was weighed into a beaker, heated, the iron precipitated with a slight excess of ammonia, the liquid again heated nearly to boiling, and filtered. The precipitate was well washed with hot

---

* The figures are misprints, which unfortunately escaped notice at the time. They should have been "sp. gr. 0·924," and "1 per cent." An erratum for the former was printed in the Journal of the following week, p. 60.—ED. PH. J.

water, dried, and ignited. The filtrate was acidified with pure nitric acid, and the chlorine precipitated as silver chloride.

The specific gravities were taken with great care in a long necked sp. gr. bottle, the water value of which had been accurately determined. They were taken at 18° C., and compared with water at the same temperature. The results are given in the following table :—

	Source.	Reaction.	Sp. gr.	Fe_2O_3 per cent.	Cl per cent.
I.	London, M.	Neutral.	1·0439	4·707	0·206
II.	German.	Acid.	1·0572	5·866	0·219
III.	Fer Bravais.	Neutral.	1·0316	3·430	0·194
IV.	London, H.	„	1·0560	4·484	0·051

The above table tells nearly all that we have to say. We may add that as to the quality of taste, all the samples but one might be described as almost tasteless. No. 2 was the exception, it having a much more marked chalybeate flavour. It will be noticed that this was the only sample showing a distinctly acid reaction to test paper. When it is compared in other respects with 1, 3, and 4 we find it with the highest specific gravity, and also higher in the percentage of both ferric oxide and chlorine. In fact, the amount of ferric oxide exceeds that which is possible in dialysed iron. It may be remarked that this was offered at a much lower price than the other samples, and it is probably one of the class of imported preparations condemned by Professor Maisch.

From its readiness the reaction with test paper should always be determined. Blue litmus paper may be wetted with the specimen under trial, and washed by the finger under a stream of water, then dried. No. 2 was the only sample yielding a distinctly red colour, the others retaining a more or less purple tint.

The determinations recorded in this paper were made by Mr. C. H. Bothamley in the laboratory of the Yorkshire College, Leeds.

Professor ATTFIELD said he had been lately looking into the grand volume relating to Graham's researches, printed at the expense of Mr. Young, with regard to the question of the dialysis of oxychloride of iron, and he found that Graham did not succeed in obtaining a non-chlorinous dialysed iron. His solution of oxychloride of iron contained about 1½ per cent. of chlorine to about 98½ of iron, whereas the authors stated that they obtained specimens containing 4·84 of iron, and 0·055 of chlorine, which would be only about one part of chlorine to 99 of iron. He should not have drawn attention to that but for noticing that Mr. Bothamley had obtained his oxide of iron by adding ammonia to the iron solution, and in that case he should have thought the hydrate of iron, in going down, would take a little chlorine with it. It was desirable to know that this dialysed iron was not merely a solution of iron, but that there was some chlorine there which doubtless had some function in keeping the iron in solution.

Dr. SYMES said he had dispensed dialysed iron for the last ten years at least, and he had found that the more of the chloroxide it contained the longer and better it would keep. If the process were carried too far it would become pectised on the dialyser ; the secret of preparing dialysed iron was simply in stopping the process at that particular point at which as large an amount as possible of the crystallizable chloride of iron was got rid of without carrying it too far and producing a product which would either pectise on the dialyser or become of that gelatinous condition very soon afterwards. One of Graham's difficulties was to prepare a solution which should be as nearly as possible that of the oxide, which would keep for any length of time, and any one reading his paper would feel that it was almost hopeless to prepare a solution which could be kept pharmaceutically. A syrup had been recently introduced and prescribed, which he regarded as unsatisfactory, for almost anything mixed with dialysed iron was liable to decompose it after a time, apparently by bringing about that particular change which Professor Graham referred to. The question had often been put to him with what substances it was compatible, and his advice generally was to mix it with a little water and nothing more. A little syrup might be added, but if kept for any length of time afterwards it was liable to gelatinize.

Professor MARKOE said a practical rule would be to stop the process of dialysis the moment there was not a distinct reaction with nitrate of silver. The average composition, if his memory served him, would be the molecule of ferric chloride to nineteen of ferric hydrate.

Mr. UMNEY remarked that they had frequently had occasion to regret calling preparations by wrong names, and this was a glaring instance. Instead of dialysed iron it should be called colloid iron, because the iron solution did not pass through the dialyser, but remained behind.

Professor ATTFIELD said that Professor Graham called the fluid that went through the dialyser the diffusate.

Mr. GREENISH said he made syrup of dialysed iron some time ago, and had dispensed it several times. It had not apparently undergone any change but seemed to keep very well. The strength was about 3 per cent.

The PRESIDENT said that in the absence of any well recognized strength, that which he had adopted had been that which exactly corresponded with the liq. ferri perchloridi of the Pharmacopœia. He found a simple method of manipulation was to convert an ordinary Wedgwood funnel into a dialyser, spread a nice piece of parchment over the bottom, gather it up the side, tie it round the neck, and introduce the mixture of liq. ferri perchloridi fortior, water, and ammonia, through the little aperture in the funnel. It was manipulated simply by changing the water twice a day for a fortnight, by which time the object was perfectly attained. It was a sort of rule of thumb process, but all the crystalloids were thus well dialysed from it and the result was not in a condition for pectising.

Mr. WILLIAMS remarked that a far simpler plan was to take an old sieve, tie it round with parchment paper, and put it in the water-bath.

Dr. SYMES said it would be better if a current of water were allowed to run underneath it.

Mr. GREENISH said some syrup was green, and some very dark. It would be well if they could come to some understanding what the strength should be.

Mr. WILLIAMS thought 5 per cent was about the strength usually considered the best. That was understood to be Bravais' strength.

A vote of thanks was accorded to the authors of the paper.

The next paper read was—

PRELIMINARY EXAMINATION OF PITURI OR PITCHERE.

BY A. W. GERARRD, F.C.S.,

Teacher of Pharmacy, University College.

I recently received from Professor Ringer a small drug specimen labelled "Pituri" or "Pitchere," and presented to him by a student of our college from Australia, with the observation that it was a most powerful substance in regard to its physiological action and required to be used with great caution. The specimen weighed thirty grains and was composed of small broken leaves and herbaceous twigs. The leaves were of a pale green colour, and coarse surface, averaging one eighth of an inch in width ; being all broken transversely, their length could not be determined ; the back of the leaf only showed an indistinct midrib; veins were not discernible.

A portion of the leaf when moistened with water and examined by a lens, displayed upon its upper surface a

coarse prominent honeycomb-like venation, forming an irregular fringe each side of the midrib; in the depressed portions of the leaf were displayed small rounded glands, transparent and of a brown colour. The form of the leaf, as far as I could judge by the broken portions, appeared to be subulate, narrowing at the base.

At a recent evening meeting of the Pharmaceutical Society, in the course of a discussion, pituri was incidentally mentioned by Dr. Bancroft as a drug most extraordinary and remarkable in its effects, supplies of which he was expecting. Further references being sought they were found in the 'Year-Book of Pharmacy,' 1874, p. 52, and were written by Dr. G. Bennett to the *New South Wales Medical Gazette*. He describes the pituri in the form of dried leaf, the botanical character of which could not be ascertained through its broken state. In the same connection is an abstract of a paper by Dr. Bancroft, read before the Queensland Philosophical Society, March, 1872, on the pituri. They are very interesting. I will give a few extracts.

"The plant is used by the natives as a stimulating narcotic, and its use is confined to the men of a tribe called Mallutha, all the males of which tribe are circumcised."

"The old men before any serious undertaking chew the leaves, and are then in a sufficiently courageous state of mind to fight or undertake any serious business."

"One old man refused to have anything to say or do until he had chewed the pituri, after which he rose and harangued in grand style, ordering the explorers to leave the place."

In small doses pituri has a highly intoxicating effect; also causes vomiting and a free secretion of saliva; in larger doses paralysis and death.

A later reference to pituri has been made by Baron Mueller, 'Year-Book of Pharmacy,' 1877, p. 222. The drug is to be found growing in the desert scrubs, from the Darling River and Barcooto to West Australia. In his opinion it is derived from *Duboisia Hopwoodii*. The blacks use it to excite their courage in warfare; a large dose infuriates them.

On first receiving this drug I concluded from the very small amount of it at my disposal it was not worth attempting to isolate its active constituent; but a second consideration, based upon its active attributes, led me to make the following experiments:—

The pituri was finely powdered and exhausted with 85 per cent. alcohol, containing a little tartaric acid; upon dispersion of the spirit the extract was dissolved with water and filtered, and the solution thus obtained treated with the following reagents (as it was necessary to be very economical drops only of my solution could be examined). With tannic acid it gave an abundant white precipitate. With iodohydrargyrate of potash an abundant white precipitate. With molybdate of soda and nitric acid a yellow precipitate, soluble in sodic hydrate. With perchloride of platinum a brownish-yellow precipitate. With the hydrates and carbonates of potash, soda and ammonia I obtained no precipitates, but the mixed drops of these latter were treated with chloroform, and the chloroform upon evaporation left a residue powerfully alkaline; this was diluted with a little water and nitric acid, and gave confirmatory reactions.

After these conclusive results the bulk of my solution was treated with ammonia and chloroform, when I obtained a nearly colourless moist film of a powerful alkaloidal substance. This alkaloid, or "pituria" as it may be called, is freely soluble in water, alcohol, ether, and chloroform. The film of alkaloid left after evaporation of the ether showed at its outer edge a fine fluorescence. A small portion tasted did not yield much bitterness but rather the numbing sensation of aconitia, but much less persistent than aconitia; with acids it forms neutral compounds. The nitrate and chloride of pituria which I prepared, drops of which were placed on watch glasses, did not crystallize on evaporation, but left a varnish. I think it very probable with more material at disposal crystalline salts may be easily prepared.

The remaining portion of the pituria I have placed in Professor Ringer's hands, who will investigate its physiological action so far as the amount at disposal will admit.*

In conclusion, with only one grain of the leaf of pituri it is possible to demonstrate most plainly the presence of the alkaloid: simply moisten the leaf with water, add a drop of ammonia, and shake with one drachm of ether; the ether will leave upon evaporation sufficient alkaloid to show several of its reactions.

Mr. DRAPER asked if Mr. Gerrard found the solid alkaloid itself fluorescent, as this was a rare phenomenon amongst solid bodies.

Mr. GERRARD said the edge of the solid film left after the evaporation of the ether was fluorescent. There were other alkaloids which presented the same appearance.

A vote of thanks was passed to Mr. Gerrard.

The next paper read was a

NOTE ON PHOSPHORUS IN THE PILL FORM.

BY A. W. GERRARD, F.C.S.,

Teacher of Pharmacy at University College.

During the past four years much has been said and written about the dispensing of phosphorus, and various methods have been suggested for presenting this active and useful drug in a form which shall be at once reliable, uniform, and elegant. Of the various novel suggestions made, none seems to have received anything like a general adoption; and glycerine, resinous and albuminous solutions of this drug are rarely or never seen in the physician's prescription.

Of the two methods by which phosphorus can be exhibited, solid and liquid, the pilular or solid is that to which preference is mostly given, and this preference may be explained upon good reasons; for instance, the material in which the phosphorus is diffused in a pill is small in bulk as compared with an emulsion or mixture, therefore the phosphorus in the pill is more likely to be preserved from change or loss by oxidation and to yield a more uniform therapeutic effect. Again, as a rule pills do not produce the nauseating effects of a dose of phosphorus in the fluid form; pills are also more convenient and portable.

Of the various methods recommended and mostly used for rendering phosphorus into pills I shall mention two, and the objections attached to them. The first method is to dissolve phosphorus in carbon disulphide, to pour this upon compound tragacanth powder, and make into a mass with water. The other method is to dissolve phosphorus in melted cacao butter, and when cold rub smooth in a mortar, and divide into pills; of these two processes I give the preference to the former, as the latter is most impracticable, for from the greasy nature and low melting point of cacao butter, it cannot be handled without clothing the fingers with a covering of phosphorescent fat, very annoying to the operator; and the mass does not yield well and regularly under the pressure of the pill cutter, but breaks into irregular fragments, which necessitates a remixing. My principal objection, however, to both processes is that much loss of phosphorus takes place by oxidation during the process of manipulation, and unless the manipulation be dexterously and expeditiously carried out this loss is considerable; the prevention or reduction of this loss to a minimum is the main object of this note, and the following is the process

* As Dr. Ringer and myself are anxious to obtain further supplies of pituri, none being obtainable in this country, any gentleman or pharmacist in Australia or New Zealand forwarding small parcels of an ounce or so, shall receive our best thanks.

I have employed for a period extending over a year with very good results.

I will give a formula for thirty pills, each pill to contain one thirtieth of a grain of phosphorus.

Take of

Phosphorus	1 grain.
Carbon Bisulphide	20 minims.
Compound Tragacanth Powder	90 grains.
Chloroform	a sufficiency.
Water	a sufficiency.

Place the phosphorus in a Wedgwood mortar, pour over it the carbon bisulphide, then add the tragacanth powder and ten minims of chloroform, mix into a uniform product, then add water a sufficiency to form a pill mass, maintaining during the whole of the process the presence of chloroform; divide into thirty pills.

The novelty in this method depends upon the presence of chloroform; and the explanation of the part it serves is as follows:—Whilst chloroform is present in the mortar it forms a heavy vapour which surrounds the phosphorus, preventing the contact of air and the consequent oxidation; of course as soon as the materials are kneaded into the necessary uniform mass the whole of the chloroform is allowed to evaporate; when the chloroform has evaporated, some surface—and only surface—oxidation takes place.

In conclusion, I would advise those who wish to try the experiment of dispensing phosphorus, to compare the method I have given both with and without chloroform; in the one case you have much phosphorescence and irritating fumes evolved; in the other there is no apparent phosphorescence, and very little fume. In fact I have worked eight ounces of mass into pills easily by this new process, which otherwise would almost have been an impossibility; the greatest advantage, however, I consider it offers is that the patient gets the nearest possible approximation to the dose given in the prescription.

Mr. GREENISH said he had paid some little attention to the dispensing of phosphorus pills, and the plan adopted was somewhat different to that described. He dissolved the phosphorus in bisulphide of carbon, then mixed the cacao butter with it, and after that anything else required. By putting the cacao butter into the mortar with the solution he considered the difficulty mentioned by Mr. Gerrard was got over.

A vote of thanks was passed to Mr. Gerrard.

The next paper was—

NOTES ON A NEW DOUBLE IODIDE.

BY FREDERICK W. FLETCHER, F.C.S.

The strong tendency exhibited by many of the iodides to form double salts is well known. Within the last ten days a new and striking instance of this characteristic feature has come under my notice, and the compound produced is in many respects so remarkable, that I venture to submit the few notes which I have been able to make respecting it, to the consideration of the Conference.

In experimenting upon a complex solution, which amongst other things was known to contain a salt of quinine, I was somewhat astonished to find a copious scarlet precipitate produced on the addition of potassium iodide. The colour was not sufficiently vivid for that of mercuric iodide, and with the exception of the little known but curious double iodide of mercury and copper, no iodide with a like appearance, produced under similar conditions, suggested itself.

Having collected and washed the precipitate, I proceeded to examine it qualitatively, when it was found to contain besides the halogen, bismuth and quinine. Solutions of these last two substances were then prepared and mixed, and I found that not only in each case was this brilliant precipitate obtained on the instant that an iodide was introduced, but that by experimentally regulating the proportions of the three salts, it was possible to remove the whole of the quinine, the bismuth, and the iodine from the solution in the form of this beautiful double salt.

A few ounces of the compound having been carefully prepared, I submitted a portion to analysis in order to ascertain the relative proportions in which the elements present were combined, and thus arrive at its proper formula.

The bismuth was thrown down from a solution of the salt in ammonium citrate containing excess of acid, by hydrogen sulphide, 1 gram yielding ·322 gram Bi_2S_3, equivalent to 26·2 per cent. of metal.

The quinine was estimated in a similarly prepared solution by Allen's ether method, a process which always gives unexceptionable results.

1 gram of the salt yielded ·202 gram anhydrous quinia, or 20·2 per cent.

The iodine was separated as a silver salt, 1 gram yielding ·989 gram AgI, equal to 53·4 per cent. of iodine.

From these results it is evident that the salt is a compound of tri-iodide of bismuth and hydriodate of quinine, in the proportion of two molecules of the former to one of the latter substance, and it would therefore have the formula—

$$(BiI_3)_2C_{20}H_{24}N_2O_2.HI.$$

The theoretical and actual results bear the following relations:—

	Calculated.	Found.
Bismuth	25·7	26·2
Quinine	19·9	20·2
Iodine	54·4	53·4

The salt is very sparingly soluble in cold, but more freely in hot water.

Rectified spirit dissolves it slightly in the cold, but very readily when warmed.

It is completely taken up by an alcoholic solution of potassium iodide, forming a brilliant crimson solution.

It is decomposed by the stronger acids with liberation of iodine. Digested in strong solution of ammonia, its colour is destroyed, and an insoluble residue of oxide of bismuth and quinine remains.

Gradually heated in a porcelain crucible, it at first fuses to a shining purplish-black mass, and as the temperature increases, fumes of iodine, together with scarlet coloured vapours are evolved, which condense upon a cold surface, in a particoloured deposit, which presents under the microscope a crystalline structure.

When a few grains of the salt are rubbed upon paper and gently warmed, like the double iodide of mercury and copper, it becomes black, regaining its original colour gradually, if allowed to cool spontaneously, and instantly if the paper be laid upon something cold, such as a steel knife or bottle of water.

Whether this compound possesses any special medicinal value is a point which, of course, experiment can alone determine. All that can at present be said is, that if it is desired to administer quinine and bismuth in conjunction with iodine, the salt under notice affords an admirable method of doing so.

From a chemical point of view, the salt is interesting, and the decomposition which gives rise to its formation might possibly be found of value as the basis of a volumetric process for the estimation of salts of bismuth and quinine.

Mr. ALLEN said this substance was particularly interesting, as giving another instance of the curious property of iodides of changing colour on exposure to very slight heat. Another case was the iodide mentioned by Mr. Fletcher as produced by mixing a solution of a cuprous salt with solution of a mercuric salt; if this mixture were added to an iodide, such as iodide of potassium, it gave a double iodide of a similar colour to the one now shown, but at the least increase of temperature it turned perfectly

black. If a piece of paper covered with this compound were warmed, the compound turned black, and if a finger were drawn across the back of the paper it made a red stain. Upon cooling it again became red and the experiment could be repeated indefinitely; and it was the most delicate instance of change of colour due to a slight change of temperature that he knew of.

Mr. GERRARD thought this red double salt had been noticed before and a very close research made upon it by a gentleman in London, whose name he forgot, but he believed it was reported in the Journal some three years ago.

A vote of thanks was passed to Mr. Fletcher.

The Secretary read a paper entitled—

LABORATORY NOTES.

BY HENRY BARTON.

Liq. Ammon. Citratis.

This preparation is unsatisfactory from its proneness to change, and when required in a hurry, has to be freed from its unsightly appearance by filtration through paper or cotton wool; but prepared four times the strength of the Pharmacopœia solution it keeps perfectly, and the addition of three parts water to one of the concentrated solution has always the freshness so satisfactory to the dispenser.

Tinct. Cort. Limonis.

Tinct. Aurant. Recentis.

The fresh peel sliced thin enough is a simple and original process and when carefully performed presents considerable surface to the spirit; but undoubtedly the best method of proceeding is to grate the rind from the surfaces of the fruit; the grated, light, almost wool-like peel is in splendid condition for the action of the menstruum and repays any extra patience required in its preparation.

Sapo Durus.

Sapo Animalis.

The weighed average result of drying into a suitable pulverizable condition numerous recent samples from different warehouses, has in my hands given an average loss of 25 per cent.; taking into consideration that parcels are received into stock and kept for longer or shorter periods, under the varying circumstances of storage in damp cellars, cold or hot warehouse rooms, etc., the liquid preparations of soap must vary considerably both in the amount of solid matter and the water they contain.

I would suggest that in all cases dried soap should be used, not in the form of powder, but in that of shavings produced by planing the bars and exposing the thin curls to a suitable temperature until a sufficient dryness has been attained. The amount used in the various formulas could be readily adjusted.

Chloric Ether.

Upon the introduction of tinct. chloroformi co. and sp. chloroformi, it was said that the former would in strength represent chloric ether and probably supersede it; whilst the latter would be used as a weaker preparation, as also by those who did not desire the coloured tincture. Both are a great deal prescribed, but neither so much so as the chloric ether, and it is to the want of uniformity in the latter I would draw attention, the amount of chloroform varying as much as 50 per cent. in different specimens, and would suggest that the strength of the compound tincture, one in ten, should be taken as the standard, which would sometimes obviate the remark, "This mixture does not taste the same as before."

Pil. Phosphori.

The Pharmacopœia formula is not a popular one in the profession; and amongst all the various preparations and modes of preparation, from resin to suet, none appears to me to produce a mass in all respects so satisfactory as that suggested by Messrs. Allen and Hanbury in the *Pharmaceutical Journal* of May 20, 1876; the phosphorus dissolved in the bisulphide in a small phial and added as directed to the other ingredients, requires neither the aid of fire nor water, the process is rapidly conducted and the result admirable. For stock I have usually made the mass into fifty grain balls, representing one grain of phosphorus, and covered them with a pill coating. When required with other ingredients a minimum of spirit is usually all that is requisite.

The thanks of the trade are due to Messrs. Hanbury for formulating the process.

A vote of thanks was passed to Mr. Barton.

The last paper read was a—

NOTE ON REICHERT'S IMPROVED THERMO-REGULATOR.

BY CHARLES SYMES, PH.D.

Thermo-regulators are amongst the very useful and much neglected aids to pharmacy. The instances do not perhaps occur daily, but certainly not unfrequently, where the maintenance of a uniform temperature is most desirable if not indispensable. Extracts when not manufactured on the premises are often received too soft for dispensing purposes and have to be further dried by the pharmacist himself. This is an operation of some delicacy, if the desired result is to be accomplished without injury to the product. The use of a thermo-regulator simplifies the work and renders it such as to require little care or attention.

In drying small quantities of precipitates, pepsine, and indeed in all operations where desiccation or digestion is to be conducted at an uniformly moderate or even high temperature, these instruments save the operator a considerable amount of time and anxiety. They vary in form; that with which I have the most experience is the one introduced by Mr. Benger some years since, and it works admirably, except perhaps when from frequent and lengthened use the small tap ceases to be air-tight, and this of course can easily be remedied; in fact the weak point in these instruments generally is the possibility of leakage.

This will occasionally occur in the Bunsen regulator if it is not in a vertical position, and in it the mercury after a time becomes slightly oxidized and sluggish in its movement.

Reichert's instrument is specially adapted for small operations, such as heating liquids in flasks; being thin it readily passes into a narrow neck or through a perforated cork. Its action depends on the direct expansion of a column of mercury, instead of air acting on mercury as in the other instruments, and thus the possibility of leakage is reduced to a minimum. In its original construction the tube connected with the gas supply was fused into the instrument, but this was found inconvenient, and it was then passed through a perforated cork, which however has now been replaced by a well ground tubulated stopper. The improvement is apparently slight, but it is nevertheless important; it allows the instrument to be used at a higher temperature, near to the boiling point of mercury if so desired; the constant flow of gas can be regulated for low temperatures as well as the more or less intermittent one, and the point of the tube being always brought into exactly the same position and held rigidly there it is protected from injury by any undue vertical pressure or lateral motion.

The PRESIDENT said this seemed a very valuable practical piece of apparatus.

Mr. GROVES said the special advantage of it was that the gas furnished by the small hole sufficed to keep the gas burner always going, and from time to time the gas was added to by the action of the instrument to keep up the proper temperature.

Dr. QUINLAN asked if a difference in the pressure of the gas had any effect on the action of the instrument.

In Dublin the gas company had to maintain a minimum pressure of 6-10ths, but it sometimes went up towards evening to 32-10ths. Could this instrument be used in connection with a "Peebles" automatic gas regulator, such as he used himself, so as to keep the gas always at a pressure of not exceeding one inch?

Dr. SYMES said one object of the regulator was to meet the difficulty arising from varying pressures. Immediately more pressure was put on at the gas works the temperature would rise in the flask, and then the supply of gas would be partly cut off by the instrument.

A vote of thanks was passed to Dr. Symes.

CLOSING BUSINESS.

THE PLACE OF MEETING IN 1879.

At the conclusion of the reading of the papers,

Mr. WARD (Sheffield) said he had much pleasure in delivering a message with which he had been charged by his brother pharmacists of Sheffield, namely, to give a warm and hearty invitation to the Conference to meet in that town next year.

Professor ATTFIELD moved that the thanks of the Conference be given to the chemists of Sheffield, and that their invitation be accepted. The pharmacists of that town had been warm supporters of the Conference from its birth; he knew that there were many of them who highly appreciated the work of the Conference, and he was sure they would find many friends there.

Mr. J. WILLIAMS seconded the resolution, which was carried unanimously.

Professor MARKOE begged to add that the American Pharmaceutical Society would probably hold its annual meeting in New York in the beginning of September, 1879, when any members of the British Pharmaceutical Society who were travelling that way would be heartily welcome.

Mr. WARD said they should be very pleased to see as many of their Irish friends as possible in Sheffield next year.

ELECTION OF OFFICERS.

The following were elected as the Officers of the Conference for the ensuing year, and a resolution was also passed empowering the Executive Committee to fill up the vacancies, viz., one Vice-President, one Member of the Executive Committee, a Local Secretary, and an Auditor, from Sheffield:—

President.

G. F. SCHACHT, F.C.S., Clifton.

Vice-Presidents.

Professor TICHBORNE, F.C.S., Dublin.
R. REYNOLDS, F.C.S., Leeds.
J. WILLIAMS, F.C.S., London.

Treasurer.

C. EKIN, F.C.S., Bath.

General Secretaries.

Professor ATTFIELD, F.C.S., London.
F. BADEN BENGER, F.C.S., Manchester.

Other Members of Executive Committee.

M. CARTEIGHE, F.C.S., London.
T. GREENISH, F.C.S., London.
H. N. DRAPER, F.C.S., Dublin.
A. H. MASON, F.C.S., Liverpool.
C. SYMES, Ph.D., Liverpool.
W. A. TILDEN, D.Sc., F.C.S., Clifton,
C. UMNEY, F.C.S. London.
J. C. THRESH, F.C.S., Buxton.

Auditors.

W. HAYES, Dublin.

A resolution was also passed empowering the Executive Committee to alter the place of meeting if it should happen, which was not anticipated, that the British Association did not hold its meeting in Sheffield.

Mr. EKIN said the present meeting had been eminently successful; in fact he did not remember any occasion on which the arrangements for the comfort of the members had been so thoroughly carried out. They all knew that Irish hospitality was proverbial, and they had abundantly proved the truth of the saying. He begged, therefore, most cordially to move the following resolution:—

> "That the hearty thanks of the non-resident members of the Conference be given to the Irish members, and especially to Mr. William Hayes, Messrs. Tichborne, Draper, Hodgson, and Boyd, and the other members of the Irish Committee for their kind and successful efforts in organizing the present meeting."

Mr. FRAZER, in seconding the motion, said they thought they had done pretty well in Scotland, but he must confess that in some respects they had been outdone by their Irish friends.

After a few words in support by Professor Attfield, the resolution was carried unanimously.

Mr. HAYES in responding on behalf of himself and the local committee, said it had given them infinite pleasure to receive the Conference, and although it might be a long time before their visit was repeated, he hoped the time might come when they would again have that pleasure.

Mr. DRAPER proposed that the best thanks of the meeting be given to Mr. Schacht for the able manner in which he had conducted the business of the present Conference.

Dr. QUINLAN had much pleasure in seconding the motion. He had not previously the pleasure of Mr. Schacht's personal acquaintance, but he had long known him by reputation, and by the several admirable preparations he had introduced. Some of them it had been his duty as teacher of materia medica to explain to his class, and as a practising physician to use with advantage. The skill, judgment, and urbanity with which Mr. Schacht had conducted the proceedings augured well for their meeting next year. Besides the scientific merit of the papers which were read, he thought these meetings did a great deal of good, for the more they brought Englishmen, Irishmen, and Scotchmen together, the better. They would all find that some of the prejudices these countries had on all sides entertained towards each other were groundless, and he hoped the day would not be distant when the Conference would meet in Dublin again.

The resolution was put by Mr. GROVES, and carried unanimously.

The PRESIDENT having acknowledged the compliment, said there was one resolution which ought to have come first, and which he would take the opportunity of moving. They were all much gratified by having had the use of such a fine suite of rooms to meet in, and he would therefore propose—

> "That the best thanks of the Conference be given to the King's and Queen's College of Physicians of Ireland for their kindness in placing at our service their elegant and convenient suite of rooms."

The resolution was carried by acclamation, and the proceedings of the Conference terminated.

Parliamentary and Law Proceedings.

HEART DISEASE *v.* STRYCHNIA.

On Saturday, Sept. 21, Mr. G. H. Hull held an inquiry at Battersea, on the body of Sarah Annie Adams, aged 16. Charlotte Grubb stated that the deceased, with her father and mother, were lodgers in her house. On Wednesday morning, at about 7 o'clock, the witness heard her leave the house to go to her work; but she returned in half an hour, and went up to her bedroom. Witness went

upstairs, and deceased asked for some water, stating that she had been taken ill. Witness went several times upstairs to see her, but on going to her room at half-past 11 she found the deceased dead. Mr. Edwin Howard, surgeon, said he had made a *post-mortem* examination. The heart was soft and diseased, but in the stomach he found a portion of Battle's vermin killer wrapped tightly in a piece of paper. The poison, however, had not been absorbed into the system, and he was of opinion that death was due to the diseased condition of the heart. If the paper had burst and the powder been absorbed into the system, it would have been sufficient to cause death. After some deliberation, the jury returned a verdict of "Death from diseased heart."

Robbery at a Co-operative Stores.

At the Middlesex Sessions, on Monday, Richard William Rees, 34, a chemist,* was charged with having stolen two bottles of patent medicine of the value of 6*s.* 8*d.*, the property of Frederick Bradford M'Crea, his master, who is the general manager of the Army and Navy Co-operative Stores, at 117, Victoria Street. Mr. Forrest Fulton prosecuted. Rees had entered the service of Mr. M'Crea on the 26th of August last as storekeeper, at £1 10*s.* per week, and on the 18th of September, as he was leaving the stores after his day's work, he was stopped and searched, when two bottles of medicine were found in his trousers pocket. He was given into custody. He alleged, in defence, that he intended to pay for the bottles in the morning; but it was proved that no *employé* of the stores could purchase anything without going through certain forms which Rees had on this occasion not gone through. The jury returned a verdict of Guilty with a recommendation to mercy, and the Assistant Judge sentenced Rees to two months' imprisonment, with hard labour.—*Times.*

Dispensing Memoranda.

[117]. If, as Mr. Griffin suggests, every prescriber who orders "Tinct. Card." is to be sought out and questioned by every dispenser into whose hands the unlucky prescription may fall, there will soon be a cry of annoyance from the medical profession and its trust in the good sense of the pharmacist seriously jeopardized.

Would it not be a safe rule to dispense the B.P. preparation unless any other is specially indicated?

Pulvinus.

[147]. Liquor Secalis Ammon.—A few weeks ago I asked for a formula for preparing this liquor. Numerous replies have been sent to the Journal stating the names and addresses of six different makers, but no one has been able to venture a process for its manufacture. Now, as this preparation is a most valuable therapeutic agent to the obstetric practitioner, safe and reliable in its action, combining all the virtues of the fresh ergot and the antispasmodic properties of the sal volatile, why should it not possess a recognized formula known to every dispensing chemist, in the same manner as the recipes for the production of liquor Hoffmani, Parrish's and Easton's syrups, and many other specialties are known all over the kingdom, and which preparations would never have gained the reputation they at present enjoy had their manufacture been exclusively confined to one or two wholesale houses. I would therefore suggest that a tinct. ergotæ ammon., prepared as directed in the B.P. process for tinct. valerian. ammon., would be a convenient form. I have already mentioned extract. ergotæ liquid., three parts, sp. ammon. aromat., one part; each fluid drachm would thus equal forty-five grains of fresh ergot and fifteen minims of sal volatile, but the former mode would, I should think, yield a more suitable and satisfactory preparation.

Sub Umbra Floresco.

[155]. Replying to "Sub Umbra Floresco's" query, I beg to subjoin a letter which may, to some extent, elucidate his difficulty. It was published in the *Lancet* of August 22, 1868, and was penned by the (I believe) original prescriber of etherized cod-liver oil, but whether such authorship will constitute it a "recognized formula," I am unable to decide:—

"*Ether and Etherized Cod-Liver Oil in the Treatment of Phthisis.*

"Sir,—Will you allow me to reply in your columns to the many inquiries addressed to me respecting the composition of the etherized cod-liver oil?

"I have three formulæ:—

"No. 1 consists of ten minims of pure ether (æther purus, B.P.) in two fluid drachms of cod-liver oil.

"Nos. 2 and 3 consist respectively of fifteen and twenty minims of pure ether in the same quantity of oil.

"The dose of the etherized oil to commence with is two fluid drachms. In some cases the ether may be given in the same or larger doses in water before meals.—Yours, etc.,—Balthazar Foster."

Of course it is a matter of conjecture whether, in the prescription handed to "Sub Umbra Floresco" to dispense, No. 1, 2 or 3 was intended, or whether Dr. Foster's preparation was intended at all, but in the absence of more distinct definition I should feel justified in adopting a medium course and dispensing No. 2 strength as meeting the requirements of the case.

Manchester. Charles Swinn.

[159]. Explosive Mixtures.—"An Assistant" will find an account of similar "explosive mixtures," and a reply by E. H. Holmes, and also an article in "The Month," if he refers to the following pages of the Journal:—3rd Series, Vol. VII., pp. 1054 and 1073; 3rd Series, Vol. VIII., p. 66.

F. A. B.

[159]. "An Assistant" will probably find out the cause of his disastrous experience by testing his bismuth with blue litmus paper.

Pulvinus.

[159]. In reply to "An Assistant," I should say that the cause of the bottle containing the ingredients named bursting was the disengagement of carbonic acid gas from the carb. ammon. by the action of bismuthi subnitras. If hot water were used to dissolve sodæ bicarbonas, and the spt. ammoniæ et chloroformi added, and the bottle at once closed, the vapour of both spirits might cause sufficient pressure to occasion the accident. Of course hot water ought not to be used.

S. F. C. P.

[160]. The precipitation of calcis carbonas, as well as the incompatibility of the vinum opii with alkalies, should have been sufficient to indicate to the dispenser the necessity of giving directions for shaking the bottle of mixture.

S. F. C. P.

[161]. I have frequently dispensed from a prescription ordering these ingredients and proportions. It is impossible to prevent the decomposition taking place, and, therefore, to dispense a clear mixture. I find that if hot water is used to dissolve the citrate, and the spirit added to the solution, the abominable appearance of the medicine is greatly mitigated. But I cannot recommend the use of heat, as, if the bottle is quickly closed to avoid

* There is no person of this name registered as a Chemist and Druggist.—Ed. Ph. Journ.

loss, there is danger of it bursting, and I am afraid the considerably improved appearance of the mixture is gained only by the loss of the carbonate of ammonia. I direct the bottle to be shaken, and, pardon me for remarking, use the B.P. citrate invariably.

S. F. C. P.

---

[162]. In reference to this query we have received a note from the writer to the effect that the last ingredient in the prescriptiou should read—

Aq. Camph. . . . . ad ℥vj.

---

[163]. What is the proper quantity of pulv. acaciæ or mucilage to use in this prescription; and what is the rule followed in dispensing houses, when mucil q. s. is ordered?

℞ Bismuth. Trisn. . . . . ℥iss
Sodæ Bicarb. . . . . ℥iss
Mist. Acaciæ . . . . . q. s.
Inf. Gent. Co. . . . . ad ℥viij
M. PULVINUS.

---

[164]. In preparing acid. nitrohydrochlor. dil., the strong acids are ordered to be mixed and allowed to stand for twenty-four hours before adding the water, "in order," as Squire remarks "to develop the chlorine." Is there no further chemical change after the water is added? I ask this question because Dr. Wood, of Philadelphia, in his 'Treatise on Therapeutics,' a work that seems to be held in high esteem by the medical profession, asserts that there is, and that the change goes on "more rapidly after the water is added" than before.

Is Dr. Wood right or wrong? J. S.

---

[165]. Can any reader inform me how he would dispense the following which was presented to me a few days ago?—

Lap. Divin.
Aquæ Rosæ . . . . . ad ℥iv.
Ft. lotio. To bathe the eyes occasionally.

MAJOR.

Notes and Queries.

[519]. LIME JUICE CORDIAL.—The following recipe makes a highly satisfactory preparations:—

℞ Glucose (by weight) . . . . . ℥iv.
Syrup, B.P. . . . . Oj.
Lime Fruit Juice . . . . . Oj.
Water . . . . . ℥xxxvi.

Tincture of Lemon Peel and Triple Orange Flower Water, of each sufficient to flavour.

M. SUB UMBRA FLORESCO.

---

[522]. A WHEAT-DRESSING said to prevent the ravages of birds, etc., on newly sown lands has recently been introduced. It is supposed to contain carbolic acid or some preparation of tar. Would any reader kindly give the names and proportions of the articles used for the purpose, and oblige?

"QUERIST."

TOUGHENED GLASS.—The following paragraph occurs on p. 431, of the *Lady's Magazine*, A.D. 1820, and published in London:—

"Let the glass be put into a vessel of cold water, which water is then to be made boiling hot, and afterwards allowed to cool gradually. Glasses thus treated may be suddenly filled with boiling water, without any danger of cracking, but the process is improved by using oil."

The modern discovery of "toughening" glass by annealing in oil is, therefore, merely a revival, with some modification, of an old process.

Grantham. G. WELBORN.

DANGEROUS DOSES AND DIFFICULT PROBLEMS.

Sir,—It is scarcely fair, perhaps, to judge of another man's actions without placing ourselves in an exactly similar position, and this is not always easy to accomplish. However, the subject now being dealt with under the above head is, as Mr. Greenish has well remarked, "one of immediate interest to every dispenser, and a legitimate subject for discussion in the *Pharmaceutical Journal*."

The digitalis case, still fresh in the memory of most of us, and quoted by him, is one of real difficulty. A pharmacist, unaware of the fact that tincture of digitalis had been given in very large doses for delirium tremens, received a prescription ordering half an ounce in a single dose, does his best to get this order confirmed by the prescriber, fails to find him, refuses (in the absence of confirmation) to dispense the prescription, the patient dies, the medical man makes the worst of the matter, and the coroner's jury (to my mind) very unjustly censure him.

Compared with this the case of "Beta," now under discussion, is exceedingly simple, and on reading the letter in your Journal of July 13, the following were my reflections: "If a physician cannot get his prescription dispensed at a pharmaceutical chemist's in a leading London thoroughfare, because it involves some responsibility, whither must he send his patients? Surely it is no light matter that such a powerful argument should be placed in the hands of those practitioners who still dispense their own medicines. Something ought to be done to set this matter right. I will write to the Journal! But there will be many answers to this and my letter might not appear till the thing is almost forgotten." And so I did not write. Perhaps others thought the same and what bid fair to elicit so much correspondence, lay dormant till resuscitated by your article "The Month." Here you point out that the apothecary and not the pharmacist is the man who is legally bound to dispense a prescription; but we must not forget that the moral is quite as forcible as the legal bearing of the subject; the latter has, to a great extent, superseded the former and the dispensing apothecary has now nearly ceased to exist. If then the pharmacist by his survival is to prove himself the fittest, he must accept the position in its entirety. The dispenser's duties, it is true, are sufficiently serious without being increased by having to decide whether large doses are or are not intended when ordered, and it is unfair that he should have this additional responsibility thrown upon him. The digitalis case did good service in this respect; since that time many medical men either underline strong doses or write the quantities in words instead of signs and figures to indicate that they have given special consideration to the quantities prescribed.

In the cantharides case the dose is large but not excessive, and in such instances there is some delicacy and etiquette involved in asking a medical man for confirmation of his prescription and some danger of weakening the confidence of the patient. We must bear in mind that it is almost equivalent to asking a man if he knows what he has been doing. Doubtless "Beta" gave this due consideration and framed his query with proper care; but it would have been well if it had been published, so that we might have judged how far it merited the curt and not over-courteous, but certainly most definite reply, on the receipt of which, to my mind, his path was clear; he should most assuredly have dispensed the prescription. As to whether he should have given 18 or 100 pills, the fact of this quantity being requested should have been mentioned to the physician and the reply acted on accordingly. For my own part I would much rather dispense such a prescription than one ordering eight minims of prussic acid for a dose, although it is not in excess of the Pharmacopœia quantity, and the risk to the patient would be less; but I do hold that the dispensing of such prescriptions should be well paid for, and it is doubtful if the patient would have complained so much at

the charge as at having his prescription returned to him undispensed after he had paid the physician his fee for writing it.

Liverpool, September, 1878. CHARLES SYMES.

Sir,—In writing from Mr. Greenish's letter I overlooked the fact that the dispenser after receiving the prescriber's reply still hesitated and finally declined to dispense the prescription. Here, I think, he was in error, as the medical man had clearly taken the responsibility upon himself.

Manchester, September, 1877. WM. LANE.

Sir,—In your last week's issue Mr. Henry Brown, in referring to my letter on the above subject, has apparently overlooked a material point bearing on the second question.

It is stated in the original letter of "Beta" on this subject, that the writer of the prescription was referred to and gave his emphatic sanction to the prescription as written, which ordered eighteen pills only, but the conditions were altered by the bearer of the prescription requiring for the patient one hundred pills, and it is to these altered conditions that my second question refers.

20, *New Street, Dorset Square*. THOMAS GREENISH.

EXAMINATION DISCREPANCIES.

Sir,—I shall feel obliged if you will give me a few lines on this much talked about question. G. W. W., whose letter appears in the *Pharmaceutical Journal* of the 14th inst., speaks of the recognized school at which he studied having *vivâ voce* examinations, which enable the teachers to have an intimate knowledge as regards the ability of their men, and that the best men are sent up the first day, next best men next day, etc. It may be so at that particular school and also at some other schools, but not at all. Now I have just left one where we also had *vivâ voce* examinations, and those thought qualified were all advised to send in their names early; those second and third best men G. W. W. speaks of were not advised to wait a few days longer and then enter, but to wait until the next examination.

My opinion is that whether a man goes in the first or the last day, if he be as he ought to be, he will not get "plucked" (of course there are exceptions). I know of many men who entered from one school on the last day and all passed, Why? Simply because they were men who had worked, and they consequently passed, not by the skin of their teeth, as I hear some students say they do, but to their credit and that of the pharmaceutical world.

I also was summoned to attend at Bloomsbury Square at 10.30 a.m., and it also happened that my name came last, being a W., but I did not feel the want of any refreshment, and I think that students are much better without it.

Some complain of the examiners being unfair, etc. I found them gentlemen in every sense of the word, and enjoyed my examination very much; indeed, so much so that I was in one way sorry the next day I had not to go before them again; however, I hope to do so soon.

When students go up for examination without the slightest knowledge of the dose of pulv. ipecac. comp., or when asked what a potato is in botanical language say it is a vegetable,—and I know of such cases—no wonder if the examiners should then lose their temper and students get plucked, as I think they ought to be.

If students work they need not fear first or last day, and I trust this may encourage some, besides

September 17, 1878. LEPO.

PHYSICIANS AND SURGEONS *versus* CHEMISTS AND DRUGGISTS.

Sir,—I am surprised that Dr. Williams's letter in last week's *Pharmaceutical Journal* has not called forth a greater response, for though apparently well intended, its suggestions are manifestly impracticable, and somewhat discourteous. Since no abler pen has done so, I take up mine with all due deference to register a protest against the insinuation that all the "brains" are on the side of the doctors, while the chemist is a mere shopkeeper, unable to manage his own affairs; for the practice of pharmacy, at least in its connection with the medical profession in the dispensing of prescriptions, partakes considerably of the nature of a profession, requiring skill and technical knowledge, only to be obtained by study and experience, remuneration for which is regulated, and rightly so, rather by a scale of fees (varying necessarily in different localities) determined by the kind and quantity of medicine dispensed than by its actual intrinsic value. Even supposing dispensing to be a mere commercial transaction, surely it is hardly the way to prevent chemists from prescribing by reducing their present profits, which, though they may be proportionately large, from the small amount of business done, are not sufficient in amount to afford a living without supplementing them by the sale of numerous "sundries." A constant inducement is thus presented to the chemist and druggist to bring grist to the mill by giving additional "brains" in the shape of medical advice to his customers, which by the way surely he has as much right to do as any other individual who has no knowledge whatever either of medicine or of the properties of drugs, in spite of any Acts of Parliament or decisions of magistrates. Not that I would in any way advocate counter prescribing, but rather discourage it, except inasmuch as it is a natural demand of the public, which must be supplied, the chemist being passively helpless in the matter, the *onus* of rectification lying, I think, between the public and the profession. So let the latter take the first step by ceasing to dispense their own medicines, and regulate their fees to suit all classes; it would then be left to the honour of the chemist, as also to his interest, to discourage, if he could not prevent, the public from coming to him for advice.

September 16, 1878. A PHARMACIST.

Sir,—I am sorry to see so much criticism by chemists against Dr. Williams's charges for dispensing, which appeared in the Journal of the 7th inst. It would be a difficult matter for one to write a suggestion upon this subject (or any other) that would meet the approbation of all chemists. Most medical practitioners dispense their own medicines for several reasons, in the first place many cannot afford to pay a chemist to dispense them; secondly, their class of patients generally cannot or will not pay the chemist 1*s.* 6*d.* for medicine after paying 3*s.* 6*d.* or 5*s.* to their medical man for advice.

A. F. thinks Dr. Williams's charges "absurd:" it might be so, or it might not be so, but there are scores of chemists (who keep assistants), and do not charge a penny higher than those prices stated, without the medicine contains large doses of quinine or other expensive drugs; then they charge accordingly. But the general routine of practitioners' prescriptions are very inexpensive and the chemist may charge even more reasonably for the larger size bottles to the poorer class. I might surprise A. F. by stating that I charge medical men for their prescriptions 5*s.* and 6*s.* per dozen, taking large and small mixtures together; also that I send them, then get a fair profit thereby.

Several medical men with whom I am acquainted make a practice to write "P. P." (poor person) in the corner of their prescriptions when they prescribe for a poor person who can scarcely afford to pay for medicine. In such cases also I moderate my charge, and such cases as these Dr. Williams, I presume, alludes to chiefly. But the chemist will grumble,—strangely it is his nature,—nevertheless the only way to met the difficulty is to use our endeavours to come to terms as reasonably as possible, which the surgeon could arrange mutually with his neighbouring chemists. It is a matter of impossibility to draw a definition between the duties of a surgeon and those of a chemist, because the latter is obliged to give advice in minor ailments; by refusing he would not only lose a very great portion of his business, but be looked upon by his customers as an ignoramus. But I am sorry so many chemists overstep their duty by either undertaking a case they know nothing of, or visiting Mrs. So-and-so's baby opposite, who might be a customer, which naturally causes a jealousy; then no one can blame the Apothecaries' Society for intervening in such cases.

"TENENS."

Sir,—In the very long letter which you published on the 7th inst., headed as above, there is a very strong feeling of *animus* underlying the whole communication, which has not been touched upon by your correspondents in your issue of the 14th. Possibly they may have intentionally passed it

over, thinking it wiser not to notice it. If so, I will not question their judgment and wisdom in so doing. But perhaps it might be as well for gentlemen who sign themselves "M.D." to remember that chemists, even if they are only tradesmen, have sufficient education and intelligence to guard their own interests; and while honourably serving the public, seek and expect in return that compensation which their social position and despised ability justly entitle them to.

I doubt not that chemists, equally with the higher branches of the medical profession, would gladly hail a settlement of this long vexed question of counter prescribing, and as honourable men, do their best to escape an unpleasant position of responsibility, which through the combination of circumstances they have gradually though unintentionally fallen into, if the "profession" will have the good taste to leave the question of chemists' charges to those who are more competent to decide so delicate a matter. The chemist is not so arrogant as to dictate what a physician's or surgeon's fee should be; nor is he so offensive as even to offer an opinion. Let the physician's conscience govern his claim upon the public purse, and the chemist's conscience will not permit him to extort more than his due for the part he takes in the public good.

I might criticize much, nay most, of Dr. Williams's letter, to show that he has very imperfectly studied the matter upon which he has written; and I might also suggest that that portion which opens up the weak points of the medical profession, relative to "advice gratis," would have been much better left out, as by it he casts a reflection of impure motive upon the profession, which it is to be hoped as a body of honourable men they will repudiate.

One word more. Is Dr. Williams aware that by Act of Parliament we are required to copy all prescriptions containing poision? Are we to make distinction between prescriptions containing poison, and those which do not? Are we to disregard the law and be a law to ourselves? Are we to conduct our businesses with order and precision, or jumble them in such a manner as to bring disgrace upon ourselves and calamity to the public? If the public have that confidence in the chemist which Dr. Williams says they have, there is doubtless good ground for such confidence. Is it because the public give him the credit of possessing "brains" in common with the medical profession?

London. CHEMICUS.

JURY SERVICE.

Sir,—The reminder from the Registrar in this week's Journal will, no doubt, put all pharmaceutical men on the alert, and the 'Jury List' be duly scanned lest they be honoured by appearing *in nomine* thereon.

But the many members who are not so fortunate may be glad of a hint. I have just returned from serving at the Central Criminal Court, where I have been engaged the last two days, with every prospect of two or more to follow. But a respectful note handed up to the judge, pointing out the serious inconvenience my absence entailed, was courteously recognized, and I am excused from further attendance.

Similar action may relieve other poor pharmacists of much anxiety and expense if unfortunately called upon to discharge this duty of a citizen's life.

26, *Clapham Road, S.W.*, BYATT WALKER.
Sept. 19, 1878.

THE ADULTERATION OF DRUGS.

Sir,—In Dr. Tichborne's paper, read at the Pharmaceutical Conference in Dublin, on the above subject, and the discussion thereon, no mention is made of the fact that a powder of colocynth pulp and seed, prepared by grinding the two together as they occur in the dried fruit, is commonly to be met with in English pharmacies. It is purchased by the public for preserving cloth and furs from moth, its cheapness in comparison with the price of the officinal powdered colocynth pulp induces the British housekeeper, who, unable to distinguish between quality and quantity in this case, prefers the cheaper article.

The pulp from which the seed has been separated is, or should, alone be used in medicine, but there is considerable difficulty when operating upon large quantities in completely eliminating the seed. The difference in colour between the true powdered colocynth pulp and that contaminated with the seed is not alone sufficient to distinguish between the one and the other. By agitating colocynth powder with ether, filtering and evaporating the tincture, the fixed oil of the seed will be discovered. Ether does not separate oil from the pure pulp.

In the discussion which followed the reading of Dr. Tichborne's paper, Mr. Umney stated that he had seen instances in which the seed not having been completely excluded in the preparation of the compound extract, the oil dissolved by the proof spirit employed had interfered with the successful preparation of the powdered extract. In a note read by myself at an evening meeting of the Pharmaceutical Society* it is shown that by making an aqueous extract of colocynth pulp, evaporating to dryness over a water-bath, and subsequent exhaustion with proof spirit, the weight of extract obtained is the same as if the pulp had been treated with spirit only; this result shows that in preparing the compound extract in the manner indicated considerably less spirit is required than when prepared according to the instructions of the Pharmacopœia. Mr. Umney's experience on the question is an additional reason why an aqueous extract of colocynth should be first prepared, and the spirituous extract made from it. If the next Pharmacopœia Committee were to order a watery extract of colocynth to be used instead of the powdered pulp, which may contain 47 per cent of inert seed, in the preparation of the compound colocynth pill, a more definite result would be obtained.

Knightsbridge, Sept., 1878. J. B. BARNES.

Sir,—In the last issue of the *Pharmaceutical Journal*, just to hand, I have read with interest Professor Tichborne's paper on "The Adulteration of Drugs," as well as the criticisms bestowed on it. As the subject of colocynth powder has been introduced, I may be permitted to remind your readers that a paper by myself, "The Microscopy and Adulterations of Colocynth Powder," was printed in this Journal for December 23, 1876, and contained a description of the various parts of the seed, etc. Mr. Umney, in the course of his criticism, considered the presence of potato starch in colocynth powder to be unknown or at least of rare occurrence. In the paper above referred to I stated that out of a dozen samples, obtained from different parts of the country, three contained notable quantities of wheat starch, one having apparently 75 per cent. of it. I ascertained at the time that these had been supplied by English houses, the names of which were not furnished to me. I shall be glad to learn that since January 1, 1877, such a marked improvement has taken place in the quality of powdered colocynth as now found in the market. With regard to the recognition of powdered seed, Mr. Greenish has mentioned the curious stellate cell found in the epidermis, but this is much more difficult to discover than the numerous albuminous granules contained in the cotyledons, and which are an infallible test. The appearance of these is shown in the diagram accompanying the paper.

VIOLET POWDER.

Sir,—If your columns are not quite closed on this subject I should like to add two practical facts illustrating the inconvenience and annoyance likely to arise from the common though pernicious habit of not calling things by their proper names.

And first, as to starch. Some time ago I was shown some starch by a friend who had it to examine as to what kind of starch it was. I said, Well, I have some pure wheaten starch, which I use for my violet powder, we will compare it first with that. On comparison, I was much surprised to find the two starches identical; further inquiry showed that both were maize starch, and that therefore what I had been buying (I admit I ought to have examined it) as wheaten starch was not so at all. The discovery explained another fact. I had had several complaints of infantile irritation being caused by my violet powder; the cause was obvious, for instead of the small, round, smooth granules of wheaten starch, the large, rough granules of maize starch had been used, and some infants were clearly susceptible to the difference.

* See *Pharm. Journ.*, Nov. 8, 1873, p. 361.

Secondly, as to violet powder. Some short time since a medical man brought me some to examine, chiefly as to arsenic. Imagine my surprise in not only failing to find arsenic, but starch also, for until the late trial I had not the remotest idea that selenite and steatite were employed, and sometimes, as in this case, exclusively, in the fabrication of violet powder; but this was not all, neither the worst. I reported against the powder, and having done so, I thought I would examine my own (having quite recently taken to buy the 1*d.* packets instead of putting them up), with the annoying result that I found it to be amylo-steatitic. Of course now I, personally, have rectified all this.

In conclusion, let me express my gratitude to Dr. Redwood, who has again came forward as the champion of fair and honest dealing, and advocated the course he took up and so well sustained at Knutsford with regard to milk of sulphur, *i.e.*, not to give similar names to totally distinct preparations. In other words, let manufacturers and others make what they like, but not give their preparations names calculated to mislead their customers and the public generally.

South Norwood, S.E. J. H. BALDOCK.

Sir,—Professor Redwood, in his letter referring to the various powders sold under this name, states, "the mistake has been in applying the same name to two essentially different articles." Supposing, attributing to the name an existence which it certainly had previous to the appearance of these compounds, this sentence be inverted and be made to read thus, "the mistake has been in applying two essentially different articles to the same name."

The Professor suggests as a remedy, that powders other than those of starch only should be called amylo-selenitic or amylo-steatitic, and so forth. The precedence of the name of each article would, I presume, stand in relation to its amount in the powder. Thus we have in addition to amylo-selenitic and amylo-steatitic, steatitic-amylo-selenitic and selenitic-amylo-steatitic, and possibly, occasionally, selenitic-steatitic-amylic cō arsenico, as the Professor states "the public often like long names, especially if they cannot easily interpret them."

Let pharmacists relegate to oil shops and hucksters these "wooden nutmegs," and hold to the pure starch, free from admixture, with its time-honoured name of "Violet Powder."

20, *New Street, Dorset Square.* THOMAS GREENISH.

WATER ANALYSIS.

Sir,—Mr. Stables at the end of his paper on "Potassic Permanganate in Water Analysis" invites information and suggestions. There are one or two points that do not seem quite clear, and in no captious spirit I venture to ask a question and make one or two remarks.

Do I understand Mr. Stables to claim for the solution he recommends "as a sensitive and reliable test" "which will at once determine whether or not a water is fit for dietetic purposes" that the mere addition of a fraction of a grain of potassium hydrate imparts such an additional sensitiveness to the action of the permanganate as to transform what he, justly considers a worthless test into one of great value?

To establish this it is desirable first, at all events, that his experiments should be given that show that a simple solution and a faintly alkaline solution of permanganate differ in their action on one and the same water. It does not appear from the paper that this has been done, but no doubt it has.

Although it will be a highly interesting fact, if proved, that one drop of a solution containing 1 grain of potassium permanganate, 4 grains of potassium hydrate and 160 grains of water shall have the power, over and above what a simple solution of permanganate of the same strength would have, of decomposing a cold and dilute solution of egg albumen, I venture to suggest that all the old objections to the use of the permanganate in water analysis would still remain in full force; such, for instance, as the reducing power of nitrites and iron in its ferrous state, the latter of which, whether obtained from the strata or from contact with iron mains is so often present in even the best waters.

I am a little surprised to find so simple a method as Wanklyn's, whatever may be its merits or demerits, characterized as "a very complicated one;" but it is hardly wise surely to form a positive opinion as to the wholesomeness of a water from the amount of organic matter only that it contains, without taking into consideration its nature or origin as testified to by the other compounds that may be present, and still less is it advisable to recommend this to "an ordinary inexperienced person" as an infallible test.

Bath, September, 1878. CHARLES EKIN.

THE CASE OF OXALIC ACID POISONING.

Sir,—I was glad to see the late oxalic acid poisoning case at Luton noticed by one of your correspondents in the Journal of the 14th inst., but there is one thing about it which does not seem so clear as it might be, and that is, Can unregistered persons, such as oilmen, grocers, etc., sell by retail poisons contained in the second part of the Pharmacy Act, even if labelled with "name of article," the word "poison" and the "name and address of the seller"; or does it require the qualification before it can be lawfully sold? S. L. C.

[*** Such sales are illegal, and information respecting them, when they are known to take place, should be sent to the Registrar.—ED. PH. J.]

A PHARMACOPŒIA QUERY.

Sir,—If George Brown will again refer to the B.P., page 278, line 10 from the bottom, he will see that "resin of scammony may be prepared in a similar way from scammony," *id est* as from the root. F. A. B.

A similar answer has been received from Mr. Thomas Green, of Belfast.

BAYCURU OR GUAYCURU.

Sir,—Baycuru referred to in your number of the 7th is evidently *Statice Brasiliensis*, as Mr. Holmes supposes. I see it enumerated in Gibert, "Enumeratio plantarum agro Monte Vidiensi," with the vulgar name Guaycuru. I believe the Pharmaceutical Society's library possesses this work, if not I will be glad to send a copy. In Rio Grande, where this plant is called Baycuru, Portuguese is spoken; in the neighbouring state, where it is called Guaycuru, Spanish is spoken, and on the frontiers a mixture of both. Although both names are written differently the pronunciation in both languages is by no means dissimilar. It is sold by all chemists in Uruguay.

4, *Finsbury Street, E.C.* W. B. CRANWELL.

[*** The work is not in the Society's library and the Council would no doubt gladly accept our correspondent's kind offer.—ED. PH. J.]

W. J. Williams.—(1) *Knautia arvensis;* (2) *Saponaria officinalis;* (3) *Potentilla reptans;* (4) *Geranium Robertianum;* (5) *Brachypodium sylvaticum;* (6) *Leontodon autumnale.*

R. Roberts.—(1) *Torilis anthriscus;* (2) *Pimpinella saxifraga;* (3) *Avena fatua;* (4) *Senecio vulgaris:* (5) Probably *Picris hieracoides:* leaves as well as flowers should be sent; (6) *Solidago virgaurea.*

R. W. W.—*Frustra foliacea*, a zoophyte. The scent must have been accidental.

H. Barcham.—Chinese blistering beetles. For information respecting them see the Catalogue of the Society's Museum, p. 256.

"*Gita.*"—Cooley gives the following recipe for dubbing:—Black resin, 2 lb.; tallow, 1 lb.; crude cod liver or train oil, 1 gallon: boil to a proper consistency. The insertion of your other question would hardly be fair towards the proprietor of a well known preparation.

G. Blackburn.—For the regulations as to the appointment of dispensers in Her Majesty's Naval Hospitals, see vol. iii., p. 364 of the present series of the *Pharmaceutical Journal*, or the Calendar of the Pharmaceutical Society. There is no corresponding military appointment.

Associate.—The quantity referred to should really have been ʒvj, but the question was, what was meant by the first ingredient?

H. P.—We do not know the works, but will make inquiries.

PROPRIETARY MEDICINES AT HOME AND ABROAD.

WE have learnt within the last few days that the vendors of foreign proprietary medicines which have not hitherto been sold with a patent medicine stamp are likely to be called upon to deal with those articles in the same way as with other preparations of the same nature, in accordance with the Patent Medicine Stamp Duty Act, that is to say that in future these articles must have a patent medicine stamp.

From inquiries we have made at Somerset House, we learn that the authorities there hold that almost all the foreign preparations which are now so much in vogue are liable to patent medicine stamp duty. In support of that view they point to the schedule of the Act 52nd Geo. III. cap. 150, where, in a row with "FOREDYCE'S cooling opening pills" and "FOTHERGILL'S pectoral pills," we find "Foreign "medicines of all kinds, except drugs."

The Act here referred to was passed in the year 1812, and probably the trade in foreign proprietary medicines was not then sufficiently extensive to render a specific mention of each preparation so requisite as in the case of British proprietary medicines. Many of the preparations enumerated in the schedule to this Act have become obsolete, and at the same time there has been such an increase in the number of foreign medicines in common use that notwithstanding the more recent additions to the catalogue of home-made patent medicines those preparations constitute no inconsiderable portion of the total number of proprietary medicines. Taking, for instance, those of French origin which up to the present time have been, perhaps, most popular, we find on reference to the catalogue of a firm specially engaged in this trade that a considerable number of these articles have hitherto been sold with a patent medicine stamp; others, however, have been sold without the stamp. Among the latter are certain capsules, pills, dragées, pastilles, granules, perles, syrups, wines, etc.

In the list that we have seen of the articles which are considered by the Inland Revenue authorities to be liable to stamp duty there are many which do not partake of the character indicated in the Act as being liable to duty if prepared in this country, inasmuch as they are not pretended to be the product of "any occult secret or art," but are plainly named in such a way as to show what drugs they contain; as for instance, ether, chloroform and turpentine perles, copaiba capsules, the granules containing digitaline, aconitine, strychnine, etc. In the case of these articles there is no secret as to the essential ingredients, and whatever else they contain is only of the nature of a vehicle, therefore it might have been supposed that they would not have been liable to stamp duty. This would seem particularly the case as regards the perles and capsules containing ether, chloroform, turpentine and copaiba balsam, most of which may fairly be regarded as simple drugs or medicines though sold in a form convenient for administration.

On pressing this view of the matter, however, we found that the liability to duty was not claimed because of secrecy in the preparation of the articles, but mainly in virtue of the recommendations attached to them concerning their utility as medicines or medicaments, for the prevention, cure, or relief of some disorder or complaint, incident to or in some wise affecting the human body. It is stated that most of the proprietary articles that are now to be made subject to stamp duty either bear labels of this kind or have been advertised and recommended as beneficial for the prevention, cure, or relief of various distempers, maladies, ailments, disorders, or complaints incident to, or in some wise affecting the human body. It is on this ground, therefore, that many of the articles above enumerated are to be held liable to the stamp duty.

To those who are in the habit of supplying these foreign proprietary articles it will no doubt be some inconvenience to satisfy their customers that the additional charge is unavoidable on their part, and on this account we trust that the Inland Revenue authorities will be as considerate as possible in making clear to the public that the apparent innovation is not due to the chemist and druggist, but is merely the result of the correction of an oversight in regard to these articles which has imperceptibly grown into a custom. So far as we can judge there is, in fact, every disposition to avoid causing difficulty to the trade.

While referring to the subject of proprietary medicines we are glad to have the opportunity of directing attention to the very anomalous state of things which prevails in France. The absurd nature of the distinction drawn between proprietary articles, according to which they are classed in one of three lists, will be at once evident on looking through the lists given in the letter of Mr. PHEASANT. One of the articles included in the products classed as perfumery is of a nature so potent that we have had on more than one occasion to report fatal results of its misuse, and there can be little doubt that many of the preparations included in the second list as medicaments, not deemed admissible by the School of Pharmacy, if not absolutely harmless, are at least much less objectionable than some of those classed as perfumery.

Another illustration of the defective way in which restrictions are carried out in France is furnished in the case of EASTON'S syrup. We lately heard of an instance in which a person accustomed to take this preparation occasionally, went with fear and trembling to a pharmacien in Paris to ask for a small supply as a special favour. Observing that his request was complied with much more readily than he had anticipated, he ventured when he had secured his bottle to ask whether the restrictions on the sale of poison were not very rigid in France, and having been told they were, he then asked how it was that he had been so readily supplied with a preparation containing strychnia. The answer was that the Government did not take cognizance of the fact that strychnia was an ingredient of the preparation, and consequently there was no obstacle to its sale. This instance is strikingly consistent with the anomalies mentioned by Mr. PHEASANT, and it is evident that there is need for some amendment in the law relating to the admission of proprietary medicines into France.

Attention was directed to this subject at the last annual meeting, by Mr. RICHARDSON, of Leicester, and on a previous occasion we placed before our readers an account of some contemplated changes in the law relating to the admission of such articles into France. These changes were suggested by the Committee of Public Health attached to the Department of the Minister of Agriculture and Commerce, and the general tendency of the report presented by the Committee was to do away with all restrictions except an import duty, and to allow foreign proprietary preparations to be sold under the same regulations as those of French manufacture. We have not, however, heard that any further steps have been taken in the matter with the object of carrying into effect the suggestions of the Committee.

TH SECRETS OF A BUSHEL MEASURE.

IN the reports of the Standard Weights and Measures Department of the Board of Trade, recently issued, there is some curious information respecting the variable results obtainable in the measurement of dry goods. The Weights and Measures Act passed last session expressly prohibits "heaped measures," and requires that the measure shall be filled as nearly level as the size and shape of the articles measured will permit. This led to some experiments as to the results following different modes of "striking" a measure, *i.e.* of bringing the level of the contents of the measure into the same horizontal plane as the brim.

A sample of corn was taken and the true weight of a standard bushel of it was ascertained to be 57 lbs. 2 ozs. But when the ordinary flat strike is used the corn left in the measure weighs 57 lbs. 3 ozs., whilst if the ordinary round strike or roller be used the quantity of corn is increased to 57 lbs. 9 ozs. If the measure be shaken when struck with a round ruler the weight rises to 62 lbs. 15 ozs.

The diameter of a vessel in proportion to its depth appears to make little difference in measuring grain unless the diameter is less than one third of the depth. The Board of Trade standard measures for dry goods,—the bushel, half bushel and peck,—have their diameters nearly double their depth, whilst those for liquids have their diameters nearly equal to their depths. But it is found that, particularly in the sale of such articles as coke, potatoes, etc., the proportions adopted in the standards for dry goods are those most likely to give just results.

THE ARGAN TREE.

MR. CONSUL DRUMMOND HAY, referring to the great scarcity of food in Mogador at the beginning of the year, the result of a visit from the locusts followed by drought, speaks of the services rendered to the natives and their flocks at such times by the argan tree (*Argania Sideroxylon*). From the seeds of this tree the natives extract an oil that is used for cooking and lighting purposes. When ripe the fruit, which is an egg-shaped drupe, falls from the trees, and the goats then enter into competition with their masters for a share of the harvest. The goats, however, only swallow the fruit for the sake of the sub-acid rind, and being unable to digest the hard seeds eject them during the process of ruminating, when they are gathered and added to the general store for oil making. In preparing the oil the natives crack the "stones," toast the kernels in an earthenware dish, and then grind them to flour. A paste is then made by stirring this flour with water, from which after being allowed to harden the oil is obtained by pressure.

THE METRIC SYSTEM.

AMONG the resolutions passed by the International Congress on Weights, Measures, and Coins, which has just been brought to a close in Paris, is one deploring that England, Russia and the United States still hold so much aloof from the metric system, and expressing an opinion that the Governments of those countries should be solicited to "give effect as early "as possible to an act of progress so eminently useful "to science, commerce and international relations," as the adoption of the metric system would be.

THE MANCHESTER CHEMISTS' ASSOCIATION SCHOOL OF PHARMACY.

WE are informed by the Secretary of the Manchester Chemist's Association that arrangements have been made for the delivery during the coming session, by Mr. L. SIEBOLD, F.C.S., of three courses of lectures—(1) On Chemistry, including the Elements of Physics; (2) Materia Medica and Pharmacy, and (3) Qualitative Analysis. Students attending these lectures, which are to commence at once, must be Associates of the Manchester Chemists' Association, the Honorary Secretary of which, Mr. F. BADEN BENGER, 7, Exchange Street, will gladly supply information as to fees, etc.

CHEMISTS' ASSISTANTS' ASSOCIATION.

THE next meeting of the above Association will be held at 32A, George Street, Hanover Square, on Wednesday, October 9, at 8.30 p.m., when Mr. BROWN, F.C.S., will read a paper on "Salicine and some of its Derivatives."

The rooms of the Association will be open every Wednesday evening, from the present month until May next; a programme of the meetings may be obtained from the Hon. Secretary, Mr. CARDWELL.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 2, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Fairlie, Frazer, Gostling, Greenish, Hampson, Hills, Rimmington, Robbins, Sandford, Schacht, Shaw and Woolley.

The minutes of the previous meeting were read and confirmed.

The SECRETARY read a letter from the Registrar of the Pharmaceutical Society of Ireland, thanking the Council for the Journal and books forwarded in accordance with the resolution passed last month.

ELECTIONS.

MEMBERS.

Chemists and Druggists.

Brodribb, John B. .....London.
Craig, John .....Hawick.
Hardman, John .....Glossop.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Hooper, Leonard .....London.
Naish, Robert Elwell .....Weymouth.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Bennett, Arthur .....Bury St. Edmunds.
Elstob, John .....Richmond, Yorks.
Kennett, Edward Couchman ...Sandgate.
Kirkby, William .. ..Ripon.
Owen, George Benjamin .....Sheffield.
Stuart, Charles Edward .....London.

Several persons were restored to their former status in the Society upon payment of the current year's subscriptions and a fine.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted and sundry accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a member, aged 63. Applicant had a grant of £5 in November, 1877.

£10 to the widow of a late annuitant on the Benevolent Fund, who had received two previous grants of £10 and £15 respectively.

Several other cases were considered and deferred for further inquiries.

The SECRETARY reported that there were now twenty-three annuitants on the Fund, viz.:—

2	over	80	years of age.		
3	,,	75	and under	80	years of age.
4	,,	70	,,	75	,,
5	,,	65	,,	70	,,
5	,,	60	,,	65	,,
1	,,	55	,,	60	,,
3	,,	50	,,	55	,,

The Committee had considered the financial position of the Fund, and was of opinion that it would be expedient to elect seven pensioners, and that the election should be fixed for Wednesday, December 18th. A list of eleven approved candidates for annuities was also submitted, which will be advertised in due course. Including the two unsuccessful candidates at the last election, there will therefore be thirteen candidates at the election in next December.

On the report being read, further information with regard to one of the deferred cases having been given by Mr. Woolley, a grant of £10 was ordered to be made.

The particulars of the cases recommended by the Committee were then stated and discussed, after which the report and recommendations of the Committee were adopted.

ELECTION OF ANNUITANTS.

Mr. ROBBINS in moving a resolution that seven annuitants be elected in December next, said the present position of the Fund was very satisfactory, this being a larger number than had ever yet been elected. Looking back five years it was evident that the Fund had greatly progressed since the change in the mode of operations was made. At that time the subscriptions were only about half what they were now and the expenditure in annuities and gratuities, had also nearly doubled. Still there was plenty of room for further improvement, and he was sure that the subscribers would still continue to support the Fund.

Mr. HILLS asked what was the difference between the amount of subscriptions last year and the previous year.

Mr. ROBBINS said the subscriptions this year had reached nearly £1200; and not only had more money been spent but their invested capital had also increased in a like proportion.

The SECRETARY said the thirty annuitants would absorb about £1000 per annum, whilst the invested capital only yielded about £540. He hoped the mention of this fact would be the means of inducing the 600 persons who subscribed last year but had not yet done so this year to continue their support of the Fund.

Mr. ROBBINS said this might be partly accounted for by many persons having sent subscriptions to the Dinner, and thought they had thus fulfilled their duty. He hoped many of them would yet renew their subscriptions.

The PRESIDENT said he thought this fact was somewhat counterbalanced by the one that there were 600 new subscribers.

The SECRETARY said there was about the same amount subscribed this year as last.

Mr. WOOLLEY asked if it was the practice to solicit the continuance of subscriptions from gentlemen who did not renew them.

The SECRETARY said he did not let any one escape for want of asking. He always sent two or three reminders, and within the last two months he had collected about £100 by this means.

Mr. BOTTLE, in seconding the motion, said he was quite satisfied seven annuitants could be elected without any danger to the Fund, and he hoped that when it was seen that money was really wanted, and that it was being well used, many of those who had discontinued their subscriptions would renew them. The estimated income of the Fund from subscriptions was £1177, and it was proposed to spend £1670. It would also be seen that although it was proposed to elect seven annuitants, there would still be six other approved candidates who could not be elected, which was a larger number than on any previous occasion. Last year six were elected and three left, and the previous year four were elected, and one or two left, so that as against the increased prosperity of the Benevolent Fund there must be set off the increased claims coming upon it. He hoped a consideration of this fact would bring forward abundance of funds for the Committee to deal with.

Mr. SHAW said he had not anticipated being present at that meeting or he should have given notice of a motion similar to one which he had brought forward before on

the subject of canvassing. He found there were thirteen approved candidates, of whom only seven could be elected, a larger number than had ever been placed before the subscribers on any former occasion. Seeing that he failed on a former occasion to induce the Council to put its veto on canvassing, he was afraid that a number of these candidates would consider it their duty to get out their cards as soon as possible. Now this was a serious matter, and would become more so as the numbers increased, and unfortunately it often happened that those who were most deserving were least helped; those who had the most friends being those who succeeded. The Medical Benevolent College had been making inquiries, and found that from £5 to £30 each was spent by the persons, or their friends, who sought election; at its annual meeting in May it determined to put a stop to canvassing, if possible. He hoped this Society would do the same, and he was quite sure it would redound to its credit. Each candidate would probably spend about £7, so that nearly £100 in all would be expended in postage and printing, quite unnecessarily. There seemed to have been some misapprehension as to his former motion preventing candidates endeavouring to obtain new subscribers or get promises of support. Candidates would be quite at liberty to write autograph letters, or make personal applications to induce their friends to come forward and subscribe for a particular occasion; but with reference to existing subscribers he thought it very desirable that a prohibitive order should be sent out. When he brought this matter forward before it was stated that it would be impossible to carry out his proposition as a direct prohibition, but that it might be carried as a recommendation, but then some gentlemen said they could not agree to it, because some candidates would observe it and others would not.

The PRESIDENT asked what motion Mr. Shaw wished to move.

Mr. SHAW replied that canvassing be prohibited.

The PRESIDENT thought it would be a very arbitrary measure to disqualify a candidate who had sent out canvassing cards.

Mr. HAMPSON thoroughly sympathized with the views of Mr. Shaw, but did not think it would be regular to pass any resolution on the subject without notice being given. Only that morning he had been called upon by a possible candidate for an annuity, who asked him to assist in obtaining a grant in order to send out canvassing cards. He hoped when the proper time came Mr. Shaw would persevere, and that the Council would by a large majority adopt a change of proceeding, but he did not see that new regulations could be adopted suddenly without due notice.

The VICE-PRESIDENT agreed that there was great evil in the present system, but he did not see how it could be avoided. He believed that two years ago the Council passed a resolution that the names of those subscribers who desired not to be canvassed should be printed in a separate list, but only about 600 availed themselves of it. Bad as the system of canvassing was, he feared that in the interests of the Benevolent Fund it must continue; some people would not take any interest in the matter unless they were appealed to for their votes.

The PRESIDENT thought it would be very well to do everything possible—perhaps by means of an article in the Journal—to discourage the system of canvassing; but if candidates felt canvassing gave the only chance they had of being elected they would naturally adopt it, and he thought it would be rather too severe a measure to pass a resolution now that any one who canvassed should be disqualified.

Mr. ROBBINS remarked that in most voting charities there were a large number of candidates nominated and a very small number to be elected, consequently the chance of success with the majority was small; therefore, all did their utmost or they would be left out altogether. In the case of the Pharmaceutical Benevolent Fund, however, it was totally different; no one had ever been placed on the list who had not been elected, if not the first time, the second or the third; and at present he might almost venture to say that those not elected this year would be elected next, so that really there was no occasion for their spending so much money in canvassing.

Mr. SHAW read the motion he had proposed on a former occasion, which was to the effect that the Council disapproved of canvassing cards being issued. He had put it in that form in order to meet the objections of some gentlemen who objected to a total veto, but if this was not thought sufficient he would move to prohibit it entirely.

Mr. ATKINS asked if this discussion was in order, as there had been no notice of motion given.

The PRESIDENT thought it arose fairly out of the motion before the meeting.

Mr. ATKINS thought before making an important change of this kind notice ought to be given so that it might be thoroughly considered and discussed.

Mr. BETTY said the Council was not prepared at that moment, nor was Mr. Shaw willing to ask it, to make a radical change, but he very properly took this opportunity of bringing before the Council what was a gross case of mismanagement in the administration of charity. This was a question on which the public at large, and perhaps even that Council, could afford to be educated. These discussions had that tendency, and he hoped Mr. Shaw's views would bear fruit before long. Every gentleman who had spoken had expressed his dislike to the present system of things, the result of which was that the strongest secured the prizes whilst the weaker went to the wall. He knew that public opinion was advancing on this point, and he thought it would be a bold step for the Council to take to introduce the change proposed and it would redound to its credit as much as anything it had done for years. He hoped that next year the Council would be in a position to deal with the question.

The motion for the election of seven candidates was then put and carried unanimously.

The VICE-PRESIDENT moved that the list of subscribers be arranged under the names of the towns, as was done formerly. The Council had been told that 600 subscribers had fallen off, and this might be partially due to a want of application on the part of local secretaries. If the names were arranged under the towns it would bring this falling off more clearly under the local secretaries' notice, and would be much more convenient for them in collecting subscriptions.

Mr. SHAW said that in Liverpool the local secretary sent round a circular to every chemist and druggist in the town, whether a subscriber or not, soliciting subscriptions to the Benevolent Fund.

Mr. CHURCHILL said that two years ago Mr. Southall and he visited many of the chemists in Birmingham, and obtained a good many subscriptions. This year, not having the list, as they had before, they could not repeat the process, as they would have liked to have done. He thought a local list would be a great convenience.

Mr. ATKINS suggested that it would be worth while for the office to have a form of circular prepared which could be sent to local secretaries in small towns where it would not be worth while printing special circulars as had been done in Liverpool. He had made it a point every year to instruct his assistant when collecting subscriptions for the Society to ask for contributions to the Benevolent Fund, but hitherto he had failed to get any. If he were supplied with circulars it might produce a good result.

The PRESIDENT thought this a very good suggestion.

Mr. FAIRLIE said the plan adopted by the local secretary in Glasgow was to visit personally all the members, and he was very successful in obtaining contributions. He thought in small towns it would be quite easy for the local secretary to make personal applications.

The PRESIDENT said it must be remembered that local

secretaries had to attend not only to the towns in which they resided, but to the surrounding districts.

Mr. RIMMINGTON thought circulars and papers were frequently sent to all subscribers to the Fund. It might be a good suggestion, but he was not very sanguine about it.

Mr. ATKINS said it was indisputable that a personal application in any matter outweighed a mere circular, but Mr. Fairlie should be aware that in small centres there were often difficulties which did not apply to large ones. There were local feelings and, unhappily, sometimes local jealousies which prevented that free intercourse which could be desired, so that in some cases a circular was the more delicate and perhaps the more efficacious way of reaching members of the trade.

THE GERMAN APOTHEKER-VEREIN.

The PRESIDENT said that immediately after the last meeting of the Council, he found that Mr. Greenish and Dr. Paul intended to go to Coblentz to attend the general meeting of the German Pharmaceutical Association, but that through inadvertence it had not been mentioned at the Council table. He, however, took upon himself to write a letter to the President of the Association introducing Mr. Greenish aud Dr. Paul, and he understood that they met with a cordial reception, the particulars of which he would ask Mr. Greenish to state.

Mr. GREENISH said that Dr. Paul and he having determined to attend the meeting of the German Pharmaceutical Association at Coblentz, the President was good enough to furnish them with an introduction to the President of that Association. He had to report that immediately on presentng their credentials they were very cordially received, and furnished each with a book containing an admirable map of Coblentz and its surroundings, together with free passes to various places of interest in and around the town, amongst others to a very instructive exhibition of pharmaceutical and chemical preparations, drugs, dietetic preparations, utensils, apparatus and drug mills, together with presses, etc., suitable for pharmacy. The members of the Association went, by invitation, to the Emperor's palace, where they were met at the entrance by the Empress, who gave them permission to go all over the grounds and palace. There was also a dinner at which above 500 guests, ladies and gentlemen, sat down, and an excursion up the Rhine by a steamer specially chartered for the occasion ; and on their return the whole town was brilliantly illuminated with bengal fires. He believed this was the first time that any member of the Council had attended a general meeting of the United North and South German Pharmaceutical Association, but he hoped that when it held its next meeting, which would be at Hanover, some members of the Council would be induced to attend. It would be only necessary to take an introduction from the President of that Society, or from the President of the Pharmaceutical Conference if they were members of that body, and they would be sure of a hearty welcome.

The PRESIDENT said he could only rejoice that the gentlemen who went to Coblentz were received so cordially.

Mr. GREENISH desired to add that every meeting of the Association was well attended, and that in the intervals of business addresses having a practical bearing on pharmacy and the education of the pharmacist were delivered by Professor Mohr, Dr. Reichardt, and Herr Schlickum.

Mr. ATKINS desired to express his great satisfaction that Mr. Greenish and Dr. Paul had gone to Coblentz to tender this act of international courtesy, and he hoped that their example would be followed next year.

It was then moved by the PRESIDENT and seconded by the VICE-PRESIDENT—

> "That the thanks of the Council be passed to the President and members of the Deutscher Apotheker-Verein for the cordial reception they had given the English visitors."

The resolution was carried unanimously, and it was also resolved to send a copy of the Journal as published to the German Society.

GENERAL PURPOSES.

The report of this Committee included a report from the Solicitor giving particulars of certain cases in which legal proceedings had been commenced. In one case, that of Mr. Lund, of Bradford, the defendant had written enclosing the amount of penalty about to be sued for, and promised to discontinue the sale of poisons and the use of the title "chemist and druggist." Some other correspondence direct with the office from parties charged with breaking the law was also read.

The Committee recommended the re-appointment of Mr. Stenhouse as Assistant-Secretary in Scotland.

A letter had been received from the President of the North British Branch, enclosing a copy of a minute relating to requirements for the examination-room in Edinburgh, and asking for authority to make certain purchases of specimens, fittings and books. The Committee recommended that the Council of the North British Branch be authorized to carry out the recommendations of the Visiting Committee of that Council.

It had been reported by the President that in carrying out the alterations in the dispensing department of the examination room in London it had been found necessary to re-cover the floor, and the Committee recommended that linoleum should be used for the purpose.

The report and recommendations were received and adopted.

AMENDMENT OF THE PHARMACY ACTS.

Mr. BOTTLE moved the following resolution of which he had given notice :—

> "That a Special Committee be appointed to take into consideration and report to the Council what amendments are required to be made in the Pharmacy Acts."

He said it would be in the recollection of those members who were present on the last meeting that he called attention to the fact that there had been in olden times a committee appointed to consider and recommend certain alterations and amendments in the Pharmacy Acts. When he asked the question whether that committee was still in existence, there seemed some amount of uncertainty whether there was any committee existing having that special matter committed to its care, and on going into the matter he found that there was not. In January, 1877, the Council passed a resolution that the Law and Parliamentary Committee be requested to appoint a sub-committee with a view to preparing or suggesting any alterations that might be considered expedient, and to report to the Law and Parliamentary Committee. This sub-committee was appointed, and from its minutes it appeared that various suggestions were made, which he read. That brought matters down to April, 1878, prior to the election of the present Council; but no action had been taken in the matter since the election of the present Council, and consequently that sub-committee had really died out. It occurred to him that the matter was of some importance, and that it should not be allowed to drop. It seemed to him that the present was a very advantageous time for the Council to prepare and carry before the Legislature some resolution for the amendment of the Pharmacy Acts. His resolution included the words "if any," but after what he had mentioned as to the views of the members of the previous committee he should ask permission to strike out those words because it was shown already that they were unnecessary. He did not propose to go into any detail as to what alterations were desirable; that would be left for the committee to discuss. But it seemed evident, after the recommendation which the previous committee had made, following upon a good deal of mature consideration, that there were amendments which were desirable

and if a fresh committee were appointed he thought he should be able to show that still further amendments were requisite. With that view he would move the resolution, and he would ask the committee to take the matter into its early consideration. In the next session of Parliament he believed the Medical Bill would be re-introduced, and there would then be a fair chance of having any amendments in the Pharmacy Acts remitted to the same committee as took charge of the Medical Bill. He must say that he should like to see the line of demarcation between chemists and druggists and medical men laid down by a modern statute, so that some of those little causes of ill-feeling which had cropped up between the medical profession and themselves might be settled for ever.

Mr. ATKINS, in seconding the motion, said he was quite willing to accede to the suggestion that the words "if any" should be struck out. He had no doubt that the object of Mr. Bottle in inserting them was to secure the hearty assent of those who might not so distinctly realize as some did that amendments were requisite; but he believed it would be in the power of Mr. Bottle in committee to demonstrate that amendments were needed. Mr. Bottle was quite wise in not attempting to define what those changes were, and he certainly had no intention of going into the details. He should prefer to deal with the general principles. Such a committee as this would, under ordinary circumstances or in ordinary times, have its own special work to do, but he imagined the present were not ordinary times or ordinary circumstances. There was a large amount of discontent existing amongst pharmacists, as was evidenced by the correspondence in the Journal and in other ways, as to the present condition of the trade, and if only it could be shown that by a most careful analysis of the whole conditions of legislation that the Council had done all it possibly could do, then it would have effectually disarmed a large amount of this dissatisfaction. He held that the Pharmaceutical Council had full powers for the due protection of pharmacy, and if the Council did not discharge those duties, but relegated them to some other body or bodies, it was guilty of neglecting its duty. It was because he held that conviction that he thought the Council ought to examine into any special complaints that might exist, and see whether they could be met. The present was confessedly an age of transition; the whole condition of legislation with regard to medical bodies was in an undefined and uncertain state, and this was just the time when the Council should take measures either for protecting the rights of the trade in some other bill or in a bill of its own, and it was this work for which the watchful action of a committee of this kind was specially required.

Mr. SANDFORD said he could not give a silent vote on this question. Mr. Bottle had said that in olden times a committee had been appointed to deal with it. He remembered meeting Mr. Bottle at that table for some twenty years past, and he thought he was going back to the good old days when some of the best friends of pharmacy were members of that Council. He did not mean to say that it had not as good friends there now, but he looked back with the greatest possible respect to those who were there when Mr. Bottle and himself first became members of the Council, and he was quite disappointed when he found that gentleman only going as far back as January, 1877. In the first place, he would remark that that committee was not appointed by the Council, and he was extremely vexed the other day on reading the report of the September meeting, at which he was not present, to find that nobody seemed to know what occurred in the month of June, when the Committees were appointed. The sub-committee was then mentioned, and it was asked whether it should be appointed again; the answer was that the sub-committee was appointed by the Parliamentary Committee, not by the Council, and that doubtless that Committee would if it saw occasion re-appoint a sub-committee. It was so completely a sub-committee that when its report was brought up the Council objected to receive it, because it had not been first adopted by the Parliamentary Committee. He thought that in due course, if necessary, the General Purposes Committee would nominate a certain number of its members as a sub-committee to attend to this matter. Mr. Bottle had said there was no committee having special care of such subjects, but he held that every man on the Council had special care of them. The President had special care, and if occasion arose he should be the first man to take action in the matter. Then there was the Secretary, who was always looking out for opportunities with regard to these matters; owing to his vigilance the Society secured exemption from jury service, one of the most advantageous things which it had ever obtained. He contended therefore that there was always a committee on the watch, and he further thought that to appoint such a committee as this was to a certain extent keeping open a perpetual blister. Mr. Bottle had read the proceedings of the committee during the last year, but he had not read the report with which it concluded its labours, and in which it stated the amendments considered desirable in the Pharmacy Act, should an opportunity present itself for obtaining them. The committee worked very hard and received all sorts of suggestions, but it all ended in three very trifling recommendations. And he asked was there anything there which rendered it necessary to perpetuate the constant irritation, and keep open such questions as that committee brought forward. He thought it was unwise to appoint such a committee, and that this was not a suitable time to do so. Mr. Bottle had alluded to the probability of the Medical Act Amendment Bill re-appearing next session, and suggested that it would be well for the Council to move at the same time, whilst Mr. Atkins thought the Society might get a bill of its own. Now if Mr. Bottle's course were taken it would in all probability bring the trade under the purview of the Medical Council, which was not desirable. The Society had hitherto, in getting Acts of Parliament, managed to steer clear of the Medical Council; in 1868, it was successful very much because the Medical Council had said that pharmacists should be better educated, and pharmacists replied "If we are to be regulated let us do it independently, and not be under the Medical Council at all." The danger was that if the Society went to Parliament with the Medical Council the trade would be placed under it, to which he for one should object. Mr. Atkins thought that great discontent existed amongst pharmacists, and he knew that this was the case, but he could not help thinking that a great part of that discontent had been stirred up, and was fostered, and would be perpetuated by such questions as these being kept alive through the appointment of such committees. He thought it would be a source of great mischief, and keep up constant irritation, and though perhaps the majority would be against him he could not help protesting against the whole thing as being uncalled for.

Mr. HAMPSON said he should like to say a few words because he had been instrumental in establishing the sub-committee whose report was looked upon by Mr. Sandford with such contempt. He did not know whether it was in the recollection of that gentleman that he himself had been instrumental in drawing up that report which he now condemned. He wished to express his delight that Mr. Bottle, an old member of the Council, should have taken this matter up *de novo*, and that instead of having a sub-committee, there would be a committee appointed for the consideration of these questions in proper form. It was much better to have a separate committee than that it should be left in the hands of the General Purposes Committee to appoint such a committee at its pleasure. It was no use blinking the question; the Council would have to go to Parliament before long to amend the Act. Experience had proved that it was defective, not simply in unimportant parts, but in its essential points, and if

this matter were to be taken at all into consideration, it ought to be the business of a special committee. Mr. Sandford had said the Council would take the matter up on a fitting occasion, but he contended that a fitting occasion had arisen, that now was the time if anything was to be done at all to consider this matter with the greatest possible deliberation, and he was astonished that Mr. Sandford, the author of the last Act of Parliament, should throw such cold water on the proposal; he had expected to find him the seconder of the motion. He would not attempt to analyse the blister which Mr. Sandford had alluded to as a continual source of irritation, but all the members of that Council knew that unless they, as a responsible body, took these matters into consideration and endeavoured to remedy the grievances which existed, they would fail in their duty. Facts of daily occurrence showed that the Act in many respects was a dead letter, and his opinion was that if there had to be a new Act it must be an Act of their own.

Mr. SCHACHT had not much to add excepting one parenthetical remark on an observation of Mr. Sandford which was deserving of a little more consideration than it might receive if present attention were not directed to it. He seemed to deprecate the trade being in any way mixed up with things which might come within the scope of the new Medical Bill, but he ventured to think, it was worth while considering whether that should be the sentiment which should guide the Council in future. There were undoubtedly many reasons which should make the trade jealous of the interference of any other body in their own concerns, but, on the other hand, there were reasons which made it desirable that at any rate those matters of seeming antagonism between themselves and the medical body should not be settled by a mutual struggle, but that they should rather be determined by the high authority of the Legislature, which would take cognizance of the claims of both parties. He thought if there were one thing they should aspire to lay down as a law for the future and as a principle which should guide them it should be that pharmacy was a portion of the medical art, and if so, it seemed to him that any regulations affecting the practice of pharmacy might very properly be determined by some such system as that which determined the privileges and duties of any other portion of the medical body. Therefore he thought it would be highly desirable from many points of view that the Council should not altogether refuse to come into that same process of limitation which was likely to rule the duties and privileges of other portions of the medical body.

Mr. SANDFORD said he should be extremely sorry if anything he had said were considered in opposition to the Medical Council or the medical profession. He held that profession in as high respect as any one. It was simply a matter of government; he thought there should be independent government for the two bodies, and he was not alone in that view. He believed the Medical Council itself would object to take pharmacists in hand. Mr. Hampson had said that he, Mr. Sandford, had had a hand in drawing up the report of the sub-committee; and so he had, but he had only the facts which Mr. Bottle had mentioned to summarize.

The PRESIDENT reminded the Council that the appointment of a committee involved a great deal of trouble and labour to those nominated upon it, which would be merely wasting of time if nothing was intended to come of it. He hoped, therefore, it would not appoint a committee, unless it saw its way clearly to carry on the matter to the point of going to Parliament. If it was to be merely a talking committee he hoped the Council would not appoint it. If members did see their way to action in the next session of Parliament, by all means appoint a committee, but not otherwise. There were two sides to this question. Going to Parliament might stir up questions which might turn against pharmacists, and they might get, not what they wanted, but what they did not. It was one thing to go to Parliament and another to get a bill through. There were certain points which it might be depended upon Parliament had not forgotten and would certainly remember at the proper time and place. If the Council went to Parliament he hoped it would meet with success, for in spite of what had been said by Mr. Sandford he thought there were points on which improvement was required. The Act was passed when circumstances were very different to what they were now, but it would be no use appointing a committee which was to do nothing.

Mr. SANDFORD had never said there was no need of improvement in the Act; he simply thought there was no chance of getting it at present.

Mr. WOOLLEY was rather sorry to see old members like the President and Mr. Sandford arguing on the "let-well-alone" system, and still more sorry to hear them preach the timidity gospel which they had done just now. He could recollect six or seven years ago, when the Society had the poisons regulations before it, the Council was told not to go against the Privy Council, because if it did there would be penalties imposed upon the trade, but it persevered and was perfectly successful. The members of the Council ought not to hold their hands now, because they were afraid of any ulterior consequences. That was not the way in which Englishmen in olden times had been accustomed to win their privileges. There was one question which might be taken in hand at once, and that was the patent medicine question, for if the Council did not take it up some one else would. However, he would not go into details, but he hoped the committee would be appointed and he did not think it would be simply a talking committee.

Mr. BETTY thought the observations of those who considered the committee would not be a really operative committee might be explained away by the fact that this matter had now gone beyond the first stage; in fact it had gone beyond the second, and, he hoped, was approaching the third, through which all political matters in this country had to pass. There was, first, the stage of incubation, second, of discussion, and third that of real action. He did contend that this subject, having been before the Council some time and having gone through a considerable portion of the second stage, was now in such a position that the Council might take it up and carry it through to a practical issue. Remarks as to the feasibility of appointing a committee would have been perhaps pertinent before any committee had been appointed, but that committee having been appointed and the principle having been accepted that it was desirable to report what amendments were necessary, the committee could not now consistently be spoken of as only a talking committee. It had approached its second and almost its third stage, and he hoped the process would be completed during the sitting of the present Council. Every member would regret that Mr. Sandford hesitated to take part in the committee. He grieved to see that at present they did not get his hearty approval and support; but he still hoped that, as in days gone by, when the time for action really arrived he would find his old fire rekindle, and that he would then come to the front and be not only the Nestor, but the Achilles of the conflict. It might be said that the first report of the sub-committee was a small one, but it was never looked upon as a final one. It was not to be expected that an Act of Parliament which had occupied the attention of the members of the Legislature for four months was to be disposed of by a small sub-committee in its first report. That report was simply presented as the foundation on which the future Council should act. and small as it was, it might be taken as an earnest of what should be done in the future. If the Council had a principle to act upon, it could not fail in getting a good result. And what was the principle that should be acted upon in looking into the defects which might exist in the Pharmacy Act? The grand principle was that where the State imposed grave responsibility, and where it also demanded a most crucial technical education, there were

rights and privileges created. That was a broad principle, and he believed there was such a feeling of justice amongst their fellow countrymen, and such a disposition to adopt the good policy of giving rights as well as duties to every class of Her Majesty's subjects, that chemists and druggists would not be denied those rights or privileges to which they were entitled from the very conditions pertaining to their position. They would be able to prove to the Legislature that by change of time and circumstances the Act required amendment. The spread of pharmaceutical education and the success of the Pharmaceutical Society itself would be the banner under which they should fight, and he did not think they would appeal to the House of Commons in vain on the great principle he had attempted to put forward, that responsibility and privileges or rights should go together.

Mr. FAIRLIE said the only fault he had to find with this motion was that it did not go sufficiently far, and he would beg to suggest a rider or amendment which he thought would carry out the ideas expressed by the majority of those who had spoken. The President had expressed his wish that the committee, if appointed, should come to some practical result, but he was afraid that if Mr. Bottle's suggestion were passed the Council might ask for a report month after month and no report be forthcoming. He should therefore propose the following rider to Mr. Bottle's motion:—

> "That a special Committee be appointed to take into consideration what amendments are required to be made to the Pharmacy Acts, and, if possible, report to the Council at its meeting in December, with a view to taking the necessary steps to have a Bill introduced into Parliament next session."

He said, if possible, in December, because that gave the committee two months to consider the matter, and by that time the framework of the old report of the committee would enable it to have something in shape which might be considered by the Council and discussed in order to the introduction of a Bill. Of course there was a great deal of preparatory work to be done, and he had several amendments to suggest himself, but he would not go into details at the present moment. He hoped Mr. Bottle would accept his amendment, which was simply carrying out his motion to a practical result.

Mr. SHAW sympathized very much with the motion before the meeting. It was only natural that during the ten years which had elapsed since the passing of the Pharmacy Act some defects should have made themselves manifest. It was very desirable that the point should be decided what was within the limit of the duty of a chemist and druggist. With regard to the suggestions of Mr. Fairlie, he thought it might fairly be left to the committee to report when it was ready.

Mr. HAMPSON seconded the amendment or rider. He remembered the difficulty the Council experienced in getting the report of the former sub-committee, and therefore he thought it desirable that something like a fixed time should be named when the report should be received.

Mr. FRAZER felt in some difficulty on this matter. He thought there was one point on which an amendment was needed, and it was desirable a committee should look into the matter. After the committee had dealt with it it would still be open to the Council to negative its report if it were considered unwise, and he had no doubt the views of many gentlemen would be considerably modified when they came to details. What one would support another would oppose. Every section of society had its rights, and chemists and druggists wanted their rights; but they could not get their rights at the expense of those of others, and it was quite possible when they looked into the matter they would come to the conclusion that it would be better to leave things as they were.

Mr. GOSTLING thought the Council ought not to enter on this subject without due consideration, especially with reference to the action taken by the older members of the Council. Not only the Council but pharmacists generally were greatly indebted to the efforts of Mr. Sandford and the other gentlemen who took such great pains in the introduction of the Pharmacy Act. There was no doubt that they had now in Great Britain a class of chemists and druggists far superior to those previously existing, thanks to that Act, but it was the public who received the benefit, not the chemists and druggists. The public was really benefited by the education required from candidates for the diploma. At the same time every good thing was capable of improvement and they all found in their private affairs it was desirable from time to time to overlook them and see if previous decisions were not capable of improvement. Mr. Sandford had spoken of a perpetual blister, but if they had a good blister which brought the disease to the surface and cured it they could not have a better thing. He did not however approve of confining the action of the committee to two months.

Mr. SANDFORD said there was nothing special in the amendment beyond the latter part of it, which seemed to pledge the Council to introduce a bill into Parliament next year. A great deal had been said, very kindly, about the action which he took, with many others, in getting the Act passed in 1868, but it must be remembered in 1868 they were able to ask Parliament to pass that Act for the benefit of the public and to show that the safety of the public was endangered by unqualified dispensers of medicine; on that plea they got their bill. But it could not now be said that the safety of the public was in danger. All that could be said was that the private interests of the trade were in danger, and that was why the change was wanted. What he submitted was, that the Council ought not to bind itself definitely to go to Parliament next session with no better plea than that. He thought as much of those private interests as anybody, but he knew perfectly well it was no use going to Parliament on such a plea. If in providing for the safety of the public, chemists and druggists served their own interests indirectly, well and good, but with no better plea than their own interests it would be the greatest folly possible to attempt legislation, and therefore he hoped the Council would not pledge itself to such a course.

Mr. FAIRLIE did not think the amendment tied the Council down definitely to go to Parliament next session; it said "with a view of going to Parliament."

The VICE-PRESIDENT said he sympathized very much with the remarks which had fallen from Mr. Sandford; but at the same time he thought it would be well to appoint a committee to consider what amendments were necessary. If when those amendments were brought forward they did not meet with approval they could be rejected.

Mr. BETTY said he should oppose the amendment as energetically as he supported the original resolution. He was quite prepared to acknowledge that there was a great responsibility devolving on those who undertook this task, and in speaking in favour of the motion, he had no idea the Committee would be shackled with the provision that it was to prepare a report within a certain time. Those who went into this matter should do it methodically and carefully; it was not a thing to be done in an off-hand way. Of course if the Act of Parliament was to be amended, the sooner it was done the better, but he did not think any committee would consent to be appointed with the provision that it was bound to produce a report at a certain time.

Mr. ATKINS said he was not at all prepared to accept the amendment, and it seemed to him absurd to expect that a committee could do such an important work as this within two months. At an earlier stage of the discussion Mr. Sandford had referred to the discontent existing as being due mainly, if not entirely, to the constant irritation due to the constant debate of such questions. To that view he entirely demurred; the discontent and

dissatisfaction existed, mainly because of the impression outside, that the Council did not sufficiently consider these questions. He was not prepared to concede that that view was correct, but it existed, and it was the duty of the Council to show that it did all it possibly could by investigation, and by action if necessary, to remove those causes of discontent.

Mr. BOTTLE said he could not accept Mr. Fairlie's amendment as a rider, and in fact he should prefer that the motion dropt through, to accepting the amendment. He had avoided going into details altogether, but as a country member he would supplement what Mr. Atkins had said with regard to the discontent which prevailed with reference to the working of the Pharmacy Act. Whether that was fairly grounded or not was a matter that would have to be considered, but his impression was very strong that if the Council did not take upon itself to look into the working of the Pharmacy Act very speedily, the country would elect a Council which would. He therefore hoped a committee would be appointed which would calmly consider all these matters. He did not want a committee of one-sided views, and hoped Mr. Sandford would be a member of it, so that all matters might be fairly talked out, and then the report would be duly considered by the Council.

Mr. HILLS hoped Mr. Sandford would join the committee. He thought it rather doubtful whether this was a proper time to go to Parliament, but at the same time when the time did come he was sure nobody would be found more ready to take care of the interests of the Society than Mr. Sandford.

The PRESIDENT then put the amendment, with the following result:—

For—Messrs. Churchill, Fairlie and Hampson.

Against—Messrs. Atkins, Betty, Bottle, Cracknell, Frazer, Gostling, Greenish, Hills, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, Williams and Woolley.

The original resolution was then put and carried *nem. con.*

The following gentlemen were appointed a Committee:—Messrs. Atkins, Betty, Bottle, Gostling, Greenish, Hampson, Mackay, Sandford and Woolley.

PHARMACEUTICAL MEETING.

Wednesday, October 2, 1878.

The opening meeting of the session took place on Wednesday last. The chair was taken by the President at half-past 8.

The minutes of the previous meeting having been read and confirmed, the Chairman called upon Professor Redwood for his—

REPORT ON THE CHEMISTRY AND PHARMACY CLASS.

Professor REDWOOD said the duty which the professors had to perform on these occasions was always a very agreeable one. They came there to speak good words for good students; and those who were to be the recipients of commendation came with smiling faces to receive it, while those who were perhaps equally meritorious, but who had not been equally successful, already knew the result and were therefore not disappointed. They all had one object in view, the encouragement of industry and the reward of merit; and when the company present heard his statement of the awards which had been made, and saw the phalanx of well informed young pharmacists who were to bear away the trophies of these their early successes, they would all feel that there was some hope for the future of pharmacy. He had to report on the subjects of chemistry and pharmacy, on which subjects two courses of lectures had been given during the session. The Council had decided to award to the successful candidates at an examination at the end of a single five months' course, a bronze medal, and certificates of merit to those who had attained a certain standard; but to those who had attended more than one course there was a higher prize offered, of a silver medal and certificates also. To be brief, his duty consisted in stating the result of these examinations in connection with his own subjects of chemistry and pharmacy. In the first place an examination was held at the expiration of the first five months, and in April last the awards were made by the Council in accordance with the list which had been published. The first gentleman, Mr. Mason, obtained 90 marks out of a possible 100, and five others obtained respectively, 85, 80, 78, 75, and 75. At the expiration of the second course of lectures there were two only whose answers possessed sufficient merit to entitle them to recognition, and they obtained 80 and 76 marks respectively. At the same period there was an examination of the higher class, of the men who had attended more than one course. Mr. Allen obtained the silver medal with 90 marks; four other gentleman who would receive certificates of honour, obtained 85, 84, 82, and 76 marks, respectively, and another obtained a certificate of merit. In conclusion he could only say that he believed all these gentlemen to be highly entitled to the distinction which was thus conferred upon them.

The following is a list of the students in this class to whom prizes have been awarded:—

TEN MONTHS' SESSION.

Silver Medal.....Allen, Henry.

Certificates of Honour.....Cox, John Goodwin.; Sangster, John Graham.; Warrick, F. Walmsley.; Jackson, Alfred Henrick.

Certificate of Merit.....Cook, William Richard.

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal.....Mason, Wm. Brandwood.

Certificates of Merit.....Sangster, John Graham.; Allen, Henry.; Cox, John Goodwin.; Collinson, Fredk. Wm.; Ashweek, John Sydney.

SECOND COURSE.

Bronze Medal.....Jackson, Alfred Henrick.

Certificate of Merit.....Furness, Joseph Machin.

The following were the questions for the examination:—

CHEMISTRY AND PHARMACY.

FIRST COURSE. BRONZE MEDAL.

1. State the equivalents in grains of the milligramme and centigramme.

2. What are the weights, in grains, of a fluid ounce of hydrochloric acid, B.P., and of a pint, fluid ounce, and minim, of distilled water?

3. What is the meaning of the term, specific heat, and what are the specific heats of water, olive oil, and mercury?

4. Describe the production of carbonic oxide, and marsh gas, and state the composition, specific gravity, and properties of each of these gases.

5. Describe the production of chlorate and hypochlorite of potassium, and state what you know respecting the conditions which favour the production of these products respectively.

6. Describe the production and composition of oxalic acid, lactic acid, and butyric acid.

7. Describe the Pharmacopœia process for the production of ether, and explain the changes that take place in the process.

8. What is the composition of aldehyde, and how is it produced?

Describe cyanide of potassium and its production.

SECOND COURSE. BRONZE MEDAL.

1. What is the weight of a cubic inch of water at 62° Fahr.?

2. What is the length of a pendulum that will vibrate in seconds of time in the latitude of London?

3. Explain the difference between the centigrade and Fahrenheit thermometers, and the method of converting the terms of one into those of the other.

4. What is the specific heat of olive oil, and how would you determine it?

5. Describe the sources and the methods of preparation of sulphur in the different states in which it is met with in commerce.

6. Describe the process of the Pharmacopœia for the preparation of *emplastrum plumbi*, and describe the chemical changes that occur in its production.

7. What is the composition of glycerine, and how is it produced?

8. Give the Pharmacopœia process for the preparation of oxide of zinc, and describe any other method you may know for the production of this oxide, including in your description defective methods which have been adopted and rejected.

SESSIONAL COURSE. SILVER MEDAL.

1. Give the weights of a fluid ounce of each of the following liquids, namely, *chloroform*, *glycerine*, *nitric acid*.

2. Describe the process of dialysis, and explain the principle on which it is based.

3. What is the meaning of the term, "mechanical equivalent of heat," and what is the unit expressed in foot-pounds?

4. What is the latent heat of water at 32° and at 212° F., and the latent heat of the vapour of water at 100°, 212°, and 300° F.?

5. Describe the preparation and properties of nitrous oxide and carbonic oxide.

6. State the sources from which our supplies of potash salts are derived, and describe the methods of preparing pure carbonate, and also the iodide of the Pharmacopœia.

7. Describe the production of mercury from its native ore, and the preparation of calomel and corrosive sublimate.

8. Describe the production of alcohol from sugar, of ether and also aldehyde from alcohol, and of acetic acid from alcohol and also from aldehyde.

The CHAIRMAN next called upon Professor Bentley to make his—

REPORT UPON THE BOTANY AND MATERIA MEDICA CLASS.

Professor BENTLEY said he would not detain the meeting long, as he knew there was much other business to be done that evening. It was quite unnecessary for him to speak of the diligence, regularity, attendance, good conduct and progress made by the students in the school of the Pharmaceutical Society. That was understood, and in point of fact the mention of a student of pharmacy in the school was an indication at once that he was attentive, regular, punctual and diligent. All this had been said year after year, but he could say so again most conscientiously. There was only one matter in connection with the school which he wished particularly to mention, and that was the examinations after lecture. In his view it was very important that students should not only attend lectures but also examinations after lectures. He knew nothing so well calculated to promote the progress of the student as to be examined on the subject of the lecture, and it had been his custom to examine for half an hour after each lecture on the preceding one, and that practice he should continue. The number of competitors for the bronze medal at the end of the first course in February was large, and the number of marks very high, for in fact all the students who passed the examination in the school must obtain a large percentage of marks or they got no recognition. Then at the end of the second course there was another examination, for the bronze medal, when it appeared that the two first candidates in Chemistry and Pharmacy were also first in Botany and Materia Medica. In the competition at the end of the session for the silver medal Mr. Allen, who obtained the bronze medal in the first course examination, got the silver medal for the ten months' course, and no one could more honourably deserve it. He might also say of the other competitors that they had obtained their distinctions with great credit, and he felt sure they would be a honour to the Pharmaceutical Society, and that in future contributions to pharmacy these gentlemen would be found taking a high place.

The following is a list of the students in this class to whom prizes were awarded:—

TEN MONTHS' SESSION.

Silver Medal	Allen, Henry.
Certificates of Honour	Sangster, John Graham. Cox, John Goodwin.
Certificates of Merit	Jackson, Alfred Henrick. Thompson, John Hartley. Cook, William Richard.

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal	Henry Allen.
Certificates of Merit	Cox, John Goodwin. Mason, Wm. Brandwood. Ashweek, John Sydney. Sangster, John Graham. Warrick, Fred. Walmsley.

SECOND COURSE.

Bronze Medal	Jackson, Alfred Henrick.
Certificate of Merit	Furness, Joseph Machin.

The following were the questions for the examinations:—

FIRST COURSE. BRONZE MEDAL.

Time allowed: Three Hours.

1. What are the contents of young vitally active cells? Describe their physical and chemical characteristics.

2. Define the following: Cell, vessel, latex, stoma, receptacle of secretion, air cavity, exogenous, endogenous, acrogenous, rhizome, bulb and parasite.

3. Of what does the food of plants consist, and how is it taken up?

4. Describe the physical and chemical characters of aconite root, and enumerate its official preparations and doses.

5. Describe the physical and chemical characters of jalap, and mention the substances which are commonly used as substitutes or adulterations, and the means of distinguishing them. Mention its official preparations.

6. How would you detect guaiacum when used as an adulterant of scammony?

SECOND COURSE. BRONZE MEDAL.

Time allowed: Three Hours.

1. What are the general and chemical characters of starch?

2. Define the following: Corm, rhizome, bulb, tubercule, epiphyte, pinnate, pinnatifid, phyllode; and describe the characteristic venation of the leaves of dicotyledonous and monocotyledonous plants.

3. Define the following terms as applied to the floral envelopes: Inferior and superior calyx, pappus, gibbous, spurred, unguiculate, papilionaceous, labiate, personate, and ligulate.

4. Describe the physical and chemical characters of black and white mustard seeds.

5. What are the geographical and botanical sources of the official gamboge? How is it procured, and what are its physical and chemical characters?

6. What is saffron? Describe its general characters and mention the principal substances which are used for its adulteration, and the means by which they may be detected.

SESSION. SILVER MEDAL AND CERTIFICATES.

Botany.

Time allowed: Three Hours.

1. Describe the different kinds of woody tissue; and mention the plants and parts of plants in which they are respectively found.

2. Define the following terms as applied to the stamens:—hypogynous, perigynous, epigynous, syngenesious, exserted, gynandrous, monadelphous, didynamous, isomerous, innate, versatile, and extrorse.

3. Define and give examples of the following fruits:—drupe, follicle, achenium, pome, etærio, cynarrhodum, capsule, legume, cremocarp, and pepo.

4. Describe the structure of the ovule, and explain the process of fertilization.

5. Distinguish the Melanthaceæ from the Liliaceæ, Iridaceæ, and Amaryllidaceæ.

6. Give the essential characters of the following natural orders:—Malvaceæ, Rutaceæ, Compositæ, Gentianaceæ, Polygonaceæ, and Papaveraceæ.

Materia Medica.

Time allowed: Three Hours.

1. What are the botanical and geographical sources of cusparia bark? Describe its general and chemical characters, and show how it may be distinguished from nux vomica bark.

2. What are the botanical and geographical sources of asafœtida? Describe its general and chemical characters, and enumerate its official preparations.

3. What is santonica? What are its botanical and geographical sources, and its general and chemical characters?

4. What are the official substances derived from the Gentianaceæ? Describe the characters of the official chiretta, and show how it may be distinguished from spurious kinds.

5. Describe the characters of official matico, and show how it may be known from spurious kinds.

6. Mention the official drugs of the Melanthaceæ. When should colchicum corm be collected for use in medicine? How is it known from tulip bulb, and what are its general characters, and its official preparations and their doses?

The CHAIRMAN then asked Professor Attfield for his—

REPORT ON THE PRACTICAL CHEMISTRY CLASS.

Professor ATTFIELD said he had a very short and simple duty to perform, that was, to submit his report on the class of practical chemistry, as drawn up for the Council of the Society in the form prescribed by the Council. The number of students attending during the session 1877—78 was 75. Seventy were pharmaceutical pupils, five studied for purposes other than those connected with pharmacy. Twenty-one of the students worked for ten months; fifteen entered for a five-months' course, twelve for three months each, the remainder working for longer or shorter periods other than these. The men who worked for shorter terms were, in almost every case, pupils who had studied in previous sessions or who intended to study in a future session. One gentleman came to spend in laboratory work the time given to him for a holiday. Averaging these different periods of study it might be said that seventy-five students worked five-sixths of every day for five and a-half months. Comparing the figures with those of previous years it would be seen that last session the pupils in practical chemistry studied for a greater number of hours per day and for a greater number of months than in any session for the past ten years. This was accounted for by the fact that with scarcely an exception the pupils of the session were young men who had come to acquire a sound and thorough and, above all, a lasting knowledge, with the object, as many of them said, of more successfully prosecuting their business rather than merely preparing for examinations. It would be gratifying to the Council and to all members of the Society to find that men thus come to their school with the prearranged design of running on lines identical with those which have been so wisely laid down from time to time by various Councils of the Society since 1842. The number of such students was still insufficient to render self-supporting a school in which separate professors were employed to teach the respective subjects, but there were good indications that the number was likely to increase. If some method could be practised of giving to such students at the close of their studies credit for the quality, as distinguished from the mere quantity, of the knowledge and improved brain-power they possessed great impetus would be given, not alone to the prosperity of the School of Pharmacy of the Pharmaceutical Society of Great Britain, but to the cause of true, thorough, practical pharmaceutical education throughout Great Britain itself. During the whole session the conduct of the students had been without exception that of gentlemen. He regretted that in the laboratories he would lose the services of Mr. Henry George Greenish as junior demonstrator, but was glad to state that for that office the triple first prizeman, Mr. Allen, had been engaged. The professor who had last spoken had usefully drawn their attention to the circumstance that in the three different classes, although somewhat different modes of estimating the relative position of candidates necessarily obtained, the same men rose to almost similar positions, evidence that the modes of judging the men were sound. That was satisfactory, but the fact was that in any examination, or indeed without any examination, there was no difficulty in identifying the few best men, or the few worst men. Where all examinations systems failed was in accurately fixing, in any practicable number of hours or days, the intellectual position of the 90 per cent. of intermediate men. In the prize competition at the end of the session, out of twelve candidates seven obtained positions as follows and the Council had awarded prizes accordingly:—

Standard Number of Marks, 100.

Silver Medal .....Allen, Henry, 87 marks.
Bronze Medals .....Sangster, John Graham, 82 do.; Jackson, Alfred Henrick, 77 do.
Certificates of Honour ...Cox, John Goodwin, 75 do.
Certificates of Merit ...Thompson, John Hartley, 70 do.; Ward, John Septibo, 68 do.; Smith, James William, 62 do.

The following were the questions for this examination :—

PRACTICAL CHEMISTRY.

Two Days' Examination.

Hours 10 to 5 each day.

(*Books and Memoranda permitted*).

FIRST DAY.

1. Analyse the accompanying "powder" and state your results.

2. How much bicarbonate of sodium is present in the "soda water" supplied to you ?

SECOND DAY.

3. Is there any common poison in the "coffee" placed before you ?

4. What is the percentage of alcohol in the "tincture" given to you ?

NOTE.—Manipulation as well as results will be scrutinized.

The PRESIDENT said he need hardly say that the reports of the Professors were eminently satisfactory. The idea had struck him sometimes that they should much prefer if the prizes could be more distributed, for they found them very frequently concentrated, and it constantly happened that one man came and swallowed up most of the prizes. In this instance, Mr. Allen had taken all the silver medals ; and in consequence the gift of books so kindly presented to the Society by Mr. Thomas Hanbury, consisting of the 'Pharmacographia' and 'Science Papers' of the late Daniel Hanbury, for the acceptance of students who obtained silver medals, could only be partially distributed. It was, however, very gratifying to find that there were men coming into the profession who were evidently possessed of such talent that they could not fail in after years to bring credit on the profession of pharmacy.

Having distributed the above-mentioned prizes with a few appropriate words in each case, the President called upon Professor Bentley to give his report on

THE BOTANICAL PRIZE.

Professor BENTLEY said he need not dilate on the advantage of a practical knowledge of botany. The Council in their wisdom many years since saw the importance of leading students and apprentices, especially those residing in the country, to a study of botany from a practical point of view, and he should on that occasion only again venture to urge upon those present particularly the importance of studying practical botany in that period of life when they were best able to do so. On the present occasion it had been his peculiar pleasure to examine three excellent collections, which might be seen in the Museum, and which abundantly testified to the perseverance and knowledge of those who had collected them. Those only who knew what it was to look through a collection of some 700 specimens of English plants would know what amount of labour was involved in examining these collections, but it was a labour of love. The first prize had been awarded to a collection containing 650 specimens, which were well preserved, named, and put together. The next two collections, containing 600 and 540 specimens each, were so good that he recommended the Council to award a bronze medal to each, and he believed it would not be the last they would hear of all these gentlemen in connection with pharmacy.

The following were the awards that had been made :—

Silver Medal .....Shrivell, F. W. Edward.
Bronze Medals .....Hooper, David.; Foggitt, John Blackett.

THE COUNCIL EXAMINATION PRIZES.

The PRESIDENT having presented the Herbarium prizes, said he had next to distribute the Council prizes. All who had passed the Major examination during the year were entitled to compete for these prizes, and by the kindness of Mr. Hills, valuable books were added to them. It had been usual to call on the examiner who conducted this examination to state what had been the nature of the questions and the quality of the answers, but on this occasion the examination was conducted in Edinburgh, and therefore, he was not in a position to do so.

The following were the persons to whom the prizes had been awarded :—

Pereira Medal (*silver*) ; *and Books value* £5, *presented by Mr. T. H. Hills.*

John Graham Sangster.

Pharmaceutical Society's Medal (*silver*) ; *and Books value* £3, *presented by Mr. T. H. Hills.*

Alfred Henrick Jackson.

Pharmaceutical Society's Medal (*bronze*) ; *and Books value* £2, *presented by Mr. T. H. Hills.*

John Septibo Ward.

The following were the questions for this examination :—

MATERIA MEDICA.

Time allowed : Three Hours.

What is elaterium, how is it obtained? Describe its general characters, varieties, and composition, and the processes by which its active constituent may be obtained.

What official plants belong to the order Thymelaceæ? Give the characters of the part employed, enumerate the preparations, and state how the extract is prepared.

Mention the sources, botanical and geographical, of guinea or cayenne pepper, state the adulterations to which it is said to be subjected and how to detect them, and describe the process by which the constituent is obtained on which its physiological activity is supposed to depend.

What is creasote, how is it obtained and its purity determined? Explain fully the object of the pharmacopœial tests.

BOTANY.

Describe the leading forms of valvular dehiscence, and give examples of each.

Describe the structure of the ovule and the changes of position which it undergoes.

What are the distinguishing characters of the following natural orders :—Rosaceæ, Papaveraceæ, Ranunculaceæ?

State what you know regarding the nature, growth and development of the yeast plant, *Torula cerevisiæ*.

CHEMISTRY.

Time allowed : Three Hours.

1. What is chlorinated lime? State how it is prepared commercially, and some of the methods for determining its strength.

2. Starch, dextrine, cane sugar, grape sugar, alcohol, aldehyde, chloral.—The method of preparation, properties and mutual relation of these bodies.

3. Give a concise account of as many of the metallic derivatives of glycerine as you can, stating how they are obtained, and their physical and chemical properties.

4. Certain oxides are precipitated from acid solution by H_2S, the precipitate being soluble in NH_4HS. Name them, and the best method for separating each from the other.

5. Light moves in straight lines, the direction of which may either be divergent, convergent, or parallel. Illustrate this by means of diagrams, making the rays of light impinge on suitable lenses.

The CHAIRMAN requested Mr. Taylor to report upon the examination for—

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

Mr. TAYLOR commenced by expressing his regret that there had not been more candidates for these valuable prizes. Last year his colleague, Mr. Umney, himself an old Bell scholar, expressed the same sentiment, and drew forcible attention to the value of these scholarships, and he must say he was extremely surprised that there were not more candidates to compete. This year there had been one candidate less than last, the number being thirteen. The question naturally arose, How was it that there were not more? and he thought that employers and teachers might do more to encourage their students and pupils to try, for there surely must be amongst the vast number of young pharmacists many more than thirteen who would be perfectly justified in competing. It was no mean distinction to be a Bell scholar, for young men to have their names in a list which began with Tilden and included the names of many others who had done honour to themselves, to the Society, and to the name of that deservedly respected man in memory of whom these scholarships were founded. He was sorry to say there were no competitors from Scotland; there were six from London and seven from different parts of England, but large centres like Liverpool and Leeds were not represented. The successful candidates were Mr. Alcock and Mr. Allan. He could congratulate those gentlemen on the creditable manner in which they had acquitted themselves, and he had no doubt they would become useful and accomplished members of the pharmaceutical body.

The PRESIDENT said Mr. Taylor's remarks were very pertinent, and the fact of only thirteen persons competing seemed to show that the advantages of these prizes were hardly sufficiently known. They were open to the competition of all, and included a grant of £30 and free instruction in the laboratories and attendance at the lectures, which could not be valued at less than £30 or £40 more. By the generosity of Mr. Hills a set of valuable books was also added to assist the young student in his career and to complete his education. It was gratifying to find that so many Bell scholars succeeded in becoming leading men in the profession, and that was another reason why these scholarships should be competed for by a greater number in future.

The following were the questions for this examination:—

CHEMISTRY AND PHARMACY, AND BOTANY.

Time allowed: Two Hours.

1. Describe the allotropic forms of carbon. How would you prove that these different substances consist of the same element?

2. Describe the mode of manufacture of bleaching powder. Write the formula of this compound, and explain what happens when hydrochloric acid is added to it.

3. Write the formulæ of the most important compounds of *iron* used in pharmacy.

4. Explain what takes place when chlorine gas is passed over red hot (1) iron; (2) arsenic; (3) alumina.

5. State fully the process of the Pharmacopœia for preparing green extracts. Explain minutely the objects of each part of the process.

6. Describe the structure of the leaf of the dandelion.

7. Give a description in appropriate botanical language of the common buttercup and white dead nettle.

LATIN, ETC.

Time allowed: Three Hours.

LATIN.

(*Virgil, Æneid, lib. i., ii., or iii.*)

1. Translate into English:—

Postquam introgressi, et coram data copia fandi,
Maximus Ilioneus placido sic pectore coepit:
O Regina! novam cui condere Jupiter urbem,
Justitiaque dedit gentis frenare superbas,
Troës te miseri, ventis maria omnia vecti,
Oramus: prohibe infandos a navibus ignis:
Parce pio generi, et propius res adspice nostras.
Non nos aut ferro Libycos populare Penates
Venimus, aut raptas ad littora vertere praedas:
Non ea vis animo, nec tanta superbia victis.

2. Decline *pectore, urbem, maria, generi.*

Name the case of each and state the reason for the case in each instance.

3. Give the present, perfect, supine and infinitive of *coepit, condere, dedit, prohibe.*

4. Write the following prescription in full Latin *words*:—

℞ Hyd: Perchlor: . . . . . gr. $\frac{1}{20}$.
Pot: Iod: . . . . . gr. $\frac{1}{2}$.
Ext: Aloes Barb: . . . . . gr. i.
M. ft. pil. s. q. *m* xij.
c. i. o. vel. alt. noct.

ENGLISH.

1. Parse fully:—

When I came back to England, I did not expect our results would be appreciated for ten years.

9. Write a short essay on steam, or telegraphy.

ARITHMETIC.

1. Multiply £24 5*s.* 9$\frac{1}{2}$*d.* $\frac{6}{7}$ by 62$\frac{5}{12}$.

2. How many ounces are there in ·65390625 ton?

Reduce 33 yards to the decimal of a mile; 3*s.* 5$\frac{11}{20}\frac{1}{0}$*d.* to the decimal of a dollar, a dollar being 4*s.* 3*d.*

4. Though the length of my field is one-seventh greater than that of my neighbour's, its quality is one-ninth better, yet, as the breadth of mine is one-fourth less, his is worth five guineas more than mine. What is my field worth?

FRENCH AND GERMAN.*

Translate into English:

Je suis, dans notre temps de chocs et de fureurs,
Belluaire, et j'ai fait la guerre aux empereurs;
J'ai combattu la foule immonde des Sodomes,
Des millions de flots et des millions d'hommes
Ont rugi contre moi sans me faire céder;
Tout le gouffre est venu m'attaquer et gronder,
Et j'ai livré bataille aux vagues écumantes,
Et sous l'énorme assaut de l'ombre et des tourmentes
Je n'ai pas plus courbé la tête qu'un écueil;
Je ne suis pas de ceux qu'effraie un ciel en deuil,
Et qui, n'osant sonder les styx et les avernes,
Tremblent devant la bouche obscure des cavernes.

* The candidate is at liberty to chose either French or German, and is not required to show a knowledge of both.

Or:—

So warst du denn im Paradies empfangen,
Als wärst du werth des ewig schönen Lebens;
Dir Blieb kein Wunsch, kein Hoffen, kein Verlangen,
Hier war das Ziel des innigesten Bestrebens;
Und in dem Anschaun dieses einzig Schönen
Versiegte gleich der Quell sehnsüchtiger Thränen.

Inaugural Sessional Address.

The following address was then delivered by Mr. Octavius Corder, of Norwich:—

My Friends,—"I find I know not anything." Thus writes one, who has probably done more to influence and modify the train of English thought in this nineteenth century of ours than most men; one, the influence of whose opinions, quietly and without any great show, will be unceasingly felt, not only in his own day, but as time rolls on will be recognized as "current coin," when the writer himself will have long passed away. And yet with all this grasping for knowledge, this constant craving for more light, it comes after all to little more than glimpses of things, or perhaps better expressed,

"An infant crying in the dark,
And with no language but a cry."

After I had read the very excellent address of my friend, Mr. Southall, delivered before the students last October, I could not but feel that the work was so thoroughly done, and the subject so exhausted, that there remained but little for me to do; and when we consider that an address is a yearly affair, you can hardly expect any amount of original research or thought; and so I was reminded of an incident, recorded by one of the old chroniclers, who tells us that when the Venerable Bede had well nigh finished his last great work, his amanuensis, wishing to encourage his now rapidly failing master, said; "But one more chapter;" then later on, "but one more verse;" then, "the last word." The difficulty of addressing you can hardly be sufficiently estimated, for what I say to you this evening had to be noted down, from time to time, just as the thought or the leisure presented itself; so that you must not expect any very settled or elaborate essay.

He who writes professionally does so to some extent mechanically, but he who delivers but one address, finds it a much more serious affair. And so I would ask of you to judge of this attempt, not as critics, but as friends who have met me this once, some of you only this once, in the journey of life. This word, Life, suggests to me that I may say a few words to you this evening concerning it; not that we know much about it, either in the plant, the mollusk, in the bird, or in the mammal. If you can tell me what it is, I could much more readily tell you a great deal about it. We may argue and theorize, talk much, and write great folios to show what it is, but after all we have merely proved its existence; the vital principle, the strange secret essence remains unknown, and must remain unsolved: to be able to demonstrate a life seems beyond human power. It has been said, and the idea to some extent appears a feasible one, that we have lost a sense, that of seeing the invisible. Tennyson's words become very real, and give much food for thought when he says:—

"Flower in the crannied wall,
I pluck you out of the crannies;
Hold you here root and all in my hand,
Little flower! but if I could understand
What you are, root and all in all,
I should know what God and man is."

As far as the plant or life in general is concerned we know that sun-light and sun-heat

"Give the reed and lily length,
Give to oaks and oxen strength."

And thus we feel that the old Fire Worshippers had no mean notion of the Most High when they gave to the sun highest honour as the source of light and heat and life, the withdrawal of his rays causing darkness, decay, and death. Beyond sun-light and heat being the sustaining power, we know but little; the questions which puzzled the author of the Book of Job, written most likely in the days of the Shepherd Kings, when man's life was much more recent on the earth than now, continue equally to puzzle us, several thousand years further down in time. We are told that the corpuscles in the amœba, low down in the scale of animal life, are identical with those of the highest mammal; of the sap in the tree pursuing its wonted course between the bark and the cambium layers of the wood, propelled onward and upward by an invisible force, but by a fixed law depositing carbon to form cells and fibre and tissue, giving strength and stability to the stem, freshness and greenness to the leaf, beauty and colour to the flower; of the blood propelled by a pump-like force, never ceasing whilst life lasts, giving energy to the mind, power to the frame, and mantling the cheek of beauty. These and hundreds of other instances may be cited as caused by life, are the results of it, but are not the life itself. Wiser heads than mine have thought much on the potentiality of matter, so much so that they would account for the existence of all life to its power. But however powerful matter may be (as witnessed by the force of the glacier slowly grinding its way down an alpine valley or the mountain-stream wearing its hollow bed out of the rock), or however clever the chemist, yet with all the power of matter at command, with all the knowledge he possesses of the exact proportions of the elements required, yet man or matter have never yet been able to evolve *de novo* a life in plant or animal of even the lowest and most humble form. And this, to me, is the great stumbling block to the reception of the so-called development theory, that we have never found (if I may so say) a life produced *per se*. We can take a flower, pull off the calyx and corolla, examine the stamens, scatter the pollen off the anther, dissect the pistil and ovary, but in opening out we have at the same time destroyed, so that, however put together again, it will never be fertile; the life has escaped, the strange mysterious essence has gone, so that the rose will never again delight with its beauty or refresh with its fragrance. We take an egg from the nest of the wild bird and break it, but, however carefully put together, that egg can never again be fertile; the something, which came we know not whence, has gone we know not whither, so that the *Te Deum* of praise which would have risen in spring and summer from the throat of that wood bird will never find an utterance; therefore, before exercising what you may consider your prerogative to kill, remember you are taking what you can never give back! We must choose one of two views as to the progress of life on the earth: one of development, the other of a series of successive creations, commencing low down in the scale both of the animal and vegetable kingdoms, each one higher than that which preceded it. These creations, as far as we know (I would speak as far as I possibly can with a freedom from dogma),

have long ceased; indeed, as far as we can see, we may fairly presume that man was the last work. Old forms have died out both of plants and animals, variations and varieties without number appear and disappear; education, culture, selection, and care will account for these. We see that all life is progress. The lowest forms of animal life dividing and subdividing; the caterpillar weaving its own shroud to emerge to something higher and brighter; the egg brooded with tender care or laid in the sand careless whether the foot may crush or the beast devour; everything points upwards and onwards. Nothing without its use and place in the great whole; and as amongst the dust and turmoil of Lebanon the stones were hewn and the timber made ready, each beam and rafter for its place, in the Great Temple; so, in nature's chain, each is so needful to the well-being of the other, and at the same time so complete, that it matters not "which link you strike, tenth or ten-thousandth breaks the chain alike." Without attempting to say what life is, we can search downwards and at least with some degree of assurance arrive at the beginning of it, and for this purpose we must go back to time so remote that, to us of a few years' growth, we cannot but fail to appreciate its remoteness. Life, from the creation till now, has evidently not been an eternal succession of like forms of being, but rather the humblest first. In the Laurentian rocks, deepest and oldest known to the geologist, long supposed to be azoic, devoid of the remains of all life, most altered by heat and heated matter, we find, according to recent research, the first glimpse of animal life in the *Eozoon Canadense*, or Canadian dawn animal; and thus, looking back, we cannot but feel a certain amount of awe to hold in our hand very near to us the print of the first creature into which was breathed a life. This "life-dawn" is not confined to the Laurentian rocks of Canada, but is found in Norway, Sweden, and elsewhere; nothing very elaborate in its construction—a protozoon or amœba-like creature.* This, then, we may consider a starting point, and corresponding with it what is generally called a low form in the vegetable world. And feeling, as I do, that this is not the time, nor do I profess to be qualified, to determine any theory which has been advanced or received, yet this much I think will be allowed by all, that the higher animals and man have only comparatively recently appeared on the stage, and also at the time when all was prepared and made ready for them.

With the first appearance of animal life, such as the various forms of protozoa, we find, as might be expected, a life of the lowest forms of algæ produced, as we know all such are, by spores. Each generation of life grows a tiny deposit, so that one thousand feet deep of chalk may be traced to the remains of foraminifera, many of them so minute as to require microscopic power to examine them. How long this may have taken to deposit must be a matter of conjecture; but when we consider the immense bulk of the material and the minuteness of the agent, at least we must allow many thousands of years for its gradual accumulation.

Next comes the era for corals, mollusks, and crustacea in the animal world, and with them the higher forms of algæ amongst vegetables, simple plants of cellular construction, pointing to a period when all seemed a waste of waters. No need of insect intervention here, for these grew as they do now, by cell development, by division of cells, by cellular prolongation. Here all increase takes place by very simple means, by spores contained in mother-cells or perispores. In some, reproduction is effected by spores which are formed in the interior of cells by a change in the arrangement of the granular matter contained in them; in others, as in diatoms and desmids, increase is effected by division of the parent cells into two portions which become more or less detached, and so new individuals are formed. This occurs only within certain limits, conjugation and the formation of sporangia is for the permanent continuance of the species; but in all cases each seems sufficient of itself to insure increase without any intervention of outside means. Again another era, and we find a fresh life has appeared. Fishes, amphibians, with strange uncouth saurians, such as Milton might well have portrayed, they, happily for us, now long passed away; with these we find plants of acrogenous growth, giant ferns, and lycopods, huge club mosses, and great equisetums, of which our present ferns and meadow horse-tails are very feeble types. To this era we are indebted for our coal formations, the impressions left behind enabling us to judge of what the vegetation consisted. Leafy lepidodendrons with their delicate and feathery fronds; sigillarias with their fluted stems and enormous matted roots; calamites with their singular branches; tree ferns and coniferous plants, resembling the Norfolk Island pine, towering high above the rest of the forest, reproducing in the quiet way our ferns still have, or in the secret manner the fircones still know. Not for long ages after did the grasses spring up with their graceful nodding plumes, or flowers come making bright and lovely every knoll and thicket. A new creation now takes the place of the old forms. Mammals displacing saurians, cycads and palms to some extent the ferns and club mosses, till at last comes man before us, and with him angiosperms in all their beauty and brightness. All this time nothing lost, nothing wasted in the great laboratory of Nature, nothing really gone wrong all these thousands of years, if we except death and decay, which, by the way, are but the beginning of life. And thus the round has gone on, oxygen and carbon combined by the mammal; oxygen set free from the carbon by the plant. Is not, then, all life a strange mystery, beyond our tissue-paper thickness of understanding? Why am I saying such simple facts to you? Simply, that you may think out a little of the wondrous truths which are around and about you, only waiting for your notice and observation. Speaking of a Californian plain, a recent writer says, "For six months of the year it is a barren waste, a scorched and dust-swept desert; in April it becomes a flower bed, well nigh four hundred miles long and thirty broad, set there bright and blooming under the snow mountains. Go where I would, north or south or east or west, I still plashed on in flower gems." I saw something of this sort during the past summer in the Engadin; flowers which to us in England are rarities known only by name, some indeed unknown in cultivation: *Eritrichium nanum*, a dwarf forget-me-not flower of loveliest blue; *Androsacea glacialis*, one of the *Primulaceæ*, impatient of restraint in English horticulture; *Ranunculus glacialis*, above the snow line,

* Messrs. Kay and Rowney, of Galway College, repudiate the idea and refuse to acknowledge that the animal nature of *Eozoon* is by any means an ascertained fact.

generally pining and lingering on with us as an alpine; *Gnaphalium leontopodium*, or Eidel Weiss of the Germans; *Dianthus superbus*, a beautiful fringed pink, scenting the air for yards around it; *Aquilegia alpina*, a columbine, only recently introduced by our florists; *Anemone sulphurea*, of richest yellow, with *alpina* and *vernalis*, neither of them British species; *Woodsia alpina*, a delicate tufted fern, and *Aspidium Lonchitis*, the holly fern (both now almost extinct in England, thanks to the "adventurous botanist" who "eradicates the lot"); *Papaver Pyrenaicum*, a bright yellow perennial poppy, growing amongst stones near the glacier; Primulas and saxifrages, with numerous gentians: these and hundreds of others at every turn gladden the heart of the botanist and every true lover of nature, so that we feel that it has been very truly said, "How God loves beauty!" and "What barns He has!" I saw here what I have never before noticed or indeed heard of, the *Viscum album*, or mistletoe, growing most luxuriantly on the fir tree. Does it any way change its nature by its growth on a highly resinous tree? Also, that probably more than one gentian produces the roots we use in medicine. *Gentiana lutea* and *punctata* producing roots so alike in appearance and bitterness, that they would pass, mixed together, a fairly critical examination; *Colchicum autumnalis*, springing up in all the meadows (this valley is too high for the growth of any cereals or even potatoes); *Veratrum viride* and *Aconitum napellus*, plentifully spread by every wayside; *Atropa belladonna*, abundant in many places; *Hyoscyamus niger*, *both* annual and biennial,—as also *aureus*, which I suspect forms at least a portion of our imported henbane, and from its slight smell and almost entire want of clamminess, should judge that it has very little medicinal value; *Arnica montana*, very plentiful, enlivening every knoll with its bright star-shaped composite flowers; St. Bernard's and St. Bruno's lilies in abundance, with *Lilium croceum* and *Martagon*. But time fails to enumerate the botanical treasures of this till lately almost unknown valley. Here, those who are well may go to enjoy life, those who are ill may go to make life enjoyable.

As might be expected, most of the plants are herbaceous or perennials. The short and uncertain summer failing to ripen the seeds, etc., annuals as a rule would die out. But on this subject I cannot do better than quote from one of our best authorities, Professor Balfour, when he says—"There is, moreover, something peculiarly attractive in the collecting of alpine plants. Their comparative rarity, the localities in which they grow, and frequently their beautiful lines, conspire in spreading around them a halo of interest, far exceeding that connected with lowland productions. The alpine *Veronica*, with its lovely blue corolla, on the verge of dissolving snow,—the "Forget-me-not" of the mountain summit, whose tints far excel those of its namesake of the brooks; the *Woodsia*, with its tufted fronds adorning the clefts of the rocks; the snowy gentian, concealing its eye of blue in the ledges of the steep crags; the alpine astragalus, enlivening the turf with its purple clusters; the lychnis, choosing the stony and dry knoll for the evolution of its pink petals; the sonchus, raising its stately stalk and azure heads in spots which try the enthusiasm of the adventurous collector; the pale flowered oxytropis, confining itself to a single British cliff; the azalea forming a carpet of the richest crimson; the saxifrages, with their white, yellow and pink blossoms, clothing the sides of the streams; the saussereas and erigerons, crowning the rock with their purple and pink capitula; the pendent cinquefoil, blending its yellow flowers with the white of the alpine cerastiums and the bright blue of the snowy veronica; the stemless silene, giving a pink and velvety covering to the decomposing granite,—all these add such a charm to highland botany as to throw a comparative shade over the vegetation of the plains." With some it may be said, as Wordsworth has written of 'Peter Bell'—

> "In vain for him each changing year
> Did nature lead him as before:
> A primrose on the river brim
> A yellow primrose was to him,
> And it was nothing more."

I trust none of you are of that class.

A few words only in conclusion. The "true moral lesson, 'See what comes of being good,'" has been set forward so often that I will not enlarge upon it. I presume that your presence here is sufficient to warrant me in supposing that you have set your minds on passing certain examinations; keep that idea as much as possible in the background. Study because you like it and I have no fear as to the result. That which is grudgingly attained will, as a rule, be found equally grudgingly parted with: hence to some extent the impossibility of at all times forming a correct estimate of the knowledge possessed by the candidate. The desire of the examiner (I speak from the experience of several years in that capacity) is to pass, not to send back the student; believe me, it is by no means a pleasant task to affix an "0" to any man's name. A threefold duty has to be performed—justice to the candidate, security to the public, and satisfaction to the examiner. What I hope is that the session 1878-79 will afford a striking contrast in its favour compared with previous years. We must, by the nature of human fallibility, be liable to errors in judgment, but, as a rule, I believe the results have not fallen far short of the desert. I am not in a position to offer you either a panacea to arrest failure in life, or to ensure success, except one word—work! This much I do know, that the best life does not consist in abundance. I have sufficient faith left in honest endeavour to believe that a living may be obtained by fair trading, notwithstanding the lowering aspect of trade interests; surely not by keeping open shop an hour later than your neighbour, or by cutting down fair prices—cheap physic, to say the least, has ever proved a failure and an abomination; the race has not yet come who will take double quantity because of a reduction in price. Reduction in price and cutting may appear to succeed for a time, yet the Nemesis will surely come and avenge herself on the offender.

Life is real: see, therefore, that it be earnest. The journey can only be gone over once; therefore, let it be done well.

Whether the coming generation prove a better one than the present is very questionable. I rather fear the worse. An age of reason is not likely to be an improvement on an age of faith. The one leans on self, the other rests on a sustaining Power. Why discredit the miraculous, because it is said to have happened long ago and in distant places, seeing as we do in all before us hourly, daily miracles of wondrous portent? True, the one is distant by reason of time and place; the other plain to us and appreciated by our several senses.

Do you need an instance? Take incubation. An egg consists of (as you well know) a phosphatic shell, a film of parchment-like covering enclosing the yelk and the white, nothing else save a small opalescent looking speck. Is there anything here to lead you to suppose what will be the outcome of this? We find in a day or two after incubation has commenced a blood streak, later on an indistinct form of bird-life, later still the different parts appear—head with brains, body with heart as motive power, feathers and all complete; in some twenty-one or more days the chick is ready to tap the phosphatic covering and emerge forth in all the being of bird-life! Is this, then, no marvel? It may be called old fashioned; but think it well over before you throw aside old truths, the more especially if you have nothing better offered you than husks in the place of what has passed as grain. Let it not be found that half the pages of life have been so blotted and smeared that there is nothing worthy to record. Bear in mind, that in a very few years you must take the foremost rank and place of those who are now standing in the front. You may not expect to surpass Sir Humphrey Davy in Chemistry, Buffon in Natural History, Linnæus in Botany, or Pereira in Materia Medica; but you may so do your duty and so employ the talent that "Well done!" will be your award.

"I say to thee, do thou repeat
To the first man thou mayest meet,
In lane, highway, or open street,

That he and we and all men move
Under a canopy of love,
As broad as the blue sky above.

And ere thou leave him, say thou this
Yet one word more, They only miss
The meaning of that final bliss

Who will not count it true that love,
That blessing not cursing rules above,
And that in it we live and move.

And one thing further make him know,
That to believe these things are so,
This firm faith never to forego.

Despite of all that seems at strife,
With blessing or with curses rife,
That this is blessing—this is life!"

At the close of the address—

Professor MARKOE (of Boston, Massachusetts) moved a vote of thanks to Mr. Corder, saying he felt it a great honour to be called upon to do so, and that it would be appreciated as such by the Massachusetts College of Pharmacy which he represented. Nothing could give him greater pleasure than to propose the thanks of the meeting for the scholarly, able, interesting, and thoughtful address to which they had listened, one fraught with good advice to the young men who had received the well merited rewards of their faithful work and attention to their studies. It had been hinted to him that perhaps some little information with regard to the way in which pharmaceutical education was pursued in the States might be of interest to gentlemen who had pursued the course of studies in that school, and with the President's permission he would briefly state the leading points in which they in the United States differed from the Pharmaceutical Society of Great Britain. In the first place the United States Government did not permit of national interference with the domestic affairs of the various States. The United States consisted of a large number of different States or commonwealths federated together for common defence and the development of commercial produce, but in their domestic relations each State was free and independent, so that anything like a universal pharmacy law would be quite at variance with the genius of their system of government. It therefore devolved upon every State, and frequently on individual cities, to pass such restrictions on the practice of pharmacy as citizens might deem fit. In a general way there were no such legal restrictions, but any one who thought fit to do so could open a store, and in some parts of the country this liberty was largely exercised. Still, pharmacy as a profession had been recognized and organized in America rather longer perhaps than it had been in Great Britain. Starting with the Philadelphia College of Pharmacy, which was the oldest—it was about to commence the fifty-sixth annual session of its School of Pharmacy; the College of Pharmacy of New York followed with an age of only one or two years less; and the Corporation of Pharmacy of Massachusetts was nearly twenty years of age, although it did not see its way to avail itself of its corporate rights to establish a school and grant diplomas until about twelve years ago. Still with only that short record it had ninety-five students last year, and he should be greatly disappointed if, on returning to his duties in the course of twelve or fifteen days, he did not find the class increased to something like one hundred and twenty-five. He should be within the mark in saying that there would be not less than fifteen hundred students throughout the United States attending the courses of instruction at these public colleges of pharmacy. Pharmaceutical legislation was making considerable progress, and pharmacy laws were now in action applying to the cities of Philadelphia, New York, Baltimore, San Francisco, Louisville, Chicago, and the States of Rhode Island, New Jersey and New Hampshire. There was every reason to suppose that other States would rapidly follow with more and more stringent restrictions on the practice of pharmacy. These various laws were carried out by State Boards of Pharmacy, nominated by the pharmacists themselves, and appointed from those nominated by the Governors of the State. Each city had a right of petitioning the Legislature for a law which should apply to that city alone, for there were often communities where the population was so sparse as not to make it judicious to apply such restrictions as would be proper to enforce in older and more settled communities. In general their pharmaceutical legislation had comparatively little to do with the large number of students who attended the various schools of pharmacy, but it was simply a desire on the part of young men for a better education, and to fit themselves for the responsible duties, which impelled them to avail themselves of the course of instruction offered. This was certainly the case in Massachusetts, because there they had no legislation at all, and yet in Boston alone they had a class of ninety-five, who were not compelled to attend, except from a desire for education, and this spoke well for the future of pharmacy in the United States. He could not help confessing to a feeling of surprise, coming as a stranger to London, to find that it did not support a larger school of pharmacy. He scarcely knew what to make of it, in a grand old city like that, which contained a larger population than the whole State of New York, that there were not greater numbers attending that school. If such

advantages were offered in any community of the United States, that building would not be large enough to hold the classes. But perhaps the system under which their schools of pharmacy were conducted might explain it. The term "college of pharmacy" in the United States was applied to a corporation of druggists. They did not necessarily have a school, because frequently a college of pharmacy was formed in a locality which was not populous enough to support a properly endowed school, and they contented themselves by getting premises, collecting a library, and giving occasional lectures without any systematic course of instruction. When they became strong enough they established a school, and if such schools were in a weak state, they were frequently carried on at the expense of the members of the various colleges of pharmacy. Limiting himself to Boston, he might say that managers of that College ensured a full attendance at the classes by the arrangements they made with their apprentices. They had no indentures in the States, but the young man came and agreed to stay four years, during which time he became familiar with the details of practical pharmacy, and in most cases the employer covenanted to send him to the lectures of the College of Pharmacy and to pay the fees as part of his regular compensation. This had become the rule in all the leading establishments, so that they did not leave it to the young men to say whether they would go to school or not; but, republicans as they were, they compelled them to do what was right in this respect. There was no trouble about it, however; the difficulty rather being to restrain the eagerness of the young men to attend the schools. This practice had been followed by the leaders in pharmacy in Boston and other large towns, and the mere fact that the College in New York was preparing to get larger premises in order to accommodate the class was sufficient to speak as to its success in that city. A young man who wished to become a graduated pharmacist must take a degree in these, the only, colleges; they did not allow him the right of studying at random, but a certain amount of study must be carried on in one of these, the only, schools. For instance, if a young man had studied in Philadelphia, and attended a course of lectures there and then came to Massachusetts, he brought to the faculty of the latter college a certificate showing that he had attended regularly the junior course in Philadelphia, and passed his examination, and he was then admitted to the senior class in Massachusetts College. If he had attended portions of two classes and wished to take his degree, he would be only credited for one. In localities where there was no college of pharmacy, he was credited with one course, provided he brought certificates that he had passed a suitable examination in some medical college where the same branches were taught. They also insisted that a young man should, under any circumstances, present satisfactory evidence that he had served four years with a competent pharmacist in the actual dispensing of prescriptions, and the regular colleges refused to acknowledge diplomas given by one or two schools who attempted to fit young men for the branches of pharmacy by a purely theoretical education. Such briefly was the system in Massachusetts, and he was glad to say that very soon other colleges would open schools and that there was a perfect accord between the regular schools of pharmacy in America so far as the conditions required for graduation were concerned. There was a convention every year of the teaching colleges, where delegates from each college met together and agreed on the character and conditions of the examinations. This would give some idea of the way in which pharmaceutical education was pursued in the States, showing that the law had comparatively little to do with the large number who attended the schools, but that it was mainly due to the desire on the part of young men to get a better education. Not perhaps that it was a mere love of science, but the American desire for business success which prompted them as often as not, because they recognized the fact that a man acquainted with the theoretical portion of his business was more likely to succeed than one who was only familiar with the practical portion. In conclusion, he would say one word to the gentlemen who had acquitted themselves so nobly during the past course. He could sympathize with the Professors of that school, because he had often had the pleasing duty of commending successful students, but he begged to tell them that the honours they had gained to-night were simply the certificates that they had perhaps only obtained the minimum amount of knowledge necessary in their profession; their *alma mater* expected much of them in future, and they would fail in their duty if the Pharmaceutical Society of Great Britain did not hereafter have much excellent work from them.

The vote of thanks was passed unanimously, and briefly acknowledged by Mr. Corder.

Dr. GREENHOW then proposed a vote of thanks to the President for the manner in which he had presided over the proceedings. Holding the position he did of official visitor, and thus, to some extent, being placed in opposition to the authorities of that establishment, he could speak with the warmest feeling of the kind courtesy he had always received from the President and from his predecessors. He had put aside another engagement in order to be present that evening, but he must say that he felt himself in the position of virtue rewarded. During his connection with that Society he had made many warm friends, but amongst the many friends he had on the Council and the Board of Examiners, Mr. Corder was by far the oldest, and he had listened to the address which he had given with the greatest pleasure. He referred especially to the latter part of it, and as there were young men there who were still in the state of pupilage, he would venture to impress upon them one remark made by Mr. Corder which he, as a teacher, had been in the habit of making for many years, and which had also been made by one of the Professors, namely, study because you like it, and have no fear as to the result. Professor Attfield had remarked that there was a spirit amongst the students of that institution to acquire knowledge rather than to prepare for examinations, and that was the right spirit to cherish. He often told his young medical friends that no man had a right to be plucked. Every examination, whether it was at one of the great universities for a medical diploma, or for the qualification of that Society, was necessarily pitched to suit the minimum qualification, and the capacities of the minimum class of students, and therefore the minimum class of student ought, if he used common diligence, to pass that examination with credit to himself. No man who took proper pains would ever fail. It might happen once in a thousand times, from some for-

tuitous concurrence of circumstances, or from unusual nervousness that such a man might fail, but, apart from that, any one who properly prepared himself would be sure to pass. He was led to speak of this the more because Mr. Corder had expressed a hope that the Session of 1878—9 would afford a striking contrast to the results of previous years, and in that hope he most cordially concurred. The way to realize that hope was to carry out the suggestions which had been made, and which he now repeated, namely, to set before themselves, not success in passing the exmination, but the endeavour to qualify themselves for the duties of life. Life was a serious matter; as Mr. Corder had said it only came once, and if they realized that truth they should take every possible pains to qualify themselves for the business of life, and there would then be not the slightest doubt that they would pass examinations with credit, and there would be a larger number of candidates coming up for those prizes which, as they had heard, were not sufficiently sought after. With regard to the examinations he need say nothing, but there was one observation he wished to make, especially directed to the parents and teachers of future students. One of the examinations in which young men failed most frequently was the Preliminary, and it did strike him as a very remarkable fact that so many young men coming to that Society should fail in that Preliminary examination, which really comprised nothing more than a thorough acquaintance with the three R's, which were considered to be thoroughly well taught in many national schools, and a moderate amount of Latin. It seemed to him inconceivable that young men well connected, coming of parents who certainly had the means of giving them an education, should so often fail in that simple examination. It was a lamentable thing, and he would impress on those who had to train young men for these examinations that the first step was to train them thoroughly for the Preliminary. In doing so they were awakening their mental powers and sharpening the tools which they would have to use hereafter in acquiring that more technical knowledge which was essential in passing the subsequent examinations. If they would more impress upon young men that this was a part of the serious work of life, he was quite sure that in the course of a short time they would have a better story to tell.

The vote of thanks having been passed, the President briefly acknowledged it, and the meeting was adjourned to Wednesday, November 6.

Parliamentary and Law Proceedings.

Poisoning by Morphia.

An adjourned inquest on Charles Henry Wills, retired army lieutenant, of Rose Cottage, Kingskerswell, was held on Monday. The inquiry had been adjourned in order that Mr. J. W. Cocks, chemist, Torquay, might be called to give evidence as to how deceased became possessed of a number of half-grain morphia pills, contained in a box found in deceased's medicine chest.

John Walter Cocks, pharmaceutical chemist, Torquay, was called, and said he had known the deceased for about five years, during which time he had constantly supplied him with medicines. On the 3rd of July last he sold deceased a box of morphia pills, similar to the box produced, which contained twenty-four half-grain morphia pills of Cox's make, Brighton. Deceased had never before bought any such pills of him. He came to witness some days before the pills were supplied, and asked for two dozen Cox's half-grain morphia pills. Witness did not then keep these pills, and was obliged to get a gross. The box was sent to Kingskerswell by Mr. Crocker, butcher. When deceased ordered the pills, witness said to him, "It's a full dose, captain," to which deceased replied, "I know it, I have been having such pills from Dr. Brown, and I don't want to be constantly troubling him for them." The supply was duly entered in his ledger, and witness marked the box "Poison." Knew that a half-grain dose of morphia was a full Pharmacopœia dose. Deceased had always conversed with him like a man who knew a good deal of medicine, and he was not an ordinary customer. He had furnished pills double the strength of those in the box to other customers, but that was from a prescription. Was well aware of the danger of such pills. Had supplied deceased with sedative medicines on various occasions previous to supplying the pills. Amongst these medicines had been syrup of chloral hydrate of double strength and laudanum in one ounce bottles. Deceased had told him that he suffered from sleeplessness. The chloral hydrate was given under medical advice.

An uncle of the deceased said deceased had at one time, shortly after taking his commission in the army, acted as doctor on board ship whilst taking a number of convicts to Bermuda.

The Coroner, in summing up, characterized the case as a sad and important one. Mr. Cocks, however, had satisfactorily explained the circumstances under which deceased purchased the pills, and had shown that he had not sold them without giving proper caution. The evidence had been sufficient to show that there was no reason for deceased's taking the pills with the intention of committing suicide. If the jury thought that deceased took the pills unwittingly, and only for the purpose of alleviating pain, they would say so.

In reply to the Foreman, Mr. Brown, surgeon, said it would be almost impossible to find in the stomach any traces of poison after the treatment employed.

The Coroner pointed out that narcotic poisons affected the brain and not the stomach.

After a brief deliberation the jury returned a verdict as follows:—"We find that the death of the deceased, Charles Henry Wills, was caused by an overdose of morphia, contained in pills taken by him for the purpose of allaying pain and procuring sleep." The jury added that they hoped the press would warn the public against taking morphia pills without first consulting a medical man, and recommended that labels should be attached to the boxes bearing the words:—"One only to be taken at a time."

Obituary.

Notice has been received of the deaths of the following:—

On the 7th of August, 1878, at Dunedin, Mr. John McGill Murdoch, Chemist and Druggist, of Sauchiehall Street, Glasgow. Mr. Murdoch became an Associate of the Pharmaceutical Society in 1872.

On the 4th of September, 1878, Mr. Thomas Lacey Ashby, Chemist and Druggist, Penzance. Aged 27 years.

On the 7th of September, 1878, Mr. Joseph Rees Price, Chemist and Druggist, Week Street, Maidstone. Aged 54 years.

On the 21st of September, Mr. Robert Barrett Rooke. Chemist and Druggist, Notte Street, Plymouth. Aged 61 years.

Correspondence.

THE ADMISSION OF ENGLISH MEDICINES INTO FRANCE.

Sir,—As we English chemists in France are to a certain extent dependent on the sale of English and American specialties, I herewith forward copy of a list, issued by the French School of Pharmacy, of specialties which it forbids to be passed into France. We had a case of articles stopped at Boulogne, and returned to England last winter. It was not only annoying to have none of these things to offer to our customers, but also to have to pay carriage each way:—

List A. *Produits classés dans la Parfumerie.*

Roche's Embrocation.
Floriline.
Leath and Ross' Glycoline.
Bunter's Dentine.
Howard's Enamel.
Gowland's Lotion.
Leath and Ross' Neuraline.
Bunter's Nervine.
Rowland's Odonto.
Perry Davis' Pain Killer.
Jewsbury and Brown's Tooth Paste.
Areca Nut Paste.
Conimau's Paste.
Holloway's Ointment.
*Meedmann's Dentifrice.

The French School of Pharmacy evidently has not known what the different articles were, because Roche's embrocation is classed as a perfume.

It would be very inconvenient for French subjects in England, and annoying to chemists, should the English Pharmaceutical Society forbid the many French specalities to be passed into England.

I hope that the Pharmaceutical Society of Great Britain may be able to make a satisfactory arrangement with the French School of Pharmacy concerning these forbidden articles.

Nice, Sept. 26. WM. PHEASANT.

VIOLET POWDER.

Sir,—Mr. Greenish is consistent with himself in endeavouring to apply the *argumentum ad absurdum* to my suggestion that distinctive names should be applied to some of the varieties of violet powder, for he approves of the application of this very indefinite name to "pure starch, free from admixture." I am not aware, nor do I believe, that pure starch, free from admixture, has received the "time-honoured name of violet powder." There has always been some, and not always the same, admixture. In the days of periwigs and pigtails, starch was found to require something of the glutinous property of flour to cause it to adhere and produce the required stiffening effect, although sometimes too much flour or clay was added. It was at that time called either "powder" or "hair powder," but when powdering hair went out of fashion hair powder dropped its prefix, and with a little modification its use was chiefly confined to the nursery and lady's boudoir, where the powder box and puff became permanently established. The glutinous property was not now required, but manufacturers endeavoured to adapt the "powder" for the purposes for which it was used, the name having a signification wide enough to admit of much modification. Starch without the gluten or kaolin was mixed with orris powder, or essential oils, or both, and as wheat starch made by the old fermentation process was the only sort of starch then made, it formed the basis of the so-called "violet powder," for which an increased demand was arising for nursery use. But with the march of improvement the old-fashioned wheat starch has been superseded by starches made with caustic alkali, some of which is often retained in the product, and I would suggest to Mr. Baldock that this circumstance, or the presence of essential oils in his violet powder, or the occurrence of fermentive change when the moist starch is subjected to a blood heat in contact with decomposing matter, would probably afford a more rational explanation than that which he assigns of the cause of the "several complaints" he has received of "infantile irritation" caused by his amylaceous violet powder. At any rate it appears from this, as well as other representations, that starch is not always free from objection.

On the other hand, powdered selenite, notwithstanding the angularity of its particles, is, to my knowledge, in cases of moist, inflamed, or chafed skin, a valuable application, by which irritation is speedily allayed, and a slight astringent action produced, which is very beneficial. The perfect neutrality and slight solubility of the selenite probably contribute to the result. When or how this substance came to be added to or substituted for starch in violet powder I know not, nor does it appear to me to signify much whether the mountain came to Mahommed or Mahommed to the mountain, if the prophet has fulfilled his mission, and is believed.

Hair oil has been generally made with olive oil and pomade with animal fat, but if I should prefer almond oil to the former, or mineral fat, such as vaseline, to the latter, I may surely make the substitutions, and sell the products under those names, without subjecting myself to the charge of adulteration. If the substituted ingredients are unobjectionable in all cases in which the articles are used, and the names under which the articles are sold are applicable to them in their altered forms, it may be unnecessary to add to or alter the names; but if, as appears to be the case with violet powder, this is not so, it is desirable that more distinctive names should be used.

The advocates for the use of "starch, pure and simple," to be quite consistent, should also advocate the use of the pure and simple name. Why call it violet powder? I suppose the answer to this question is that it belongs to the "powder and puff" system. And shall we expel everything that appertains to this system from modern, approved and high-class pharmacy? I confess that I retain a sufficient spice of the commercial element to make me doubt the expediency of adopting such high-flown notions.

DIALYSED IRON; ITS PREPARATION, COMPOSITION, AND SOME OF ITS PROPERTIES.

BY A. H. JACKSON.

The experiments described in this paper were commenced in the Laboratory, of the School of Pharmacy, 17, Bloomsbury Square, at the time when dialysed iron was exciting a large amount of interest in pharmaceutical circles, and when conflicting statements were being made as to its composition; consequently it was thought that a scientific (as opposed to a trade) contribution to the study of its preparation and composition would be acceptable to pharmacists. Lot A was a sample of *completely* dialysed iron, made in the usual manner, so as to give me a reliable article for analysis. The details of its preparation show the gradual manner in which hydrochloric acid is eliminated from the dialysing iron, also that the acid is accompanied by a solution of iron nearly to the end of its passage through the dialyser. This phenomenon may be due to the difference in delicacy of the respective tests for iron and acid. Lot B shows that an ordinary acid solution of iron simply undergoes diffusion without decomposition when put to dialyse. Lot C was undertaken at the suggestion of Professor Attfield. We thought that, as in the usual mode of preparation a solution was used which contained as small a quantity of acid as possible, it would be interesting to ascertain whether an aqueous solution of neutral chloride would dialyse; the result shows that it will not.

The analysis of dialysed iron shows that it contains some chlorine; contradictory statements have been made, owing, I think, to the defective method of testing for it.

The good keeping property and pleasant taste of dialysed iron render it decidedly preferable to ferric hydrate as an antidote for arsenic, in case it should be proved efficient; but as the best published experiments in this direction extend no further than its action in an artificial stomach only, more extended experiments are necessary before medical men would be justified in relying upon it. My own investigation in this department is incomplete, partly owing to the closure of the laboratory on July 31, partly to the impracticability of getting living animals or their secretions for experiment (owing to the Vivisection Act), and partly to the difficulty of getting the abdomen in a fresh state—within laboratory hours—during the hot weather of July. As my time since then has been and still is otherwise occupied, I prefer to publish this contribution as it is rather than wait for the much desired opportunity of concluding it.

Preparation (*Lot* A).—1 lb. of a solution of ferric chloride was poured into a dilute solution of ammonia, until the whole after well stirring had an ammoniacal smell; the mixture was poured on to a calico filter and washed with distilled water until the washings gave no precipitate with a solution of silver nitrate; the precipitate was then transferred to a beaker containing 4 oz. of the solution of ferric chloride, and heated on a water-bath with stirring and addition of a little hydrochloric acid. Allowed to stand all night, it was all in solution next morning. This solution was poured into a dialyser, consisting of parchment-paper stretched between two gutta-percha rings, which was floated on about 1½ litres of distilled water (15th February). After a couple of hours the wash water was replaced by another 1½ litres. On testing it gave evidence of the presence of ferric chloride. On the 16th the amount of hydrochloric acid in the wash water was determined by a standard solution of caustic soda; it showed ·288 per cent. On the 18th the wash water was renewed with 1 litre; it gave evidence of ·115 per cent. of HCl. On the 20th the litre of wash water was renewed; it contained ·0438 per cent. of HCl. On the 22nd, the litre of wash water was renewed; it contained ·0182 per cent. of HCl. On the 25th this wash water was tested and gave no precipitate with potassium ferro- or ferri-cyanides, but gave a slight red colour with sulphocyanate, indicating only a trace of iron; with a solution of silver nitrate it gave but a faint opalescence, showing a trace of hydrochloric acid. On the 27th and 29th, also on April 2nd, 4th and 6th, the litre of wash water was renewed; it no longer gave a red colour with potassium sulphocyanate, but slightly reddened blue litmus paper. The wash water was renewed on the 8th, 10th, 12th, 15th, 17th, 24th, and 29th, by which time it was neutral to test paper, so that the now thoroughly dialysed iron was poured out of the dialyser and reserved for analysis, etc.

Preparation (*Lot* B).—Dialyser a parchment paper tied over a gutta-percha ring. 8 oz. of Liq. Ferri Perchlor., B. P., were put into a dialyser floating in a litre of distilled water, on the 18th February; on the 25th the wash water contained 5·548 per cent. HCl, and gave a voluminous precipitate of ferric hydrate; the solution in the dialyser contained 5·694 per cent. HCl, and gave a larger precipitate of ferric hydrate. The wash water was renewed with a second litre; on the 29th this was of a yellow colour. The wash water was renewed, and again on the 2nd and 29th April, by which time a colourless solution remained both in the dialyser and bath; it was therefore thrown away.

Preparation (*Lot* C).—On 27th March, made some neutral ferric chloride by passing dry chlorine over hot iron tacks; removed the tacks and dissolved the deliquescent crystals in water; heat was rendered sensible, and the solution when analysed showed the presence of 3·6 per cent. of iron. This solution was put into a dialyser, made by tying parchment paper over the mouth of a broken beaker, and suspended in a quarter of a litre of distilled water; the wash water was renewed on the 28th and 30th of March, and the 2nd, 4th, 6th, 8th, and 10th of April, at which time a pale muddy liquid remained on both sides of the dialyser. That in the dialyser showed upon analysis the presence of ·485 per cent. of iron, and was therefore thrown away.

Composition and Properties.—Lot A, being the only true dialysed iron of the three, is now referred to. It contained 95·52 per cent. of water, the mean of two determinations at 100° C.; ferric oxide, Fe_2O_3, 3·86 per cent., weighed as such; ferric chloride, Fe_2Cl_6, ·154 per cent; the Cl was weighed as silver chloride.

After evaporating some of the dialysed iron to dryness at 100° C., the shiny residue was boiled in water and the colourless solution had a faint inky taste. It gave a slight white precipitate with silver nitrate solution, and a faint red coloration with KCNS; no change with either $K_4FeC_6N_6$ or with $K_3FeC_6N_6$. Thus boiling water appears to extract all the chlorine, perhaps by decomposing the ferric chloride, if present in that form.

To detect the chlorine in dialysed iron, warm with ammonia, filter, and acidulate the filtrate with nitric acid; a solution of silver nitrate will then give a white precipitate. Silver nitrate solution added directly to dialysed iron has failed to give the precipitate of silver chloride in all the cases in which I have seen it tried.

The dialysed iron was a clear liquid, black by reflected and red by transmitted light; it was precipitated as a brown hydrate of iron by the laboratory water (which contained calcium salts); also by chlorides of Na, Ba, and Am; also by ferri- and ferrocyanides of potassium; sp. gr. 1·043.

The palatable character of dialysed iron caused me to make a further* investigation as to its efficiency as an antidote for arsenical poisoning. Preferably a living animal would be used. An account is given in the *Phil. Med. Times* of its successful use in the case of a woman, but circumstances have prevented my experimenting in this direction. The abdomen of a sheep was therefore procured (a pig's being unobtainable), washed from adhering food, and cut up in pieces. In three pots were placed portions of the stomach, with 5 c.c. of dialysed iron in each, and in A, 50 c.c., in B, 100 c.c., in C, 150 c.c., of an aqueous solution of arsenic tri-oxide (·004 per cent.). The three were kept at a temperature of about 37° C. for three hours with occasional agitation; then on applying Fleitmann's test, each gave evidence of the presence of arsenic in solution.

A similar experiment was made substituting portions of pancreas, small intestine, and bile for the stomach, and with similar results. Experiments were thus made because of the known fact that although the saliva and gastric juice first exercise their solvent power on food, etc., brought into intimate contact with them, yet the process does not end there, but is continued by the bile, pancreatic juice and *succus entericus;* therefore, to be thorough, the substance under experiment should be exposed to the action of all these solvents, and it is in this that an advance is made beyond Mattison's experiments.

Thinking that during the performance of Fleitmann's test some of the liquid might have spurted on to the silver nitrate paper, another experiment was made. On the 31st July a sheep was killed at 2.30 p.m. the stomach, etc., were washed free from adhering food, and at 3 p.m. were placed in a warmed glazed earthenware jar, along with 2½ grams of rock salt (that representing the amount of chlorides present in the stomach), 25 c.c. of dialysed iron, and 25 c.c. of the arsenical solution. The whole was kept at about 37° C. until 5 p.m., and on testing with Fleitmann's apparatus, modified by placing a piece of cotton wool at the mouth of the tube to prevent liquid particles being mechanically carried on to the silver nitrate paper, no blackening occurred. Some was put into a Marsh's apparatus; the hydrogen flame remained unaltered and no arsenic was deposited on the cold porcelain. Some of the liquid flowing over from the generating flask stopped the experiment, and as further opportunities were not allowed the investigation was closed.

This investigation was conducted in the laboratory of the School of Pharmacy.

Manchester, September 1, 1878.

* See *Pharmaceutical Journal*, 1878, for Messrs. Mattison and W. Gibbons's experiments.

THE PARIS EXHIBITION.

(*Continued from page* 225.)

Essential Oils, Perfumery, etc.

The perfumer's art has now attained such a development that it may be conveniently divided into two sections:—(1) the first operations of distillation, enfleurage, etc., upon the raw material, and (2) the application of the products so obtained to the aromatizing of articles for the toilet. Akin to these are industries in which the preparation of certain essential oils for special application in medicine or the flavouring of liqueurs, etc., are carried on. According to the classification adopted in the Paris exhibition the first products are, as a rule, included among the chemical and pharmaceutical products in Class 47; whilst the perfumed soaps, pomades, toilet waters, etc., which are less pertinent to the subject of this report, form Class 28 of the Group devoted to household furniture and its accessories.

France has long been famous for both these classes of perfumery, the manufacture of the first products being chiefly carried on at Grasse, Nice, and Cannes, whilst Paris is the chief seat of the toilet articles industry. Under the first empire about a dozen important perfumery houses already existed, and by the year 1820 the annual value of the products amounted to four millions of francs. The trade continued to increase "by leaps and bounds" until 1866, when the perfumery exported from France was estimated to weigh 3,500,000 kilograms (nearly 3500 tons), and to be worth 16,000,000 francs, besides which there was a home consumption valued at 10,000,000 francs. In 1876 the estimated weight of the exports had fallen to 2,500,000 kilograms, though the value had increased to 17,000,000 francs. This is explained by the increasingly marked tendency of foreign dealers, from considerations connected with customs dues, to confine their purchases of French perfumery to the higher priced goods. The articles manufactured may be roughly classed as being one-fourth alcoholized products, one-fourth soaps, and the other half various. England stands at the top of the list as the largest customer,—taking nearly one-tenth of the whole quantity of perfumery exported from France,—followed by Belgium, the Spanish Possessions in America, Brazil, Germany, and the United States, in the order in which they are named. During the last ten or twelve years numerous improvements have been made in the apparatus employed in the manufacture of perfumery; machinery has taken the place of hand labour, and chemistry has lent its aid. Nevertheless, in France, from 3500 to 4000 hands, including women and children, are still employed, besides those engaged in the accessory industries, such as glass-making, printing, box-making, etc.

In the French courts the principal display of essential oils and first products comes from Grasse, Nice, and other places in the department of the Alpes Maritimes, in the South of France. Precedence of seniority may probably be given to the house of Court, founded at Grasse, in 1750, among whose specialties are pomades which are claimed to represent the highest degree of saturation of the fat possible, obtained by hot and cold enfleurage, and suited for the economical preparation of extracts. The essential oils of neroli and petit grain are prepared by this firm on the spot where the orange flowers and leaves are collected, so that the materials are thrown into the still whilst quite fresh. The manufactory at Grasse is described as

consisting of immense subterranean vaults excavated from the rock; these are thoroughly lighted, and from their coolness and humidity present conditions favourable to the operations and the preservation of the flowers and products.

The case of M. Lautier fils, of Grasse, is also worth attention. It contains a series of pomades, scented oils, and extracts and essences of the "eight ground odours," viz., rose, orange flower, jasmin, tuberose, cassie, violet, jonquil, and reseda. Rose water and orange flower water are also shown, together with a collection of essential oils. The following information as to the local plants used in the perfumery industry in this district is taken from a small pamphlet placed at our disposal by M. Lautier.

Angelica Oil is distilled from the root of the angelica plant; 150 to 200 kilos of roots yield 1 kilo of essential oil.

Oil of Celery (*Ol. Apii*) is distilled only from wild plants, about 400 kilos of which give 1 kilo of oil.

The Tarragon plant (*Artemisia Dracunculus*) is cultivated on a large scale in the neighbourhood of Grasse. There are two crops in the year, the first in July and the second in October. 300 to 500 kilos, according to season and location of culture, yield 1 kilo of oil.

The Fennel plant (*Fœniculum vulgare*) grows wild in the South of France, and is generally distilled in July and August. One kilo of essential oil can be obtained from 500 kilos of plants.

The Rose Geranium (*Pelargonium roseum*) is grown in the environs of Grasse, but, as will appear presently, on a larger scale in Algeria. The plant grown in France yields the finer oil, but it is much dearer, as more than 1000 kilos of plants are needed for 1 kilo, while only 800 to 1000 kilos of the Algerian flowers are required for the same quantity.

Hyssop (*Hyssopus officinalis*) is grown in the environs of Grasse in large quantities. One kilo of oil can be got from 400 to 500 kilos.

Cherry-Laurel trees are cultivated at Grasse, and the leaves are distilled in the month of August, chiefly for the sake of the laurel water.

The Lavender (*Lavandula vera*) grows on the mountains which cover the south-eastern corner of France and part of Piedmont, not further west than the river Rhone, and not beyond the 44th degree of northern latitude. The best quality of oil is drawn from flowers grown on the highest points of the chain which has given its name to the department, "Alpes Maritimes." The flowers are cut in July and August. 150 to 200 kilos of flowers give 1 kilo of essential oil when the season is favourable.

Spike-Lavender (*Lavandula spica*) grows in the same districts; the oil obtained from it has a more camphor-like smell than that from *L. vera*.

The Marjoram (*Origanum Majorana*) grows wild in the mountain valleys. One kilo of essential oil can be obtained from 400 to 600 kilos.

Peppermint (*Mentha piperita gallica*) is cultivated in the territory of Grasse with all possible care. The production is considerable, and the essential oil is much esteemed. 400 to 500 kilos yield 1 kilo of oil.

The Myrtle (*Myrtus communis*) grows in great quantity on the hills surrounding Grasse, and is distilled in September, about 300 kilos producing 1 kilo of oil.

Oil of "Neroli Bigarade" is distilled from the flowers of *Citrus Bigaradia*, which are brought in during the month of May. In the best years 1000 kilos of fresh flowers yield 1 kilo of essential oil. The finest trees bear about 30 kilos of flowers. The firm of Lautier fils uses annually from 120,000 to 150,000 kilos.

Oil of "Neroli Portugal" is got from the flowers of *Citrus Aurantium*.

Origanum creticum grows on the mountains of Southern France. About 300 to 500 kilos yield 1 kilo of essential oil.

Parsley grows in the environs of Grasse. 250 to 300 kilos furnish 1 kilo of essential oil.

Oil of "Petitgrain Bigarade" is a product of the leaves of the bitter orange tree. The most esteemed oil is got in the months of June, July, and August from fresh leaves. About 500 kilos yield 1 kilo of oil.
