No one who has visited a fruit room in the warm days of September, when there was a quantity of fruit all ripening into that mellow condition which betokens perfection, but must have been struck by the odour which is emitted from them. This odour, it is needless to say, must be as hurtful to the well-keeping of fruits as anything can be—say, for instance, a quantity of Williams' Bon Chrétien Pear all ripening at once into the condition fit for table, and in a day or two all will be in a stage beyond this, and become a mass of juice which it is difficult to handle without bursting them. Now, I always look on a mass of this kind as the most dangerous to a fruit room, and as all early fruits ripen in warmer weather than other kinds do, they ought to be furnished with ventilation almost amounting to complete exposure, in order that the odour emitted by ripening fruit, which very quickly takes a decaying turn, may not contaminate the rest. Fruit at that time ought also to be kept thin. But to return to the Ribston Pippin. It often happens that these have to be gathered when the fruit room is more or less occupied by fruits in the condition spoken of; and if the weather be warm at the time, the fruit is impelled onward to a condition fit for table much earlier than they otherwise would be if kept cooler, and the character of the atmosphere they are in hastens on decay some time before ripeness or mellowness has done its part, hence fruits that ought to be in perfection in January are ready by the end of November—not Ribston Pippin Apples only, but all other kinds of fruits as well. This is one of the reasons why fruits in certain seasons keep longer and better than they do in others—the simple fact they are not ready to gather until cold weather insures their keeping, as more fruit generally perishes in November than in December and January, and no amount of mere cleanliness and care of removing diseased fruit can compensate for the crowded condition of the fruit room in the early autumn months, when the

weather at the same time is of a kind that favours "forcing," which it certainly does when it is warm at the periods spoken of. Now, as the Ribston Pippin cannot be preserved under circumstances as described, let us suppose an opposite case—a backward unkindly season, half-perfected fruits, presenting little but a thick tough skin, and a core quite as large as usual. Some of these fruits possibly might keep longer than was ever known before; as they contain so little saccharine matter there was scarcely anything within them to engender decay, hence a sort of withering or shrivelling-up instead of the usual spot and rot which consume the better class of fruits.

From the above it will be seen that warmth favours decay by forwarding the fruits and thereby hastening on the period of their existence; so in like manner cold encourages preservation by retarding the natural ripening of the fruit, and when it has approached that condition it tends to keep it from advancing further. But this unnatural state of things has its disadvantages. Fruits so treated are never good. Pears may be kept in an ice-house to a period much beyond that of their usual keeping time; but the flavour is gone. The same may be said of summer fruits, as Strawberries, Peaches, and the like, which have been so tried frequently. We may therefore learn from this that Nature cannot be so far outraged as is here shown with impunity. There exists a proper time for such fruits to be had in perfection, and to retard them much beyond it only produces an article much diminished in its most important qualities. From this we therefore learn that an ice-house is not a suitable place to preserve fruit intended for table, although it may become a very good medium to preserve some that it may be desirable to keep from motives of curiosity for as lengthened a period as possible. Some other conditions are also necessary to the well keeping of fruit, as will be shown.

Whenever a quantity of fruit is piled up in a heap it begins what in common language is called "to sweat." This sweating brings out an oily substance to the outside. Sweating will also occur without the fruit being so closely piled up as spoken of, but it is more slow; and if it be thinly on a shelf it is in its most legitimate way. This sweating coats the skin with a sort of varnish, which resists the action of the atmosphere, and certainly promotes the keeping qualities of the fruit. This varnish ought not to be removed by any means, handling being one of the certain ways to do so. Let the fruit, therefore, be placed at first singly on the shelves, and little else will be wanted but looking over them and picking out decayed ones; and the place being kept cool and ventilated there is a tolerable certainty of their keeping well, other things also being favourable.

As everyone is agreed that perfect cleanliness and sweetness are indispensable requisites in a fruit room the situation ought to be so chosen as to insure these as far as external circumstances will do so, but a full southern exposure is not good. The best fruit room I ever remember to have seen had broad shelves surrounding the building, and in the centre a tier of shelves with drawers in the bottom compartment, the whole affording ample space to get round, and the shelves not too crowded. I forget the means of ventilation, but believe it was ample. Some other useful fruit rooms that I have seen are lean-to against the north wall of a garden, the great defect in these being the want of ventilation which, in part at least, ought to be at top, and is rarely thought of in a lean-to shed. The sides being low, the exhalation from fruit cannot well be all carried off them; it is better, therefore, to leave an opening at top to allow it to escape, otherwise the fact of being behind a wall is an advantage rather than otherwise, and more so if it be isolated, and not form part of a series of buildings, as by that means end ventilation could be more easily accomplished. I have also seen a very useful fruit room half underground; but this is only advisable on a dry, gravelly, or sandy soil. I have also seen one under the shade of a tree, not in a dense wood (which is bad), and it answered very well. The main thing to stipulate for is plenty of space and ventilation, and to use the latter on all occasions except perhaps in damp warm weather, and the probability is that fruit will keep as long as it is required to do. A Kentish farmer stores his Apples away in the oast kiln, than which nothing can be more airy; and although the large quantity they often have compels them to lay them thicker than they otherwise would, they often contrive to keep Nonpareil and Golden Knob Apples in a good condition till March, and French Crabs still longer.—N.

#### THE PROTECTION OF ALPINE PLANTS.

THE Association for the Protection of Plants, founded in 1883 at Geneva, gives us in its bulletin interesting accounts on the necessity for their protection and the procedure to follow to gain this result.

It is requisite to form an efficacious protection, as the number of the Alpine species diminish in an alarming manner. Sometimes it is a question of species which, badly provided for the struggle, are but little

and slowly reproduced; sometimes and most frequently it is a question of species which man pursues in a disastrous manner. The culprits are chiefly botanists and plant sellers. Botanists who are acquainted with the rarity of certain plants do not hesitate to collect all the specimens they meet with in order to make exchanges with their confrères; the plant sellers who do the same to re-sell to the botanists and also to the public chiefly in the markets of Geneva, Lausanne, &c., to enable it to satisfy its tastes and cultivate Alpine plants in its gardens. This persisting demand has brought about a certain number of fatal results which it is good to signalise in passing. *Cyclamen hederifolium*, a plant which is never abundant, is also disappearing gradually from the Alpine Flora. Many native Orchids have become very rare or totally disappeared from the woods in which they abounded twenty years ago. *Tulipa sylvestris*, the Martagon Lily, *Erythronium Dens-canis*, are also disappearing. We no longer find *Anemone stellata*, *Lysimachia punctata*, *Euphorbia sagittalis*, or *Malaxis paludosa* in their former stations; of *Geranium lucidum*, formerly abundant in certain localities, there only remain six specimens; *Trapa natans* has during the last sixteen years totally disappeared from a pond in which it was growing. *Calla palustris* is cultivated by the peasants who know its station, and at Lofingue where there were many species of Orchids, a single man exterminated them all except three of a common kind; he sold them to amateurs for their gardens. *Daphne cneorum* and alpina have been destroyed in certain stations. Near the railway station of Aarbourg *Holosteum umbellatum* was established, the only example in Switzerland. A botanist exterminated it.

It may seem extraordinary that so many misdemeanors are to be ascribed to botanists, that is to say to those who should better understand the necessity not to destroy plants. The best and wisest amongst them are aware how dangerous are collectors, and many professors in large towns can tell the ravages made by twenty or forty pupils who throw themselves on the rare species indicated to them, and an hour later or the next day throw into a corner these "weeds," for which they care nothing, and which they gathered to be like others, and appear to take an interest in botany. On the other hand, the exchange societies do still more harm. These societies are formed between persons of distant localities, each undertaking to obtain for its colleagues the rare plants of its own locality; in this manner members can make very interesting herbaria, but it is to the great detriment of the rare local species, without science profiting much. They are chiefly amateurs and not savants who compose these exchange societies. M. H. Correvon, President of the Association for the Protection of Plants, saw a list of demands addressed to a member of one of these societies. Here, amongst other things are the demands.

*Papaver alpinum* (all that can be found); *Arabis arenosa*, *Iberis saxatilis* (idem); *Dianthus cæsius* (thirty large tufts); *Heracleum alpinum* (many, but only fine specimens); *Inula Vaillantii* (100 fine specimens); *Centranthus angustifolius* (a barrowful); *Hieracium lycopifolium* (cartload); *Pyrola minor* (as much as possible); *Myosotis versicolor* (100 specimens); *Scrophularia Hoppi* (barrowful); *Lysimachia thyrsoflora* (100 specimens); *Centunculus minimus* (a case full). Altogether they demanded more than 5000 specimens! And the species of which they required most were naturally the rarest. If we add to the depredations of the botanists the extension of culture, the clearing of forests, and the draining of marshes, it is not surprising that the unfortunate plants succumb with exceptional rapidity, especially when these combined efforts are increased by those of the sellers and their agents. One collector absolutely destroyed the station of the *Dracocephalum austriacum*. He took away all he could carry, and pulled up and destroyed the rest. This was done to increase the market value of his own specimens. These collectors are the worst enemies of plants. They arrive with an order for 10,000 specimens for example, and that chiefly for uncommon species. The peasant sends his children in search of them, and as they do not always know how to pluck up the plant properly, we have seen 400 or 500 stocks refused for 100 accepted by the collector. In 1884 one of these agents forwarded to America 4000 plants of *Edelweiss* taken in Engadine, and in England there are firms which require from 10,000 to 20,000 specimens of the same plant.

Cattle and sheep dogs destroy many species, or at least limit the propagation. They are cropped before arriving at florescence and fructification. In these conditions the number of specimens can only increase with extreme difficulty. Amongst the causes of the destruction of plants there are two of which it is not easy to appreciate the importance. The struggle for existence amongst plants—that is to say, the conditions that favour or restrict the multiplication or extension of the species; the variations in the world of insects.

The result of these multiplied causes of destruction is known; it is the extreme rarity of certain species and the complete disappearance of some others. It is good to signalise both, the first especially, and the "Association for the Protection of Plants" has published several works from the pen of Mr. H. Correvon amongst others indicating the species to protect. They are numerous. *Tulipa Billiciana*, very rare, known recently, and with a very circumscribed habit; *Tulipa Oculus Solis*, almost impossible to find; *Carex ustulata*, very scarce in Switzerland, where there are only three stations, each comprising 100 plants at most; *Iris virescens*, very rare; the Snowdrop (*Leucojum vernum*), *Hottonia palustris*, *Utricularias*, *Alisma ranunculoides*, *Anagallis tenella*, of which only one station is known in Switzerland; *Trientalis europæa*, formerly abundant, is now only found in three stations. I cannot mention all. The Association, which naturally occupies itself chiefly with the Swiss flora, is gradually making a catalogue of

the rare and notably diminishing species in order to draw the attention of all benevolent "preservers" to them who try to aid the Society by their endeavours. It is quite time, for without assiduous attention many species will disappear as many of their fellows have done in historical times, and in the majority of cases since a very recent date. *Butomus umbellatus*, which was still at Yuerdon at the beginning of the century; the *Calla*; the *Zannichellia tenuis*, which is probably a local form of the *Z. dentata*, and is no longer to be found; *Lysimachia punctata*; and many others it would be easy to mention. One must act under pain of seeing certain plants entirely disappear, like that unfortunate *Psadia rotundifolia* of St. Helena, which witness of the captivity of Napoleon I. remains as the unique specimen in the world of its species, and its seeds will not grow!

Act, one may say; but how? The Association for the Protection of Plants shows us a way, and a good way. It works in two ways. In the first place it has formed in the environs of Geneva a botanical garden for the exclusive culture of alpine plants, and which sells these plants to botanists and amateurs, hoping thus to deter them from pillaging mountains and valleys. This garden has proved a success, collectors apply there and are sure to find what they want at a cheap rate. The plants have nearly all been raised from seed. The Association sells seeds and plants, paying special attention to the culture of high mountain flora of the Alps, also of the Himalaya and Andes. It may seem strange that plants from great heights are successfully cultivated in the plains, yet, nevertheless, such is the case. Generally the sowing is performed in autumn before the cold, and on this point the Association gives all the necessary instructions to those who buy seed and wish to make experiments in acclimatisation or extension in gardens or on mountains. To those who doubt the possibility of acclimatising alpine plants in the plain, I shall simply answer by mentioning the example of that horticulturist of Berne, who grew 30,000 plants of *Edelweiss* from seeds; the same *Edelweiss* which in Switzerland is only found at the level of the continual snow, is still prosperous at Geneva; still more, it lives and flourishes at Paris and in the environs. In truth, it displays an astonishing toughness.

An objection at once presents itself to the mind of the naturalist. Admitting that one can really cultivate the Alpine species in the plain at a very different altitude, in a medium totally varying from the point of view of temperature, aëration, light, perhaps the chemical constitution of the soil, &c., it is certain the plants will vary but little; but slight differences will occur, owing to the change of medium which stimulates the natural variability of the plant, and the species perhaps will change in character from certain points of view.

Such being the case, and as it is most probable, the naturalist will be overjoyed. In these conditions the Alpine garden of Geneva will render great services to science, and the botanist, curious to study the modifications imposed upon the species by the change of medium, will find in this garden a real laboratory. It is not, at least, I hope, exclusively commercial, and those who direct it will doubtlessly understand the interest of the studies they can favour without injuring in any way their trade. But then one will object, If the acclimatised plants vary however little, it will not be the original species that are preserved, and the object of the Association is only half gained. The objection is well founded, but the Association seems to have anticipated it, and the second of the methods employed for the protection of the Alpine Flora springs from a knowledge of the necessity of maintaining and protecting the species *in situ*, in their normal or actual habitat. This is attained by the creation of botanical gardens in the mountains themselves. In these gardens are to be grouped the rare species of the heights, and they will be in normal conditions from the point of view of medium, and certain species which do not reach floescence in the plain will here receive special culture. These gardens supply the seed employed in the gardens of Geneva.

One of these gardens—the *Linnæa*—was inaugurated last year in Valais, at Bourg-Saint-Pierre, on the route of St. Bernard; others are to follow. It seems to us that there might easily be found in different parts of the Swiss mountains pieces of ground often unfit for agricultural purposes where certain species might be introduced and preserved. There ought to be communes, or even private individuals, who would allow acclimatisation experiments of this kind to be made in their property, and the Association could deal with them as the "Jardin d'Acclimatisation" of Paris with regard to those to whom it confides cattle. However, it may be by the creation of the garden of Geneva the Association certainly diverts from the mountains many botanists, amateurs, and sellers, and assures the preservation of rare species, and in the Alpine Gardens it completes its work by preserving plants *in situ*. It is of importance that this last protection should be multiplied as much as possible.

To the two preceding means others may be added. It is good for the authorities to decree interdictions and penalties, as they have already done in Switzerland in France. It is good particularly to make the majority understand the scientific, and often practical utility, of the protection of plants. Besides, a marked tendency is manifested in this direction. In England, France, and different countries many persons begin to comprehend and consider the question, as we can judge by the notes published in the *Bulletin de l'Association pour la Protection des Plantes*.

We can only applaud this movement, in which the Association has certainly a large share, but we particularly insist upon the scientific interest it presents. By preventing the disappearance of vegetable species, and assuring their protection and survival, and by furnishing at

the same time the naturalist with means of studying curious and important facts, botanists and their friends do what zoologists regret not having done, when there was still time for many animal species. So many species disappeared, so many documents lost, leaves torn in the book of nature, and we cannot decipher this last with such ease as to be able to permit ourselves the whim of skipping a page here or there and risk omitting an important passage.

The protection of plants is a work of public utility, because it is a work of scientific utility, and this is why we have spoken on the question.—HENRI DE VARIGNY.—(*Revue Scientifique*.)

#### THE CRYSTAL PALACE ROSE SHOW.

"WANTED, a single official at London Bridge Station, who can tell, even before the Crystal Palace train starts, from which platform it will go." This was the despairing cry of two East Anglian rosarians on the cold wet morning of July 5th, and it was cried in vain. We missed the train, and had to kick our heels for an hour, which was sadly wanted, for one of us was showing in large classes. It was cold indeed—how cold I did not realise till I found myself seated at the base of a statue of Flora (who was doubtless much astonished at my occupation), trying with breath and budding knife to open a bloom of *Annie Wood*! Those who are acquainted with that faithless *Rose* will understand that any assistance required by it in opening after a long summer night's journey is a wonderful sign of the coolness of the morning, as described by "J. H. P." The general character and quality of the *Roses* shown in the largest classes would probably be considered as hardly up to the average, the best growers having not yet got to their strongest H.P.'s, and the first flush of southern Teas being either over or spoilt by rain.

There was a close contest in the nurserymen's class for the champion trophy. And here, with the sanction of "D. Deal," I should like to offer a remark or two on the judging of seventy-twos in general and for the trophy in particular. Those who have never officiated in a class of these dimensions, and who may wonder at the time expended on it, must remember that a seventy-two is probably nearly 4 yards long, and that five seventy-twos in a row are approaching 20 yards long; that the first general survey to see which, if any, of the stands require pointing, must by no means be hurried (for first impressions go a long way), and should, I think, be independent, *i.e.*, performed separately by each of the Judges; and that if, for instance, in a row of five stands, Nos. 1, 3, and 5 are pretty close together in merit and require pointing, a very considerable amount not only of time and labour, but also of patience, attention, and clearness of head are necessary. It should also not be forgotten that it is a responsible business; that it is a serious matter to our good friends the nurserymen; that a large amount of care, labour, and cost have been expended; that it must be done within a certain time, not only because of the incoming of the public, but also because the blooms may change in an hour or less; that, therefore, no pains should be spared in coming to as just a decision as possible, and yet that it must be done quickly.

The rules for judging issued by the N.R.S. teach us that in pointing a certain bloom should be chosen as the standard of three points. This is, I think, most important; I hope it is never omitted; I cannot see how any accurate pointing can be done without it; and I think the bloom should be carefully chosen—not just the first fair one that comes. We must remember that this is the standard. Every *Rose* in at least two seventy-twos (equal 144), or perhaps three (equal 216) must be judged by this as the type or example of three points. It must be remembered, too, that if any seventy-two has a tail it is a gradual one; not only because in setting up a man naturally puts his best *Roses* in first and his weakest when he is finishing, but also because he will do it designedly, if he has any weakness, since the smaller blooms gradually shading off will suffer less by contrast. Can anyone keep this standard accurately in his head through a gradually deteriorating scale of 144 blooms without frequently referring to it? My suggestion, therefore, is that in a matter of closeness and importance the standard *Rose* should be carried by one of the Judges, and compared directly there is a doubt as to the number of points any *Rose* is worth—a bother, no doubt; but let us be as sure as possible in our decisions.

Again, has anyone after handing in his judging card in class 1 with a light heart to the Secretary, remembered with a perfectly clear conscience that he and his partners (see Rules 4 and 6) are solely responsible on the question of duplicates in that class? Are they often, or ever, sure that not only the same *Rose* but also the same name has not appeared more than once in the same stand? It is too much to expect of them in the time, in my opinion. The seeing that the same name is not repeated in any one stand is purely clerk's work, which anyone might do; but even then the Judges ought to see how every *Rose*, even the best known ones, are named; and I therefore suggest that, if possible, other persons should be appointed to look for duplicates, at least of names, in the big classes.

In the competition for the amateurs' trophy the contest was not quite

so close. Mr. Lindsell has fulfilled our anticipations of last year, and received our hearty congratulations on attaining the premier position in the first year that he has tried for it. But "J. H. P.," though beaten, was not disgraced; it was plain, to those who knew his resources, that his Roses were not out, and later (how much later I do not know—he was still winning in open classes on August 2nd and 5th, and may be showing in good form still for all I know) his blooms were grand indeed, and though, weak or strong, he never shrinks from the highest classes, there were few even among nurserymen who could beat him. It is no detraction from Mr. Lindsell's fine performance of winning the metropolitan trophy to say that "J. H. P." at his best has this season, as in several others, been invincible as an amateur; it is a matter of congratulation and comfortable remembrance with some of us, if at any time we have lighted on him when he was weak or weary, and snatched a momentary triumph.

The suggestion thrown out by him in last week's Journal that the metropolitan challenge trophy should be competed for on the same lines as the northern one is worthy of consideration, and is manifestly disinterested, as it would be (at least I should think so) to his own disadvantage; but at present I am hardly inclined to agree with it, though fully understanding that there is much to be said in its favour. Mr. Burnside has made a very distinct advance in his Tea Roses this season, and has put a larger distance between himself and his rivals; his Teas have always been well shown, and they have now become also really fine blooms in themselves.

I quite agree with "J. H. P." that class 17 for those amateurs who have never won a prize at a N.R.S. exhibition is a good test of the health of the Society, by registering the number of working recruits that are being gained. I matriculated there about ten years ago, and I think I could name my six Roses now. I had second prize with a pretty box, whose arrangement cost me much care, but I thought then, and think still, though with less severity, that I ought to have been first.

The most interesting classes for me are those for new Roses, but I think it is open to question whether something ought not to be altered in the class for six new Roses, amateurs. With rare exceptions, of late years, only two exhibitors show in it, and often only one of them. Of these "J. H. P.'s" Roses are good, and the other gentleman's (I am not afraid of offending him) are bad; visitors can see specimens of the new sorts in greater variety in the corresponding nurserymen's class, but there also there is not much competition.

In the gold medal class, so very interesting as one wonders over the future reputations of the new-born claimants, it was delightful at last to find a real competition, and I concur with "J. H. P." that this is a most important piece of judging, and one on which no time and care should be grudged. I will wait to see his notes on new Roses before offering my own ideas, but I may here say that I hope the Judges in awarding two gold medals remembered that Salamander was shown on an exceptional morning when Thomas Mill, Annie Wood, and other frail beauties were unimpaired, and when the trustworthiness of the exposed centre of Mr. G. Paul's fine Bourbon could not be strongly tested. To the outward seeming Margaret Dickson, the gold medal winner at Birmingham, was far the best of the three.

I should like, in this connection, to record my conviction that in the death of Mr. H. Bennett of Shepperton the rosarian world has sustained a severe loss. Not to mention his former triumphs, I opine that in a year or two few Tea Rose stands will be able to spare Cleopatra; and, whatever strides the art of scientific Rose raising may make in future years, I think he will not be forgotten as one of its best and earliest pioneers.—W. R. RAILLEM.

I HAVE read Mr. Pemberton's notes on the last N.R.S. Crystal Palace Show with some interest, and although I agree with some of his views, I do not quite follow him in others, nor do I quite see what he wishes to have in competition for the amateurs' trophy. He says that the competition should be open to twenty-four and thirty-six. Does he mean that the trophy class should be of a size (such as twenty-four) as would bring in more competition? If so I quite agree with him, as forty-eight is a prohibitive number to all except growers of 2000 to 5000 Rose trees. Most growers with any pretension to showing could show in good form twenty-four varieties, and if the N.R.S. Committee altered the trophy class to that number it would admit of a very large number competing and make the entry very large.

Mr. Pemberton seems to think seven a large number of exhibits for class 17 (those who have never won a prize), but last year there were seventeen competitors in that class. He also refers to the winners in that class as likely hereafter to come to the front, but surely he knows Mr. Shoemith (who is Mr. Hodgson's gardener) is a veteran at showing Roses and Chrysanthemums, and is a well-known prize winner, and can thereafter hardly be called a new man—although possibly he has never showed at the National, as his present master was not a member till this year.

I hope Mr. Pemberton will ventilate the trophy question at the N.R.S. Committee meeting.—CHARLES J. GRAHAME.

#### CAMPBELL'S FUMIGATING INSECTICIDE.

HAVING given this invention a fair trial I have no hesitation in saying that I consider it the most effective and easily applied destroyer of insects without the slightest injury to the most tender plant that has

come under my notice. I have applied it strictly according to directions, and have found it everything the vendors claim for it. A house of show Pelargoniums was first treated, and by way of testing it several tender plants usually most susceptible of injury from fumigations of tobacco paper were put in the house. Among these plants was an Adiantum euneatum with tender, half-expanded fronds; also some shoots of Gros Colman Vines with young fresh leaves, than which I know of nothing more susceptible of injury from tobacco paper smoke. The result of one evening's fumigation was the most thorough destruction of green fly and thrips without the slightest injury to any of the plants named. The old blooms of the Pelargoniums that were naturally ready to fall to pieces dropped off, but not younger trusses. A house of Tuberous Begonias—very sensitive to ordinary fumigations—and a cool Orchid house have been fumigated with Campbell's rolls, and the effect was perfect in every way. At my recommendation Messrs. Thomson of Clovenfords have fumigated three of their largest vineries with it in which red spider was very troublesome, the result being death to the spider and no injury to the Vines. I consider this last fact of very great importance to all Grape growers, for to keep spider in check, to say nothing of killing it outright without injury to the bloom of Grapes and the foliage, has long been an unsolved problem. I had no occasion to apply the rolls to spider, as I had previously completely routed it without fumigating or any injurious application, though it was a tedious process compared to one night's fumigation. An

FIG. 27.—CAMPBELL'S FUMIGATING INSECTICIDE.

immense recommendation for this invention is its simplicity of application. The rolls are hung up like a lantern, and set fire to and left. In no instance have I found more attention needed.—D. THOMSON, *Drumlanrig*.

[We have received some of the rolls referred to from Messrs. W. Clibran & Sons, Altrincham, the agents for their distribution, and who also supply us with the accompanying illustration.]

## HORTICULTURAL SHOWS.

### BASINGSTOKE.

By the kind permission of C. Hoare, Esq. (the present tenant) this Society was enabled to hold its fourteenth annual Show of plants, fruits, &c., in the beautiful, extensive and well cared for grounds in close proximity to the mansion in Hackwood Park. We may say in passing that the keep of the grounds and gardens reflect great credit upon Mr. Bowerman, the head gardener at Hackwood, and whose name will figure frequently in the prize list. The Show was considered the best the Society has ever had. The weather, which was bright with a refreshing breeze up to three o'clock in the afternoon, then changed, and rain fell at intervals during the afternoon, making the grass very damp and uncomfortable for the thousands of people who put in an appearance, not only to see the exhibits which filled the large marquees, but also to witness the military tournament and various other attractions provided for their entertainment. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park; Mr. T. Russell, gardener to W. Bradshaw, Esq., Audleys Wood; Mr. Weaver, gardener to W. Cooper, Esq., Oakley Park, Oakley; Mr. Wills, gardener to Mrs. Pearse, Bassett, Southampton; and Mr. Curry, gardener to Colonel Pepper, Milford Hill, Salisbury, were the principal exhibitors in the plant classes.

### PLANTS.

For six stove and greenhouse plants in flower.—First, Mr. Russell, showing, among others, a large and grandly flowered plant of *Eucharis amazonica*, in fine condition. Mr. Curry was a good second, and Mr. Wills a good third, both showing fresh well flowered plants. For a like

number of stove and greenhouse foliage plants Mr. Curry was first with very good plants, his Crotons being bright, and his Palms green and fresh; Mr. Wills and Mr. Russell taking second and third positions in that order with good all-round stuff. For a specimen stove or greenhouse plant in flower Mr. Russell was a good first, showing another magnificent and profusely flowered plant of *Eucharis amazonica*, Mr. Bowerman being a close second. With a specimen foliage plant Mr. Bowerman and Mr. Curry were first and second, both showing fairly good and well coloured plants of Croton. Mr. J. Holdaway, gardener to Colonel May, Hawkfield, was the only exhibitor of six *Achimenes*, and he received a first prize for fine plants. Mr. Weaver had the best half-dozen exotic Ferns, distinct varieties, showing good plants of *Adiantum cardiochleana*, *Davallia Mooreana*, &c., Mr. Curry being second, and Mr. G. Southcote, gardener to Captain Oldfield, South Warnborough, was third. With a like number of British Ferns Mr. Tripp, gardener to Mrs. Field, Goldings, was first. Mr. Russell was first for four Fuchsias, distinct, with good plants. Mr. Weaver was first for Zonal and double Pelargoniums with neatly trained, well flowered plants. Mr. G. Best, gardener to C. W. Chute, Esq., The Vyne, was first for four plants of tuberous-rooted Begonias, staging small, fresh, well flowered plants; Mr. Russell being second with larger, but sparsely flowered plants. Mr. Best had the best six plants suitable for table decoration, Mr. Bowerman the second best, and Mr. G. Southcote the third best; all showing small, even, fresh plants of Palms, Crotons, *Pandanus Veitchi*, &c., in good condition.

**SPECIAL PRIZES.—Groups.**—Five good groups were arranged in a half-circle of 16 feet the longest way. It took the Judges some time to decide the relative positions of these, the plants employed being of a very choice and suitable character and arranged with excellent taste. First, Mr. Gibson, gardener to H. Harris, Esq., Steventon Manor; second, Mr. Bowerman. This group contained a choice assortment of plants—*Eucharis grandiflora* being freely employed—and presented a very imposing appearance; and had there been fewer Palms in the background it would have been placed first instead of second—a position accorded to it by the calling in of a third Judge. Mr. Weaver was an excellent third. Mr. Wills and Mr. Curry also showed well in this class. Mr. Wills had the best twelve plants in or out of bloom, Mr. Curry being second, and Mr. Bowerman third, all showing well. Mr. Southcote had the best four plants of pyramidally trained *Coleus*.

#### CUT FLOWERS.

Mr. Neville, gardener to Mr. Flight, Twyford, Winchester, had the best stand of twenty-four Roses, his bloom of Mrs. John Laing winning the prize for the best bloom in the Show. Mr. Neville was also first with a good stand of twelve Roses, and Mr. Russell was first for stand of twelve Dahlias, Mr. Neville being second. Asters, &c., were also shown extensively and well.

The ladies' classes were well filled, the prizetakers being Miss Wadmore, Miss Flight, Miss N. Owen, Miss Loe, and Miss Ladsham of Shirley, all for excellent arrangements, foliage and berries being very effectively intermixed with the flowers, Grasses, and Fern in the stands arranged for decoration of dinner table.

#### FRUIT.

This made a very fine display. The grand examples of Black Hamburgh Grapes staged by Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, would be hard to beat at any Show. The bunches were "single," of good size and shape, the berries large and beautifully coloured. With a collection of six kinds Mr. West was first, staging a good all-round lot, his Peaches and other fruit dishes being very good. Mr. Osman, who was second, had grand Black Hamburgh Grapes, but his other dishes were a long way behind those in the first prize collection. Mr. Osman was well first with grand bunches of Black Hamburgh; Mr. Holloway, gardener to F. Read, Esq., Down Grange, being a good second with two bunches of black Grapes, not Hamburghs. Mr. Osman was first with fine, well-coloured bunches of Black Alicante. Mr. Bowerman was a good second with bunches of Gros Maroc. With two bunches of white Grapes, any variety, Mr. Osman was first for Buckland Sweetwater, large and handsome, and having large and fairly well-coloured berries, just beginning to damp in the centre of the bunch. Mr. Holloway was second for good pieces of Foster's Seedling, and Mr. Neville third for large bunches of the same variety, only requiring a couple of more weeks to ripen properly. Mr. Osman was first for two bunches of Muscat Grapes and Mr. Bowerman second, both staging good bunches. Mr. Bowerman was first for a green-flesh Melon with Hero of Lockinge, Mr. Weaver being second. The last-named exhibitor had the best flavoured scarlet flesh in a fine fruit of Blenheim Orange, Mr. Bowerman being second. Mr. Bowerman staged the best dish of Peaches, also the best three dishes of culinary Apples and the best three dishes of Plums; Mr. Osman and Mr. Bowerman being first and second in that order for six Apricots, showing clear, bright, even fruits of Moor Park. Special prize for eight kinds of Fruit.—Mr. Bowerman was first, showing Peaches, Apricots, Nectarines, Figs, and Grapes. Mr. Osman's Grapes were a strong feature in his second prize collection, which also contained a medium-sized Queen Pine.

#### VEGETABLES.

These were shown very extensively and in fine condition, the collections staged in competition for Messrs. Sutton & Sons' prizes and Messrs. Webb & Sons' prizes were set up with great taste, and were very close to each other in point of merit, only one or two points being between the first and second collections in two instances. Mr. Lye, gardener to W. H. Kingsmill, Esq., Sydmonton Court, Newbury, secured first

position in the open class for nine kinds, and he also won first in Messrs. Sutton's, and first in Messrs. Webb's special classes for six kinds, staging, as already stated, grand produce in all his collections. Mr. Kneller of Malshanger House, and Mr. Bowerman also showed well in these classes, being a close second respectively. Mr. Bowerman had the best brace of Cucumbers. Mr. Kneller was first for twelve Onions, staging Ailsa Craig of immense size, even, and firm; weighing in the aggregate 34 lbs.

**Miscellaneous Exhibits.**—Messrs. Sutton & Sons sent a grand and varied collection of plants and spikes of herbaceous plants from their nurseries at Reading, which were greatly admired. Mr. Ladsham also contributed cut hardy flowers, which served to illustrate their great usefulness and adaptability for floral decoration.

#### CALNE.

THIS long established and popular Wiltshire Society always holds its annual Exhibition at Bowood, the beautiful seat of the Marquis of Landsdowne, than which no more beautiful site could be found. The whole of the grounds, park, and drive are thrown open to all visitors, and nothing but fine weather is wanted to make the Show a great success. Unfortunately the best portion of the day was extremely wet, and a serious pecuniary loss must have resulted. Mr. F. Henly is the Honorary Secretary, and, aided by an efficient Committee, everything was well done.

#### PLANTS.

On this occasion the prizes for specimen plants were smaller than usual, and as a consequence some of the best known exhibitors were not represented. Their plants were certainly missed, but local growers made a very creditable display. The best nine stove or greenhouse plants, flowering or otherwise, were staged by Mr. J. F. Mould, Pewsey, who had several good *Ericas* and *Lapageria alba*, with a few other well flowered specimens, fairly fresh. In the second prize collection, shown by Mr. J. Brice, gardener to Herbert Harris, Esq., Calne, were very well grown specimens of *Crotons Victoria* and *mutabilis*, and a fine *Latania borbonica*. The third prize was awarded to Mr. Curry, gardener to Colonel Pepper, Salisbury, who had several faded flowering plants. For six fine-foliaged plants Mr. G. Smart, gardener to Mrs. C. Harris, Calne, was placed first, he having a grand plant of *Davallia Mooreana* fully 9 feet across, a good specimen of *Gleichenia rupestris*, a neat *Cycas revoluta*, two Palms, and a Croton. Mr. Curry was a close second, his best being *Kentias Belmoreana* and *Fosteriana*. Mr. G. Smart was easily first for eight exotic Ferns, having large healthy specimens of *Gymnogramma chrysophylla*, *Gymnogramma calomelanos*, *Davallia fijiensis*, *Nephrolepis davallioides furcans*, *Adiantum Williamsi*, *A. cuneatum*, and *A. peruvianum*. Mr. T. Price was first for Tuberous Begonias, and H. C. Henly, Esq., Calne, second, the last-named also gaining the special prize offered by Messrs. J. Laing & Sons for the same class of plants. Mr. J. Lye, gardener to the Hon. Mrs. Hay, Market Lavington, was easily first for six well grown and freely flowered Fuchsias, the varieties being *Abundance*, *Lye's Rival*, *Mrs. Bright*, *Elegance*, *Constancy*, and *Charming*. Mr. T. Price was second.

In the amateurs' classes for plants, or those not open to all comers, the competition was not very keen. The best six exotic Ferns were shown by Mr. G. Smart, who had very well grown plants of *Gleichenia Spluncea*, *Adiantum gracillimum*, *Gymnogramma Laucheana*, *Adiantum grandiceps*, *Lomaria gibba*, and *Adiantum cuneatum*. The same exhibitor was also well first for six fine-foliaged plants, among these being good specimens of *Kentias australis* and *Belmoreana*. Mr. Herbert Harris was the only exhibitor of Orchids, and staged well-flowered plants of *Epidendrum vitellinum majus*, *Cypripedium Dayanum*, *Odontoglossum hastilabium*, *Oncidium Harryanum*, *Cattleya Gaskelliana*, and *Odontoglossum Alexandrae*. Mr. Henley was first for *Coleus*, and Mr. W. A. Cook, gardener to Major Heneage, V.C., Compton Bassett, second. The last-named had fine Cockscombs, and was first, being also successful in several other classes for pot plants.

#### CUT FLOWERS

Formed quite an attractive display, the competition being good throughout. A first prize of £5 was offered for thirty-six varieties of Roses, single trusses, and this attracted several noted growers. Messrs. J. Jefferies & Son, Cirencester, were well first, their stands including very fine fresh blooms of Captain Christy, Marie Baumaun, John Laing, Mdle. Susanne Radocanachi, Star of Waltham, Madame Eugénie Verdier, Charles Lamb, A. Colomb, Comte Raimbaud, Marie Rady, Madame Lambard, Magna Charta, Innocente Pirola, A. K. Williams, and La France. Dr. Budd, Bath, was a good second, and Messrs. Perkins & Sons, Coventry, third. The best twelve Roses were shown by Mr. G. Humphries, Chippenham, H. Ash, Bath, being second. Mr. Humphries was easily first for show Dahlias, having Mrs. Gladstone, H. Walton, Vice-President, W. Rawlings, Harry Keith, Agnes, Nellie Cramond, Goldfinder, General Gordon, Maud Fellowes, Crimson King, and J. T. West, Cara, Rosetta, and T. Hobbs, all in first-class condition. Mr. S. Cooper was second. Messrs. Walters of Hilperton, S. Cooper, and J. Perkins, Chippenham, were the principal prize-winners in the classes for Asters, and *Gladioli* were well shown by Messrs. J. Jefferies & Sons. The twelve best bunches of choice cut flowers were shown by Mr. G. Smart, and Mr. W. A. Cook was a good second. These two exhibitors were also the most successful in other local classes for hardy and other cut flowers.

#### FRUIT.

Fruit was fairly well shown, but there is good room for improvement in this department. The best collection was staged by Mr. Smart, this

including the usual assortment of Grapes, Melons, Peaches, Nectarines, and Apricots. Mr. Cook was second. The first prize Black Hamburgh Grapes, shown by Mrs. Spicer, were very well coloured; and in this class Mr. H. J. Harris was second. With white Grapes Mr. Smart led with Buckland Sweetwater; Mr. H. J. Harris being second with Foster's Seedling. Messrs. Henly, Cook, and Smart and Mrs. Spicer were the principal prizewinners in the various other fruit classes. Mr. Cook was well first for a collection of vegetables, these comprising good dishes of Autumn Giant Cauliflower, Pragnell's Exhibition Beet, Moore's Cream Vegetable Marrow, Duke of Albany Pea, Lady Truscott Potato, Perfection Tomatoes, Lyon Leeks, and Runner Beans. Mr. J. W. Akerman was second, and Mr. H. J. Harris third. The first prize for a collection of Potatoes was awarded to Mr. J. Akerman.

The most prominent non-competitive exhibit was from by Mr. B. S. Williams, Holloway Nurseries, who sent a capital group of plants, which occupied one end of a tent. Included were all well flowered plants of *Cattleya gigas*, *C. Bowringianum*, *C. Dowianum*, *Oncidium incurvum*, *Odontoglossum vexillarium*, *Cypripediums* in variety, and other Orchids; *Nerine Fothergilli*, Pitcher Plants, Crotons, Palms, and other serviceable decorative plants.

Messrs. G. Cooling & Son contributed a capital collection of Apples, included among these being Beauty of Bath, The Queen, Cox's Pomona, Duchess of Oldenburg, Stirling Castle, Grenadier, Peasgood's Nonesuch, Pott's Seedling, Ecklinville Seedling, Worcester Pearmain, Lord Derby, Lord Suffield, Reinette de Canada, and Cellini. These were all gathered from small trees on dwarfing stocks, and which are bearing remarkably well this season.

#### SHERBORNE.

IT is to be feared the death blow has been given to this old established and popular Society, a heavy downfall of rain during a greater part of the afternoon of the Show day effectually checking the attendance of visitors; this, following upon other bad years, must leave the Committee in a very unenviable position. The Show, as usual, was held on the site of old Sherborne Castle, the tents being actually interspersed among the ruins. Mr. Digby, in accordance with the custom of his predecessors, kindly threw open the whole of his beautiful and well-kept grounds, and more delightful fine-weather promenades could not well be found, among other attractions being the favourite seat of Sir Walter Raleigh, who for many years was associated with Sherborne Castle. As far as the exhibits and competition generally was concerned the Show was a great success, the arrangements and courtesy of Mr. Stokes, the Honorary Secretary, and a good working Committee leaving nothing to be desired.

#### PLANTS.

Mr. T. Wilkins, gardener to T. M. Guest, Esq., Inwood, was by far the most successful exhibitor in the plant classes, though in several instances the competition was very keen. For twelve specimen fine-foliaged plants Mr. Wilkins was well first, the second prize going to Mr. T. Kidley, gardener to A. Helyar, Esq., Coker Court, Yeovil. Mr. Wilkins was also first for a miscellaneous collection of plants in or out of flower; and Mr. G. Runnacles, gardener to C. Thurburn, Esq., Leweston, second, both having very meritorious collections. Another class was provided for a group of miscellaneous plants arranged for effect in a half circle, and this was the making of the Show, there being five competitors, and all made good displays. Here again Mr. Wilkins was first, his group being composed of choice materials, including Orchids, elegant Palms and Crotons, Ferns, Grasses, and such like. Mr. W. G. Pragnell, gardener to J. K. D. Wingfield-Digby, Esq., Sherborne Castle, was a very close second, only wanting a few Orchids to give him first place. The third prize was awarded to Mr. Runnacles, and an extra prize was given to Mr. J. Lloyd, gardener to V. Stuckey, Esq., Hill House, Langport. The last named was placed first for twelve Ferns and Mosses, Mr. Wilkins being second. Both had a well-grown lot of plants. Tuberous Begonias were remarkably good. With these Mr. G. H. Copp, gardener to W. E. S. Drax, Esq., was well first, the second prize going to Mr. J. Andrews, gardener to General Place, Thornford.

#### CUT FLOWERS.

These are always a feature at the Sherborne Shows, but we have seen a much better lot of Roses staged there. Dr. Budd, Bath, was the only exhibitor of twenty-four triplets, and was rightly awarded the first prize. Dahlias, on the other hand, were remarkably well shown, Messrs. Keynes, Williams & Co. competing in their usual first-class style. This firm was easily first for twenty-four varieties, second honours going to Mr. J. Nation, Staplegrove. Mr. R. H. Poynter, Taunton, was first for Gladioli, and Mr. Tottle, Taunton, second. The best twelve bunches of choice flowers were staged by Mr. Williams, Mr. Poynter being second.

The foregoing were all open classes, and in addition there were a considerable number confined to amateurs and their gardeners. The best Fuchsias were shown by Mr. G. Gillingham, gardener to R. Phelps, Esq., Yeovil, Mr. T. Anthony being second. Very rarely are Coleuses so well shown, the first prize group of eight plants grown by Mr. W. G. Pragnell being exceptionally good. Mr. Runnacles was second. Mr. Copp was very successful in various plant classes, as also was Mr. Andrews and Mr. Williams. The most tastefully arranged basket of cut flowers was shown by Miss Lyne, Wimbleton, Mr. E. C. Trevelyan being second, and Miss Percival, Wimbleton, third.

#### FRUIT.

Classes for fruit were very numerous, professional gardeners and amateurs not employing a regular gardener, all having classes open to them only. There were five competitors for the five-guinea cup and

other prizes offered for a collection of eight dishes of fruit, Mr. J. Lloyd however being well first; the second prize going to Mr. T. Wilkins, and the third to Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury. The premier collection consisted of Madresfield Court and Muscat of Alexandria Grapes, very well finished in each case. Hero of Lockinge Melon, Bellegarde Peach, Pineapple Nectarines, Brown Turkey Figs, Jargonelle Pears, Morello Cherries, and Goliath Plums, all in good condition. There was good competition in the class for Black Hamburgh Grapes, Mr. W. G. Pragnell being first with well finished bunches; and Mr. J. Lloyd second. In the any other black class Mr. Goodall, gardener to A. Morrison, Esq., Fonthill, was placed first for very fine examples of Gros Maroc; the second prize going to Mr. W. Conolly, gardener to F. R. C. Talbot, Esq., Lyme Regis, who had the same variety in fairly good condition. Mr. Lloyd was first in the Muscat of Alexandria class with small, well finished bunches; the second prize going to Mr. Conolly for immense clusters not sufficiently ripened. Much the same thing happened in the class for any other white variety, Mr. Lloyd being first for Foster's Seedling; and Mr. Conolly second with the same variety, perfect in all but colour. The best Melon was staged by Mr. H. W. Ward, who had a selection from Hero of Lockinge in very good condition. Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, was second with the true Hero of Lockinge. Peaches and Nectarines were extensively shown. With the former Mr. Ward led with Sea Eagle, good in every way. Mr. Pragnell following with fine fruit of Dymond. Mr. Ward was also first for Peaches grown in the open air; and Mr. Harris second. Mr. W. G. Pragnell had a good dish of Pit-maston Orange Nectarine, and was first; the second prize going to Mr. A. Crossman. The principal prizewinners in the other classes were Messrs. Lloyd, Kidley, T. Moore, Copp, Pragnell, Runnacles, Trevelyan, Peters, and Williams.

#### VEGETABLES

Are always good at these shows, professional gardeners, amateurs, and cottagers all exhibiting in first-class style. The best collection of twelve dishes was staged by Mr. G. H. Copp, who had very fine Autumn Giant Cauliflowers, Ellacomb's Parsnip, Pragnell's Exhibition Beet, Sutton's Seedling Potato, New Intermediate Carrot, Wright's Giant White Celery, Perfection Tomato, the Lyon Leek, Ne Plus Ultra Runner Bean, Duke of Albany Pea, and Tender and True Cucumber. Mr. T. Wilkins was a good second, and Mr. A. Crossman third. With eight dishes, Mr. Bowers, gardener to T. Holford, Esq., was well first, this successful vegetable grower having Autumn Giant Cauliflower, Student Parsnip, Dobbie's Cheltenham Beet, Rousham Park Onion, Girtford Giant Runner Bean, Wright's Giant White Celery, Duke of Albany Pea, and Perfection Tomato in fine condition. Mr. W. Paulley, gardener to A. W. B. Clarke, Esq., was second, and Mr. S. Kidley third, each having excellent produce. Onions, Potatoes, Celery, Peas, Beans, and Tomatoes were all well shown, and in the various classes the most successful were Messrs. Pragnell, Wilkins, Copp, Bowers, Kidley, Lloyd, Harris, Runnacles, and Crossman.

There were several good non-competitive exhibits, foremost among these being a capital collection of cut Begonias, Dahlias, Poppies, and other flowers from Mr. B. R. Davis, nurseryman, Yeovil. Messrs. Jarman & Co., Chard, also had an extensive exhibit of herbaceous flowers, Gladioli, Phloxes, Dahlias, and other hardy flowers. Mr. Scott, nurseryman, Yeovil, and Merriott made a capital display of plants and flowers. and Messrs. Keynes, Williams & Co., Salisbury, had a fine exhibit of Dahlias.

#### SANDY.

THE twenty-second annual Exhibition of the popular Bedfordshire Society, nominally horticultural, but which takes under its wings gardening in all its branches, farm produce, poultry, pigeons, rabbits, cage birds, dogs, &c., was held in the Park of Sandy Place on Friday last, and proved even more successful than its predecessors. The day proved fine, and a very large gathering of exhibitors and visitors from far and near was the result, the Show being, perhaps, the best the Society has ever held, the fruit department only showing a falling off owing to the ungenial season.

#### PLANTS.

In the open class for ten stove and greenhouse plants in flower Mr. W. Finch, gardener to Mr. Alderman Merriott of Coventry was first with very fine and well flowered specimens, the most striking being *Rondeletia speciosa* major, *Stephanotis floribunda*, *Lapageria alba*, *Erica Eweriana*, and *Ixora Duffi*. Mr. Jas. Cypher of Cheltenham had also attractive plants of *Bougainvillea glabra*, *Allamanda Hendersoni*, *Franciscea calycina* major, *Erica Eweriana*, and *Statice profusa*, and proved a close competitor, coming in, however, second. Mr. F. Mould of Pewsey, Wilts, was third, his collection including fine examples of *Miltonia spectabilis*, *Lapageria alba*, and *Erica Jacksoni*. Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynesbury, Hunts, was also an excellent fourth; all four collections forming a very effective bank, although much too elevated, as is always the case at Sandy. For twelve Zonal Pelargoniums in the open class Mr. Redman was first, his specimens being all in good form and colour, and fair size. In the amateurs' division Mr. Redman also led with six foliage plants, and also for Coleus. For six stove and greenhouse Ferns Mr. G. Claydon, gardener to Mrs. Astell, Woodbury Hall, was first with beautiful and healthy specimens of *Adiantum grandiceps*, *gracillimum* and *cuneatum plumosum*, *Lomaria gibba*, and *Gymnogramma chrysophylla*. Mr. Claydon was also the exhibitor of the six best Fuchsias.

#### CUT FLOWERS.

These were extensively shown. In the open class forty-eight Roses from Messrs. G. & W. H. Burch, of Peterboro', were remarkably fine, and

as the conditions stipulate for not less than twenty-four distinct varieties, the class constituted an effective test of the best autumnal bloomers, and it was noticeable that Mrs. J. Laing was the most repeated, some five or six beautiful and varied blooms being put up in Messrs. Burch's stand, Ulrich Brunner, Marie Baumann, Alfred Colomb, and Star of Waltham amongst H.P. being also frequently repeated in the stands, and amongst Teas The Bride was most apparent, and in fine condition. Messrs. Burch were well first, Messrs. Paul and Son, Cheshunt, second, and Mr. F. Cant, Colchester, third. Roses from amateurs were sparsely and poorly represented, Mr. G. Moules of Hitchin, however, having a good stand of six. Gladiolus from Messrs. Burrell & Co. of Cambridge were very good, the spikes of enormous size, and the varieties, which included some remarkable seedlings of their own as yet unnamed, were striking and distinct, and the collection was altogether attractive and creditable to Messrs. Burrell, who were awarded first prize for twenty-four spikes. For twenty-four show Dahlias in the open class the competition was strong, Messrs. Heath & Son of Cheltenham leading with fine blooms all well up and well matched, of W. Rawlings, T. J. West, Thos. Hobbs, Mrs. Gladstone, John W. Lord, Henry Bond, Burgundy, and Vice-President, top row; Hon. Mrs. Wyndham, Jos. Ashby, Miss Cannell, Geo. Dickson, Constancy, J. Henshaw, Flora Wyatt, R. Dean, middle row; and Clara, H. Weir, Prince of Denmark, J. Keynes, W. Garratt, Lady G. Herbert, Mr. J. C. Reade, and Mrs. Harris in the front row. Mr. A. Rawlings, Romford, was third with almost equally fine blooms, and Mr. J. Myers, Huntingdon, third, six fine collections being staged. For twelve show blooms in the amateurs' class Mr. G. Arnold, Leighton Buzzard, was to the fore, and for six fancies Mr. H. Glasscock, Bishop's Stortford, led.

The open class for twenty-four bunches of cut hardy herbaceous or bulbous flowers formed a great attraction, Messrs. Paul & Son, Cheshunt, taking first with large masses of the most showy species, Gladiolus purpureo-auratus, Rudbeckia purpurea, Senecio pulcher, Aconitum autumnale, Delphinium conspiciuum being very striking. Messrs. Burrell & Co., Howe House Nurseries, Cambridge, were a very close second, including splendid masses of varieties of hybrid Gladiolus, Montbretia crocosmiflora, Eucomis punctata, Chrysanthemum leucanthemum semi-plenum, Phygellus capensis; Messrs. Laxton Bros., coming third with a choice and showy lot, including Scabiosa caucasica, Chrysomela stylosa, Helianthus multiflorus Soleil d'Or, Lobelia cardinalis Queen Victoria, Echinops ruthenicus, and Eryngium amethystinum. Several good forms of Helianthus multiflorus were shown, but Solcil d'Or appeared to best advantage.

African Marigolds were, as usual, very good here, Mr. R. Burgin, Eynesbury, winning with perfect flowers. He also took first for twelve in the class for French. Asters were poor and unsatisfactory. Double Zinnias from Mr. R. M. Jones, Cambridge, who was placed first with perfect flowers.

The prizes for table decorations fell—the first to Miss Mould, Ickwell House; the second to Miss Richardson of Sandy Rectory; and the third to Miss Orlebar and Miss Barratt of Wellington, for pretty, simple, and effective displays.

#### FRUIT.

For the collection of eight varieties, Mr. G. Allis, gardener to Major Shuttleworth, Old Warden, had well-finished samples of Hamburgh and Buckland Sweetwater Grapes, Melons, Figs, Peaches, Nectarines, Pears and Cherries, all in prime condition, and was deservedly awarded the premier position, Mr. C. Forbes, Cambridge, obtaining second place, and Mr. J. Myers, Huntingdon, third. For the collection of six varieties, Mr. R. Carter, gardener to Col. Duncombe, Waverley Park, was first with Black Hamburgh Grapes, Melons, Peaches, Apricots, and Morello Cherries, all very creditable samples, and Mr. J. Cook, gardener to Col. Stuart, Tempsford Hall, second. For two bunches of black Grapes (Hamburghs excluded), Mr. Forbes was first, and Mr. Allis second, with Alicantes. For two bunches of Black Hamburghs, Mr. C. Moore, St. Neot's, came to the front, and Mr. F. Fanit, Hertford, second. For white Grapes, G. E. Foster, Esq., Cambridge, was first, and Mr. Allis second, with very fine Buckland Sweetwater. For two bunches of Muscat of Alexandria Mr. C. Forbes had first place and Mr. Foster second. Mr. Allis took first also for cooking Apples and for six pretty and tastefully mounted pots of table plants, the outsides of the pots being neatly dressed with green Box. For scarlet-fleshed Melons Mr. R. Carter was first, and for green-fleshed Mr. Foster. Mr. E. T. Leeds Smith, Sandy, was first for well-ripened dessert Pears. For dessert Apples Mr. R. M. Jones, Cambridge, led, Mr. Foster for Figs, and Mr. J. Laxton, Bourn, Cambs, for a splendid dish of Morello Cherries, Mr. Foster coming first for dessert Plums with Green Gage, and Mr. G. E. Foster second with a striking dish of Golden Esperen, a good sized deep golden yellow Plum of great merit as shown.

#### VEGETABLES.

There was a remarkably fine display in all departments. Potatoes especially were almost unequalled. For the collection of twelve varieties of vegetables in the amateurs' class Mr. F. Fanit, Hertford, was first, closely followed by Mr. H. Ridgewell, Cambridge; Mr. W. Pepper, Welwyn, coming third, and Mr. J. Myers fourth. For the collection of Potatoes, three sorts round and three sorts kidney, Mr. J. Simkins, Shillington, Beds, was first with remarkably large and perfect specimens of Sutton's Satisfaction and Sutton's Scedling, Abundance, Best of All, Windsor Castle, and Matchless. Mr. P. Meyer, Orwell, was second. For twelve white kidneys Mr. Simkins was again first with wonderful examples of Satisfaction, and also for white and coloured

rounds; and for coloured kidneys Mr. J. Bradford, Thorney, Cambs, came first with Mr. Bresee. In the market gardeners' class Mr. H. Ridgewell led with a grand lot of, in which Laxton's Beds Hero, large Myatt-shaped kidney; Ridgewell's General Stuart, pure white round; Perfect Peachblow, and Snowdrop were especially striking. For twelve kidneys in this class Mr. Ridgewell was first with fine examples of Laxton's Beds Hero, as also for twelve coloured kidneys with Beauty of Hebron, and twelve white round General Stuart; and for coloured round Mr. G. Single, Beeston, was first with Adirondack. For twelve Globe Onions Mr. J. Simkins showed very large and clean examples of Brown Globe; Mr. Dale, gardener to J. N. Foster, Esq., Sandy Place, coming first for White Spanish with Laxton's Sandy Prize, some grand specimens, which variety was also shown by Messrs. Laxton Bros. of Bedford, several of these girthing over 16 inches.

Tomatoes were largely and well shown, the first prize for Reds going to Mr. J. Myers, Huntingdon, for large samples of Trophy; Mr. R. Brown, Somersham, taking second; and Mr. G. Banes, Stratford, Sandy, third for a very even dish of medium-sized rounds. For Yellow Tomatoes Mr. A. Barker, St. Ives, had the best exhibit. Peas were only mediocre; some good examples of Evolution, Autocrat, Sir F. Millbank, and Duke of Albany were shown. Cauliflowers and Beans were perhaps not so good as usual, but other vegetables were shown in excellent form and great quantity.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.—Earliest Forced Trees.**—The leaves will soon be off, then loosen the trees from the trellis, clean the house, attending to the needful repairs, and paint the woodwork and trellis. The mulching and loose surface soil should be removed and fresh loam with a tenth part of bone dust and a twentieth of wood ashes added, affording a moderate watering if dry. Whatever pruning is required should be done as soon as the house is in order, but if the trees have been properly attended to little work need be performed with the knife. Dress the trees with an insecticide. It is well to wash the whole of the trees by means of a brush with a soapy solution, say 4 ozs. of soft soap to a gallon of water, adding a quart of strained tobacco juice, and if there be any scale add a wineglassful of spirits of turpentine, keeping it well mixed by frequent stirring. In applying insecticides take care to reach every part, and use the brush in such a manner as not to injure the buds. Trees cleansed and neatly secured to the trellis have a better appearance than those left untrimmed until the latest period before starting.

**Second Early Houses.**—The roof lights have been removed from houses that were started at the new year and ripened fruit in late May or early June. Trees exposed to the weather after the wood becomes firm and the buds plumped are invigorated by the rains and the dews. The border is thoroughly moistened through, premature ripening of the foliage is prevented, and the trees have an early rest, which assists them in retaining the buds and making a good start. Premature bud development is a chief cause of buds falling, aided by a deficiency of moisture at the roots. Trees under fixed roofs should have all the air possible and be duly attended to in watering. Liquid manure assists weakly trees to plump their buds and retain the foliage in health. Moderately vigorous laterals help to keep the roots active, but those that are gross must be removed, and the unduly long pinched back. Laterals must never be allowed to interfere with the free access of light and air to the young wood and leaves, but be kept subordinate to the chief growths.

**Midseason Houses.**—Trees from which the fruit has been gathered should have the bearing wood of the current year cut out, always excepting parts needful for extension. This will admit of the trees being thoroughly cleansed by syringing, and if necessary applying an insecticide, it being of the greatest importance that the foliage be kept clean and healthy until the buds and wood are thoroughly matured. This will be assisted by the increased light and air. If the growths are too crowded thin them, leaving sufficient young wood for next year's bearing. It is better removed now than at the winter pruning. The remaining parts are benefited and there is less danger of inducing gum. Ventilate freely, and afford water as necessary to keep the soil duly moistened to the drainage.

**Late Houses.**—The fruit is swelling well and liberal supplies of water are required until the ripening is well advanced, when moderate supplies will be sufficient; enough, however, should be given to maintain the foliage in a healthy state. Trees that are making gross growths and have a tendency to late growth should be marked for lifting, an infallible remedy for indifferent setting and uncertainty of stoning. Any trees that do not ripen the wood well should be curtailed at the roots by taking out a trench so as to detach the roots at about one-third the distance from the stem the trees cover on the trellis, doing it about the end of September or as early in October as the fruit is gathered.

**FIGS.—Planted-out Trees.**—These not infrequently grow strongly, and consequently produce thin crops of fruit. In that case root pruning

may be resorted to, and the roots be confined to a border from 3 to 4 feet in width. If the drainage be defective it will be necessary to lift the trees in the autumn as soon as the leaves commence falling, and replant in fresh soil. Place in 9 to 12 inches of rough stones or brick-bats for drainage, and over them a covering of rather rough lime rubbish, using the finer parts for mixing with the compost in the proportion of a sixth to the bulk of turfy loam, and a twentieth of crushed bones. In replanting ram the soil well about the roots, for short-jointed fruitful wood cannot be so well secured as by a solidified compost. The border must be 24 to 30 inches deep. Should the drainage be good it will only be necessary to confine the roots to the narrow border, removing some of the old soil from amongst them, and top-dressing with fresh loam, with an admixture of lime rubbish and crushed bones as above stated. If the loam be light add a sixth of clayey marl, if heavy a sixth of road scrapings. The proper time to operate in the manner indicated is as soon in late summer or autumn as the foliage gives indications of maturing.

**CUCUMBERS.**—The shorter days and longer nights necessitate the earlier closing of the house, and the employment of the syringe also earlier, so as to have the foliage fairly dry by dusk. Fire heat, now the nights are colder, will be necessary to maintain the night temperature at 65°, and to maintain a day temperature of 70° to 75°. Afford every encouragement to the autumn fruiters, removing the first fruits and the staminate blossoms and tendrils.

No shading will be necessary, and avoid syringing as far as possible, damping being usually sufficient. Sow from now to the middle of the month for a supply of fruit at Christmas and the new year onwards. Telegraph is a good kind for this, indeed for any sowing, while Cardiff Castle is free and excellent for everyday use. Winter-fruiting plants must have a light and well-heated structure, otherwise fruit cannot be had in perfection with certainty. The plants from appearing above the soil must be kept well up to the glass, so as to insure a sturdy thoroughly solidified growth, which are essential to fruitful plants.

#### KITCHEN GARDEN.

**DIGGING POTATOES.**—The early and second early varieties are now matured, and the sooner they are dug and harvested the better. In our case the work will be less interesting than it has been for many years, as the disease has destroyed half the crops in all cases and more in many. As a rule the finest tubers are the worst diseased, and many are reduced to a pulp. The harvesting will have to be done with extra care. Digging should be commenced early on a fine day and continued until midday, then allow the tubers to lie exposed until well into the afternoon, when they will have dried considerably, and it may be readily seen which are free from disease. In good seasons we have generally taken the tubers direct into the shed where they are stored for the winter, but that will not be a safe practice this season, as all will be spread out in an airy shed for several days, and none will be stored until they are quite dry and the sound tubers can be detected; only the tubers for use will be removed to a dark shed, and the smaller ones left for seed will be allowed to become somewhat green and hardened before being stored. It is a common practice to remove all the sound tubers and allow the decayed ones to remain on the ground. They decay there and become mixed with the soil, but we do not approve of this, and gather them up carefully. We object to allowing decayed Potatoes to be placed on the manure heap, and they are thrown away in a corner by themselves. The haulms are also objectionable, and they should be cleared off the surface and burned.

**HARVESTING ONIONS.**—These are smaller and greener in September this year than they are generally at this season. In many cases the bulbs have hardly begun to form, but will make little more progress, and if the weather is fine and sunny they should be pulled up and laid down with the bulbs facing the sun to dry. Plants that have failed to bulb may be thrown to the rubbish heap. In a few days after drawing them up turn the bulbs and allow the stems to wither, then twist the bulbs off and place them in an open airy shed to dry. We have finished treating a number of ours in this way, and the ground on which they were growing has been hoed deeply and sown with prickly Spinach for winter. Run the Dutch hoe between the rows of autumn sown Onions now coming through the soil.

**CAULIFLOWER.**—Those who sow their early Cauliflower seed in the autumn must now attend to it. Early London is one of the best for this sowing. Sow broadcast in a narrow bed on a south border, and some of the plants may be left there during the winter, while others may be planted in handlights and frames.

**HOEING.**—The weeds have been most troublesome this season, and before the damp weather of winter occurs every inch of surface in the kitchen garden should be hoed and cleaned thoroughly. This must be done early in September, because the removal of the weeds allows the light and air free access to the plants, and render them hardier.

**LETTUCE AND ENDIVE.**—Many Lettuces and Endive are now ready for transplanting. Sufficient for a crop is left in the seed beds or rows, and the others are transplanted. The former will be ready before the latter, and the check experienced in transplanting will cause the latter to follow in succession. Be careful with the roots in drawing up the plants, and plant at once in good soil. They should be put into a warm sunny sheltered position, as they may experience frost and cold weather before they are ready or used, and a favourable site does not entail early protection, which is not always convenient. Plant in rows about 10 inches apart, and see that the slugs and snails do not destroy them, which they are very apt to do at present. Sow more seed of the hardy winter Lettuce.

Thin late-sown Carrots and Parsley. Where young Radish are very thick in the rows thin them to 2 inches apart before they bulb. See that Asparagus stems are staked and tied up. Many roots and plantations are injured by allowing the stems to be blown over and broken by the crown before they have matured. Remove all roots and plants from which the crops have been secured, and on no account allow the vegetable garden to become a wilderness when it is thought the season is over.

#### PLANT HOUSES.

**Zonal Pelargoniums.**—These should be placed in cold frames or cool houses, where they can have abundance of air, the atmosphere about the plants being kept as dry as possible. The present cool wet weather is unfavourable to them, and if they are not under cover they will make soft growth, and fail to flower satisfactorily. Supply water carefully in dull weather. Insert cuttings singly in 3-inch pots for flowering early in the year. Supply with stimulants plants that are root-bound and have been flowering for some time. Ivy-leaf varieties should also be placed under cover; select for them a light airy structure. Insert cuttings singly in small pots for flowering during the early spring months.

**Bouvardias.**—These are not safe outside unless the weather changes and proves warm and dry. Place them in a cool airy house, or in frames where the lights can be thrown off if the weather changes for the better. Plants that have their pots full of roots should be supplied with a little artificial manure once a fortnight.

**Chrysanthemums.**—Where large blooms are required the plants must be examined at intervals of a day or two, for crown buds will now appear in quantity. As soon as the growths that start from the axils of the leaves can be removed the better, the point of a small knife being most suitable. If the buds are deformed or injured in any way, allow one shoot only to extend from each, and a fair boom will result. Lose no time in removing all but one shoot on each stem, so that the whole energy of the plant can be devoted to its development. Directly flower buds are secured, top-dress the plants with rich material to keep their roots active. Supply them liberally with weak stimulants, and change the food for this purpose occasionally. Avoid strong stimulants, for they are almost certain to burn the roots of the plants, and flat poorly developed blooms will result. Tie the shoots securely, but rather leave 2 or 3 feet to sway about with the wind than 6 inches or a foot, which is almost certain to be broken off and the whole season's work rendered futile. Early flowering varieties should be placed under cover; they will soon come into bloom. Summer varieties that have flowered must be cut back to induce them to produce cuttings, which should be rooted directly they are ready. It is a mistake to delay the propagation of these varieties until cuttings of later flowering varieties are ready for insertion.

**Mignonette.**—A good number of 5 and 6-inch pots should be filled with loam, one-seventh of manure, and a little sand and seed of the best strains sown thinly over the surface. The seed must only just be covered, and the pots placed in cold frames until germination takes place. Thin seedlings that are large enough; nothing is gained by leaving them thickly together. Expose them to abundance of light and air, to induce dwarf compact growth. Standards and pyramids will need constant attention; be careful that they do not become rooted into the material upon which they stand. Remove the flowers as they appear, and train the shoots evenly over the trellis. Do not attempt to hurry them, for they only grow weakly and will yield puny spikes of bloom in return.

**Roman Hyacinths.**—Some of these should now be potted; 5-inch pots are suitable for five or six bulbs. For cutting the smaller sized bulbs may be placed thickly together in boxes. After potting place these in a northern position and cover with 4 or 5 inches of ashes. Do not water after repotting, but be careful that the soil is in an intermediate state for moisture before the pots are filled. A few early Paris Hyacinths may also be potted. They are useful for cutting and decoration after Romans are over.

**Narcissus.**—Where the old double yellow Daffodil and other border varieties are appreciated indoors, no time should be lost in placing them in pots. They will commence to form roots at once, and may then be brought forward into flower under almost natural conditions. Place them under ashes, the same as advised for Hyacinths.

#### APIARIAN NOTES.

##### SUPPRESSING THE DISEASE.

SOME clamour for an Act of Parliament, and to have inspectors appointed; but I am inclined to think this will become a sure means of spreading the disease, just as I have witnessed medical officers carry contagion from an infected to a healthy house. No intelligent bee-keeper will care to submit his hives to any inspector who may have just been examining an adjoining infected apiary. For my own part, and I believe many others share my

spirit, I resent any person opening up four hives, when we consider it would be detrimental under our own supervision. The best means to suppress the disease must come from the bee-keepers themselves. Hitherto there has been much talk about what has been done for the cottager bee-keeper, but we cannot disguise the facts that much which would really benefit the cottager has been kept in the background to benefit the dealers, who had the management of affairs in their own hands. This is a fact so far as shows have been concerned in the past, and we fail to see any improvement for the future.

Happily, bee-keepers are beginning to see things in the true light, and to learn that their neighbours' loss is also their own, and are taking the proper course of stamping out the disease the moment it is discovered. This is the right method, and the only one that will give apiaries immunity from the destroyer, and in the end reward the bee-keeper for his action and attention.

#### THE WEATHER.

Our bees have now been fully three weeks at the Heather, and with the exception of three nearly fair days the whole time may be described as continuously wet, with occasional clear frosty nights, the daytime giving but chance glimpses of summer temperature, seldom lasting more than five minutes at any time. Although I have no instruments to take the temperature I should say the mean temperature is little above 40° Fahrenheit. The air is light, and the moment the evaporated moisture reaches an evidently cold stratum down falls the rain, often too in torrents. Farmers are in a plight, their hay either lies uncut or in the swathe, and has been so for nearly a month. The Oats are scarcely out of the ear.

#### HONEY PROSPECTS.

Another week will end the Heather, of which the bloom could not be finer. I had some hopes on the morning of the 28th ult. that honey would be obtained, as the bees started to work in earnest, and a finer sight I have seldom witnessed than the great number of bees pouring out and in from our strong hives, a thing unknown to many modern bee-keepers. But by midday a thunder shower, which lasted three hours, put an end to their labours for the day.

#### EXPERIMENTS.

I have not been able to make the intended experiment to test varieties of bees and the weighing of hives, for instead of rising in weight they have fallen, the extreme cold being a great means to this.

#### SOURCES OF HONEY.

The same cause has prevented my tracing the sources from which bees gather honey, and from what flowers a bright green pollen is derived, which seems plentiful all the season, but I have never witnessed bees collecting it.

#### FERNS YIELD HONEY.

Sometimes the common Bracken yields large quantities of honey, as do some kinds of grasses, but the low temperature prevents the secretion, and of course precludes the possibility of my being an eye witness to bees collecting it.

#### CONDITION OF THE HIVES.

It is perhaps of more interest to bee-keepers to know that hives that were sent to the Heather in good condition are those only that will rise much in weight should they get a chance. Such hives have lost few bees, and drawn no worker brood, whereas those that had little food beside them have done both, and many colonies are reduced to mere handfuls of bees, and it is worth emphasising the fact that it holds good at all seasons, notwithstanding the assertions of modern ideas to the contrary.

#### SWARMING.

Swarming and non-swarming bees may be placed in the same category. I have in an earlier article dealt with this subject, and

lately stated that bees would, in all probability, swarm at the Heather from the cause I have pointed out in these letters, and have frequently endeavoured to show, amidst much opposition, that bees will swarm whether they be crowded or not, and that Carniolians do not swarm more readily than other varieties. Although the weather has been wintry, a good many hives have swarmed, the majority being what their owners term original black bees, while only one first-cross Carniolian has swarmed. The causes and particulars I need not repeat, but what is worth mentioning is that our bees stand on a dry site, which absorbs much heat, neither high nor very low, and there is scarcely a dead bee to be seen, while of those in the lowest part of the valley, where the wind sweeps along in strong gusts, thousands are chilled to death. The most sheltered situations are mostly to be found at some distance from the base. By the time this appears in print the honey season of 1890 will be closed, and if without profit not without lessons, the loss being neither the fault of the bees nor of their owners.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Lobelia Omen (G. H.).**—The flowers were spoiled through not being firmly fixed in the box, but the colour is similar to that of the above variety which is grown to some extent in the London parks, though does not become very popular.

**Tomatoes Diseased (J. H.).**—The plants are no doubt infested with the fungus (*Phytophthora infestans*). There is no remedy, but it is well to destroy all the infested plants and fruit, and have a change of seed, planting in fresh ground well dressed with quicklime. The season has been a bad one for outdoor Tomatoes, inducing a grossness of plant highly favourable to the disease.

**Overwatering Vine Borders (W. E. T.).**—Shanking will certainly be induced by a saturated state of the border, but it would not cause the Grapes to crack unless the house had been kept unusually arid, and then closed so as to cause the deposition of moisture on the Grapes. Guttering ought to have been put up at first, but you will have to encourage more growth in the Vines, yet not having more foliage than can have full exposure to light and air, and be careful not to over-crop them, which is a common cause of shanking. Are you sure the border is well drained? It must be seen to, and the Vines if the roots are deep should be lifted and laid in fresh soil near the surface. This can be effected without loss of crop by lifting the roots in the inside border one year, and those in the outside border the next, as soon as the leaves begin falling.

**Larva on Pear (A. B. D.).**—This is the slimy black larva or grub of the Pear tree slug, which Curtis calls *Tenthredo adumbrata*, allied to a similarly troublesome species that infests the Cherry. It generally makes its appearance about the end of August, and if unmolested will continue to feed till October. Wall trees are particularly attacked by it, and the effect of its feeding numerous upon the leaves is that the elaboration of sap is interfered with, and the fruit falls off. It clings tightly to the leaves, protected by its slimy secretion, and appears to be untouched by birds. After four changes of skin it becomes adult, and descends to the earth, where it forms a cocoon. From this emerges an active fly of sawfly tribe, about three lines long. There is no better remedy for it than dusting well with quicklime, repeating if needful. Tobacco water will also destroy them, and syringing the trees with strong soapsuds.

**Prizes at Shows (R. D.).**—The rules to which you refer are conflicting, and need careful revision. According to rule 4 the judges have the power “to recommend prizes for any article they may deem worthy,” which evidently means that the Committee will decide whether they can be granted or not, as is customary at other shows. The question for the Committee to decide is not concerned with the “merit” of the exhibit, but as to whether the award is in accordance with their rules. Without seeing a schedule we cannot express an opinion upon this subject.

**Epacris (G. L.).**—For soil good fibry peat must be provided, and sharp silver sand mixed with it to keep it open. Efficient drainage, efficient watering, and firm potting are also necessary. When once plants which are firmly potted in peat become dry ordinary waterings are not sufficient to moisten the soil thoroughly. They must be watered again and again until the water pours from the hole in the bottom of the pot. Indeed if the dryness is allowed to go too far there is nothing for it but steeping the pot in the cistern until the air balls, which are displaced by the water, cease bubbling up. After the ball is thoroughly soaked no more water should be applied until necessary, when a thorough supply should be given. This is one of the secrets in successful Epacris growing. Another, as we have said, is firm potting. Another consists in growing them in an airy greenhouse, where as little fire heat as possible is used, and where a constant circulation of air is kept up on all favourable occasions. After the flowers have faded the growth should be cut back. Erect kinds should be cut back close to the old wood, and drooping kinds scarcely so far back. After they are cut back they should be kept rather close until they begin to grow again, when, if necessary, they should be potted into larger pots. After they have fairly recovered from cutting back and potting they should be plunged in ashes out of doors for the summer. By the end of September they should again be housed. They are rather difficult to raise with ordinary appliances, and raising plants from cuttings is hardly worth an amateur's trouble, for your flowering plants may be purchased very cheaply. The amateur should purchase his plants when in bloom, so as to suit his taste, or a respectable nurseryman will generally advise him as to the best kinds to buy. We, however, name a dozen good varieties. E. Butterfly, E. campanulata and campanulata alba, E. Fireball, E. hycinthis-flora fulgens, E. Ingrami, E. impressa, E. Lady Panmure, E. Lowi, E. miniata splendens, E. odorata alba, E. Sunset, E. Vesta.

**Gloxinias from Leaves (R. M.).**—Various methods are followed in multiplying Gloxinias by this means. Some make incisions in the main veins on the lower surface of the leaves, and lay them flat on a bed of silver sand in the propagating house. Over the cuts small pebbles are placed to prevent the leaf shifting until roots are formed, and in the course of time small crowns are formed, and each makes separate plants, which will flower the following summer if carefully ripened and preserved over the winter. Another plan is to cut up the leaves into slips, following the direction of the veins, and running the knife out without damage to the margin. This operation should be performed with a very keen edged knife, so that the tissue of the leaves is not lacerated. By this means the leaves may be divided into a number of wedge-like pieces, narrowing to the bases. These are inserted into pots filled with silver sand intermixed with a little peat soil; and after moistening the body of the compost cover with a bellglass, or place the tops inside the glass case if the house is furnished with such. Keep moderately close, and never wet the leaves while applying water to the roots, at the same time being careful that the cuttings do not suffer from damp. Under such favourable conditions roots will soon be formed, to be succeeded by bulbs and minute leaves; but it is the best plan to pot off singly as soon as well rooted, so that the progress of the two latter is not checked, and that plump tubers may be produced before the fall of the year. After the rooted portions of the leaves have been put separately into pots, have them watered and returned to the place they formerly occupied, and give them the same watchful attendance as hitherto, not once allowing the soil to get dried, which would permanently cripple their growth, until indications of their going to rest are shown at the end of summer. No more water will be required after such symptoms, except enough to prevent the soil from getting dust dry, and thereby causing them to shrivel.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens should be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. C. S.).—1, *Lycosteria formosa*; 2, *Hieracium aurantiacum*; 3, *Echinops ruthenicus*; 4, *Erigeron speciosus*; 5, *Sedum spectabile*. (W. W.).—1, *Adiantum caudatum*; 2, *Asplenium bulbiferum*; 3, *Davallia Mooreana*.

**CHANGES IN AGRICULTURE.**

It has been laid down that changes in agriculture are merely the result of circumstances, and are not to be regarded as a sign of progress. To this dictum we take decided exception, for if such changes are made with the judgment and caution which mark the actions of men of light and leading in agriculture, then assuredly they mark time in progress better than anything else can do. No better proof of this can be had than the agricultural returns of Great Britain just issued by the Agricultural Department, for they show change and real progress in a manner not to be mistaken or set aside by any carping critic.

Of the changes in cropping the most remarkable is the decline of Wheat and Barley, and the steadily progressive increase in the culture of Oats. We need hardly remind our readers how persistently we have advised the extension and improvement of Oat cultivation, and it is indeed gratifying to find our views so entirely in accord with those of farmers generally. An increase this year of 14,294 acres of Oats on 1889, and of 6452 in that year on 1888 shows conclusively that Oats bid fair to become our leading cereal. To emphasise this view we have a decrease of 63,018 acres of Wheat in comparison with last year, and 177,901 acres less than 1888, and 10,352 acres of Barley less than 1889. The Wheat area is the smallest since 1887, and if the average computation of the

yield of 28½ bushels per acre proves correct the total yield will only be 68,010,576 bushels, which points to a probability of some advance in the price of home-grown Wheat. But there are so many outside influences upon the Wheat trade that prices must always remain speculative. Importers are keen to take advantage of an increasing demand for Wheat in this the best market of the world, and we may rest assured of a full supply to meet any demand which may arise. We only hope that any such momentary advance may not induce farmers to sow more Wheat this autumn. Only those who have really good mixed soil should grow Wheat extensively. By high culture on such land a yield far exceeding the average may be had, and a profit made sufficiently high to render it worth while going on. The heavy land men who have the land down to pasture will do far better for themselves and the country if they keep it down, and strive to improve it to the utmost of their power.

Certainly live stock is increasing in no uncertain manner. The returns show a cattle total of 6,508,632, which is the highest number ever reached in this country, being 369,077 more than 1889, in which year there was only a slight increase upon the numbers of 1888. Flocks are improving, the total of sheep and lambs being 27,272,459, or 1,640,439 more than last year, but they have, as yet, by no means reached the numbers returned in 1874. Pigs, too, are increasing, the total number being 2,773,609, or an advance upon 1889 of 262,806, all which tends to show a healthy reaction and decided improvement in farming practice. Well said *Bell's Weekly Messenger* last week, that as breeding and feeding of cattle is the most remunerative side of the farming balance sheet, it is gratifying to find agriculturists producing something that is more likely than corn to yield a profit. It attributes the increase primarily to favourable calving, yearning, and littering periods, and secondarily to plenteousness of keep and comparative absence of disease.

We can hardly agree with either conclusion, and rather take the practical view that the steadily increasing profits upon live stock act as an inducement to rear more, and to bestow more care upon both the breeding and general management of all farm animals. It is a matter beyond question, that in the past, heavy losses have been caused by mismanagement and carelessness in the treatment of live stock. Sweet, if severe, are the lessons of adversity, it brings out the sterling worth and latent power of the British character as nothing else can do. Often are we for the moment left behind in the race, but the way lost is invariably recovered, and then we can hold our own with the best.

Taken as a whole the returns afford matter for congratulation, and we certainly take them as a sign of improvement. Hopefully may we look forward to less of cattle buying, and more, much more, of cattle breeding throughout the country. There can be no reason why cattle cannot be bred just as well as sheep in what are known as the great corn-growing districts. More and more do we hope to see every farm become self-contained, growing much of its own food, and breeding all its own live stock. A full head of stock is better than a comfortable balance at the bank, for upon it now, at any rate, we can realise principal and interest that is much higher than we ever had from our bankers.

#### WORK ON THE HOME FARM.

Corn stacks are being built whenever we have enough fine weather to dry the sheaves, but there has been no regularity about harvest work this year. Hardly a day has closed with those signs of a bright morning which we have in really fine settled weather, and extra care has been necessary in every detail of the work. Often has the reaper had to wait for wind and sun to dry the corn; the shocks have been made with the heads pressed closely together, the tie or knot of the bands placed inside to prevent the accumulation of damp in it, the sheaves set sufficiently aslant to throw off rain quickly and to allow free passage for a current of air between them. Small shocks are a necessity this year, and they are opened awhile before the carting to get the bottoms of the sheaves quite dry. A steep slope is given to the stack roofs, as the corn is then safe for a few days should any hindrance arise in the thatching, but the thatch should be got on as quickly as possible, and the work must be done well enough to withstand high wind. The sides of every stack should be trimmed closely, and the trimmings either given to the pigs or placed with the rakings. This is really an important matter, for an

untrimmed stack attracts sparrows so long as a loose ear of corn can be got at, and Barley ears so exposed become so discoloured as to spoil the sample. So trim, say we, however soon you may intend threshing.

Sparrows will come to the rick yards as the corn fields are cleared, and if a special effort is to be made to destroy them it can easily be managed during the next two or three weeks by the judicious use of a little poisoned grain, so placed that poultry cannot get at it. Both rats and sparrows only exist on sufferance, and it is simple nonsense to say there is any difficulty in the destruction of these pests.

Foul stubbles are common enough this autumn, and the best way of treating them is to plough or skim the surface slightly. Clear off the weeds with light harrows, and then leave the land long enough for germination of weed seeds, which will only require a few days in the warm moist soil. This will tend materially to clean the land and keep down expense in corn hoeing next spring. The season has been most favourable to the growth of green crops, and much White Mustard has been ploughed in.

#### FARMING OUTLOOK IN NORTH LINCOLNSHIRE.

THIS harvest month of August, 1890, brought not brilliant sunshine, but cold boisterous winds, heavy rains, sharp hailstorms, with occasional gleams of brightness, which serve to remind us that there is a sun somewhere if not here. Harvest began generally on the 15th ult., and the Wheat crop is here more than an average as regards straw. The ears are well set with grain, and only needed a little more sun to develop a plump bold grain. As it is, the threshing machine will bring to light a good proportion of poor thin, "hen corn." "Square Head" is well filled to the very top of the ear. Hybrid King begins to taper off about the middle.

Of the Barleys a good report can be given. Quantity and quality both good, and a fine upstanding crop. A new variety, introduced by Carter, and called "Goldthorpe," seems to be the "what's wanted" of this brewers' cereal. Colour will be determined by the weather of the next week or ten days. Where Barley was forward the high winds of August 15th did great damage, severing the bold heads as ruthlessly as ever French guillotine during the Reign of Terror.

If Dr. Johnson of dictionary fame could see a field of Oats not a stone's throw from where we write, he would surely change his opinion, and allow that they were good enough for men as well as for horses. Taking the district through they are a capital crop. If there are Oats in abundance for the horse, sheep, too, will have a good time among Turnips, and Webb's Mangolds are almost as large as the seductive catalogue picture. A few cases of "finger and toe" are to be found in some Turnip fields, and it is most difficult to define a cause, as this disease crops up under varied management and on varied soils.

Then as to the Potato crop. Up to August 1st the prospect was wonderfully good. About that date began a week of close muggy weather, which produced the fatal black spot on the leaf; the haulm was rapidly giving way, and was only checked by the gale of the 15th, which was so disastrous to the Barley. The weather of the last few days will, it is to be feared, cause any latent disease to develop rapidly. Regents, Hebrons, and Elephants are the most affected; Imperators and Magnums but slightly. However, it is hardly possible to give as yet a full and correct estimate of the Potato crop of 1890. When the bulk of the corn is garnered no doubt there will be a move in the Potato market, as dealers have already been seen lurking about the villages.—PARTS OF LINDSEY.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

24th.—Bright and sunny till 1 P.M.; thunder in afternoon, and shower at 5.30 P.M.  
25th.—Bright and sunny till 4.45 P.M., then spots of rain, with a fresh breeze; dull night, with shower.  
26th.—Dull throughout; sharp shower at noon, and heavy rain at 2.45 P.M.  
27th.—Dull early; bright till 3 P.M., then heavy rain and dull evening and night.  
28th.—Bright, sunny day; fine night.  
29th.—Dull early; bright day and night.  
30th.—Bright all day and night.  
Quite an autumnal week, the temperature having fallen to about that of the latter part of September.—G. J. SYMONS.

## TUBEROUS BEGONIAS.

THE improvement of plants during the past half century has very deservedly received much attention from horticulturists, and the grand advances that have been made in many genera afford abundant evidence of the success which has attended well-directed efforts. Careful cultivation, judicious crossing, and thoughtful persevering selection have yielded most satisfactory results, the number of usefully ornamental plants being largely increased and their beauty greatly diversified. Many instances of this could be given, but a few will suffice, one of the most striking, perhaps, being the Clematises, the progress of which was noted some time since in these pages. Pelargoniums, especially the Decorative and Zonal sections, have also advanced greatly; while amongst fine-foliaged plants may be instanced the Dracenas, Crotons, and Coleuses, all of which have progressed considerably in recent years. There is, however, another genus of flowering plants—the Begonia, that has profitably employed the attention of hybridisers; but it is in one section alone—namely, that including the Tuberous species and varieties, that the most astonishing results have been obtained, and to a consideration of the means by which such success has been achieved the following notes are devoted.

All who have visited Forest Hill, Reading, or Swanley during the past and present months have been greatly attracted by the display of Tuberous Begonias there provided, which well illustrate the excellence that has been attained with these plants. Visitors have been surprised, not only at the brilliancy of the colours and the abundance of flowers, but also at the great size of the individual blooms, the breadth of the petals, and the symmetrical form which distinguish so many handsome varieties. Contrasting these with the narrow-petalled earlier forms shows at a glance the progress that has been made, and reminds us forcibly of the similar difference between the early Zonal and bedding Pelargoniums and those finely formed varieties at present in cultivation. Attention has further been paid to the habits of these Begonias, and there are now two well-marked groups—namely, those of erect growth and those with slightly drooping stems, though gradations may be found between the extremes. The first-named may be again subdivided, according to the height of the plants, into tall, medium, and dwarf varieties, all having their particular advantages and uses. Some advance has also been made in obtaining a race with ornamental foliage, though at present this is chiefly confined to the Pearcei type with yellow or buff flowers, yet greater success is confidently expected, and will doubtless be attained. Hundreds of varieties, all more or less distinct and beautiful, have received names and been sent out by nurserymen; but it is now found that seed saved from a good strain yields so many excellent varieties that some firms have discontinued naming these plants, their efforts being directed to rendering the strain generally as meritorious as possible. So that now the purchaser of a packet of seed can rely upon obtaining varieties quite equal to some of the best named forms, and there is the possibility even that something superior may be secured. At some nurseries many thousands of seedlings are raised every year, and these are planted out in prepared beds for trial, all that are really worthless being discarded. In the autumn the young plants are lifted, the small tubers being dried and sold like other tuberous or bulbous plants. A great demand exists

for these, as they come within the means of many who cannot afford the higher-priced novelties.

Having considered the present characteristics of the Tuberous Begonias, it may be well to briefly allude to the means by which so high a degree of merit has been attained, and the original forms that have been employed by hybridisers in producing such satisfactory results. Although the varieties and hybrids are so numerous, the species that have contributed to their formation are comparatively few, and, moreover, are nearly all of recent introduction. The lofty Andes of South America is the chief home of these Begonias, distinguished by possessing a tuberous rootstock and herbaceous fleshy stems; but one of the latest introduced, *B. socotrana*, which also shares these characters to some extent, is, however, as the specific name signifies, a native of Socotra. This will doubtless play an important part in future attempts to improve or vary the Tuberous Begonias, and already some highly important results have been obtained in that direction. The other species—namely, *B. octopetala*, *B. boliviensis*, *B. Veitchi*, *B. Pearcei*, *B. rosæflora*, *B. Clarkei*, *B. geraniifolia*, *B. Davisi*, *B. Frœbeli*, and *B. cinnabarina*, are found on the Andes of Peru, Ecuador, or Bolivia at high elevations, frequently up to 10,000 feet above sea level. The oldest of these is the greenish white-flowered species *B. octopetala*, which appears to have been introduced from Peru about 1835, but was subsequently lost and reintroduced by M. Roezl. This is chiefly interesting as one of the oldest of the section, for it has not been of great service to hybridisers. Next in order of introduction is another rather unimportant species, *B. cinnabarina*, a native of Bolivia, with vermilion flowers, which made its appearance about ten years later than the preceding. *B. boliviensis* is well known, and has been largely employed in crossing with other forms. It is a Bolivian species, and was originally found by Mr. Weddell, but not introduced until some years after—namely, about 1857.

*B. Pearcei*, a comparatively dwarf form with large yellow flowers, dark green velvety leaves, veined with a lighter hue, and reddish on the under surface, is also a Bolivian species, for which English cultivators are indebted to Messrs. J. Veitch & Sons of Chelsea, by whom it was sent out twenty-five years ago. It was found by the traveller Mr. Pearce, whose name it bears. Most of the yellow-flowered varieties owe their origin to this species. *B. Veitchi*, also a dwarf form, has bright scarlet flowers, which are produced freely, and it has been very useful in giving rise to a race of dwarf but vigorous habit. The petals are rounded, imparting a symmetrical appearance to the blooms; the leaves are bright green, broad, and rounded in outline. This was found in Cuzco, Peru, at the great elevation of 12,000 feet, whence it was introduced by Messrs. Veitch about 1867. Two other pretty species allied to the preceding, and resembling it in habit and form of flowers, are *B. Clarkei* and *B. rosæflora*, both from Peru; but the *B. Clarkei* inhabits rather warmer regions than *B. Veitchi*, though *B. rosæflora* is found at a similar altitude. The last-named has large rounded flowers of a fine clear rose colour, and its parentage may be traced in many of the varieties that are now grown with flowers of a like tint. *B. Clarkei*, which is named in honour of Colonel Clarke, who first brought it into general notice, has large scarlet flowers, but not quite so brilliant as *B. Veitchi*. Both these appeared in England about the same time—namely, in 1866 or 1867. Later still—namely, from 1874 to 1876, *B. Frœbeli* and *B. Davisi* were added to the list of species in this section, and both have contributed to some extent to the improvement of varieties and hybrids. *B. Frœbeli* is of compact habit and somewhat related to *B. cinnabarina*, having scarlet flowers freely produced. It was introduced by MM. Frœbel & Co. of Zurich from Ecuador. *B. Davisi* is a charming dwarf species, having neat light green leaves, red on the under surface, and rich in scarlet flowers of moderate size, but good form and extremely abundant. Small plants of this are highly ornamental for cultivation in pots, and

the fine double form obtained a short time since is a most valuable plant.

The intercrossing of these species and careful selection from the numerous seedlings raised have produced with surprising rapidity the handsome race of plants which are now becoming such general favourites for decorative purposes either in pots, baskets, or for bedding out, and their popularity is still increasing. Selections of varieties have been frequently given in these pages, and it is not necessary to repeat these now, but a glance may be given to the earliest of the hybrids obtained, though it would be almost impossible to trace the parentage of all those cultivated at present. One of the first hybrids secured, and certainly the best, was *B. Sedeni*, which was obtained at Messrs. Veitch's Chelsea Nursery by Mr. Seden as the result of a cross between *B. boliviensis* and an unnamed species. This was subsequently employed as a parent with *B. boliviensis*, *B. Veitchi*, *B. Clarkei*, and *B. Pearcei*, giving rise to *B. Chelsoni*, *B. Stella*, *B. Vesuvius*, *B. Model*, and *B. Chambersi* respectively, the last two resulting from two crosses with *B. Pearcei*, all improvements of more or less value. *B. Veitchi* crossed with *B. boliviensis* resulted in the production of *B. Chelsoni*, and this with *B. Sedeni* produced the variety *Acme*. Thus the first hybrids raised have been repeatedly utilised by intercrossing with each other, the diversity and excellence of the progeny being steadily and satisfactorily increased.—L. C.

### GATHERING APPLES AND PEARS.

THIS is apparently a very simple matter, and so it is, but there are in connection with it a few points of the utmost importance to which attention must be given if we would store the fruit in sound condition, and not destroy the fair promise of another crop, which most trees in full bearing give to us now in a clear and unmistakable manner. Go to any tree laden with fruit, and close to the junction of fruitstalk and branch you will see one or two plump buds, which if the fruit is plucked roughly or carelessly will most probably be broken off with it. Those buds contain the embryotic blossom of another crop, which is thus destroyed through ignorance or carelessness.

It is the intermediate and late sorts of fruit that require most care. Keswick Codlins and Kerry Pippins almost fall into our hands if we touch them now, but the fruit of the later ripening sorts requires careful and repeated examination, for the time of gathering is entirely dependent upon the nature of the season, and it is certain to be a little later than usual in such a cold wet one as the present is. If by a gentle turn upwards some of the fruit parts readily from the tree then the whole of it may very soon be gathered, but it should not be forgotten that a week or two longer on the tree may be conducive to the better keeping of the fruit, and it should be so treated upon all dwarf-spurred trees, which are not swayed by high wind. The fruit of standard trees should of course be gathered as soon as possible, but it is as well to be on one's guard against premature gathering, and the resultant shrivelled fruit.

There should be a few cordons of early Pears on walls on every garden, from which to obtain a full supply of really fine fruit. A large quantity of such fruit is never wanted for the ordinary supply of a family, and the fruit from a wall tree is always superior to that from a plantation bush or pyramid. The first ripe fruit is to be had near the top of the cordon, and so on to the bottom, and by gathering a few fruit every day or two the brief season of even Summer Doyenné is lengthened. Gardeners who have to supply the wants of a large establishment should be on their guard with the Pears of summer and early autumn, and take care that only fresh sound fruit goes to table. It is neither pleasant for themselves or their employers that a tempting looking dish of Jargonelles should prove uneatable, and the disappointment is all the greater from the fact of a really good Jargonelle being so delicious. Every good old garden contains a Jargonelle Pear, a Moor Park Apricot, a Green Gage Plum, a Brown Turkey Fig, a Grosse Mignonne Peach, a Morello Cherry, an Elruge Nectarine, and a Ribston Pippin Apple; and a good supply of all these grand old standard sorts of fruit is much appreciated in a new one.

I must not close this note without a word of warning as to the importance of great care in the handling of fruit. Depend upon it the bushels of rotten fruit taken from so many fruit stores during winter is not owing so much to natural as to premature decay, caused by bruises received in the gathering or storing. Only

for cider making should Apples ever be gathered into a sack slung under the left arm. Every fruit required for dessert or cooking should be handled precisely as though it were an egg, contact with any hard substance or with other fruit involving a risk of bruising that should always be remembered by the fruit gatherer. A well-stored well-arranged fruit room is indeed an interesting and attractive sight, replete with instruction to the grower, and with satisfaction to all concerned in it. That satisfaction will be complete if the building itself has been constructed on sound principles, and is really calculated to preserve the fruit well.—EDWARD LUCKHURST.

### GLADIOLUS FOR CUTTING.

No autumn flower is more valuable than the *Gladiolus* for vase decoration. All are useful, but there are some which are better adapted for cutting than others. The varieties of the *Gandavensis* section are the most generally grown, and any of these are useful for cutting from. Care is necessary in making selections to choose those which have a strong constitution. Early ripening sorts will be found to be almost without exception of a vigorous habit, and continue for years in health and strength, while most late-flowering varieties under ordinary cultivation deteriorate, until in many cases they disappear altogether. Many of the newer sorts with extra large flowers possess excellent constitutions, and while small-flowered old varieties are beautiful in their way, they are generally far behind the latter productions. *Pasteur*, *Amitié*, *Dalila*, *Enchantresse*, *Opale*, *Baroness Burdett Coutts*, *Dr. Bailly*, *Celimene*, *Eugène Souchet*, *Sultana* are varieties of capital constitution, with long spikes and very large flowers. Of smaller dimensions are the following, some of which are, however, very beautiful:—*Caprice*, *Horace Vernet*, *Shakespeare*, *Bicolore*, *Penelope*, *Mascarille*, *Panorama*, *Lady Bridport*, *De Brazza*, *Flamboyant*, *Le Phare*, *Brenchleyensis*, and *Diamant*, are varieties I particularly like.

Of even greater beauty than the varieties of the above section are some of the hardy hybrids of the *Lemoinei* type. The later productions are almost as large as some of the *Gandavensis*, but I do not know that these are recommendable on that account. *John Laing*, for instance, is of large size and brilliant colouring, but I do not think it is so good for decorative purposes as the older *Bossuet*. The best of the large flowered sorts I am acquainted with are *W. E. Gumbleton* and *Lafayette*. The former has a very long stem, and can be employed most effectively for the decoration of very large vases in large apartments. For brilliancy of colouring *M. Leroque* is very noteworthy. But the most beautiful of all are such small-flowered sorts as *André Chenier* and *Etoile*. Beautiful also is the clear yellow *Sceptre d'Or*. These are of the greatest service, either for medium sized or large vases. Some of the new *Nancianus* section are extra fine for decorative uses. Some, however, are of a colour which, as a rule, do not find favour in the north country, but they are nevertheless very handsome. *Charles Baltet* is one of these, a curious mixture of slate and crimson; *Maurice de Vilmorin* is a slaty bluish violet. *President Carnot* and *M. Lefebvre* are perhaps the two finest from the general point of view, but for cut flowers I imagine none is so good as *De Candolle*, the flowers of which are open, narrow petalled, and loose, but of the best effect when cut. *P. Duchartre* is in the same way. We have had some fine arrangements with these alone, and with the *Lemoinei* varieties to brighten them with yellow tones. I should be inclined to advise those who do not succeed with the finer *Gandavensis* section to try both of *Lemoine's* types. Some of the *Nancianus* are of the strongest growth, and appear of as easy culture as the others.

A word as to setting up *Gladiolus*. The spikes should be cut early, say when three to four flowers are expanded. They are perhaps more effectively arranged by themselves than in any other manner. The foliage we employ is either *Iris germanica*, *Iris ruthenica*, the common Sedge, *Iris pseudo-acorus*, the common Rush, *Juncus triquetris*, or some strong grass.—N. B.

### THE BRITISH FRUIT GROWERS' ASSOCIATION.

A SUCCESSFUL meeting of the above Association was held in the Crystal Palace, Sydenham, on Friday, September 5th, where there was a good attendance of fruit growers and amateurs interested in the subjects on the programme. G. T. Rait, Esq., Deputy Chairman of the Crystal Palace Company, took the chair at 3.30 P.M., and opened the proceedings with a brief but appropriate introductory speech. He referred to the fact that the British Fruit Growers' Association, which was doing so much good work, really originated at one of the Shows in the Crystal Palace, and he had much pleasure in extending a cordial welcome to the members this year. He complimented the Committee and the Hon. Secretary, Mr. Lewis Castle, upon the energy and judgment displayed in the management of the Association's business. He referred to his own experiences as a fruit cultivator, and in reviewing the programme for the day observed that Messrs. Castle and

Gordon's report with regard to their Irish tour would be the first one to be taken.

This paper (which follows) was followed by considerable discussion, in which Mr. W. H. (Bullock) Hall, Mr. Denny Lane of Cork, Mr. Albert Bath, and others, joined. The remaining papers were then taken in this order:—"Peaches and Nectarines," by Mr. T. Francis Rivers; "Plums for Market," by Mr. J. Smith of Mentmore, admirably read by Mr. J. Cheal in the unavoidable absence of the author; and "Cherries for Market," by Mr. G. Bunyard.

The Exhibition of Irish fruit, provided by members and friends of the Association in Ireland, comprised 150 dishes, chiefly Apples and Pears. The exhibitors were:—Lord O'Neill, Shancs Castle, Antrim (gardener, Mr. C. Warwick); the Rev. A. H. Pakenham, Langford Lodge, Crumlin (gardener, Mr. Harding); Sir Charles B. Barrington, Bart., Glenstal Castle, Murroe (gardener, Mr. Richard Weller); J. F. Lambard, Esq., Dublin; and J. F. Bannatyne, Esq., Summerville, Limerick (gardener, Mr. Elliott). Samples of the local varieties from old and neglected orchard trees were shown for comparison with fruits from well grown trees of good varieties, to indicate what could be effected by suitable attention.

### FRUIT PRODUCTION IN IRELAND.

By Messrs. GEORGE GORDON and LEWIS CASTLE. Read by Mr. GORDON.

EARLY in the year it was decided by the Committee of the British Fruit Growers' Association to prepare a report on the present condition, and the possibilities of fruit culture in the United Kingdom, it being believed that a report, at once comprehensive and trustworthy, would have great practical value. In considering the form the report should take it is felt that as the climatic and economic conditions in Ireland differ widely from those which obtain in other parts of the United Kingdom, it would be necessary to devote special attention to that country. It was thought that whilst our local secretaries in Ireland would be able to render valuable assistance, it would be an immense advantage were some members of the executive to visit Ireland for inquiring into various matters of special importance, that the view presented of the condition and the possibilities of the fruit growing industry in that country might be as clear and exact as it is possible to make it. Eventually Mr. Castle, the Honorary Secretary, and myself, although well knowing the severe tax it would impose upon our time and strength, undertook the task, and we have now to inform you that it has been accomplished. We have also to give you a summary of our tour, and an indication of the impressions produced upon us in the course of the journey. This we shall do as briefly as possible, leaving details until the publication of the full report.

As many of you are aware, we devoted the greater part of the month of August to the work in hand, and I would mention, as a matter of some importance, that our inquiries extended from the counties of Antrim and Derry in the north to Cork, Kerry, and Waterford, which form the southern seaboard. In this tour, which involved travelling nearly 900 miles by rail and car, we saw much to deplore in the present condition of fruit culture, and not a little that filled us with hopefulness as to the possibilities of the industry. We met also with much kindness and great interest in the object we had in view, and an evident desire on the part of those with whom we came in contact to render all the assistance possible. Commencing our inquiries in Ulster, we soon found ourselves on farms that would bear a favourable comparison with the best holdings in England. We found also in this province that orchard planting had not been altogether neglected in the past, and that on many of the farms there were considerable breadths of Apple trees. On examining the orchards in Antrim and Armagh, we found that whilst the utmost care and skill had been brought to bear upon the Wheat, Oats, Flax, and other staple crops, it had been thought sufficient to simply plant the trees and leave the rest to Nature. When I tell you that the greater part of these orchards were planted from seventy to eighty years ago, and have since been practically left to themselves, you will readily understand that they give a very poor return. As a matter of fact, the majority consist of old worn-out trees, bearing plentiful crops of lichen and moss, with but little fruit, and that of the most inferior description. Not only are thousands of trees utterly exhausted, but a considerable proportion represent local varieties of the most inferior description, and therefore quite unfit for sending to markets in which the finer kinds make their appearance. We were repeatedly told by those who were old enough to remember the orchards when the trees were in a vigorous condition, that they had now ceased to bear satisfactorily because of a change in the climatic conditions, whereas the cause, as you so well know, is the exhaustion of the trees in consequence of old age and an impoverished condition of the soil. We saw but few signs of these old orchards being replaced by new ones. Here and there a few trees had been planted during the past few years; but instead of their having fresh ground they had

almost invariably been planted in the positions occupied by trees that had died out. As might have been expected, they had become a prey to mildew, lichens, and mosses, and presented a miserable starved appearance. Had we taken a superficial view of the case as presented to us in Antrim and Armagh, where Apple orchards occupy much space in proportion to their area, we should perhaps have regarded the production of first-class fruit in these counties as an impossibility. Knowing from practical experience and wide observation that the condition of the greater proportion of the orchards was due to old age and want of attention, we sought those which had a reputation in the several districts for the excellence of their fruit. We turned our attention also to gardens near at hand that were under the charge of men who had received a training in fruit culture. In the orchards that were in a fruitful condition we found the trees to be much below the average in age, and to have received some attention in the way of pruning and manuring. The gardens, however, afforded the best indications of the possibilities of fruit culture, not only in Ulster, but in the whole of Ireland.

Proceeding southwards we passed through a district on the boundaries of the counties of Meath and Dublin in which fruit growing is carried out on much the same lines as in the market gardens in the neighbourhood of London. In Ulster the whole of the orchards were in grass, but here the Apple and other standard fruit trees were planted at wide distances apart, and the intervening spaces filled with Gooseberries, Currants, and Raspberries. The whole of the standard trees were in a healthy state, showing that they received proper attention, but the crop was comparatively light, and as we were assured by those who were well acquainted with them much below the average. The various bush fruits presented the most satisfactory appearance, and had as usual borne heavy crops. It may here be stated that throughout the whole of Ireland, excepting of course in the mountainous districts, the whole of the bush fruits grow vigorously and bear heavily, the fruit being of the finest possible quality. No better crops of Currants and Gooseberries could possibly be desired than those we met with both in the north and south. For many years Gooseberries were rather largely imported, but they are now being planted somewhat extensively in one or two districts in Ulster, and they appear to be yielding satisfactory returns. The district between Drogheda and Gormanstown is not only remarkable as representing the most advanced stage of commercial fruit culture in Ireland, but it is distinguished by the general prosperity that prevails on all sides. In no other part of Ireland did we see the labouring classes so well dressed or having such comfortable well-kept houses as in the neighbourhood of Gormanstown, and it is fair to assume that the air of prosperity is chiefly due to the profitable character of fruit culture as there carried out.

South of Dublin the orchards on farms are comparatively few in number, and, as in the case of those in the north, they are chiefly furnished with old trees, more remarkable for the picturesque appearance of their lichen-laden branches than for their fruitfulness. But from the appearance of the orchards attached to the homesteads of some of the landed proprietors, and the condition of the trees in large gardens, it is evident that Apples of the finest quality might be profitably grown in many districts in the several counties between Dublin and Cork. In the Golden Vale there is ample evidence of the practicability of growing Apples of the finest quality, and here we met with an instance of the way in which suitable land might be increased by the judicious planting of fruit trees. On a large estate in which the rent of much of the land does not exceed 10s. per acre, there are several orchards that are let at a rent of about £3 per acre, which was not regarded by the tenants as in any way excessive. Here we found in full force the barbarous practice which obtains throughout Ireland of shaking the Apples from the tree, with the result that the greater proportion are bruised and rendered worthless for keeping beyond a few days. To gather the fruit by hand is considered a waste of time. We inquired of a young lady who was busily engaged in shaking down the fruit, how she secured the Apples that could not be shaken off, and she at once replied, "We knock them down with a long pole." In the valley of the Suir between Limerick Junction and Waterford, much of the soil and many of the situations are suitable for Apples. At one time cider of excellent quality was manufactured from Apples produced in this district, and the trees appear to have been allowed to die out. Whether the manufacture of cider was profitable or not we could not ascertain, but the fact that there were large breadths of free-bearing Apple trees is a proof that the district is on the whole well suited to their cultivation.

In speaking of the possibilities of fruit culture in Ireland, we are

anxious to be as guarded as possible in any expression of opinion. We should, however, fail in our duty were we not to state in the most emphatic manner that there is room, not only for improvement, but for an enormous development of the industry. There is no reason, apart from the apathy of the people, why Ireland should not only be independent of America and other countries for its supplies of Apples, but be in a position to export large quantities of that important fruit. We know that it receives immense quantities of American Apples during the winter and spring months, and in August we saw considerable quantities of Tasmanian Apples in the shops. There is evidently a good demand for Apples, and it is assuredly not a satisfactory state of things for the Irish people to import from countries some thousands of miles distant fruit that can be produced at home. The climate is admirably adapted to the growth of Apples, the heavy rainfall and the atmospheric humidity being favourable to the production of fruit large in size and clear in the skin. Cultivators not well acquainted with the conditions that obtain regard the atmospheric humidity as fatal to success. They, in fact, consider the ripening of the wood and the formation of the flower buds an impossibility with an annual rainfall of 40 inches. As the result of our observations and inquiries, I have to tell you that there is but little difficulty as to the maturation of the wood. On the shores of Lough Neagh, with an annual rainfall of about 35 inches, we saw in gardens and orchards under the charge of experienced cultivators heavy crops of all our best kinds of Apples. The fruit was not only plentiful, but of the largest size and finest quality. We were particularly struck with the crop of Stirling Castle, which was then being gathered for market, the price realised in Belfast being 16s. per cwt. The finest of our dessert and kitchen Apples were also met with in the most productive condition some ten miles south of Cork, where the annual rainfall averages 45 inches. In a fruit garden in the last named county Pears were bearing not less satisfactorily in the open quarters than were the Apples, the fruit of many of the varieties being equal to the finest samples received from the Channel Islands. Pears, Plums, and Cherries have so small a space in orchards, and are so generally grown against walls in gardens, that the extent to which they can be successfully cultivated in the open cannot at present be satisfactorily determined. It is a question well worthy of the attention of those who have opportunities for experimental culture. The probability is that they might in many districts be grown with considerable success. Inquiring of one cultivator whether he had many Damson trees, he said No; he had only two, and these usually produced about 3 cwt. of fruit each. The excessive moisture of the atmosphere is highly favourable to the growth of both mosses and lichens, more particularly the latter. They quickly attach themselves to the fruit trees, and when allowed to remain undisturbed they soon cover the whole of the branches and impose a check upon the growth, but evidently not so severe as might be imagined. To keep the tree free from both lichens and mosses is by no means difficult. We had a striking proof of this in a garden near one of the great cities belonging to a merchant, who devotes much attention to fruit culture. The garden contains comparatively large collections of Apples and Pears. The trees were all bearing heavy crops, and the fruit was so finely developed that it was not surprising to find the proprietor regarding fruit of Warner's King, weighing 1 lb. each, as by no means exceptional. The point, however, that we wish to bring out is the fact that there were no traces of either moss or lichen on the trees, and the immunity from these plagues was due to the trees being annually painted with a mixture of which clay, lime, and petroleum form parts. The cost is practically nothing, and the trees were equal to any that could be found in Kent.

To effect a general improvement in the condition of fruit culture in Ireland will be slow work, but with well directed efforts we have no doubt as to the ultimate success. We must first endeavour to create an interest among the owners of land, whether they be private individuals or corporate bodies such as the great City companies. Probably one of the best means for doing this will be to show, as in our report we shall be able to do, that many of the districts are well adapted to fruit culture, and that by judicious planting and management the value of the land may be greatly enhanced. What is especially wanted is the planting of experimental orchards on large estates in various parts of the kingdom. These are required for the purpose of testing the relative merits of varieties for the respective districts, and training young men in the management of orchards and the marketing of the fruit. The cost of planting from 10 to 20 acres with fruit trees would not be great, and whilst giving a good return annually the plantation would form a practical school of immense value. The conditions under which farms are now held are favourable to the planting of fruit trees, but

in the present state of their knowledge it is hopeless to expect tenant farmers to plant largely. Nor perhaps is it desirable they should do so until they have had opportunities for acquiring sufficient knowledge to engage in the work with the full assurance of success. Knowing how fruit culture may be made to increase the wealth of many districts, we are naturally anxious that there should be as few mistakes as possible. It would also be an enormous advantage if, in conjunction with these experimental plantations, the bottling and preserving of the soft fruits were carried on exactly as in the case of Lord Sudeley's fruit farm at Toddington, as it is essential that the utilisation, as well as the production of fruit, should receive a full share of attention. In the meantime much might be done to show that existing orchards may be greatly increased in value by judicious thinning of trees, by re-grafting worthless kinds still vigorous with the finest sorts, by manuring trees that are in an exhausted condition, and by keeping the wood free from lichen and moss by application of limewash or other suitable dressing.

It is not only desirable that there should be an extension and improvement in the culture of fruit for market, but the fruit trees should be planted more extensively on small farms and in cottage gardens for home supply. At the present time this phase of fruit culture receives but scant attention. Mr. Bullock Hall, one of our Vice-Presidents, has for several years past been doing much to promote the planting of fruit trees in Ireland, and has generously distributed large numbers amongst various classes of the community in the south. He is still engaged in the good work with such modification as experience has suggested, and it was gratifying to hear how greatly the majority of those who had received trees appreciated them. In a recent letter he complained that but little interest had been taken in the matter by the parish priests, and we refer to that point for the purpose of saying that with their influence they might do much to promote the profitable culture of fruit in gardens and small holdings, and thus render valuable service in the cause of the health and welfare of a large body of the community.

## PEACHES AND NECTARINES.

By Mr. T. F. RIVERS.

THE continually increasing imports of Peaches of not very good quality point to the fact that a demand exists. Although the Peaches on the street barrows are at present very inferior, if a profitable sale can be made the quality of the fruit will soon be improved, and the continental Peach orchards from which the supply is drawn will be planted with sorts that will command a ready sale and probably a higher price. In America the sale of Peaches is enormous, and thousands of acres are planted for the supply of this demand. The distance from their markets being as great as the available districts of France are from us, we may look forward some day (if a favourable soil and climate can be found) to the supply of the English markets by foreign growers. It will be for English growers to consider whether it is possible to compete successfully with the out-of-door Peach orchards, and to create a demand by the production of fruit which will tempt buyers to give a sufficient price to pay the producer.

It is absurd to suppose that in England wall culture without glass can ever be employed with profit for Peach growing, but a reasonable profit may, I think, be derived from cultivation under glass. Span-roof houses may be erected at a moderate cost. By planting half-standard trees with untrained heads the great expense of training will be avoided, and if the trees are not overcropped an annual and certain return may be expected in unheated houses from July to October. If glass cannot compete with foreign orchard Peaches in the supply of the streets, they can at all events supply the shops. During the last thirty years many varieties have appeared in England which have altered the conditions of Peach growing. Many gardeners can recollect that July Peaches, as a rule, were small and very inferior, this precocity being their only merit. In place of these small and worthless sorts we have large and good fruits, the earliest being the Alexander, which I received from Messrs. Capps & Son of Fort Pulaski, Illinois, U.S.A., about 1874. This is a large bright coloured fruit of excellent quality, freestone, and firm enough to bear carriage well. At the same time Messrs. Capps sent me the Amsden June Peach, quite as early, but not so good in quality. This Peach, however, appears to have improved since its introduction, as it seems to be popular with some. I have, however, invariably found it to be a clingstone and bitter. The Waterloo is another American Peach of good quality, ripening in my orchard house about a week after the Alexander. This is also a large bright Peach. After the Waterloo there is a series of July Peaches: the Early Beatrice, small, but a most abundant bearer; the Early Louise,

Early Rivers, Hale's Early, Early Leopold, all ripen in July in an unheated orchard house. In August the succession is continued by Rivers' Early York, a very valuable market Peach, the Early Grosse Mignonne, the large Early Mignonne, the Condor, Dr. Hogg, Crimson Galande, and Early Alfred. In September Peaches are numerous enough, and the best sorts are well known, the principal varieties being the Grosse Mignonne, Galande, Goshawk, Alexandra Noblesse, Noblesse, Royal George, English Galande, Stirling Castle, Dymond, Barrington, Princess of Wales, Nectarine, Late Admirable, Walburton Admirable, and Gladstone. Lady Palmerston and Golden Eagle are late yellow Peaches of excellent flavour. In October we have the Desse Tardive and Catherine, and in November the Salway and Comet. This seems a long list of Peaches, but I assume that Peach growing will be eventually entirely carried on under glass, and instead of the cumbrous trellis, trees will be grown in their natural form—that is, either as half-standards or bushes; and more varieties can, of course, be planted even in the area of a glass house than on trellises.

Of late years a very considerable advance has been made in the varieties of Nectarines. Before the Stanwick Nectarine was introduced into England the available sorts were very limited both in season and quality. The small and worthless Fairchild's Early was the earliest, ripening about the second week in August. We have now the Advance Nectarine in July, and in August and September a series of large and fine Nectarines very much superior in size and flavour to the older varieties. These are Lord Napier, Improved Downton, Spenser, Stanwick Elruge, Newton, Milton, Goldoni, Rivers' Orange, Humboldt, Pine Apple, and Victoria. These Nectarines will supply fruit from August to October, and there is a steadily increasing demand, consequent, I imagine, on the discovery that Nectarines of the present day are much better than those formerly offered for sale. This improvement is due in a great measure to the mixture of the Stanwick Nectarine race with the old sorts. There are two very distinct types of Nectarines, the orange fleshed and the green fleshed, the former being the more popular from its peculiar richness of flavour, especially when allowed to shrivel.

In my opinion a profitable business may be made by the cultivation of Nectarines alone, but no large profit can be expected from either Peaches or Nectarines grown on walls, or by the very expensive trellis training. Trees trained to walls are cultivated under conditions which can hardly succeed for any length of time. It cannot be conducive to the health or well being of a tree to place one side in perpetual shade during the summer when its best energies are required, this is done when the tree is placed against a wall, and when portions of the bark on all the branches are prevented from enjoying the healthy action of the sun by fastening with woollen shreds. Trees trained to trellises under glass are not, of course, grown under the same vicious conditions, but the system is expensive and the training tedious, and also requires to be managed by skilful practitioners.

The dwarf standard, either planted out or grown in pots, is the most profitable form. Span-roof 18 feet wide will take three rows of trees, and all the pruning and training can be managed with the budding knife and the finger and thumb. With an abundant supply of water and a calcareous soil I believe that a fair profit can be made even by cultivators who have not been specially educated for the business, but who have their wits about them and a good faculty for observation. I should not recommend lofty houses. Every tree should be grown at a height which the cultivator can reach, as during the time when the Peach is starting in growth it seems to be singularly liable to the attacks of those intolerable nuisances red spider and aphis, which will certainly prevent success if not destroyed as soon as observed, on low trees they are sooner found out, and when once a vigorous and healthy growth is established there is no danger to be feared. Abundant ventilation and sunlight are two of the primary elements to bring about this desirable result.

## PLUMS FOR MARKET.

By Mr. J. SMITH, of Mentmore, Bucks.

IN the few practical remarks that I am about to make it is not at all necessary for me to decide from what part of globe we first obtained our cultivated Plums, whether from America, Asia Minor, or if they were found wild in Europe; this can be best determined by our botanical friends. I consider the Plum next in importance to the Apple in a commercial point of view. In years of plenty they can be dried, in which state they will keep good for years. They can also be made into jam, which will keep for a considerable time.

In growing for market one of the first questions asked is, What varieties would you recommend? Now, this is a very important point,

for when you go into a nursery to purchase trees you will find, as a rule, all varieties are charged the same price, except it be some new and untried variety, which may be charged a fancy price for a year or two. It is a well-known fact to fruit growers that in certain localities and on certain soils one variety will flourish and bear abundant crops year by year, while other varieties will never grow enough fruit to pay for the first outlay. I may just give one well-known instance to impress on growers the importance of this being well understood before recommending certain varieties for any given district or soil. At Sawbridgeworth Messrs. Rivers have, as a rule, splendid crops of Rivers' Prolific Plum; in fact that variety seems perfectly at home in the stoney clay of that district. Here, in a chalky clay which suits many varieties admirably, Rivers' Prolific grows freely, but seldom bears any fruit, although, as a rule, the trees flower freely. The question of selecting suitable varieties for any given district can only be learned by practical experience and observation. Growers of the Plum are aware that the number of varieties of the cultivated Plum is almost legion. I have just gone through one catalogue before me, and find no less than 237 varieties described, with a supplemental list of some 180 more, or in all, say, about 400 varieties. Now, this would plant about 4 acres of ground of one plant or tree of each variety. But would any grower who had any idea of making a profit be foolish enough to plant these, or even half this number? It would be a far more profitable investment to plant only one variety on the 4 acres, but this I should by no means recommend. My idea of Plums for market is to find out five or six varieties that are known to succeed in the district, and plant only these.

I have already remarked that certain varieties favour certain districts. Here the soil is a strong chalky clay, and the following varieties are grown by hundreds, and in the case of the Damson by the thousand:—Green Gage, Jeffersons, Mitchelsons, Gisbornes, Victorias, and Damsons. Victorias and Damsons are most grown.

This might well be termed the "Home of the Damson," for many acres are planted, and during the fruit season from twenty-five to thirty tons per week of these are sent away from our railway station. The Damsons here sell for more money than any other variety grown. In seasons of plenty they have been sold as low as £3 per ton, and other years they have made from £35 to £40 per ton.

The plan adopted is to plant on grass land at a distance of 22 feet apart each way. This will give about 105 trees per acre. Nothing but standards should be planted, and they should always have a clear stem of 6 feet. Before deciding to plant a field, the ground selected should be thoroughly drained, as stagnant water about the roots would soon prove fatal to the trees. In planting young trees a small portion of rotten manure may be mixed with the soil if the ground is poor, but I never make a point of recommending much manure to be placed in immediate contact with the roots while the trees are in a young state. I consider it better to merely mulch the trees with rotten manure after they become established. In planting the trees should be kept slightly above the ground level, as they are sure to settle down, although the ground is made firm, which I should strongly recommend. Immediately the trees are planted they should be securely staked, and the heads cut close back, only leaving two or three eyes on the young growths. Established trees should be gone over every year, and a certain portion of the small shoots removed, so as to keep the centres of the trees clear and open for the sun and air to reach every part of the trees. In many districts where the Plum flourishes I am aware that they are grown much closer, and many growers prefer bush trees, but of this style of growing I have had no practical experience, and shall pass it over for someone who has had experience to take this part of the subject up. In the orchards here sheep, calves, and poultry are kept to the mutual benefit of all.

It sometimes happens that some of the young trees will in a few years become "stunted" and hardly make any growth, more especially Damsons. My plan with such trees is to cut them hard back, almost to the stem; by this means they often start away and make vigorous growth. If the ground is at all poor it is a good plan before cutting them back to lightly break up the surface all round the trees, say 6 or 7 feet all round, and on this ground spread three or four barrowfuls of good manure. If this is done early in the autumn, so that the rains can wash the properties of the manure to the roots, the trees will start away with fresh vigour, and form fine healthy shoots the first season. I consider the Damson the most profitable for field cultivation. Next to it comes the Victoria Plum. Many acres of Damsons are grown here, and from experience I find the Farleigh, or Cluster Damson, is the hardiest of all; it will be found fresh and good when other varieties of the Damson are completely spoiled by frost. The Prune Damson as grown here is

very late and hardy ; the tree is of a spreading habit of growth, and the leaves are larger than any other variety I know.

I shall conclude with a few remarks as to the marketing of Plums ; next to growing them this is of the most importance to the gardener. How to make the best of them is the question ? I have known growers who have taken great pains to pack as much straw as possible in the bottom of the sieves, so that they may have more bulk for market ; this, I can assure growers, is a mistake. It is also a mistake to select the very best samples for the top of the baskets. I have been sending Plums to market by the ton for the last fifteen years, and my plan is to pack the bulk of one uniform quality throughout, and where this is done the buyers soon get to know and purchase accordingly.

### CENTROPOGON LUCYANUS.

THIS is an evergreen plant with pale green rather large leaves, and terminal heads of bright red, long tube-like flowers. It is of moderate growth, attaining a height of about 2 feet ; but small plants may be flowered at a height of from 9 to 15 inches.

Cuttings of the young shoots may be inserted at any time, and in a gentle heat they root freely. I usually insert the cuttings as soon as shoots 3 or 4 inches in length can be had. They are cut below the lowest joint, the leaves removed 2 inches up the cutting, and then inserted singly in pots 2½ inches in diameter, using a compost of two parts fibrous loam, one part leaf soil, and one part sandy peat, with a free admixture of silver sand. In putting in the cuttings make a hole in the centre of the pot, drop in some silver sand, and fill up round the cutting with the same material ; then water gently, and place the pots in a close frame with a temperature of 70° to 75° at night, keeping close, shaded, and moist until the cuttings begin to grow ; afterwards admit air, and gradually harden them off. They will root all the more freely if they have a bottom heat of 75°.

When the roots are matting the sides of the pots shift the plants into 4½-inch pots, using the same kind of compost as before, and place them in a house with a temperature of from 65° to 70° at night, having a moist well-ventilated atmosphere. The shelf of a stove so situated that the plants may be 15 inches from the glass will answer well. They will need to be encouraged by a gentle sprinkling overhead two or three times a day, and moderate watering at first, increasing the supply as the pots become full of roots ; but when the plant has taken to the fresh soil after having been potted, the shoot ought to be cut back to within three or four joints of the surface of the soil, which will render watering less necessary for a time, and yet the moisture must be sufficient for free growth. By August the plants should be in their largest pots, which for this class of plants may be 7 inches in diameter. The drainage should be good, but need not be excessive, and the plants must have a moist atmosphere and due supplies of water to keep them in a free state of growth. This treatment should be continued until they have made a good growth, and as it will be of no use for flowering unless it is strong, stiff, and short-jointed, they must be kept close to the glass and well attended to in point of ventilation.

No training is required, for by turning the plants round frequently and exposing opposite sides to the light, they will grow evenly. Irregular growth, however, may need some regulation, which should be seen to in time ; a peg at first may give the required direction to a shoot, which, if allowed to grow unassisted, might require a stake to bring it to the position desired.

After October the plants should have the lightest and most airy position in the stove, and the watering should be no more than is sufficient to keep the foliage fresh. This will cause the wood to ripen, and the terminal head or point of the shoot to set for flower. When the plants show signs of flowering water more freely, but avoid making the soil sodden, or syringing much overhead. Though sprinkling overhead once or twice a-day does good, yet when it is heavy, and the leaves remain long wet, they become spotted and fall. The plant usually flowers in January, and continues until April. The heads of bloom are excellent for cutting, and though it is not so attractive a plant as many, it is nevertheless useful for decorative purposes, and deserves extended culture.

Centropogon Lucyanus is a stove plant, but may be grown in a house having a winter night temperature of 50° to 55°. The main point is to secure good growth in summer by giving plenty of heat and moisture, and in winter it endures dryness and coolness, and flowers all the better under these conditions.

Should plants in small pots be wanted, the points of the strong-growing shoots may be taken off in July, inserted in small pots, and struck in heat, shifting them in August into 4-inch pots, and keeping them on shelves near the glass. Thus treated they will flower on stems from 6 to 9 inches high, and are very pretty.

The old plants need only have the worn out and weak wood cut out in April, and after they have pushed fresh shoots a few inches long, they should be shaken out and repotted, keeping them close, moist, and shaded for a few days until established. Shift them into their largest pots at the end of July. A well-grown large plant is very handsome at midwinter, and invaluable where cut flowers are in demand, as it will in no way be impaired by the removal of the bloom, for all the blooming shoots need to be cut back.—G. A.

### INSECTS OF THE FLOWER GARDEN.

(Continued from page 68.)

A NOTORIOUSLY destructive group of insects is that we call the straight-winged order, or the Orthoptera, insects wonderfully agile, sometimes musical, sometimes strange in form and mysterious in habit, but which, happily for us, do not much infest our English gardens. One member of the tribe, the migratory locust—a chance visitor here—is not only terribly injurious in Asia and Africa, but comes as near to us as the Continent, where flowers, vegetables, and fruit are often swept away by their ravenous hordes. These insects pass through a pupal stage, but they are as active in that as in the larval and winged stages, and though the wing-cases are soft, the jaws are like those of the beetles, and powerful. This fact may be easily ascertained by anybody who has a chance of laying hold of the great green grasshopper, which is a haunter of hedges, and occasionally leaves these to take an excursion in any flower garden that may be near. If seized, it can bite sharply enough to cause pain, but as entomologists think this grasshopper is partly carnivorous in habit, it need not be expelled, possibly it feeds upon aphides and similar “small fry.”

The grasshoppers, locusts, and crickets belong to that division of these insects known as the “jumpers,” the other divisions are the “walkers” and the runners. Some have expressed surprise to me that the common house cricket, fond as it is of warmth and moisture, is not frequently found resident in stoves and forcing houses ; the species does indeed occur sometimes, but it is unusual, so far as I have observed. The preference these insects show for bakehouses and kitchens indicates that such places yield them not only shelter but food, and the latter they may not be able to get in our houses. Though some years ago it was agreed, from the quarrelsome character crickets exhibit, that they must be carnivorous naturally, it seems now ascertained their food is of a vegetable kind. Perhaps it is quite as well that our gardeners have comparative freedom from the monotonous “song” of this species, which is to many persons a very worrying sound, and according to old authorities on the subject of insect-killing, to slaughter crickets is a sure way to bring ill-luck upon oneself. The common species of field cricket now and then quits the fields, and disports itself amongst our shrubs, or leaps over our lawns ; however, it does neither good nor harm. Erasmus Darwin credited it with the power of foretelling a change of weather, for he states that the chirp is sharper before approaching rain, the damping acting upon the insect's drum or sounding board.

In some of the midland counties, and in the west of England, the mole cricket (*Gryllotalpa vulgaris*), also called the churr worm, or croaker, by some rustics, from the sound it makes, is noticed some years to be the cause of mischief in flower gardens or amongst vegetables ; in other seasons it confines its operations to banks and fields. It is a remarkably muscular insect, and there is a peculiar development of the forelegs, suggesting a comparison to the limbs of the mole, as there is a broad and flattened digger armed with claws. Aided by this the mole cricket makes long runs or tunnels, gnawing the roots of plants, and, like its namesake, often betraying the course it has taken by a ridge of earth raised over the track. There must be some natural check upon the increase of mole crickets, for the females deposit a large number of eggs, about 300 Rosel reckoned, and like their parents their life is subterranean, but they cease to eat during very cold weather. It has been found that the adults cannot turn round in their burrows, but they are able to move backwards as well as forwards. At night they fly out to start new colonies, moving rather oddly by a succession of jerks. I am afraid there is not much advantage in trying to kill mole crickets by applying poisonous compounds to the soil, and the best way of dealing with them is to catch the adults at the egg-laying season when they are taking their excursions.

A household insect of this order, too, unpleasantly common in town and country, is the cockroach (*Blatta orientalis*), also called blackbeetle incorrectly. I have already noted the fact in these pages that this repulsive insect sometimes quits the domestic regions, which are its headquarters, and goes out of doors for a change, generally preferring the autumn. I have seen them along flower beds where they cannot do much harm, but if a greenhouse

is accessible they will enter that and gnaw the stems of young plants. Owing to the nocturnal habits of the species they may escape detection, concealing themselves in nooks and corners till they return to the kitchen or laundry. This insect is not truly British, but a native of the Levant, and far surpasses in size our own species of the same tribe. I have received specimens of one of these taken in some border, sent on the supposition that it had been doing mischief. It bears the name of *B. germanica*, given to it, probably, because it is so abundant in many parts of Prussia, also in Russia. This is of a pale brown colour, about half an inch long, and, like its larger relative, fond of keeping out of view by day. From its being usually observed amongst heaps of dead or decaying leaves I should consider it is an insect almost harmless.

Where there are ponds near flower gardens dragon flies are likely to be seen during the summer and autumn flying over the flowers, intent upon capturing some of the numerous insects that are attracted to the plants. Mostly it is only the dragon flies of size and strength that occur in gardens; the small and more delicately formed "demoiselles" of brilliant colours, with other species akin to them, are only now and then found on the wing at any distance from the stream or pond in which their larval life has been spent. It is to the larger species, those we usually see about gardens, that the popular name of "horstinger" belongs, certainly inappropriate, as they make no attacks upon horses or animals; nor can they sting at all, though the tail in some of them has a curious appendage that might pass for a sting. These flies, indeed, seldom try to bite the hand if they are grasped, and, like the rest of the species in the order Neuroptera, or the net-winged insects, they are either serviceable to man or not injurious to plants he cultivates. It is a pretty sight to see one of these "dragons of the air," as they may well be called, careering above our garden paths and beds, both wings and body glittering in the sunshine. They possess the power owned by no other winged insect, of flying backwards, forwards, and sideways without turning; this enables them to chase their prey rapidly whenever it happens to double. Of course, among the insects they capture there are some that are harmless, butterflies for instance, but they kill many that are mischievous; thus a dragon fly will tackle a wasp bravely enough, and it now and then happens that in the conflict the dragon fly is worsted. A much smaller, very pretty, and decidedly useful insect of this order, which we may often see crawling on herbaceous plants and on Pelargoniums, is the lace-winged fly (*Chrysopa vulgaris*), and whenever one of these is observed displaying its thin greenish-pink wings and eyes of gold, it should be left unmolested. If a female insect, it is probably engaged in the work of depositing eggs upon the leaves; these eggs are placed upon footstalks some lines in length, and would not at first be taken for the eggs of any insect. The larva of this fly devours enormous quantities of aphides, yet it is supposed to have no eyes, therefore it must hunt them by the sense of touch, and it is remarkably agile in its movements.—ENTOMOLOGIST.

## ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 9TH.

THE exhibits were not numerous at this meeting, but comprised fine representative collections of Dahlias, Gladioli, trees, and shrubs. In the afternoon the paper by M. Lemoine on Gladioli attracted a good audience.

FRUIT COMMITTEE.—Present: John Lee, Esq., in the chair, and Messrs. F. Jamin, R. D. Blackmore, P. Crowley, Harrison Weir, A. H. Pearson, G. Bunyard, J. Smith, G. Norman, J. Hudson, F. Q. Lane, A. Watkins, and J. Cheal.

Messrs. J. Carter & Co., Holborn, sent fruits of Market Favourite Tomato and large Melon named Holborn Favourite. Mr. R. Maher, Yattendon Court, Newbury, sent samples of two seedling Grapes from Black Alicante crossed with Black Hamburg, and the "Early White Hamburg" from the Red Sweetwater. The Committee desired to see the former again; the latter was passed without comment. The Rev. W. Wilks, Shirley, Croydon, sent two fruits of a Pear named Marguerite Marrellat, thought to resemble Souvenir du Congrès. Mr. A. Selby, Radcliffe-on-Trent, showed seven dishes of fine Potatoes. (Cultural commendation.)

Mr. J. Walker, Ham, exhibited twenty-three dishes of Apples, comprising good examples of Lord Grosvenor, New Hawthornden, Grenadier, Lord Suffield, Stirling Castle, Lane's Prince Albert, and others (silver Banksian medal). Mr. T. H. Crisp showed a collection of fruits—Apples, Pears, Figs, Peaches, and Nectarines, all good specimens (cultural commendation). Messrs. Paul & Son, Cheshunt, showed ten varieties of Nuts, Red and White Filberts, Cut-leaved Nut, Pearson's Prolific, Kentish Cobs, Princess Royal, Purple-leaved Filberts, Frizzled Nuts, Cosford, and Merveille de Bollwyller. (Vote of thanks.)

*Melon Ely's Seedling* (Mr. Ely, Joyce Grove, Henley-on-Thames).—A green-flesh Melon of good flavour, the flesh deep, and the skin well netted.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair;

and Messrs. R. Dean, H. B. May, H. Cannell, C. T. Druery, Shirley Hibberd, F. Moore, G. Paul, J. Fraser, C. Noble, W. Holmes, J. Walker, J. O'Brien, Lewis Castle, Dr. M. T. Masters, and Rev. H. H. D'Ombraim.

Messrs. H. Cannell & Sons, Swanley, had a most attractive group of Cactus Dahlias, amongst which the following varieties were noteworthy:—*Lacineata aurea*, bright yellow; Lewis Castle, rich bluish purple; Empress of India, deep maroon; Dr. Peters, orange red; Cannell's Favourite, deep orange; and Maid of Kent, maroon-tipped white, for most of which awards of merit were adjudged.

Messrs. Kelway & Son, Langport, had a wonderful collection of Gladioli spikes. (Silver-gilt medal.)

MM. V. Lemoine et fils, Nancy, contributed an interesting collec-

FIG. 28.—HABENARIA MILITARIS.

tion of Gladioli of the Lemoinei and Nancianus types (silver Banksian medal), Gladiolus Nancianus Le Grand Carnot (M. V. Lemoine et fils). spike long, flowers large for the type, salmon red, creamy white in the centre. (Award of merit.)

Messrs. Paul & Son, Cheshunt, had an exceedingly interesting and extensive collection of specimens of finely variegated and ornamental trees and shrubs (silver Banksian medal.) Specimens of Acer Van Volxemi were shown by Dr. Masters to illustrate the rapid growth of the tree at Ealing. (Vote of thanks.)

Mr. T. H. Crisp, Canford Manor Gardens, Wimborne, secured the medal offered by Messrs. Kelway & Son for twelve varieties of Gladioli with well-developed spikes and flowers.

ORCHID COMMITTEE.—Present: Harry J. Veitch, Esq., in the chair, and Messrs. J. O'Brien, S. Courtauld, Lewis Castle, F. Sander, J. Douglas, E. Hill, J. Dominy, C. P. Pilcher, and Dr. M. T. Masters.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (gardener, Mr. W. White), exhibited seven remarkably well-grown plants of Habeneria militaris bearing large heads of its peculiar bright red flowers. See fig. 28. (Silver Banksian medal.) A plant of Cypripedium glanduliferum was sent that was considered to be identical with C. præstans.

Messrs. F. Sander & Co., St. Albans, sent several interesting Orchids, comprising grand specimens of *Miltonia candida superba*, having eight long racemes of richly coloured flowers (cultural commendation). T. A. Gledstones, Esq., Gunnersbury (gardener, Mr. H. Denison), was awarded a cultural commendation for a strong plant of *Dendrobium formosum*, with twenty fine flowers. A plant of *Vanda Sanderiana* was also sent, with a raceme of nine flowers. T. Statter, Esq., showed several plants, for which awards were granted. A large plant of *Dendrobium album*, having four long flowering growths, received a cultural commendation.

## PLANTS CERTIFICATED.

*Cattleya aurea Statteriana* (T. Statter, Esq., Stand Hall, Whitefield, Manchester; gardener, Mr. R. Johnson).—A handsome variety, the sepals and petals yellow, the lip rich gold, edged light crimson, and veined with deep crimson in the centre. (First-class certificate.)

*Laelia elegans Turneri*, Stand variety (T. Statter, Esq.).—A fine variety, distinguished by the size of the broad, rounded, rich purplish crimson lip.

*Crococoma aurea var. maculata* (Mr. J. O'Brien).—Bright orange flowers with a deep crimson blotch in the centre of the three inner divisions.

*Godetia Duke of Fife* (Messrs. Daniels Bros., Norwich).—Flowers deep crimson with a silvery centre.

*Dahlia Lorina* (C. Turner).—A Show variety, orange bulb, fine bloom.

*Rubens* (C. Turner).—A Pompon variety, crimson tipped white, neat.

*Marion* (C. Turner).—A neat Pompon of a soft rosy tint.

*Gladiolus Leonard Kelway* (Kelway & Son).—A distinct velvety crimson, faintly edged purple.

*Gladiolus Lemoinei Mié Blanc* (M. V. Lemoine et fils).—Very distinct; the flowers small, of a distinct bluish purple shade.

*Gladiolus Lemoinei E. V. Hallock* (M. V. Lemoine et fils).—Flowers neat in form, creamy white, two inner small petals reddish crimson at the base tipped with golden.

*Dahlia Black Prince* (Mr. J. Green, Dereham).—One of the "Cactus" type, of an exceedingly dark maroon colour.

*Dahlia Crimson Beauty* (Mr. T. S. Ware).—A very neat Pompon variety, dark velvety scarlet, florets flat.

*Dianthus caryophyllus Margaritæ* (James Veitch & Sons, Chelsea).—An attractive strain, with red, rose, orange, salmon, and white flowers (award of merit). It was stated that "the seed was sown early in March in a warm frame; the seedlings were transplanted in a cold frame as soon as large enough to be removed, and they were planted out of doors early in June. The plants were lifted from the open ground."

EVENTS OF THE WEEK.—To-day (Thursday) the National Chrysanthemum Society's early Show is continued at the Royal Aquarium, Westminster, also the Brighton Horticultural Society's Show in the Royal Pavilion. In connection with the last-named, the British Fruit Growers' Association hold a conference at 4 P.M. in the King's Room, the Mayor of Brighton in the chair. On Friday, September 12th, and Saturday, September 13th, the Royal Botanical Society at Manchester will hold a large fruit Show in the gardens at Old Trafford. The annual Exhibition of the Galashiels Society also takes place on September 13th.

— THE WEATHER in the METROPOLITAN DISTRICT has been exceedingly fine during the past week, bright, warm, sunny days being followed by clear nights. The day temperatures have on several occasions risen very high, Monday and Tuesday being especially hot; but at night there has been a corresponding fall, with slight frosts in some low situations.

— MANY will learn with regret that MR. JAMES BACKHOUSE died at West Bank, York, on August 31st, aged sixty-five years. Mr Backhouse was the head of the firm of Messrs. Backhouse & Son of York, and had from his earliest years devoted himself to the study of plants. Ferns were great favourites, and his beautiful fernery and wonderful collection of Filmy Ferns had many admirers. Under his management also large collections of Orchids and hardy plants were formed in the York nurseries.

— WE are informed that the B. S. WILLIAMS MEMORIAL is making fair progress, and the list of the Committee has been consider-

ably enlarged. In the list recently published the name of Mr. Henry Cannell of Swanley should have appeared, as he was one of the members appointed at the meeting of August 12th. The omission was the result of an error in copying. Mr. Cannell has subscribed 5 guineas.

— GARDENING APPOINTMENT.—Mr. Albert E. Sutton has succeeded Mr. R. Burn as gardener at Naworth Castle, Brampton, Cumberland.

— MR. W. BARDNEY writes:—"On the morning of the 30th ult. we experienced what may be termed our FIRST FROST. There had been every sign of frost for some days previously, for the grass early each morning was white. On Saturday it was hard and stiff. This was followed by a sharper frost on September 1st. Not a mile from the garden, on the slope of a hill facing north, there was ice the thickness of a penny. The gardens are sheltered, and lay to the south. Fortunately we escaped without injury, but tidings reach me of the destruction of French and Scarlet Runner Beans only a few miles away."

— THE same correspondent remarks:—"POTATOES are very badly diseased. In several cases more than half the crop is affected, and large quantities have decayed since they were housed. So far Empire State has resisted the disease more than any other variety. The tubers are large—too large—many of them for table use, but the crop was abundant. Beauty of Hebron has perhaps suffered more from the disease than any other variety."

— YOUR correspondent, Mr. John Williams, asks for further information respecting TRUFFLES. At one time they were very common on this estate, and several trained dogs were kept for the purpose of finding this fungus. This was done in the following manner:—The head gamekeeper had charge of these dogs, and when he received orders for Truffles, these dogs were taken to the most likely parts of the woods or plantations. Truffles have a peculiar smell, which attract the dogs, and when they come upon them they immediately commence to scratch. The Truffles were then dug up, and for each Truffle the dog which found it received a biscuit; and sufficient Truffles were found in a morning search for the requirements of dinner in the evening. Of course all this is a thing of the past. No dogs have been kept for many years, but no doubt the Truffles grow the same; indeed I have found them many times under Beech trees, and I think I could soon secure some again if I made a search. I have never seen one approaching that figured in your last issue. The largest I ever saw was not larger than a Walnut. Those found in this neighbourhood are not unlike a Walnut in shape; dark brown in colour, with warts all over them, which are almost black. The flesh is of greyish colour, and, as you say, veined with blackish marks; and the smell they give off is certainly not unpleasant. If they are such a luxury why is not their cultivation taken up? Or are they too long in coming to maturity? One thing is evident, I shall not be the first to make the attempt.—T. ARNOLD, Cirencester.

— MR. YOUNG also writes, "It may interest Mr. Williams to know that Truffles are fairly plentiful in some parts of Herefordshire. Whilst living at Holme Lacy we found numbers under Laurel bushes."

— RUNNER BEAN NE PLUS ULTRA.—In common with many other gardeners we have given the above Runner Bean a trial, and must say that it is a decided improvement. The pods hang in bunches, are long and handsome in appearance. The quality is good.—A. YOUNG.

— LILIUM LONGIFLORUM.—I send you a photograph of a group of *Lilium longiflorum* grown in a corner of my garden at Croydon. I planted twenty-four bulbs bought late last autumn—about November—and they have turned out splendidly, the stems being about 3½ feet high, and throwing in most cases three to five flowers, I think in one case only two flowers, the flowers being fully 9 inches long, and perfect, not a single case of splitting, which I have found to be rather a common failing of *L. longiflorum*. In this clump there were about sixty flowers open at one time, and they had a very fine appearance, the photograph not doing justice to the reality. I bought and planted at the same time ten *L. auratum virginale*, twenty *L. a. platyphyllum*, and ten *L. lancifolium Melpomene*. They are all doing very well, as have most of my Lilies this year, the sole exception being *candidum*, of which having a large number I am getting rather despondent. I have tried various remedies for the disease so prevalent. New loam and replanting seem, so far, to have had no effect. The bulbs seem quite

healthy when lifted.—CHARLES T. GRAHAME. [The photograph represents a border of vigorous well-flowered plants of *L. longiflorum*, a beautiful feature in any garden.]

— THE best crop of fruit that has this season come under my notice is at THE GRANGE, CO. LIMERICK, the residence of Captain Croker. Strawberries and all other small fruits have carried enormous crops. The Plums and Pears on walls would surprise many people, who run away with the notion that fruit cannot be grown in Ireland. Pyramids in the open garden were carrying equally heavy crops. Apples, too, are an astounding crop on pyramids and espaliers, but the palm must be awarded to an espalier-trained tree at the back of the herbaceous borders. As near as I can recollect the tree would be 20 feet long and 6 feet high, and was carrying several hundreds of magnificent fruit. The gardener, Mr. Wilmot, calls it Summer Queen. Is it a local variety? I have never seen or heard of it before.

— BEGONIAS.—In a conservatory in the same gardens I saw the finest collection of single and double Begonias raised from seed purchased from Messrs. Laing of Forest Hill, that I have yet seen outside of that famous home for Begonias. If The Grange were near London the Messrs. Laing would have to look to their laurels. The present wet season has again proved the value of Begonias as bedding plants. Here, as at home, we find the beds of Begonias a brilliant mass of flower. Pelargoniums, on the contrary, had no flower at all, but a grand lot of leaves. In the flower garden two large beds of Clematis Jackmanni—formed by training the growth to wires fixed a foot high—were strikingly beautiful objects, and well worthy of imitation.

— EUCHARISES appear to be happy enough at The Grange, judging from the luxuriant foliage and the forest of spikes now commencing to push up. In the same house—an ordinary plant stove—was a small collection of Orchids. Dendrobiums had made excellent stout short-jointed growth, and the plants were then being removed to an early vinery to rest. Cattleyas were making grand growth; all were in excellent health. A fine piece of *Davallia fijiensis*, measuring 12 feet in diameter, was especially noteworthy. A few specimen *Adiantums*, with other foliage and flowering plants, are grown here. Fruit under glass calls for no special notice. It may interest your readers to know that Nuts are a grand crop this year in this county.—HANDY ANDY.

— NAMING EXHIBITION FLOWERS.—In order to avoid disappointment to exhibitors of such flowers as Begonias, Cinerarias, Calceolarias, Cyclamen, &c., would it not be as well if those who have the drawing up of prize schedules would state in their rules that such plants should be exhibited without names? Let the exhibitor only put one card, naming the class of plants for the public benefit, for information of visitors. The present rule of schedules, which compels the naming of everything, surely ought not to apply to seedlings. In these days, when so many new varieties of softwooded plants are constantly coming to the front, something ought to be done at flower shows to avoid confusion of varieties. For my part I do not approve of gardeners exhibiting seedling plants or flowers and placing whatever names they choose upon them. If they exhibit a collection of Gladioli or Dahlias which have been grown from mixed seed, let such be named, "seedlings only," otherwise a visitor might be tempted to take down a name of some striking variety, and in vain try to obtain the plant at some nursery. I consider only nurserymen ought to name seedlings, at the same time to enter them in their respective catalogues, then the public would have a better chance to obtain the varieties exhibited.—A. J. L., *Hants.*

— THE news of the death of MISS MARIANNE NORTH, the accomplished botanist and artist, who a few years ago presented to the nation an exhaustive botanic picture gallery at Kew Gardens, will be received with widespread regret. This lady, in the course of her travels, made a collection of pictures of highly interesting subjects, painted by herself from Nature. It is virtually a pictorial record of her expedition round the world. Among the countries whose natural products were thus carefully delineated may be mentioned Teneriffe, Brazil, Jamaica, California, India, Ceylon, Borneo, Singapore, Java, Japan, Australia, and New Zealand. Besides the scientific interest of the collection there are several fine landscapes and striking bits of natural scenery, as well as glimpses of the social aspects of life in those lands. The pictures and objects are to be seen in a building, specially erected at her own expense, in the Royal Gardens, Kew. In the pursuit of her art Miss North visited more lands than any painter of the time. A quarter of a century

ago she visited the East, and for two years knew the fascinations of Egypt and Syria. It was her Eastern tour, perhaps, that determined her final choice of painting as a profession; for though she had practised it for years it was rather as a pastime and an accomplishment. As a painter Miss North specially cultivated landscape and natural history. Her Sicilian landscapes, painted twenty years ago, are well known, and attracted much attention at the time. Miss North's last journey to South America brought on a long and painful illness, to which she has just succumbed at her residence in Gloucestershire. She was sixty years of age.

— THE YORK GALA.—A meeting of life members and guarantors of the York Gala Society was held recently at the North-Eastern Hotel, under the presidency of Sir Joseph Terry. The following were present:—Ald. Rooke, Ald. McKay, Councillors Browne and Milward; Messrs. Balmford, Blenkin, Dunkley, Anderson, Craven, and Border. Sir Joseph Terry said it was a pleasure to learn that this year the Society had been very fortunate. They had given freely of their profits, and they anticipated another year giving as they had done on the present occasion. The total profit on the fête had been £258 13s. 2d., and the Committee had agreed to make the following donations:—County Hospital, £40, Dispensary £40, Bootham Asylum £20, Charity Schools £20, Boys' Industrial School £10, Girls' Industrial School £10, the Penitentiary £10, and the Yorkshire Society School in London £10. A few days after their last meeting the Committee received information of the death of Mr. B. S. Williams of Upper Holloway, and a request that they would contribute to the proposed "Williams" Memorial fund. They had had the advice of Mr. Williams since the inauguration of the gala. It was, therefore, with much satisfaction that the Committee had resolved to give a donation of £10 to the Memorial fund. Votes of thanks were accorded to the following officers:—The Sheriff of York (Mr. Councillor T. Clayton), President; Sir Joseph Terry, Chairman; Mr. Joseph Wilkinson, Treasurer; and Mr. C. W. Simmons, Secretary. Similar acknowledgments were paid to the officers of the 10th Royal Hussars, for allowing their band to play at the gala; to the donors of special prizes; and to Mr. J. Welburn (N.E.R.) for providing a satisfactory service of trains. The fixing of the date of the next gala was left to the Floral Committee.

— MANY of our readers to whom the name of "WILTSHIRE RECTOR" has long been familiar, will regret to hear that through ill health he has been obliged to resign his living of Hardenhuish, near Chippenham. For many years Mr. Headley charmed as well as instructed the readers of this Journal by his admirable papers on rural subjects generally, and more particularly by those treating of fowls and pigeons. We extract the following from the *Devizes and Wiltshire Gazette*:—"We regret to learn that the Rev. A. Headley, for many years rector of Hardenhuish, and who has been well known in and near Chippenham for more than a generation, has been compelled to resign the living through failing health. After being at Christian Malford as curate to the late Rev. R. V. Law, Mr. Headley went to Hardenhuish in 1856, first as curate in charge, and afterwards (in 1857) as rector. During the thirty-three years that have since elapsed many changes have taken place; and we may add, many improvements, and as long as health and strength lasted we know of no one in the neighbourhood of Chippenham who took a more lively and sympathetic interest or who was always more ready to lend a helping hand in any good cause, not only in his own parish, but in the town in whose immediate neighbourhood his lot had been cast, than Mr. Headley. In his earlier years he was a most active supporter of the Chippenham Literary and Scientific Institution, and delivered various interesting lectures in the Town Hall. He was also the President of the Chippenham Penny Readings in their earlier and better days, and was widely known as the 'Wiltshire Rector' of the *Journal of Horticulture*, on whose staff he acted as a valued correspondent for upwards of twenty years. He was one of those who helped to start the Chippenham Horticultural Society, now twenty years since, and always took a lively interest in gardening, poultry, pigeons, and other kindred pursuits, which do so much to make a country clergyman friendly with his neighbours and parishioners. Turning, in conclusion, to the most important part of his work, the spiritual welfare of the parish in which he was so long rector, the parishioners generally will mourn his loss as one who preached powerfully and eloquently the great message of Salvation; while as a kind friend in trouble and affliction he will long be held in affectionate remembrance. Mr. Headley was an earnest supporter of the Church Missionary Society, and for many years local Secretary of the Church Pastoral Aid Society. Two years since he had a slight seizure, followed by another in the beginning of

this year, and we understand he leaves next month under medical advice for the milder climate of South Hants, where he has taken a house, and where, we trust, he may be spared for some years to come."

— ALLOTMENTS AND SMALL HOLDINGS.—The return of allotments and small holdings in Great Britain, obtained from the Board of Agriculture by the Inland Revenue Department, has just been issued as a Parliamentary paper. It appears that there are 455,005 separate detached allotments now existing, and 409,422 small holdings other than allotments. These figures show a very large increase in the number of recorded allotments, and an increase also, although less remarkable in extent, in the number of small holdings. The growth of allotments may be estimated by the following figures referring to the three periods named:—1873, 246,398; 1886, 357,795; 1890, 455,005. It will be observed that the rate of annual increase in the last four years has been apparently three times as rapid as between 1873 and 1886. In the report which precedes the return Mr. P. G. Craigie, Director of the Statistical, Intelligence, and Educational Department, points out that considerable local variations occur in the proportions of allotments of a quarter of an acre or less and allotments between that size and 1 acre. On the whole the smaller class outnumber the larger by much more than two to one; but in particular counties the proportions are reversed, while in England as a whole there are 310,698 allotments under a quarter of an acre, and only 130,326 above that limit in Bedfordshire, Huntingdon, Norfolk, Suffolk, and Worcester the larger type of allotments prevails, and in the East Riding of York, Lincolnshire, and Cambridge the allotments exceeding a quarter of an acre are nearly twice as numerous as those below that area. The counties showing the largest number of allotments are Northampton with 26,229, Wiltshire with 23,723, Leicestershire with 23,396, and Nottingham with 21,253. An examination of the details now supplied indicates that many allotments are in urban parishes, and presumably occupied by artisans. The mining counties of Durham and Glamorgan show a remarkable increase since 1886, their allotments appearing to have been more than doubled in the last four years. Large increases also appear in Kent and Stafford. In Devon, Essex, and Warwick comparatively little change is reported. In only four English counties is any decline apparent. In Cornwall the collectors ascribe the diminution as partly due to the removal of country labourers to more remunerative railway work. In Hereford, Northumberland, and the East Riding of Yorkshire there appear to be also fewer allotments, some of those returned in 1886 having been improperly included under that title, while in other instances plots then occupied as allotments have been required for building and other purposes. Adding to the 409,000 small holdings and 455,000 separate allotments, the special allotments granted by railway companies, so-called garden allotments attached to cottages and other cases, it is estimated that in one form or another *petite culture* is in existence in Great Britain in at least 1,300,000 separate instances.

### MONTBRETIAS.

*M. CROCOSMÆFLORA* is a well known plant of great value for cutting at this season. *M. Pottsi* I have cultivated for years, but it never yet flowered; nor do I think that this experience is singular, as others who have tried it have had the same unpardonable offence to complain of.

I have had the pleasure of making the acquaintance of a group of varieties raised by the indefatigable hybridist of Nancy, M. Lemoine, which supplies us with a new and what will be an indispensable class of flowers for summer and autumn decoration. They are quite hardy, very floriferous, and the flowers of the most beautiful shades; in fact, in the yellows especially I know no flower of exactly the same tones as are to be found in these. Like *Gladiolus*, the flowers continue opening after being cut until the last is reached. They have the advantage of the *Gladiolus*, however, in the rapidity with which they can be increased. Some of the sorts are still rather expensive, but none of them extravagantly so. The following are sorts of yellow shades, and must be seen to be appreciated:—*Elegans*, very pretty; *Gerbe d'Or*, a very beautiful plant, extra free; *Drap d'Or*, very fine clear yellow with large flowers; *Rayon d'Or*, most beautiful with a brown ring near base of petals; *Solfaterre*, very fine clear yellow. These which follow are of different shades:—*Etoile de Feu*, light vermilion, very pretty; *Pottsi grandiflora*, red and yellow; *Incendie*, red, with clear yellow centre, very fine; *Transcendant*, fine clear vermilion shade, throat yellow, very fine. The new sorts of the present year I have not had an opportunity of seeing, but

judging by the advance made in previous years they may safely be added to any collections which may be in course of formation.—B.

### DALECHAMPIA ROEZLIANA ROSEA.

THIS may not inaptly be termed a perpetual flowerer, for it produces its flowers nearly throughout the year, and that on plants only a few inches high. The leaves are long, Oak-like, deep green when full-sized, but pale rose-coloured in a young state, very durable, and so abundant as to completely cover the stem. Above this mass of deep green foliage are produced the flowers, which owe their beauty to the large rosy-pink bracts, which are very persistent, continuing several days in beauty. Its flowers are sweet-scented, but its chief attractions are its dwarf leafy habit, free-flowering character, and continuous flowering. It springs up freely from seed; indeed is such a weed with me in the stove that I have not had to resort to any other mode of propagation, and owing to its continuous blooming the seedlings are plentiful at most times of the year. I usually take up the plants in spring when they have two or three leaves besides the seed leaves, place them singly in 3 inch pots, using a compost of equal parts turfy loam, sandy peat, and leaf soil, with a free admixture of silver sand, and place them on shelves in the stove. I sprinkle the foliage twice daily, and shade from bright sun for a few days if the sun is powerful. In these pots the plants remain until the end of July, when they are shifted into 4½-inch pots, and encouraged with heat and an abundance of moisture. Syringing twice a day may be practised up to October, when they should be kept rather dry—not so much so as to affect the foliage, though the plant will endure the extremes of dryness and wet, heat and cold, better than any other I know. By keeping the plants moderately dry we cause however, a cessation of growth, and they will flower as soon as the days have turned, and continue doing so from January to May.

If we wish the plants to flower in less than 4½-inch pots we have only to turn them out of the 3-inch pots, remove all the soil we can, and place them again in the same size of pot. They will flower well in this size of pot, and whether we pot them or not they invariably flower when 3 to 4 inches high. In fact I have some plants now in 3-inch pots that have not been without their bracts for months, and are not likely to be, as they still throw out more.

It is well to know, that though this plant is almost a continuous flowerer, there are times when the flowers are produced more abundantly than at others. These periods are with me early in spring and late in summer—February, March, and April; and September, October, November, and December. Whenever it begins to grow it begins to bloom, for the flowers are produced from the axils of the leaves, and by remembering this we can have the plants in flower at any time required. We have only to keep the plants rather dry and cool for, say, two or three months, and then introduce them into a house with a temperature of from 70° to 75°, fresh pot, encourage with free watering and atmospheric moisture, and it begins to grow and flower. Half its beauty consists in the manner in which it clothes the stem with its persistent long leaves, which hide that completely, and hang down over the pot.

As a plant for table it is unique, and very handsome specimens may be formed. The way to do this is to stop a seedling plant when 3 inches high, which will cause it to break and produce two or three shoots. These should be stopped again at the third leaf, and repeated until we have half to a dozen shoots, no flowers being permitted to more than show until we secure the number of shoots required; then it is well to keep the plant rather dry and cool for a few weeks, and introduce it into heat and moisture when we want it to bloom, a month or six weeks being required. The plants need not be potted oftener than twice a year, and I consider March and July the best months. The compost for both old and young plants may be the same. It seems to delight in vegetable soil, and the bracts are improved in size by the addition to the compost of one-fourth of old cowdung or well-decayed manure.

A 6-inch pot is large enough for a plant with half a dozen shoots, whilst an 8 or 9-inch pot will well grow one with a dozen. The plants for decorative purposes are best in small pots; in their case, instead of shifting into a larger one, at potting, reduce the ball and return it to the same sized pot. The fresh soil seems to do wonders—plants do not grow any better because we leave the old soil, but seem to benefit only by the fresh. A plant in a 6-inch pot with half a dozen shoots, each carrying as many flowers, or twice the number of bracts (they just appearing so high above the foliage as to show to good advantage) not more than 9 inches to a foot high, and with foliage drooping over and partly hiding the pot, is a subject well worth our attention, and a plant twice the size is

very handsome. Whether grown in the shade or in the full sun—at a few inches or several feet from the glass, it is always dwarf, always free-growing and free-flowering.—G.

#### SOLANUM WENDLANDI.

SPECIMENS of this handsome *Solanum* were shown from the Royal Gardens, Kew, at one of the meetings of the Royal Horticultural Society this year, and the plant is so well worthy the attention of cultivators that we have had the accompanying illustration prepared to

deposits of stratified drift cover its surface, almost everywhere making sandy and gravelly soils or light sandy loams. The flat coast plain, intersected by large bays, and smaller inlets surrounded by marshes, is fringed along its shore by hillocks of loose and often drifting sand. The long-leaved Pine or Cuban Pine form very open forests, which cover a large part of the plain. The damp, sandy soil of these flat woods, devoid of surface drainage, is covered with a dense carpet of Cyperaceous plants, *Rhynchospora*, *Scirpi*, *Fuirenas*, *Elcocharis*, and numerous species of *Nyris*, *Eriocaulon*, and *Sarracenia*s. Their monotony is relieved by groves of Live Oak and Wax Myrtle on the sands of the seashore and the more varied tree growth of the richer spots of the swampy depressions. *Magnolias*, *Laurel Oak*, *Water Oaks*, *Sweet Gum* and

FIG. 29.—*SOLANUM WENDLANDI*.

give an idea of its characters. As grown at Kew in the old Lily house it is very attractive, its rich purplish crimson flowers being produced in profusion. It is not difficult to manage, but requires a good stove temperature, a moist atmosphere, and an open well-drained soil.

#### THE FLORIDA SPRUCE PINE.

THE littoral belt extending from the alluvial lands of the Mississippi River eastward to the neck of the Peninsula of Florida presents no essential difference in climate or soil, or in the general features of vegetation throughout its entire length. Meteorologically it all belongs to one province. The line of 68° mean annual temperature follows the northern border along the thirty-first parallel of north latitude, and the isotherm of 72° follows the seashore. The mean annual precipitation between these limits varies from 48 to 54 inches, showing but slight differences in its distribution throughout the year. Highly silicious

*Black Gum* are the most prominent on the hammock land, while the *Bald Cypress* represents the water-soaked banks of the rivers and their estuaries.

One who travels this coast from west to east is struck by the successive appearance of plants which are never or very rarely met with in the section left behind. If he leaves the eastern shore of the Bay of Mobile his attention is constantly directed to the plants which he has never encountered in the coast region between the western shore of the bay and the Mississippi delta. After crossing the extensions of the sea which intersect this coast, and entering the basins of the great streams which empty into them, he is surprised by the sudden appearance of plants not observed before, most of them becoming more frequent as he approaches the region which discharges its waters into the Atlantic. It would seem that while the wide bays of this coast, with the river basins connected with them, form the only obstacles to the general diffusion of plants over the littoral region of the eastern gulf States, yet to many species which are found on the South Atlantic seaboard these

obstacles prove insurmountable, and absolutely prevent their spread toward the west. It would seem also that other plants whose centre of distribution lies toward the western confines of this belt are prevented by the same difficulties from making any progress toward the east. At another time it may be of interest to give instances of this restriction of different species to given limits, instances which cannot but excite interest in the problem of plant distribution throughout a region in which the same climate, soil, and topographical features prevail.

Among the forest trees which one would observe in connection with this distribution of plants, *Pinus clausa*, the Florida Spruce Pine or Sand Pine, would occupy a prominent place. Among the Pines of the Southern United States this species is confined to the narrowest limits. It is found from the western boundary of Florida to Key West, where it was observed by Professor Sargent, and along the eastern coast of the peninsula, on the rolling uplands to their termination in the lower part of Volusia County, in the flatwoods and swamps of the further south. This Pine is strictly confined to an arid sandy soil; it flourishes on the dunes of pure white drifting sands which fringe the shore, where its roots often fail to obtain a firm hold, so that it often succumbs to the force of storms, and it is seen bent low in the direction of the prevailing wind, and sometimes is entirely prostrate. On these sterile wastes the tree is rarely more than 20 or 25 feet high, while on the dry ridges with a more solid soil, as near Pensacola, it attains the dimensions of a medium-sized tree, and on uplands of the best quality, where the apparently barren ground is underlaid by a sub-soil of the fertile tertiary marls, it arrives at the dimensions of a stately forest tree, associated with mighty Magnolias, large upland Hickories (*Hicoria glabra* and *H. tomentosa*), Live Oaks, Laurel Oaks and Post Oaks.

On these fertile upland hammock-lands, as found prevailing back of Halifax Bay, the Sand Pine arrives at its best development. Trees over 75 feet in height and fully 25 inches in diameter are frequently seen here. In this best state of its growth the tree somewhat resembles the Spruce Pine, *Pinus glabra*, with which it is frequently confounded by the settlers.

By the structure of the wood, as well as by morphological characters, this species forms, with *Pinus glabra* and *P. echinata*, a natural group of southern distribution. The leaves are in twos, with a short, deciduous sheath from half an inch to 2 inches or more in length, a half line wide, slender, flexible concave, and slightly keeled on the upper side. The cones are sessile, horizontally inserted during the first year, and strongly reflexed as they reach maturity during the second year. They are from 2½ to nearly 3 inches long, and from 1¾ to 2 inches when open. The exposed portion of their scales, with a slightly prominent umbo, is crowned by an erect, short, and blunt prickle; they remain on the tree closed for several years. The bark of the young trees is rather smooth, roughish in those of fuller growth, furrowed and divided in square scales. The young shoots are tender. At all seasons and stages of growth this Pine is readily distinguished from the Scrub Pine (*P. inops*) by the less rigid, more slender foliage of dark green, and from its allies by the ashy grey, reflexed, rigidly closed cones. It produces its fruit abundantly, and almost without failure, season after season.

The wood of this Pine is of a yellowish colour, the broad sap-wood of a lighter tint. It is soft, easily worked, but wanting in strength and elasticity, and is not durable. Hence as a timber tree it is regarded as of no importance. The old trees of stunted growth from the sand-dunes along the seashore, with a wood of close grain and of greater toughness, are used for masts for the boats of fishermen and other small craft. As pointed out by Professor Mayr, this tree will in future be undoubtedly of importance in the forestry of the States of the lower south, when the reforestation of the denuded sandy Pine barrens, immense in their extent, is demanded by necessity.—CARL MOHR (in *American Garden and Forest*).

#### SOME NOTES ON NEW ROSES.

THE glorious seed-ripening summer of Her Majesty's Jubilee must surely have had much to do with the fact that three gold medals of the National Rose Society were awarded for seedling Roses this year. To the wonderful advance recently made in light Roses let Her Majesty, Mrs. John Laing, Susanne Rodocanachi, and Madame Joseph Debois bear witness. Is there a grander quartette for robustness of habit, depth of petal, and symmetry of form to be found anywhere? And now we await a corresponding advance in the darker varieties for the back row of the exhibitor's stand. Is one such to be found in Mr. W. Paul's strong growing Salamander, with his fiery crimson centre and regular form? This was without hesitation rightly voted a gold medal. Following the king comes the queen medallist of the year, Margaret Dickson, raised by Messrs. Dickson of Belfast, a pure white Hybrid Perpetual, quite distinct from anything yet sent out, with high centre, perfect form, and such thick foliage, bidding fair to rival William Warden in his mildew-resisting capacities. The blooms at the early Show (the

Crystal Palace) were a trifle thin, but later on in the height of the season, both at Wirral and Birmingham, it was well staged. I should imagine it to prefer a cool season and a good Rose soil.

The third gold medallist was Mrs. Paul, a pink Bourbon of a most distinct shade. Having seen it at home at Cheshunt, I can bear witness to its being a free flowering variety, and will, like its parent, Madame Isaac Pereire, prove a good garden Rose, but I fear it lacks form, an indispensable quality with exhibitors. There was among the new Roses of Messrs. Paul & Son a dark red Hybrid Perpetual which took my fancy as destined for a high position, if not a gold medal, when sent out. Of comparatively new Roses seen at Cheshunt was Scipion Cochet, a dark red H.P. something after the style of Prince Camille de Rohan; Madame H. Pereire, a fine Duke of Wellington; Bruce Findlay, a good red; Monsieur Trievoz, of the Comtesse d'Oxford group, and Ernest Metz, a promising Tea. Other varieties seen at the shows that are worth mentioning are Jeannie Dickson (a dark G. Luizet), Comte Henri Rignon, Cleopatra, Maid of the Mist, and Lady Arthur Hill. The last-named I have grown, and consider it to be an acquisition to the exhibition list, being vigorous, free-flowering, and distinct in colour, though not over-large. For this, as for Jeannie Dickson, we are indebted to the brothers Dickson of Belfast.

Before I finish these brief notes there is yet one more new Rose to notice, Captain Hayward, exhibited at the Crystal Palace, a bright red H.P., à la Gloire de Margottin, with strong wood and good foliage, which will, if not too single, be found useful. This is the last exhibited by one who was of great eminence as a Rose raiser, and to whom exhibitors are indebted for some of the finest Roses in their stands. Princess of Wales, Heinrich Schultheis, and Lady Mary Fitzwilliam (1882), Grace Darling (1884), Her Majesty, and Viscountess Folkestone (1886), Mrs. John Laing (1887), Maid of the Mist and Cleopatra (1889), and several others. By these Roses the name of the late Mr. H. Bennett will long be had in remembrance, and in whose death the Rose world has sustained a grievous loss.—J. H. P.

#### THE NATIONAL DAHLIA SOCIETY.

THE annual exhibition of Dahlias by this Society must be pronounced a distinct success, for despite the somewhat untoward character of the season, and the fact that sharp frosts were experienced in several localities, some very fine blooms were staged, many of them, indeed, being of exceptional quality. At the same time, there were evidences of roughness and coarseness. No exhibitor appeared to have come farther north than Ipswich, and it is extremely probable the northern growers are reserving their forces for Manchester on the 12th. In a few of the classes open to amateur cultivators the absurd and needless distinction between "Show" and "Fancy" Dahlias is maintained; but in all the nurserymen's classes these two types are shown together, to the manifest added attractiveness of the stands.

In the class for seventy-two blooms, not less than forty-eight varieties, and not more than two blooms of a sort, Messrs. Keynes, Williams, and Co., nurserymen, Salisbury, were placed first with a lot of very fine and clean blooms, including Mr. Spofforth, Miss Cannell, Maud Fellowes, a charming light variety; J. F. West, James O'Brien (Fancy), Rev. J. B. M. Camm (F.), Imperial, Mrs. Langtry, William Rawlings, Duchess of Albany (F.), Majestic (Keynes) a new variety, white ground, edged with purple; Hope, W. Keith, Harry Turner, Mrs. Foreman, Prince of Denmark, a very fine shaded dark variety; Royal Queen, Nellie Cramond, Prince Henry (F.), a very bright and attractive flower; Mrs. Kendal, Flora Wyatt (F.), Gaiety (F.), Madame Soubeyre, Henry Bond, Lady Gladys Herbert, Prince Bismarck, James Vick, very fine shape; Henry Walton, Seraph, Countess of Ravensworth, cream coloured; Richard Dean, a fine purple self; Mrs. Gladstone, the most beautiful light Dahlia grown, and so very constant; King of the Purples, &c. Mr. M. V. Seale, Vine Nursery, Sevenoaks, was a very good second indeed, as might be imagined when the flowers from the Royal Nursery, Slough, had to take second place, having excellent blooms of Henry Walton, Vice-President, James Cocker, Henry Eckford, Mrs. S. Hibberd, J. B. Service, a fine yellow self; Mr. Dodds, James O'Brien (F.), Harrison Weir, James Vick, Purple Prince, W. H. Williams, Henry Eckford (F.), Mrs. S. Hibberd, Willie Garratt, a flower of beautiful form, and very bright; Parrot (F.), Mrs. W. Slack, Mrs. Gladstone, Sunbeam, Peacock (F.), Senator, R. T. Rawlings, a very fine yellow self; Fanny Sturt (F.), General Gordon, J. N. Keynes, &c. Third, Mr. Charles Turner, Royal Nursery, Slough.

In the class of forty-eight varieties, distinct, Mr. C. Turner was placed first with a superb lot of blooms, having evidently reserved his full strength for this class. He had William Rawlings, Agnes, a new yellow self of fine form; Harry Keith, Maud Fellowes, John Standish, an old but still very useful bright crimson self; Perfection (Fellowes), Royal Queen, Clara, Mrs. Hodgson, Robina, Glowworm, very bright orange scarlet; Mrs. Langtry, one of the finest of the tipped flowers; Harry Turner, Flag of Truce, Sunbeam, Richard Dean, J. B. Service, Diadem, John Bennett, Emperor, Constancy, Lustrous, a very bright scarlet crimson flower; James Vick, Mrs. Saunders (F.), James Cocker, Prince Bismarck, R. T. Rawlings, J. B. Service, Goldfinder, Perfection, Agnes, Nellie Tranter, &c. Second, Messrs. Keynes & Co., with John Hickling (Keynes) a new bright yellow self; Illuminator, Mrs. Gladstone, William Keith, Agnes, Miss Fox (Keynes) new, bluish ground heavily edged with lake; J. N. Keynes, Mrs. Foreman, Mrs. Langtry, Miss Cannell, Triumphant, Wm. Rawlings, Eclipse, Flora Wyatt (F.), Parrot (F.), Prince Bismarck, Richard Dean, Majestic (Keynes) new, white ground

heavily edged and shaded with purple; James O'Brien (F.), Gaiety (F.), Duchess of Albany (F.), Henry Bond, King of Purples, James Vick, Thomas Goodwin, &c. Third, Mr. M. V. Seale; fourth, Mr. E. F. Such, nurseryman, Maidenhead.

In the class for thirty-six blooms, not less than twenty-four varieties, and not more than two blooms of each, Mr. George Humphries, florist, Kington Langley, Chippenham, was first with some finely finished blooms, including Maud Fellowes (a variety that seems destined to become as popular as Mrs. Gladstone), Nellie Cramond, R. T. Rawlings, Harry Keith, Crimson King, Mrs. Gladstone, T. S. Ware, Mr. David Saunders, white ground edged with purple; Countess of Ravensworth, Earl of Ravensworth, General Gordon (F.), George Barnes (F.), Willie Garratt, Agnes, Colonist, Ovid, Henry Walton, Harry Turner, Miss Cannell, Rosetta, Mrs. Saunders (F.), Lustrous, Vice-President, a fine old and very useful flower; William Rawlings, Agnes, Goldfinder, Mr. Glasscock, John Henshaw, James Stephens, Mr. Harris, Matthew Campbell (F.), &c. Second, Messrs. Heath & Sons, nurserymen, Cheltenham, with good blooms of William Keith, Seraph, Richard Dean, Mrs. Langtry, Harry Turner, John Standish, Henry Bond, Flora Wyatt (F.), Mrs. Gladstone, Mrs. G. R. Jeffard, Thomas Hobbs, Clara, John Henshaw, Sir C. Mills, a Kentish raised yellow self; Statesman, Henry Bond, and Lord Chelmsford. Third, Messrs. J. Saltmarsh & Son, nurserymen, Chelmsford.

There were six collections of twenty-four blooms, distinct, and Mr. John Walker, nurseryman, Thame, came in a good first with Mr. Gladstone, Prince of Denmark, Maud Fellowes, James Vick, Mrs. F. Foreman, Jesse McIntosh (F.), Colonist, Willie Garrett, Miss Cannell, John Standish, J. C. Reid, Crimson King, F. J. Rawlings, Senator, Mr. George Rawlings, James Cocker, Mandarine (F.), Hope, Flora Wyatt (F.), Seraph, Imperial, Mr. W. Dodds, and James Bennett. Messrs. Saltmarsh & Son were second, their leading blooms being Harrison Weir, James Vick, Willie Garratt, H. W. Ward, Mrs. Langtry, William Rawlings, Mr. Saunders (F.), Shirley Hibberd, Mrs. Gladstone, Criterion, and Prince of Denmark. Third Mr. G. Humphries.

In the class for twelve blooms there were five competitors, and Messrs. J. Gilbert & Son, St. Margaret's Nursery, Ipswich, were first with capital blooms of Mr. Saunders (F.), Rev. J. Godday, Rev. J. B. M. Camm (F.), Imperial, Crimson King, R. T. Rawlings, Henry Keith, Henry Walton, Ethel Britton, William Rawlings, T. J. Saltmarsh, and Mr. Harris. Second Mr. S. Mortimer, Swiss Nursery, Farnham, a rising young grower, with Peacock (F.), Lord Salisbury, W. H. Williams, Willie Garratt, Mrs. Gladstone, John Cooper (F.), white, heavily striped with lake; Mr. Glasscock, &c. Third Mr. J. R. Tranter, florist, Henley-on-Thames.

In the amateurs' division there was one class for twenty-four blooms of Show and Fancy Dahlias mixed, six varieties being staged. The best, a very excellent lot of blooms, one of the best stands this veteran grower has staged for years, came from Mr. Thomas Hobbs, Lower Easton, Bristol, who had R. Dean, John Hickling, William Keith, R. T. Rawlings, Hartie King (F.), William Rawlings, Joseph Green, Prince of Denmark, Nellie Tranter, John Standish, Mrs. Gladstone, T. W. Girdlestone (Keynes), a new Fancy, lilac, heavily flaked and splashed with deep red; Mrs. McKenzie, Excellent, Vice-President, Mr. W. Slack, Willie Garratt, Alice Emily (Keynes), a new delicate buff yellow self of fine quality; Thomas Hobbs, Arthur Blick, Henry Walton, Mr. Harris, and Mr. D. Saunders. Second, Mr. J. T. West, gardener to W. Keith, Esq., Cornwalls, Brentwood, with excellent blooms of William Keith, Mrs. Gladstone, R. J. Rawlings, Alice Emily, Mrs. Langtry, J. W. Lord, Crimson Globe, Glowworm, Willie Garratt, Mrs. Saunders (F.), J. T. West, Shirley Hibberd, J. B. Service, Henry Glasscock (F.), Prince of Denmark, &c., and third, Mr. Henry Glasscock, Bishop Stortford.

With twelve blooms of show Dahlias only Mr. S. Cooper, Hamlet, Chippenham, was first, with T. J. Saltmarsh, Willie Garratt, George Barnes, self; R. T. Rawlings, Maud Fellowes, Crimson King, Goldfinder, Harry Keith, Thomas Hobbs, Vice-President, Mrs. Gladstone, and Harry Turner. Second, Mr. George Arnold, Leighton Buzzard, whose best blooms were W. J. Lord, J. C. Quennell, a yellow self; William Rawlings, Mrs. Gladstone, Chris. Ridley, and Joseph Ashby. Third, Mr. A. Ocock, Havering Park, Romford. The best six out of five competitors came from Mr. H. Heremans, jun., Chippenham, who had R. T. Rawlings, Harry Keith, Eclipse, T. J. Saltmarsh, Major Clark, a dark choice late self; and Mrs. Gladstone. Second, Mr. J. Hurst, Putney Road, Enfield Highway, with R. T. Rawlings, Lord Chelmsford, Harry Keith, Mrs. Langtry, Mrs. Gladstone, and Willie Garratt. Third, Mr. J. Gilbert, Freshwater, Isle of Wight.

With twelve blooms of Fancy Dahlias, Mr. J. T. West was first with Mrs. Saunders, Dorothy, T. W. Girdlestone, Duchess of Albany, Frank Pearce, one of the best formed Fancy varieties in cultivation; Gaiety, Salamander, Mrs. N. Halls, Henry Eckford, George Barnes, John Forbes, and Hugh Austin. Second, Mr. S. Cooper, with Major Barttelot, orange, heavily striped with maroon; Mrs. Saunders, Dorothy, John Cooper, Mrs. N. Halls, Duchess of Albany, Henry Eckford, &c. Third, Mr. H. Glasscock. Mr. H. Heremans had the best six Fancy varieties, showing good blooms of Major Barttelot, orange, heavily striped with maroon; John Cooper, white, striped with lake; Dorothy, Mrs. Saunders, Matthew Campbell, and Mrs. N. Halls. Second, Mr. T. Hobbs, with Flora Wyatt, Frank Pearce, Chorister, Magnet, Hartie King, and Mrs. Saunders. Third, Mr. W. Seaman, Brentwood.

A series of very interesting classes are those for Show and Fancy Dahlias in colours. The best six blooms of any dark Dahlia were those of Willie Garratt, from Mr. Thomas Hobbs, Mr. T. Anstiss, Brill,

coming second with James Cocker; Messrs. Keynes & Co. third with Harry Keith, and Mr. Henry Glasscock fourth with Prince of Denmark. The best six blooms of any light Dahlia found eight competitors, all showing Mrs. Gladstone, undoubtedly the most perfect light Dahlia of its day. Mr. J. Walker was first, Mr. Seale second, Mr. J. T. West third, and Mr. T. Anstiss fourth. The best six blooms of any two yellow Dahlias were R. T. Rawlings and J. B. Service, from Mr. J. T. West; and Mr. Seale was third with the same; Messrs. J. Gilbert & Son second—J. C. Quennell and R. T. Rawlings. The best two tipped Dahlias were both Fancies, viz., Peacock and Mrs. Saunders, from Messrs. Keynes & Co., Mr. J. Walker coming second with Mrs. Langtry (S.) and Mrs. N. Halls (F.). Messrs. Saltmarsh & Son were third also with Peacock and Mrs. Saunders. The best two striped Dahlias were Pelican and the Rev. J. B. M. Camm, from Messrs. Keynes & Co. Mr. Glasscock was second with unnamed flowers, and Mr. Seaman third with Professor Fawcett and Duchess of Albany, all Fancy varieties.

Cactus Dahlias made a fine display shown in bold and striking bunches of six blooms. In the nurserymen's class for eighteen varieties Mr. C. Turner was first with Zulu, Professor Baldwin, Empress of India, Amphion, King of the Cactus, Mrs. Hawkins, the old *Picta formosissima* in fine condition, St. Patrick, Panthea, William Darvell, Mrs. Raynor, Honoria, Juarez, Constance, Sir T. Lawrence, Beauty of Brentwood, Cochineal, and Asia. Second Messrs. J. Cheal & Son, nurserymen, Crawley, with Professor Baldwin, Marchioness of Bute, white tipped with rosy purple; Duke of Clarence, new, extra fine; Empress of India, William Darvell, Mr. Douglas, bright pinkish salmon; H. Patrick, Lady Marsham, Zulu, William Rayner, Robert Mayher, a fine yellow, &c.

The best twelve came from Mr. M. V. Seale, who had excellent examples of Henry Patrick, Juarez, Mrs. Hawkins, Empress of India, William Darvell, Charming Bride, Cochineal, Panthea, Zulu, Lady Marsham, Centennial, magenta crimson with side margins of deep maroon; and King of the Cactus. Second Messrs. Paul & Son, Old Nurseries, Cheshunt, who had William Darvell, Henry Patrick, King of the Cactus, Zulu, Honoria, Mrs. G. Reid, pure white edged with lake; Cochineal, Asia, and Mrs. R. Smith. Third, Messrs. Keynes & Co., having fine blooms of Amphion, Centennial, Panthea, Beauty of Brentwood, Honoria, and Marchioness of Bute.

Pompon Dahlias were grandly shown also in handsome bunches of ten blooms each. Messrs. Keynes & Co. were first with a very fine lot, consisting of Lady Blanche, Whisper, Favourite, Darkness, Red Indian, Dove, Golden Gem, E. F. Jungker, Mabel, Hector, lilac purple; White Aster, Phoebe, orange shaded with red; Rosalie, Fairy Tales, Grace, Little Duchess, Gem, Eden, Leila, Little Ethel, Little Darkie, Achilles, pale soft rose shaded with maroon; Janet and Admiration. Second, Messrs. J. Cheal & Sons with a very fine collection also, having Isabel, Gazelle, Little Duchess, Iolanthe, H. E. Searle, Favourite, Don Juan, Grace, Guiding Star, Rosalie, Gem, Ariel, Red Indian and Eurydice. Third, Mr. Charles Turner, having the following very fine—Rubens, Thomas Moore, Eccentric, Amelie Barbier, The Mikado, Mabel and Dandy. Messrs. Paul & Son were fourth. In the class for twelve bunches Messrs. J. Burrell & Son, Cambridge, were first with capital bunches of Grace, Karl Goldenburgh, Mabel, White Aster, Favourite, Isabel, Whisper, Henriette, Fanny Weimar, E. F. Jungker, Fairy Tales and Darkness. Second, W. G. Humphries with Gem, Lady Blanche, Darkness, Leila, Dove, Eurydice, H. Milliesky, &c.

Single Dahlias were, as usual, very fine, the large bunches of ten blooms each being particularly striking. Messrs. J. Cheal & Son were first, and indeed they appear to be unconquerable in this class. They had delightful examples of W. C. Harvey, Miss Linnaker, W. Kennett, Albert Victor, Mrs. J. Conninck, Mrs. Bowman, James Scobie, Marion Hood, Miss Henshaw, Maria Lenden, Miss Roberts, Amos Perry, Duchess of Fife, Eclipse, orange centre with mauve edgings; Alba perfecta, Cetewayo, Victoria, Hugo, Guilclaud, white with margins of yellow; Formosa, Duchess of Westminster, Miss Ramsbottom, Duchess of Albany and Northern Star. Second, Mr. M. V. Seale with Amos Perry, Terra Cotta, Victoria, Huntsman, W. C. Harvey, Miss Henshaw, Hugo, Miss Roberts, Mauve Queen (improved), Duchess of Westminster and Lucy Ireland. Third, Messrs. Paul & Son with Winifred, Paragon, Topaz, Dulejnea, &c. There was but one exhibitor of twelve bunches, Messrs. J. Burrell & Co., who had W. Kennett, Mrs. J. Conninck, Amos Perry, Florrie Fisher, W. C. Harvey, Scarlet Defiance, Huntsman, Miss Roberts, Miss Gordon and Cetewayo.

In the amateurs' division the best six bunches of Cactus Dahlias, six blooms in a bunch, came from Mr. J. T. West, who had Honoria, Empress of India, Marchioness of Bute, Panthea, Mr. Hawkins, and Mr. H. M. Stanley. Second, J. G. Fowler, Esq., Woodford, with Mr. Hawkins, Annie Harvey, King of the Cactus, Henry Patrick, Zulu, and William Darvell. Third, Mr. W. Mist, Ightham. With six bunches, three blooms in each, Mr. H. Glasscock was first with Mr. Hawkins, Amphion, Black Prince, Beauty of Brentwood, Panthea, and Robert Mayher. Second, Mr. S. Cooper; third, Mr. H. Gibbs, Ightham.

The amateur element in Dahlia culture do not appear to care much for single Dahlias, as in the two classes set apart for them there was but one exhibitor in each. The best six bunches, ten blooms of each, came from Mr. H. Glasscock, who had Duchess of Fife, The Mikado, A. J. Harris, James Scobie, Miss Jefferies, and Duchess of Albany. Mr. E. Mawley, Berkhamstead, had the best six bunches, three blooms of each, in Enchantment, Amos Perry, Marian Hood, Miss Henshaw, Gertrude, and Sunningdale White.

Several seedling Dahlias were exhibited, but only a few first-class

certificates of merit were awarded. Messrs. Keynes & Co. received one for Fancy Comedian, deep apricot ground, striped with dark crimson and slight edgings of pale mauve, a finely formed variety, quite novel in colour. To Messrs. J. Cheal & Sons for Cactus Dahlia Duke of Clarence, maroon with side edgings of crimson, a bold and striking flower of large size. To Mr. T. S. Ware for single Dahlia Duchess of Fife, bright deep yellow, with side edgings of brownish red, a medium-sized flower of fine shape; and Maude, white, with side margins of crimson purple.

In addition Messrs. Keynes & Co. had The Kaiser, a large crimson, self, rather flat in shape; J. C. Vaughan, a small yellow self, pure in colour, fine shape, petal, and substance; Dandy (Fancy), buff yellow, heavily flaked with crimson; Miss Barber (Show), white tipped with purple; and the Hon. C. Bouverie, crimson and maroon shadings. Mr. G. Harris, Orpington, had Model (self), orange, red shaded, fine shape and petal; Favourite (F.), pale mauve, pink ground shaded with crimson, very promising; Canary Bird, yellow self; and Freedom. Several new Cactus and single Dahlias were shown, but nothing worthy of notice. Mr. T. S. Ware made a great display with cut blooms of Dahlias of various types, and Messrs. Cheal & Son also staged a quantity, with hardy flowers, &c.

## THE CRYSTAL PALACE FRUIT SHOW.

SEPTEMBER 5TH AND 6TH.

THE annual Fruit Exhibition at Sydenham was held on the above dates under most favourable circumstances as regards the weather, number and quality of the exhibits staged in competition for the liberal prizes, and the attendance of visitors was large on both days of the Show. This may certainly be regarded as the National Fruit Show, and the great event of the year. All the classes are open. There are no entrance fees to pay, and, the prizes being liberal, the best growers residing in various parts of the country enter into the contest in all the leading classes. The Show held on Friday and Saturday last was the best all-round Exhibition of fruit held there during the last five or six years. Grapes, Peaches, Nectarines, Pears, Apples, and Plums were all well represented for the season. As in other years the fruit was staged on continuous tables about 6 feet wide, these being divided by placing a longitudinal row of bright foliaged plants and Ferns along the middle. The arrangements made by Mr. W. G. Head, the courteous and efficient garden and Show Superintendent, for the convenience of exhibitors and the public were everything that could be desired.

### COLLECTIONS OF FRUIT.

The three classes usually devoted to these make quite a grand show in themselves. The first was that for not less than twenty dishes, to consist of eight bunches of Grapes in four varieties (two white and two black, two bunches of each variety), two Pines, two Melons, two dishes of Peaches, two of Nectarines, and two of Plums, the remainder to be distinct kinds. The prizes were £12, £8, and £4. Four capital collections were put up in competition for these by Mr. James McIndoe, gardener to Sir Joseph W. Pease, M.P., Hutton Hall, Guisborough, Yorkshire; Mr. H. W. Ward, gardener to the Right Hon. the Earl of Radnor, Longford Castle, Salisbury; Mr. Goodacre, gardener to the Right Hon. the Earl of Harrington, Elvaston Castle, Derby; and Mr. R. Dawes, gardener to the Hon. Mrs. M. Ingram, Temple Newsam, Leeds. The contest for first position, however, was between the productions staged from Hutton Hall and Longford Castle Gardens, the latter consisting of twenty-seven dishes, and the former of twenty-one. Mr. McIndoe ultimately secured the premier position with a very imposing collection, comprising well-coloured bunches of Alnwick Seedling and Gros Maroc Grapes, good sized bunches of Trebbiano Grape having small green berries, and fairly good bunches of Buckland Sweetwater Grapes, a good sized Queen Pine, having regular well-developed large bright pips, and a small Smooth Cayenne Pine, large well-coloured fruits of Blenheim Orange and Lockinge Hero type, Melons, medium-sized even fruits of Exquisite Peach, Humboldt Nectarines of fair size and good colour, Darwin Nectarine, and medium-sized pale fruits of Prince of Wales Peach, fine Brown Turkey Figs, and Bryanston Green Gage and Kirke's Plums, Imperial Lemon, good in size, shape, and colour; Exquisite Orange, large and bright; good, bright, even fruits of Ribston Pippin Apple, Bigarreau Napoleon Cherry, Williams' Bon Chrétien Pear, and a large dish of Moor Park Apricots. Mr. Ward was placed second, and had large solid bunches of Muscat of Alexandria Grapes, having well-coloured berries; large shapely bunches of Alicante, Gros Maroc, and Foster's Seedling Grapes, fine in berry and colour; good Cayenne Pines, about 5 lbs. and 5½ lbs. each; well coloured Lockinge Hero and Blenheim Orange Melons; exceptionally fine Sea Eagle and Prince of Wales Peaches; Elruge and Pineapple Nectarines, even, well-coloured fruits; fine Guthrie's Late Gage, and moderate Mitchelson's Plums; grand Brunswick Figs, Imperial Lemon and St. Michael's Orange, the fruits being clean, even, and bright, though not quite so large as those in the first prize collection; clean bright fruits of Moor Park Apricot, dishes of fine Worcester Pearmain Apple, and Williams' Bon Chrétien Pear, and a pyramid of large well-coloured Morello Cherries, and Vicomtesse Hericart de Thury Strawberry, with some dishes of small fruits. Mr. Goodacre was third, his best dishes being large handsome bunches of Muscat of Alexandria and Gros Maroc Grapes, the berries being large and beautifully coloured; Lockinge Hero Melon, Violette Hâtive Peach, and Victoria Nectarine.

In Mr. R. Dawes' collection were fine bunches of Alicante and Gros Guillaume Grapes, the latter being about 7 lbs. each, fine in berry and well coloured.

In the next class, for a collection of twelve dishes, six bunches of Grapes, three white and three black, and two Melons, were required; the remainder to be distinct kinds. Five good all-round collections were staged. The three prizes offered were £8, £6, and £4. Mr. P. Blair, gardener to the Duke of Sutherland, Trentham Hall, Stoke-on-Trent, was placed first for large loose clusters of Alicante and fairly good bunches of Muscat of Alexandria Grapes, an even dish of well coloured Violette Hâtive Peaches, good Williams' Bon Chrétien Pear, a fully ripe Queen Pine, Trentham Seedling and Best of All Melons, the latter being half green; Brown Turkey Figs, medium size and over-ripe exhibition purposes; Morello Cherries, Lord Napier Nectarine, and Moor Park Apricots in good condition. Mr. A. Miller, Rood Ashton Park, Trowbridge, was second. He had fine bunches of Muscat of Alexandria and Black Alicante Grapes, Pine, Melons, Peaches, and Brunswick Figs. Mr. H. W. Ward was third, his collection having solid well coloured bunches of Muscat of Alexandria Grapes, fine Brunswick Figs, Pineapple Nectarine, Sea Eagle Peach, Lockinge Hero and Blenheim Orange Melons.

In the collections of eight kinds four entered in competition for the three prizes offered. Mr. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, was first, staging good Black Hamburg and Muscat of Alexandria Grapes, Golden Perfection Melon, Williams' Bon Chrétien Pear, Noblesse Peach, Brown Turkey Figs, Pineapple Nectarine, and Worcester Pearmain Apples, all being in good condition. Mr. Charles Warden, Clarendon Park Gardens, Salisbury, was a close second, showing good Madresfield Court Grapes, Sea Eagle Peach, Pineapple Nectarine, and Brunswick Figs. Mr. L. Budworth, gardener to C. Hill, Esq., Rockhurst, East Grinstead, Sussex, was third.

### GRAPES.

The principal class was that for a collection of ten varieties, two bunches of each, and those staged included fine well-coloured Grapes. Mr. Goodacre was first, having Black Prince, good Alnwick Seedling, Alicante, fairly well coloured, and of good size and shape; good Lady Downe's; large bunches of Muscat Hamburg, with the colour going off; good bunches of Muscat of Alexandria; Black Hamburg, deficient in colour, though good for the time of year; Foster's Seedling, good bunches; also good and fairly well coloured bunches of Madresfield Court and Gros Maroc. Mr. McIndoe's second prize bunches comprised good Lady Downe's; Gros Colman, beautifully coloured and good in berry; Buckland Sweetwater, small Duke of Buccleuch, Trebbiano, small and green in berry; two good bunches of Gros Guillaume, perfectly black, but one bunch was badly rubbed; good sized Black Hamburg, and fairly coloured; Madresfield Court, and Gros Maroc. Mr. Warden, Clarendon Park Garden, Salisbury, was third with bunches of medium size and well coloured, his Muscat Hamburg and Madresfield Court being neat and perfectly black.

Four good collections of ten bunches in five varieties, two bunches of each, were staged, Mr. Taylor, gardener to Alderman Chaffin of Bath, being first; Mr. Osman, gardener to S. J. Baker, Esq., Ottershaw Park, Chertsey, being a very good second; and Mr. Reynolds, Gunnersbury Park Gardens, Gunnersbury, third. Mr. Taylor's collection consisted of handsome well-finished bunches of Muscat of Alexandria, Madresfield Court, Alicante, Alnwick Seedling, and Gros Maroc, Messrs. Osman and Reynolds staging nearly the same varieties. The Lady Downe's in the other show production were splendid.

*Muscat of Alexandria.*—Mr. Taylor deservedly secured the post of honour with long tapering bunches of a beautiful amber colour. Second, Mr. C. Griffin, gardener to Miss Christy, Coombe Bank, Kingston, who also had large bunches fairly well coloured. Mr. Blick, gardener to Martin B. Smith, Esq., The Warren, Hayes Common, Kent, was a good third. Four competed.

*Gros Maroc.*—Seven were staged, the first prize going to Mr. A. G. Hooking, gardener to D. W. Graystone, Esq., Hurst Hill, West Molesey, for large well developed bunches beautifully coloured. Second, Mr. G. Reynolds, with good sized bunches and splendid berries well coloured. Third, Mr. W. Goodall, gardener to F. Morrison, Esq., Fonthill House, Tisbury, Wilts, who also had well coloured bunches.

*Madresfield Court.*—Six good lots of this fine Grape were staged. Mr. Gibson, gardener to Earl Cowley, Draycot House, Wilts, was first, having long handsome bunches, well coloured, and carrying a fine bloom. Second, Mr. Howe, showing neat well coloured bunches, but not so large as the first prize Grapes. Third, Mr. Warden, who also had well finished bunches.

*Alicante.*—This class was a very strong one, Mr. Osman, among nine competitors, coming first, with large bunches and berries finely coloured. Second, Mr. C. Griffin, with shapely bunches carrying a fine bloom. Third, Mr. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common.

*Any other White.*—Mr. Ward here secured the premier position amongst eight competitors with large, well-ripened bunches of Foster's Seedling. Second, Mr. Bury, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, with the same variety, fine compact bunches, not so well coloured as the preceding. Third, Mr. F. Jordan, gardener to B. Foster, Esq., The Hill, Witley, Surrey, who also staged Foster's Seedling.

*Any other Black.*—First, Mr. W. Taylor, with fine bunches of Alnwick Seedling, splendidly coloured, and carrying fine bloom. Second, Mr. Bury, with bunches almost equal in point of merit to the

first prize, but not so well coloured. Mr. Goodacre was third. All the prizes in this class going to Alwick Seedling. There were six entries.

Classes were provided for baskets of black and white Grapes, containing not less than 12 lbs. each. In the class for black the competition was very keen, six splendid samples being shown. The first prize went to Mr. A. G. Hooking, gardener to W. Graystone, Esq., Hurst Hill, West Moulsey, for Alwick Seedling in grand condition. Mr. McIndoe was second with the same variety, wonderfully good. Third, Mr. E. Longley, gardener to W. J. Twigg, Esq., Croxted House, West Dulwich, with Gros Maroc, also in good condition. In the corresponding class for white Grapes, Mr. G. Winter, gardener to Mrs. Maw, Walk House, Barrow-on-Humber, was easily first with remarkably fine and well coloured bunches of Bowood Muscat. Second, Mr. McIndoe, with Duke of Buccleuch. Third, Mr. Hooking, with fairly good Foster's Seedling.

#### PEACHES AND NECTARINES.

The former of these two popular kinds of fruit were staged in large numbers, and in fine condition; scarcely a faulty one could be found among them. Nectarines, though not so extensively staged, were of first-rate quality, the winning dishes in each case having fruits of good size and fine colour. A class was provided for four dishes of Peaches, distinct, six fruits of each. The first prize was well won by Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., Ketton Hall, Stamford, with good sized, highly coloured fruits of the following varieties—Crimson Galande, Prince of Wales, Crawford's Early, and Dymond. Mr. McIndoe was second with good fruits of Golden Eagle, Exquisite, Violette Hative, and Princess of Wales; third, Messrs. Rivers & Son, nurserymen, Sawbridgeworth, Herts, Sea Eagle and Gladstone being good in this collection.

Twenty-one dishes were shown in the single dish class, the majority of them being remarkable for great size and good colour. Mr. A. Alderman, gardener at Effingham Hill House, Dorking, Surrey, was first with splendid fruits of Sea Eagle, Mr. H. W. Ward being a close second with the same variety, and Mr. Divers third with Prince of Wales, finely coloured. For four dishes of Nectarines, distinct, Mr. Divers was well first with large fruits well coloured, the varieties being Rivers' Orange, Pineapple, Dryden and Victoria. Second, Mr. W. Carr, gardener to S. Clark, Esq., Croydon Lodge, with smaller but well coloured fruits of Lord Napier, Rivers' Orange, Spencer and Elruge. Third, Mr. Goodacre, Pineapple being very fine in his lot. Twelve single dishes of Nectarines were staged, that sterling variety, Pineapple, winning all three prizes; Mr. Divers again being first, Mr. Geo. Pymm, gardener to Mrs. Gouldsmith, Rodwell Hall, Trowbridge, second, and Mr. C. Blick, gardener to Martin R. Smith, Esq., The Warren, Hayes Common, Kent, third.

For a collection of six dishes of Peaches and six dishes of Nectarines, distinct, Mr. Divers followed up his previous successes by again taking the first prize with fruits similar to those shown by him in his other collections. The varieties were: Peaches—A. Bec, Crimson Galande, Crawford's Early, Dymond, Prince of Wales and Violette Hative; Nectarines—Rivers' Orange, Humboldt, Pineapple, Dryden, Lord Napier and Victoria. Second, Messrs. Rivers & Son, Sea Eagle and Gladstone Peaches and Byron and Pineapple Nectarines were well represented in this collection.

#### MELONS.

Sixteen green-flesh Melons were put up. Mr. Mortimer, Swiss Nursery, Farnham, was first with a well-netted, juicy-looking fruit of Sutton's Monarch. Second, Mr. McIndoe, with Best of All. Third, Mr. L. Budworth, gardener to C. Hill, Esq., Roekhurst, East Grinstead, with Hero of Lockinge. Thirteen scarlet-flesh Melons were tabled. First, Mr. J. Neighbour, Bickley, with Scarlet Gem. Second, Mr. G. Woodham, Model Farm Gardens, Green Lane, Dulwich, with Blenheim Beauty. Third, Mr. G. Griffin, gardener to Miss Christy, Coombe Bank, Kingston, with same variety.

#### PLUMS.

Mr. Ward was first for four dishes of red Plums, distinct, with good examples of Pond's Seedling, Red Magnum Bonum, La Delicieuse, and Sultan. Second, Mr. Neighbour, with Pond's Seedling, Cox's Emperor, as his best dishes. Plums, yellow and green, four dishes, distinct. First, Mr. McIndoe, with clean, well-coloured fruits—the varieties being Jefferson, Green Gage, Bryanston Green Gage, and Magnum Bonum. Plums, purple, four dishes, distinct.—First, Mr. Blick, with very fine fruits of Grand Duke, Monarch, Kirk's, and Prince Englebert. The two first-named varieties are not so much grown as their merits deserve. As shown here the fruits were large and shapely, of a rich purple colour and dense bloom. Second, Mr. Neighbour. Third, Mr. McIndoe. Figs, two dishes, distinct. Six were put up. Mr. Ward was a good first with fine Brunswick and White Marseilles. Second, Mr. Evans, gardener to J. Stewart Hodgson, Esq., Lythe Hall, Haslemere, with Brown Turkey and White Marseilles. Third, Mr. Goodacre.

#### APPLES.

A class was provided for a collection of twelve kinds, six to be dessert and the remainder kitchen, all the fruits to be orchard-house grown. The first prize was easily won by Messrs. Geo. Bunyard & Co., nurserymen, Maidstone, Kent, with grand specimens of the following varieties—Belle Pontoise, Lady Henniker, Emperor Alexander, of enormous size; Warner's King, Stone's Apple, Bismarck, large, and splendidly coloured; Washington, Worcester Pearmain, extra good; Okera, Lady Sudeley, Cox's Pomona, and Ecklinville. Second, Mr. McIndoe, with large fruits, but in most cases they were deficient in

colour. The varieties were—Emperor Alexander, Bismarck, Striped Beaufin, Peasgood's Nonesuch, Washington, Gascoigne's Seedling, Maiden's Blush, Worcester Pearmain, Queen Caroline, Duchess of Gloucester, Greenup's Pippin, and Grand Duke Constantine. Messrs. G. Bunyard and Co. were again first for three dishes of ripe Apples, distinct, with Worcester Pearmain, Cellini, and Washington, in first-class condition. Second, Mr. McIndoe, with smaller but well-ripened examples of Worcester Pearmain, Queen Caroline, and Ribston Pippin.

#### PEARS.

For a collection of ten kinds, distinct, Mr. C. Blick was first with a very fine well ripened lot, which included several dishes of exceptional merit. The varieties were Souvenir du Congrès, Pitmaston Duchess, Magnate, Princess, Doyenné du Comice, Durondeau, Fondante d'Automne, and Doyenné Boussoch, Brockworth Park, and Williams' Bon Chrétien. Mr. McIndoe was second; many of his dishes, though large, were rather green, the ripest among them being Clapp's Favourite and Brockworth Park. For three dishes of ripe fruits Mr. McIndoe secured the premier award with Souvenir du Congrès, Williams' Bon Chrétien, and Louise Bonne of Jersey, all well ripened. Second, Mr. Divers, with Clapp's Favourite, Souvenir du Congrès, and Doyenné du Comice. Third, Messrs. G. Bunyard & Co., with large fruits scarcely ripe.

#### TOMATOES.

These were well shown, but not so extensively as is generally the case at the Crystal Palace. For a collection of six distinct kinds Mr. C. J. Waite, gardener to the Hon. Col. Talbot, Glenhurst, Esher, was a good first, showing the following varieties in very fine condition:—Reading Perfection, Waite's Glenhurst Favourite, Laing's Pedigree, Carter's Perfection, and Carter's Sandwich Island. Second, Mr. E. Rider, Northumberland Nursery, Orpington, Kent, with smaller but clean even samples. Third, Mr. Wells, florist, Earlswood, Redhill. Four lots were staged.

#### SPECIAL PRIZES.

Messrs. James Carter & Co. offered prizes for the best basket of vegetables, in six distinct varieties. The first prize was won by Mr. Waite, with produce grown and staged in his usual good style. He showed Carter's Extra Early Autumn Giant Cauliflower, Carter's Perfection Tomato, Golden Noble Onion, Holborn Abundance Potato, Telephone Pea, and Carter's Scarlet Perfection Carrot. Mr. F. A. Becket, Colehatch Farm, Amersham, Bucks, was a good second, showing similar varieties. The same firm offered prizes for the best six fruits of Carter's Blenheim Orange Tomato.

Mr. H. Deverill, Seed Merchant, Banbury, also offered prizes for the best six fruits of Waite's Glenhurst Favourite Tomato. Mr. Waite was first with a fine dish, Mr. Beckett second, and Mr. Palmer, Thames Ditton, third.

#### NON-COMPETING CLASSES.

Messrs. G. Bunyard & Co. of Maidstone, Kent, staged a grand collection of Apples in forty-five varieties. One magnificent specimen of Peasgood's Nonesuch weighed 1 lb. 10 ozs. Messrs. J. Cheal of Crawley, Sussex, also staged a large collection of good quality, and Messrs. J. Peed & Sons, The Nurseries, Mitcham Road, Streatham, exhibited a similar collection, several dishes being particularly fine. James Carter and Co. of High Holborn put up some fine blooms of the rare and beautiful *Clanthus Dampieri*, which were much admired. The same firm staged several varieties of Tomatoes, including Conference, Blenheim Orange, Sandwich Island, and Market Favourite.

#### MISCELLANEOUS.

A few classes for cut flowers, came in at the end of those for fruit. Handsome prizes were offered for a collection of cut spikes of Gladioli, not more than 100, and in not less than thirty-six varieties. The only exhibitors were Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, who had very fine lot of ninety-six spikes, the major part of them grandly developed. The leading varieties were *Iolanthe*, *Pyramide*, *Rayon d'Or*, *Conquérant*, *Imperial Couronne*, *Africaine*, *Grand Rouge*, *Mrs. Lindsell*, *Amitié*, *Atlas*, *Baroness Burdett Coutts*, *Celestine*, *Dalila*, *Crépuscule*, *Minos*, *Mascarille*, *Meyerbeer*, *Cygnets*, and *The Mikado*. With eighteen spikes, shown by amateurs, Mr. E. B. Lindsell, Hitchin, was first, and the Rev. H. H. Dombrain, Westwell Vicarage, Ashford, second. The latter had a few of the finest spikes, but he had some of the weakest. The leading varieties were *Mont Blanc*, *Celestine*, *Dalila*, *Snowdon*, *Carnation*, *Grand Rouge*, *Mons. A. Brongniart*, *Atlas*, *Baroness Burdett Coutts*, *Conquérant*, *Rossini*, *Bicolor*, *Horace Vernet*, and *Flamboyant*. There was no competitor in the class for twelve spikes.

Very good quilled German Asters came from Mr. Sidney Cooper, Hamlet, Chippenham, who was first with twenty-four, and Mr. John Walker, nurseryman, Thame, who was second. The best twenty-four French Asters, all good blooms of the *Paeony* flowered type, were from Messrs. J. Saltmarsh & Son, nurserymen, Chelmsford; Mr. John Walker being second with the same type. But the season has not been a good one for Asters. Hollyhocks were poor, and a third prize only was awarded in the class for twenty-four blooms. In that for twelve Mr. Thomas Hobbs, Lower Easton, Bristol, was the only exhibitor, and was awarded first prize.

Stove and greenhouse cut flowers made a very fine feature, especially as the collections were unlimited. Mr. J. Prewett, Swiss Nursery, Hammersmith, was first with a large collection, in which Orchids played a very important part. Mr. P. Blair, gardener to His Grace the Duke

of Sutherland, Trentham, was second, having some fine Orchids also; and Mr. Gibson, gardener to T. T. B. Atkins, Esq., Halstead Place, Sevenoaks, third.

Plants included collections of early flowering Chrysanthemums in pots, and here Messrs. J. Laing & Sons, Stanstead Park Nursery, Forest Hill, were first with a bold and striking group. Messrs. Reid & Borne-man, nurserymen, Sydenham, were second with a remarkably good group also; and Mr. N. Davis, nurseryman, Camberwell, third. Mr. G. Saunders, gardener to W. H. White, Esq., Charlwood Park, Crawley, was first with six Cockscombs. Mr. R. Spinke, Victoria Road, Horley, was second.

Miscellaneous collections, which greatly helped the display, were furnished by Messrs. J. Laing & Sons, who had an imposing mass of valuable double and single Begonias in pots, relieved by Ferns. Messrs. W. Paul & Son, nurserymen, Waltham Cross, Roses, hardy shrubs, &c.; Messrs. Paul & Son, Old Nurseries, Cheshunt, a good collection of hardy flowers; Mr. Alexander Lister, florist, Rothesay, a wonderful collection of cut blooms of Show and Fancy Pansies, Marigolds African and French, the latter in fine double and single forms, &c.; Mr. W. Innes, florist, Rothesay, Pansies, Marigolds, Antirrhinums, &c.; and Mr. E. F. Such, florist, Maidenhead, hardy cut flowers in variety. Messrs. Cannell and Sons, Swanley, also had a handsome collection of Dahlias and other cut flowers.

First-class certificates of merit were awarded to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, for *Papaver orientale* var. *semi-plena*, with brilliant vermilion flowers; and to the Rev. H. H. Dombrain for *Gladiolus Mont Blanc*, a very fine light, almost a white variety of high quality.

## HORTICULTURAL SHOWS.

BATH.—SEPTEMBER 3RD AND 4TH.

THERE have been a good many fine shows held at Bath of late years, but it was generally conceded that none has ever equalled that under notice. Not only were the entries far in excess of any previous numbers—many of the competitors hailing from a considerable distance all round—but the quality and extent of the display was much in advance of what has ever before been seen at the Bath September Show. No less than five tents, three of these being of the largest size, filled to overflowing, and in addition there was a capital open-air display of vegetables, and which travellers by the Great Western Railway had a brief and free view. The Committee, with Messrs. Pearson and Jefferies as Honorary Secretaries, having had long experience in all matters pertaining to holding flower shows, always arrange everything in a very satisfactory manner to all concerned, and fine though dull weather being experienced a capital and most appreciative attendance of visitors resulted.

### PLANTS.

Fuchsias are always a feature at these September Shows, and nowhere else probably are so many fine specimens brought together. The greater portion of the plants shown were perfect pyramids, ranging from 6 feet to 9 feet in height, and all were freely flowered and much fresher than usual. The best nine varieties were shown by Mr. G. Tucker, gardener to Major W. P. Clark, Trowbridge, the collection including such fine exhibition sorts as Lye's Favourite, Charming, Bountiful, T. King, B. R. Pearson, Doel's Favourite, Arabella, and Mrs. Rundell. Mr. G. Snell, gardener to Mrs. Counsell, Bath, was a close second, his plants, though not so large as those in the premier collection, being more perfectly furnished over the rims of the pots. Mr. J. Lye, the veteran grower and raiser, was third, he also having fine well-flowered specimens. The competition with six varieties was equally good, Mr. A. Hawkins, gardener to Mrs. Jolly, Bath, being well first with very freely flowered specimens 8 feet to 9 feet in height of Mrs. Rundell, Charming, Charming, Doel's Favourite, Arabella, and Final. Mr. Weston, gardener to the Rev. C. C. Layard, was a good second; and Mr. Pocock third. The first prize for four Fuchsias was rightly awarded to Mr. H. Marchant, gardener to J. Murch, Esq., Bath; Mr. C. Adlam, gardener to Mrs. Woodroffe, Bath, being second. There were also classes for single specimens of different shades of colour, these attracting many fine specimens.

Specimen stove and greenhouse plants were more largely represented than usual and, interspersed among the Fuchsias, well filled the largest tent. Mr. J. Cypher, Cheltenham, had no difficulty in carrying off the principal prizes, his plants giving but little signs of having done so much good work this season. The principal class was that for eighteen plants, six to be in bloom; and in this Mr. Cypher showed very fine Crotons, Palms, and other valuable specimens. The second prize was awarded to Mr. Curry, gardener to Colonel Pepper, Salisbury, who had good, fine-foliaged plants, but was decidedly weak with flowering plants. Mr. J. F. Mould, Pewsey, and Mr. Wills, gardener to Mrs. Pearce, Southampton, were placed equal thirds, with which awards neither party were satisfied. Mr. Curry was first for eight fine-foliaged plants, Mr. Wills being second, and Mr. Jones, gardener to Mrs. Doherty, Bath third, there being, however, nothing particularly noteworthy in the class. Mr. Cypher was easily first for six flowering plants, having *Allamanda nobilis*, *Ixora Duffii*, *I. Pilgrimi*, *Franciscea calycina major*, *Bougainvillea glabra*, and *Erica Eweriana* in excellent condition. Mr. G. Tucker was second with neatly trained, well-flowered plants, and Mr. Jones third. With three plants Mr. J. Hiscox, gardener E. R. Rodway, Esq., Trowbridge, was first, having creditable specimens of *Dipladenia*

*amabilis*, *Allamanda Hendersoni*, and *Dipladenia boliviensis*. Mr. Wills was second. Heaths were well shown by Messrs. Cypher, J. F. Mould, and Mr. Wills, who took the principal prizes in two classes. There were also classes provided for single specimen flowering and fine-foliaged plants, in all of which there was good competition.

The display of Orchids was unusually good. With six plants Mr. Cypher was well first, his collection consisting of *Vanda Sanderiana* with one spike bearing eight fine flowers, *Aerides Sanderiana*, *Cattleya Gaskelliana*, *Dendrobium formosum*, *Odontoglossum Harryanum*, and a fine pan of *Odontoglossum grande*. The second prize was awarded to Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, his best being *Cattleya Loddigesi* and *Cattleya Leopoldi*. In the class for a new or rare plant the first prize went to Mr. C. Richman, gardener to G. L. Palmer, Esq., for a fairly good form of the beautiful *Cattleya Dowiana*, Mr. Cypher being second for the quaintly flowering *Catasetum Bungeirothi* with a spike bearing nine flowers.

Mr. Richman was well first for Gloxinias, and Mr. Tucker second; and the first named was also first for six double and six single flowering Tuberos Begonias, showing exceptionally well flowered plants of five varieties in both instances. Mr. W. Clifford was a good second in each class. The competition in the various classes for Pelargoniums was very keen. The best six Zonals were shown by Mr. H. Marchant, these having very good foliage and extra fine trusses of bloom, and the varieties were *Aurora Borealis*, *Dr. Aiton*, *Queen of the Whites*, *John Fellowes*, *Lizzie Brooks*, and *Henry Jacoby*. Messrs. Cray of Frome, G. Tucker, Weston, E. B. Titley, and S. Fottle were the other leading prizewinners with Pelargoniums. Mr. J. Lye was first for Petunias, Messrs. Cooling & Sons and T. Truckle, gardener to T. Carr, Esq., for Liliams, Messrs. Cooling & Sons for Cockscombs, and Mrs. Woodroffe for *Coleus*; the competition being good in every instance.

Ferns were extensively and well shown. The best twelve exotic varieties were staged by Mr. G. Tucker, who had medium-sized very healthy specimens of *Lomaria gigantea*, *Asplenium nidus avis*, *Davallia hemiptera*, *Cheilanthes hirta*, *Gymnogramma chrysophylla*, *Dicksonia antarctica*, *Gymnogramma peruviana argyrophylla*, *Adiantum cuneatum*, *Cheilanthes elegans*, *Gymnogramma sulphurea*, *Adiantum concinnum latum*, *Adiantum gracillimum*. Mr. Truckle was a good second, and Mr. H. Jones third. There were five competitors with a group of plants arranged for effect, to occupy a space not less than 100 square feet, good taste being displayed in each instance. Mr. Cypher, however, was well first, the very choice materials available, coupled with skilful and elegant grouping, not being equalled before at any of the Bath shows. Mr. Wills was second, and Mr. Curry third, both putting up very light and pretty groups.

### CUT FLOWERS.

These were a great feature, the display being remarkably good both in point of quantity and quality. The first prize for thirty-six Gladioli was awarded to Mr. G. J. Walters, Messrs. John Jefferies & Son being a close second, and Mr. R. H. Poynter, Taunton, third. For twelve spikes Mr. S. Tottle was first, Dr. Budd, Bath, second, and Mr. A. A. Walters third. Mr. G. Humphries, Chippenham, staged grand blooms in the class for twenty-four Dahlias, the pick of these being *Nellie Cramond*, Vice President, *Agnes T. Hobbs*, Mrs. Gladstone, H. Keith, H. Turner, Major Clark, Mrs. Dodds, Maud Fellows, Miss Cannell, H. Walton, W. Rawlings, G. Barnes, and Ovid. Messrs. Heath & Son, Cheltenham, were second, and Mr. J. Nation third. The best twelve varieties were shown by Mr. T. Hodds, Bristol, who had good blooms of *J. Henshaw*, Mrs. D. Saunders, Mrs. Harris, Dr. Reilly, J. Standish, Alice Emily, W. Garrett, C. Wyatt, J. T. West, W. Jackson, Goldfinder, and H. Walton. Mr. S. Cooper was second, and Mr. S. Price third. Mr. Humphries was first for nine Fancy Dahlias, having perfect blooms of *J. Hopper*, *Hercules*, *Prince Henry*, *Major Bartlett*, *Rebecca*, Mrs. Saunders, *H. Eckford*, and Mrs. Halls. Mr. S. Cooper, Chippenham, was second, and Messrs. Heath & Son third. The prizewinners in a good class of single Dahlias were Messrs. T. Carr, Cooling & Sons, and A. A. Walters.

There was quite a grand show of Roses shown in three classes. Messrs. John Jefferies & Son were first for twenty-four varieties, their stands including fine fresh examples of *J. Laing*, *Duke of Teck*, *Lady Mary Fitzwilliam*, *Madame E. Verdier*, *Madame I. Perreire*, *Camille Bernardin*, *Mrs. Jowitt*, and *Beauty of Waltham*. Mr. A. H. Gray was very strong, especially in Teas, and by some judges would have been first. His best were *Marie Baumann*, *Francisca Kruger*, *Princess of Wales*, *Etoile de Lyon*, *Innocente Pirola*, *C. Mermet*, *Edith Gifford*, and *Madame Lambert*. Messrs. Cooling & Sons were a good third. With twelve varieties Mr. A. H. Gray took the lead, having fine rich blooms of *Grace Darling*, *François Michelon*, *Duchess of Bedford*, *La France*, *Dupuy Jamain*, *Pride of Waltham*, *Countess of Oxford*, *Mdlle. Marie Verdier*, *Mons. E. Y. Teas*, *The Bride*, *A. K. Williams*, and *Comtesse de Serenyi*. Messrs. Perkins & Sons were a good second, and Dr. Budd third. A beautiful lot of Teas were shown. With twelve distinct varieties Mr. A. H. Gray was well first, his stand comprising *Anna Ollivier*, *Madame Lambert*, *Maréchal Niel*, *Princess of Wales*, *Edith Gifford*, *The Bride*, *Alba rosea*, *C. Mermet*, *Madame Hippolyte Jamain*, *Francisca Kruger*, *Marie Van Houtte*, and *Comtesse de Nadaillac* in excellent condition. Dr. Budd was a creditable second, and Messrs. J. Jefferies & Son third.

Verbenas were well shown by Messrs. S. Walters and Weston; Geraniums by Messrs. J. Mattock (Oxford) and S. Tredwell; German Asters by Messrs. W. J. Jones and A. Langley; French Asters by Messrs. G. Garaway and W. J. Jones; Hollyhocks by Messrs. T. Hobbs and J. Newman; Phloxes by Messrs. F. Hooper and R. Palmer, the prizes

being awarded in the order named, and the competition very keen in each instance. The best collection of choice cut flowers was shown by Mr. W. James, Mr. H. Pocock being second; while with a collection of herbaceous flowers Messrs. Cooling & Son took the lead, the second prize going to Mr. A. A. Walters. The vase of flowers for table ornament, which gained Mr. J. Cypher the first prize in a large class, was nearly perfection; and the same may be said of the first prize bouquet sent by Messrs. Perkins & Son. Nearly the whole of one side of a large tent was taken up with the exhibits of collections of wild flowers, and bouquets and vases of the same with grasses, and this, probably, was one of the best displays of the sort ever seen.

## FRUIT.

One large tent was not sufficient to hold the various exhibits of house-grown and hardy fruit, and judging by what was shown, Apples especially are both plentiful and superior in quality. There were five collections of twelve dishes of fruit staged, the first prize going to Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, who had perfect bunches of Black Alicante and good Muscat of Alexandria Grapes, Blenheim Orange and Countess Melons, Bellegarde and Violet Hative Peaches, Lord Napier and Pine Apple Nectarines, Moorpark Apricots, Jefferson Plums, Brown Turkey Figs, and Williams' Bon Chrétien Pears, all shown in his well-known excellent style. Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Trowbridge, was a close second; and Mr. J. Cray, Frome, third.

The competition with eight bunches of Grapes in four varieties was also better than usual, five lots being staged. Mr. W. Taylor, gardener to Alderman Chaffin, Bath, set up perfect bunches of Muscat of Alexandria, Alicante, Madresfield Court, and Alnwick Seedling, and was first; but he had a formidable opponent in Mr. J. Gibson, gardener to Earl Cowley, Draycot Manor, Chippenham, who lost ground somewhat with his Muscat of Alexandria, but had very good bunches of Black Hamburgh, Madresfield Court, and Alnwick Seedling, and was second. The third prize went to Mr. A. Miller for creditable Grapes. Mr. W. Nash was well first with three very superior bunches of Black Hamburgh, the second prize going to Mr. Gibson for only slightly inferior bunches, and Mr. J. Lysaght third. There were thirteen of the former up, and twelve competed in the any other black class. In the latter instance Mr. Taylor was first with beautifully grown Alnwick Seedling, Mr. Pocock being second with good Alnwick, these being preferred to well-grown Madresfield Court. Mr. Taylor was an easy first in the class for Muscat of Alexandria, his bunches having very fine well-coloured berries; Mr. Gibson was a good second. In the any other white class Mr. J. Atwell, gardener to J. B. Brain, Esq., Stoke Bishop, was first with well-coloured Buckland Sweetwater, Mr. W. Dawes being second with the same variety. Mr. Pocock was the most successful exhibitor in the local class for Grapes.

Melons were not very plentiful, nor on the whole very good. Mr. W. Iggulden, Frome, was first with a green-flesh variety, staging a handsome fruit of Hero of Lockinge. Mr. H. Chislett, gardener to E. T. D. Foxcroft, Esq., was second. In the scarlet-flesh class Mr. W. Allen was first with Scarlet Invincible, and Mr. Marchant second. Peaches and Nectarines are always judged in a queer fashion at Bath, more weight being attached to flavour than to any other points. With nine fruit of the former Mr. W. Coombs, gardener to J. W. Langdon, Esq., was first for a good dish of Walburton Admirable, Mr. Pymm being second. For six fruit Mr. W. J. Atkins, gardener to S. G. Morrell, Esq., was first with Royal Charlotte, the second prize going to Mr. Iggulden for good Barrington. No mistake, however, was made in the class for nine Nectarines, Mr. Pymm winning with grand fruit of Pine Apple. Mr. J. Doe, gardener to H. W. Tugwell, Esq., Bath, being second for a good dish of the same variety. The best six Nectarines, variety Victoria, were shown by Miss Marriott, Mr. W. Tyle-Payne being second. There were a fairly large number of competitors in the classes for Plums, Figs, Cherries, and Nuts, and a capital lot of Apples and Pears were shown. Mr. W. Bannister, gardener to H. St. Vincent Ames, Esq., Clifton, was first for three dishes of Pears, having handsome fruit of Jargonelle, Souvenir de Congrès and Pitmaston Duchess. Mr. J. Goddard was second. With a single dish in a large class Mr. T. Herne was first with Williams' Bon Chrétien, and Mr. G. Horsell second. The best three dishes of dessert Apples, these consisting of Irish Peach, Worcester Pearmain, and Early Margaret, were shown by Mr. R. Palmer, Mr. J. Rogers being second. In the corresponding class for culinary varieties Mr. E. H. Caterer, gardener to T. Arnold, Esq., was first with grand dishes of Lane's Prince Albert, Warner's King, and Ecklinville, and Mr. A. Miller a close second. There were no less than thirty-five good dishes staged in the class for a single culinary variety, Mr. E. Reeves winning first position with a perfect dozen of Emperor Alexander, Mr. H. Short following with fine Warner's King.

## VEGETABLES.

These again were extensively shown, both in collections and single dishes, most of the leading west of England growers competing. In the class for a collection of twelve varieties, Mr. T. Wilkins, gardener to Lady Theodora Guest, was well first, having remarkably fine dishes of Ailsa Craig Onion, Giant White Celery, New Intermediate Carrot, Prodigy Pea, Satisfaction Potato, Perfection Beet, Lockie's Perfection Cucumber, Lyon Leek, Autumn Giant Cauliflower, Perfection Tomato, Student Parsnip, and Ne Plus Ultra Runner Bean. Mr. G. H. Copp, gardener to W. E. S. Erle-Drax, Esq., Sherborne, was a good second, and Mr. A. Miller third. Six competed for Messrs. Sutton's prizes offered for six varieties of vegetables, Mr. G. H. Copp winning the first position

with excellent examples of Sutton's King of the Cauliflowers, Sutton's Seedling Potato, Duke of Albany Pea, Sutton's Intermediate Carrot, and Perfection Tomato. Mr. T. Wilkins was second, and Mr. J. Lye third, both having good samples. The same number competed for Messrs. Webb's prizes, and in this instance Mr. W. Evry, Bath, was first, his collection consisting of Webb's Giant White Runner Bean, Duke of Albany Pea, Telegraph Cucumber, Autumn Giant Cauliflower, Perfection Tomato, and Potatoes. Mr. T. Wilkins was second, and Mr. G. H. Copp third. Sixteen competed with a single dish of Tomatoes, a fine lot of fruit being shown. Mr. H. Hopkins, gardener to H. Prodders, Esq., was first with Sutton's Perfection; Mr. T. Jones second, and Mr. F. Case third.

## NON-COMPETITIVE EXHIBITS.

Perhaps the most attractive of these, as far as gardeners and fruit growers were concerned, was the extensive exhibit of Apple trees in pots and a collection of Apples in separate dishes, these being contributed by Messrs. G. Cooling & Sons, Bath. The trees were carrying heavy crops of large handsome fruit, the best being Emperor Alexander, New Hawthornden, King of the Pippins, Cellini Pippin, Worcester Pearmain, Warner's King, Stirling Castle, Pott's Seedling, and Prince Albert. There were also fine dishes of Warner's King, Ecklinville Seedling, Blenheim Orange, Lord Suffield, Cox's Pomona, King of the Pippins, Beauty of Bath, and Reinette de Canada.

In other tents Messrs. Cooling & Sons had large stands of Roses, Gaillardias, Pentsteinons, Sunflowers, and Salpiglossis. Messrs. R. Veitch & Son, Exeter, also arranged an attractive bank, composed largely of herbaceous plants in a cut state, Gloxinias, Dahlias, Gaillardias, Carnations, including a fine stand of the popular Germania, and a variety of other flowers. Messrs. Garaway & Co., Clifton, contributed a good selection of Cactus and show Dahlias, and other flowers. Mr. Eckford had a stand of Sweet Peas of his own raising; and Mr. J. Mattock a large box of Tea Roses in bunches.

## WARWICKSHIRE.

It is customary at the annual Exhibition of the above Society to hold a Flower Show, and a remarkably good one was arranged last week in the Jephson Gardens at Leamington, which is immediately contiguous to the site of the Agricultural Show; and several tents were filled with exhibits, including one entirely filled by contributions from Mr. F. Perkins, Regent Nurseries, Leamington. This included plants of many kinds, cut flowers, fruits, and vegetables, and it had all the appearance of a small flower show in itself. As is usual, the Agricultural Exhibition appeared to overshadow in importance that formed by the plants, flowers, &c., still a great many persons attended it, the weather being on the whole favourable.

## PLANTS.

Specimen plants were a good feature, and Mr. Finch, gardener to J. Marriott, Esq., Coventry, staged in most of the leading classes, and was very successful. He was first with ten stove and greenhouse plants in bloom, having fine examples of Lapagerias rosea and alba, Ixoras Duffi and Fraseri; Ericas Marnockiana, Turnbulli, Thompsoni; Stephanotis floribunda, Dipladenia amabilis, and Phœnocomia prolifera Barnesi. Mr. J. Morris, Stoke, near Coventry, was second, his leading plants being Dipladenia amabilis, Stephanotis floribunda, and Lapageria alba. In the class for six specimens Mr. Finch was also first, having strong plants of Ericas Irbyana, jasminiflora alba, and Marnockiana; Ixora Williamsi, I. Duffi, and Lapageria alba. Mr. W. A. Mann, Lillington, was second with much smaller plants. Mr. Finch was also first in the class for three flowering and three foliaged plants, having, of the former Erica Eweriana, E. Marnockiana, and Ixora amabilis; and of the latter, Kentia Forsteriana, and Crotons Queen Victoria and angustifolium. The name of the winner of the second prize had not been placed on his plants when our report was taken.

Other flowering plants included Fuchsias, which were moderately good, but small; Zonal Pelargoniums, like the Fuchsias, shown in sixes; Begonias, only fairly good, and Gloxinias. So many of the exhibitors' prize cards were not put on until late that we were unable to gather up all the names of the exhibitors.

Foliaged plants were shown very finely by Mr. Finch. He had the best ten, which consisted of Crotons Queen Victoria, Morti, and Warreni, Kentias australis and Forsteriana, Cycas revoluta, C. circinalis, and C. species from New Caledonia, Latania borbonica, and Dasylyrium acrotrichum. Mr. Hopkins, gardener to J. D. Barbour, Esq., Leamington, was second with smaller plants of much the same character.

One of the best features were the exotic Ferns, and of these there were some very handsome specimens. Mr. Finch was first with six plants, having finely developed examples of Adiantum farleyense and cultratum, Todea superba, Trichomanes radicans, Davallia Mooreana and D. fijiensis plumosa. Mr. F. Perkins, Regent Street, Leamington, was second with smaller plants of very fine quality, having Adiantums Hendersoni, farleyense, concinnum latum and Veitchi, and Onychium auratum, a very elegant species. There was a class for six British Ferns, but only fair specimens were staged. It would be a great deal better if the term hardy were employed instead of British, as judges sometimes find it very difficult to say what are and what are not British Ferns.

Groups arranged for effect filled a tent. The best decidedly showing the highest artistic taste came from Messrs. T. B. Thompson & Son, nurserymen, Birmingham, though it did not exhibit any novel features

it was yet light and graceful. Mr. Finch was second with a bed of Fern relieved by a few ornamental leaved plants, and of which he appeared to entertain a much higher opinion than the judges. There were classes also for groups of plants for room and hall decoration, and baskets of the same, but they were of an ordinary character. There were several classes for plants by amateurs, but they were generally of moderate quality.

#### CUT FLOWERS.

A very attractive feature, and especially the class for twenty-four bunches of herbaceous plants. Messrs. Pope & Son, nurserymen, Birmingham, were first, and Mr. F. Perkins second, both with strong and weak bunches, but the balance of quality, which, after all, was not much, laid with the former. Mr. F. Perkins had the best collection of annuals, very pretty bunches of good things; but we were unable to obtain the name of the winner of the second prize. The best stand of twenty-four bunches of stove and greenhouse plants came from Mr. W. R. Mann, a very good lot indeed, representing what is usually shown in such a class. Mr. J. J. Whalley, Kenilworth, was second. Asters were represented by quilled and flat-petalled types, but they all showed the effects of the stormy weather.

The best thirty-six Roses came from the only exhibitors of the same—Messrs. Perkins & Sons of Coventry, a very good lot indeed, the leading varieties being Mad. Marie Verdier, Lady Mary Fitzwilliam, Niphotos, Ferdinand de Lesseps, Mad. J. Laing, Duke of Teck, Alfred Colomb, Marie Van Houtte, Charles Lefebvre, Ulrich Brunner, Dr. Andry, The Bride, A. K. Williams, Rosieriste Jacobs, &c. They also had the best twenty-four varieties, Messrs. Pope & Son taking the second prize.

Gladioli were shown in collections of twenty-four spikes, but they were not of a character to call for special mention. Zonal Pelargoniums, shown in bunches, were a very fine feature indeed, but we were unable to gather up the names of the successful exhibitors.

Dablias were generally shown too large and coarse, and too much advanced in bloom, the centres being quite gone in several instances. Messrs. Kimberley & Son, nurserymen, Coventry, had decidedly the best twenty-four varieties, and Mr. J. Wood, florist, Derby, was second. The best twelve came from Mr. F. J. Burbury of Kenilworth; the second prize went to Mr. C. Carrington, florist, Derby. There were several classes for cut flowers grown by amateurs, but they contained only ordinary contributions.

Table decorations included the best arranged dinner-table for ten persons with fruits and flowers. There were but two competitors; and Miss Perkins, Regent Street, Leamington, was awarded the first prize, Miss L. Perkins, of the same address, being second. The best two bouquets—one a bride's, the other a bridesmaid's—came from Messrs. Pope & Son, Birmingham; and Messrs. Perkins & Son, Coventry, were second, both remarkably good and but little to choose between them. Messrs. Perkins & Son had the best basket of Roses, and Miss Perkins, Leamington, was second. A centrepiece for the dinner table was also shown by amateurs.

#### FRUIT.

Fairly good and that was all, though the prizes offered seemed likely to tempt a greater display. Mr. Hopkins had the best collection of ten varieties, having Black Hamburg and Muscat of Alexandria Grapes, Royal George Peaches, Pitmaston Orange Nectarines, Moor Park Apricots, Bon Chrétien Pears, Figs, Cherries, &c. Second, Mr. W. R. Mann, who had similar varieties of Grapes, very fine Mr. Gladstone Peaches, Elruge Nectarines, Apricots, Jargonelle Pears, Figs, &c.

The first prize for three bunches of Black Hamburg Grapes was taken by C. J. Lefroy, Esq., Willesbourne, Warwick, and the second prize by Mr. W. R. Mann. Mr. E. F. Flower, Stratford-on-Avon, was first with white Grapes, having very good Muscat of Alexandria; Sir R. Moon, Bart., was second with the same. Collections of hardy fruits were shown in baskets, Mr. Hopkins taking the first prize and Miss Perry, Leamington, the second.

Some very good Plums were shown. The best three dishes were from Miss Perry, who had capital fruits of Washington, Victoria, and Diamond, the second prize going to Mr. Hopkins for Kirke's Victoria and Cox's Emperor, also very good.

Mr. Kitley, the lessee of Warwick Castle Gardens, had the best three dishes of Apples, staging very fine fruit of Stirling Castle, Ecklinville, and Warner's King. Mr. W. R. Mann was awarded the second prize for Lord Suffield, Warner's King, and Emperor Alexander. Mr. Hopkins had the three best dishes of Pears, staging excellent examples of Bon Chrétien, Jargonelle, and Souvenir de Congrès. Messrs. Kimberley & Son received the second prize for Louise Bonne of Jersey, Jargonelle, and Bon Chrétien. Hardy fruits of the bush type, such as Currants and Gooseberries, were well shown also.

#### VEGETABLES.

These were good and numerous, but baskets of vegetables arranged for effect appeared to be a novel feature. The Judges wisely awarded the prizes to the best examples. Some very good Potatoes were shown, but there appeared to be a tendency, in more than one instance, to show the same variety under different names. The best six dishes came from Mr. C. J. Lefroy, who had The Dean, Reading Russet, Snowdrop, Woodstock Kidney, Prizetaker, and Schoolmaster. Mr. F. J. Burbury was second with a very good set of six dishes. Vegetables were also shown by amateurs and cottagers.

#### FRUIT FORCING.

**VINES.—Houses of Ripe Grapes.**—Those that contain the thick-skinned Grapes will require, whether they are to be kept on the Vines or in the Grape room, liberal ventilation, with gentle fire heat for the maintenance of a certain ventilation of air. With the Grapes ripe, gradually reduce the strong laterals as the days decline in length, and keep the foliage healthy by means of a proper supply of moisture on the walls, paths, and floors sufficiently early in the day to admit of the atmosphere becoming light and buoyant before nightfall. Black Hamburg and other thin-skinned black Grapes are liable to have the colour taken out of them by hanging under powerful sun. Some netting should be drawn over the roof lights to prevent it. Hamburgs and Foster's Seedling will bear as much air moisture almost as the thick-skinned varieties, provided it be not stagnant, and it is very necessary for the foliage, which must be kept healthy. Madresfield Court do not endure moisture to anything like the same extent as Hamburgs, and must be treated accordingly. It, however, loses colour quite as badly, and must be shielded from the direct rays of the sun. Muscats hanging on Vines with the roots in outside borders will keep a long time, protecting the roots from heavy rains. A covering of dry fern, shutters, or tarpaulin answer, but glazed lights are better, placing in a sloping position for throwing off the wet, as they admit sun heat, and retain it for warming the borders. If the foliage is not sufficient for the protection of the tender skins of the berries, some light shading will be necessary, particularly where the houses are glazed with large panes of glass. A single thickness of pilchard netting is sufficient, or hexagon netting may be used, which effectually excludes wasps. It is hardly possible to keep Muscats well without a gentle warmth in the pipes, in order to keep the air in motion, for when the air is still moisture sometimes condenses on the berries, and they are then liable to spot. It should be accompanied with a little ventilation.

**Lifting Vines.**—This and relaying the roots in fresh compost near the surface should be proceeded with as the Vines are cleared of their crops. The sooner it is done after the wood is mature and the buds plumped the better, but it must not be attempted whilst there is doubt of that being effected. Yet it is always best to perform work of this kind whilst the leaves are upon the Vines. Good loam with some brick and lime rubbish, and a liberal admixture of crushed bones and charcoal, will meet all requirements in respect of compost. See to the drainage, make it satisfactory, and follow on with turf grass side downwards, or a 3-inch layer of lime rubbish freed of all laths or other pieces of wood. Keep the roots near the surface, always bearing in mind that a narrow border well filled with roots is preferable to a large mass of soil at the onset, as the roots can be more easily excited and fed at the proper time. The Grapes, too, in a border well in hand invariably set and colour better. Always choose dry weather for making the border, and be careful to have the compost in good working order, neither too wet or too dry, but moderately moist. Cover it when finished with a thin layer of stable litter freed of the coarse strawy portions, and keep the interior of the house close and rather moist until the foliage shows signs of fresh root action having set in, then ventilate freely, and keep the air dry. In all cases, especially in cold localities, the Vines should have inside as well as outside borders, as the roots can then be lifted and relaid in either of the borders without injury to the following year's crop. If the border in which the roots are lifted be an outside one it should be well protected with leaves before frost, covering with a little litter to prevent the leaves blowing about.

**PINES.**—Young Pine plants always present at this season, under liberal and proper treatment, a luxuriant appearance. This arises from the beneficial effects of natural means so important in cultivation. Those influences being now on the wane greater care will be necessary in the management to prevent the growth becoming soft, and measures should be taken to consolidate it by a drier atmosphere and artificial heat. Syringing will only be needed occasionally, and it should be done early in the afternoon of bright days. Water must only be given when absolutely necessary, then afford a plentiful supply of weak liquid manure in a tepid state. The bottom heat should be kept steady at 85°, or between 80° and 90°, and pay particular attention to the ventilation, which is important at this period of the year. Plants in a luxuriant condition should have air at 80°, above which ventilate freely, especially on warm sunny days, and close the house for the day at 80°. The night temperature should be maintained at 65°, allowing 70° to 75° by day artificially.

Fruiting plants should be kept together in a suitable structure for finishing the fruit well. Isolated they cannot always be furnished with their needful requirements. Plants that are intended for starting into fruit early in the year should be selected from those that were started last spring, and be arranged not later than the end of this month, where they can rest for six weeks. Those on which the fruit is swelling should be encouraged with a liberal amount of heat and moisture, keeping the night temperature from 70° to 75°, and that in the daytime from 80° to 90°, closing the house at 85° with sun heat.

**STRAWBERRIES IN POTS.**—In the earliest plants the crowns are becoming plump, sufficiently so, at least, for the detection of plants that will not be available for early forcing, and which should be removed at once, even those about which there is a suspicion of being barren, making good the deficiency from surplus stock. These should be given plenty of space and the warmest position. Worms and runners are troublesome, also weeds. Lime water will expel worms, but the drainage must be seen to afterwards and put right, putting down more ashes to prevent others entering the pots. Runners and weeds must be promptly removed. The pots in all cases should be wide enough apart to allow of the sun and air having free access to the foliage. The crowns, which are numerous in some varieties, particularly Vicomtesse Hericart de Thury, should be reduced to the central or strongest one, not deferring it until they have attained to a considerable size, but as soon as they can be taken hold of with the finger and thumb and lifted clean out of the socket. This will concentrate all the vigour in the main crown; those will afford strong flower spikes, and then by selecting the largest and best formed flowers a crop of fruit will be ensured large and creditable to the grower. Any late runners may yet be potted, and with good attention they will be serviceable for late work in 5-inch pots, and may afford very good fruit.

#### THE FLOWER GARDEN.

**Propagating Pelargoniums.**—It is not yet too late to take and root the requisite quantity of Zonal Pelargonium cuttings, but if longer delayed the result may prove disappointing. Cuttings this season are very soft and sappy, and more than ordinary pains must be taken with them or there will be many failures. After they are duly cut to a joint and freely trimmed all ought to be laid in the full sunshine or in an open place to flag. In this manner much superfluous sap will be removed and the wounds partially healed over. Nor ought water to be given for several days after the cuttings are inserted, only enough being given at any time to prevent their shrivelling badly. At this late date none should be left in the open exposed to all weathers, a dry cool staging or shelves in a house or pit being the best place for these newly inserted cuttings.

**Pots versus Boxes.**—Where extra large quantities of Pelargoniums are still bedded out the ordinary boxes must be largely used for their storage. If carefully watered and kept in dry airy houses the percentage of losses is usually small; but boxes are by no means the best receptacles in all instances where the house room is either limited or of an unsuitable character. It is surprising what a quantity can be packed away on a few shelves, swinging or otherwise, if the cuttings are inserted somewhat thickly in 3-inch or rather larger pots. Each small pot will hold five or six cuttings, and these being potted singly in the spring make fine plants by the time they are wanted for the beds. The more delicate variegated varieties frequently damp off extensively in boxes, but they keep well in pots. If, therefore, boxes must be used place the common green-leaved varieties in these and place the bicolors and tricolors in either pans or pots. In any case only common sandy soil should be used, the boxes especially being well drained, while all ought to be firmly fixed in the soil.

**Tuberous Begonias.**—The beds of these have quite eclipsed the Pelargoniums this season, and in many cases they would pay well if protected from early frosts. A light framework and either mats, scrim canvas, or cotton blinds would ward off a moderately severe frost and prolong the display considerably. Sturdy isolated plants could be potted, and would flower for a time in a conservatory or greenhouse. As far as keeping the roots is concerned, there is no necessity to lift the plants before frosts have crippled the tops, only very severe cold ever reaching or injuring the tubers. Mixed beds are very effective, but masses of one colour are even more so; and for this reason it is advisable to place a label bearing the description of colour and habit to each plant, and next season it will be a simple matter to group the different colours. The erect flowering forms are the most effective in flower beds, and during the weeding-out of inferior forms the preference might well be given to those with bold erect blooms. Cuttings inserted in either boxes or the open ground, similarly to Zonal Pelargoniums, will eventually die down, but not till most of them have formed tubers at their base.

**Verbenas.**—On the whole these have been a failure, the rains dashing the blooms as fast as they opened. Nor have the more delicate named varieties formed much healthy growth, good cuttings being scarce. Hard young shoots rarely strike freely, and even if they can be rooted they seldom grow vigorously. Select succulent young flowerless shoots, shorten to the third joint, and insert rather thickly in 5-inch pots, water-in, and place them in a frame over gentle hotbed. They must be kept rather close and shaded till well rooted, when the plants ought to be stored on shelves in a cool house. Old plants can seldom be potted with advantage, and flowering or insect-infested shoots are useless for propagating purposes.

**Lobelias.**—These have revelled in the dull showery weather, and were never gayer for so many weeks together. Nowadays seedlings are so good as regards evenness of growth, colour, and floriferousness that there is little need to propagate from cuttings or division. Nor do old plants that have been flowering all the summer succeed in pots. Cuttings are also scarce unless the plants have been prevented flowering. If they can be procured they may be rooted, and the plants wintered much as advised in the case of Verbenas.

**Heliotropes, Petunias, and Ageratums.**—All have done well this season, the first and last named especially so. Cuttings do not strike particularly well. The surest way of having a stock of

either is to keep a number of young plants growing strongly in pots all the summer, these flowering freely in the autumn, and produce cuttings in abundance from the ripened growth the following spring. This precaution not having been taken in the case of Heliotropes, the attempt should be made to root some cuttings in gentle heat, and a few old plants ought also to be potted before frost injures them. Petunias and Ageratums may be treated in a similar manner, though good strains of both can be had from seeds sown next spring.

**Tender Bedding Plants.**—Healthy or not starved plants of Coleases, Alternantheras, and Iresines kept all through the summer in pots are better for storing for stock purposes than any that can be potted up, but if these are not available then must cuttings be inserted and old plants lifted before any more frosts are felt. Soft cuttings of either of the kinds named usually strike freely in a brisk heat, while if plants are lifted not much rich garden soil should be left about the roots, or otherwise it will become sour during the winter. A light compost ought to be used, and good drainage given. The shelves of stoves or forcing houses are the best positions for wintering these plants, and rather small pots are better for them than either pans or boxes.

**Protecting Masses of Flower.**—Many good and serviceable border plants are flowering exceptionally well this season, plenty of moisture at the roots evidently suiting them. Masses of Stocks, Asters, Zinnias, Marigolds, Gaillardias, and the taller-growing Japanese Anemones, herbaceous Sunflowers, Pyrethrum uliginosum, Heleniums, late Gladioli, and any other showy plants might be preserved from frosts and heavy rains without much trouble, and their usefulness greatly prolonged with the aid of a few stakes, benders, rods, and either mats or good blinds. Everything should be kept in readiness for covering the plants, and be put on before frosts cripple them.

#### PLANT HOUSES.

**Gloxinias.**—There is no difficulty in having these in flower throughout the year. Plants that flowered early and have just started again into growth should be shook out and repotted. Introduce another batch of plants into a temperature of 60°. It is a good plan to shake them out and place the tubers amongst leaf soil in pans or boxes until they commence growing and rooting. Do not dry off too quickly plants that have flowered.

**Coleus.**—Cuttings should be rooted in quantity. Select shoots with large bold foliage, and insert them singly in small pots. Small, well furnished, highly coloured plants are invaluable for table and other forms of decoration. Root also a good batch of cuttings in 5 and 6-inch pots for stock purposes, and keep them where the temperature ranges 60°. These, if allowed to grow without pinching, will yield valuable cuttings for rooting in small pots at intervals of a month.

**Medinilla magnifica.**—If grown in the stove, where shading has been employed, it should now be removed to a cooler and drier atmosphere, and fully exposed to the sun. It will be safe in a night temperature of 55°. Do not diminish the supply of water at the root, and the syringe should be used freely once a day. Thrips are very troublesome, and once they are established they soon destroy the fine foliage of this plant.

**Epiphyllums.**—These should have completed their growth; expose them fully to the sun in a cool dry atmosphere. Do not keep them dry at their roots. Water carefully, but do not allow them to suffer by an insufficient supply. Plants that have not done growing should be kept fully exposed to the sun in a temperature of 60°. Where the Pereskia has been grown strong for stocks the shoots may be cut into lengths of 9 inches or a foot, the eyes removed, and then inserted singly in small pots. Portions of Epiphyllums may be secured to the stocks as soon as they are inserted, and by the time they are rooted the stock and scion will have become united.

**Stephanotis.**—Plants that flowered early have completed their growth, and should be placed where the temperature does not fall below 50°. Admit plenty of air during the day and maintain a dry atmosphere about the plant. The principal object now should be to harden and ripen the wood thoroughly, then abundance of flowers another season may be anticipated.

**Poinsettias.**—If not removed from cold frames these should be removed without delay to some light structure where the temperature will not fall below 55° to 60°. Ventilate freely during the day to prevent the plants again starting into growth. This must be avoided, or else their brilliant bracts will be small in comparison to what they should be.

**Caladiums.**—It is not safe to keep these much longer in a cool conservatory. They should be removed to a temperature of 60° and allowed to go gradually to rest. Do not dry them off too quickly, or else the tubers will rot; gradually decrease the supply of water, and allow them to die off naturally. The tubers will then remain sound for another year.

**Adiantum euneatum.**—Seedlings that are well established in 3-inch pots will if placed into 5 or 6-inch at once continue to grow and yield fronds for cutting throughout the winter. Place the plants in a temperature of 60° and grow them fully exposed to the sun. Use for a compost leaf mould and loam in equal proportions, and add a liberal quantity of sand. Lime rubbish broken up moderately fine and incorporated with the soil is also very suitable for these plants. Plants from which all the best fronds have been removed may be cut over, rested for a short time in a cool place, and then started into growth by placing them in the temperature advised for young plants.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### THE WEATHER.

THE weather has been extremely variable since the 29th August, as it has been all the season. It may perhaps be interesting to some to know that on the morning of the 31st August there was a severe frost. Potatoes were frozen to the ground, but singular to say the Heather was uninjured, and the bees throughout the brighter part of the day worked well. The following morning first brought us sleet and heavy showers of hail, a change of temperature to something like summer heat followed for three days, with heavy downpours of rain. The last two days were the best the bees have had this season, an evident rise in the weight of the hives having taken place, and the 5th September was the finest day of the season. With a further continuance of fair weather for a few days the bees may make up their weight wonderfully, and may enable me to lay before your readers the results of the season.

Appearances are sometimes misleading, but of six varieties the Carniolians are the most promising. Ours are a wonder to all who see them, and are a wide contrast to other varieties and to those in standard sized hives which have been preserved by driblet feeding. Not one of that sort I have witnessed but has drawn their brood long since and are unlikely now to be able to gather much surplus, but the results will prove. The largest yields will be had from the full sized hives as is always the case, there being always plenty of bees and room to store honey in the body of the hive without the necessity of having to build comb in the first place, which in a season like the present is out of the question with weak hives.

### POLLEN—BEES FLYING.

I have been much interested at seeing the bees break the rule of gathering pollen from one sort of flower or grass only. I have witnessed them frequently work alternately on different species of both flowers and Grasses.

Some years since I gave my observations and opinion upon this subject to the effect that bees were guided to their hive by possessing a knowledge of the points of the compass, and not that of any land or other mark. Following that article there appeared in a contemporary an article on the same subject as original! I have for some time past been giving the subject more thought and attention, and my opinion is that magnetic influence is the principal guide of the bee, both outside and inside the hive, and that the eyes are of most use to the insect in her flights in the field, and that their antennæ regulate every movement.

### THE AGE OF THE BEE.

We have had this subject so often under consideration that it is almost useless to say a word more upon it to refute the erroneous impression that bees live about six weeks only, were it not to point out to bee-keepers that these strong colonies are the result of having two queens' progeny living at one time, not by art, but by a natural act of the bees changing their queens without swarming about midsummer. The bees are still further preserved by being kept much within-doors through stress of weather, and being well found in stores the season throughout, being exactly in a similar condition to that which we have so long advised to be done by careful manipulations, and introducing young fertile queens at the proper time.—A LANARKSHIRE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Bulbs.*  
Dobbie & Co., Rothesay, Scotland.—*Autumn Catalogue.*  
Barr & Son, King Street, Covent Garden.—*Catalogue of Bulbs and Daffodils.*

## TO CORRESPONDENTS

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Begonias** (*Lord B.*).—You will find the information required on page 217 of this issue.

**Seedling Carnations** (*W. L. C.*).—The Carnation would never possess any commercial value, as there are many varieties in cultivation superior to the one of which you sent a flower.

**Dahlias** (*R. S.*).—It is probable that the tubers were mixed, as, though cultivation has a tendency to cause a change in the flowers such as you describe, it is not likely to be effected in one year.

**Cheap Heating Apparatus** (*S. S.*).—You could effect your object by means of any of the cheap appliances advertised in the columns of this journal. Remove some of the foliage and expose the fruits to the sun as much as possible; this will help more than artificial heat.

**Azalea Bed** (*W.*).—The best soil for Azaleas is unquestionably peat, but we have had them thriving admirably in loam on the sandstone and freestone formations, and quite luxuriantly in sawdust from loose boxes in which hunters have "run" during the summer, mixed with an equal proportion of turfy loam. We have no doubt of cocoa-nut fibre refuse being an excellent material for mixing with loam for the growth of Azaleas and Rhododendrons, having a sixth of sand added, and put in 18 inches deep and made quite firm. We have also seen them luxuriating in a shallow silicious loam overlying sand, with a good mulching each year of cowdung. The condition of your plants shows the soil to be unsuitable, and we should take it out and have 18 inches depth of peat, which is best taken from a moor where Heather grows, the top 3 or 4 inches being best, and with a goodly admixture of particles of white sand. This chopped moderately small will grow them perfectly. The brown spongy peat used for Orchids is not suitable for Azaleas. We should not cut the plants down—at least, not until they had become well established in the peat bed, and then you may cut away the stunted growths, so as to encourage stronger growths from the base, and so insure larger trusses of bloom. Hardy Azaleas in variety are not so common as they deserve to be in gardens.

**Arranging Conservatory** (*P. R.*).—The walls will look very tame covered with Ivy. We suggest that the most conspicuous be covered with ornamental rockwork to some little height from the floor, and above that have rockwork pockets for Ferns, ornamental leaved Begonias, Tradescantias, and similar plants, and cover the smooth portions of the walls with *Ficus repens* and var. *minima*. It is very close growing, forming a capital background to the Ferns, &c., and is better indoors than Ivy. Vines would not succeed in such house, nor are Roses suitable unless they are trained well up to the glass and have plenty of light. We should have a border along the front inside, and plant *Lapageria rosea* and *L. alba*. They are charming when seen together, and would grow admirably in such position, training them up the front and over the roof from 6 to 9 inches from the glass. Camellias would do well, and Oranges may be grown in pots; but it would be best to rely chiefly on Palms and other foliage plants, such as *Indiarubber*, *Aspidistra lurida variegata*, *Dracæna congesta*, *D. australis*, *Aralia Sieboldi* and var. *variegata*, *Phormium Veitchi*, and *P. Colensoi*. For hanging baskets you could not have anything better than Ferns, such as *Nephrolepis Bausei*, *Davallia fijiensis major*, *D. Mariesi*, and *Platy-cerium alaicorne majus*.

**Alternanthera Failures** (*G. B.*).—*Alternantheras* are essentially heat-loving plants, and the present season has been most unfavourable to their growth, failures being general. They rarely form much fresh strong growth after being planted, but the stunted shoots produced are invariably the most highly coloured. The best effect is produced by putting out quite small plants very thickly in the first instance. Strong plants may look well for a few days, but when the broad or fully developed leaves fail, which they very soon do, there is nothing to take their place, for some time at any rate, and a failure may be the result. Not only are *Alternantheras* very much smaller than when first put

out, but Coleuscs and Iresines are not much better. Alternantheras cannot well be dispensed with, there being no substitute sufficiently dwarf and richly coloured.

Culture of Kalosanthes coccinea (C. R. M.).—If all the shoots are cut down the plant will not flower next year, but will be fine the year after, and on this account cultivators usually have two sets of plants ; but it often happens that plants with only two shoots will produce but one head of bloom, and then the second shoot will be sure to follow the year after, and thus a plant may be made to flower every year.

Propagating Clematis Jackmani (S. T.).—These plants can be increased by cuttings of nearly half-ripened wood in the spring of the year, if inserted in sandy soil and placed until they are rooted under bellglasses in a temperature of 50° to 55°.

Names of Insects (G. H., Loughborough).—The caterpillar taken off the Apple is of the Eyed Hawk Moth (Smerinthus ocellatus), nearly full grown. Its more usual food is the Willow and Poplar, but it sometimes occurs upon the Apple, though not in sufficient numbers to do any appreciable harm to fruit or foliage.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not.

are probably local varieties. We do not know them, and they are of inferior quality.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores.

COVENT GARDEN MARKET.—SEPTEMBER 10TH.

MARKET quiet, with no alteration.

FRUIT.

Table with 4 columns: Item, s. d., s. d., s. d. Items include Apples, Lemons, Melons, Oranges, Peaches, Plums, St. Michael Pines, Strawberries.

VEGETABLES.

Table with 4 columns: Item, s. d., s. d., s. d. Items include Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Cabbage, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Potatoes, Rhubarb, Salsafy, Scorzonera, Seakale, Shallots, Spinach, Tomatoes, Turnips.

CUT FLOWERS.

Table with 4 columns: Item, s. d., s. d., s. d. Items include Arum Lilies, Asters, Bouvardias, Carnations, Calceolaria, Chrysanthemum, Cornflower, Dahlias, Eschscholtzia, Eucharis, Forget-me-not, Gardenias, Gladiolus, Gypsophila, Iris, Lapageria, Lavender, Liliium, Marguerites, Maidenhair Fern, Mignonette, Pansies, Pelargoniums, Pinks, Primula, Roses, Sweet Peas, Tuberoses.

PLANTS IN POTS.

Table with 4 columns: Item, s. d., s. d., s. d. Items include Aralia Sieboldi, Arbor Vitæ, Asters, Calceolaria, Chrysanthemum, Climbing Plants, Cyclamen, Deutzia, Dracena, Epiphyllum, Erica, Enonymus, Evergreens, Ferns, Ficus elastica, Foliage plants, Fuchsia, Geraniums, Geraniums Scarlet, Heliotrope, Hydrangea, Liliium lancifolium, Lily of the Valley, Lobelia, Marguerite Daisy, Mignonette, Musk, Myrtles, Nasturtiums, Palms, Pelargoniums, Rhodanthe, Saxifraga, Spirea, Stocks, Tropæolums.

AGRICULTURAL EXPERIMENTS IN SUSSEX.

OFTEN have we called attention in these articles to the important work being done by the Sussex Association for the Improve-

ment of Agriculture, and we have now to record other results, which were clearly explained by Professor Jamieson at the annual visit of the members to the experimental stations on the 21st ult.

Not unimportant were his preliminary remarks about the size of the experimental plots. The end and aim of the experiments is precise information, and this for some time appeared to be impossible of attainment. The learned Professor's experiments with land were begun some fifteen years ago in Aberdeenshire, and they were subsequently extended to Sussex and elsewhere, and he told how at the outset quarter of an acre plots were tried; the results were so contradictory that the size of the plots was gradually reduced, till the present size of 1-1000th of an acre was arrived at. This was eight years ago, and it has been retained ever since with most satisfactory results, to which the plan of thoroughly mixing the soil of each plot has much contributed. He told how in France Professor Grandean has adopted plots very similar in size, as also has Dr. Peterman in Belgium; and Dr. Voltmann who has been over from Germany to inspect the experimental stations of this country, gives his unqualified approval of the Sussex stations, which is highly satisfactory, as we have reason to regard German scientists as our leaders in this great work.

Turning to the plots we saw how admirably the stronger-growing Grasses hold their own in weedy young pasture. Rye Grass did not bear the test at all well, for it appeared to have gradually been overpowered by weeds; but Cocksfoot has gone on improving year by year, and we have no doubt that eventually it will be cultivated separately, just as it is in New Zealand, and just as Rye Grass is here. Cocksfoot has a remarkable future, for even those who object to the great prominence given it never attempt to deny that it is most nutritious and productive. Of Rye Grass we had another valuable lesson in the importance of seed selection and careful cultivation, both which tell materially upon bulk of crop. But perhaps the most remarkable development of plant and bulk of yield was seen in a plot sown with the strong-growing Grasses at the rate of 14½ lbs. of seed per acre, and at a cost of 7s. 10d. Nothing could be more satisfactory, and equally heavy crops of the same Grasses have been obtained at the trial station in Aberdeenshire.

The elaborate and costly mixtures generally used for new permanent pasture are calculated to meet all requirements of grazing and haymaking, and are so far desirable; but it is obvious that when hay, silage, and cattle grazing are only required, not only may a very considerable saving in cost of seed be effected, but a more satisfactory result obtained by the use of stronger Grasses only. There should, of course, be a fair proportion of Clover in all pasture of a permanent character, and Dr. Fream's recent trials of old pasture show beyond a doubt how very generally Perennial White Clover predominates in the best old pasture.

Probably nine farmers out of ten would object to the breaking up of an old pasture in view of obtaining a better by cultivation, and in East Anglia we doubt not that the tenth man would join the majority. Now we know many an old pasture that in our opinion is, and always will be inferior, simply because they contain no really good Grasses. They may be made to yield a full crop by means of judicious and persistent manuring, but the practice is not commendable under all circumstances, and it has been shown at the Bridge Farm Station how much better it answers to plough up an old inferior pasture and to re-sow it, the herbage being altogether of a superior character, and in the third year its very great superiority over the plots of old pasture was evident. A light ploughing appears sufficient to give the new plant a sufficient start to thrive and become thoroughly established in the overturned sods of old pasture. The popular plan of sowing seed on old pasture has been tried at the Bridge Farm Station with most unsatisfactory results, no real improvement being perceptible, and we were reminded of the strongly expressed opinion of the manager of a large estate, who once told us how often he had

supplied tenant farmers with seed for pasture renovation against his conviction of its usefulness.

The manure experiments are steadily continued, and they tend now more to emphasise the fact well known to our readers, that the only three essentials are nitrogen, potash, and phosphorus. Even now we occasionally read statements that sulphur, iron, and magnesia are necessary in manure mixtures. Professor Jamieson now says emphatically that to spend money upon either of these things or upon lime as a manure is waste. Lime acts mechanically in the most admirable manner upon all clay soils, and the experiments show its especial value upon heavy land. One important outcome of the manure experiments is that the best form of manure application to pasture is found in annual dressings of quick acting chemical manures. Better than dung, better than heavy expensive dressings of chemicals are they. Well do our readers know this, for have they not been reminded year after year to apply about 2½ cwt. of home mixed mineral and nitrogenous manures to pastures in February?

#### WORK ON THE HOME FARM.

Gloomy and wet as so much of August was, it gave us a parting smile on the last two days, which were bright enough, and September came in with a hoar frost and clear sky. Brisk and bracing was the air as we drove at early morn through fields still full of uncarted corn, and we are glad to add of corn that has not sprouted, despite an almost daily rainfall. There should be very little Wheat threshed before the new year, for soft corn will be the rule and hard corn fit for grinding the exception this autumn. This should tend to keep the price of Wheat firm, and we hope the price may not induce premature threshing and the inevitable loss which always follows such bad practice.

Though most of the corn has been kept from sprouting by drying winds, yet we have to deplore much discolouration of Barley, which is certain to put up the price of good malting samples, and will probably induce a still greater reduction of the area devoted to Barley culture next year, and a proportionate extension of that of Oats. The extraordinary crop of Beans will prove a boon to heavy land farmers, and will do doubt induce them to sow winter Beans extensively this autumn. New layers, both of Clover and mixed seeds, are exceedingly good and so strong in growth that we have seen some Clover in full bloom, and almost as high as the corn. This should induce caution in carting such corn, as the large quantity of herbage in the sheaves may do harm in the stacks if not well ripened.

We are giving dairy cows a little extra dry food, as the rank growth of herbage on pastures is not so nutritious as usual at this season of the year, and there is a risk of some falling off in quality of the milk. Excessive moisture and a low temperature is liable to cause trouble among the udders of cows that are out constantly on pasture, soreness being especially prevalent in herds on low marsh pasture. During the present month the yards and lodges will all be closely examined and set in order for the coming cold season. October is frequently the most trying month of the year for cattle, owing to the great fall in temperature and heavy rain. We like to be on the safe side, and begin using the yards at night according to the state of the weather. Especial care is taken to have the drainage of every yard in perfect order, so that there may be no risk of cattle having to stand about in water, or litter so sodden that a small puddle is made by every step taken by the cattle.

#### REMARKS.

- 31st.—Fine and generally sunny, but occasionally overcast.  
 1st.—Misty early, fine day, not much bright sunshine.  
 2nd.—Fine bright morning, cloudy and frequently threatening in afternoon.  
 3rd.—A little sun about 11 A.M. and 4 P.M.; otherwise overcast throughout.  
 4th.—An almost uniform covering of thin cloud till 3 P.M., then generally bright.  
 5th.—Cloudy early; bright warm day.  
 6th.—Generally overcast in morning; bright afternoon and evening.

A week of fine autumn weather, without measurable rain.—G. J. SIMONS.

## DOUBLE VIOLETS.

IT would appear almost impossible to overdo the markets with these. Send them where you will, whether to the London florists or the nearest town, they are certain to be welcomed, and on the whole they pay well too. The two most popular varieties, both with growers and those who purchase them, are Marie Louise and the white Comte de Brazzi. There are forms much resembling Marie Louise and others of a deeper shade of colour, or more nearly approaching blue, but it scarcely pays to bother with these. Private gardeners who market their surplus produce, or who have to make a certain sum "by hook or by crook" every season, cannot afford any more than the professed market grower to have any fads, and a great variety of any one thing is a fad which never pays. If a better variety than Marie Louise is forthcoming by all means let it supersede it, and if a better white than Comte Brazzi can be named those who possess it will confer a great favour by stating where it can be obtained.

The ordinary method of growing double Violets may answer very well for ordinary purposes, but those who desire to grow extra fine flowers in the greatest profusion must adopt a better system altogether. What I term the ordinary or most common practice is most faulty as regards the preparation of the young plants. When the cultivator is content to pull the old plants to pieces every April or May, selecting the best rooted pieces and destroying the rest, it more often happens than not that the choice falls on the old crowns, the young rootless runners being discarded. Now, these old plants in time become much stunted and very rarely grow away strongly, or long remain free of red spider, after they are planted out in the open. Young plants behave very differently, these forming strong crowns full of flower buds long before frosty weather sets in, and the foliage being stout and clean, is not nearly so liable to damp off during the winter as are the thin spider-infested leaves on the old stools. There are two ways of raising the requisite number of young plants, both of which are simple enough. At the present time, and also after the plants are transplanted to pits and frames, a number of runners are constantly forming, a few being short with a rootless plantlet attached and the rest mere straggling growths. All the latter ought to be kept closely pinched out, and three or four of the former reserved and pegged down when large enough. Early in September is a good time to do this, though it answers nearly as well to peg them down after the plants are in their winter quarters. All soon push roots into the soil, and during the winter produce a few good flowers. When the time again arrives for dividing and replanting, these young well rooted side plants will be found capital for making a fresh start, the worn out old crowns being thrown away. The other plan of raising a young stock of healthy plants can be practised by those who have neglected to peg down the short runners, and consists merely of taking off the latter directly the flowering period is over and treating them as cuttings. Supposing the old plants are cleared out of a pit the soil can be broken up, levelled, and will then be ready for the cuttings. Dibble these in about 4 inches apart each way, water, shut down the lights, and keep close and shaded till all are rooted. They will strike like weeds, and will soon surpass any old plants or divisions of crowns. Hundreds can be rooted in two or three lights, and many hundreds are wanted if Violets are to be grown profitably.

In most instances the stock of plants for winter flowering is prepared in the open ground, and if the site is fairly cool and well prepared beforehand, a well pulverised soil and plenty of leaf soil rather than much manure being preferable, they will usually do well. This season there has been little or no necessity for waterings over the foliage, but during a dry hot summer they require to be watered frequently, syringed nightly, and mulched with leaf soil, short manure, or grass from the mowing machine. Unless this is done the chances are red spider will be in the ascendant, and a weakly stock of plants be the consequence. A light sprinkling of salt is also beneficial in most cases where the soil is of a light gravelly character. But if this is the most common practice it is not the best. By far the finest plants and the most profitable crop of flowers can be had if the rooted runners are planted direct where they are to remain all the winter. Where the pits are wanted for a variety of other purposes this plan cannot be largely adopted, but in very many instances pits have been erected principally or solely for Violet culture, and there is nothing to prevent these being filled with plants all through the summer. Portable garden frames are also extensively used in Violet culture, and the beds for these could be got ready, the soil being kept in position by the aid of boards, and planted long before the frames are at liberty for enclosing them.

It is of the greatest importance that the Violets be raised well up to the light, air, and what sunshine we get during the winter. There should, therefore, be a fall of 24 inches from the back to the front of either a pit or frame, this angle not being a degree too sharp, and in each and every case the soil ought to be brought up to within 9 inches of the glass. I prefer a solid to a loose foundation, so that there should be little or no settlement during the winter. We are obliged to use a foundation of faggots for the frames, or otherwise moles up root everything. On the wood is placed 2 feet of old hotbed material and rubbish that can be trampled firmly, about 8 inches of good loamy soil, such as comes from Potato, Cucumber, and Melon frames, with an addition of leaf soil and charred garden rubbish, being sufficient for the plants to root in. We merely freshen up the surface of the pits, supplying fresh compost instead of some of the old, the foundation of rubbish and soil not being disturbed. Bottom heat of any kind I do not approve of, nor do Violets long thrive in heated pits. Gentle bottom heat or a little warmth in the pipes may be the means of developing a fairly good supply of flowers during the dullest part of the year, but the market grower cannot afford to weaken his plants for this chance supply. He would be the loser in the end if he did. Bottom heat is certainly not needed to forward the flowers, as well prepared plants commence to bloom early in September, and only during the most unfavourable weather do they remain in a comparatively inactive state. We usually place a few dozen strong plants in 8-inch pots to produce flowers for home use, and these being kept on a shelf in a greenhouse provide us with a serviceable supply at midwinter.

All the plants, wherever prepared, ought to be in their winter quarters before severe frosts are anticipated, these being liable to cripple the foliage badly, damping off being the sure consequence. A dull time in September, or not later than the first week in October, might well be selected for transplanting the best of the plants to the pits and frames, taking care to move all with a fairly large ball of soil about the roots. At the same time remove all superfluous runners and nearly dead leaves, and replant firmly. When plants are abundant inexperienced growers are apt to plant them too thickly. Better by far leave a portion of them in the open to take their chance than to overcrowd and risk wholesale damping off. Our plants at the present time are 10 inches across, and will be kept just clear of each other throughout the greater part of the winter. This rule should be generally observed. It is of the greatest importance that the surface soil be kept open and sweet, and if charred garden soil and rubbish is freely

distributed among the plants, this may prevent a serious spread of a fungoid disease that sometimes clears off the plants wholesale. If the soil either about the roots or in the pits and frames is at all dry, a good watering ought to be given directly after the planting is completed, otherwise this may well be deferred for a few days, or left to the next fall of rain. Keeping the plants rather close for a few days will serve to re-establish them more quickly, but on no account should this coddling be long continued or resorted to any time subsequently. From first to last Violets under glass require abundance of light and air, the lights being drawn clear off whenever the weather is mild and dry, and blocked up in the centre at other times, very frosty weather excepted. When an insufficiency of air is given, if this does not result in damping off, it will yet inevitably lead to an early and strong growth of the foliage, and with this there is certain to be a cessation of blooming. At the same time they must be well protected from severe frosts.

The price for double Violets does not vary greatly. We get nearly or quite as much for them when they are very plentiful, or say in March or April, as we do when fewer are available. What florists like are fully developed blooms with long stems. The bunches usually contain about two dozen blooms, and for every dozen (13) bunches we get on an average 2s. 6d. clear. These bunches, even if not made up afresh, are retailed at not less than 6d. each, and those who take private orders may safely charge that sum for them. Much the same price is given for the white variety, and we find it nearly as floriferous as the Marie Louise. We expect to make about 12s. per light, and this sum is more often exceeded than not. It is a mistake to pick any before they are fully expanded, one fully blown Violet being equal to three half grown, or of the size they are too often gathered. Their own foliage sets them off well, but we cannot afford to weaken the plants by picking them constantly, and use neat or coloured Ivy leaves instead. Packed closely and tightly in either stiff cardboard or light wooden boxes, they can be sent any distance cheaply by post or rail.—  
I. M. H.

## GROWING AND SELLING FRUIT.

### THE APPLE.

(Continued from page 198.)

**INSECTS AND DISEASES.**—The Apple weevil is one of the worst pests the grower has to contend with. The female lays her eggs when the flowers are unfolding. These soon hatch into small maggots, and feed on the flowers and young fruit, eventually changing to the perfect insect, which feeds on the leaves, sometimes appearing in such large numbers as to almost strip the trees bare. In the case of small or young trees handpicking is the best remedy. In large orchards and on older trees this is impossible, but much good may be done by smearing a circle of Stockholm tar and grease round the stem of the tree about 4 inches broad. This will catch a large number of the adult females when they crawl up the stem in the spring to lay their eggs. It should be put on just before the sap begins to rise. Good cultivation and keeping the trees clean and healthy will also assist in keeping down insects.

The grub or maggot of the Codlin Moth also does much damage by eating the young fruit, eventually causing them to drop from the tree, when the maggots leave the Apples and afterwards turn into a chrysalis for the winter, creeping into cracks of the bark, and similar places. This insect is also very difficult to destroy. Picking up the fallen Apples and destroying them before the maggot escapes will kill some, and scrubbing the bark of the trees in winter with water containing 8 ozs. of softsoap to the gallon and a table-spoonful of carbolic acid will destroy a lot in their winter hiding places. Whitewashing the main stem and large branches with hot limewash will also be of benefit, and will cleanse the trees of moss and lichen at the same time. Stockholm tar and grease may also be put round the stems as above advised to catch some of the maggots when they are seeking winter quarters.

American blight often infests old trees very much, and gives the places affected a white woolly appearance. It generally accompanies canker, and though not as a rule the cause of the disease, it must be got rid of before the cankered places will heal up again. Washing with softsoap and carbolic acid as recommended, for the grub of the Codlin Moth will destroy the insects

without injuring the trees. It should be well worked into the crevices with a stiff brush.

**Canker.**—The cause of this disease is a much-debated point, and possibly it has various causes. If the roots of some kinds of Apples get into a cold and wet soil it will soon appear, while other varieties will not be affected. It is often caused by frost acting on the bark when green and tender, and rupturing the sap vessels. It first appears as a swelling with a few cracks in the bark, which keeps extending until a large piece of the branch becomes bare, and the wood proves to be dead. If the tree is very much affected it is best to grub it up, and to make sure the soil is in good order before planting another one near the place; but if the tree is fairly vigorous it will, perhaps, do better if cut down and grafted with a more hardy sort. Any pieces of canker on the old stems that are left should be thoroughly scrubbed with the softsoap and carbolic acid solution as recommended for the Apple grub, and the rough places should be pared smooth with a sharp knife, then cover the wound with melted pitch, and it will gradually heal.

**VARIETIES OF APPLES.**—As stated at the commencement of this essay, it is impossible to give a selection of Apples that will suit every part of the country alike, and the intending planter should always seek advice in the locality before he commences planting. The following varieties are the most profitable, and the best croppers in the majority of places, among the older and well tried varieties. Several newer sorts also promise well, but require more testing before too much dependance is placed on them. They are, for this reason, not recommended here. It is a great mistake to grow many varieties with a view to profitable fruit culture; a large quantity of one kind will pay better than a small quantity of many different sorts. But on the other hand it is not advisable to depend solely on one variety, as sometimes one sort will escape the spring frosts, while the crop on another, which may be a little earlier in flowering, will be spoiled. If the plantation is one acre or less in size four kinds will be ample, and if larger two early kinds, two midseason, and two late should be sufficient.

**Early Varieties.**—Lord Suffield (tender, and apt to canker in some localities, in others one of the best), Keswick Codlin, Lord Grosvenor, Ecklinville, Manks Codlin.

**Midseason.**—Golden Noble, Winter Hawthornden, Warner's King, King of the Pippins.

**Late.**—Blenheim Orange, Northern Greening, Wellington, Reinette de Canada, Barnack Beauty.—W. H. DIVERS.

(To be continued.)

## HARDY FLOWER NOTES.

WITH the early days of September summer seems to have come at last, and our late flowers are enjoying the bright sunshine denied to their earlier companions. With gardens aglow with Dahlias and annuals of all forms and sizes, with tall spikes of Gladioli uprearing their magnificent flowers in beds and borders, the hardy flower has no light task to present its claims to the spectator's eye. Difficult it may be, but it can be, and is done, and many plants now present themselves for notice.

Good alpine in flower are by no means too plentiful, and one of the choicest which I saw the other day in a good collection was *Cyananthus lobatus*, which formed a beautiful carpet covered with splendid blue and white flowers. It was growing in a rockery in gritty soil, and was a pleasing picture to observe. In the same garden, and in similar soil, was *Pratia angulata*, a New Zealand plant, one of the *Lobelia* family, with white flowers, which are succeeded by purple berries. *P. angulata* is generally considered only half-hardy, but proves quite hardy with Mr. Latimer of Dumfries. It is also grown in the Edinburgh Botanic Garden, where I first saw it, but I could not ascertain whether it was hardy there. Many dwarf *Campanulas* are still in flower, but among the trailing species *C. isophylla alba* can hardly be surpassed. Like the *Pratia*, this *Bellflower* bears a doubtful reputation for hardiness, but is quite hardy with us in the south of Scotland if planted in a sunny, sheltered spot. Two neat *Polygonums* for the rock garden or flower border are *P. Brunonis* and *P. vacciniifolium*, the first of which is the taller and more attractive, but the latter has more of a trailing habit. Both of these are surpassed in brilliancy by the beautiful *P. sphaerostachyon*, which grows about a foot high, and has bright crimson flowers, which bear a strong resemblance to a large Grape Hyacinth, but of a colour we would fain discover among the *Muscari*. From the spikes of these dwarf *Polygonums* it seems a natural transition to think of the dwarf *Tritomas*, and from them to their taller congeners. *T. MacOwani* is a gem among the genus, growing from 12 to 18 inches in height, with beautiful orange scarlet flowers arranged in a symmetrical manner along the spike. *T. Uvaria nobilis* is a giant among the various species, a large plant I saw the other day having

a magnificent appearance. This would be a grand plant for the wild garden or shrubbery. Some of the others are very good, such as *T. Saundersi*; but one particularly fine one, *T. corallina*, is not hardy here, while a friend informs me that none are hardy in Lanarkshire with him. A very beautiful plant at present in flower is *Eryngium amethystinum*, which is, I think, the choicest of the genus, the whole plant being beautifully tinged with blue, while its habit is exceedingly good.

The pure white *Hyacinthus candicans* is rapidly increasing in favour in this district, and is one of the plants which would be decidedly missed should some untoward event or some fell disease banish it from our gardens. *Crocuses* and *Colchicums* are beginning to appear, *Crocus speciosus* being the only one of the former which has as yet expanded its beautiful blossoms; but of the *Colchicums* we have *C. autumnale*, *C. a. album*, *C. variegatum*, *C. lætum*, and *C. byzantinum*. It is somewhat curious that the double varieties of *C. autumnale* and *C. byzantinum* are later of flowering than the type. *C. lætum* and *C. byzantinum* are well worthy of a place. The first is of a very beautiful colour, being more brilliant than *C. autumnale* by reason of a bright rosy tinge in the inside of the flower. *C. byzantinum* is paler in colour, but is an exquisitely formed flower. Although hardly coming in under the heading of these notes I may perhaps be allowed to note that the *Gladioli* have done wonderfully well this season. They looked very bad early in the season, and one would have thought that the disease would have ruined them. They have overcome it wonderfully, and so far as I can see my losses are only two corms of *Pepita*, and some few of *brenchleyensis*. It appears singular that the latter had been left in the ground all winter, while of those planted in spring not one has failed but the two of *Pepita* already mentioned.

This has been a splendid time for the late *Phloxes*, and many of these are so fine, and there are so many varieties, that one is almost bewildered in the endeavour to make a choice among them. They seem to be again coming into favour, and can be ill spared at this time in the flower borders. The *Rudbeckias*, *Coreopsis*, *Helianthus*, and other yellow composites are exceedingly numerous in this district, where hardy flowers are becoming more appreciated; but there is still a want of front or middle row hardy flowers, and I have been urging upon many the necessity of looking out for these when purchasing flowers.

The *Journal* of 11th September has just arrived, and I have seen with great interest the notes by "B." on the *Montbretias*. I am a little surprised that *M. Pottsi* does not flower with him. Within the last fortnight I have been in at least half a dozen gardens, where it flowered well in various soils and positions. I believe the secret of flowering the *Montbretias* to be, annually tearing to pieces the clump and replanting a few inches apart. The best clumps of *M. Pottsi* I have seen were growing in a stiffish damp soil, where they were flowering freely.—S. ARNOTT.

## GRAPE CULTURE FOR MARKET.

[A paper read by Mr. J. Roberts at the meeting of the British Fruit Growers' Association Brighton, September 11th, 1890.]

THOSE who are old enough to carry their memories back thirty, or even twenty years, will be able to recognise how greatly this fruit has risen in commercial value. At the date I mention you could have counted all the large establishments devoted to the culture of Grapes for market on the fingers of both hands. The prices at which Grapes were then sold retail were quite prohibitive except to the wealthiest classes. It is only reasonable to suppose that large profits resulted to the growers, but when we take into consideration the small structures erected, and the consequent small amount of produce out of them, I suspect the net results were not much better than they are at the present day.

In my younger days I often had the pleasure and privilege of looking over the famous Garston Vineyard, when Mr. Meredith was at the height of his fame as a Grape grower. It was curious to note how Mr. Meredith gradually developed his houses from small lean-to structures with borders bricked in and raised entirely about 3 feet above the ground level to span roofs covering probably a quarter of an acre of ground. This idea has been still further developed during recent years, until at the present we see houses on the ridge-and-furrow principle covering large areas of ground, and capable of producing tons of first-rate Grapes.

Now the question is, Can we improve on this ridge-and-furrow principle in erecting houses for market Grape growing? In a house of this kind your training space is confined entirely to the roof of the house. In erecting a house for Grape growing our object should be to obtain the maximum amount of training space, and where every leaf will be under the influence of direct light. The kind of house I advocate for free-growing kinds such as *Alicante* and *Hamburgs*, is a span-roof—as large as you like—but not less than 100 feet long by 40 or 50 feet wide. The sides must

be carried up in glass not less than 8 feet, nor more than 10 feet high. On these sides I would put a roof at an angle of about 35°. I should then wire the house at each end about 16 inches from the glass, and at distances of 5 feet I would carry wires vertically from the roof to within 3 feet of the ground right through the body of the house from one end to the other. Space must of course be left for a pathway up the centre of house, allowing head room 6 feet high. You can make a house of this description as large as you please, and you can also build it on the ridge-and-furrow principle, but it will be useless for the method of training I am advocating unless the sides are of the height I mentioned, 8 or 10 feet.

The amount of training space gained in a house wired on this principle is nearly threefold over the roof alone, and consequently a treble amount of Grapes. I should only advocate this method of culture for free growing black kinds, as it is not adapted for giving the best results in the culture of *Muscats* or any choice white kind. Someone may say there would be a deficiency of light under this system of erecting and furnishing a vinery, but you must remember the roof must be kept clear of foliage. All that is wanted to produce good foliage is perpendicular light, and Vine foliage produced 10 feet from the glass is often better and holds its vitality longer than when grown within 2 feet of the glass. With a clear pathway through the centre of the house you will be able to step into each avenue of foliage, and much of the details of culture will be easily attended to without the aid of steps and other hindrances. It will require a large number of Vines to plant a house of this description, and as I have commenced with the structure first, I will go on and describe the planting before I refer to soils and other matters necessary to secure success. In my own practice I have always planted a double set of Vines, every alternate plant being a super-numerary, to be cut out or regrown after it has served the purpose for which it was planted. I plant at 2 feet, which allows the permanent Vine 4 feet of space. For planting purposes I like a well ripened yearling cane that has never been checked in its growth beyond the stopping necessary to keep it short-jointed. I have an objection to planting Vines in a green state owing to the difficulty of getting them ripened at the base or near the border.

In most things a good start is half the battle, but in Vine-growing it is everything, as a young Vine that does not get well away the first season of planting may as well be cast away at once, as they rarely ever make vigorous growth afterwards. The way I deal with the super-numerary Vines is to allow them to have a 10 or 12 feet lead over the permanent Vines. After they have made a growth of from 12 to 16 feet I stop them, and when once stopped I make them burst the end or what would be the dormant winter bud. This strengthens and solidifies them considerably, and at the same time keeps them short-jointed, and brings them into an early ripened condition for fruiting. After the first stopping the process is repeated, when an additional 10 or 12 feet of growth has been made. This stopping may be necessary several times during the season of growth, according to the strength and vigour of the Vines. The permanent Vines are treated in exactly the same manner, except that they get their first stopping when 6 or 8 feet of growth has been made. The object with the latter should be to get a well-ripened cane down to the ground. The second season of growth the super-numerary rods would be cut back to the first stopping in the previous year, which would allow from 12 to 15 feet of young rod for fruiting. The permanent rods are pruned to 3 or 4 feet, according to their strength. All the growths on the super-numeraries is rubbed off up to the point where the permanent Vines catch them in height, which would be about 4 feet from the base. This allows the side growths on the permanent rods to have free development. The same system is pursued each succeeding year—that is, the permanent rods are following the super-numeraries until such time as the latter can be dispensed with altogether; or the process can be repeated by cutting down the super-numeraries and giving them a year's growth, and then allow them to fruit again, cutting away a portion of the lower growths of the permanent Vines to give room for the renewed vigour of the old super-numeraries. By adopting this double method of planting a large house is quickly furnished with bearing wood, and the Vines can be kept in healthy and fruitful condition for many years.

## SOILS.

A free and healthy root run is an absolute necessity in the production of decent Grapes. Formerly heavy expenditure was often incurred in forming Vine borders, but where a man has to get a quick profit on the capital invested in his structures and heating; in fact, the scale on which Grapes are produced at the present day forbids a man from taking out half an acre of earth 3 or 4 feet deep to fill it up again at very heavy cost with turfy loam, which in a few years will get into a condition as unfavourable to free root action as the original bed of soil it replaced.

We have no freer rooting plant than the Vine, but like most other plants it has a partiality for some soils over others, and my experience is that the limestone formation is the most natural soil for the Vine. I have for years past noted the Grapes that have been exhibited at our largest shows, and have found that the man who holds his own best and longest is situated on the limestone; in fact, a man who could not produce the finest samples of Grapes on such soils ought to make way for a better man. Very well, if a man is about to embark on a large scale in Grape growing he cannot do better than fix himself on the limestone, and if there is a colliery and railway station near then he has the principal conditions necessary to ensure success. This limestone soil is not an absolute necessity, as we see Vines growing and thriving in the most diverse soils. The question is, how to improve and render what appear unsuitable into suitable soils. Wherever there is found 2 feet or so of decent soil, not too heavy nor too light, we may hope by bringing our knowledge of the laws that govern free root action to bring it from a sterile condition into one abounding in fertility. Many years ago I remember the question asked in the *Journal of Horticulture*, What makes roots grow? and the answer was air. Shortly afterwards a gentleman asked how that could be possible when he had a Vine growing in a solid MacAdam road, and this Vine he described as being in the most robust health. It did not strike him that in such a mixture as MacAdam there could not possibly be any great cohesion, and it was just such a mass as the air would pass through freely, and every stone would be a pasture ground for every fibry root. I have as a cultivator tried to get at the bottom of things, and if I hold one principle more strongly than any other it is that aëration is an absolute necessity to healthy underground growth or root action. It generally takes a few years to get thoroughly exhausted land into a state of fertility, but in the case of a piece of ground intended to be covered with a vinery we must try and do the thing thoroughly at one dressing. First, if I could borrow a dozen or two sheep I would willingly keep them free of cost to have the privilege of folding them for two or three weeks on the piece of ground intended for the Vines. I should then have in readiness sufficient horse manure, fresh and full of vitality—not your spent hotbed manure, which is of no value for this purpose—to make a covering over the whole border 18 inches deep. The next process is to trench the whole ground, breaking it up thoroughly, and as the work proceeds I should procure a supply of soot, and also shoddy or rag manure, the latter to be soaked in strong liquid manure, to which has been added some sulphate of ammonia. This shoddy is the finest substitute for turf I know, and is really more lasting. After the whole has been trenched I should make the surface somewhat fine, as the object now is to get the ground to absorb the ammonia and other fertilisers introduced. Where expense is not feared I would add with the above some horn shavings, but I really cannot recommend artificial manures at £20 a ton, when good horse manure can be had at 4s. After the trenching is finished the whole should be allowed to gradually subside before planting.

#### STARTING THE VINES.

I have already described the structure I approve for growing Grapes for the million, and also the planting. I will now give a few ideas on points I think essential to success. We must start with correct notions on the nature of the Vine. In my practice I have always treated it as a temperate rather than a tropical plant. Heat, light, and moisture are synonymous with motion in the vegetable kingdom, and these are the points to regulate to get a good start. If we apply too great heat we shall get too rapid motion, and if we apply too much moisture we shall get growth without solidity. The temperature I like for starting Vines is 50° night and day. As soon as growth appears 55° is sufficient during the day, and at night 50°. The houses should be freely ventilated from the expansion of the Vine's first leaf, as much of our success depends on the quality and texture of the main leaves. If these are made in an atmosphere overloaded with moisture we need not be surprised if the first scorching day curls them up and red spider finishes them. In the early stages of growth my whole object is devoted to getting all the main leaves up to three or so beyond the bunch of the finest possible substance, and capable of standing sunshine, or volumes of fresh air without injury. This can only be accomplished by very steady forcing, and I am never satisfied if the root action of the Vines has not commenced when they have made about four inches of young growth. Up to this stage the stored up food in the rods is sufficient to supply the wants of the young growths, but if quick root action does not take place you may expect shanking and other evils to follow. When the bunches are visible I remove all secondary growths below the bunch, and this has a great effect in giving additional substance to the permanent leaves, prevents overcrowding of useless growth, and saves much labour in stopping during the growing season. Good colour and every other point, including flavour, depends on the sturdy forma-

tion of the earliest leaves and their preservation intact until the crop is removed from the Vines.

Many people treat Vines as though they were stove plants—never satisfied except they are dosing them with pent-up moisture. The very nature of the tendrils of the Vine tells you that Nature has endowed it with the power to stand storms and tempests of wind with impunity. Many growers are very fond of producing what they call an ammoniacal atmosphere in the vinery. In the early stages of growth I have no objection to this, but the moment the Vines have set it should never be afterwards applied, otherwise you are sure to lose the bloom on your Grapes. Nothing equals the free air of heaven in keeping up the vigour of vegetation, whether it is in the open or under glass. We can assist Nature indoors by adding additional moisture, but I always leave out the ammonia, unless the ventilators are wide open. I have seen many exhibits of good Grapes that were knocked clean out through the polished surface of the berries, telling plainly that too much ammonia had been applied to the atmosphere directly after the setting period.

In training the young growths they should, as far as possible, be brought in a direct horizontal position from the main stem; by doing so you secure a much greater surface of foliage exposed to the light than when they are carried in an oblique direction.

#### SETTING.

This is the critical stage in the culture of Muscat of Alexandria, and though the flowers of the Vine are insignificant in appearance, there is every reason to suppose that the mass of pollen produced during the flowering period is exhausting to the Vine. All the kinds I have recommended for market culture are very prolific in showing bunches, and the Muscat especially so, often showing as many as five bunches on a single lateral. The first operation is to remove all small and ill-shaped bunches, leaving but one, and that the most shapely, on each lateral. This should be done a week or so before the flowers commence to open, so that the bunches left may get the full benefit of the extra strength that will be thrown into them through the removal of unnecessary bunches. With Muscats a night temperature of 70° is necessary, and during the day the temperature should be from 75° to 80°. In the case of Hamburgs and Alicante a night temperature of 65° will suffice, and the day temperature may rise 10° higher. I ventilate freely early in the morning to get the pollen dry and ripe, and about half-past ten or eleven o'clock, before the stigmas have had time to dry up from the heat of the day, I go carefully over the whole house, and give each bunch a gentle tap to set free the pollen. This operation is repeated every morning for about eight or ten days, and I have never failed to secure a satisfactory "set" by this means. After this operation the house may be damped without injury to the setting process, but all superfluous moisture should be expelled before nightfall.

#### THINNING.

Thinning is an operation that requires doing with a bold hand. I do not approve of doing a job twice, so I thin the first time to stand the season. It is necessary to have an idea what your Vines are capable of doing, but if you are sure they are in good root action then thin them freely, as the reward will be extra fine berries and much less exhaustion of the Vines than if you allowed them to get near the stoning period before the second thinning took place. There is one point in thinning Grapes intended for market, and that is leave the shoulders of the bunches pretty full, so as to hide the footstalks as much as possible. The advantage of this will be found when you come to send them to market, as a fine even surface of berries will be the result. My favourite liquid manure is composed of blood manure and soot, with a change occasionally out of the farmyard tank. The blood manure is very quick in its action, and will swell up the berries to a great size. A couple of waterings of weak doses of sulphate of ammonia may be applied during the growing season, but the house must on no account be closed for several hours after the watering, otherwise not only the bloom on your berries but the foliage may get damaged.

#### PRUNING.

This is a simple operation, and if your Vines are young and in good condition they may safely be cut in to one eye from the stem; but if Vines are old and enfeebled with many years' cropping, then it will be advisable to leave an extra eye to ensure a good show of fruit. Before the final pruning a partial pruning should take place a month or two after the fruit has been cut from the Vines. This partial pruning is of much value in concentrating the forces into and filling up the eyes required for the next year's crop. When I was an exhibitor of Grapes I was often struck from year to year how I invariably went to some particular lateral for my exhibit. These laterals had been cut off early in the previous season, and the

long time the few eyes left after removing the shoot and bunch had to fill and plump showed plainly that a rather severe shortening back was highly desirable, and resulted in larger and more shapely bunches the following season.

#### SHANKING.

There are so many causes for this that I cannot in the limits of this paper enter into them. But there is one cause, and I think it is responsible for more shanking than any other. It is too rapid forcing in the earliest stage of development. As I said before, the man will be freest from shanking who can, when his Vines have made from 3 to 4 inches of growth, feel comfortable from the knowledge that he has got root-action on the move, and here the great advantages possessed by an aerated border come in, as you can with much less time and patience get a start in root growth in an open border than in a border too close and adhesive. I am conscious of many interesting points in Grape growing unnoticed in this paper, but as I wished to direct attention to what I consider the most essential points I hope I shall at least have set you thinking, and also criticising my remarks if they differ from your own ideas and experiences.

#### VARIETIES FOR MARKET.

Muscat of Alexandria must be placed first as a market Grape. The price realised for well grown samples of this Grape rule high at all seasons of the year. Some of the best growers of this Grape send them to market on boards, and with the same care as if they were intended for exhibition at a horticultural show. Young beginners at market Grape growing should, if inexperienced, not start in their first efforts with this variety. It requires a high temperature compared with most varieties and much care during the setting period.

The next most popular market Grape is Black Hamburgh. It is so free under all conditions and so accommodating in submitting to forcing at all seasons that it is the Grape for giving a supply of fruit from March to November. The enormous quantities of this Grape that come into Covent Garden show many varying qualities. Good, well swelled, and coloured examples carefully packed always fetch fair prices.

Next to the Black Hamburgh I place Alicante as a market Grape—in fact, it has some advantages over the Hamburgh, especially to the retailer of fruit, as it keeps in presentable condition after being cut much longer than the Hamburgh. The great fault of the Hamburgh for retail work is the rapidity with which the stem and shoulder stalks of the bunches dry up. Alicante is coming back to be as popular as ever with growers, and I predict that it will yet drive Gros Colman clean out of the London shops and markets. You need not trouble about any other Grapes beyond the three I have mentioned, as you may with these three kinds have Grapes every day in the year. I may just mention that Gros Maroc has this season been sent into the market in good condition, and where this is the case satisfactory prices have been had for it. It remains to be seen whether it will hold its own with the Hamburgh and Alicante.

#### MARKETING.

Packing for market is a point of much importance to the grower. Every basket should be firmly and fully packed, with as little show of footstalks as possible. The surface of the basket should show a solid surface of well coloured berries. If a salesman has to keep your basket unsold for several days (which is often the case), and you have packed your basket so as to exhibit too much of the stalks of the berries, buyers are quick to note this, and know that when unpacked and exposed for sale in shop windows they rapidly shrink. So cover up the footstalks as much as possible, and you will be doing yourself, and all through whose hands the fruit will have to pass, a favour.

#### THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE first Chrysanthemum Show of the season reminds the admirers of the popular autumn flower that the busy season is approaching rapidly, though it seems difficult to think about dull November in such brilliant summer weather as we are now having. Those, however, who visit many gardens in all parts of the country, cannot fail to be impressed with two facts, first that Chrysanthemums are still extending in popular favour rapidly, and secondly that great advances have been made in their cultivation. The decline of the Chrysanthemum, so often predicted, has not yet commenced, and though the present year is likely to be the most important in its history, there is yet a long future before so useful a plant.

The National Society may be said to have entered on a period of great interest to Chrysanthemum growers, for many are looking forward to the centenary celebration next November as likely to prove a gathering such as London has not witnessed before amongst autumn floral displays. Mr. W. Holmes has taken up the direction of affairs with his accustomed skill, and the programme of arrangements for the four

days will soon be issued. The first day, Tuesday, November 10th, will be distinguished by an opening ceremony, at which the assistance of some of the Patrons or Vice-Presidents is expected. Upon the same day a Conference will also be held in the Library, when the historical and artistic aspects of the Chrysanthemum will be discussed. Upon Wednesday the Show itself will furnish sufficient attractions for visitors. On Thursday another Conference will be held, dealing chiefly with practical subjects, and a banquet will be arranged to be held in St. Stephen's Hall at 6 p.m., when Lord Brooke, M.P., President of the Society, will take the chair, and the innovation of allowing ladies to be present will be tried. The fourth day, Friday, the conclusion of the festival, will be devoted to a conversazione in the afternoon, followed by the presentation of prizes. This programme, with the unusual attractions of the liberal schedule, should result in a fine competition and a large gathering of Chrysanthemum admirers.

A few words are necessary respecting the Show at the Royal Aquarium last week, for time would not admit of a report in our previous issue, and it is unnecessary now to give all the formal details. It must be said that it was one of the best of the series held at Westminster this year, under Mr. Holmes's superintendence, Chrysanthemums, Dahlias, Gladioli, Roses, and miscellaneous collections of plants and flowers being very abundant, but the prizetakers were nearly all the same as those mentioned in our full report of the Dahlia Show at the Crystal Palace. The Chrysanthemums only can be here referred to. The groups showed a distinct advance upon those at shows in previous years both in quality and taste of arrangement. Messrs. J. Laing & Sons, Forest Hill, were the leading exhibitors, but Messrs. Reid & Borneman of Shrewsbury Road, Sydenham, and Mr. Norman Davis of Camberwell, also exhibited uncommonly well for the remaining prizes, Mr. H. J. Jones, Ryecroft Nursery, Lewisham, having so good a non-competing group that he was awarded a silver medal. The collections of cut blooms from Messrs. Owen, Davis, and Such were noteworthy; but the finest cut blooms were the examples of Madame C. Desgrange and its sports, which gained Mr. J. Blackburne, Elmstead Grange Gardens, Chislehurst, first prizes in several classes, Messrs. Blair, Howe, Beech, and Stevens taking second and third prizes in the same classes. Mr. Blackburne's blooms were specially remarked last year, and they again caused quite a sensation, their size, substance, and purity bringing them into the first rank as exhibition flowers, and such as would compare favourably with many of the best of other standard varieties at the November shows.—C.

#### THE BRITISH FRUIT GROWERS' ASSOCIATION.

##### A VISIT TO CRAWLEY.

THE third of the Conferences arranged to be held by the above Association during the present year was announced to take place at Brighton on Thursday, September 11th, and after the Crystal Palace meeting it was suggested that as a party would on that day be travelling down from London, an excellent opportunity would be afforded for a visit to the Crawley district under the guidance of the local secretary for Sussex, Mr. Joseph Cheal. The idea met with approval, and, as a result, a party of the earlier rising members of the Association reached Horley at 8.30 A.M. on Thursday morning, where Mr. Cheal had the necessary conveyances in readiness. The morning was delightfully bright and fresh, and the drive to Crawley was greatly enjoyed by all. At the Lowfield nurseries the party was received by Mr. J. Cheal, sen.—who, at the venerable age of ninety, appears to be more active in mind and body than some men at half his age—and by Mr. Alexander Cheal. A hurried inspection of the extensive and well-stocked nurseries was commenced, and much valuable information was conveyed by the conductors respecting the peculiarities or qualities of certain varieties of fruits, stocks, modes of training, &c. Apple budding was just in full progress, and a few of the members left mementos of their varying degrees of skill in this important operation by commencing a row, preparing the buds and stocks, tying and completing the work. In another portion of the nursery, a member who farms much land in Essex proved that he was master of the details of his work by guiding a plough with all the skill of an experienced hand. Several other practical demonstrations followed. The plantations and "quarters" of healthy young fruit trees in all stages were inspected with the keenest interest, particularly the cordon trees, of which so many are grown at Crawley. Dahlias of all sections and many other outdoor plants were still gay with flowers, notwithstanding the recent frosts which in some districts have caused much devastation.

This part of the morning's proceedings concluded with a substantial lunch generously provided by the Messrs. Cheal. Another pleasant drive to Three Bridges, and a rapid run to Brighton prepared the party for the more serious portion of the day's business.

##### THE CONFERENCE.

As previously announced the conference was held in the King's apartments of the Royal Pavilion, in conjunction with the excellent show of plants, flowers, and fruit provided by the Sussex Horticultural Society under the management of Mr. Edward Carpenter. The Mayor of Brighton, Mr. Alderman George Manwaring, had kindly consented to take the chair, and he was supported by the Rev. Cox Holes, Councillors Ballard and Booth, and Mr. T. Francis Rivers (Chairman of Committees); amongst others present being Mr. Philip Crowley, Mr. Lewis Castle (Hon. Sec.), Mr. J. Roberts, Mr. G. Gordon, Mr. J. Cheal, Mr. A. Cheal, Mr. R. Smith, Mr. W. G. Head, Mr. G. Hammond, Mr. Stephen

Ade, Mr. R. Turner, and Mr. T. W. Beach. There was also a good attendance of fruit growers and others in the district especially interested in the matter.

The Mayor opened the proceedings at 4 P.M. with a brief but pithy speech, in which he referred to the objects of the Association, and dwelt especially upon the importance of facilitating the distribution of fruit to consumers. Mr. T. Francis Rivers followed with a few general remarks, of which the following is the substance.

He mentioned that the British Fruit Growers' Association was founded about two years ago, at the time when public attention was directed to the fact that a great industry was in danger of passing away from this country, and that no serious efforts were being made to prevent the withdrawal, but the various speeches and essays delivered on the question caused a large increase in planting, which would no doubt have a very sensible effect upon the fruit market in time. There had been and were many diverse opinions as to the profits to be derived from fruit culture, and unless it could be proved that there was a reasonable profit to be obtained, no advocacy would extend the plantation of fruit trees in England or elsewhere. The basis must be on the firm foundation of profit to the producer and advantage to the consumer. Passing on, he expressed his surprise at the absence of any large orchards to be observed on the railway journey from London to Brighton, and argued that if the land round Brighton could be available for fruit growing, the town would alone require hundreds of acres for the constant supply which was furnished unceasingly by the purveyors. That this demand was not supplied by Sussex could not be due to the quality of the whole of the land, or to the rigour of the climate, and it seemed much to be desired that the causes of the want of production should be investigated. It was grievous that the large sums paid for fruit should not go into the hands of the neighbouring cultivators, as it surely could be placed in the Brighton Market with as little expense for carriage as when derived from London. The speaker passed on to the system of fruit growing, observing that his own system of planting was to trench 24 inches deep, to apply fifty tons of good farmyard manure per acre, and to plant Apple and Plum trees 9 feet apart, dwarf standards, with stems 4 feet clear from the surface of the soil to the first branch, and a row of Black Currants, Gooseberries, Raspberries, or Strawberries, between the rows of permanent fruit trees. This arrangement would give about 1600 trees per acre, and as all the trees would commence bearing in about three years, the time of return was rapid compared with the farm orchard, being seven standard trees. The cost of this plantation was great. It was an investment of capital, and could only be undertaken by those who could afford to wait, but the profits in the end were considerable. In dealing with the sorts of Apples and Plums to be grown, he warned growers against planting old sorts, new varieties being more vigorous and more hardy.

Mr. J. Cheal, in commenting on some of the remarks of Mr. Rivers, maintained that fruit growing could not be taken up in a day, and he went on to advise prospective growers before entering on the undertaking to consider all the circumstances and surroundings. To turn out rightly the thing must be begun rightly, and they must especially consider whether they could make a better profit by supplying the markets retail than by wholesale. For a retail supply they would have to rear a large number of varieties of fruit, but for a wholesale supply fewer varieties would be necessary. Regarding the climate, to show that it was not wholly responsible for the scarce growth of fruit in the south, he would like to point out that from one Apple tree planted by a friend of his in Essex, in ten years—1872-82—forty and a half pecks of Apples were produced, and they were sold at the Chelmsford market at the rate of about 6s. per bushel. That meant an acre of such trees was worth £363. In a part of Sussex, too, a grower had a capital produce, and realised very satisfactory prices at the Eastbourne market. He only gave this as an illustration, and did not wish anyone to run away with the idea that anything like so large an amount could be realised from every acre of trees planted. Mr. Councillor Ballard and several other gentlemen also took part in the discussion.

Mr. G. Gordon next gave a review of what had been observed by himself and Mr. L. Castle in the recent tour in Ireland, and referred to the collection of Irish fruit which had been conveyed from the Crystal Palace Show, and were exhibited in another portion of the building.

At the conclusion of the Irish discussion Mr. J. Roberts, formerly of Gunnersbury, read a paper on "Grapes for Market," which was regarded as one of the most important contributions to the subject that has yet been made public. As far as possible in a paper of this kind he dealt with all the principal aspects of the subject in a thoroughly practical manner, as can be judged from the paper itself. (See page 241).

In the unavoidable absence of Mr. W. Iggulden, who had prepared an admirable and exhaustive paper upon the "Culture of Tomatoes for Profit," the portions dealing with culture were read by Mr. J. Cheal, and excited much attention, as there were several growers present who are engaged in the production of Tomatoes for market on an extensive scale. The cultural instructions were, however, generally confirmed by those who heard the paper read. In the course of the discussion Mr. A. Cheal furnished some interesting statistics with regard to the important fruit growing industry in the Worthing district. He said that 585 tons of fruit were despatched from Worthing and 78 tons from Lancing Station during the year, a combined total of 663 tons, of which he should say fully 50 per cent. were Tomatoes. Apart from the railway despatch quite 25 per cent. were sent by road. Such figures were encouraging, and showed the increase of the industry, while he should like to say that the prices realised for the fruit averaged 5d. per pound.

The supply had increased with the demand, and perhaps the supply had created the demand. About 350 tons of Tomatoes were produced in the district, £20,000 was the estimated value of the Tomato crop, and the other fruit crop £14,000, which made a total of £34,000.

Mr. Robert Smith of Kenwards, Yalding, had prepared an able paper describing his methods of cultivating Peaches and Pears on walls, with which for many years he has been extremely successful. Owing, however, to the time occupied by the preceding papers he consented to confine himself to the culture of the Peach and Nectarine, concerning which he gave some important details. This concluded the programme, votes of thanks to the readers of the papers and to the Chairman bringing the third successful meeting of the season to a close.

#### THE MARKET GARDENS OF WORTHING.

Some of the members of the Association remained in Brighton until the next day with the intention of visiting the principal market gardens in Worthing. This was accomplished in most favourable weather, and under the guidance of Mr. A. Cheal and Mr. W. G. Head, both of whom were well acquainted with the district, an instructive tour was commenced. Some of the leading Grape and Tomato growers' establishments were visited, and at each place the members were received with a degree of courtesy and attention that was most gratifying. It would be quite impossible in the space of a brief report like this to do justice to a tithe of what was seen, but it was the unanimous verdict that better all-round Grape culture had never been witnessed. This applied with equal force to the last establishment visited, that of Mr. J. Pullen-Bury at Sompting, a short distance from Worthing and Lancing. There a house of Muscat of Alexandria and one of Lady Downe's were seen that will probably never be forgotten by any of those who were present. Such large, even bunches and berries, such a clean bright appearance, and such a crop surpassed, as regards the Muscats, everything that the visitors had ever seen before, and, as one experienced Grape cultivator remarked, "It takes all the conceit out of us." Mr. Pullen-Bury is, however, a remarkable man; an inspection of his houses shows that, and a short interview with him on business matters proves it. Indomitable energy, unflinching perseverance, and keen observation have enabled him to succeed in no ordinary degree when others would have failed. We saw instances even amongst these market gardens where the places and the businesses were evidently drifting in the wrong direction from a lack of the all-important guiding energy and attention.

In the course of the day it is estimated that between twenty and thirty tons of Grapes were seen, and with few exceptions these were all of remarkable quality, the weight of the crop on both old and young Vines being astonishing. The Tomatoes were to some extent exhausted, but in nearly all cases they were planted in rows on the floor of span-roof houses, three or four rows on each side to the centre, then trained upright to the roof, and in many instances they were a dense mass of growth, that seemed strangely opposed to satisfactory results.

Peach culture at one time occupied a good deal of space and attention at Worthing, but seems to be almost entirely discarded now. Cucumbers are largely produced, and some of the growers also cultivate Apples, Pears, and Figs out of doors, but with the exception of the last-named the under glass culture is by far the most important.

#### THE WEST TARRING FIG GARDEN.

All round the district Figs appear to thrive in a remarkable manner, and perfect fine crops of fruit; but the most interesting garden is one devoted entirely to Figs at West Tarring, a mile or two from Worthing. This is about an acre in extent, and a perfect thicket or a forest of old and grand Fig trees, which yield a bountiful crop for a small share of attention. Some of the trees are evidently of great age, and upon one is a board with the following legend inscribed thereon:—"The oldest Fig tree in England. Planted by Thomas à Beckett 800 years ago." Antiquity has certain attractions, and no doubt many have gone away deeply impressed with the above statement. Competent authorities have, however, estimated the tree to be 100 or possibly 160 years old as the extreme limit—quite old enough, and 600 or 700 years more or less are of small consequence to local historians in places of public resort. In a search for some historical particulars concerning this Fig garden, the following note from the pen of the late Mr. G. W. Johnson was found, and is so appropriate that it is reproduced. After referring to the Figs at Arundel, he says:—

"I pass on to Tarring, known by that name in Anglo-Saxon records, for King Athelstan about the year 943, gave the manor 'to the church of Christ in Canterbury,' and in Domesday Book it is mentioned as part of the Archbishop's possessions. In 1277, the tenant not paying his rent, which might be taken in kind, a record states the prices at which some of the produce might be claimed: 'a good goose 1d., two good hens 1d., five score of eggs 1d.' A quarter of Wheat was 1s. 6d., but the Archbishop thought he ought to have more for his money, and demanded two good geese for 1d., four fat hens for 1d., the first hundred of eggs for 1d., and the second hundred for nothing! Well, in process of time Thomas à Becket became Archbishop, and tradition has handed down as a fact that he planted Figs brought from Italy in the Manor grounds of Tarring. There is no record of his residing there, but it is likely that he did, for, as I have stated, it was one of the estates belonging to the see, was a pleasant place for retirement, and it is certain the Archbishop occasionally resided among the tenants of the archiepiscopal estates. A large room and a smaller one still existing, tradition tells, were the hall and chapel of Becket's palace. They may have been constructed of its materials, for they are very old, but their architecture is of a date

full two centuries later than that in which Becket lived. There is nothing to prohibit it being true that Becket brought from Italy the Fig to Tarring. Ecclesiastics have introduced this fruit to more than one of the archiepiscopal residences. Cardinal Pole planted it at Lambeth, and Archbishop Cranmer at Mitcham. In both these instances the variety is the White Marseilles, and so is the large standard in the Tarring garden, which is here portrayed, and that garden adjoins the grounds round the ancient rooms, said to have been Becket's.

"The Fig garden at Tarring is three-quarters of an acre in extent. There are about 100 trees in it, chiefly of the Purple (Brown) Turkey variety, and these bear most abundantly and unfailingly. They have no pruning, and the knife is only employed occasionally to thin the branches. These interlace, for the trees are planted only 12 feet apart, and are about 18 feet high. They form a dense grove, and nothing flourishes beneath them. The central walk shown in the drawing is an avenue of Fig trees 247 feet in length. The grand old White Marseilles tree, the most prominent figure in that drawing, is believed to be a descendant of one of those planted by Archbishop Becket. Judging from other large Fig trees, the ages of which are known, I should conclude that it is quite 150 years old. The circumference of its stem just above the soil's surface is 9 feet, and it separates into four main limbs, each nearly 3 feet in circumference, and the branches from them cover a circle

field. We used to have exhibitors from the north and from the west, but at both of the Shows of which I now write the only exhibitions where the flower can be shown in London, there was one trade exhibitor and two amateurs—Mr. Burrell in the former class, Mr. Lindsell and myself in the latter, and yet I hear from those who sell the bulbs that there is a large demand for them, so much so that Mr. Kelway of Langport has kept adding to his culture until now he has 25 acres set apart for them! And yet it is not a difficult flower to grow. It will thrive on most garden soils, although, like all bulbs, it dislikes a stiff clay. True, it has its drawbacks. Corms will die, and losses must be experienced; but they are so very cheap that some of the best show varieties may be obtained for a few pence. I look to some other cause for their absence from the exhibition table. In the first place, they get but scant encouragement in the way of prizes, and at neither Show can the amateur obtain more than one prize. Although he may not be actuated by mercenary motives, yet he does like to have an opportunity of paying his expenses; but an amateur, say from Yorkshire, goes to a good deal of expense and trouble to come up to the Aquarium on the chance of winning the munificent sum of 20s. Then it is one of the most troublesome flowers to place properly on an exhibition table, especially to come up to the standard now required. I remember when they used to be brought up in trays and baskets, but that will not do

FIG. 30.—THE WEST TARRING FIG GARDEN.

40 feet in diameter; they would extend much further if it were not for the other Fig trees crowded around. They rarely ripen a second crop, but they did so about three years since. The first crop ripens in August, September, and October, and the average produce of a tree is twenty dozen of Figs. Mr. Lower, in his "History of Sussex," remarks that a bird resembling the beccafico or Fig-eater of Italy migrates hither during the Fig season. The flocks remain five or six weeks, and then disappear as they came—seaward. The Italian Fig-eater is known to ornithologists as the *Sylvia naevia*, but the Fig-eater of Sussex is the White-throat, *Sylvia cinerea*."

This must for the present conclude the record of the most agreeable excursion the Association has yet taken, and in returning late on Friday night the wish was expressed that many more of a similar character may be undertaken.—L. CASTLE.

#### GLADIOLI AT THE CRYSTAL PALACE AND THE AQUARIUM.

It is a very disappointing experience to one who has for thirty years and upwards been endeavouring to persuade amateurs to cultivate and exhibit this most beautiful autumn flower, to find that not only does not the number of exhibits increase, but that they show an actual falling off. I have seen during my long cultivation of the flower many coming to the front, and then after a year or two retiring from the

nowadays. I had some boxes made on the late Mr. Chapman's principle, but these are useless now. The flowers would touch one another, and the spikes would not go into the box. In order to show them properly the spikes must be cut the day before. Each one must have a stalk to which it has to be tied. They have to be tied separately in the case for travelling, the most approved form of this being a framework covered with canvas; and then when the exhibition place is reached they have to be taken out, each fastened again in its place in a tray which must be taken with them; and after all this a chance of a grand prize of a pound! These things, together with my experience of many years, do not make me very hopeful as to a large increase in the number of exhibitors.

Mr. Burrell of How House Nurseries, Cambridge, was, as I have said, the sole exhibitor in the trade class at both places, and his stands were without doubt magnificent; in fact I doubt if ever such a collection was ever before set up. He showed not only some of the best French varieties, but also many of his own seedlings, which were quite equal in quality to those from abroad. Many of the spikes had twelve, fourteen, and in some cases fifteen expanded blooms on them. All flowers that have been taken in hand by the hybridiser have shown great improvement, but I do not think there is one that has shown such wonderful progress as the Gladiolus, as a reference to the plates and descriptions published years ago in the "Florist" clearly shows. Among the French varieties exhibited by Messrs. Burrell & Co were Baroness Burdett Coutts, lilac, tinged with rose and purple, a very large flower,

giving also a very fine spike, always very taking in a stand, not so good in substance as it might be, but very grand; Grande Rouge, a brilliant fiery red with violet blotch, very similar to that fine old flower Meyerbeer, but larger and earlier in blooming; Dalila, light rose, striped with white, magnificent spike of well formed flowers; Atlas, pale porcelain, lightly tinted with violet, a very beautiful and constant flower with grand spike; Conquerant, dark purplish carmine, clear white blotch and bands; Corinne, carmine, white stripe; Daubenton, suffused violet, large flower, very distinct and good; Horace Vernet, purplish red, blotched and striped white, a very fine flower; Minos, fine flower, an improvement on Celemine, which it greatly resembles, colour rose blotched with cherry; Pyramide, delicate rose. He had a large number at both places of his own seedlings; of these some have been already certificated, and one obtained a certificate at the Aquarium, while there were others which were quite equal to anything we have. Snowdon he did not exhibit, but it is a grand white flower. He was awarded a certificate at the Aquarium for Vicar of Westwell, a very fine flower, orange salmon, with white blotch and purple feather. He had also Ossian, fiery red, with crimson flakes; Iolanthe, a very beautiful salmon pink pale flower, which has already been certificated; Cygnet, a very beautiful flesh white flower; Sorcerer, a reddish orange flower, with deep brownish carmine flakes laid on much in the same way as the markings on the wings of the swallowtail butterfly (*Papilio Machaon*), a most striking flower, somewhat in the way of Tigré, one of the new French varieties; Imperator, a beautiful variety, somewhat in the way of Abricoté; and some other unnamed seedlings of which we may know something more.

I now come to the amateurs, and here I may write more freely than I have done on other occasions, for I have had to come down from my perch. Having for a long series of years taken the first place, I have this year been content to take second, my excellent friend Mr. E. B. Lindsell, whom I had frequently urged to take up the culture of this flower, having taken the first place. It is the old story,

“The old man has been beaten by the boy.”

At the Crystal Palace it was a very close run; I never saw a more careful, and I may add correct, judging of two stands of *Gladioli*, and their nearness may be estimated by the fact that there were only three points between us. Among the flowers I had there was a very fine white flower of Souchet's, Mont Blanc, for which I was awarded a first-class certificate. It is a grand flower, but I question whether in the purity of colour or in length of spike it will equal Mr. Burrell's Snowdon certificated last year. The two stands of twelve put up at the Aquarium were the best ever put up by amateurs, and whereas in the Crystal Palace stands there were some weak spikes, those of mine especially, which had been assuredly an accident, there were no weak ones in these twenty-four spikes. Mr. Lindsell's consisted of Baroness Burdett Coutts, very fine; Grande Rouge, with twelve expanded flowers; Daubenton, Titania, Horace Vernet, Rayon d'Or, Hesperide, Sceptre de Flore, Pyramide, Iolanthe, Atlas, and Adolphe Brongniart. Mine were Splendens, Dalila, a grand spike with twelve blooms; Le Vesuve, Baroness Burdett Coutts, Pollux, Abricoté, Formosa, Sceptre de Flore, Mount Etna, Atlas, Grande Rouge, and Nereide, and I may add, for the encouragement of those who may wish to grow these lovely flowers, that those exhibited on the two stands average in price from 5d. to 1s. 3d. each. I had also a very beautiful seedling, Purity, for which I read in the *Times* I was awarded a first-class certificate, the very whitest *Gladiolus* grown, pure white and absolutely without any feather or marking of any kind on the petals. I may add that this season has been a favourable one, the cool and still weather suiting them admirably, and I should hope, as I have already stated, that this fine dry September will ensure good sound bulbs. I may also add that nearly every one of these flowers were from roots which had been cut in halves before planting, showing the success of that plan.—D., Deal.

#### FIRBECK HALL.

FIRBECK HALL, the seat of the Rev. H. G. Jebb, is situated amidst sylvan scenery and undulating country, purely pastoral and agricultural, close on the boundaries of Yorkshire and Nottinghamshire. It is surrounded with a park of some sixty acres in extent, well timbered with Oaks, Elms, &c., and the house and grounds are sheltered with belts of trees, which break the fury of gales and storms. The nearest populous town is Rotherham, eleven miles away, but the pleasant little market town of Worksop, in Nottinghamshire, is only seven miles off, through which place the main line of the M.S.L.L. Railway passes. Worksop is a centre from which visitors to the far-famed Dukeries start on their pleasant excursions. The Dukeries, which include the mansions and estates of Welbeck, Clumber, and Thoresby, lie within the boundaries of Sherwood Forest, made famous by the exploits of Robin Hood and his foresters. The beautiful wooded country for which this part of the county of Nottinghamshire is famous, also extends, but in a slightly less degree, to the north-western border of the county, close to which is Welbeck, but in Yorkshire territory. Between Worksop and Firbeck there is the village of Carlton, with a pretty church and all the evidences of quiet rural customs and contentment. A Moorpark Apricot tree flourishes on a warm gable end facing south in this district, and its beautiful crop of fruit, ripe and golden in the sunshine, was a pleasure to see. The harvest was ripe and abundant, but unsettled weather had prevented the commencement of its ingathering.

My object, however, is not to describe the country and the district, but the gardens at Firbeck Hall so far as a brief visit could furnish details of much that is interesting and well worth describing in these pages. In these notes, however, the first and most important place must be given to the main object of my visit, a description of the carpet bedding.

It is in such a place as Firbeck, with its extensive stretches of green sward, of lawn and park, with noble trees in single specimens and in knolls and groups, that carpet bedding can be enjoyed to its fullest extent, there being present all the necessary conditions to its effective contrast. Then, again, the place is extensive enough to admit of other forms of flower gardening, which can be enjoyed when the eye is tired of resting on the colour and formality of the carpet beds. To say that the carpet bedding at Firbeck is well done is only to put it mildly. It is done in a very superior and artistic manner, which does infinite credit to the originality, skill, and industry of Mr. Egglestone, the head gardener. In the finished and perfect style which is there adopted it represents a vast amount of labour in the preparation of the plants and in the tedious process of planting, which has to be done at a busy season of the year, when other claims of important work have to be attended to. Large numbers of beds are treated in the carpet style, some of them being of great extent. The principal and most artistic beds are situated on the terrace in front of the house, most of them being circular and three-lobed beds. Beginning at the eastern end of the terrace nearest the mansion, the first bed is circular in form. It is edged with a band of *Sedum glaucum* and *Mesembryanthemum cordifolium variegatum*. A large Maltese cross forms the centre, having an edging of *Sempervivum californicum*, and filled up with *Echeveria farinosa*. Two of the spaces between the points of the cross are filled with an *Alternanthera* named *Firbecki*, which was raised there, and has been tried for four years. It is a very distinct and beautiful variety, having small narrow leaves of deep rich crimson shades, and is considered to be a much better variety than any similar one in cultivation. The effectiveness of many of the Firbeck beds is largely owing to the employment of this variety, which he considers worthy of a name and a place amongst the best of the coloured-leaved carpet-bedding plants. The other two spaces are filled with *Alyssum variegatum*, and in the centre of the whole bed is planted a green-leaved *Dracæna*. Between this bed and the third comes a three-lobed bed edged with a permanent edging of Yew only a few inches high, inside which is a line of blue *Lobelia*, then a band of William Sandy *Pelargonium*, the centre being filled up with well flowered specimens of *Tuberous Begonias*, interspersed with a small-leaved variegated *Fuchsia*. Next to the carpet beds the *Tuberous Begonias* are a feature of the place, and very healthy plants covered with flowers the whole of them are. They are two-year-old roots, and the stout dark green healthy foliage they produce, surmounted with bright and handsome flowers, afford an excellent contrast to the mosaic patterns of the carpet bedding. The next bed is a circular one. In the centre is placed a single plant of *Echeveria metallica*, the design being a four-pointed star filled up with *Alternanthera Firbecki*. Outside the star the groundwork is composed of *Sedum glaucum*. Four ovals are filled with *Alternanthera Firbecki*, and the points of the star run into patches of *Echeveria farinosa* on each side of *Mesembryanthemum cordifolium fol. var.*, and the outer edge is a rim about a foot wide of the above *Mesembryanthemum*. The next bed has *Begonias* edged with Yew, followed by *Lobelia* (blue), dwarf variegated *Fuchsia*, the centre filled with *Tuberous Begonias*; but the centre of all is filled with *Pelargonium White Perfection*. The above is a three-lobed bed.

Another circular carpet bed follows. *Echeveria metallica* is used as a central dot plant. Then a diamond of *Alternanthera amoena*, surrounded with a narrow edge of *Herniaria glabra*. Then follow dot plants of *Echeveria secunda* with ovals and diamonds of *Alternanthera* and *Herniaria glabra* on a groundwork of *Mesembryanthemum cordifolium fol. var.* An edging of *Echeveria farinosa*, planted 6 inches apart. This is a very attractive and pleasing bed. We next come to the most attractive and splendid bed of the whole lot. It is circular in shape. The centre is occupied with a *Dracæna*. Then a square with four running points filled with *Alternanthera Firbecki*, and running into triangles of *Echeveria farinosa* marked out with *Leucophyton Browni* with silvery white foliage on a groundwork of *Herniaria glabra*. Four Maltese crosses of *Alternanthera Firbecki*, filled up with *Sedum glaucum* and side pieces of *Spergula aurea* attached with a circle of the same, the edging of the bed forming a double row of *Echeveria farinosa* with dot plants of *Echeveria secunda*. We next come to a circular bed of *Begonias* edged similarly to the others, but the central part planted with a groundwork of *Sedum glaucum* with a view to hide the soil during the early part of the season before the *Begonias* attain some size, and cover the ground as they do now with abundant foliage. The next is another circular carpet bed with a central plant of *Echeveria metallica*, surrounded by *Mesembryanthemum cordifolium fol. var.* to match the 18-inch circular edging of the same with *Echeveria farinosa*, planted 9 inches apart, just peeping through the *Mesembryanthemum*. The groundwork of the bed is *Sedum glaucum*, in which are four heart shapes of *Alternanthera aurea* and four triangles of the dark *Alternanthera tricolor*, each one edged thinly with *Echeveria farinosa*.

The next bed is a three-lobed one, edged with Yew, blue *Lobelia*, and Mrs. Wright bicolor *Pelargonium*, scarlet *Begonias*, the centre filled up with *White Perfection Pelargonium*. The next is a circular carpet bed, the same design as No. 1, but having a central plant of *Grevillea robusta*. The end of the terrace is marked with two tall

Cedars (*C. atlantica*), at the foot of which are planted Robert Fish Pelargonium, interspersed with Fuchsias.

Passing across the broad grand walk we come to the opposite portion of the terrace, in a circular corner of which is placed a large circular bed with a large metal vase in the centre. A Clematis Jackmanni is planted in the ground at the foot, and the stems are trained round the outside, and when the plant is in flower, as it is now, a pretty effect is produced, and more especially so when the Scarlet Vesuvius Pelargonium, with which the vase is filled, is also in full bloom. Immediately under the vase the ground is filled in with Golden Feather Pyrethrum. Then placed at equal distances are eight heart-shaped spaces about 18 inches long filled with Alternanthera Firbecki, and dotted round the bed, also at equal distances, are small plants of the variegated Fuchsia. Then follow eight circles on a groundwork of Mesembryanthemum cordifolium fol. var., the main groundwork of the bed being Herniaria glabra with outer circle of Echeveria farinosa and Mesembryanthemum mixed, the whole edged with a sloping side of Sedum glaucum 18 inches wide. At the opposite end of the terrace a bed of the same size matches this.

The next bed is three-lobed edged with Yew, followed by a very distinct edging about a foot wide of the Ivy-leaved Pelargonium peltatum elegans, the centre of the bed being Lass o' Gowrie tricolor Pelargonium, and the lobes filled with Iresine Herbsti.

After this is a circular carpet bed with a Dracæna in the centre, and in the middle of a square with running ends of Alternanthera Firbecki. Side ovals of Alternanthera aurea surrounded with Leucophyton Browni on a groundwork of Herniaria glabra, and traced with Sedum variegatum, and the outer edge or circle intermixed with Kleinia repens, and the sides edged with Mesembryanthemum cordifolium fol. var. Four dot plants of Echeveria or Sempervivum tabuleforme on a ground of Alternanthera aurea. Eight squares near the edge of Alternanthera Firbecki and A. tricolor alternately. There are also dot plants of Echeveria secunda. The next bed is a three-lobed one of Tuberous Begonias and Mrs. Wright Pelargonium. Then follows a circular bed having a central star of four points filled with Alternanthera Firbecki, with a centre of Echeveria secunda. Four ovals interlaced in the centre between each point of the star, and filled also with Alternanthera Firbecki, then eight side semicircles of Alternanthera aurea. Four dot plants of Echeveria farinosa at the foot of each point of the star, each Echeveria being surrounded with Spargula aurea with Leucophyton Browni standing up among it, all the groundwork and side edging being Sedum glaucum.

Many more beautiful beds on the terrace remain to be described, but the most distinct and unique of the many attractive designs have been noticed, perhaps somewhat imperfectly, but still sufficiently, it is to be hoped, to enable the readers to imagine the tasteful combinations of colour and outline which Mr. Egglestone's beds so vividly portray.

Before leaving this lovely terrace, however, it should be stated that just below it, and reached by a flight of steps, is what is known as the Fountain Garden. This is bedded out in an attractive style, but time would not permit of an inspection of it, but sufficient was seen to show that nothing but what was useful and attractive was employed. At the western end of the house was also a splendid set of beds filled chiefly with flowering plants, a large central circular bed being composed principally of grand plants of Tuberous Begonias full of handsome bloom and dark green ample foliage, and just now, and for some time to come, they will be in their best condition. A large vase is also conspicuous among these beds, being planted all over, inside and out, with succulent plants, Echeveria secunda, and Sempervivum californicum.

Carpet bedding, however, claims a little more attention in this part of the grounds, in front of the large conservatory. Here there are four large beds, four-lobed in shape, having circles of Alternanthera amœna, and diamonds of Alternanthera Firbecki, the latter being edged thinly with Echeveria farinosa on a groundwork of Herniaria glabra. Dot plant in the centre, Sedum Sieboldi variegatum. Four triangles of Alternanthera tricolor, and a good edging of Mesembryanthemum cordifolium fol. var. all round. These beds are planted in pairs, the one at the opposite end matching this. The two inner beds are composed of a groundwork of Antennaria edged with Golden Feather. The 3 feet divisions of Iresine Herbsti; Alternanthera aurea two divisions. Four triangles of Lobelia Brighton Blue, with a central plant of Dracæna australis. Being of large area these beds are very conspicuous, and their treatment is bolder than the front terrace beds, but they are in perfect keeping with the surroundings, and exhibit the same nicety of execution, the dividing lines of each figure being clearly defined throughout, and the colours harmonise in perfect contrast to one another. Had time permitted, many interesting notes could have been taken of the other beautiful flower beds which have not been included, also of the capacious vases twined with Clematis and filled with Pelargoniums, &c., and other interesting features. It remains to be said, however, that flowers for cutting are not overlooked, all the most popular hardy herbaceous plants being cultivated for this purpose chiefly on the extensive kitchen garden borders, where they flourish and flower freely. The place is full of interest and instruction, especially to the flower gardener, who here will see the best of everything both in foliage, flowers, and colour design that can be seen in any northern garden. Absorbed and interested as we were, it was with reluctance we closed our inspection of the flower garden, regretting that we had not seen it under genial sunshine, which would have increased its beauty and added to the enjoyment of the onlooker.

Before closing these notes a few words must be said on other

features of the place, but the remarks made will necessarily be brief. Grapes are grown well at Firbeck in three spacious vineries, constituting early, midseason, and late houses, which provide a succession of good, serviceable, well-coloured bunches of fruit, lasting through the winter and sometimes far into early spring. The varieties grown are Muscat Hamburg, Trebbiano, Black Hamburg, Mrs. Pince, Lady Downe's, West's St. Peter's, the four latter with Muscat Hamburg forming the varieties grown in the late house, Mrs. Pince being the latest of all, and Black Hamburg keeps well until Christmas. The back wall of the late vinery is covered with Figs. Isca, a new variety, is being tried, but reliance is placed chiefly on Brown Turkey for the main supply. Gathering the latter variety is commenced about the end of June, and the crop lasts a month; a second crop is afterwards produced, and is now swelling.

In the plant stoves flowers of the choicest stove plants are obtained. Eucharis amazonica is in good condition, and good crops of flowers are thrown up twice a year. Allamanda Schotti is planted out in a 2-foot square border about 18 inches deep. It covers a large extent of the roof, and produces abundance of flowers. Every year about January, after a good rest, the bunches are spurred back pretty freely. There is also a fine specimen of Musa Cavendishi, which generally fruits every two years. Stephanotis floribunda is also planted out the same way as the Allamanda in good turfy material. Weak wood only is thinned out, and plenty of flowers are produced from May onwards to the end of August, after which pot plants carry the supply of bloom on to November. Dipladenia boliviensis, having white flowers with a yellow throat, is planted out, too, in a similar way, and the flowers, which are very useful for buttonholes, are gathered in quantity. Plenty of decorative plants for the house are grown, the object being to provide abundant furnishing material at all seasons. We next come to the Melon house, where we find Asparagus plumosus and Stephanotis planted out and in fine condition. A second crop of Melons is swelling rapidly, the varieties being Albert Victor and Hero of Lockinge. Winter Cucumbers are also planted, and will take the place of the Melons later on. All the Year Round and Telegraph are the varieties relied upon for winter.

The next house contains useful Poinsettias in 6 and 7-inch pots, promising to produce good bracts of bloom during the dull season of the year, extending from the beginning of December to February. Achimenes are grown too in 6-inch pots, and a number were just ready for flowering. A good plant of the strongest scented variety of Pancratium, P. fragrans, attracts attention; one strong stem bearing twelve beautiful blooms, and another stem was developing a similar number. A long shelf of Cypripedium insigne in 6-inch pots was noticed, and the plants were sending up flower stems pretty freely. There was also a similar shelf in another house of Calanthes vestita, Veitchi, and rubra, in 6-inch pots. These were growing vigorously. Tomatoes for an early supply are grown in pots in the vineries. Sutton's Earliest of All and Sutton's Perfection are found to be the best for early work. The first named, however, has the fault of coming too much corrugated, but the latter generally gives nice shapely fruits, and it is a good setter.

In conclusion, I may say sincerely that I am indebted to Mr. Egglestone for the kind and courteous manner in which he volunteered information and explanations about anything I had the pleasure and time to inspect; and if I have in these notes conveyed any interest and pleasure to the readers of the Journal, the remembrance of my brief visit to Firbeck will be doubly enhanced.—S.

#### THE ROYAL NURSERIES, EXETER.

By a combination of circumstances I found myself a short time ago in the ancient, yet still flourishing, city of Exeter, a city that teems with interest to the student of antiquities, but the shrewd and hospitable inhabitants of the Devonshire capital are not content to rest upon past glories alone, but have the energy and tact to carry on at the present time a thriving, if not a gigantic, trade. Wherever we find general business in a thriving condition we are sure to meet with established nurseries that provide for the public wants from an horticultural point of view. The nurseries above named are admirable examples of a well-managed firm, who not only do a large local trade, but whose fruit trees, Roses, shrubs, and seeds are known throughout Great Britain. These nurseries are carried on by Mr. Robert Veitch, who bears a name well known and respected among all classes of gardeners. At the time of my visit I was much struck with some fine trained trees of Dymond Peach, which were trained to a wall having a west aspect. They were in a thoroughly healthy and thriving state, carrying an exceptionally heavy crop of large highly coloured Peaches. I have not previously met with this Peach growing in the open air, but judging from the fine fruit produced here in such abundance it must prove a valuable kind for outdoor culture, especially as it was here bearing freely upon quite small trees, as well as upon larger ones. Lord Napier and Downton Nectarines upon the same wall were also carrying large highly coloured fruits. In many districts Peaches are a very scanty crop this season; it is, therefore, all the more instructive to record examples of successful culture, especially in cases like the present, when the trees have received no protection whatever. Mr. Veitch considers his success due, in a great measure, to the fact that his trees are root-pruned every autumn, so that they can at any time be lifted with complete balls of earth. All kinds of fruit trees are largely grown at the Exeter nurseries,

and the soil seems to be well adapted to that purpose, being moderately heavy and of a reddish yellow colour, resembling very much in appearance the soil in which Mr. G. Bunyard grows his Kentish fruit trees so well. Large breadths of the most popular kinds of Apples, Pears, Peaches, &c., were represented by sturdy young trees with well balanced heads. Whenever a portion of the nursery is cleared of trees Potatoes are grown upon it for one season, and when the land is prepared for this crop a dressing of lime is given, which proves highly beneficial to the fruit trees which follow the Potato crop.

Carnations and Picotees are largely grown. The majority of them were past their best at the time of my visit, a notable exception, however, being a fine yellow variety named Germanica, which was raised here, and from a packet of seed sown every plant came true, both in form and colour, and as I saw them in full beauty they were a remarkably fine batch. I also noticed in close proximity to the Carnations a nice batch of that useful early flowering Chrysanthemum Madame Desgrange, which were beginning to open their flower buds, and which are highly valued for cutting purposes. Japanese Maples have for some years been a speciality of this firm, and judging from the rare beauty of the numerous varieties grown here they are destined to become exceedingly popular plants, and are worthy of a place in greenhouses and conservatories as well as in the open air, for they are as remarkable for the light and graceful habit of their growth as for the beautiful tints of their leaves. Dahlias of all sections are well grown, and though not yet in full beauty give promise of some remarkably fine blooms. Such fine new varieties as Amphion and Panthea were included among the Cactus section.

The houses were filled with a general collection of such plants as are found most useful for supplying local wants, there being a great demand for cut blooms and small plants. I was much struck with the white form of *Agapanthus umbellatus*, which is here well grown, as were also fine batches of *Lilium auratum* and *Lilium rubrum*. A light span-roofed structure was entirely filled with a very showy collection of Tuberos Begonias, double and single forms being represented by flowers of a very superior type, good in form and substance, and extremely bright in colour, the scarlets and yellows being particularly good. Mr. Robert Veitch is especially interested in his Begonias, because they have been brought to their present state of perfection by the gradual improvement made in each generation of their own seedlings. I must not forget to mention the plants of *Cœlogyne cristata* and *Lemoineana*, which were thriving wonderfully well, without any special attention being given them.—KENTISH MAN.

EVENTS OF THE WEEK.—The chief horticultural event of the approaching week will be the Grape and Dahlia Conference in the Royal Horticultural Society's Gardens at Chiswick on Tuesday and Wednesday next, September 23rd and 24th. We may again call our readers' attention to the arrangements made for the gathering, which are as follows:—Collections of Grapes are to be arranged in groups. A.—Sweetwater Grapes, including Chasselas and Muscadines: (1) Black or purple berried varieties; (2) White, green, or golden berried varieties. B.—Muscat and Frontignan Grapes: (1) Black or purple berried varieties; (2) White, green, or yellow berried varieties; (3) Frontignan. C.—Vinous or late keeping Grapes: (1) Black or purple berried varieties; (2) White or golden berried varieties. Classes are also provided for Grapes of very high flavour (any kind). American varieties: Grapes grown entirely in the open air; Grapes grown under glass without artificial heat; foreign-grown Grapes; pot Vines with fruit; examples of packing Grapes for market, to be sent by rail; examples of packing Grapes, 4 lbs. to 6 lbs., for private use, to be sent by rail; examples of the enemies of the Grape Vine—diseases, injurious insects, &c. Thus this programme is sufficiently comprehensive, and the Exhibition should attract a large number of visitors. The Dahlia Conference will be held on Tuesday, September 23rd. Mr. Harry Turner (President) in the chair, and papers will be read by Mr. Shirley Hibberd, Mr. T. W. Girdlestone, and Mr. W. H. Williams. The Grape Conference will be held on Wednesday, September 24th, Dr. Hogg (President) in the chair, and papers will be read by Mr. T. F. Rivers, Mr. R. D. Blackmore, Mr. W. Thomson, and Mr. W. Coleman.

— THE GUILDHALL (LONDON) FRUIT SHOW.—We are informed by the Fruiterers' Company that this Show, which opens on October 4th, will be under the patronage of Her Majesty the Queen, with the following noblemen and gentlemen as Vice-Patrons:—The Right Hon.

the Lord Mayor, the Duke of Bedford, the Duke of Westminster, the Duke of Newcastle, the Duchess of Grafton, the Marquis of Salisbury, the Baroness Burdett-Coutts, Earl Spencer, K.G., the Earl of Coventry, the Earl of Jersey, the Earl of Dartmouth, the Earl of Lathom, Lord Crewe, Lord Savile, Lord Egerton of Tatton, Lord Hothfield, Lord Wolverton, Lord Moreton, Viscount Emlyn, Sir Nigel Kingscote, K.C.B., the Right Hon. W. H. Smith, M.P., the Right Hon. W. E. Gladstone, M.P.; E. H. Palmer, Esq., Master of the Mercers' Company; J. S. C. Heywood, Esq., Master of the Drapers' Company; W. R. Shaw, Esq., Master of the Lethersellers' Company; Charles Whitehead, Esq., Walter Gilbey, Esq., Charles Howard, Esq. Gardeners and others who have not obtained schedules can procure them from O. C. T. Eagleton, Esq., 40, Chancery Lane, London, W.C. It is desired that this exhibition be made known to cottagers and farmers who grow fruit in their gardens or orchards.

— THE WEATHER in the METROPOLITAN DISTRICT has continued exceptionally fine during the whole of the past week, and very rarely have we experienced such a period of uninterrupted sunshine in September. The heat on several days has been like midsummer, the shade temperature standing at 56° at 6 A.M., and rising above 70° by mid-day. Communications from different districts show that this has been general, though there are now some indications of an approaching change.

— POTATOES IN IRELAND.—I think I shall be able to prove that Mr. Wright and Mr. Castle are quite correct in presuming thick planting of Potatoes to be the main cause of the disease, having such dire results in a wet season such as we are now passing through. When planted in "lazy beds" a foot from plant to plant each way is all the space allowed. Now when it is remembered that the bulk of Potatoes grown on "lazy beds" are Champions, it will be readily imagined what a dense mass of foliage cover the beds, rendering it impossible for either sun or wind to penetrate, and thus dry the ground and under portions of stems and foliage. We make it a practice to plant Ashleaves 2 feet apart from row to row, and a foot apart in the rows; stronger growing kinds are allowed a foot more space both ways. This year, when every one around us is complaining of small, wet, and "black" diseased Potatoes, I am pleased to find when lifting ours that we have not had such good Potatoes for the last four years. They are larger than we have ever had them, free from disease, and quite dry when cooked. I attribute our good fortune to the thin planting, and thus giving root and branch abundant space for development. It is not that a good dressing of manure affected the improvement, for none was given. Manuring ground for Potatoes is a thing of the past as far as we are concerned, and we get heavier crops and of superior quality when we plant in unmanured ground. Seed of a red kidney Potato was given me a few years ago without a name. It is an enormous cropper, and to my taste a capital eating Potato. I enclose a few, and should be glad if you would test their cooking and eating qualities.—HANDY ANDY.

— WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—The monthly meeting of this Society was held on the 9th ult., the Rev. A. E. Lofts presiding. The attendance was very satisfactory. A capital paper was read by Mr. H. Brown on Strawberries, a subject in which all the members appeared pretty well posted up. A lengthy discussion followed, in which several members joined, and a hearty vote of thanks was accorded the essayist for his paper.

— I FORWARD you a photograph of a new STYLE of ORNAMENTAL GARDENING which I am showing here in twenty of the best designs that I can procure. It is as much as possible to imitate carpet bedding, but worked by minerals in six distinct colours, broken up small to the substance of rather small gravel. The materials are dark blue glass, light blue ditto, sand, gravel, ochre, black brick, red and green glass. The ground is thoroughly prepared, so as to keep down the worms from doing damage, or heavy rains from splashing the material. This work is equally as good in winter as it is in summer, the weather having no effect on it. It can be either laid loose on the ground to the required design, or on a firm and durable foundation, and may be worked out in the most elaborate designs that decorative art can produce. I have it patented, as it ought to be of use on ground where it is difficult to get much show from plants or flowers.—WM. SHERWOOD, 105, Seamer Road, Scarborough. [The coloured photograph shows an elaborate geometrical design in several tints. We have frequently seen similar beds in suburban gardens near London, but cannot say that they excite much admiration.]

— PEACH DR. HOGG.—We find this an excellent variety for growing on an outside wall. It is now ripening, and the flavour is first-rate. Last season the foliage had a decided yellow cast, but by relifting the trees this has changed to a dark and healthy colour.

— PEA VEITCH'S PRODIGY.—This is the best main crop Pea we have had this season. It has been most productive, both the pods and Peas being of large size and first-rate quality. It also keeps in use a long time.—Y.

— I HAVE not hitherto had an opportunity to remark how thoroughly I agree with all Mr. Abbey said in his recent article on CANKER. Much has been written about this matter, and very varied have been the opinions or suggestions offered, but Mr. Abbey seems to have finally cleared up all doubts and difficulties by giving us a full explanation based on indisputable facts.—J. R. S. C.

— CHRYSANTHEMUM BELLE PAULE.—I have often heard it said that there is a secret in taking the buds of Belle Paule. May I ask Will some of your able correspondents be kind enough to give their experience with this variety as to taking the buds? I find that some of the buds on the strongest shoots are liable to go blind, while those on the weaker shoots set as freely as any of the old varieties. Advice on the subject will be gladly received.—G. P.

— MR. D. B. CRANE, Archway Road, Highgate, is taking a place amongst the earnest AMATEUR EXHIBITORS, and the application of his characteristic energy to the culture of Chrysanthemums is certain to bring good results. At the Aquarium last week he secured two first prizes for twelve Pompons and twelve bunches of flowers unrestricted as to section, besides some minor prizes in other classes. Mr. Cox of Brickendon Gardens, Herts, had six wonderfully fine blooms of Edwin Molyneux, proving how well this variety comes early in the season; in size and colour they were equal to the best we have seen.

— EARLY FROSTS.—It would appear superfluous to speak of frost so early as the first day of September perhaps to dwellers in the south of England, but here, in North Somerset, such actually happened on the date quoted, as well as two or three succeeding mornings, and although not sufficiently severe to do much injury, many tender plants were drooping from its effects. I note a record of two or three degrees of frost has been registered in Shropshire, which would be much the same experienced in open places here. The fields were quite white with the hoar frost, and distinctly crisp to the feet, but in enclosed gardens less severe cold was felt.—W. S.

— THE WEATHER LAST MONTH.—August was changeable and showery, but without a great quantity of rain, the total amount being 1.76 inch, which fell on twenty days, the greatest daily fall being 0.31, on the 28th. We had thunder on 16th and 26th, and a gale on the 15th. Wind was in a westerly direction twenty-two days. It was bad weather for getting in the harvest, and Potato disease spread fast in the tops. Highest shade temperature was 81° on the 5th, lowest 37° on the 24th 30th, and 31st; lowest on grass 32° on 24th. Mean temperature of the month 58.44°. Barometer, highest 30.30 inches on 31st, at 9 P.M.; lowest 28.38 inches, at 9 P.M. on the 26th; average height 29.91. The garden spring was running eighteen gallons per minute on the 31st.—W. H. DIVERS, *Ketton Hall, Stamford.*

— BLATTA GERMANICA.—“Entomologist's” inference relative to the harmlessness of the above does not correspond with my experience of them. They have infested our hothouses and propagating cases for years, and their ravages amongst cuttings are both impartial and annoying. They are particularly fond of *Acalypha musaica*, and will soon devour the leaves from the cuttings unless special precautions are taken to prevent their doing so. We frequently find cuttings of *Ficus clastica* with the bark eaten off all round close to the soil, and this evil we can only trace to *Blatta germanica*, of which we have hundreds in all stages of growth. We have also a quantity of crickets, which are very destructive at times, especially amongst newly started Vines in spring, the leaves of which they will eat out in shreds.—J. H. W.

— TWO FINE HYDRANGEAS.—Unusual examples of good cultivation are sometimes found in unexpected quarters. An instance of this may be seen in the garden of the Crown and Sceptre Hotel, Streatham Hill, where two very fine specimens of the old-fashioned *Hydrangea* have been flowering for some weeks past. These plants have quite a little history of their own. About twenty-two years ago, Mr. Cribb, a former proprietor, rescued them from a rubbish heap and cared for them during many years. Later on, the present proprietor,

Mr. Cauldwell, took them under his care, and now each plant occupies a tub 3 feet in diameter, is 7 feet through, with a height of 5 feet from the ground, and each plant has borne upwards of 150 flower trusses this season, many of them being 7 inches across. The plants are the picture of health, and during this long period have never had the protection of a greenhouse, the only covering being some mats during severe weather. Mr. Cauldwell is proud of his plants, and delights in showing them to his friends.—E. B.

— PRESENTATION TO MR. LYNE OF WIMBLEDON.—A concert was held in the Dog and Fox Hotel one evening last week, on the occasion of a presentation to Mr. J. Lyne, one of the joint Hon. Secretaries of the Wimbledon and District Royal Horticultural and Cottage Garden Society, on his leaving to take charge of a garden at Chislehurst. Mr. M. Clarke presided, and there was a good attendance of members. The Chairman said they were all cognisant of the services Mr. Lyne had rendered to the Horticultural Society and to other local institutions during his many years' residence in the town. He had made a great many friends, and they all hoped he would be as highly esteemed in Chislehurst as he was at Wimbledon. He then handed Mr. Lyne a handsome anti-magnetic keyless half-hunter silver watch, engraved with the following inscription:—“Presented to Mr. J. Lyne by a few old friends on his leaving Wimbledon, September 13th, 1890.” He hoped that when Mr. Lyne looked at the watch it would remind him of the pleasant time he had spent in this locality. He then presented Mr. Lyne with a timepiece, in oak, as a gift to Mr. and Mrs. Lyne jointly.

## ANNUALS FOR CUTTING.

THE demand for cut flowers is increasing every year, and the gardener's energies are often sorely taxed, hence hardy annuals which are easily grown and often far more suitable for cutting than choicer flowers should be largely employed through the summer months. Some of our modern flower stands are of great size, and to dress them effectively must have long-stemmed flowers, indeed whole plants or large branches are often required, and this necessitates cutting many unexpanded flowers, which, of course, is a waste. If a choice plant is operated upon that is only grown with difficulty, it will not be surprising if the gardener becomes a little disturbed. Annuals are so easily grown and take so little time that one can freely cut or even pull up the whole plant if necessary without the least compunction.

Poppies have had much attention in late years, with the result that all sections of them have been greatly improved, so that now we have colours and shades from pure white to deep scarlet, and in the *Pæony*-flowered section we have huge double flowers, white, pink, scarlet, and glossy black. The Shirley Poppies are useful for dressing stands, but they entail much labour, as like all Poppies their petals soon fall, and the stands have to be attended to every day. For early summer use sow in autumn, and for summer and autumn sow at different times in spring. Poppies are of easy culture, doing well in ordinary garden soil, and although they may be transplanted, yet the best results are from those sown where they are to flower. They should be thinned from 1 foot to 18 inches apart. Iceland Poppies are not, strictly speaking, annuals, but hardy perennials, still they may be treated as such, and flowers better adapted for dressing small stands can scarcely be imagined. Their colours are white, yellow, and rich orange-scarlet, and they are entirely devoid of the objectionable Poppy odour; indeed, they emit a very pleasant scent. They are perfectly hardy, and should find a place in all choice herbaceous borders.

*Lavatera trimestris* (rose and white) is extremely useful for cutting purposes. It is surprising this useful annual is not more generally grown, it is so effective both for garden decoration and in a cut state. Seeds may be sown in March in ordinary garden soil where they are to remain, or they may be transplanted successfully during dull weather if well cared for. Those who wish for a stately easily grown plant, either for the back of borders or for cutting, will not be disappointed with *Lavatera trimestris*. They grow from 3 feet to 5 feet high and branch freely, hence they should have plenty of room to do them justice.

*Chrysanthemum tricolor* and its varieties are very useful for cutting, but being rather stiff plenty of foliage should be arranged with them. Improved varieties have late years appeared, so that now we have a considerable range of colour, all of which may be had in a mixed packet of seed. For a long succession of bloom sow in autumn and again in spring, and thin to 15 inches apart.

*Centaurea cyanus* is one of the few British weeds that is considered worth cultivating, at least for decorative purposes. This old Corn Bluebottle is, however, one of the most useful that can

be grown for cutting; its colours, producing beautiful shades of blue, are very uncommon and greatly needed. The best results are obtained from seed sown in the autumn, and being strong freely branching plants they should have plenty of room, 3 feet by 2 feet not being too much if grown on good soil. They will attain the height of 4 feet, and continue flowering all the summer. There are other colours of this plant—white, red, rose, purple, and striped. There are also double varieties, which we do not consider improvements.

For dressing small and medium-sized stands many hardy annuals are useful, but beyond giving the names of a few we have found suitable more need not be said about them, as their culture is easy and all much the same. The same preparation and the same soil that would grow a good crop of Carrots would grow hardy annuals to perfection, always provided they are allowed plenty of room. There is no cheaper way of filling flower beds, and if grown as recommended no more effective way, than by using hardy annuals. The too common practice of assigning them to some out-of-the-way corner, or to mixed borders where they are smothered by stronger plants, has done much in bringing them into disrepute; but give them half the attention that is bestowed upon bedding Pelargoniums and the result would be far more satisfactory than much of the ordinary bedding. The following hardy annuals will be found useful both for bedding and cutting:—All the varieties of Eschscholtzias, Godetias, Larkspurs, Sweet Sultans, Calliopsis, Candytuft, and Mignonette.—J. H. W.

### AURICULAS IN SCOTLAND.

THE English and Scottish growers are out of harmony in regard to the proper time for repotting Auriculas. As stated by English growers in the horticultural journals, repotting should be commenced immediately after blooming, and should be finished by the end of June. I have never considered the reasons given for this as sound, and have never put the recommendation in practice. On the other hand, growers in Scotland think from the middle of July to the end of August the best time, and some go into September without any doubt of the plants doing well. This year all the growers with whom I am in correspondence finished by the end of August, and I am informed that now the plants are looking well and growing vigorously. All agree that this year the increase from the newest varieties has been small, but the older kinds have given the average number of offsets. In some collections green fly has been troublesome on account of the rains preventing the frames being fully open so often as could have been wished. The best method of clearing a plant of green fly is by drawing the leaf between the finger and thumb, and blowing them out of the centre with a smart puff. If the plants are frequently looked over green fly is easily kept down. Any plant largely infested should be held under a gentle run from a water pipe, and then placed in the open air till dry. These plans are better and sweeter than fumigating with tobacco. There has been in Scotland little or no autumn bloom. In my collection Heroine and the Duchess of Oldenburg are the only two showing trusses. The Duchess never fails with me to bloom in autumn, and some growers inform me that Heatherbell is their most persistent autumn bloomer. Some Scottish growers have been parting with many of their older varieties to make room, as they say, for newer sorts. This may be so, but it may also be that they may grow more of what they consider prize-takers at shows. Competitors have their own ways of working, but the true lovers of Auriculas for their own sakes will still grow the old varieties, around which so many tender memories linger, and add to them whatever new ones are worthy of being placed beside them. In my own collection there are some of the very oldest varieties that I would not part with on any consideration, although they have faults.

I would now like to make a few observations on increasing stock by beheading the plants. This is a process of some nicety, but with a little experience and the exercise of judgment it can be done successfully. I have often done it in former years, but this year I have made experiments on a larger number, and am satisfied with the results. In no instance has there been a failure. The separation of the stem must always be made below fibres. This I hold to be a *sine qua non* in the operation. I know it is often said that the head of a plant may be cut off without fibres, and struck at the side of a pot under a handglass. This is a tedious and unsafe plan, and it is on this account that I never behead a plant except I can cut below fibres. Dress the wound with powdered charcoal, and put a pinch or two on the top of the cone of soil when potting and there will be no danger. See that the stump is good at the extremity; it not, cut off any decayed part, and dress top and bottom with charcoal. If there are eyes below the cut fill the earth up to just below them, leaving the top above the soil; but this

year I have found that even without an apparent eye shoots will come. I proved this in the case of a plant of Mrs. Dodwell, which I had to behead in consequence of a drop in the centre causing the whole head to rot. There was not the slightest appearance of growth of any kind about the stump, but after some days two strong eyes appeared on the quarter of an inch left above the surface of the soil, and at present they are over an inch long and beautifully green. It is well known to all growers that some varieties will not increase except by beheading. A notable instance of this I have had in Low's Mazzini. As all the stock of this proceeded from one plant, which I got from a friend of the raiser's, I never could get an offset from it until I beheaded it, and every year I have done this, and so have been enabled to give my friends plants. This year I have two strong shoots from the stem of it. Mazzini is not a very refined flower, but it is desirable in a collection on account of its dark blue colour. From the stump of John Simonite I have five offsets, which will be fine separate plants by next spring. From Heroine I have seven offsets, from Eliza three, from my own King Lear two, from Duke of Argyle one, from Lancashire Hero one, and several from others of which without the beheading process I would have had no increase.

In the Journal of 4th instant I notice that "D., Deal," a veteran grower, asks, "Has any grower ever noted how long-lived an individual plant of any variety is?" I can give him sure information in the case of one of my varieties. I have had a plant of Gorton's Stadtholder twelve years. There cannot be a doubt that it is the same plant, because till this year it never made an offset, and it has been potted year after year a single plant. As the stem of the Auricula enlarges upwards, and new roots are sent out as the stem grows, a plant may be, in a sense, considered new every year. But an interesting point has been raised, and Auricula growers should take note of plants when procured, and obtain authentic information as to the age of any single individual plant.—JOHN MORRIS, *Mains by Dundee*.

CATLEYA EMPRESS FREDERICK.

AT the meeting of the Royal Horticultural Society on July 8th this year, Baron Schröder exhibited an exceedingly fine Cattleya, under the name *C. Mossiæ Dowiana* var. *Empress Frederick*, and so beautiful was it that a first-class certificate was at once accorded by the Orchid Committee. Possibly it is the result of a cross between a good variety of *C. Mossiæ* and *C. Dowiana*, but in any case it is remarkable for the large size of its bold, distinctly coloured, and fragrant flowers. The sepals and petals are pure white, the lip very broad, rounded, and of an intensely rich deep crimson or magenta, very neatly edged with white, and deep golden yellow in the centre. The plant shown was dwarf in habit, and had five flowers similar to that depicted in fig. 31.

*C. Dowiana* now ranks as a variety of *C. Mossiæ*, and Messrs. Veitch thus describe its history:—

"Originally discovered by Warscewicz in Costa Rica about the year 1850. He sent plants to Messrs. Low & Co., at Clapton, but arriving in bad condition they eventually died. The dried specimens that accompanied the living plants were sent by Mr. Low to Professor Reichenbach, but the parcel containing them failed to reach their destination; hence it happened that for some years afterwards doubts were entertained of the existence of so superb a Cattleya as that which the letters of the traveller described, and in which he expressed a wish that it should be named in compliment to Mrs. Lawrence, of Ealing, at that time one of the most liberal patronesses of Orchid culture and Orchid collectors in this country, a request of which Mr. Bateman could not have been aware when describing it many years later for the "Botanical Magazine," dedicating it by request of Mr. G. Ure Skinner to Capt. Dow, of the American Packet Service. It was re-discovered in 1865 by Mr. Arce, a native naturalist, while engaged in collecting natural history objects in Costa Rica for Mr. G. Ure Skinner. He sent plants of *C. Dowiana* to Mr. Skinner in England through Captain Dow, which were acquired by us, and one of them flowered for the first time in our Chelsea establishment in the autumn of 1865. The habitat of this Cattleya appears to be restricted to a small area on the slopes of the great central mountain range facing the Pacific Ocean, and where it is said to exist in very limited numbers. The variety *aurea* was discovered by Gustav Wallis; in

1868, near Frontino in the state of Antioquia, while collecting plants in New Granada for M. Linden, and four years later by Butler while on a mission to the same region for Messrs. Backhouse, of York. The late M. Roezl placed its habitat in the state of Antioquia, near the river Cauca at a considerable distance above its confluence with the Magdalena, a locality upwards of 600 miles distant from the native home, in Costa Rica, of the typical *C. Dowiana*."

### CHERRIES FOR MARKET.

[A paper by Mr. G. Bunyard, read at the Conference of the British Fruit Growers' Association, Crystal Palace, September 5th, 1890.]

KENT is the greatest Cherry producing county in England. They were introduced there in the time of Henry VIII, and put under the care of Richard Hains, the King's fruiterer at Newington, a village near

finest fruit, large, juicy, and of good colour, these orchards are maintained by fattening sheep in them, such being well fed on corn, cake, and rich foods. Pigs are sometimes kept in such orchards, and in order to get direct benefit they should be penned in a limited space until the grass is eaten away, and then they are moved to the next space, and so on. It is better to do these limited portions thoroughly than to allow the animals a full run. During the time the leaves or fruits are on all cattle are kept out, as they will break the lower boughs, and in young orchards do irreparable damage.

In starting fresh plantations there are several ways of procedure—

(A). If the land is already in grass, holes of 2 feet square are prepared, and the trees planted at 24 to 30 feet apart, the roots being as much upon the surface as possible, and they are "cradled" with chestnut battens securely fixed. As this wide planting is a great loss of space, the smaller-growing Apples, Plums, and Damsons are planted

FIG. 31.—CATTLEYA EMPRESS FREDERICK.

Sittingbourne, on the main road from London to Dover, and the family is now represented there by men of the same name in the fruit trade. This parish still maintains its reputation as the best district for the culture of the Cherry, and in the deep brick earth there they attain to a great size, as much as 70 or 80 feet high. The annual sales attract buyers from all parts, and are the event of the year in the locality.

The older orchards have been planted in a haphazard way, but the more modern are in straight lines at 24 to 48 feet apart, and are perfect visions of Paradise when in full flower with their graceful wreaths of snowy white, the beauty of which cannot be imagined by those who have never seen them; in fact for the blossom alone Cherries are worthy of a place in parks and garden enclosures. All these orchards are in grass, and form convenient sheltered spots for lambing and for cattle, which, however, are not put in when the leaves fall, or into young orchards where they eat the boughs. In order to produce the

between them, such extra trees paying for their cost before the Cherries come to a profitable age; and when the Cherry boughs meet the other trees, which would be in fifteen or twenty years, they are cut out. Old Cherry orchards cannot be too highly manured, and one grower told me he had fattened about four sets of sheep per annum in his orchards, and that the Cherries were so fine that he sold the crop for £1000 on a small average; but young orchards of Cherries should only be planted in the ordinary soil.

(B). Another way, and one which brings a quicker return, is to plant Cherries at 30 feet apart, and fill up with Apples, Pears, or Plums at 15 feet, and then to plant the ground with Red or Black Currants and Gooseberries at 5 or 6 feet apart. In this case the land has to be dug annually and heavily manured in winter, but a crop is taken the second year, and in the fourth or fifth year the Apples and other fruits come to bear, the Cherries following about the sixth or eighth year.

It is important that land under Cherries should not be cultivated, and for the first three or four years 4 feet from the trees is left untouched; this is gradually increased when in about ten or twelve years the bush fruit is removed and the land laid to grass, the intermediate trees being removed as before.

(C). A Kentish plan is to put Cherries in Hop gardens at 36 feet apart, and after eight or ten years to lay the whole to grass; they make much progress in this way, as Hops must be cultivated highly to be remunerative. A danger in this case arises from too free growth, as gum is induced by occasional frosts acting on the sappy wood.

The pruning of Cherries is of the simplest. They are best allowed a year's growth before cutting back, which should be severely done in order to produce a well-formed balanced head of, say, five branches. The extra shoots are cut away, and from this time onward the trees make a naturally regularly balanced head, and only require the boughs to be thinned when they cross each other or are too thickly placed. A man should be able to get his head and shoulders between them easily. If any shoots break or twist off in a gale or through the burden of fruit, they should be cleanly cut away with a sharp knife, and if the form of the tree is seriously injured by this loss, the trees must be cut in hard to form them again; but, as a rule, the less cutting there is the better, and if a saw is necessary the exposed end should be rounded with a sharp knife to assist Nature in healing the wound. All young orchards should have the fruit gathered by means of step ladders, as the boughs cannot bear the weight of the ordinary ladders when young (under ten years old).

When the trees make over a foot of growth yearly they will be better left without any stimulants, but if the new wood is but 6 to 9 inches long they should be assisted with the manure before named, or by the application of liquid manure or top-dressings of any description of dung, or failing that bone dust, Odam's blood manure, Thomson's manure, or any similar chemical fertiliser will assist them. The Cherry naturally roots upon the surface, and this feels the benefit at once.

In making new orchards care should be taken to plant a considerable quantity in one spot, otherwise birds will take the crop. A few Cherries in a mixed orchard are rarely a paying investment. When in bulk it pays to have a man to scare or shoot the birds on the ground day and night. To do this a hut should be provided for him to sleep in, and he can thus keep off other larger animals to whom Cherries are a luxury. In the day he assists to move the ladders for the pickers, who in Kent are frequently women, who earn good money at the work, either by day pay or agreement per half sieve of 24 lbs. One gathering generally clears the trees, but it pays well to pick the sunny side first, and also the outsides of the branches; this causes the remaining fruit to swell up, and if these larger examples are marketed in 12 lb. baskets or "quarters" they frequently make 20s. to 30s. per bushel, or 5d. to 9d. per lb.

In setting out an orchard of Cherries care should be exercised to keep all of one kind together, and if alternate rows of the stronger kinds (such as Napolcon, Black Tartarian, Bigarreau, and Elton) are made to alternate with such growers as Black Cluster or Corone, Black Hearts and Brown Hearts) the grass below is not so much shaded, and consequently is of better feeding quality. Another useful and delicious race of Cherries, but little grown out of Kent, are what are locally called Reds, being the Kentish and Flemish, or the Montmorency of the Continent.

These are rather later than the sweet Cherries, and are far more delicious to preserve or for tarts than any others; in fact, the jam from these sorts is a perfect sweetmeat, and comes near to Tamarinds in its delicate and pronounced ratafia like flavour. These (Reds) never make large trees, and are short lived, so that they are frequently used to plant between the larger kinds or for the odd distances on the outsides or in angles where there is not space for the strong growers. I would specially commend these to the Scotch growers, who would find them even better than their noted Dundee marmalade. Taste sample made 1889. After the main boughs decay they send forth fresh growth from the stem or the stumps, and in that way fruit for fifty years, but their average life is only about twenty-five years, by which time they have well paid their way. This race are also the best for drying. The Morello Cherry is of similar growth, succeeds well as a standard, while the May Duke and others of that race are useful for sheltered spots.

As regards varieties, the following list includes those generally planted for profit, and can be relied on for extended culture; fully developed trees of two or three years in the head are worth 180s. to 250s. per 100, but the Kent growers prefer those with one year's heads, at 130s. to 170s. per 100.

*White or Heart Cherries.*—Kent Bigarreau or Amber, Napolcon Bigarreau, Florence, Elton, Frogmore Bigarreau, Governor Wood.

*Red Cherries.*—Kentish, Flemish, Olivet, Morellos.

*Black Cherries.*—Early Rivers, Werdor's Black Heart, Waterloo, Black Eagle, Black Cluster or Caronc.

*Duke Cherries.*—May Duke, Late Duke, Royal Duke.

For private gardens the following are useful as standards:—Early Lyons, Emperor Francis, Ludwig's Bigarreau, Nouvelle Royale, Tradescant's Black.

In connection with this subject I would suggest that orchard trees should have at least a stem of 6 feet, and should be trees worked on the wild Gean, as the stems so formed are hardier and less liable to gum and die than when they are worked low and run up on their own stems; and grafted trees are preferable to those "budded."

Grass orchards of Cherries are largely planted in Kent, as there is always the chance of three crops, viz., Cherries, mutton, and wool, and it is rare for all these to fail. The following notes may interest your members as to the nature of Cherry orchards in Kent. The custom is to sell the fruit upon the trees about fourteen days after the flowering, and from the fall of the hammer the buyer puts in his own men and takes all the risk, finding his pickers, overlookers, packers, &c., and delivers them to the rail himself, the grower simply taking the proceeds of the sale less 5 per cent. commission. When it is considered that this only represents a part of the produce of the land, you will understand that a Cherry orchard on a holding often adds letting value to an estate or single farm. In fact a Cherry orchard never goes begging for a tenant. From £20 to £40 per acre is an average price for an established orchard; choice lots have made £80 per acre. Plantations of dwarf Cherries are not grown except the Morellos, which, as pyramids, bear as fine fruit as from a wall, and from the large number of trees per acre must prove a profitable investment.

There is yet another Cherry grown in Kent of great importance. It appears to be the wild Morello, or the native form of it. This produces a small flat fruit, which is somewhat acid in taste, but the juice is of high specific gravity, and is the base of the famous Grant's Morello Cherry brandy, which is made at Maidstone only, and is to the so-called Cherry brandies of the trade and the Kirsche-waters of the Continent as real Highland whisky to poor gin. The maker is a neighbour of mine, and a most conscientious and painstaking and scientific distiller, who spares no pains or expense to maintain the high qualities of this wholesome and delicious cordial. The growth of this tree resembles a Birch more than a Cherry, and it soon assumes a pendant form from its copious crop and the wiry growth it makes yearly.

I have dealt hitherto with Cherries on a large scale, but they may be profitably grown by cottagers on the gables of their houses, and by farmers on their walls and buildings, and will in these positions produce fine large fruit, which can readily be protected by fish netting, which is doubtless cheap in these parts. Such fruit would be ready to pick before the outside crops, and command a good price packed in  $\frac{1}{2}$  lb. or 1 lb. punnets.

The packing of Cherries is in Kent done in this way. After having first lined his basket with blue paper, the ends of which lap over about  $1\frac{1}{2}$  foot (in order to turn back to cover the fruit when the basket is full). The fruit being gathered, the packer carefully passes them through his hands in tipping out the picker's basket, and then removes any bird-pecked, unripe, or smashed fruit, and with a quick shake settles the fruit firmly in the receptacle. This is generally placed on the scales, so that the proper weight (24 lbs.) is given, allowance being made for the basket. He then levels the top with his hand, and spreading the paper over and tucking in the edges, places a small portion of brake, short dry grass, or fine straw upon the top, and fastens this with two pieces of wood pointed at each end to fix under the rim of the sieve. After cutting off the ends that protrude beyond the outside of the rim the work is done.

The baskets have a hollow base, so that when set one on the other the fruit is not smashed. The sticks usually used to pack are split hazel of about 2 inches round, or the shoots of the Cob nuts taken out in "wanding" the Nut plantations.

The price of Cherries varies much with the weather and the crop, from 1d. to 8d. per lb. In your district, where possibly Cherries could be delivered direct to the shops, the packing at the top could be avoided by using baskets which fit one on the other, and they would in this way be less bruised, and open, fresh, and inviting.

#### GARDEN CHERRIES.

For pyramids on Mahaleb stock, where they can be netted, Early Rivers, Belle d'Orleans, May Duke, Black Eagle, Governor Wood, Arch-

duke, Nouvelle Royale, Royal Duke, Waterloo, Ronalds' Late Duke, and for tarts, &c., Morello, Kentish Red, Flemish, Olivet. For walls the best are Early Lyons, Early Rivers, May Duke, Governor Wood, Black Eagle, Bigarreau Napoleon, Florence, Bigarreau de Mezel, Black Tartarian, St. Margaret's. Amongst the little known kinds Emperor Francis, Guigne de Winckler, Ludwig's Bigarreau, and Windsor from America we think are destined to become established favourites.

Cherries are in some places very successfully grown up the rafters of cold Peach houses as single cordons, grand examples are thus produced which attain a large size. For this purpose the following are useful, and possibly cordons on the Mahaleb are preferable—Black Eagle, Black Tartarian, Florence, Early Rivers, Bigarreau Napoleon, St. Margaret's would be the best.

### CULTURAL INDUSTRIES IN WEST AFRICA.

OUR possessions on the West Coast of Africa, consisting of the Gambia, Sierra Leone, Gold Coast, and Lagos, occupy, for the most part, narrow strips of country parallel to the seacoast, and extend to no great distance inland, except along the banks of a few of the principal rivers. The circumstances of these possessions and their relations to the natives in possession of the high lands in the interior have hitherto prevented attention being devoted to any agricultural pursuits of a settled character.

Both the European and native communities have so far directed all their energies to the development of trade in such commodities as are brought to them from the interior. These commodities, with the exception of some gold and ivory, are mainly the natural products of the forest, such as have required little at the hand of man except the trouble of collecting and conveying them to the coast. There are, it is true, a few native agricultural industries carried on in a crude manner, such as Ground Nut, Cotton, and the raising of corn, Yams, and vegetables. The value and extent of these would appear at present to be very small. Owing, however, to the depreciation in the value of Ground Nuts, Palm oil, and Palm kernels, which have hitherto formed the staple exports of West Africa, a change is gradually taking place in the sentiments and feelings of the natives, and a desire, wisely fostered by the intelligent policy pursued by the local Governments, is expressed in favour of giving more attention to the systematic cultivation of the soil. Botanical stations have recently been established at Lagos and the Gold Coast for the propagation and experimental cultivation of industrial plants, and, as shown in the *Kew Bulletin*, considerable interest has been taken at Kew in the development of numerous plant products which have been sent to this country from West Africa for valuation and report. The present Governors of our West African possessions are keenly alive to the desirability of directing attention to the development of agricultural industries, and at no time, possibly, in recent years have these possessions received more attention in this country than at present. For this awakened interest we are indebted to Sir Alfred Moloney, Governor of Lagos; Sir W. Brandford Griffith, Governor of the Gold Coast; Sir James Shaw Hay, Governor of Sierra Leone; and Mr. T. Gilbert Carter, Administrator of the Gambia. These officers, it is needless to say, have fully realised the importance of encouraging agricultural enterprises, and taken a leading part in the steps necessary for directing attention to them.

Sir Alfred Moloney published in 1887 a "Sketch of the Forestry of West Africa, with particular reference to its Principal Commercial Products." In this work all available information has been brought together respecting plants yielding oils, gums, rubbers, coffee, cacao, medicinal substances, spices, and many others.

As an additional sign of the times, it may be mentioned that a small work has recently been published in this country by a native of Sierra Leone under the title of a "Manual on the Cultivation and Preparation for Export of some of the Commercial Products indigenous and exotic in Sierra Leone." A youth from the same colony has just carried off a prize at one of our agricultural colleges; and we may add that Governor Moloney has a scheme under consideration for sending some native youths from Lagos to be trained at Jamaica in the culture of economic plants suited for West Africa.

As frequent inquiry is made at Kew in regard to plants likely to flourish in West Africa, the following Memorandum, prepared, in the first instance, for the Royal Niger Company, is now published in an expanded form for the information of those interested in our West African possessions:—

#### MEMORANDUM ON THE EXPERIMENTAL CULTIVATION OF ECONOMIC PLANTS IN WEST AFRICA.

Experimental plantations in West Africa, where systematic cultivation has not yet been carried on, to show what is really suitable to the soil and climate, should include at first a large number of economic plants, for the purpose of testing those which afford the best prospect of being adapted to local circumstances. The reports which have already reached Kew from this region, and especially from the botanical stations at Lagos, the Gold Coast, and the Gambia, show that many useful plants could be grown there. These centres will in time be in a position to select a few of the most promising plants, and distribute them for extended culture in different portions of their respective colonies. Many of the ordinary tropical plants requiring a damp, humid atmosphere all the year round and entire freedom from droughts

are evidently not suited to many parts of West Africa. The prolonged drought experienced during several months of the year, often accompanied by very dry winds, would be fatal to the remunerative culture of such plants.

It is evident, however, that if it were possible to plant large areas with a few select plants, such as Liberian Coffee, fibre plants, Egyptian Cotton, Cardamoms, Ginger, Indigo, Black Pepper, and similar plants yielding raw material in large commercial demand in this country, there would be a fair prospect of the results being eminently satisfactory. The plants mentioned above may be regarded as in many ways suited to the soil and climate of West Africa, and the number could be yearly increased as the results of the cultivation in the experimental plantations are more fully known.

If any of the colonies possess stretches of sandy coast land, it might be taken up for the planting of Cocoa-nut Palms. The Cocoa-nut thrives in deep, sandy soils near the sea, and already the plantations established in various parts of West Africa show that this valuable plant could be grown upon a large scale most successfully and profitably. It is true it takes a long time to come into bearing. On the other hand, the fruit is always in demand, either fresh, made into oil, or prepared in various ways, such as "copra," to suit the markets of the world. Recently an industry has arisen in Germany to prepare a very palatable butter from the kernel of the Cocoa-nut. The process so far is entirely in the hands of a private firm (Messrs. Müller & Sons of Mannheim, Baden), but if the industry is extended, it will undoubtedly increase the demand for fresh nuts in European markets. Cocoa-nut coir, the fibre prepared from the husk of the Cocoa-nut, is an article extensively used for manufacturing purposes in Europe. Coir prepared experimentally at Lagos under the direction of Sir Alfred Moloney was lately valued in London, and proved of good quality. Particulars in regard to the requirements of the London market for Cocoa-nut coir are given in the *Kew Bulletin* for June, 1889, pp. 129-132.

Egyptian Cotton is just now attracting attention. When the staple is long it fetches a high price. It might be tried in West Africa on a large scale, and with this view it would be desirable to obtain seed direct from Egypt. Full information respecting West African Cotton and its value in the English market is given in the *Kew Bulletin* for June last, p. 135.

Coffee of both sorts, Arabian and Liberian, should be cultivated on a large scale in every West African colony. The Liberian Coffee grows freely at almost sea level, while the Arabian Coffee will flourish on any of the hills in the interior. Now Coffee production in the East Indies is so greatly reduced on account of the leaf disease, there is likely to be a large demand for this important food product at remunerative prices. Where any difficulty exists in pulping and curing Coffee it might be shipped to this country in "cracked" state, that is, in a thoroughly dry condition after being directly gathered from the trees. Information on this subject is given in the *Kew Bulletin* for May, 1888, pp. 129-132; and November, 1888, pp. 261-263.

Of fibre plants there are several that are adapted to West Africa. Already the Bowstring Hemp yielded by one or more species of *Sanscevieria* has been successfully prepared at Lagos, and the market value of the fibre has shown it to be of high quality. To establish an industry in Bowstring Hemp it would be necessary to plant at least 200 or 300 acres before steps should be taken to introduce machinery to clean the fibre. The Death Fibre Machine Company, of 147, Leadenhall Street, E.C., might be in a position to supply particulars as to the success of growing Bowstring Hemp in Cuba and also as to the best machines for preparing the fibre.

The Sisal Hemp plant, *Agave rigida*, variety *Sisalana*, could very easily be introduced to West Africa. Small plants in quantity are probably obtainable from Florida. The Sisal Hemp would grow in dry, arid districts unsuited to almost any other plants. If 500 plants were introduced at first, these after two or three years would yield sufficient suckers to establish several acres. The Ramie or China Grass plant may be regarded as unsuited to West African enterprise at present, and it would be useless to devote attention to it unless there is a sufficient supply of labour to work large plantations and suitable machinery is obtainable to decorticate the fibre at a low cost.

Of the Jute class of fibre plants there are two very valuable fibre plants already abundant in West Africa. There are the Bolobolo (*Honckenya ficifolia*), fully discussed in the *Kew Bulletin* for January, 1889, and the Toja (*Urena lobata*). The fibres of these plants are probably worth £18 to £20 per ton, and the price is always likely to be maintained at such a figure as would render a Jute industry remunerative. It might be possible to get the natives to clean these fibres by hand and sell the produce in small lots locally.

Amongst plants usually cultivated in tropical countries and already under experimental trial in some parts of West Africa are the Annatto (*Bixa Orellana*), Cassava (*Manihot Aipi*), Arrowroot (*Maranta Arundinacea*), Vanilla (*Vanilla planifolia*), and Pimento or Allspice (*Pimenta officinalis*). These do not appear to yield remunerative results at present. They are, however, well worthy of attention, and especially if the natives can be induced to grow any of them. Annatto seeds are now sold at prices that cannot pay expenses. It might, however, be a matter for consideration whether the colouring matter could be manufactured into what is known as Annatto roll, cake, or paste. These could be easily prepared as indicated in the *Kew Bulletin* for July, 1888. For paste or cake there is a more steady and satisfactory demand than for seeds. Indigo, as is well known, requires a special system of cultivation and manipulation, and if taken up at all it must be on a

large scale. The Yoruba Indigo yielded by *Lonchocarpus cyanescens*, *Benth.*, is described in the *Kew Bulletin* for November, 1888, p. 268, with a figure of the plant. Yoruba Indigo sent to Kew by Sir Alfred Moloney was valued in 1883 at 4s. to 4s. 6d. per lb. It is possible that this sort might be more successful in West Africa than the ordinary Indigo. The natives are accustomed to the preparation of it, and it is only necessary to eliminate the earthy matter and portions of the stems usually found in Yoruba Indigo to produce samples worth nearly as much as the best Bengal Indigo.

Vanilla and Pimento are valuable spices, but probably not everywhere suited to the soil and climate of West Africa. They might, however, flourish inland where it is damper and moister, and it would be well on this account to keep them under observation and increase the stock in view of future action.

It is a little doubtful whether the Cacao or Chocolate will eventually justify the hopes at present entertained respecting it. Although the plants survive the dry seasons it is possible that they may not ultimately yield remunerative crops. On the other hand, in sheltered valleys inland and in damp localities free from prolonged droughts Cacao should do very well. Next to Coffee, fibres, Egyptian Cotton, and spices, I would regard Cacao or Chocolate as a most promising and reliable industry for West Africa if only the right soil and climate are found for it. Tea may be tried, and also Tobacco, but unless an expert is engaged to grow and prepare the produce there is no hope of establishing a permanent industry to supply European markets with either of these at present.

It may be very well worth while to try and establish the Ceara Rubber (*Manihot Glaziovii*) in West Africa. It has apparently established itself at the Gambia in very poor sandy soil and under very arid conditions. It requires little attention, and yields rubber at an early period. It very much resembles the Cassava plant in habit and requirements, and as the natives already cultivate the latter they would be likely to take very readily to the rubber plant. Seed of the Ceara rubber could be obtained in quantities from Ceylon.

The cultivation of fruits in West Africa might be greatly extended, if only for local demands. Pine Apples, Bananas, Guavas, Oranges, Limes, Mangoes, Bread-fruit, Custard Apple, Avocado Pear, Tamarind, Granadilla, Papaw, Water Melons, are already found growing at or near most of the Settlements. Little or no attention is, however, devoted to their systematic culture, and hence the yield and quality are below what they ought to be. It may be found ultimately practicable to export some of the fruits in a fresh or preserved state to this country. An account of West African fruits and the production of each at Sierra Leone, Gold Coast, and Lagos is given in the *Kew Bulletin* for October, 1888, pp. 221-224.

In reports which have reached Kew from West Africa considerable stress is laid upon the difficulty of keeping plants alive during the dry season. It is evident that a continuous supply of fresh water, easily accessible to nurseries and plantations, is of the highest importance. Water should be abundantly provided by means of small irrigation channels all over plantations in dry districts, with holes or wells here and there to facilitate watering any plants that require it. The saving in labour under such circumstances would be very considerable. Shelter trees should be planted, where they do not already exist, to protect the plantations from winds and to shade such plants as require it from the direct rays of the sun.

There are several species of Figs in West Africa that are admirably adapted to this purpose. Live fences made of such plants as Logwood and the Madras Thorn (*Inga dulcis*) would protect the plantations and afford some relief from dry winds. The Logwood is a tree of great promise for West Africa. Seeds of Logwood could easily be obtained from the West Indies, while seeds of the Madras Thorn might be got from Ceylon or India.

The question of soil should receive the most careful attention. A rich loamy soil of good depth, with good natural drainage and within easy reach of water, is most essential for cultivated areas. There should be considerable time spent over the selection of sites for plantations, and every point should be carefully considered before the site is ultimately settled.—D. MORRIS (in *Kew Bulletin* for September).

### THE LIVING EARTH.

IN connection with the recent Congress at Brighton held by the Sanitary Institute, Dr. G. V. Poore, M.D., F.R.C.P., who is President of section I., presided over the meeting of that section, and delivered an address on "The Living Earth," the substance of which is given in the following paragraphs.

Sanitation in large cities is, at the best, a makeshift, and no high level of health is attainable in a place where the chief object of hygienists seems to be to enable persons to live as densely packed as possible. This prelude is necessary, because the remarks which I am about to make are addressed mainly to persons who live in the country, and who enjoy the luxury of elbow room, and I trust that what I am about to say will make them hesitate before they hastily copy the sanitary methods of the town, and heedlessly begin to foster overcrowding, the bane of all sanitary and social virtue. I say that my remarks are addressed to dwellers in the country, because I have taken for my subject the "Living Earth," a subject which those who live on paving stones, tarred blocks, asphalt, or macadam have to take upon trust. The "Living Earth!" Some of you may ask what I mean by this, and

whether I intend to apply the epithet "living" to the dark coloured inert mould which the countryman sees in the fields and gardens, and the town dweller finds in the flower pot which holds his struggling Geranium? My reply is, "Certainly." We have arrived of late years at a certain knowledge of the fact, that the mould which forms the upper stratum of the ground on which we live is teeming with life, and as this fact seems to me to be one of prime importance to sanitarians, I propose to bring some points in connection therewith before you this morning.

It has long been recognised by agriculturists that the upper stratum of the soil differs from that immediately below it in fertility; and in treatises on gardening (notably in that admirable work written by William Cobbett nearly seventy years since) the warning is invariably given to be careful, in trenching, not to bury the top spit of soil beneath the lower spit, because the top spit is by far the most fertile. The fertility in this case was supposed to be due to prolonged exposure to air, and the lower stratum of soil, if brought to the surface, would only become fertile after a considerable interval. It is interesting to observe that although these early writers were unacquainted with the whole truth they had grasped the most important fact, and their practice was sound. This is often the case, and I feel sure that we act rashly when we hastily abandon the custom of centuries, because some new fact dazzles us and distorts our vision. In connection with William Cobbett I will draw attention to a term which he uses more than once in the work referred to, viz., the fermentation of the soil. I have not found this expression employed by any other writer, but I have made no special search, and my knowledge of agricultural authors is limited. Cobbett tells us that the earth begins to ferment in the spring, and that before sowing a thorough tilling and mixing of the upper strata of the soil is very necessary, with a view not only to the disintegration of the soil, but to a thorough leavening of the whole mass with fermentable matter. There is no doubt that this term "fermentation," as applied to the soil, is perfectly apt, as we shall find further on. The black vegetable mould which lies upon the surface of the earth is largely composed of organic matter, which is not to be wondered at, seeing that every organised thing, whether animal or vegetable, which inhabits this globe falls, when dead, upon the earth, and becomes incorporated with it. Darwin, in his book on "Vegetable Mould and Earthworms," has forcibly drawn attention to the enormous amount of work which worms perform in the aggregate. How they disintegrate the soil. How they riddle it with burrows, which admit air to the deeper recesses of the soil. How their castings, which are incessantly being thrown off, tend to level inequalities, and gradually to bury stones or whatever dead inorganic matter is incapable of solution, digestion, or disintegration. Earthworms are found almost everywhere, and they are probably the most important of the animals which live in the soil; but I need scarcely say that there are many others, and everyone who has a garden must recognise the fact that gardening is only carried out at an enormous sacrifice of animal life, for with every thrust of the spade into rich garden mould a death blow is dealt to many of its inhabitants. The disintegration and aëration of the soil, which is effected by the quiet tillage of the earth-dwellers, is of the greatest importance to the agriculturist, for it is hardly conceivable that the delicate rootlets of plants could grow and extend unless the soil had been softened and pounded by the earthworms and their neighbours.

Although the amount of animal life in the earth is considerable, it is nothing compared with the richness of the soil in the lower forms of vegetable life. The dead and excremental matter becomes the food of saprophytic fungi, which abound in the soil to a very great extent. This must be the case, for we know that saprophytes and their allies abound everywhere, and as the surface of the earth is the common reservoir of all forms of life, it follows that these low vegetable microbes must be more abundant in the earth than elsewhere, and more abundant at the surface than deeper down. In Watson Cheyne's edition of Flügge's work on micro-organisms (New Sydenham Society, 1890), this is very clearly stated: "Enormous numbers of bacteria have always been found in the soil by the most various observers. Infusions made from manured field and garden earth, even though diluted 100 times, still contain thousands of bacteria in every drop, and the ordinary soil of streets and courts also shows the presence of large numbers. Bacilli are present in much the largest numbers; but in the most superficial layers and in moist ground there are also numerous forms of micro-cocci." These micro-organisms of the soil are very active in producing changes in organic matter added to the soil. These changes are usually in the direction of oxidation; occasionally the change is one of reduction. One thing is certain, that if the soil be sterilised by heat or other means it is no longer capable of producing any chemical change in organic matter. This seems to me to be a fact of prime importance to the sanitarian. The oxidation and nitrification of organic matter in the soil is a biological question, pure and simple. It is an effect produced by the living earth; a process analogous to fermentation, which Cobbett seems to have appreciated. Whether the nitrifying process which takes place in the soil is due to one or to many varieties of microbe is doubtful, but the latter supposition is probably correct, and experiments seem rather to point to the conclusion that, given favourable conditions—the free admission of air to a soil which is not unduly moistened—nitrification will go on. Many attempts have been made to isolate a nitrifying organism, and one of the latest, by Professor Percy Frankland and Grace Frankland, the results of which were communicated to the Royal Society in February 1890, appears to have been successful, for these observers isolated a "bacillo-coccus," the power of which in producing nitrification

appears to be most remarkable. Whether this bacillo-coccus is one of many having similar power, or whether it stands alone, is not known; but in any case we must regard it for the present as the "Nitrate King" among microbes. It has been asserted that fungi of a higher class, mould fungi, are also active in producing the disintegration and oxidation of organic matter in the soil. It is possible, however, that the *Bacillus mycoides*, which forms threads closely resembling mycelium, has been mistaken for mould fungus. The *Bacillus mycoides* is one of those which is constantly present, we are told, in garden soil. It has been conclusively shown by Flügge, Koch, and others, that the microbes are most abundant in the superficial layers of the soil, and that they tend to disappear in the deeper layers. They are practically absent in the deeper layers unless the earth has been deeply stirred or trenched, or unless sewer or cesspool has conducted filth to the deeper layers without touching the superficial ones. Numerous filtration experiments on a large and small scale have shown most distinctly that a layer of earth  $\frac{1}{2}$  to 1 metre in thickness is an excellent filter for bacteria, and hence the purification of fluids from bacteria must be still more complete in cultivated, and especially in clay soil, and where the fluid moves with extreme slowness. Further, it has been repeatedly shown that wells which are well protected against contamination with bacteria from the surface and from the sides of the well furnish a water almost entirely free from bacteria; that, further, wells of water containing bacteria become the purer the more water is pumped out, and the more ground water comes in from the deeper layers of the soil.

The vegetable living mould on the surface of the earth is, in short, a filter of the most perfect kind. It is very rich in saprophytic bacteria, whereas the subsoil at a depth varying from 3 to 6 feet is barren of bacteria, as well as of other kinds of life. The subsoil is mineral, inorganic, and dead; the mould upon the surface is organic, and teems with life. Anything which is thrown upon the surface of the ground soon disappears. This is especially the case with water. The absorbing power of soil for water varies according to its mineral constitution. Loose sand and chalk absorb water very readily, and clay less readily; but the absorbing power of vegetable mould, or humus as it has been called, is infinitely greater. Humus is said to be able to absorb from 40 to 60 per cent. of water, and to hold it very tenaciously. This is from two to three times as much as the most porous dead mineral soil is capable of absorbing. We all know that in times of heavy rains it is infinitely rarely that we see water lying in pools on the surface of cultivated soil, whereas it soon collects on roadways and paths, which are made of dead mineral matter. The tenacity with which mould retains water is due to the fact that the water is absorbed into the interior of millions of vegetable cells, and is not merely held by capillary attraction in the interstices between small mineral particles. It is the swelling of individual cells which forms so effectual a barrier to the passage of bacteria. Not only water but everything else when thrown upon the soil disappears sooner or later. Such things as pieces of wood, or leather, about the toughest of organic materials, become softened and permeated by fungoid growth, and finally crumble away. In some parts of the country rags of all kinds are largely used for manure. Through the autumn and winter these may be seen lying on the surface, but when in spring the tilling of the land goes forward, and the fermentation of the soil commences, the coarsest of these rags disappear. If wood, leather and rags disappear, leaves and animal excrement disappear, as we all know, far more readily. The disintegration is forwarded by birds, insects, worms and their allies, until finally by the action of saprophytic fungi these organic matters become fertile "humus," which is the only permanent source of wealth in any country, the source whence we derive all the materials for our food and clothing.

The question whether among the bacteria which are found in the soil some may not be hurtful to mankind is a question of great interest and importance. If disease-causing organisms find their way into the soil may they not multiply, or at least continue to live, and then prove a danger to health? There can be no doubt that pathogenic organisms do exist in the soil, but their power for harm would seem to be practically very small indeed, and to regard the soil as dangerous because some pathogenic organisms may lurk in it would be about as rational as it would be to condemn vegetable food because of the occasional dangers of Hemlock, Aconite, or the deadly Nightshade. The workers of the soil, agricultural labourers and gardeners, are amongst the healthiest classes of the community, and that they are not credited with any diseases which are special to their calling. It seems to be a fact that the great doctrine of the survival of the fittest holds good for microbes in the soil as for all other organised things everywhere, and that organisms which flourish in the human body languish and cease to multiply in the soil where the conditions are unsuited for their multiplication or even for their survival. They get overgrown by saprophytic microbes, and even if they do not die the risk of their finding their way into the ground water is practically nil, for we have seen that humus is the best of filters.

Sanitation is purely an agricultural question, and in the country, where every cottage has, or should have, a patch of garden, there ought to be no difficulty in the daily removal of refuse from the house and in applying it to agricultural purposes, without any risk of contaminating the water supply. Given the patch of garden, the only thing necessary to bring about this, the only complete form of sanitation, is the will to do it—the will, that is, to do a profit to one's self without the possibility of damaging one's neighbour. This, unfortunately, is rarely forthcoming, in spite of the Christian religion and the Education Act, and we go on, even in country places, polluting our streams and wells, with

our minds agitated, as well they may be, as to when our water will become too poisonous to drink, and where we shall turn for a pure supply in the future. Sanitation is a purely agricultural and biological question. It is not an engineering question, and it is not a chemical question, and the more of engineering and chemistry we apply to sanitation the more difficult is the purifying agriculture. This, at least, has been the practical result in this country. The only engineering implements which the cottager with a bit of garden requires for the sanitation are a watering-pot and a spade, and if his garden be an allotment away from the cottage a wheelbarrow may become necessary. The cottager, to whom the produce of his bit of land is a matter of consequence, will endeavour to fertilise as much land as possible with the organic refuse at his disposal, and as long as this endeavour is made there need be no fear of failure, either from the agricultural or sanitary point of view. When, however, an engineer, by means of water under pressure, has collected the organic refuse of a province at one spot, has diluted it a thousandfold, and endeavours to submit it to a mock purification, by means of the least amount of land possible, failure is inevitable, both in the agricultural and sanitary sense. It was in 1848 that the advice to "drain" was tendered with a light heart by the pioneers of modern sanitation, who thought it would be an easy thing to purify the sewage and make a profit from it. The Thames, the Liffey, the Clyde, the Mersey, and the Irwell are a standing testimony to the failure of these great engineering schemes, and I would remind you that the last engineering scheme put forward with regard to the sewage of London—viz., to convey it all to the Essex coast and cast it into the sea—is not only a most lame and impotent conclusion, quite unanticipated by the pioneers of '48, but it is an experiment which, like our previous experiments, may be productive of unforeseen results.

(To be continued.)

## HORTICULTURAL SHOWS.

### ROYAL CALEDONIAN SOCIETY, EDINBURGH.

THE autumn Exhibition of the above Society was held on the 10th and 11th insts. in the Waverley Market, Prince's Street, and was in all respects a good show. Numerous exhibits came from trade growers and others, among which may be noted a group of autumn-flowering Lilies set up by Messrs. T. Methven & Sons, Prince's Street, a table of fair Tuberos Begonias from Messrs. Ireland & Thomson, Prince's Street, and another table of cut greenhouse plants and Carnations from Dickson and Co., Waterloo Place. The latter comprised their new rose variety Maggie Lawrie, W. M. Welsh, bright scarlet, but small as shown, and Caledonia, bright purple. Many groups of cut flowers were shown, Mr. Forbes, Hawick, contributing Phloxes, Pentstemons, Hollyhocks, Violas, and extra fine Tuberos Begonias. Messrs. Dobbie & Son, Rothesay, set up an extra fine group in which their new strain of Violas in bunches, African and French Marigolds, Asters and Dahlias were noticeable. Choice strains of Turnips and White and Red Celery were also shown by this firm.

Mr. Campbell of Gourrock had a stand of Gladioli, and Mr. Campbell, Auchencraigh, in addition to a representative collection of Dahlias, Carnations, and Picotees, showed a new white Carnation, Mrs. Muir, in plants, wreaths, and crosses. A most interesting collection of hardy flowers was admirably staged by Messrs. Cocker & Sons, Aberdeen, who, in addition, had some stands of the very best Canations and Picotees in the Show, and a stand of Tea Roses in bunches, which furnished conclusive proof of the hardiness of these beautiful flowers. Fine border and Clove Carnations were contributed by Messrs. Laing & Mather, Kelso, a novelty in their arrangement being a miniature flower garden furnished with Carnations. Messrs. Lamont & Son, Musselburgh, staged some fine single Dahlias, of which they apparently make a specialty with much success. Ferns were contributed in beautiful order and in the greatest variety by Messrs. Birkenhead of Sale, Manchester. This was an exhibit of much value, bringing before the gardening public as it did all the best forms of this interesting family. Some noteworthy examples of high culture in vegetables, flowers, and fruit were brought together in a large stand belonging to Messrs. A. Cross & Son, 19, Hope Street, Glasgow. These were intended to illustrate the qualities of a manure they are producing for horticultural purposes. Specially fine Onions, comprising Cocoa Nut, Ailsa Craig, Anglo-Spanish, Rousham Park, and others, were contributed by Mr. J. Wilkins, Inwood House, Blandford.

Of the Show proper the cut flowers and fruit nearly equally divided the interest of the visitors. The former are year by year assuming a position of greater importance in the northern capital, and a little more money judiciously spent by the Society would give an increased impetus. Of the latter, Grapes and Apples were represented in the greatest numbers. Pears were also well shown, but Peaches, Nectarines, Piums, and small fruits were not numerous.

Taking the collections of fruit first, five were staged for the prizes offered for twelve dishes, Mr. McKinnon, Melville Castle Gardens, Lasswade, securing first place with extra good Grapes, comprising three excellent bunches of Alicante, two of good Muscat of Alexandria, extra Gros Maroc, and fair Black Hamburg. Fine Souvenir du Congrès Pears, Kirke's Plums, and Gascoigne's Scarlet Apples were the most noteworthy of the other dishes. The second place was secured by Mr. McIndoe, Hutton Hall Gardens, Yorks, with Gros Maroc, Gros Guillaume, and Alnwick Seedling Grapes, fine Pitmaston Duchess Pears, and good Exquisite Peaches. Among other dishes Mr. Hunter, Lambton

Castle Gardens, Durham, was third. Seven competed in the class for eight dishes, Mr. McIndoe being first with a Pine Apple, white and black Grapes, fine Pears, Duke Constantine Apples, Peaches, Nectarines, and Plums. Mr. McKelvie, Broxmouth Park, Dunbar, was second, and Mr. Murray, Culzean Castle, Ayr, third. The collection of twelve sorts hardy fruits brought six competitors, Mr. Day, gardener to S. Massey, Esq., Galloway House, being first, fine Castle Kennedy Figs, good Bon Chrétien Pears and Peaches being the chief dishes. Mr. Murray, Ahercairn, was second and Mr. Dow Newhyth, Prestonkirk, third. For twelve dishes orchard house fruit Mr. McIndoe had the first place, very fine being Peasgood's Nonesuch and Alexander Apples, Clapp's Favourite Pear, Lemons, and Peaches. Mr. Hunter was second and Mr. McKinnon third.

The Grape classes were well filled, though the general quality was perhaps below that of late years. For six bunches Mr. McHattie, gardener to the Marquis of Lothian, Newhattle, Dalkeith, secured first place with extra fine Muscat of Alexandria, good Lady Downe's and Black Hamburg, all large and well finished clusters; Mr. Murray, Polmont, second with large examples of Alnwick Seedling and Muscat of Alexandria; Mr. Murray, Culzean, third. In the four-bunch class Mr. McKinnon was first with extra good Gros Maroc and Alicante, good Muscat of Alexandria and Mrs. Pince; Mr. Kirk, Norwood, Alloa, second with extra fine Gros Colman, Gros Maroc and Alicante, and Mr. D. Murray third. Mr. McHattie secured the first prizes for two bunches of Muscat of Alexandria and two of Black Hamburg, with in each case extra fine examples. Mr. Day being second for the former, and Mr. S. Paterson, Langholm, second for the latter. In the classes for single bunches Mr. W. G. Pirie, Sunderland House, Selkirk, had the finest Muscat of Alexandria, and Mr. Leslie, Pitcullen House, Perth, second. Mr. Kirk in a good class secured first for Black Hamburg, Mr. Watson, Stirling, second, each with fine examples. The best Alicante was set up by Mr. McKinnon. Mr. Caldwell, Langholm, was second. A good example of Alnwick Seedling from Mr. Murray, Polmont, secured first for this Grape; Mr. Bell, Alnwick, being second. Mr. Kirk secured first for Gros Colman with a beautifully finished cluster, and Mr. W. Murray second. For Lady Downe's Mr. Caldwell was doubtfully first, Mr. W. Murray second with what appeared to be a better bunch. Mr. Day had the best Gros Maroc in any variety class, and Mr. McKinnon with fine Golden Hamburg had first in the corresponding class for white Grapes. Mr. McIndoe had the best flavoured black Grapes and Mr. McKelvie the best flavoured white, the bunch with finest bloom being from Mr. Day.

Mr. McIndoe secured first prizes for one Queen Pine Apple, one Smooth Cayenne, and for two Pine Apples; Mr. Kirk second for the Queen, and Mr. Ramsay third. Figs were poor, as also Peaches and Nectarines; a fine dish of Salwey Peach being the noteworthy exception. Plums were generally good, the best collection coming from Mr. McIndoe, and comprising fine examples of Magnum Bonum (white), Jefferson, Bryanston Gage, Pond's, Kirke's, Monarch, Belgian Purple, and Prince Englebert; Mr. Hunter second. Pears were fairly numerous, but generally small. Mr. Day had the best six varieties; Mr. Henderson, Hafield, second; and Mr. D. Murray third.

Mr. D. Murray secured first place for collection of twelve sorts Apples; Mr. Brotherston, Tynningame, Prestonkirk, second; and Mr. Cocks, Spalding, third. Many of the newer varieties were represented in these and the other collections shown. In the single dishes the competition was very good, fine dishes of Warner's King, Ecklinville Seedling, Stirling Castle, Ribston Pippin, and Lord Suffield being numerous and noticeable.

Of plants the chief items in the schedule were the groups or tables, one for nurserymen the other for gardeners. The former were represented by Messrs. R. B. Laird & Son, Pinkhill, Corstorphine, who set up a hold oval group, the conspicuous feature being some grand plants of Madame Desgrange Chrysanthemums with large blooms. Good Palms, Crotons, and other decorative plants were used with good effect, and the first prize was secured with this; Messrs. Ireland & Thomson were second. In the gardeners' classes two competitors also staged, Mr. Grossart, gardener to J. Buchanan, Esq., Oswald Road, being first with a bright table; and Mr. McIntyre, Darlington, second with a group much too carelessly arranged, the plants being remarkable for high-class cultivation. Stove and greenhouse plants were not numerous but good; for six in flower Mr. Morris, Newcastle, and Mr. Patterson, Millbank, having a sharp contest, but the former had to give way to the veteran Scottish plant grower. Mr. Crichton, Liberton, had the best three flowering plants; and Mr. Patterson and Mr. Morris were again first and second for one plant respectively. For three and for one Cape Heath Mr. Patterson was also successful in securing first prizes. Mr. Tindley, 14, Osborne Terrace, had the best four Orchids, of which a good Vanda tricolor and a V. suavis were the best plants; Mr. Currer, Eskbank, was second; and Mr. Grossart third. For two Orchids Mr. Patterson was first; and for one Orchid Mr. Grossart.

The Fern classes brought out some grand examples, the first prize six from Mr. Niel Fraser, Murrayfield, being particularly good, and comprising a grand example of *Goniophlebium appendiculatum*, *G. glaucophyllum*, *Phlebodium aureum*, *Davallia dissecta*, *Gymnogramma laucheana*, and *Microlepia hirta cristata*. Mr. Grossart was a good second, and Mr. Crichton third. Mr. Fraser had also the best four Adiantums, while Mr. Patterson secured first with three *Gleichenias*. The first prize for Filmy and for hardy Ferns was also secured by Mr. Fraser, and that for the best Tree Fern by Mr. Laing. For the various class of foliage plants there was good competition, Mr. McIntyre,

Darlington, being first for four foliage and two Crotons. Mr. J. Patterson had the best Caladiums and six Palms, Mr. Grossart the best four and single Palm, and Mr. Cummins the best three *Dracenas*. In the trade classes Messrs. R. B. Laird & Sons were first for Palms, foliage plants, and Chrysanthemums, and Messrs. Dickson & Sons, Hanover Street, had the best collection of Conifers.

Of cut flowers there was a very good display, the competition in many cases being extremely keen. Of Gladioli there were over a dozen stands, Messrs. Stuart & Mein, Kelso, being the only exhibitors in the trade class for thirty spikes, and received the first prize. In the gardeners' class for twelve spikes eight stands were forward, Mr. Whitelaw, Brechin, being first, Mr. Brotherston second, and Mr. Braydon, Innerleithen, third. Mr. Smith, Prestwick, Ayr, also showed well. In the six class were five stands Mr. Cockburn, Tynningame, being first, Mr. Dickson, Glenormister, second, and Mr. Veitch, Carlisle, third. Grand examples were shown in the various stands of the following sorts:—Grand Rouge, Bicolore, La Vesuve, Enchantresse, De Mirhel, Marie Mies, Archduchess, M. Christine, Beatrix, Baroness Burdett-Coutts, Dalila, Amitié, Horace Vernet, Crépuscule, Arrière-Garde, and Meyerbeer. Dahlias were a striking show, most admirably grown examples being staged, Mr. Walker being first for twenty-four Show, and Mr. Campbell, Auchincraigh, second; and Mr. Campbell first for twelve Fancy varieties, and Messrs. R. B. Laird & Sons second. In the gardeners' class for twenty-four varieties Mr. Spoor, Gateshead, Newcastle, was first, and Mr. Pearson, Beechwood, second; and for twelve hlooms Mr. Spoor was again first, and Mr. Veitch, Carlisle, second, grand examples of W. Rawlings, R. J. Rawlins, Earl of Ravensworth, Mrs. Gladstone, Crimson King, Clara, Champion Rollo, Peacock, H. Keith, Mrs. Langtry, and Willie Garrett were very noteworthy. Messrs. Lamont & Sons, Musselburgh, had the best single Dahlias. R. B. Laird & Sons were second, and Mr. Walker, Gateshead, third. Roses again were especially fine, and in the nurserymen's classes Messrs. Cocker & Sons, Aherdeen, easily took first in each class—viz., for thirty-six, eighteen, and twelve. Messrs. Smith, Stranraer, and Hugh Dickson, Belfast, were the other successful growers, Messrs. Croll, Dundee, showing fine Tea Roses. Especially fine were Her Majesty Mrs. J. Laing, White Lady, Charles Lefebvre, Senateur Vaisse, Ulrich Brunner, Marshall P. Wilder, Merveille de Lyon, and Eugène Verdier. In gardeners' section Mr. Ramage, Wallhouse, was first for twenty-four; Mr. Wallace, Rothesay, second, and Mr. Parlane, Roselea, third; Mr. Archibald, Broughty Ferry, being first for twelve varieties and also for twelve Tea Roses. There was strong competition for Carnations and Picotees, but the blooms were mostly small. Madame Desgrange Chrysanthemums in white and yellow were excellently shown, Mr. Rushton, Corstorphine, taking first with a grand dozen. Hardy flowers were largely shown, but there was nothing noteworthy among them. Annuals were good. Bouquets, buttonholes, sprays, &c., were also well shown and very pretty.

Vegetables were, of course, good, but not so large a competition as last year, the collections being less numerous. The first prize for twelve dishes went to Mr. Richardson, Perth; second to Mr. S. Bigham, Edgerton; third to Mr. Johnston, Hawick. Mr. P. Robertson, Hartrigge, Jedburgh, had the best six dishes; Mr. Hall, Kelso, second, and Mr. Ormiston, Jedburgh, third. Celery, Leeks, Onions, Peas, and Cauliflowers were the outstanding dishes of greatest merit. In the classes for different vegetables grand Leeks, Celery, Onions, Lettuces, Cauliflowers, Peas, Tomatoes, and Parsnips were very noteworthy. There was also a fair display of honey. The weather was of the finest, and the Show well patronised both days.

#### MANCHESTER BOTANICAL AND HORTICULTURAL SOCIETY. SEPTEMBER 12TH AND 13TH.

THE usual Exhibition of fruit and flowers took place in the Botanical Gardens on the above dates, and, favoured by beautiful weather, there was a large attendance. It was an exceedingly good Show throughout, and the contest in the class for eight bunches of Grapes, added to the superb culinary and dessert Apples shown by Mr. Samuel Barlow, J.P., were the most striking features. The grand Roses shown from Bedale were remarkably good for the season of the year, and the names of the varieties shown may be taken as representing some good autumnal bloomers.

*Grapes.*—The great point of interest in the Exhibition was the class for the best collection of eight bunches of Grapes in four kinds, the handsome first prize of fifteen guineas being given by Messrs. Thomson and Sons, Clovenfords. There were eleven competitors, and the Judges were occupied nearly an hour in making the awards. Eventually Mr. Taylor, gardener to Mr. Alderman Chaffin, Bath, was placed first with two bunches each of Muscat of Alexandria, Madresfield Court, Black Hamburg, and Alnwick Seedling. Second, Mr. W. Allan, gardener to the Earl of Suffield, Gunton Park, Norwich, who had two bunches each of Duke of Buccleuch, Alnwick Seedling, Alicante, and Gros Maroc. Equal third Mr. McHattie, gardener to the Marquis of Lothian, Dalkeith, who had three bunches of Muscat of Alexandria, two of Lady Downe's, two of Black Hamburg, and one of Madresfield Court; and equal third Mr. Goodacre, gardener to the Earl of Harrington, Elvaston, Derby, who had, like Mr. McHattie, three bunches of Muscat of Alexandria, two of Alicante, two of Madresfield Court, and one of Muscat Hamburg. The judgment in this class was much criticised, and some thought Mr. McHattie ought to have been placed first. We think—having regarded that his bunches were much too crowded and the majority of the berries small, Lady Downe's particularly so—that he was in his proper place, and that Mr. Allan's collection ran that of

Mr. Alderman Chaffin very close. What weakened the collection of the former was the fact that he had no representative of our three high class Grapes—Muscat of Alexandria, Black Hamburgh, and Madresfield Court. His two bunches of Duke of Buccleuch were very fine in bunch and berry, but yet lacking colour; his Alicantes were very fine in bunch; his Alnwick Seedling superb. Still, the collection lacked high class quality as far as the dessert table is concerned. The best two bunches of any black Grape were finely finished Black Hamburgh from Mr. McHattie, though small in berry. Mr. F. H. Gossage, Woolton, Liverpool, was second with Madresfield Court, and R. H. C. Nevill, Esq., Grantham, third with Alicante. The best two bunches of any white Grape were Muscat of Alexandria, finely finished, from Mr. Alderman Chaffin, W. B. Davenport, Esq., coming second with the same, and Mr. McHattie third.

Collections of fruit in eight dishes came from four exhibitors. The best from Mr. Goodacre, who had fine Muscat of Alexandria and Gros Maroc Grapes, Barrington Peaches, Victoria Nectarines, Ischia Figs, Powell's Late Apricot, a good Queen Pine, and Read's Scarlet-fleshed Melon. Mr. Wallis, gardener to the Rev. W. Sneyd, Keele Hall, Staffs, was second with the same varieties of Grapes, very fine Sea Eagle Peaches, Pitmaston Orange Nectarines, Moor Park Apricots, Transparent Gage Plums, white Ischia Fig, and Queen Pine. Third, Mr. Dawes, gardener to the Hon. Mrs. Meynell-Ingram, Temple Newsam.

The best dish of eight Peaches was that of Barrington, very fine indeed, from Mr. Wallis; Mr. George Meakin, Stafford, coming second with fine Royal George. The best dish of Nectarines was that from Mr. Lambert, gardener to Colonel Wingfield, Shrewsbury; Mr. Goodacre was second with Violette Hâtive; and Mr. W. Brocklehurst, Macclesfield, third with Pineapple. The finest fruit of a Pine was a Queen from Colonel Dixon, Astle Park, Chelford; R. H. C. Nevill, Esq., Grantham, with the same; the third prize going to a well coloured Charlotte Rothschild from Mr. Dawes. The best flowered scarlet-fleshed Melon was Read's from Mr. Goodacre; Miss Lord, Ashton-on-Mersey, coming second with a scarlet seedling. The best white flesh was Hero of Lockinge from Mr. Goodacre; Mr. Hunter, Lambton Castle Gardens, coming second with Best of All. Mr. Allan brought from Gunton the best dish of Plums, having fine Pond's Seeding; Mr. Hunter coming second with Magnum Bonum; and Mr. Wallis third with Kirke's.

The best three dishes of Pears grown under glass came from Lambton Castle, and consisted of very fine Beurré Diel, Pitmaston Duchess, and Souvenir de Congrès. Second, Mr. Goodacre, with very good Beurré Superfin, Doyenné du Comice, and Souvenir de Congrès. Mr. Samuel Barlow, J.P., Stakehill House, Manchester, came third with very finely coloured Doyenné Boussoch, unfortunately overripe, very fine Louise Bonne de Jersey, and Pitmaston Duchess. The best three varieties grown in the open air were Beurré de l'Assomption, Bon Chrétien, and Brockworth Park, fine—Mr. R. H. C. Nevill. Mr. Allan was second with Marie Louise d'Uccle, Durondeau, and Doyenné Boussoch. Third, Mr. Samuel Barlow, with fine Windsor, Pitmaston Duchess, and Beurré Diel.

There were eight collections of twelve dishes of culinary Apples, and Mr. Samuel Barlow was first with some very fine examples grown in his garden at Shimala Hir, Llandudno, and only just inferior, if indeed that, to the superb collection shown by Messrs. G. Bunyard & Co. of Maidstone at the Crystal Palace the previous week. They consisted of Gloria Mundi, very fine indeed; Frogmore Prolific, Peasgood's Nonesuch, very fine; Cat's Head, Potts' Seedling, New Hawthornden, Stirling Castle, Gravenstein, very fine in colour, and of good size; Golden Noble, Cox's Pomona, Blenheim Orange, and The Queen, very fine. Second, Mr. T. W. Baker, Gorrddinog, Llanfairfechan, with very fine Peasgood's Nonesuch, Mère de Ménage, Lord Suffield, Lady Henniker, Warner's King, Grenadier, Blenheim Orange, &c. Mr. C. L. Campbell, Ross, with a very good lot indeed, that appeared to deserve the second prize, but the Judges no doubt had good reasons for preferring the other collection. With eight dishes of dessert Apples Mr. Barlow was again first with superior examples of Margil, Washington, Herefordshire Beaufin, Worcester Pearmain, Ribston Pippin, very fine; Fearn's Pippin, very fine; and Duchess of Oldenburg. Second, Mr. C. L. Campbell, with Pineapple Russet; Worcester Pearmain, very fine; King of Pippins, Cellini, White Transparent, &c. Third, Mr. R. H. C. Nevill. Cherries were represented by Morellos. Mr. Goodacre was first with very fine fruit indeed. Mr. Lambert took the second prize.

Collections of vegetables in twelve varieties were a very fine feature. Mr. Lambert was first with a remarkably good collection, consisting of Autumn Giant Cauliflower, Major Clark's Celery, Perfection Tomato, Ailsa Craig Onion, very perfect Snowball Turnip, Lockie's Perfection Cucumber, Ne Plus Ultra Runner Bean, &c. Second, Colonel Cornwallis West (Mr. P. Ruthin), with a very fine lot also. Mr. Jas. Watt, Cheadle, was third. The best Tomatoes were all of the Perfection type, large and well coloured fruit. Mr. Jas. Mason, Manchester, was first, and Mr. J. F. Campbell, Uttoxeter, second. Cucumbers were represented by Lockie's Perfection. Here Mr. J. Mason was again first, and Mr. J. Grant Morris, Liverpool, second.

Cut flowers were represented by Dahlias, Roses, Gladioli, &c. The best twenty-four Dahlias came from Mr. W. Walker, Newcastle-on-Tyne. Mr. Thos. Painter, Stoke-upon-Trent, was second; and Mr. C. Hockney, Stokesley, third. The northern cultivators for exhibition appear to cut their flowers too far advanced, and in making the awards the Judges have to discriminate not so much as between the best, but the worst. Open centres are a common fault, and deficient backs. Mr. Painter

certainly had the largest and boldest looking flowers, but on close inspection many of them were found to be defective.

Collections of hardy cut flowers, unlimited in extent, made a very fine display, and Messrs. Harkness & Son, nurserymen, Bedale, were placed first with a superb collection of fifty-four large bunches, generally of fine quality, consisting of *Lilium trigynum splendens*, very fine *Tigridia pavonia*, *conchiflora* and *alba*; *Scabiosa caucasica*, brilliantly coloured; *Gladiolus* in variety, especially Lemoine's hybrids; fine Phloxes, Iceland Poppies in variety, *Tritoma Uvaria*, single and double Pyrethrums. Second Messrs. Dicksons (Limited), Chester, with a large and very interesting collection, comprising various Montbretias, Tritonias, Tritomas, Gladioli, Lilies, hybrid Gladioli, *Colchicum speciosus*, *Papaver bracteatum*, &c. Third Mr. Samuel Barlow, who had several very fine and striking varieties of Lemoine's Gladioli, Carnations and Picotees, Asters, Pansies, &c. Collections of cut Roses were a very fine feature also, and Messrs. Harkness & Sons were first here also with a superb collection for the season of the year, including a box of twenty-four blooms of H.P. Mrs. John Laing of great beauty, also fine blooms of The Bride, Madame Alphonse Lavallée, Duc de Rohan, Dr. Andry, Madame Chas. Crapelet, Beauty of Waltham, Countess of Oxford, Star of Waltham, Marie Verdier, Général Jacqueminot, Alfred Colomb, Crown Prince, &c. Second Messrs. Dicksons (Limited) with a very good collection also. The best collection shown by amateurs came from Dr. S. P. Budd, Bath, who had very fine blooms of Duchess of Bedford, Jean Ducher, Comte de Raimbaud, Madame Cusin (finely coloured), M. P. Wilder, Charles Lefebvre, Fisher Holmes, Madame Lambard, Louis Van Houtte, Victor Hugo, Francisca Kruger, Grand Mogul, &c. Second Mr. A. Whitton, Bedale. Third Mr. Samuel Barlow.

The best collection of forty-eight spikes of Gladioli came from Mr. Smith, Prestwick, Ayr, which contained some very fine spikes, but none named. Mr. S. Barlow was second with a good collection also, but unnamed. The best collection of twenty-four spikes was shown by Mr. A. Whitton, this included fine examples of Baroness Burdett Coutts, Orphir, Ondine, Gigantea, Le Phare, Horace, Grande Rouge, &c. Second Mr. S. Barlow. Third Mr. R. G. Burgess, Knutsford. Mr. A. Whitton had the best collection of cut blooms in bunches of early flowering Chrysanthemums, fine plants growing in the open; and Mr. Samuel Barlow was second. Both staged about fifty bunches, but unnamed, still the collections were of a very interesting character.

Show and Fancy Pansies in twelves came from several growers; a stand of twelve of the former from Mr. Thomas Fitton, Castleton, were very correct, and Messrs. Harkness & Son were second; the latter had the best twelve Fancy Pansies, Mr. R. G. Burgess was second. Collections of stove and greenhouse cut flowers were a very attractive feature. Mr. F. H. Gossage was placed first with a very fine and varied collection, including *Eucharis amazonica*, *Miltonia vexillarium*, *Bougainvillea glabra*, *Anthurium Andreanum*, *Allamanda grandiflora* and *nobilis*, *Lapageria rosea* and *alba*, *Vallota purpurea*, *Lycaste cruenta*. Second, Mr. Thomas Barnes, Chirk, with a fine lot also, and unlike the foregoing, shown in handsome bunches; it included *Allamanda nobilis*, *Hendersoni* and *grandiflora*, *Ixora Williamsi*, *Erica Marnockiana*, *Stephanotis grandiflora*, *Billbergia rhodocyanea*, *Dipladenia Brearleyana*, &c. Third, Miss Lord, Ashton-on-Mersey. The best collection of Orchids came from Mr. P. Blair, gardener to His Grace the Duke of Sutherland, Trentham, a very fine lot unnamed, but consisting of *Cattleyas*, *Miltonias*, *Vandas*, *Odontoglossums*, *Cypripediums*, *Laelias*, *Calanthes*, *Oncidiums*, *Masdevallias*, &c. Second, Mr. Thomas Statter, Stand, Whitefields, Manchester, with an excellent collection of similar character.

Messrs. Perkins & Sons, Coventry, had the best two bouquets, Mr. P. Blair being second. Messrs. Perkins & Sons also had the best two bouquets of Roses. Miss Lord was second. It may be remarked that the bouquets became the property of the Council, who sent them to the hospitals. The best stand for the dinner table came from Miss Lord. Mr. J. Brown of Heaton Mersey was second.

Among miscellaneous contributions was a large and interesting collection of culinary and dessert Apples from Messrs. Dickson, Brown, and Tait, seed merchants of Manchester, which included fine examples of Warner's King, Lord Suffield, Emperor Alexander, extra fine; Manks Codlin, Stirling Castle, Ringer, Potts' Seedling, Lord Grosvenor, Ecklinville Seedling, Keswick Codlin, Peasgood's Nonesuch, Lord Clyde, Dumelow's Seedling, a pretty soft early Apple named Grand Sultan, &c., together with a large collection also of Dahlias, Gladioli, African Marigolds, hardy flowers of various kinds, some fine Potatoes, a bloom of a finely marked *Lilium auratum rubro-vittatum*, &c. From Messrs. W. G. Caldwell & Son, nurserymen, Knutsford, cut Dahlias of various types. From Mr. John Robson, nurseryman, Altrincham, several boxes of cut blooms of Pompon, single, and Cactus Dahlias. From Messrs. Dickson & Robinson, seedsmen, Manchester, came Gladiolus, Dahlias, Roses, Marigolds French and African, hardy cut flowers, Tomatoes, &c. From Mr. A. J. Bruce, Sale, came a collection of Palms, Ferns, and Zonal Pelargoniums. From Messrs. Clibran & Son, nurserymen, Altrincham, a very fine strain of cut blooms of Tuberos-rooted Begonias, hardy flowers, and various insecticides. From Mr. R. H. Poynter, seedsmen, Taunton, spikes of Gladioli. From Messrs. Ryder and Son, nurserymen, Sale, a large assortment of single, bouquet, and decorative Dahlias in bunches, and cut blooms of the beautiful white Mignon Aster, awarded a first class certificate of merit for its purity and superb finish.

A first-class commendation was awarded to Mr. T. Statter, Stand Hall, Manchester, for a fine bunch each of Muscat of Alexandria and

Madresfield Court Grapes. A white seedling Show Dahlia, named Ivory White, from W. R. Shakeshaft, Lymm, of a promising character was commended. A semi-double brilliant scarlet Dahlia, named John Burn, from Messrs. Harkness & Son, nurserymen, Bedale, was highly commended as a decorative border variety.

M. W. D. Bason, Town Wills Fold, Wolverhampton, exhibited his new Milltrack Mushroom spawn, which has acquired a great reputation in the north and midland districts, and Messrs. Dickson, Brown, and Tait McDougall's Self-acting Tobacco Sheets, which consist of cellulose saturated with tobacco extract of standard strength, and so prepared that they will fume or smoulder when a lighted match is applied.

#### CHIPPENHAM.

THIS Show was held recently in the beautiful grounds of Hardenhuish Park. The chief features were not so much the exhibits of nurserymen and professional gardeners, of which, however, there was a very fair display, as the unusual excellence of the cottagers' exhibits, which were displayed in a large tent quite distinct from the rest, a provision which afforded a pleasing contrast to that of many shows where the cottagers' productions are too often to be seen either exposed to the full glare and shrivelling influence of the sun without any protection whatever, or crowded together under a tree in some out-of-the-way place, where the visitors cannot see them properly.

This tent was not only well filled with vegetables, fruit, plants, and cut flowers, but each exhibit was so much above the general average of cottagers' productions that to me, who am not accustomed to cottagers' shows, it was an agreeable surprise. Not only did the exhibits consist of the best kinds, but they were set up in a trim and businesslike manner, plainly showing great care and deep interest on the part of the exhibitors. The fruit—which with cottagers generally means a few dishes of Apples, Gooseberries, and Currants—was here represented by really good collections and single dishes, comprising Apricots, Cherries, Green Gages, Pears, Melons, and Grapes, in addition to the commoner kinds. The plants were also very creditable, showing such health and vigour as is seldom seen amongst cottagers' exhibits. As to the cut flowers, which consisted chiefly of Asters, Dahlias, Marigolds, Roses, Stocks, and Zinnias, they were exceptionally fine, the Zinnias and Marigolds being unusually large, perfect in shape, and most brilliant in colour. I was so favourably impressed with these exhibits as to be induced to inquire what were the special causes which contributed to such good results, and I found that one of the causes was undoubtedly the capital list of prizes offered for competition, also the excellent provision made for the exhibits, and to the careful consideration shown by the Committee. There was to be seen amongst the exhibitors a keen spirit of rivalry and a businesslike professional method seldom witnessed amongst cottagers.

I was also informed that the most successful had now invested not only in glass frames, but also in miniature greenhouses, and the possession of these of course accounted for the presence of such flowers as *Lapageria alba*, Lilliums, and other uncommon flowers in some of their bouquets. One other cause, I was informed, contributed in no small degree to their success—viz., the general adoption and utility of the earth closet system in the district, also the care exercised in saving and judiciously utilising the household slops and refuse, which are too often thrown away as worthless. The earth closet is so simple and economical in construction, and its contents are so valuable in the garden, that the only wonder, in this sanitary age, is that it is not more generally and more freely provided, especially where in those towns and villages which, from their flat position, or other causes, good drainage is almost impracticable; and also, because in numerous cases the cottager, for sanitary reasons, is now prevented keeping that most liberal manure producer, and most useful animal, the pig. Whether or not the cottagers of the Chippenham district would, if asked, attribute their proficiency in horticulture chiefly to the judicious use of the contents of the earth closet, would be interesting to know.

The Chinese, who are clever and very successful gardeners, are great believers in this system, and depend largely upon it for the supply of manure used in their gardens; indeed, so much do they value it, that it is said they look more favourably on the visitor who makes a discreet use of it before he takes his departure.

Some persons say that to adopt this system would be taking a backward and insanitary step, but the former objection is not a forcible argument against its use, because, as time passes, we do occasionally find such a step advantageous, even in horticulture; and as to the latter objection, it can only apply when the system is improperly or indifferently carried out. Whether or not the proficiency of the cottagers of the Chippenham district be chiefly due to this cause, or to any other yet unexplained, I beg to congratulate them on the best all-round cottagers' show I have seen this season.—T. CHALLIS.

GLOBE ARTICHOKE.—These have been plentiful, but most of them are now over. There are some more forming, and if properly treated these may be useful in October or probably in November. In cutting the heads they are generally taken off at the top of the stem, and the stumps are allowed to remain full length. The whole of these should be cut over close to the ground, all decayed leaves being removed at the same time, and the young heads will soon show how much they have benefited by it.—M.

#### FRUIT FORCING.

PEACHES AND NECTARINES.—*Houses to be Started at the New Year.*—The trees will be shedding some of the leaves, but they must not have them brushed off with a broom as sometimes occurs to save trouble in clearing up the leaves as they fall naturally, which they must be allowed to do. If the trees are weakly from continued forcing and continued full crops of fruit, they may have, the border being properly drained, a good supply of liquid manure, which will assist the trees in keeping the buds, and to some extent invigorate them by inducing root action and a good start at the proper time. If, on the other hand, the trees do not set and stone the fruit satisfactorily, they should be lifted. This must be done carefully, preserving all the roots practicable, and keeping them as much as possible from the drying influence of the atmosphere. The drainage must be seen to, and if necessary rectified, putting in fresh drains, which, to be of use, must have proper fall and outlet, and providing clean rubble for drainage, with sweet soil for planting in. If a thorough renovation of the border has to be made the lifting must not be attempted until most of the leaves have fallen, as it will necessitate the trees being kept out of the soil some time; but they should have their roots damped and covered with moist mats, and the trees should be shaded and occasionally sprinkled with water from a syringe. Cut away any long bare roots, and shorten back or pare the ends smooth of those damaged in lifting to sound parts, laying them in the fresh compost evenly, with soil worked into their interstices, keeping them well up to the surface and making it firm. It is no use attempting to grow Peaches and Nectarines in loose soil; firm wood is the outcome of firm soil, and fruitfulness resultant of aliment steadily furnished for elaboration and storing in the fruit, wood, and buds for future crops. Afford a good watering after lifting, and when settled mulch with a few inches thickness of rather short stable manure. The trees being sprinkled occasionally for a few days will keep sound in the wood, and roots will be pushed more or less into the fresh soil, which usually is a great incitor of root action. The most unsatisfactory trees carefully lifted and replanted in properly drained borders of suitable material never fail to fruit satisfactorily under proper management in light and well ventilated structures.

*Lifting in Succession Houses.*—When the growth is too free, the crops not being satisfactory, the trees should be root-pruned or lifted as soon as the foliage shows indications of falling. If judiciously performed this will check their vigour and induce short-jointed fruitful wood. Any lifting or root-pruning should be performed before the leaves fall, affording a good watering afterwards, mulching with a couple of inches thickness of short manure, and syringing the trees each evening for a few days. The trees will soon produce young active feeders.

*Late Houses.*—The weather is all that could be desired to insure the perfect finish of those very fine varieties—Barrington, Princess of Wales, Sea Eagle, the finest of all late Peaches; Gladstone, Walburton Admirable, Nectarine Peach, Lady Palmerston, and Comet. These are unsurpassed in appearance by any of the early and midseason varieties, and properly fed and duly ventilated they are juicy and full-flavoured. They are now ripening the fruit in houses that have been freely ventilated, well watered at the roots through a mulching of lumpy manure, and the foliage kept clean and healthy by forcible syringings. The trees should now have the benefit of a free circulation of air, utilising sun heat by keeping the ventilators closer than usual, as with ventilation in the early part of the day the temperature may be allowed to run up to 80° or 85°, which will do more to ripen the fruit and wood than sharp firing in dull weather. A somewhat drier condition at the roots is desirable when the fruit is ripening, but they must not be allowed to suffer from want of water so as to affect the foliage, and though the trees are not to be syringed, an occasional damping of the floors will greatly tend to keep the foliage in health. In dull wet weather a gentle warmth in the pipes will be serviceable in securing a genial warmth and allowing of a circulation of air.

*Unheated Houses.*—The late varieties before mentioned ripen perfectly in these structures when they are given a good aspect and the climate is not unfavourable or the location high and cold. Means of affording warmth in spring to insure a good set, and in autumn to perfect the fruit and mature the wood, are necessities in cold damp late situations to have the late Peaches in perfection, than which there is no finer ornament for dessert, irrespective of their particular flavour in the autumn months; but in a majority of locations the late Peaches ripen well in unheated houses, we having had Sea Eagle first-rate up to the middle of October. Induce ripening by a somewhat dry atmosphere. Make the most of sun heat by allowing a considerable advance under its influence, closing early, but putting on a little top ventilation before night. Keep the wood thin, cutting away any gross growth, and shorten any sappy shoots to 12 or 15 inches, and keep all laterals closely pinched to one joint.

MELONS.—The latest plants having been stopped when they extended two-thirds across the trellis are well up it. There is no better system for houses than the single cordon—viz., the plants have all the

laterals rubbed off up to the height of the trellis, and then every alternate lateral on opposite sides of the primary, stopping it when two-thirds across the trellis. The laterals show fruit blossoms at the second or third joint, if not the laterals are pinched at the second joint, relying on the sub-laterals for the show of fruit. If the plants are weak and there is no hurry for the fruit remove all staminate and pistillate flowers on the laterals, stopping at the second or third joint, waiting for fruit on the tertiary growths or sub-laterals, which is an advisable plan where time is not a consideration, and a full crop and larger fruit is desired. By a little contrivance both systems may be had in the same house, which gives a longer succession of fruit—*i.e.*, plants allowed to fruit on the first laterals; those give from two to four fruit on a plant, and those that fruit on the second lateral or sub-laterals four to six fruits each, the latter being a fortnight to three weeks later. Where a succession of fruit has to be maintained from an early to a late period—say May to November inclusive—the plan is an excellent one. A rather dry condition of the atmosphere, with a little ventilation so as to ensure a circulation of air, is advisable, with a bottom heat of 80° to 85°, and impregnating the blossoms after they become fully expanded is advantageous to a good set. Do not earth up the roots until the fruit is set and swelling. Fire heat will be necessary to maintain a temperature of 70° to 75° by day artificially, rising to 80° or 85° from sun heat, losing no opportunity of closing early, so as to run up to 90° or 95°. Be sparing of the syringe, only use it for damping in the morning and afternoon, syringing the foliage on bright days, and in the early part of the afternoon. Water at the roots only when necessary, using liquid manure to assist in swelling off the crop, giving a thorough soaking when needed. Sprinkling with liquid manure all available surfaces in the afternoon is highly beneficial to the foliage, but it must not be overdone, and it is a good plan to sprinkle the surface of the border with a few fresh horse droppings about twice a week, and a little soot, just a dusting, is sufficient. A handful of superphosphate sprinkled on the surface of the border to each plant after the plants are earthed assists the swelling, fruits of plants to which it is applied being heavier than those the plants of which are stimulated by nitrogenous manures, and there is no comparison of the two in respect of quality. Manure is best not mixed with the soil unless it be devoid of humus, when a fourth of fresh horse droppings mixed with it will insure activity at the roots, and some lime rubbish and charcoal refuse secure a supply of sweet health-sustaining aliment.

Plants with the fruit swelling require careful attention in guarding against canker and preventing the fruits cracking. Fresh slaked lime applied on the first appearance of canker will subdue it, repeating as necessary; but it is aggravated by a close atmosphere, moisture on the stem, and too rich moist soil. A lessened supply of water both at the roots and in the atmosphere, particularly the latter, is the proper remedy for cracked fruits, or cutting the shoot half way through a few joints below the fruit in the case of vigorous plants. Fruit ripening should have a little air constantly, with a temperature of 70° to 75°, and as much more as can be had from sun heat under 100°, with a corresponding increase of ventilation. Cut the fruits as soon as there is the least indication of the footstalk parting from it, even earlier than that if the fruits are expected to keep, and place them in a light and moderately airy fruit room. They will have more flavour and be more mellow than fruits allowed to bake in the sun. The foliage of plants in pits and frames must not be sprinkled, but be kept as dry as possible, watering only to prevent the foliage flagging. Renew or renovate the linings to finish off the crop directly the heat is found to be on the wane, and employ a covering on cold nights. In dull damp weather, and especially at night, leave a little ventilation; a little tilting of the lights at the back will allow the pent-up moisture to escape, and it will keep off cracking to a great extent, as well as aid the fruit in acquiring quality. Keep the foliage thin and the fruit well exposed to the light, but a slight shade from bright sun following a period of dull weather is an advantage.

**CUCUMBERS.**—Keep young plants well up to the glass to insure a sturdy growth, and secure the growth to a small stake. Pinch out the growing point at the second leaf if the plants are to be trained with more than one stem, and it is important whether the plants are to have one or more stems that all the laterals up to the trellis be rubbed off as soon as discernible, leaving the leaves, when they may be allowed, make side shoots for bearing. Continue the preparation of fermenting materials where such is employed for bottom heat. Manure will require to be turned over every three or four days, while tan will only require to be turned once, and that as soon as it is fairly warmed through. In forming the beds whatever material is used tread it well down. Use the syringe sparingly, giving a light sprinkling only in the early part of the afternoon on bright days, but moderate moisture must be secured by sprinkling in the morning every available surface, and damping before nightfall. The temperature should be maintained at 70° to 75° by artificial means, falling 5° through the night, and allowing an advance to 80°, 85°, or 90° from sun heat, closing at 80°.

In pits and frames the temperature must be maintained by renovating the linings as necessary, and employ night coverings to prevent too great diminution of temperature during the night. Water very carefully, and sprinkle the foliage only on bright days and early in the afternoon. Keep the foliage thin, removing bad leaves and exhausted growths, and husband the sun heat as much as possible by early closing. Ventilate early, just a little to allow of a change of air, and keep up a good heat by allowing a moderate amount of air when the sun affords opportunity.

#### KITCHEN GARDEN.

**THE WEATHER AND THE CROPS.**—At the time of writing the weather has improved considerably, but August was a bad month throughout, and vegetable crops are in a worse condition to withstand a severe winter than we ever knew them in September. The growths are soft and watery, and are quite destitute of a robust character, and bright dry weather for a month or six weeks is urgently needed to fortify the winter crops. Nothing should be allowed to interfere with this, and all weeds, superfluous leaves, and such like, should be removed from amongst the winter crops, that the sun and air may play fully upon them. Some may think because they have massive leaves now that they are all right, but when Broccoli and other greens appear as if their foliage had been boiled after a few degrees of frost has occurred, it proves that they were not prepared to meet this as they should, and when once the main leaves are withered the produce will always be of an inferior description.

**RUNNER BEANS.**—These were unusually late in commencing to fruit this season, none being gathered until August, but they have made up for it since, having been immensely prolific. Readers generally should have taken advantage of this to salt a quantity of pods. Our cook has stored many bushels, and when they come to be used at midwinter it will be difficult for anyone to tell that they are not newly gathered from the plants. As all know, the Kidney Bean is most easily injured by frost. So long as frost does not occur they will continue to bear until very late in the season, and to insure their doing this never allow a pod to remain on the row that is too old for use. It is then the seed begins to form, and this causes all the later and very young pods to cease swelling.

**POTATOES.**—As we have previously indicated, the greatest failure of the year is in the Potato crop. The best of weather will not remedy the evil now, but good weather will be an advantage in storing the tubers in dry condition, and if the soil and atmosphere are favourable the storing should be pushed on as rapidly as possible. Nothing is to be gained by waiting, but wet weather later on would make the storing in proper condition most difficult. Fortunately we find those stored several weeks ago keeping much better than was anticipated, but we attribute this to extra care in storing, hence our reason for again referring to it.

**TOMATOES.**—The indoor crops have been as good as ever, but the open-air ones greatly deficient. A full supply can only be secured from the plants under glass this season, and the plants should therefore receive extra attention. Those that have been fruiting all up the stem may appear withered and unsightly on that part now, but if the points are green and bearing fruit, the old foliage may be cut off the stem and the fresh points encouraged to grow. If the pots, boxes, or beds in which they are growing are very full of roots and exhausted soil, give them a surface dressing of turf and manure in about equal parts. Water freely afterwards with liquid manure. Cut all the fruit off as soon as it begins to change colour, that the latest may have the full benefit of the energies of the plant. It will be found that on fine sunny days they will make more progress with abundance of ventilation than by keeping them close in a high temperature. Plenty of dry air is highly advantageous to them, not only in causing the fruit to swell, but also in making it firm. By keeping our open-air plants strictly confined to one stem they are now producing ripe fruit, but some we noticed elsewhere that were a mass of foliage and shoots, had not swelled their fruit to half its size, and it did not give any indication of maturing. If this growth is allowed to remain on, the fruit will not ripen this season, but by fully exposing it much may still ripen before the end of October. Plants with a superabundance of growth are better kept rather dry.

**BIRDS AND LATE PEAS.**—Row after row of Peas may be grown at midseason without the birds doing them any great harm, but the late rows which are most available are often much injured by them. In many cases they will clear out the pods so completely that they are hardly worth gathering, and this is sometimes done before one is aware that they have been feeding on them. It is the sparrows that are most destructive on late Peas, and the protection of all late rows should be seen to from the time the pods are first formed, as they often attack the young pods whether there are peas in them or not. The only mode of protecting them is to cover the rows with nets, and this should be done at once, and continued until the Peas are finished.

**AUTUMN-SOWN CABBAGE.**—The young plants placed out two or three weeks ago are now growing freely, and another plantation should be formed. The advantage of planting at two or three times and at intervals of a few weeks is that with a mild or severe winter some of the plants may suffer, or be pushed on too much and induced to flower prematurely; but one or more of the plots are sure to be successful, probably all. By planting at two or three different times the most forward can also be planted, which gives the later ones a better chance to become robust. All must be planted in good rich soil. They will never swell and heart freely in spring in poor material. Those who wish to market some of their produce should plant these Cabbage largely so as to have them ready very early in spring, as they are a most remunerative crop at that time.

**RHUBARB FOR FORCING.**—Roots intended for early forcing should have the foliage removed from the crowns as soon as any of the leaves die, as when the crowns are well ripened they force much easier than when soft and green, which they will be if the foliage is allowed to remain on them as it falls to the ground.

**SWEET BASIL.**—This distinctly flavoured herb is often called for. Most cooks prefer it green, and a cutting box or several 6-inch pots

should be sown with the seed at the present time. If placed in a gentle heat and kept in the light the plants will be ready for gathering from in November, and give a supply all winter.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE UNEXPECTED.

ALTHOUGH I had almost abandoned all hopes of obtaining a single drop of honey, at the last hour, the 3rd of September, brought hopes that there might be an exception, and we were not disappointed. On September 5th a favourable change took place, which continued, and such splendid weather we have not experienced for years before, the bees working with a vigour seldom witnessed, some of the strong hives rising nearly 50 lbs. A slight change to the worse came upon the 10th, which lasted three days, the lower temperature driving the crowding out bees inside, and reducing the honey gathering to little more than what would afford a living. On the 12th there were indications of a favourable change, and should it keep fair with a higher temperature for three or four days, instead of having to record 1890 as a total failure in a honey yield, it may be one of the highest. We are not yet out of the wood, but an average yield is certain, and we cannot say it is "the worst season in the remembrance of man."

The Carniolians and Syrians are the heaviest colonies at the present. We are only two hours by rail from England, and if those south of the Tweed desire to do good to the cottager bee-keeper they should come north, and I will do my utmost to initiate them in the art of bee-keeping, which our once light but now heavy hives will illustrate.

The result of the present year confirms what I have taught. As I am still with my bees I must close with the promise of full particulars, and advise to all bee-keepers to have their bees fed and finished up in their winter coats this month, so that both bee-master and bees may have a winter of repose after so tantalising and fatiguing a summer.—A LANARKSHIRE BEE-KEEPER.

### BEES AND THEIR WAYS.

BEES are to be regarded from two points of view—as the exponents of various social and moral qualities, and as honey making machines. For the moment let us consider them from the former point of view. The opinion expressed by Aristotle, that the humming sound made by a bee is caused by the "illusion of an inward spirit," has always seemed to us sound common sense. If a bee is not possessed by a spirit, and an aggravating kind of spirit too, how can her manners and customs be accounted for? There is nothing else in nature so contrary, so persistently fussy and disagreeable as a bee—unless it be a wasp. The bee is an impostor of the rankest kind, for it has set itself up as an example to youth on just those particular points that are most disagreeable to the young, and it has not really fulfilled its own ideal. People praise bees for their wisdom, but they will enter the same flower six times over, and never find out they have been there before. They are credited with prudence, but they will gorge themselves on any poisonous blossom placed within their reach. Universal suffrage, free education, and a free breakfast table we admit they have, and a number of other things that people will talk about and think they want. What we complain of is the immorality of pointing out to young people of both sexes that the persistent and unremitting fussiness of the bee is worthy of admiration. That bees strain all their energies after acquiring honey all day is no reason why we should do so, or why we should admire them because they don't smoke tobacco or go to the theatre. They don't want to do these things; they would do them if they wanted to. As to their cleverness, they are clever enough to go out for a fly and find their way back to their hive if it is not moved 6 inches on one side. Shift the hive a little and every bee will fly back to where it started from and stay there. If the hive is moved 3 feet they will not be able to find it, but lie there and die in the cold rather than look for it. Then as to economy. A bee has no sense of proportion; it will go on storing up honey far beyond what it can eat, and fags itself out every day for something it does not want. A bee has no pleasures, for it is always in a temper about something. The way it swears when it gets into a flower and can't find the way out again is demoralising in the extreme. The only real luxury bees seem to indulge in is fighting. If a strange bee comes to make a call the inhabitants of that hive sting her to death. As the call is usually made for the purpose of robbery there may be some sense in inflicting the death penalty, but what of the morality of a nation that keeps organised bands of robbers and employs lynch law!

Bees are well known to be of the female sex, but not entirely so. The unrestricted female would be too much even for bees. The only

perfect female is the queen. Mature consideration has led us to the conclusion that most of the imperfections of bee-life arise from its too exclusively feminine elements. Drones are at a discount, and are not allowed to vote or to be in the government; consequently the women have it all their own way, and we see what comes of it. A hive is nothing more nor less than a gigantic nursery and store cupboard. The whole energies of the community are concentrated on feeding-bottles and pap. They have no picture galleries, no concerts, no clubs, no art critics, no amusements; everything is brought down to a dead level of industry. Hexagons are employed for keeping honey in because those women put their heads together and found that hexagons took up less room than any other form, and rent costs money. Trust a woman for small economies! A man would have varied the shape a little occasionally—thrown in a cornice, or built out a buttress, or run up a spire, or something to get a little variety. Not so the woman; give her utilitarianism. Then as to visitors. A woman doesn't want visitors when she has a baby to attend to, and she does not want her husband to have them either. Bees don't care about news from the outer world; they can make their own gossip for themselves. There is a popular superstition that bees surround their queen when she moves about in order to show due reverence to majesty. Not a bit of it. They are only keeping their eye on her. Fancy the position of that one defenceless perfect woman among so many of her sex who are not so perfect as she is. To show what a life one poor defenceless female has among so many, bee-keepers tell us that the queen is expected to lay from two to three thousand eggs a day for several weeks, and if she does not give the nurses enough to do she is turned out into a cold world to tend for herself.—(*St. James's Gazette*.)

[What has "A Lanarkshire Bee-keeper" to say to the above amusing summary of his little friends?]

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Trees "Barked" by Cattle (*Anxious*).**—If the bark has been removed all round the trees and quite down to the wood the injury cannot be otherwise than detrimental. We have known such accidents to end fatally, but large trees are slow in dying. Usually the removal of bark is not so complete as is suggested, and often feared. Paring smooth the torn edges of the bark, and bandaging a thick plaster of clay worked into a smooth pigment, and fresh cow manure in equal parts, round the stems may be of considerable value to your trees.

**Eucharis not Thriving (*W. H. L.*).**—There is nothing whatever amiss with the leaf, and although you say the plants have plenty of roots they may be attacked by mites and will soon disappear. We should give the plants bottom heat if possible, 85° to 90° at the bottom of the pots not being too much, and when the plants have made good roots and are growing freely afford liquid manure copiously, maintaining a moist, genial condition of the atmosphere, and they will probably outgrow their complaint.

**Spawn from Old Mushroom Bed (*A Beginner*).**—The mouldy portions permeated by very fine threads of mycelium may sometimes be used for spawning new beds, but the spawn of old beds is generally too exhausted and often so filled with the mycelium of other fungi as not to be reliable or desirable. Good new spawn only should be used, securing the best possible as the cheapest in the end. The filament you have sent is totally unsuited for any purpose; indeed it is the mycelium of a very undesirable *Agaricus*, probably *A. muscarius*, due probably to the presence of wood forming the bottom of the bed, and ought to be cleared away, dusting with quicklime.

**Double Whin, Gorse, or Furze Cuttings (*J. B.*).**—August or early September is perhaps the best time to insert cuttings of this very beautiful plant in sandy soil, surfaced with about an inch of sand on a shady border, or preferably under a handlight. We have also seen

them inserted in autumn and spring, and successfully, but the most success attended the insertion of the cuttings at the time indicated. The cuttings are best with a heel, but strong cuttings cut transversely below a joint will also strike. The current year's growth should be chosen, or, if in spring, the previous year's growth, removing all the side leaves, inserting about two-thirds their length in the soil, making it firm, giving a good watering to settle the soil about them. If under a handlight allow the water to soak well in before placing the light over them. They must be shaded from sun, a north border being the most suitable place, and they will be ready to be transplanted the autumn following.

**Keeping Black Hamburgh Grapes (W. W.).**—The Grapes will keep much best on the Vines until the foliage falls or begins to fall, when they should be cut, bottled, and kept in a room with as equable a temperature as possible, between 40° and 45°, ventilating freely above the latter temperature. Damp should be carefully guarded against. Rain water should be used with a few pieces of charcoal in each bottle to keep the water sweet. The Grapes being ripe the chief thing is to guard against damp. That is best done by free ventilation in the daytime, and a gentle warmth in the pipes, the heat being turned on in the morning or the fire lighted, and it should be turned off about noon so as to allow the pipes to become cool before night. No fire heat will be required at night, or only to prevent the temperature falling below 40°. On fine nights a little ventilation may be left on, but in damp foggy weather the house should be closed, with a slight warmth in the pipes. In fine weather ventilate early so as to prevent the deposition of moisture on the Grapes. The Grapes should be examined frequently, removing decayed berries as they appear.

**Cottage's Red Potato (Handy Andy).**—The Potato of which you send sample tubers is the Cottage's Red Potato, and is thus described in Vilmorin's "Vegetable Garden:"—"Tubers flattened, oblong, usually very regular in shape, from about 3 1/4 to 4 inches long, and about 2 inches in diameter; skin smooth, of a rather vivid red colour; eyes faintly marked, not sunk; flesh yellow; shoot pink. Stems tall, erect, very vigorous growing, almost always branching, often 3 feet or more in height, quadrangular, slightly winged, and very deeply tinged with brownish red. Leaves large, composed of very unequally sized, quite oval-rounded, very much reticulated leaflets of a dark, slightly greyish and dull green. Flowers of a pale violet colour, in very numerous clusters usually intermingled with the leaves, very rarely producing seed. One of the best kinds for winter use, and most extensively in request in Paris late in autumn. The flesh is somewhat compact, but becomes more floury as the season advances. This variety is rather free from the Potato disease properly so called, but it often suffers from the affection known in France as 'la Frisolée,' which shrivels up both leaves and stems at the commencement of their growth. This is its only defect."

**Culture of Stephanotis floribunda (J. G.).**—It is a great mistake to keep this plant too warm, for its growths are more sturdy and it flowers more profusely when grown under cooler and more airy conditions than the plant is generally subjected to. Cool, airy treatment after flowering is of the utmost importance to thoroughly harden and ripen the wood before the season for complete rest arrives. The plants that flowered early in the year have had no artificial heat for the last six weeks, and none will be given as long as the temperature can be kept from falling below 50° at night. Abundance of air should be admitted during the day, and a little ventilation allowed all night when the weather is mild. The atmospheric conditions of the house should also be much drier than is generally the case. If this plant is infested with mealy bug it should be thoroughly syringed once a week with petroleum and water, one ounce of the former being added to a gallon of the latter. If the oil is well mixed in the manner frequently described, and the plant shaded from strong sun for about two days after syringing, the bug may be thoroughly eradicated. Half measures are next to useless, and syringing with petroleum two or three times a year only reduces the bug and does not prove effectual in clearing the plants entirely of the pest.

**Grapes Falling (J. S.).**—The berries you send are large, but the skins very defective, while the footstalks are by no means satisfactory. You probably top-dress the border with manure and give adequate supplies of water, also, possibly, liquid manure. This treatment would cause the fruit to swell to a good size, but would not, of necessity, impart substance to the skins and footstalks, as the liquid might not contain the necessary ingredients. Generally speaking, the skins of Grapes, when in good condition, contain about 47 per cent. of potash, 22 of lime, 16 of phosphoric acid, besides small quantities of magnesia, sulphuric acid, iron, silica, &c. Your Vines have not had what they need of those essentials, especially the first three named; and are the less likely to obtain them with the roots 18 inches below the surface, and some of them probably much deeper. Your Vines need lifting and the roots placing in fresh and better soil nearer the surface and there kept moist. If this cannot be done, the removal of the old soil down to the roots, liberating some of them, and pruning and placing them in a suitable medium, would cause a multiplication of fibres. Good loam, with a large addition of wood ashes and finely crushed bones, or some of Thomson's Vine manure, would form a suitable compost; but we suspect that manure applied to the surface of the present border would do little good. We should clear off the fruit as soon as possible, and at once commence action at the roots, shading and syringing the Vines if

requisite for maintaining the freshness of the foliage, as this will at once encourage the production of fresh roots. We should renovate the outside border this autumn and the inside border another year. The Vines have done as much as they could be expected to do since they were planted, and deserve to be encouraged in the manner suggested.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*T. T.*).—1, Lord Grosvenor; 2, Stirling Castle; 3, Golden Winter Pearmain; 4, Winter Greening. (*E. R. P.*).—1, Rymer; 2, Tower of Glamis; 3, Manks Codlin; 5, Doyenné du Comice; 6, not known. The Pears are not in condition to be named.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens should be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. R. O.*).—1, *Potentilla fruticosa*; 2, *Helenium autumnale*; 3, *Bocconia cordata*. (*Capt. Lambert*).—1, *Polygonum cuspidatum*. (*M. T.*).—1, *Polypodium vulgare*; 2, *Trichomanes radicans*; 3, *Hymenophyllum tunbridgensis*; 4, *Asplenium Adiantum-nigrum*.

## AFTER HARVEST.

YES, we are at length able to speak of harvest in the past tense once more, as indeed are most farmers south of the Trent. Some laggards there are and always will be both in sowing and reaping, but the majority gladly hastened to turn to full account the spell of fine weather which set in just when the long waiting for it had proved so disheartening. No doubt those who got much soft Wheat together in August feel some regret that they did not wait awhile, but as they took good care to make small ricks the corn will certainly soon dry and harden; and then, too, there is the comforting reflection that it was saved without sprouting.

We have recently listened to the exchange of congratulations upon the improvement in the price of Wheat. We heard them with regret, because of the certainty of a downward tendency again which was inevitable. The fall in price has already begun, and is likely to continue, for much Wheat that was in shock at the end of August was left out fully exposed to sun and wind well into the second week of September, and then carted directly to the threshing machine. All this will be speedily on sale, for even 35s. per quarter is too tempting a price to pass in these times, the 5s. over 30s. being sufficient to pay the rent of most of the Wheat land at any rate.

Barley is a better trade, good malting samples ranging as high as 45s. for the highest quality. This certainly points to an entirely satisfactory result, for the crop on many farms was excellent. Some of the best ears we have seen were quite green on the 9th inst. This was an exceptionally late field in Leicestershire, which was evidently sown very late. To save it in good condition will just be a stroke of luck, and it is always better to sow Oats when such late cropping becomes a necessity, as they are a safe late crop. The Barley season can hardly be said to have begun yet, for buyers are always shy of early samples, and do not buy with confidence till the sweating in stacks is over. So far as prices go they average nearly 7s. per quarter higher than a year ago.

Prospects of good Clover seed are so bad that old seed is in strong demand, and prices are advancing. The second crop of Clover is fast being mown where it is intended for hay, and more of it than usual will probably be converted into hay or silage owing to the abundance of feed. Trefoil seed is also almost a failure, and seed another season is quite certain to be dear. A dripping summer is unfavourable to seed development, but we have some compensation in the free growth of all forage crops.

A recent journey through Worcestershire enabled us to see a moderate crop of fine bright Hops being picked in excellent condition. Most pleasant is the sight, sound, and scent of the Hop picking, and the local pickers in the west must escape much of the competition to which those in the home counties are subject from the thousands of Londoners who throng to the Hop gardens now for work, and bring down the price of picking. It is always a matter for regret when foreign competition or trade experiences prove hurtful to such home industries, even though, like Hop picking, they are but things of a brief season, and low prices have caused a serious curtailment of the Hop area.

It is unfortunate that a poor fruit crop occurs just when efforts are being made to extend fruit farming. The general failure is among Apples and Pears, but remarkable exceptions are to be met with, and we came upon a Worcestershire orchard with a full crop upon most of the Apple trees, and we were shown a huge standard Apple tree in a cottage garden bearing a marvellous crop of fruit which was valued at £4. Both the orchard and garden were well sheltered, and farmers who intend planting will do well to re-

member that shelter often makes the difference between a full crop and none at all. Another important point is to plant standards and to fill up the space between the trees with bush fruit. We much desire also to see more fruit trees in pasture, for if only the trees are planted 40 or 50 feet apart, both the pasture and fruit trees answer perfectly, and while the trees are growing the pasture will pay the rent and something more. Very few and simple are the points of importance in this work—healthy trees, good sorts, careful planting, thorough support till the roots are so well established in the soil that they cannot be loosened by wind, and the protection of the stems sufficiently to prevent bark nibbling by sheep or hares and rabbits. Readers of the Journal are so familiar with all such matters that we need not enlarge upon them, but we may call attention to the importance of so supporting the trees that the bark sustains no harm. In the Worcestershire orchards the young trees are placed in a sort of cradle consisting of two stout posts driven into the ground on opposite sides of the tree, with parallel strips of wood nailed to the post near the top, between which the tree sways about with the wind, and the bark is battered about so much that growth must suffer.

## WORK ON THE HOME FARM.

Every effort is being made to turn the fine autumn to full account; and with harvest work ended, broadshares, harrows, and ploughs are kept going briskly to get the land clean. The corn stacks are a goodly show, and we shall keep the threshing in abeyance till autumn tillages are ended and winter corn is sown. A little threshing must be done for seed corn; but that is a trifle—easily managed by threshing some of the corn in barn for that purpose.

With the corn so long about, between the reaping and stacking there has been much waste. We have done our best to utilise fallen grain by driving turkeys upon fresh stubbles daily, and moving all our portable poultry houses frequently to clear up the corn before the surface is broken up. Sheep and swine consume fallen ears greedily enough, but poultry are required to make clean work of the grain. As old hens cease laying they are got rid of, as it never answers to keep them over for another season; and our early pullets give fair promise of soon beginning to lay. A supply of turkey poults should now be ready at the home farm, and there should be a sufficient stock of young birds to afford one or two weekly till spring. Geese are not so much in request, and a comparatively small number is sufficient.

It is well to take stock of the poultry occasionally, and to see that a full supply of each kind is bred for all possible requirements. Chickens, ducks, turkeys, geese, guinea fowls, and pigeons are all in regular seasonable demand. It is well to try always to have plenty of young pigeons when game is scarce. The dovecots of old manor houses show how highly our forefathers relished such fare, and though we have a much more varied and more wholesome dietary than was possible for them, pigeon pie is still in high favour.

Among chickens we have reason to give Minorcas a high place as table birds. We were induced to purchase some last spring by the excellent accounts we heard of the abundant supply of fine large eggs which this breed affords, and we have found them alike good for eggs and for table. It is true that they are not so large as some breeds, but they have small legs and nice plump breasts, are not at all coarse, and precisely the sort of chicken liked by a connoisseur. We call special attention to this matter, as the table poultry of home farms is so frequently unsatisfactory, and we know the value of a little special information in overcoming a difficulty.

## REMARKS.

7th.—Bright and warm; rather hazy early.  
 8th.—Misty early and hazy morning; bright warm afternoon.  
 9th.—Misty early, and dull till about eleven, then bright and warm.  
 10th.—Bright and warm throughout.  
 11th.—Warm and brilliant.  
 12th.—Bright throughout.  
 13th.—Slightly foggy all morning; bright afternoon.  
 Another rainless week, with very pleasant temperature.—G. J. SYMONS.

## GRAPES.

MR. J. ROBERTS, in his excellent and suggestive paper on "Grape Culture for Market," published on page 241 last week, observed:—"Those who are old enough to carry their memories back thirty, or even twenty, years will be able to recognise how greatly this fruit has risen in commercial value." The increase in the production of this princely fruit during the period indicated has been little short of marvellous. Not only has the market supply increased enormously in bulk, but the advance in value, as represented by the size and good appearance of the fruit, is equally remarkable. Twenty or thirty years ago the general character of market Grapes was the reverse of inviting, and much of the fruit by its rubbed and bedraggled appearance was more calculated to repel than to invite purchasers. No doubt superior Grapes could be had, but they were exceptional, and the prices were high accordingly. Grapes, large and practically faultless in colour and quality, were regarded as luxuries a generation ago; whereas they now abound and are obtained by thousands of persons to whom the prices of the old days would be prohibitive. It is to the improvement in culture and packing, as well as to the increase in quantity, that the present popularity of Grapes may be ascribed, and the best cultivators are yet able to derive profit by their skill, or they would not continue in the occupation. The prices for their fruit have undoubtedly fallen considerably, but many, if not all, the chief growers have in some way contrived to increase the bulk of their produce without impairing its quality, and so they have managed to "struggle on," while some who might be heard declaring that Grape growing was "done for" have extended the cultivation of this most popular of all exotic fruits.

Mr. Barron, in his useful and highly popular work, "Vines and Vine Culture," refers to the commercial supply of Grapes and the general fall in prices as follows:—"The average prices now realised are from 25 to 50 per cent. lower than they were ten years ago. Many feared that the enormous increase of the Grape trade would swamp the market and ruin the growers. On the contrary, however, more money in the aggregate is realised by the growers than was formerly the case with high prices. They base their calculations on the actual costs and gross returns, and argue thus: that to sell a ton of Grapes at 2s. or 3s. per lb. is better than, as formerly, to sell a few hundred pounds at 10s. or 20s. per lb.—prices that were practically beyond the reach of the consumers. Cheap prices now enable retail fruiterers to maintain a supply on sale at all times, thus increasing the consumption." How great this was when those lines were written in 1887 the author of the above work gives some examples. One commission agent in Covent Garden is said to have disposed of over 40,000 baskets, or an equivalent of about 250 tons, in the preceding year; and a Kensington fruiterer is recorded as having sold to his customers during the same period 40,144 lbs, the cost price of which averaged a little over 1s. a pound. It is clear that the public are very well served with Grapes, but with the increase of population and wealth the demand will increase also, and perhaps in greater proportion than before, since the dietetic and hygienic value of fruit is becoming more and more appreciated.

Mr. Barron has done good service in disseminating sound knowledge on Grape culture during the past few years; but there is another gentleman to whom the world is immensely indebted—

the veteran cultivator and effective teacher, Mr. William Thomson of Clovenfords. Mr. Thomson has been growing Grapes, such as have seldom, if ever, been surpassed, between fifty and sixty years, and twenty-eight years have elapsed since the first edition appeared of his "Practical Treatise on the Grape Vine" (Blackwood). Practical it undoubtedly is, as it is a record plainly and clearly told of his actual practice and its excellent results. It is impossible to estimate the amount of good that has been done in the Grape growing world by the publication of this work. Gardeners all over the kingdom have been made wiser by its teaching, and Grape growing was never so well understood before as it became after its appearance. Ten editions of the work have been issued, and the last of them has been for some time on our table. What may be termed the "Grape Conference week" at Chiswick appears appropriate for a brief allusion to the re-issue, and also for recognising the great services of the author by the publication of his portrait, which will be found on page 273.

We have no intention of writing the history of the great cultivator. We know he took charge of the gardens at Wrotham Park, Barnet, in 1837, and in the work he has graphically described the bold treatment to which he subjected the Vines there. It is worth repeating.

"In a house 65 feet long and 22 feet wide there was a row of strong cast-iron pillars running along the centre of it to support the rafters, and against these the Vines were planted, twisting round them like enormous snakes. My employers were loth to have these old Vines destroyed, and wished me to make an effort to renovate them if possible. I made a careful examination of the state and position of their roots, and found that none of them were within a foot of the surface of the soil. It was the custom to keep all the bedding plants standing on the floor of this house, and the constant watering and treading had made the whole surface, which had not been broken up for years, as hard as asphalt. This I had picked up, and removed from the house, to the depth of 1 foot. I then got hold of the leading roots and traced them as far as possible. When they could be pursued no farther without going a great depth I cut them and coiled them round the pillars that supported the stems, till in this way I had raised some eight or ten of the roots of each Vine, not one of which, as far as I traced them, had any live rootlets on them. I had mats put round these bundles of roots, and kept them damp for the time being. I then laid out all the roots on a bed of new soil, making a regular set of incisions with the knife right and left, about 9 inches apart, along their whole length, covering them over with 6 inches of the same compost, and giving them a good watering with warm water. This was done in March, just as their buds were beginning to swell. They broke as weak as straws, and looked very miserable till about the end of July, when they showed some signs of making second growths of a more vigorous character than the first. Shortly after this time I dug down to several of the roots I had made the incisions in, and found that from the lip of each wound nearest the parent stem a great number of young roots, like porcupine quills, had started off into the new soil. This was in the summer of 1838, and in 1839 they broke comparatively strong, showing a fair crop of fruit, which they brought to perfect maturity. In 1840, and for seven or eight years afterwards, they bore first-rate crops of excellent Grapes colouring well. They were Black Hamburgs."

That successful example of Vine renovation has been copied in hundreds of instances with excellent results. After bearing for some years the Vines were removed, all but one that was left for experiment, and this Vine we saw thirty years subsequently in the best of condition and bearing splendid fruit.

Having given an extract from the first edition of the work we take another from the tenth, in which are embodied sensible remarks on Vine borders, thus:—

"In making up the border, if the soil is what may be termed light loam, let it be well beaten and made evenly firm by a steel fork; but do not tread it hard with the feet, or wheel barrows over it. If the soil is what may be termed heavy, and especially if damp when the border is made up, the above caution is even more necessary. I know of nothing in the field of horticulture that exhibits greater lack of scientific knowledge than ramming damp soil hard together in positions where it is to remain for years,

unless it be the thumbing of soil in a damp state round the roots of a plant in a pot, forgetting altogether that the action of the air in the soil is most necessary.

"It is of great importance that nothing should be added to the soil of a Vine border which, after the plant-food it contains has been absorbed, leaves a residuum of inert humus, which shuts up the pores of the soil, hinders the healthy action of the atmosphere, and retains an excess of water like a sponge, in time rendering the border what gardeners justly term sour. This, farmyard manure at its best does. There is the additional danger of horse dung breeding fungi.

"If Vine roots are not confined by bricks and mortar to such a border as I have indicated, they escape from it to soil that was not prepared for them, and sometimes thrive better in the latter than in the former.

"Another mistake that, up to the present date, is not uncommon, is that of mixing half-inch bones in Vine borders. They are of little or no value. I have seen them as whole as when mixed with the soil, after being thirty years in it, and not a root near them. Bones are an excellent element in a manure for Vines or any other fruit-bearing plant, but they should be ground as fine as possible. In this state they form a considerable portion of the manure I feel bound to recommend.

"For good reasons it is best not to make up the whole width of the outside border when the Vines are planted, especially if it is to be a wide one; 6 feet in width outside the arches will be ample for two years. This has more than one advantage. It gives time to procure soil, not always an easy matter, and roots enter new soil with greater rapidity than they do soil that has been lying soaked with wet for two years, by which time the chance is it has become sour; rich soil is much more liable to do this when unoccupied by roots than when it is.

"While on the subject of borders I must enter a protest against the extreme folly of planting flowers or growing vegetables on Vine borders. The roots rob the soil of the food intended for the Vines, and, even worse than this, keep off the genial heat of the sun. I called at a fine garden down the Clyde last autumn. The gardener took me into a range of vineries, and remarked that of late years the Vines had yielded very inferior Grapes. I replied that little else could be expected, seeing the enormous crop of plants on the borders up to the vinery front sashes. First a row of single Dahlias 3 feet high; then came *Perilla nankinensis*, Stocks, Geraniums, &c. The gardener said his view was the same as mine with regard to the cause of the injury to the Vines, and he had often pointed it out to Mrs. —; but she said she could not bear to see naked borders, at the same time she expected good Grapes. This is one of the many difficulties gardeners have to contend with."

The citations show the thoroughly useful nature of this treatise. Both it and Mr. Barron's book should be possessed by every gardener and amateur who desires to grow Grapes of the first quality, either for home use or for sale, as only the best crops of the best fruit can be satisfactory or profitable.

Passing to the Chiswick Conference, at which representative exhibits of Grapes and Dahlias were invited, and writing some days before the event, we suspect that Dahlia growers will make the greatest response. Collections of all or most of the different types of Grapes are grown in comparatively few establishments, and we anticipate no such imposing display of fruit as is forthcoming at great competitive shows of the popular varieties. The attention that is devoted to those which are exclusively grown in the majority of gardens, is causing many Grapes of distinct characteristics, and possessing special qualities, to be overlooked, if not forgotten, and it was a happy idea, on the part of the Royal Horticultural Society to afford an opportunity for bringing such less known varieties together for purposes of comparison and instruction.

#### AMONGST THE TREES AT ST. JOHN'S NURSERY, WORCESTER.

WHILE the trees are still in the full glory of summer foliage, and the tinge of autumnal beauty is only just perceptible, is an excellent time to see and compare one sort with another, and to obtain a sufficiently clear idea of growth, foliage, and habit, and of the relative value of sorts, new and old, to enable one to make a judicious selection for the planting season, which will soon be with us once more. Such was partly my object. I went to Worcester to select trees for planting in Leicestershire, where I am engaged

in the very interesting work of the restoration and improvement of an old family seat, one of several which once belonged to the family of its present owner who has recently acquired it, and with whom, therefore, it is a labour of love to restore and make beautiful an estate which was the inheritance of a long line of ancestors, who lost it, and many another fair domain, for the sake of that "trouthe and honour" which was the guiding star of old Chaucer's "Verray perfight gentil knight."

Down in a valley stands the fine old Tudor mansion, and from it ascend gently swelling uplands, which rise and fall in picturesque contours, and which it is intended to clothe sufficiently with timber trees to impart to it the beauty and dignity of a true English park, with its avenues, glades, clustering trees, specimens—detached, yet so entirely a part of the whole, so contributing to the general effect as to be indispensable to its completeness and entirety.

With such an object in view went I to the famous Worcester nurseries, and certainly I was well rewarded for my journey. I never saw so fine and healthy a collection of young trees, remarkable alike collectively and individually, for though most sorts are grown here by the acre, yet every one of them—aye, even amongst the forest trees—is a perfect specimen: clean, symmetrical, in robust health, and full of growth, which is so free and vigorous that it was not till I saw one of the largest trees lifted with its densely clustering fibrous roots that I realised how fully, how thorough, is the system of transplantation at St. John's, and why the trees from this nursery are removed with such safety and answer so well.

Turning now to the trees, the Elm must have the first place because it is the pride of Worcestershire, where it is seen in all the majesty of full development, and is certainly a most stately tree, whose noble proportions rival those of the Oak, and whose effect as a timber tree is entirely satisfactory. One old giant which I saw on Lord Beauchamp's property near St. Cloud, the residence of R. Smith-Carington, Esq., was probably fully 30 feet in circumference; and in Mr. Berkeley's park near Worcester I saw an avenue of Elms about 200 years old, the trees of which are equally remarkable for size as well as for uniformity of growth. But fine Elms abound in Worcestershire, and there are trees at the nursery 50 feet high that were planted well within living memory, and are regarded as somewhat remarkable from the free manner in which they have continued to grow, notwithstanding the frequent disturbance of the soil right up to the stems. This is the true *Ulmus campestris*, or English Field Elm, and there is a large stock of it at the nursery, from which enough will be selected to plant an avenue a mile and a half in length on the Leicestershire property. The large stock of Wych Elm and the Huntingdon or Chichester Elm showed that both sorts are much in demand, and of other highly ornamental sorts there are *campestris aurea*, *plumosa*, *pyramidalis*, *Dampieri aurea*, the Wheatley Elm, and the silver variegated variety of *campestris*.

Of Oaks, I saw a very interesting collection of upwards of forty varieties, several of which are highly desirable for mixed clumps. Fine tree as the common English Oak undoubtedly is, we can have too much of it. A park with the timber principally of fine old Oaks is certainly a remarkable sight, but the effect of even such trees is tame and insipid in comparison with that evolved by tasteful mixed planting. Take, for example, Whittlebury Park in Northamptonshire, where there are hundreds of old Oaks, every tree a fine specimen, yet it was with a delightful sense of restful relief that one turned from them to gaze through a vista of the tapering forms and soft feathery foliage of Douglas Firs to the lofty clustering groves of stately Stow in the distance.

The Turkey Oak is a tree one would like to see more frequently, for it has a singularly elegant and refined appearance, to which its habit of growth, foliage, bole, and even the bark all contribute. It grows freely in a deep loam, and soon tells in effect, especially as a detached specimen. There are cut-leaved and variegated forms of it at St. John's, both worthy of a place in belts and clumps. Most beautiful is the Scarlet Oak, as the leaves change from summer greenery to the brilliant hue of autumn whence it derives its distinctive title. A mass of it will now soon be all ablaze with colour. How wonderfully effective it is on a hillside among feathery Larches or the deeper hues of Scotch and Austrian Pines. It is deservedly popular, as the fine stock of it at the nursery showed, but its position must be chosen with due regard to effect at this season of the year. Of the other sorts which attracted my attention by the size or form of their foliage, I select as especially worthy of planting *macrophylla*, *pectinata*, *americana discolor*, *latifolia dentata*, *tinctoria*, *villosa*, *Prinos*, *Louetti* and *olivæformis Hampteri*.

Most tempting was the appearance of the Maples, with their handsome foliage and luxuriant growth. The entire collection well repays one for close inspection, most of the varieties being worthy of a place, and especially so are *Acers macrophyllum*, *Schwedleri*,

*lutescens*, *heterophylla*, the Norway Maple and the purple leaved Sycamore. Planes, Poplars and Limes, too, are all evidently in large demand. Caution is necessary in planting the first two, for Poplars are apt to become too obtrusive, and Planes are not suitable for cold heavy soil or low damp situations. Plant them there, and the most frequent result is the curious anomaly of a few healthy trees whose growth is entirely satisfactory, and many sickly ones with branches destroyed by frost, or roots perishing in a sodden soil. Yet I have seen fine Planes low down on the slopes of a valley that had been sufficiently sheltered when young to escape damage from frost, and once above the frost line they were safe from check or damage from atmospheric influences. The soil was an alluvial deposit that evidently suited them; for in sixty years they had become fine timber trees of such stately appearance as to show how effective a grove of them would be if they were planted far enough apart for individual development.

To all readers of the Journal who intend planting trees in forest, park or orchard this autumn, I say Go to St. John's and see the trees now, and especially try and see the Acers, the Corstorphine Planes, Silver Lombardy Poplars, Acacia Decaisneana, which grows faster than the ordinary kind and has pink flowers, the Purple Plum (*Prunus Pissardi*) with its rich purple foliage, the Golden Elms, Purple Sycamores, the Silver Spruce (*Abies Parryana glauca*), the Silver Cedar (*Cedrus atlantica glauca*), and pray do not forget the Hollies. Never before had I seen such a magnificent lot of Hollies of all kinds, every one of them an example of careful cultivation, all of them symmetrical, healthy specimens, and yet they are but an example of everything else here where the aim is perfection, and the result a very close approach to it.—EDWARD LUCKHURST, *Warrens, Harold Wood, Romford.*

### TAINTED FRUIT.

It is a fact not perhaps generally known that it is possible to spoil the flavour of almost any kind of fruit grown in this country. No fruit that I am acquainted with is more susceptible of injury in this respect than the Strawberry. Who has not, at some period of his gardening career, discovered that the greater portion of a crop of this favourite fruit has been spoilt by tobacco fumes, the fumigation in some instances actually taking place before the fruit is half ripe? When once the fruit has become tainted in this manner it is spoilt beyond recovery. A too free use of strong-smelling manures is also liable to injuriously affect the flavour of Strawberries, and the more pure and airy the atmosphere is kept during the ripening period the better will the flavour always prove. If it is advisable that the surroundings of ripening Strawberries should be kept as sweet as possible, it is absolutely necessary that the ripe fruit, after it has been gathered, should not come into contact with anything that smells in any way, and above all should not be packed in scented boxes, or a flavour foreign to it will inevitably be introduced.

Peaches are nearly or quite as liable to be spoilt by contact with any scented substances, and though I have never tasted any fruit flavoured with tobacco, I should be sorry to risk anything by fumigating a house containing a crop of Peaches and Nectarines after the final swelling had commenced. But if instances of fruit having been spoilt before it was taken from the house in which it was grown are rare, I have frequently tasted both Peaches and Nectarines which were badly tainted, owing to the fruit either resting on or being packed in scented material or boxes. As a rule our fruit, according as it is gathered, is laid on sheets of cotton wool covered with clean packing paper. This season we are using wood shavings—a new packing material—this smelling like newly cut deal when first opened out. Ripe Peaches and Nectarines were laid on without a paper covering for about four days, and at the end of that time were badly tainted or nearly spoilt. Even moss is apt to impart an earthy flavour to Peaches; and on the whole cotton wool, though not perfect, is the least objectionable material for packing this class of fruit in. In any case, it is imperative that every fruit be carefully and completely folded in soft tissue paper prior to surrounding it by other soft springy material. Enclosing the fruit in paper will not, however, prevent injury accruing to it if scented boxes of any kind are used, and I shall never forget tasting a Peach that had been kept in a fragrant soap box for about twenty-four hours. What holds good with regard to Peaches and Nectarines is equally applicable to Figs, the flavour of these being very easily tainted, and nearly as much care must be taken of Melons, or they will be spoilt.

Many years ago I was under the impression that when a noble lady asserted she could detect the flavour of almost any kind of material used for packing Grapes, and the bunches had to be packed in Lime leaves whenever these were procurable. Since that time I have had good reason to think there was "something in it," as it

has forcibly come home to me that Grapes can be more easily tainted than many gardeners are aware. With their smooth and apparently non-porous skin, it might be imagined that the berries are impervious to tobacco smoke even, but such is not the case. Instances could be given where fumigating was resorted to after the Grapes were nearly ripe in order to check the spread of thrips, and it was subsequently found that the crop was spoilt, all the bunches being badly tainted by the tobacco. That Grapes are among the least susceptible of injury from odours of any kind I readily admit, but maintain that no risks should be run, and that the packing material and boxes used should be of a non-scented character.

With regard to most of the fruits just mentioned these remarks are not particularly opportune, but when we come to Apples and Pears the case is different. There are far more of these in many parts of the country than is generally known, and even if there were fewer this would be a stronger reason for taking good care that they should not be spoilt in any way. Apples are remarkably porous, and the flavour may be spoilt in a few days, yet very few growers appear to be aware that such is the case. I have before mentioned in these pages, having once had to take part in the tasting of about sixty dishes of fruit staged at a November Show at Bath, the class being for a single dish of any variety, to be judged by flavour; but of that number 75 per cent. gave only too strong evidence of having rested for some time on straw. Worse material for the fruit to rest on could not well be selected. At the outset it may be sweet and fresh enough, but it is not long before the moist fruit causes it to become musty, and in a short space of time this disagreeable flavour is communicated to the Apples. Not merely should the material on which the fruit rests be clean and sweet, but the surroundings ought to be equally so. Dark musty sheds, disused Mushroom houses, dirty badly ventilated cellars, and other makeshift storing places are apt to spoil the flavour of both dessert and culinary fruit, and should be avoided as much as possible accordingly. A clean room, with newly whitewashed ceilings and walls, and the boards and shelves covered with fresh kitchen paper, will not injuriously affect the flavour of the fruit stored in it, and such ought to be connected with every garden. Failing these Apples keep admirably and without detriment to the flavour in clean boxes or paper-lined hampers stored in dry rooms. None but sound fruit being placed in them the lids may be put on, and no further trouble beyond protecting from severe frosts need be taken with them.

It is my impression that Pears are scarcely so porous, and therefore not so easily tainted as Apples; but whether this is so or not there is yet every necessity for storing them amidst sweet surroundings, and also for packing in unscented material and boxes. They do not suffer for a few hours' storage or transit in soft sweet hay, always providing each fruit is wrapped separately in a square of clean paper, but on no account should hay any more than straw be used as a bed for resting Pears on in the fruit room. In many instances nothing but latticed stagings or shelves are used for the storage of single layers of fruit, but I have a weakness for the boards to be covered with fresh kitchen paper, especially in rooms where there is no possibility of excluding severe frosts. Paper below, and more on the top when necessary, will frequently prevent injury from frosts, and if need be cotton blinds can also be used without tainting either Apples or Pears.—W. IGGULDEN.

### THE CARNATION.

[Read before the Sheffield Floral and Horticultural Society by Mr. F. Hardy.]

#### PROPERTIES OF A GOOD CARNATION.

CARNATIONS are divided into three classes—namely, bizarres, flakes, and selfs. The flowers of a good Carnation should not be less than 2½ inches across; the guard or lower petals, not less than six in number, should be broad, thick, and smooth on the outside, free from notch or serration on the edge, and lapping over each other sufficiently to form a circular Rose-like flower. The more perfectly round the outline the better. Each layer of petals should be smaller than the layer immediately under it. There should not be less than five or six layers of petals, laid regularly over each other, and the flower should be stiff and slightly cupped. The stripes or markings should be clear and distinct, and not running into each other. The ground colour must be perfectly clear, and the other colours must be bright and clear, whatever variety they may be; if there be two colours the darker one cannot be too dark, or form too strong a contrast with the lighter. That is a great point in an exhibition bloom. If the colours run into the white and tinge it, or the white is not pure, the fault is very great. The pod of the bloom should be long, to enable the flower to develop without bursting it; but this is a rare occurrence. The best way is to tie each pod half way up, and open each section down to the

tie. There are a few varieties that do not require this, but they are very few. I do not consider it necessary to give a list of varieties, as there are so many good lists in the catalogues and journals that it is a very easy matter for anyone to make a good selection.

#### PROPAGATION.

There are three ways of propagating—viz., by seed, layers, and by pipings or cuttings. Taking them in the order named seed is the first to be considered. We have in the first place to procure good seed. I recommend saving seed, and only from the best blooms that produce seed. It is not every bloom that does produce seed, but you should endeavour to make the purest, clearest, and most distinct flowers, for by so doing you save time and labour in not having to weed out so much from the seedlings, because, no matter how carefully the flowers are selected, there will always be a large proportion of worthless seedlings. The less the number of seeds in a pod the more likely are they to be of the best quality and to give good results. Seed is always scarcer in pods from double flowers, or in pods containing seed that will produce double flowers. The seed should be gathered as soon as ripe, and if not sown at once it should be kept in a cool dry place. It is better to sow it as soon as gathered, for two reasons—first because it germinates more quickly, and secondly the strongest plants raised will bloom the first season, whereas if it is not sown until spring flowers are not produced until the following year. Sow the seed in pans or boxes according to the quantity, and place these in a humid temperature. As soon as the seedlings appear they should be placed near the glass in a greenhouse, and when large enough pricked out into boxes in a rich compost, such as loam, leaf mould, sand, and a little dried horse droppings in proportion. They can remain in the boxes until early spring, when they may be planted in a well-prepared bed, remaining until they flower, when the finest varieties should be marked and the rest discarded, though the best of them may do to brighten some dark corner.

#### PROPAGATION BY LAYERS.

A layer is a shoot brought down to the ground, and when rooted separated from the parent stem. This is a simple and perhaps the safest way of increasing the stock. I need not make any remarks about the way it is done, as it is an old practice, and no doubt familiar to all. The soil used for placing round the layers, when they are cut and firmly pegged down to the ground with a hooked peg, should be fine with plenty of sand in it. After the soil is placed round the layers should have a slight watering, and the business is completed until they are rooted, when they may be taken up and potted, either two small ones or one strong plant in 60-size pots, and placed in a cold frame, care being taken not to keep them too wet, and plenty of air should be admitted on all favourable occasions.

#### PROPAGATION BY PIPINGS OR CUTTINGS.

This mode of increasing the stock is very simple, but not so safe as layering, and should only be practised when it is desirable to propagate largely, and there are more shoots on a plant than can possibly be layered. It is a good practice to make up a gentle hot-bed for the purpose of plunging the pots, in which the cuttings are inserted round the edges. The pots must be well drained and filled to within an inch of the top with fine soil, the remaining space to be filled with silver sand. After the cuttings are inserted give them sufficient water to settle the soil around them, and keep them shaded from the sun until rooted. It is easy to tell when they are rooted, as they begin to make new leaves. They should then be potted and treated in the same way as described for layers.

#### SOIL.

A good compost for pot plants consists of two parts rich fibrous loam, one of leaf mould, half of sand, and half of well dried horse droppings, not old Mushroom bed manure, as that is liable to cause fungus. These materials well mixed together will form a suitable compost. With regard to manuring ground intended for planting Carnations, the nature of the soil should be taken into consideration; if it is heavy ground, well dried horse droppings would be the best manure, but, on the other hand, if the ground is light, well dried cow manure would be the best. It is also good practice to prepare the ground in autumn for planting the following spring, as this allows the rankness, if any, to escape from the manure.

#### CULTIVATION IN POTS.

Besides being effective in borders and beds, Carnations are equally attractive when grown in pots for the embellishment of the greenhouse. Many people have their own fancy with regard to the size of the pot they use, and as a matter of course each size has its own advantages. For my own part I like to grow them in 8-inch

pots, four plants in a pot. By growing four plants together a greater mass of bloom is obtained, as each plant only sends up one flower stem. If the bloom is intended for exhibition two plants in an 8-inch pot will be quite sufficient, and all potting should be completed by the beginning of April. One great point in the cultivation of Carnations in pots is to have the pots properly drained; the drainage should be at least 1 inch deep, and well protected by the roughest materials of the compost. After potting the plants should be placed in a cold frame with plenty of ashes in the bottom for the pots to stand upon, so that the plants are well protected from worms and slugs. The reason I advise them to be placed in cold frames is that in case of heavy rains the lights, which may remain off altogether in favourable weather, can be easily placed over the plants. A gentle rain, however, will do them no harm. At all times they require careful watering, and occasionally a little weak liquid manure may be given them when they appear to require extra support.

When the flower stems appear they should be staked, great care being taken in tying to give them sufficient room, so as to enable them to grow to their full length without forming knees or bent joints; if this happens they will most likely break off at the affected part. When the flowers begin to expand it will be necessary to give them a little shade from bright sunshine, and to look after the pods to see that they do not burst. These should either be tied as before mentioned, or, better still, procure a few small indiarubber bands, which are sold for the purpose by most nurserymen.

With regard to thinning the buds, you must take into consideration what they are wanted for. If for exhibition blooms, select two or three of the strongest on each shoot; if to be shown in the pots as they grow, leave six or seven pods; and if for home decoration and cutting, leave them all.

During the discussion which followed the reading of the above paper, Mr. Collier said the Carnation was a favourite flower for buttonholes, and recommended the following varieties:—Laura, with large pink flower, one of the best bloomers in pots; Miss Joliffe, grown largely by market people; White Swan and La Belle, both very good whites.

## GROWING AND SELLING FRUIT.

(Continued from page 240.)

### STRAWBERRIES.

NEXT to the Apple this is the most profitable fruit for the small grower and cottager, if he is near a town where he can dispose of his crop. This makes all the difference between profit and no-profit, Strawberries having to be sold quickly after they are gathered, twelve hours being quite long enough for them between gathering and eating. This is also a crop in growing which the cottager's wife and children can render very great assistance by gathering the fruit, cleaning the plantation of runners and weeds, putting straw under the fruit to keep it clean, scaring away birds, catching snails, &c.

SOIL.—The Strawberry is perhaps the best of all fruits in this respect, as with care and attention it will grow in any kind of soil, even in those that are chalky, although it is not advisable to plant many in doubtful places until a few have been tried to see whether they will perfect enough fruit to render them a source of profit. The best soil for them is a rich, deep, and moist loam, but any good deep soil will do if well manured before planting. They may be grown among the standard Apple trees, or in an open spot by themselves; and a warm bank, where many other fruits would not succeed, will often grow good Strawberries with proper care and attention.

PLANTING.—The rows should not be less than 2 feet apart to allow room for gathering, and for a small horse hoe to work amongst them if the plantation is large enough. If the soil is very rich 3 feet apart will be a better distance, and the plants 2 feet apart in the rows; in poor soils the latter distance may be reduced to 18 inches. It is sometimes advised to plant much closer than this, but unless the soil is very poor—in which case Strawberries will not pay for growing—it is not a good plan to do so, because if a wet season occurs the fruit cannot become dry quick enough, and soon decays. It is a bad plan to dig among Strawberries after they are planted; the ground should therefore have plenty of manure, and be well dug some little time before planting. The small plants at the end of the runners are the best for making new plantations, and where only a few thousand are required they should be specially prepared before they are cut off. The best way is to get some 60-sized flower pots, fill them with good soil, lay the runners on, and put a stone on the top, keeping them well supplied with water; but the cottager will seldom have flower pots

at hand in sufficient quantity to follow this system. Another way, almost as good, is to cut some turves 2 inches thick and 12 inches square about the end of May, and stack them in rows four or five deep, with the grass downwards; this will kill most of the grass. About the first or second week in July the runners will be ready to commence rooting. Cut each turf into nine pieces, lay one of these down for each young plant, scoop a little of the earth out of the centre (the grass side being downwards), lay the young plants in, cover the earth over the lower part of it, and place a stone on the runner to keep it in its place. These should have water every day if the weather is dry, and placing the turves close together in lumps renders watering much easier. In about a month they will be ready to cut off the old plants for planting out in the new plantation; this is best done in showery weather. They should be planted very firm, putting the pieces of turf in the ground with the young plants, and ramming the soil around them with a wooden rammer. The earliest varieties should be planted in the most sunny and warm portion of the ground, and the later ones where they will be cooler, thus prolonging the season as much as possible. They will not require any other attention until the following spring beyond keeping them clear of weeds and removing all runners as soon as they appear. If an acre or more has to be planted the grower may not be able to take all these pains in raising the young plants; in that case the runners may be cut off the old plants and planted during showery weather, and will eventually do well; but a year's crop is saved by preparing the runners properly, and on the principle of quick returns it is always best to have good plants at first, as they will then give a crop the first summer after planting.

**CULTIVATION.**—Early in spring, as soon as the ground is dry enough, the hoe should be run through the plantation to destroy all weeds, and this should be repeated as often as necessary until the flowers begin to show. They will then require some short strawy manure placed all round to protect the fruit from being spoiled by the rains, and to prevent the land drying up too much in hot weather, the nourishment from the manure will be washed down to the roots by rain and assist in swelling the fruit. If manure cannot be had, grass cut from the roadside will do, but it is not so good as straw, as it encourages snails more and is not so apt to take root and grow; also, it does not enrich the ground so much as stable manure.

**GATHERING AND MARKETING.**—As soon as the fruit becomes red and before it is over-ripe it should be gathered. This must be done when it is perfectly dry. The pickers should, therefore, have work near at hand until the dew has passed off. If Strawberries are gathered when damp they will not look rich and glossy when they reach the market, and if they are required for preserving purposes the jam does not keep well, but goes mouldy. Fruit for eating should be gathered into 1-lb. flat punnets, these can be had from the market salesmen at 6s. per gross. A few leaves should be put into the bottom and round the sides, or one small Cabbage leaf laid in each basket is better still if it can be had. Do not gather any small or decaying fruit. Make each basket as near 1 lb. in weight as possible while gathering, then weigh each one and send to market or to their destination as soon as possible. They travel best if the punnets are placed in boxes 21 inches by 34 inches and 22 inches deep, inside measurement. These should have a small ledge on two of the sides for a false bottom to rest on about 4 inches from the box; this false bottom should be made of strips of deal three-eighths inch thick, long enough to reach the small ledges at the sides. One ledge should be fixed at 4 inches from the bottom of the box, the next at 8½ inches, the next at 13 inches, the next at 17½ inches. A box of this size and form will hold five layers of punnets, fifteen in a layer, that is 75 lbs. of fruit. Before the false bottoms are placed in position each layer of fruit should have two or three Rhubarb or Cabbage leaves that are perfectly dry laid over them to keep the fruit from shaking about in transit. Everything should always be kept perfectly dry, this is very important; the stalks and midribs should be taken out of the Rhubarb leaves before putting them into the box. The boxes should be fitted with handles and lids with locks, &c., and be sent off in spring vans, or if by rail arrangements should be made with the porters that they are not knocked about. Preserving fruit may be gathered in the punnets and emptied into glazed earthenware jars holding 18 to 24 lbs. each; these should then be packed and sent to their destination without any of the juice being lost; the smaller fruit does for this purpose which would not be suitable for dessert use; they should always be gathered without the stalks for preserving. Where there is a good demand near the provincial towns, Strawberries generally fetch good prices. Selected fruit very early in the season will often fetch 1s. 6d. per lb., coming down to 1s. when they get more plentiful, and afterwards 8d. and 6d. The next size will range from 8d. to 5d. per lb., and preserving fruit should generally bring 3d. to 4d. and 6d. per lb., according to the crop. An acre planted 3 feet

apart by 2 feet will yield about 1000 lbs. the first season if the ground is rich and the plants are specially prepared before planting, increasing to 3000 lbs. the third year. These should be worth £50 clear money at an average estimate for well grown fruit, but as actual facts are the surest guide I will give the returns from half an acre of Strawberries which I had to assist in marketing in 1882. From a piece of good rich and deep land not quite half an acre in extent 1501 lbs. were gathered; these realised from 3d. to 1s. per lb., and averaged 6½d. per lb. (nearly), the total amount obtained being £39 13s. 4d. for the half acre. The estimated average cost of labour for the year was £14 19s. per half acre; this gives a profit of £49 8s. 8d. per acre for freehold land; the season was a very showery one, market was two miles from the place of growth, the sorts were chiefly Vicomtesse, Burghley President, Sir C. Napier and Oxonian, and the age of the plants varied from one to three years, so that this may fairly be taken as an average result under high cultivation. After the third or fourth crop has been taken (according to the soil and condition of the plants) it is better to chop up the plants and plant afresh. When all the crop is gathered, if the weather is not too hot and dry and the runners are not wanted, the mulching should be cleared off. If left too long around the plants the labour of clearing off the runners is increased tenfold, as they soon obtain a strong root hold in showery weather, and weeds also grow fast. An old sickle or similar hooked knife should be passed round the plants to take the runners off, leaving every leaf entire on the old plant. The straw and runners, &c., should then be collected and burnt, and the horse hoe worked through to loosen the surface and keep down weeds as often as necessary.

**INSECTS, &c.**—The enemies of the Strawberry are not numerous, and may be generally included as snails, mice, or birds. The two former must be searched for and killed, and the latter frightened away or kept off by means of netting placed over the plants. In large open plantations a youth with a gun should be able to keep them away if on the spot from daylight to dark.

**VARIETIES.**—The best market varieties for profit at the present are Laxton's Noble, Burghley President (this will not do in poor dry soils, but is one of the best where the soil suits it), Sir Charles Napier, Sir Joseph Paxton, and Oxonian. They are mentioned in their order of ripening, but, as stated at the commencement of this paper, it is not possible to give a list of Strawberries that will succeed everywhere, as different soils affect them very much, but with the exception of Burghley President I have never known any of the above sorts to fail, either in the north, south, or midland districts.

**MANURE.**—To obtain large fruit that will sell readily plenty of manure is necessary. That from a cowyard is the best, and if a good dressing of twenty tons to the acre is given before planting they will not, as a rule, require any more for the three years they are growing; but if they show signs of becoming weak a good dressing of guano may be given early in spring before the flower trusses appear, and the hoe worked over after to cover it in as soon as possible. Sewage is one of the best manures to secure large Strawberries, but should never be applied after the flowers commence opening.—W. H. DIVERS.

(To be continued.)

## VIOLETS.

WHILE agreeing with "I. M. H." that for market purposes a great number of varieties is a mistake, I think that he errs in the opposite direction by recommending growers to stick to only two sorts, Marie Louise and Comte de Brazza. After an experience of many years I may safely say that the pale lavender-coloured De Parme is quite as indispensable as the other two named above, and with ladies, as a rule, a much greater favourite. Another beautiful form of the Neapolitan is Madame Millet, rose coloured with a white eye. This has the true Neapolitan fragrance, and looks very well by lamplight, which is not the case with purple-shaded Violets. The above four sorts are free growers and bloomers, and "will pay;" but among the numerous readers of this paper comparatively few care about the "will pay." The true florist does not measure his satisfaction by the £ s. d. standard. His "pay," and it is good pay too, is the delight of witnessing the wonderful variety of form and colour which Nature contains in her inexhaustible storerooms. Gold and silver will not purchase the intense interest and delight which he experiences when, after much entreaty and waiting at the gates of her house, she is induced to thrust forth some new bewildering form of an old familiar plant. No amount of argument will ever convince a true lover of Nature that he can have too many good varieties of one species, be they Roses, Carnations, Orchids, or Violets. So, as I am writing about the last-named, let me mention a few other double varieties that are well worth growing.

First among the Neapolitans there is the true old palest lilac sort, with many still the first favourite, as there is no other quite of the same

delicate tint. Duchess of Edinburgh is perhaps the nearest approach to it, and comes next in order of interest. New York is another, somewhat like Marie Louise, but a trifle darker and rather a stronger grower. All the above require the protection of a frame in winter to see them at their best. Among the hardier double varieties which bloom well in the open ground are Patrie, an all the year round Violet, of a deep purple colour; in a damp summer like the present there are always flowers to be found on it, and every other month in the year, autumn, winter, and spring. Belle de Chatenay cœrulea and Carter's Mazarine Blue are also fine dark blue Violets which bloom in spring only. Victoria (Chambers') is perhaps the finest of this class, and it has the merit of blooming freely after the frame Violets are all over; the colour is a brilliant deep blue, and the flowers are produced in great profusion. Blandyana is another very distinct variety, striped red, white, and blue. Double red Russian is also interesting. There is no really good double white Violet except Comte de Brazza. Belle de Chatenay and La Reine are only called white by courtesy, being nearly always much tinted with purple. Among single Violets I can speak most highly of Willsiana, sent out some few years since by Mr. Charles Turner; it is the earliest to bloom of all the single purple sorts, and the flowers are very large, well shaped, and fragrant, with fine long stout stalks. Other good purples are Czar, Russian, Victoria Regina, and Odoratissima, the last named the bluest of all, and very fine late in the spring. I have one or two sorts of singles obtained from a French raiser, which are very fine, especially Sans Pareille and Gloire de Bourg la Reine, the latter a very beautiful clear blue colour. The best white is White Czar. The reddest Violet is Odorata rubra, very rich deep rose. A perpetual bloomer is Argentæflora, purplish white. As to cultivation no one can do better than follow the directions of "I. M. H."—R. W. BEACHEY.

#### DEATH OF MR. WILLIAM HOLMES.

WITH the deepest regret we have to announce the somewhat sudden death of Mr. William Holmes of the Frampton Park Nurseries, Hackney, and Honorary Secretary of the National Chrysanthemum Society. This sad event, which will come as a most painful surprise to a large number of readers, occurred on Thursday morning, September 18th, after a few hours' illness, for Mr. Holmes was attending to his business on Wednesday morning. It was known to his friends and to some members of the National Society that he had been suffering from diabetes for several months, and last year he had a severe illness, but of late he had seemed to recover his usual energy, and he returned early in September in excellent spirits from a holiday spent with his family at Lowestoft, to complete the arrangements of the Chrysanthemum Centenary Festival, and to undertake the management of the September Show of the National Society at Westminster. Numbers of his friends who saw him at the last named Show heartily congratulated him upon the apparent improvement in his health, and hopefully anticipated a busy and pleasant season in his company, wishes that were doomed to be unfulfilled.

Mr. Holmes was just in the prime of life, being only thirty-eight years of age; he had for a number of years taken a prominent place in the horticultural world, and was widely known and respected. In early manhood he succeeded to the charge of his father's nursery at Hackney, and speedily gave proof of his ability as a practical horticulturist and skilful manager by considerably developing its resources. He applied himself specially to landscape and contract work, and acquired an excellent reputation for taste in design and promptitude in execution. Several of his more recent works have been referred to in this Journal, notably the garden in connection with Dr. Barnardo's Homes in Essex, and the Vauxhall Park, of which a plan was given on page 21, July 10th this year. On the occasion of the opening of the Park just named Mr. Holmes had the honour of being presented to the Prince and Princess of Wales by the Princess Louise, and was personally complimented upon his share in the work.

It was chiefly in his connection with the National Chrysanthemum Society, however, that Mr. Holmes was known to the horticultural world generally, for to this Society he had devoted a large share of his time and attention, and what may be termed the modern history of the Society is really a portion of Mr. Holmes's career. In the year 1877 the Borough of Hackney Chrysanthemum Society required an Honorary Secretary, and to this post Mr. W. Holmes was elected, with the result that an energetic course of action quickly changed the character of the Society, and rendered it of much more than local importance. The shows were removed to Westminster, and in a few years the number of members rose from fifty-two to 200 in all parts of the country, which amply justified the adoption in 1884 of the title "National." A vigorous policy has maintained the progress, and at the present time there are upwards of 700 members, while the income of the Society is something like £900. Two provincial shows have been held, one at Sheffield, and the other at Hull, a Floral Committee

was formed, a catalogue of Chrysanthemums was issued, and in several other ways the "National" has endeavoured to render useful service to the growers and admirers of Chrysanthemums. It is only just to say that most of these ideas originated with Mr. Holmes, and he assisted very greatly in their development. His counsel and guiding power will indeed be sadly missed in the deliberations of the Committee. Few but those who have been intimately associated with him in the work of recent years can adequately judge the time and thought he devoted to the various details and projects. He was thorough in all his undertakings, and he spared no personal effort to ensure success.

Recognising the valuable assistance rendered to the Society by Mr. Holmes, a fund was raised in 1886 for the purpose of according him some recognition, and at the annual dinner of that year he was presented with an illuminated address and three silver epergnes, when Mr. Sanderson referred in feeling terms to the career of his friend. It had already been suggested that the Centenary Celebration would have been a fitting opportunity for another presentation, as he had seriously talked of resigning at the end of the year duties that were undoubtedly imposing too heavy a strain upon his health.

Mr. Holmes was a devoted horticulturist, a Fellow of the Royal Horticultural Society, a member of the Floral Committee of that Society, and a frequent judge at autumn shows; but he did not confine his energy to these, for he took a prominent part in local affairs, was chairman of a political association; in 1888 he was elected Chairman of the Overseers for the parish of Hackney; he was also connected with a building society, and had taken office in the Freemasons.

Our friend has left a widow and six children to mourn the loss of an affectionate husband and father, and many associates who will unite in the heartiest sympathy with them, have also to regret the loss of a true friend and a worthy man.—LEWIS CASTLE.

#### CHRYSANTHEMUM MADAME DESGRANGES.

AUGUST and September are two months when flowers for the conservatory are scarce, and although this defect may be somewhat made up by using foliage plants, still they do not wholly make up for a sparsity of flowers, neither do they command the admiration, especially from the ladies, that flowers do; therefore, plants that will develop their flowers during these months, and that will bear the ordeal of a cool airy conservatory with impunity, are of great service, and is sure to be appreciated. Chrysanthemum Madame Desgranges, and its primrose-yellow sport G. Wermig, have been in cultivation for some years, but it is not grown to the extent that its intrinsic merits entitle it to be, neither is it often met with grown to a very high state of perfection. Its habit is free, dwarf, and bushy, and a plant 2 feet 6 inches high, with twenty-four shoots carrying as many perfect flowers, is a thing of beauty at any time, but particularly so during August and September when arranged in the conservatory amongst plants which at that time are so totally distinct.

To grow these Chrysanthemums into good bushes for the above purpose, strong cuttings should be secured about the middle of October, preference being given to those springing from the roots, and place them singly into small thumb pots, using loam, leaf mould, and sand in equal parts. Plunge them in a half-spent hotbed, and keep them close until rooted, only admitting sufficient air to dispel superabundant moisture, and thus prevent damping. When rooted, they should have abundance of ventilation during favourable weather, and keep them near to the glass, so as to induce a short-jointed, stocky growth, nothing being so detrimental to Chrysanthemums as "coddling" at any stage. Grown under airy, bracing conditions, they will bear a few degrees of frost without injury, and although the growth will be slower, yet in the spring the plants will possess far more stamina than those grown under close, warm conditions, and may, moreover, be placed out of doors a month earlier in spring. When the plants have grown about 6 inches pinch off 2 inches; this will induce them to throw out a number of side shoots. Select three of the strongest, and rub off all the others. At this stage, which will be the end of November, they will require placing into 5-inch pots, using a compost of three parts fibry loam, and one part each of well decayed manure, leaf mould, coke, and sand, adding one quart of bonemeal and soot to each bushel of compost. They should be potted firmly and returned to a cold frame with a south aspect, if possible, and as the days are short and damp they will not require keeping close, neither will they require watering for at least a fortnight, and every opportunity should be taken to give air, and on mild days to remove the lights entirely. During very severe weather the lights may be covered in the usual way, but, as before hinted, a little frost will not hurt the plants. Damp, however, must be expected during the dull days of winter, but this can be largely obviated by making a wooden slatted stage for the frame, and arranging the plants on it near to the glass, giving them plenty of room. Watering also should be attended to during the early part of the day. Early in February the shoots should again be pinched back and two growths selected from each, which will give six shoots to each plant. Early in March place them into their largest pots, using 8-inch size for the smallest plants, and 9-inch for the largest. Employ the same compost as before, only in a rougher state, with a few half-inch bones mixed with it; also put a layer of half-inch bones and soot over the drainage. If the compost is in the right state—that is, not so wet as to remain in a sticky ball, or too dry to show the impression of the fingers when squeezed in the hand—it is impossible to pot Chrysanthemums too firmly; it induces a short-jointed, sturdy growth, which invariably results in good flowers, other things being equal. Good drainage is also essential, and 2 inches should

be left for a rich top-dressing as soon as the buds are set. As the days lengthen they will make rapid growth, and by the middle of March the shoots should be again stopped, and two more growths secured from each. This will give twelve shoots to each plant. Early in April they may be stood out of doors in a sheltered place, and the shoots secured to thin stakes. Those plants required for flowering early in August should have their shoots stopped early in May, and those for flowering in September a month later, and in both cases select, as before, two growths from each shoot, and rub off all the others; each plant will thus have twenty-four shoots.

When the pots are full of roots the plants should be watered with weak liquid manure, made either from the farm tank or from animal manure, with a little soot added. When the flowers appear remove all except one on the point of each shoot, for plants in 8-inch and 9-inch pots will not develop more than twenty-four blooms to perfection—indeed, they will not do that unless they have been well managed throughout. Each shoot should be secured to stakes reaching about 5 inches above the point of the last break, and top-dressed with equal parts of mellow manure and loam. Gradually increase the strength of the manure water, and continue giving it to them until the flowers show colour, for there is little fear of “damping” when plants are carrying this number of flowers. Just before the flowers unfold remove them to a light cool airy house, as the wet and wind out of doors often soil the blooms and hasten decay. If any of the plants are required for cutting purposes about four buds should be allowed to expand, as although they will not be large perfect blooms they will be found more serviceable for arranging in stands.

Aphides and mildew are sometimes troublesome on Chrysanthemums, but are easily destroyed by syringing with the following mixture:—2 ozs. soda, 4 ozs. softsoap, 2 ozs. petroleum oil, and twelve gallons of water thoroughly mixed, and used at a temperature of 100°. It is a good practice to use this mixture just before the flowers unfold, even if there are no signs of insects, for it often happens that there are invisible germs of insect life lurking about the plants, which only requires the more confined conditions of the conservatory to bring them into activity when it is too late to grapple with it. Many promising Chrysanthemums have come to an untimely end through not taking this simple precaution before housing them.—J. H. W.

## CULTURE OF THE PEACH AND NECTARINE ON OPEN WALLS.

[A paper read by Mr. Robert Smith, of Yalding, Kent, at the meeting of the British Fruit Growers' Association, Brighton, September 11th, 1891.]

HAVING been a successful cultivator of these grand old fruits on open walls for the past twelve years, I propose to speak first of the Peach. The Peach is generally considered to be of Persian origin, and is supposed to have been carried into Egypt during the reign of Cambyses, then into Greece, and after a lapse of time into Italy, where it only became known about seven years before the Christian era. The native country of the Peach is, however, still a doubtful point, and as such I may pass it over. It is extensively grown, with frequently but limited space of cultivation, between latitudes 30° and 40° in Asia, Europe, and America. Under particularly favourable circumstances it will succeed considerably beyond these limits, but as its deciduous nature requires a period of rest it is not fitted for a tropical climate. On the other hand, beyond latitude 48° the ground is too cold for its roots, and it will not long continue to thrive unless budded on some hardier species. The Peach also requires the shelter of a brick wall in this country and other protection.

If the summer is hot enough to ripen the wood it will stand a severe winter uninjured in localities where the mean temperature of February is 40°, and that of March 44°. The Peach tree will be in full flower against a south wall the last week in March, but often earlier on warm—that is, dry soils; and if the mean temperature of April is 49°, that of May 55°, June 61°, July 64°, and August 63° the season may be considered a favourable one. The early Peaches will begin to ripen about the middle of July, or a little earlier or later according to the season, whether early or late; and if the trees have been well cared for the fruit will acquire a high degree of perfection.

Our south walls at Kenward are rather extensive, and are 14 inches thick and 10 feet high, are well built, and have an 11-inch board at the top, resting on iron brackets; these boards are easily removed, and are taken down every year about the end of May, and put up again about the end of October. These are the only protection the wall trees get during the spring months while the trees are in bloom, and afford sufficient protection in our case against spring frost, and have done so for the past twelve years. We have not failed to get good crops of the Peach and Nectarine every year of the twelve years mentioned.

In planting a young tree I have about fifteen tiles similar to those used on buildings, placed at the bottom of the hole where the tree is to be planted, and upon these tiles the tree is placed for planting, and then the hole filled up with good maiden loam cut twelve months previously, the soil well trodden in and made firm.

A good mulch of decomposed manure is placed over the top, and then well watered. I prefer the first week in November for planting if the weather is suitable. The shoots of the tree planted should not be fastened to the wall for some time, but in case of high winds the top part of the shoots might be fastened to the wall. But if no danger from winds is apprehended I much prefer the tree left unfastened in any way. In the spring following the planting of the tree the shoots should be nailed to the wall their full length (not cut back as in the olden time); when growth commences in April, take care the new shoots are kept free from insects, upon this being done the future health of the tree depends, and I have no hesitation in saying that many cultivators fail here. Continue to keep the growth of the tree healthy, and towards the middle of April—assuming the newly planted tree is in good health—disbudding might commence by taking the foreright shoots away, and a few from the top part of the shoots. The cultivator should endeavour to have the shoots from the base of the shoots nailed in in the spring to fill up the spaces—the wood for the future use. These spring shoots to be retained for the building up, as it were, of the tree might be kept fastened from time to time to the wall, otherwise high winds are apt to bruise or break off the tops, and sometimes disfigure the tree entirely. Encourage a good growth by all means possible, but it must not be over-vigorous. No liquid manure should be applied the first year. If the tree is healthy it will make sufficiently strong growth. Medium growth is the best for fruiting—this I have proved in trees of all ages to be the best.

Having shown the planting and after-management of the young tree, I propose to deal with older trees, trees of bearing size. The same difficulty occurs in spring with the spring shoots; if these are not kept clean and free from insects the future well-being of the tree or trees is impaired, and so much depends on management that I cannot too strongly enforce this upon the notice of young cultivators who may have other pressing work to do at the same time, not to neglect the Peach trees on open walls, for in a day or two if left unattended insects might cause much injury to the young shoots.

I remove more fruits at the first thinning than many cultivators, in fact I thin early in May, and leave only the number required for a crop. Select the shoots for laying in during the month of July for the future crops of fruit. Many cultivators lay in too many shoots, which is quite a mistake, and yet many do it yearly. So much depends on this operation, that I propose to explain a little here. Take only the best placed shoots, and only the medium sized ones, leave space of 6 inches between each shoot, or nearly so; this space may appear to many too much, and particularly when the cultivator has plenty of good wood to lay in he is often tempted to lay in too much, this is where the mistake is made; 6 inches of space will not be too much for the well-being of the wood or shoots. These shoots must be well ripened before winter, and the 6-inch space between each shoot helps very much to ripen these shoots; the sun and air can reach the surface of the wall to warm the bricks. Every shoot laid in ought to be required for the next crop. My opinion is that much of my success in the cultivation of the Peach and the Nectarine has been through having the wood well ripened.

A few words may now be said about the fruit—that is, the crop that ought to be taken. I find one fruit to every foot of surface of wall to be the right guide, a few more or a few less according to the vigour of the trees. If the trees have been kept clean and free from insects the early Peaches will begin to ripen about the second week of July. I find Waterloo to be an early one, and it does well with us, also Alexander, and then Early York; then comes Hale's Early, which is an excellent Peach for open walls; then I have the latter variety upon a west wall, to come in after the one on the south wall, otherwise I had a break between Hale's Early and Royal George; then Bellegarde and Dr. Hogg; and next comes that highly flavoured Peach, Noblesse; then follow the later varieties, such as Barrington, Late Admirable, and Princess of Wales. We keep up a supply of Peaches daily from July to October. This, of course, can only be done by having a good run length of wall, we have about 200 yards run of south wall at Kenward. If an amateur wishes to grow a few Peaches I should recommend him Waterloo for early, Hale's Early for succession, and Noblesse for midseason variety, and Princess of Wales for a late crop. Nectarines—Lord Napier as early, Rivers' Advance, Elruge, and for a late one, say Pitmaston or Pine Apple.

When the fruit of the Peach and Nectarine begins to ripen the leaves that shade the fruit should be fastened away, so as to expose the fruit to sun and air, or part of the leaves might be pinched off. It is good practice to begin early at this work, before the final swelling of the fruit takes place. I find fruit that has been exposed all through the season are much higher colour, and stand the rough weather better than those fruits not so exposed. Colour is very desirable in Peaches and Nectarines.

It is very important to keep the trees healthy year after year by taking reasonable crops of fruit and wood. The shoots should be well ripened by November. If a spell of dry weather occurs in May, or June, or July, water should be applied at the roots, particularly at the foot of wall, where many useful roots will be found. A few cans of water might be applied there three times a week while the dry weather lasts. I need scarcely say that the water should have been exposed to the sun before being used if possible, and should a long spell of hot weather come a thorough soaking must be given over decayed farmyard manure as a mulch that will help to keep down red spider very much. A space of 3 feet from the wall should be kept firm, not dug at any time, only pricked over and kept free from weeds. I like a little short manure or leaf mould always upon this 3 feet space winter and summer. One more important point is when the leaves begin falling, say early in October, I have all the leaves cleared off and taken away: this exposes the wood for hardening and has more chances of being ripened.

The failures in the cultivation of the Peach and Nectarine of recent years are probably due to the fact that the same care and attention are not bestowed upon the trees upon open walls, as was the case many years ago. Cheap glass has done much to increase the early crops of Peaches, but very few establishments can keep up a daily supply of Peaches from the middle of July until October, as we do, not even with the help of glass houses. A Peach tree with eighteen dozen finely coloured fruits, and every fruit of even size, is a sight long to be remembered; this we have had every year for the last twelve years at Kenward, and during these twelve years there have been many bad seasons for the cultivation of the Peach on open walls. If strict attention is paid to the cultivation the Peach can be as well grown in many places in the south of England as ever it could. This I have proved; but practice and science must ever go hand in hand to insure the best results.

#### INSECTS.

The green and black aphides are often very troublesome in the spring months upon the young shoots of the Peach trees, and unless means are taken to destroy them, these insects will soon injure the growth of the shoots, and if neglected for a very short time will destroy the young shoots. At this stage many cultivators fail with the Peach tree, for if the spring shoots are lost, as very often they are, the cultivator has to wait for the midsummer shoots, which never ripen sufficiently to mature flower buds for the following year. I dwell on this subject, knowing so well that many cultivators fail with the spring shoots. Our Peach tree growth for the season is complete by midsummer, or nearly so; the consequence is, there is length of season to ripen the wood. I am fully convinced that many failures occur from neglect of taking strong measures during the spring months. Curl of the leaves of the young shoots in the spring is often injurious to the growth, but must be removed daily—that is, pinched off and taken away and burnt. Very often an enlargement of the young shoot or shoots will occur from this disease, known as "curl." It is often caused from unripened wood, and sometimes from the ungenial spring weather, and troublesome, more noticeable in some varieties than others. For instance, we have it more in the variety Dr. Hogg than any other with us; but I am in hopes, as the tree becomes older and the wood more ripened, to be rid of it altogether. I clear away all shoots affected with blisters if possible in July, when we make the final selection for laying in the following season's wood.

For destroying the green and black fly we use tobacco powder only, as I strongly object to any liquid at this season for the Peach tree. In fact, I never use any liquid insecticide for the Peach or Nectarine because of the stains these leave on the fruit, and particularly the Peach, which is of a woolly nature in a young state. I caution young cultivators against using liquids in any form if there is any fruit worth considering, either of the Peach or Nectarine.

Red spider is very destructive to the foliage, and if not checked early will soon cause the leaves to fall, and consequently the trees will collapse altogether if the pest is allowed head-way. Syringe with clear soft water every afternoon for a time.

Woodlice are very troublesome. They can be trapped and destroyed. Again, earwigs are most troublesome. I find bean stalks, cut into lengths about 9 inches, placed in and about the branches, and blown through every morning into boiling water, will soon get rid of many of these. I find them more troublesome to the Nectarine than to the Peach, but they are a pest to the fruit of the Peach when ripening, spoiling the face of the fruit if not caught. Often in looking round the trees with a lantern after dark I find the earwig busy eating away the face of Peaches and Nectarines, and the best fruit will be spoilt by them if not caught and destroyed early in the season.

The worst enemy is, I think, the wasp. These noxious insects are very destructive to the Peach, and also to the Nectarine, when ripening. This season we have destroyed 233 queen wasps, and taken 97 wasps' nests up to date—within flying distance of the fruit gardens, many of them in the park meadows and hedgerows of the estate. We wage war against them with a determined spirit, but still they come. Let me give cultivators of the Peach and Nectarine on open walls one more piece of advice; that is, to find out one good cultivator, and visit him during the spring and summer months. I am convinced that much good is done by cultivators visiting each other during the different seasons of the year. If a cultivator in any district can grow the Peach and Nectarine successfully for twelve successive years on open walls, others should be able to do so, remembering that constant attention during the spring and summer months is required.

EVENTS OF THE WEEK.—A meeting of the General Committee of the National Chrysanthemum Society will be held in Anderton's Hotel, Fleet Street, on Monday next, September 29th, at 7 P.M. Business of a very important nature will have to be transacted, and a full attendance of members is desired. At King Street, Covent Garden, and Chancery Lane the usual sales will be held during the week.

— THE WEATHER around London still continues favourable for the time of year. More rain has fallen however, and on Tuesday a rather severe thunderstorm was experienced, accompanied by heavy rain, in the afternoon. The temperature has been high, and the sunny weather is having a good ripening effect on fruit trees.

— THE funeral of the late MR. WILLIAM HOLMES (whose death is recorded in another page) took place on Wednesday last at the Abney Park Cemetery at 3 P.M. There was an extremely large attendance of friends from Hackney, and the National Chrysanthemum Society was well represented by members desirous of paying the last tribute of respect to their able officer. Many handsome floral wreaths were contributed privately, and on behalf of the various societies with which Mr. Holmes was connected. At the meeting of the Royal Horticultural Society's Floral Committee on Tuesday it was unanimously resolved that a message of sympathy and condolence be sent to Mrs. Holmes, in which the members expressed how deeply they regretted the loss of their late associate.

— REPORT OF THE EDINBURGH PLUM CONGRESS.—We have received a copy of the report of the Plum Congress that was held in Edinburgh in September, 1889. It is a closely printed, admirably compiled, and well edited work of 164 pages, and reflects at once the practical and literary ability of Mr. M. Dunn. Selections are given by cultivators of the best Plums for different purposes and districts in Scotland, England, and Ireland, and valuable information is scattered throughout the work. We shall probably refer to it again, and in the meantime ask Mr. Dunn and his coadjutors to accept our best congratulations. The report is published by Messrs. Neill & Company, Edinburgh.

— MALTESE APPLES.—I send you a sample of one of the four varieties of Apples grown in Gozo and Malta. They are cultivated principally in Gozo, and entirely for home consumption, being never exported. I am informed that although four kinds are recognised they are probably reducible to two only. The Apple is called Toffich in Maltese, and the four sorts are—1, Toffich abiat, having a small yellowish fruit of fair flavour; 2, Toffich ta Gian Mattia, yellowish streaked with red, of a rich aromatic flavour, the pulp being spongy; 3, Toffich ta Billudia, greenish with red stripes or blotches—it is seldom eaten raw, and is the variety sent; 4, Toffich ta regina, the Gozo Apple. This is a small very hardy tree, producing large fruits, yellowish green splashed with red. The flesh is greenish white, fine grained, mildly sub-acid and aromatic. The season for Apples is from September to November, and the price from 1d. to 2½d. per pound.—GEORGE HENSLOW. [The Apples are too deficient in sweetness and aroma to be of value for dessert, and they are also wanting in the acidity essential to culinary Apples.]

— UNDER date September 20th, a friend sends the following NOTES IN THE MIDLANDS:—"We have some fine Chrysanthemums, plenty of buds now as large and as hard as nuts. I am taking all the terminal buds on promising plants, but shall leave some plants most of their own way, as we want a show as well as specimen blooms; also some dozens of trained plants, showing a mass of bloom and fine dark foliage through using Thomson's manure, which I most prefer to liquid manure, as it does not encourage rank growth. In the conservatory is a sight worth seeing—viz., a large Bougainvillea glabra, fully a cartload of bloom is hanging from the roof; but for surpassing anything I ever saw is a plant of Gloriosa superba climbing about the stove roof, which is greatly admired by everyone; also some good Tydeas, very pretty and well worth anyone's care."

— "PINES have been very irregular this year, through our having a weak supply of fruiting plants, but the fruits from the increased space have been very fine, and the quality very good, this being remarked at headquarters. In our new Peach and Chrysanthemum house we have some fine Peaches, Nectarines, and Pears. The latter are very bright in colour. They have done well, and are still doing good service for garden parties; and we have also good Tomatoes, somewhat late, but they have fruited well; and the Chrysanthemums will come in shortly. In the late vinery we have extra good Gros Colman Grapes, berries fine and well coloured; but a new one, Mrs. Clarke's Seedling, is much its superior, equally as good in berry and bloom, very heavy, similar to Madresfield Court. We have had to protect the Grapes from wasps; the fruit houses completely swarmed with the pests, and although we have destroyed over forty nests, still they seem as plentiful as before. I found a strong hornets' nest in a hollow tree the other day. The creatures are very savage and soon give the alarm, making a peculiar buzz, and dart about with great force, but a strong fuse will quiet them down, taking precautions as to the outlet."

— CHIPPENHAM COTTAGERS' SHOW.—Having read Mr. Challis's commentary (page 258) on the excellence of the above Exhibition, I for one congratulate Mr. Challis on having the moral courage to recommend the earth system, and a direct application of all household refuse to the fertilisation of the soil. No doubt the general health and wealth of many village communities would be improved in the first instance and increased in the second by an intelligent use of the above means of sanitation. When thoroughly dry earth is used it is the most perfect sanitary arrangement known. This, with the ashes from a fire for weeds, trimmings, and other substances that decay slowly, would be generally sufficient for the fertilisation of most cottage gardens. The poor man's pig seldom has room enough, is generally a nuisance, and the gain from keeping him usually a myth. An intelligent bricklayer told me after having fattened a good pig, and counting the cost, he found his bacon cost him 2s. per lb.—R. MAHER, *Yattendon Court*.

— FRUIT AS FOOD.—As the question of hygiene is now "in the air" it will, we may hope, soon be applied to our food. The present is a very seasonable time to suggest the study, with careful experiments of fresh ripe fruits and nuts as food. These most enjoyable products are being found at least as profitable crops as any that can be grown, as our native fruit of some sorts thrive in every soil; and if juicy and fresh they become often also all-sufficient as a beverage for all kinds of work. There seems, therefore, every reason to hope that a more general use of fruit as food would enable us as a nation gradually to eat ourselves out of our agricultural difficulties, and also very materially to benefit the general health. I shall therefore be glad to forward to all sending an addressed wrapper and two stamps some literature recently issued, "Hints on a Fruit Diet," and also a tract on "Bottling British Fruit," by which fresh fruits can be enjoyed all the year round. As we are now on the eve of a very prolific crop of Blackberries these would prove probably to be the most suitable of all to make experiments with in "canning," as the Americans style it, as well as to lay the foundations possibly of a new industry for rural districts, for our Blackberry crop rarely fails us anywhere.—W. S. MANNING, *Woodlands, Vanburgh Hill, Blackheath, S.E.*

— PREPARING FOR THE WINTER MOTH.—Mr. Joseph Masters contributes the following note to the *Evesham Standard*:—"As the season of the year is approaching when the winter moth will be making its appearance, a few hints by way of reminder to fruit growers may not be out of place. The wingless female moth will soon be making its ascent of the tree to deposit its eggs for the future brood of caterpillars. The best-proved method of intercepting the moth is to band the trees with cartgrease. Buy none unless guaranteed as free from

tar. Numbers of young trees have been killed by injurious compounds sold as grease. Do not use oil in the grease to make it thin. If the daub is stiff it will last the longer. It is important to have it sticky, and look after it and keep it so, otherwise the moth will creep over it. If trees are young and the bark is smooth and tender, some grease-proof paper should be tied next to the bark of the tree, and the daub placed on the paper. If trees are matured and the bark is rough good grease will not injure the tree. Trees where grease-proof paper is used will not require so much grease, as the paper prevents the bark from absorbing it. If all the trees were banded with paper it is probable that the saving of the cost of grease would be an equivalent for the cost of paper banding. Grease may be applied with the hand or a thin flat piece of wood or a small brush; in either case put on a thick layer of the grease. Grease banding should not be delayed after the second week in October, and will require attention until the end of November. The appearance of the moth may be known by taking out a light in the dusk of the evening, when the male moth, if any are present, may be seen. If no male moths are seen you need not trouble to grease-band the trees. Do not be discouraged if, after all your pains, some caterpillars are found; when numerous they are not to be exterminated in one season."

— ORCHARD INSECTS.—As the time has now arrived again for adopting measures to check so far as possible insect enemies on fruit trees, no time should be lost in commencing operations, as the winter moth will shortly appear. The earliest date which I have seen the male flying about is October 8th, a fact which points out the necessity of getting all greasing of the stems completed by the first week in next month. Two years ago we greased all our young trees (dwarfs) without any good results, causing me to have a poor opinion of such a method. Vast numbers were caught in the grease bands, but still sufficient females were conveyed into the trees by males to deposit numberless eggs, so that all this labour and expense was in vain. That grease bands are of little good on dwarf trees I have not much doubt, but in the case of standards the case is different, because the male moth has more difficulty in carrying the female into the trees. I have occasionally caught both sexes together as high as 6 feet, but as a rule they do not fly more than about 3 feet high. I have spent many an hour with a lantern watching their proceedings, which was the means of my being the first to discover how the female moth managed to get over the grease bands to deposit hundreds of eggs on the tree. As above stated, this is not such an easy matter for the moths to accomplish in the case of standards, and that grease bands are of great importance was very conclusively proved at Toddington this last spring. In this instance one tree was accidentally missed, the other trees all round being greased. The result was that the foliage was completely eaten by caterpillars, whilst its neighbours were scarcely touched. I think it a good plan to put two bands on—one near the ground, and another just below where the head begins, as if they escape the one they are very liable to get in the other. It cannot be too strongly urged that no grease be allowed to come in direct contact with the bark of young trees, as serious results will follow from the grease choking up the tissues. A band of strong or grease-proof paper several inches wide should be tied both at top and bottom, and on that the composition spread of just sufficient thickness to prevent it running off on the bark. Put on in this manner no insect will escape alive that gets in it. After storms, and also occasionally dead insects, will render it necessary to regrease, as the bands must be kept sticky till the last moth has disappeared. If once the eggs are laid in the trees it is a difficult matter to save them from injury, as caterpillars will certainly appear. Fruit trees look splendid for another year. Let us hope for better fruit crops and less trouble with insect pests.—S. T. WRIGHT.

#### THE LATE MISS MARIANNE NORTH.

SOME particulars concerning the travels of the late Miss North were included in a recent brief paragraph recording her death, but the full account, from the *Richmond and Twickenham Times*, is so full of interest, that we have reproduced it here.

There are perhaps few residents in Richmond and Kew of those who have ever set foot inside Kew Gardens who will not experience a more or less keen sense of regret in learning of the decease of Miss Marianne North, the creator and donor of the North picture gallery. This unrivalled collection of oil paintings are, without exception, the work of the deceased lady herself, and are displayed in a building which was erected entirely out of her own expense. They illustrate the flora of every quarter of the globe in astonishing variety, and incidentally not a little of the fauna as well, conveying also in many cases much graphic illustration of geological features and of spots of historic interest. They

combine to an astonishing degree scientific accuracy in the minutest detail with a keen appreciation of beauty and artistic effect. The flowers and leaves seem in many cases to actually stand out from their backgrounds with a vivid reality which almost deceives those most familiar with them. Perhaps a greater marvel even than the character of Miss North's work is the fertility of her brush. The many hundreds of paintings in this gallery were all executed within the space of fifteen years, a large portion of which time was occupied in travel, every exhibit having been completed directly at the scene which it represents.

Miss North was born at Hastings in 1830. Her father was Mr. Frederick North of Rougham in Norfolk, who successfully contested the Parliamentary representation of Hastings in the same year in which his daughter Marianne was born, and in after years Miss North was wont to say that her earliest recollection was that of the reform dinner at Hastings. The family was one of some little note both in politics and literature from the time of the second Charles. Her mother was the eldest daughter of Sir John Majoribanks. She was a child of precocious talent. "Travelling onward," says the writer of the article we have mentioned, "from childhood to girlhood, from girlhood to womanhood, Miss North, like most clever women of the last generation, owed much of her education to herself and little to her teachers." She was "gifted with a rarely beautiful voice and an admirable eye for colour and form, passionately fond of music, of flowers, of books, devoted to the study of natural history, taking an eager interest in all the developments of insect and animal life, in all form of vegetation." In her early years she devoted herself chiefly to the development of her strong musical abilities, but subsequently turned to painting, for which she displayed an even greater aptitude. A keen student of botany and other branches of natural history, she soon turned the exercise of her artistic faculties in this direction. Frequent continental travel with her family gave her much opportunity for these combined pursuits.

The years 1865 to 1867 she spent chiefly in Syria and up the Nile in company with her father, and the fruit of this journey was a series of Nile sketches, which received very high praise from competent judges. Mr. North died in 1869, and from this time onward his daughter appears to have devoted herself with absolute singleness of purpose to the development of art as the hand-maiden of science. In her own words, she made her brush the master of her existence. It was at this time also that she definitely abandoned water-colours as a vehicle for her work in favour of oils. In 1869 and 1870 she travelled and painted in Sicily, but it was not until 1871, during a journey in America and the West Indies, that she commenced to produce the series of paintings which now adorn the walls of the gallery in Kew Gardens. During the West Indian portion of this tour she spent more than two months in solitude in a lonely house amongst the hills. Returning to England she voyaged next year to Brazil, where she lived for several months in a deserted cottage in the heart of the primeval forest. On her way home she visited Teneriffe.

Her next flight was a still longer one, embracing the circuit of the globe through California, Japan, the Indian Archipelago, and Ceylon. The very rich store of artistic work which she brought with her created quite a sensation in learned circles, and her position in the world of science was thenceforth an established one. Especially noteworthy among her discoveries during this journey were the rare Javan Pitcher Plants, her illustrations of which induced Messrs. J. Veitch & Sons of Chelsea to at once send a special messenger across the world on a hunt for specimens. Setting out again in the same year, Miss North visited India. While she was away the collection of some five hundred of her paintings was on view at the South Kensington Exhibition.

It was after her return from India that she conceived the project of presenting her works to the nation. Needless to say her offer of them on this behalf to Sir Joseph Hooker was gladly accepted. Mr. James Fergusson, F.R.S., very kindly gave his services in drawing up designs for the building which was to contain them, and with which most visitors to the gardens are now familiar. The style is light and pretty, as well as suitable to the purpose, and it is considered one of the best lighted buildings of the kind in Europe, daylight being admitted, not from skylights, but from small windows placed close under the roof, after the ancient Greek models. By Darwin's recommendation Miss North next visited Australia, returning thence with a yet more wonderful series of paintings. She then devoted a year to the arrangement of her collection in the new building, which was opened to the public in 1882. A second room was added at the rear in 1883. Between that date and the present, Miss North made several more journeys to different parts of the world, constantly adding to the size and value of her collection, and it was while upon her latest tour, to the interior of South America, that she acquired the seeds of the long and trying illness which has now proved fatal. Here death took place at Wotton-under-Edge, Gloucestershire, on Saturday last, and her remains were interred there on Wednesday afternoon.

Sir J. D. Hooker thus commented on the value of Miss North's paintings in his preface to the catalogue:—"The unique collection of paintings of which the following pages contain an instructive catalogue, is, together with the gallery in which it is placed, a free gift to the Royal Gardens on the part of the accomplished lady-artist and traveller whose name the gallery bears. The pictures were painted by herself, on the spot, in the country indicated; and were arranged by herself in the positions which they occupy; and both the preparation and printing of the catalogue are due to her munificence. On the beauty of the collection it is unnecessary to dwell, and it is not possible to overrate its interest and instructiveness in connection with the contents of the

gardens, plant-houses, and museums of Kew. Visitors may, however, be glad to be reminded that very many of the views here brought together represent vividly and truthfully scenes of astonishing interest and singularity, and objects that are amongst the wonders of the vegetable kingdom; and that these, though now accessible to travellers and familiar to readers of travels, are already disappearing or are doomed shortly to disappear before the axe and the forest fires, the plough and the flock, of the ever advancing settler and colonist. Such scenes can never be renewed by Nature, nor when once effaced can they be pictured to the mind's eye, except by means of such records as this lady has presented to us, and to posterity, which will thus have even more than we have to be grateful for her fortitude as a traveller, her talent and industry as an artist, and her liberality and public spirit."

#### CLEVELLY, ALLERTON.

CLEVELLY, the residence of T. Sutton Timmis, Esq., is situated some three miles from Liverpool, and is one of the many places around Liverpool in which gardening is seen at its best in all departments. Having a few hours to spare I drove over to Allerton, and was kindly conducted through the houses and grounds by Mr. Cromwell, the head gardener. The houses are all of the most improved style, and have been erected of the best materials regardless of cost. Passing through the commodious potting shed we enter the corridor, from which nearly all the houses are reached. The corridor itself is furnished on one side with fine plants of *Plumbago alba* and *capensis*, *Chorozeas*, *Bougainvilleas*, *Tropæolums*, and other climbing plants, which clothe the walls and hang in festoons from the roof, the other side being devoted to plants in pots, *Coleus*, *Begonias*, *Pelargoniums*, &c., all of which make a capital display, whilst from the roof are suspended some fine baskets of *Achimenes longiflora major* and *alba*. The cool Orchid house has a teak stage on which are four rows of pots, comprising some hundreds of plants, the best varieties of *Odontoglossums* and *Masdevallias*, with *Epidendrum vitellinum majus*, *Sophronitis grandiflora*, and others. The front part of the stage is banked by *Begonias* and *Ferns*, and small ponds between give the house a cool appearance. Along the front of the house suspended from the roof are hundreds of pans of *Odontoglossum Rossi majus* and *Sophronitis grandiflora*, all the picture of health. Although not the best time to see the cool Orchids, still there was promise of a grand show of bloom in its proper season. *Odontoglossum cirrhosum* and *Epidendrum vitellinum majus* were flowering in abundance. A span-roof house comes next in two divisions, the first being occupied with *Muscats* of Alexandria at present carrying good serviceable bunches excellent in colour, the second with two fine Peach trees, *Royal George* and *Violette Hâtive*, which cover each side of the house, and which bear enormous crops of fruit each season. At the time of my visit the roots were being examined, and the border was being made heavier by the addition of a little clay to the compost. No. 3 is a vinery in two divisions, the first being filled with the *Black Hamburgh*, the second with *Alicantes* and *Lady Downe's* just finishing and carrying some good bunches fine in the berry. The borders in this house, as in the *Hamburgh* house, were extended last season, the result being good wood and healthy foliage, which should give a good return next season.

The next range entered is a span-roof stove in two divisions, the first having a choice collection of Orchids on the side stages, including capital *Calanthes*, numerous *Cattleyas* in variety and in the best possible health, *Cypripedium Curtisi* in flower, grand pieces of *Lælia anceps*, and splendid *Phalænopsis* on teak cylinders. The centre bed was occupied with fine exhibition plants of *Allamandas Hendersoni*, *Chelsoni*, *grandiflora*, and *nobilis*; *Crotons Evansianus*, *Countess*, *Sunset*, *Aureus marmoratus*, *Williamsi*; *Anthurium Schertzerianum*, 4 feet across; *Gloriosa superba*, and a very fine *Nephrolepis davallioides furcans*. Here, as in the first house, were noticed the plants which brought Mr. Cromwell into such prominence at the late Liverpool Show—viz., *Ixoras coccinea superba*, *Dixiana*, *Pilgrimi*, *Westi*; *Rondeletia speciosa major*, splendidly coloured examples of *Crotons Queen Victoria* and *Disraeli*, each 8 feet through; a fine specimen of that handsome Fern *Nephrolepis rufescens tripinnatifida*, *Davallia fijiensis*, 5 feet through, and other miscellaneous stove plants, the side stages being filled with Orchids, numbers of *Cattleya Trianae* bearing sheaths, stout and strong, from which a harvest of bloom may be expected; fine plants of *Cymbidium eburneum*, *Cattleya citrina* on blocks, *Peristeria elata*, a dozen plants of *Cœlogyne cristata*, comprising *Chatsworth*, *Trentham*, and *Lemoniana* varieties, and fully 3½ feet through, and the glorious *Lælia anceps grandiflora*, which has been figured in the gardening journals several times—on a raft 3½ feet by 3 feet, and showing abundance of bloom. In this house I noticed the following Orchids in bloom—*Cattleya aurea*, carrying twelve fine flowers; *Miltonia candida grandiflora*, fourteen spikes; *Odontoglossum grande*, a great number in bloom, with many more in various stages; *Oncidium ampliatum*, &c.

The *Camellia* house contained healthy plants well set with buds. Most certainly the feature of this house are the plants of *Lapageria alba* and *rosea superba*, which cover the whole side of the house, and at present bearing thousands of flowers. Here I noticed some good plants of *Imantophyllum miniatum*, *splendens*, *princeps*, *Milneri*, and *Marie Reimers*. Passing through the entrance proper to the houses (which contains a fine standard *Camellia*), and which is used as a smoke lounge, we come to the *Azalea* house. The plants are healthy and well set with buds, and there are some good plants of *Rhododendron Veitchi*

Passing outside we come to the forcing houses, the first the Tomato house, in which was a good crop of fruit. The Melon house had a good late crop, Mr. Cromwell speaking in the highest terms of Sutton's Scarlet Invincible, and certainly the fruit was very fine, with Sutton's Monarch and Hero of Lockinge. In the Cucumber house the latest had just been planted, and here I noticed some grand plants resting of *Dendrobium thyriflorum*, *fimbriatum oculatum*, *crassinode*,

King, and Marie Louise, and Duchesse d'Angoulême being the best. The pleasure grounds are well kept, and contain some fine specimen Hollies, a choice collection of herbaceous plants, and I was pleased to notice a fine bed of *Lilium lancifolium rubrum*, with hundreds of flowers, in a sheltered position on the lawn, and an oblong bed of *Lilium auratum*. Altogether the place is kept up in first-class style, and certain to be with such a man as Mr. Cromwell at the head of affairs. My

FIG. 32.—Mr. WILLIAM THOMSON (see page 263).

&c. A large roomy Peach case 90 feet long has been reared against a south wall. The trees are specimens of good culture. A few fruits of Barrington large in size and of good colour, and Princess of Wales, very good, were still on the trees, the other varieties grown being Royal George and Grosse Mignonne, and of Nectarines Lord Napier, Pineapple, and Violette Hâtive. The frames are filled with a good selection of Cyclamens, Primulas, Poinsettias, Gardenias, and other plants. About 600 Chrysanthemums are grown, but of these I will speak later, as they will be worth noting. Fruit is very scarce, Lord Suffield and Warner's

visit was a thoroughly enjoyable one, and I left Clevelly with a knowledge that things were going on in the best possible manner.—  
R. P. ROBY.

#### THE AURICULA.

##### ITS LONGEVITY AND TIMES FOR REPOTTING.

By the life of any one stem, head, lead, growth, or plant the Auricula is a limited perennial. An individual growth will maintain its vigour

and blooming powers for a few years, but plants of some varieties are slower in coming to maturity and longer lived than those of others. In a dozen plants of any one variety no two may live for exactly the same time, or during their life be in corresponding health. It is impossible to define the life term of this plant by the duration of a single plant. It may eventually so break into several heads that which of them is the real original may be a difficult thing to say. It may give off increase, and in favour of strong young plants the parent may have been thrown aside when comparatively worn out; or in its evident old age the plant may have been cut over, and the much reduced and narrowed head induced to go on afresh in restored strength for awhile. Some varieties constitutionally die young, Mr. Ben Simonite and myself having had many examples of young seedling beauties that were short-lived, sometimes even to the dying of the seed plant without issue.

I think it may be said that if in a vigorous collection no young plants were any longer to be kept, a term of half a dozen years would see it in a poor way, and with some varieties quite gone out of it. By way of example I would instance the grey edge Geo. Lightbody as a long-lived plant, and Alex. Meiklejohn as one of short duration. The original plant of Heroine was in good health at seven years old, but whether alive now or not I cannot say. The seed plant of Magpie is yet able to flower at five years of age, but has been beheaded to save its life.

From all this the fact is plain that to maintain a collection of Auriculas in vigour it is imperative to secure a due succession of young plants. If neither young nor old will grow as once they did it is worth while to try for an exchange of young stock with a grower in another part of the country. Further, to maintain the flower itself in the characteristic attributes of its lovely florist forms the raising of fresh varieties from seed is vital to its existence. The span of human life may not suffice to measure the lifetime of an Auricula. We have inherited some old beauties and may raise others that will be grown when we ourselves are gone far hence; yet not only do individual plants but whole varieties as surely if more slowly wear out. In the course of years are vigorous or brilliant examples of these more rarely seen. They do not come in character so constant or so grand as they used to do. They become more difficult to keep up and pass out of cultivation, not through displacement only by superior newer kinds, for these cannot be rapidly accessible, and there are always growers who cherish the favourites of olden times, but because, as with all perishable things, the evening of a long day has come at last. Those who grow the Auricula, thinking the old varieties will live for ever, and those who raise seedlings of much merit and think they never can be beaten, live alike in error. It is as sure as possible that flowers more fixed and rich in qualities of recognised excellence than the former ones can be raised, and that our improvements will be improved upon if only men follow us who will care to give the love and thought and time required.

My friend Mr. Morris thinks the Scottish and English growers are out of harmony on the subject and practice of repotting. I would not put it so. There is not necessarily disagreement in a difference. The whole range of the time mentioned for that operation lies easily within the convenience of the Auricula. There is no more difference between England and Scotland on this point than there is between growers in England itself. Some of us repot our plants early and some late. Some are not particular, but repot them sooner or later, according to opportunity. Some superb plants have been exhibited in our best shows that had not been repotted for two years, while, as instances of a different extreme, some of my own best plants have only been lifted from the open ground six or eight weeks before the flowers expanded. There is room for much difference, without injury to results.

The Auricula can be repotted either early or late. It can be disturbed, shifted, potted, dug up, knocked about at the roots at any time from the end of April till well into September; but unless something is going wrong it is not wise to disturb a plant in the dreary months of November and December. By the middle of January, if such need be, a plant may have change of soil, and in February and March it may be disturbed with none or little apparent check; but of course it is far the best to have Auriculas thoroughly established at the roots by the time the spring growth commences.

I repot my plants as they pass out of flower for reasons that satisfy myself, and which I have sufficiently explained long since and more than once; yet I would not call my friend, Hy. Wilson of Halifax, with his grand plants, a discordant and inharmonious brother because he prefers July for that operation.

Perhaps there is one advantage in repotting early which I may not have previously mentioned. From a plant "beheaded," or cut short over in May, there will spring offsets from the dormant eyes which may be young rooted plants by the time that a grower who repots late is beginning to think about starting with the work. Time saved is life saved.—F. D. HORNER, *Lowfields, Burton-in-Lonsdale.*

## TOMATOES FOR PROFIT.

[A paper by Mr. W. Iggulden, Marston Gardens, Frome, read at the meeting of the British Fruit Growers' Association, Brighton, September 11th, 1890.]

It is doubtful if any industry can be said to have progressed more rapidly than Tomato growing for profit. During the past six years or thereabouts, the increase in the number of houses erected specially for the purpose has been something stupendous,

and as far as my experience goes there are few or no signs of any cessation in building. What is even more satisfactory is the fact that it is not a few extra speculative growers that are responsible for this great attempt to meet the demands of an ever increasing Tomato-loving public, but it has been the means of giving hundreds of deserving men in various parts of the country a good opening for gaining a livelihood, and, let us hope, eventually an honourable independence.

The question is often asked, "Will the supply soon exceed the demand, and prices drop below a remunerative price accordingly?" This is a reasonable query, though as it happens it is not growers who put it, but rather men who are contemplating making a beginning. I have never met with one of the former who complained of having more fruit than could be sold at a fairly profitable rate, and it is my firm belief that the time when the supply of home grown Tomatoes will exceed the demand is far distant. I could prove, if time would permit, that not only is the Tomato becoming a necessary article in the diet of many men of business, but that also the industrial classes are becoming equally alive to their good qualities. They supply a need long felt—viz., something to tempt the appetite, and which also is wholesome and fairly nutritious. Particularly popular are Tomatoes among supper-eating folk—a rather numerous body we may reasonably presume—and who shall say how much good they do towards allaying thirst, and thereby prevent an undue use of injurious alcoholic drinks?

### SUCCESSFUL TOMATO GROWERS.

It may not be generally known, but it is an indisputable fact nevertheless, that the majority of the most successful growers of Tomatoes for sale are men who began with little or no experience in the matter, or indeed of horticulture generally; nor is the reason far to seek. Private gardeners, many of whom have lately taken to Tomato growing on their own account, and who formerly perhaps marketed the surplus fruit grown by them for previous employers, have been accustomed to quite a different class of houses to what the shrewd market grower thinks proper to erect, and in addition may have imbibed notions very difficult to eradicate. Those who know next to nothing as a rule make various inquiries among those who do, and the wiser of them make a point of visiting some place where the best and cheapest houses are to be seen, and then go to work accordingly. The market grower cannot afford to build houses that are to last a century, but, on the contrary, he ought to have got all he wants out of them in one-quarter of that time. Instead, therefore, of erecting an expensive house or houses he prefers to put up double that number of cheap structures, his returns from the first being doubled accordingly. Nor are "kid glove gentlemen" likely to realise such quick returns as are those who both know how and are not afraid to work. From the Channel Islands the greatest number of Tomatoes are sent to the markets on the mainland, and these are grown by men who do the principal part of their own building, and also much of the subsequent work. Not a few of these hard working, enterprising, and most deserving men previously followed some kind of employment totally different to what they are now doing, one much-respected friend of mine who has got on well in Tomato and Grape culture having for many years been a sailor. Many a private gardener also fancies he knows all about Tomato culture, but an "eye opener" in the shape of such crops as he has never seen before, and which by his methods he cannot obtain, awaits him who is not so well experienced in Tomato culture as he imagines himself to be. Perseverance is a quality needed above all things by the would-be successful grower, and the more practical the man the greater the likelihood of his succeeding, faddists being simply nowhere in the race for supremacy.

### PAYING CROPS AND HOUSES FOR THEIR PRODUCTION.

There is really a good demand for Tomatoes all the year round, but naturally the prices vary considerably. With so much foreign fruit in the markets at nearly all times fancy prices will never be had, but home-grown produce being so much superior in every respect it will always sell the most readily. It must not be imagined I am thinking only of the London markets, although these certainly absorb a considerable proportion of the Tomatoes either imported or grown in this country. As a matter of fact there is a good demand for this fruit in every town in the country, and it is all a mistake for anyone to imagine that the vicinity of London is the only neighbourhood where Tomatoes can be grown with a good prospect of the best returns being had. Even the far north, or such an inclement county as Durham, has been found to answer well for Tomato culture, cheapness of fuel and slack competition more than compensating for climatal disadvantages.

As a rule the majority of growers aim to have their crops ripening from May to November inclusive, the start being made as early in the year as possible. In these cases the prices vary

from about 1s. 6d. per lb. in May to 4d. per lb. in August and September, though since the widespread prevalence of disease, and whenever outdoor crops fail, 6d. is the lowest figure reached for the best fruit. What are wanted to produce heavy crops during the months named are fairly roomy, light, airy, and well heated structures, as no dependence whatever can be placed on any houses that do not admit plenty of light and are not well heated. Span-roofed houses will be found the cheapest and best in the long run, and these may be of any dimensions, though experience has taught us that there is greater likelihood of combating disease if the structures are of medium size rather than extra large. A good length would be about 60 feet, and suitable heights and widths are 14 feet and 25 feet respectively. Above all would I advise that the sides be of a good height, or fully 6 feet above the level of door sill, and the less brickwork there is the better. The plants being grown all over the body of the house, and trained up either stakes or strings, it follows they must have good head room, and unless abundance of light is admitted the growth may be soft and unfruitful. All the wood, preferably red deal, required can be bought at wholesale rates, nearly or quite ready for putting together, this including the light rafters—which also must act as sash-bars—and what fittings may be necessary. Very little skill is needed in putting these together, and seeing that glass can also be bought very cheaply and of any size, the glazing is another simple matter. Any attempt to adopt the plan of sliding the glass in grooves, or to butt the squares together in any way, usually proves disappointing in the end, and the plan most generally adopted is rabbeting the rafters, bedding the glass in putty, and finishing off neatly, no top putty being used, but only a good coating of paint. Top putty in time gets loose and admits moisture to the under side, whereas a smooth paint-covered surface holds good for many years. Ample front and top ventilation ought to be provided.

It is my firm belief that winter crops would pay well, the start being made with young plants in August or early in September, and the crops set early in the autumn. A long succession of fruit would ripen during the winter, and an equally good crop could be set and ripened in February, March, and April, or long before the majority of growers have any ready for the market. Well ripened fruit, available during the winter and early spring months, ought to fetch on an average 2s. per lb., and would pay well even if sold rather cheaper. Unfortunately, the large high structures previously alluded to will not answer for these midwinter crops, as the plants fail to set fruit freely unless grown near the glass, or say are trained up the roof about 10 inches from the glass. We have had the roof of a house covered with leading growths about 9 inches apart, furnished with clusters of fruit at every second joint, and that, too, in December. It is the low span-roofed houses, of the style usually erected for Cucumber and Melon culture that answer well for winter crops of Tomatoes, and during the summer these might, with advantage, be devoted to the growth of either Melons or Cucumbers, for both of which there is usually a good demand. With regard to heating Tomato houses, I can only briefly point out that it is possible to purchase really good boilers that require no deep stoke-hole, and but little setting, and that the expansion joints for the hot-water pipes are both the best and the most simply connected by an ordinary labourer.

#### THE MOST PROFITABLE VARIETIES.

Not a little depends upon the choice of suitable varieties for any particular crop. Some growers swear by the ribbed section, the most popular of which is the Large Red, while others pin their faith on the Perfection type, or those with smooth, rich, red round fruit. The former are much the most free-setting, but are not so attractive in appearance or heavy weighing as the more solid Perfection, Hackwood Park Prolific, Ham Green Favourite and Chemin Red. I would, however, strongly recommend the beginner to rely principally upon a good stock of Large Red, and which he could easily get by purchasing a few fruit at a market stand or of a fruiterer. Most undoubtedly the Large Red is by far the best for the winter crops, and on the whole it is perhaps the most profitable for all seasons of the year. What it lacks in weight and loses in competition with more showy sorts it more than compensates for in bulk, the smooth, round fruited forms very rarely setting so freely even under the most favourable circumstances. The time is not far distant when the Tomato will figure as a dessert fruit. I have met numerous lovers of this "fruit vegetable" who eat them in their raw state with even greater avidity than they would either an Apple or Pear, and if tempting fruit were placed before them in the way of dessert they would be fully appreciated. It should be the market grower's aim to foster this love for Tomatoes, and this can best be done by growing varieties both tempting in appearance and good in quality. Extra large fruit are not to be recommended at any time, and are certainly not the most calculated to tempt anyone to eat Tomatoes much as

they would an Apple. What should be grown are the comparatively small, smooth, round fruited varieties, such as Horsford's Prelude, and the improvement on this, The Conference, either of which present a very tempting appearance in small punnets and are really good to eat. The Peach, another comparatively new variety, is very distinct in every way, and is one of the best that can be grown for selling in punnets. The fruit are produced in long clusters, are somewhat small, ruby red in colour, prettily veined, carry a bloom like the Peach, and are of a pleasing flavour. Nor ought the yellow fruited forms to be lost sight of. These, though attractive in appearance, are unfortunately somewhat wanting in acidity, the principal exception being the Blenheim Orange. If the latter is eaten before it is "dead ripe" the flavour is decidedly distinct and pleasing, and it may yet become a favourite. Golden Sunrise may be briefly described as being a yellow form of Perfection, and it is of very attractive appearance. Those growers especially who get rid of their Tomatoes in their own vicinity ought to make a point of supplying fruit well ripened and of the best quality, and in time they will earn a reputation for the same, and obtain better prices accordingly. Fruit that has to be sent a considerable distance ought not to be very ripe when packed, but at the same time it should be well coloured, or it will fetch no better prices than foreign Tomatoes.

#### CULTURAL HINTS.

Without going into minute details I shall yet venture to offer a few hints that may prove acceptable to some of my hearers. Where so many have erred is in forming a too rich border for Tomatoes, looseness also being a condition of soil that ought to be avoided. What is wanted is a moderately rich root run, and this ought to be rammed, rolled, or trampled as hard as a road. A loose, rich root run promotes a rank unfruitful growth, firmness having the effect of causing a hard, short-jointed, and fruitful habit, or just what is wanted. If a depth of about 18 inches of fresh loamy soil, if turfy so much the better, can be provided that is all needed for the first season, and this can be renewed by the addition of fresh loam and bonemeal or some kind of special manure for the next year or two. A free use of animal or solid manure ought to be avoided. When a good crop is set, or if the plants present a very starved appearance, liquid manure or a surfacing of some kind of phosphatic manure may be given with advantage occasionally. If these conditions are observed the plants are less likely to suffer from overcrowding. Some growers arrange their plants 2 feet apart each way all over the house, others dispose them nearer 12 inches apart in rows 2 feet apart, in every instance training or confining each to a single stem, and if the border is very firm the latter distances answer very well, the crops in the aggregate being the heaviest. Instances have come under my notice of 8 lbs. of fruit being taken on an average from each plant in a high span-roofed house, but the greater distance mentioned was given, and of course disease was absent.

The cheapest way of training these plants is to place a string to each, fastening this from a peg in the ground to the roof, coiling the stems round them as they advance. The more common practice, as before stated, is to give each a tall stake, none of the plants in either case being topped before the roof is reached. Many succeed in growing strong healthy plants, but fail badly in effecting a good set. Much may be done towards correcting this unfruitful habit by withholding water from the roots for several days together, plants that flag badly in the sunshine owing to dryness at the roots not unfrequently setting much the best crops. A plan adopted by friends at Lewisham in Kent, and at Bath, is well worthy of a trial. This consists merely of going over all the plants in flower towards midday, or as soon as the pollen has been dried either by means of fire heat and air, or sunshine and air, and smartly tapping each bunch of bloom with a Hazel twig. This dislodges the pollen grains in a cloud, sufficient of this becoming attached to the moist pistils to effect a good set. I have seen plants thus treated furnished with large clusters of fruit from the ground up to the roof, there being no failures in the house. I would here add that open air crops are far from being generally satisfactory this season, but those who have a quantity of small green fruit on their plants, and which will not ripen, ought to convert these into a good hot pickle and market it. Such pickles, if well made, would soon become popular, and I venture to opine that the day is not far distant when there will be a good demand for small green Tomatoes.

#### DRAWBACKS IN TOMATO CULTURE.

There would appear to be no pleasures or profitable occupation without drawbacks of some kind, and unfortunately the Tomato grower has rather more than his share of them to contend with. As far as open-air culture is concerned, this has always partaken somewhat of the character of a lottery, but it is only of comparatively

recent date that bad forms of disease have worked so much havoc among very many plants under glass. To make matters worse, there would appear to be no perfect remedy for the *Cladisporium*, or whatever this new fungoid enemy may be termed, and already it has had the effect of stopping several growers on a rather large scale from running any risks in the matter. That it is to be combated with I have good reasons to assert, but, as I shall show, it is by no ordinary means that it can be stopped, while the consequence of any such extreme preventive measures is an inevitable loss of weight in the crop of fruit grown. Better, however, be satisfied with two-thirds of a full crop than risk losing the lot from disease, especially seeing that it is owing to the depredations of this disease that prices keep up to the figure they now do. In relation to this part of my subject I think I cannot do better than to largely quote from a letter I received from Mr. F. Williams of Devizes, a Tomato grower for profit, who has made such progress in a short time as to be able to cut from 5 tons to 6 tons of fruit in a single season. In this communication, dated July 30th, 1890, he states that last year disease appeared on his plants, "some turning black in the stems and fruit, some had woolly growth upon them, the foliage of others turned off to a very queer blotchy appearance, yellow shiny spots also being noticed on the plants being prepared in the open for winter work, and these after being housed became so badly over-run with disease that all had to be turned out and burnt." These symptoms made it only too evident that the dreaded disease had at last effected a lodgment in his houses. He continues: "My treatment last year consisted in several good syringings of sulphide of potassium as strong as the plants would bear, with a little carbolic softsoap mixed with it to make the sulphide stick on. Plants were, moreover, given more air and much less water than hitherto."

When starting operations for the present season I determined to have a try at what could be done in the way of anticipating the disease. I bought twelve sorts from different firms, but pickled all the seeds for twenty-four hours in a strong solution of sulphate of copper before sowing. The soil in the house was moved out to a depth of 1 foot and fresh brought in. The plants, when ready to put out, had a thorough dipping once or twice in the sulphate of potassium solution. In addition, the hot-water pipes were dressed once every week with linseed oil and sulphur, and the stink thereof was almost diabolical. We used to dress the pipes just after watering. Mr. Williams' aim throughout was to eradicate any germs which might have lodged on the seed, or which might be hanging about the premises, and also to make the atmosphere as disagreeable and unhealthy as possible for the said germs if any put in an appearance later on. In this he appears to have succeeded well, as he only had seven plants die off, and two touched with disease, the germs finding things generally in such a dry sulphurous condition that they have apparently left him in disgust for more promising scenes of action. A dry atmosphere and a good circulation of air, this being maintained more with the aid of fire heat and top air rather than strong currents of cold front air—coupled with a very firm root run, acts, to a certain extent, as a preventive of disease, but is no cure.

The early removal of the principal leaves, which some growers advocate, does more harm than good, its only effect being to weaken the plants. At the same time disease is not long before it overruns all the lower leaves, and unless more are laid in to take their place the fruit will soon cease swelling. We had the disease in our plants badly last season, but kept them in good bearing order throughout the winter in spite of it by simply keeping a dry atmosphere and constantly laying in young shoots in order to have leaves to take the place of those destroyed by disease. We are doing the same thing this season, and our crops are most satisfactory. We have also tried sulphuring the pipes, and if this does not much check the *cladisporium*, it has the effect of exterminating that other troublesome pest, a small white fly known as *Aleyrodes vaporarum*.

## ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 23RD AND 24TH.

THE meeting at Chiswick was opened on Tuesday last, but was not favoured with fine weather, as following heavy showers in the morning a thunderstorm in the afternoon effectually spoiled the day for visitors. The business on the first day was confined to the Fruit and Floral Committees, whose duties were not very heavy; and to the Dahlia Conference, at which there was a good attendance. Grapes and Dahlias constituted the chief attraction, and to these we will briefly refer.

### THE GRAPES.

The schedule prepared for the great exhibition of Grapes had been carefully considered, and was as follows:—

Class I.—General collection of Grapes.—Group A.—Sweetwater Grapes, including Chasselas and Muscadines. (1.) Black or purple

berried varieties. (2.) White, green or golden berried varieties. Group B.—Muscat and Frontignan Grapes.—(1.) Black or purple berried varieties. (2.) White, green or yellow berried varieties. (3.) Frontignans. Group C.—Vinous or late keeping Grapes.—(1.) Black or purple berried varieties. (2.) White or golden berried varieties. Class III.—Grapes of very high flavour. Class IV.—American varieties. Class V.—Grapes grown entirely in the open air. Class VI.—Grapes grown under glass without artificial heat. Class VII.—Foreign grown Grapes. Class VIII.—Pot Vines with fruit. Class IX.—Examples of packing Grapes for market to be sent by rail. Class X.—Examples of packing Grapes, 4 to 6 lbs., for private use, to be sent by rail. Class XI.—Examples of the enemies of the Grape Vine—diseases, injuries, insects, &c.

Had a moderate number of entries been obtained in each of the classes a highly interesting display would have been obtained, but unfortunately this was not the case, and the result was disappointing both in the number and quality of the Grapes shown. A really representative exhibition of varieties beyond those usually seen at shows would be extremely useful, and a few of the exhibitors had made an attempt to provide this. The Frontignans were especially well shown in one of the collections, and attracted much notice, while several other little known Grapes were included and examined critically by the authorities present. The Grapes, together with other miscellaneous fruits, were arranged in the large vinery, a most appropriate place, as the Grapes hanging above imparted a pleasing appearance to the house. The exhibits were as follow:—

Messrs. T. Rivers & Son, Sawbridgeworth, exhibited twenty-one bunches of Grapes, comprising specimens of Lady Downe's, Golden Queen, Mrs. Pince, Gros Colman, Alicante, San Antonio, a late black Grape with oval berries; Gros Maroc, Ryton Muscat, Madresfield Court, Muscat of Alexandria, Mrs. Pearson, Early Saumur, Early Silver Frontignan, Tokay Frontignan, Esperione, grown in a cold house; Buckland Sweetwater, Royal Muscadine, and Black Hamburg, the last two from cold houses. (Silver medal.)

From Mr. H. J. Hookings, gardener to S. W. Graystone, Esq., Hurst Side, West Molesey, came seventeen bunches of Grapes, the four specimens of Gros Colman being remarkably alike for size of bunch, berries, and colour. Four bunches of Gros Maroc were also notable for similar characters. Foster's Seedling, Alicante, and Mrs. Pearson were represented by three bunches each (silver medal). Mr. W. Williamson, The Gardens, Tarvit, Cupar, Fife, sent specimens of Grapes affected by Vine moth (*Tortrix angustiorana*) with rust and mildew.

Mr. J. Wallis, Keele Hall Gardens, Newcastle, Staffs, exhibited eighteen bunches of Grapes, representing that number of varieties, their names being as follows:—Black Hamburg, Barbarossa, Gros Maroc, Black Prince, Mrs. Pince, Black Muscat, Madresfield Court, Muscat Champion, Muscat Hamburg, Mrs. Pearson, Muscat of Alexandria, Golden Queen, Lady Downe's, Alnwick Seedling, Gros Colman, Alicante, West's St. Peter's, Trebbiano, and Old Tokay. (Silver medal.)

A most interesting collection of rarely seen Grapes came from Mr. W. Roupell, Harvey Lodge, Roupell Park, comprising twenty-seven varieties, and though most of them were small both in berry and bunch, several exquisitely flavoured varieties were included, notably the Grizzly Frontignan, Diamant Traube, the Strawberry and Raspberry Grapes. The others were Trebbiano, Alicante, Gros Colman, Alnwick Seedling, Lady Downe's, Primavis, Frontignan, Early Golden Frontignan, Black Frontignan, Troveren Frontignan, Dr. Hogg, July Frontignan, Purple Constantia, Canon Hall Muscat, Muscat of Hungary, Muscat Hamburg, Mrs. Pearson, Madresfield Court, General della Marmora, Chasselas Vibert, Royal Muscadine, Black Hamburg, and Duke of Buccleuch, true, but with quite a reddish tinge from being over-ripe. All the Vines are grown in pots in small lean-to houses facing south, the pots being placed on the return pipes. (Silver-gilt medal.)

From the Society's Gardens, Chiswick, twenty-two varieties of Grapes were shown, and they were represented by good well coloured bunches. The varieties were Black Hamburg, Madresfield Court, Black Prince, Gros Maroc (excellent colour), Royal Ascot, West's St. Peter's, Dutch Hamburg, Mrs. Pince's Black Muscat, Muscat Hamburg (superior), Gros Colman, Lady Downe's Seedling, Barbarossa, Alicante, Black Monukka, Alnwick Seedling, Muscat of Alexandria, Royal Muscadine, Raisin de Calabre, Foster's Seedling, Golden Hamburg, and Buckland Sweetwater. These were tastefully staged in neat shallow circular baskets, the white Grapes on pink paper, and the black on white paper. Mr. J. Clark, Albion Nursery, Farnham, showed twenty-eight bunches of Grapes grown under glass without fire heat, "average crop forty-five to fifty bunches on each Vine, and twenty-seven Vines in one house." The varieties were Muscat of Alexandria, Alnwick Seedling, Madresfield Court, Gros Maroc, Gros Colman, and Lady Downe's, the bunches of moderate size, but fairly good colour. (Silver medal.) Messrs. John Peed & Son, Roupell Park Nurseries, Norwood Road, sent nine large bunches of Alicante, Trebbiano, Golden Queen, and White Syrian, the black Grapes being particularly fine.

Several baskets of very fine Grapes were sent from Mr. George Munro, Covent Garden Market, on Wednesday morning, and added greatly to the interest of the Show. They included fine samples from Messrs. Sweet, Kay, and others. Some Grapes were also sent from the Channel Islands.

A silver cup offered by D. Morris, Esq., for the best example of packing Grapes (4 to 6 lbs.) for private use, sent by post or rail, was awarded to Mr. Robert Dawes, Temple Newsam Gardens, Leeds, amongst fourteen competitors. The Grapes (black) were packed closely

in a small square box padded at the sides with moss and covered with tissue paper. No string was used, but the Grapes were quite firm even when the box was turned upside down, and they had suffered very little in their journey.

The Grape Conference was held on Wednesday in the conservatory. The proceedings were opened at 2 P.M. by a few words from Dr. R. Hogg (Chairman). The programme was arranged in this order:—Mr. T. Rivers a paper on varieties of Grapes, Mr. R. D. Blackmore to deal with "The Enemies of the Vine," Mr. W. Thomson with Vine borders, and Mr. W. Coleman with packing Grapes. We hope to refer to some of the chief points discussed in our next issue.

#### THE DAHLIAS.

The long exhibition tent was devoted to the Dahlias, and a brilliant display was produced, far exceeding the anticipations of most visitors. All the types were represented, and large numbers of varieties were included, far too many to be enumerated here, particularly when it is remarked that some of the exhibitors claimed to be showing over 400 varieties each. Such numbers are overwhelming, but they serve a useful purpose in enabling the Committees to make selections, and some of these will no doubt be published as in the case of former displays of a similar character. Handsome collections were contributed by the following exhibitors, and the medals named were awarded. Silver-gilt medals to Messrs. J. Cheal & Son, Crawley; Paul & Son, Cheshunt; J. Laing & Sons, Forest Hill; Keynes, Williams & Co., Salisbury; and C. Turner, Slough. Silver Banksian medals were adjudged to Messrs. H. Cannell & Sons, Swanley, who had 420 varieties; Dobbie & Co., Rothesay; G. Humphries, Chippenham; Heath & Son, Cheltenham; and Saltmarsh & Son, Chelmsford. Silver Flora medals were accorded to Messrs. Arthur Rawlings, Romford; G. Phippen, Reading; T. S. Ware, Tottenham; and E. J. West of Brentwood. Bronze medals were also awarded to Messrs. J. Peed & Son, and Mr. W. Salmon, West Norwood.

In addition to the Dahlias there were some remarkable groups of Tuberous Begonias from Messrs. J. Laing & Sons, and Messrs. H. Cannell and Sons, which were tastefully arranged with Ferns and other foliage plants, and silver-gilt and silver Banksian medal were adjudged for these exhibits in the order named. A choice and effective collection of hardy flowers from Messrs. Harkness & Son, Bedale, also furnished an attraction of much interest.

The Conference was held on Tuesday in the Conservatory, a portion of which had been screened off for the purpose, and the proceedings commenced at 2.30 P.M., Mr. Harry Turner in the chair. The first subject was "The Origin of the Florists' Dahlia," which was dealt with by Mr. Shirley Hibberd in his customary interesting manner. Mr. T. W. Girdlestone followed with some remarks upon single and decorative Dahlias, and Mr. H. Williams discussed "Show Dahlias." The attendance was good, and the papers were worthy of the attention they received from the audience.

#### THE COMMITTEES.

Exhibits were comparatively few before the Fruit and Floral Committees; while the Orchid Committee had but one plant to consider, a *Lælia*, for which, however, an award of merit was granted.

**FRUIT COMMITTEE.**—Present: John Lee, Esq., in the chair; and Messrs. J. Willard, G. Wythes, J. Hudson, W. Bates, G. W. Cummins, P. Crowley, H. J. Veitch, J. Douglas, F. Q. Lane, H. Balderson, J. Cheal, A. Dean, G. Bunyard, and Dr. R. Hogg.

Mr. R. Miller, Ruxley Lodge Gardens, Esher, sent two baskets of handsome Barrington Peaches, gathered from trees on an east aspect (cultural commendation). Messrs. Keynes, Williams & Co., Salisbury, showed a seedling Apple named Chorister Boy, a moderate-sized red streaked Apple. Mr. L. Castle sent a local Essex Apple known as Marie's Pippin, which is to be seen again when ripe. Mr. W. Palmer, Thames Ditton House Gardens, sent fruits of Hero of Lockinge and Sutton's Triumph Melons, the former of excellent flavour. Messrs. J. Carter & Co., Holborn, showed fruits of Cucumber Success, 2 feet long each; also large fruits of Holborn Favourite Melon. Seedling Melons were also sent by Mr. Maher and Mr. Wythes. A fine collection of large Apples came from the Society's Gardens grown under glass. Tomatoes, Capsicums, and Aubergines were also shown from the same garden.

Mr. T. Bradshaw, gardener to the Marquis of Downshire, Hillsborough Castle, Co. Down, Ireland, exhibited samples of a seedling white Grape having large oval berries. It was not in quite its best condition, but was referred to the Conference Committee for further consideration.

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq., in the chair; and Messrs. J. O'Brien, R. Dean, J. Walker, G. Paul, H. Cannell, W. H. Williams, H. Turner, J. R. Tranter, R. C. Leach, R. B. Lowe, J. T. West, J. Dominy, J. Douglas, J. Cheal, B. Wynne, G. Hill, E. Mawley, and L. Castle.

Messrs. J. Veitch & Sons, Chelsea, showed several rare and interesting plants, *Gynerium argenteum* aureo-variegatum being graceful in habit with narrow golden edged leaves. A box of greenhouse Rhododendrons was also notable (vote of thanks.) Mr. J. R. Tranter, Henley-on-Thames, had a collection of Show and Fancy Dahlias (bronze Banksian medal). Messrs. Reid & Borneman, Sydenham, sent a collection of early Chrysanthemums (bronze medal). Messrs. J. Laing & Sons, Forest Hill, showed two plants of Chrysanthemum Mrs. Alpheus Hardy, with two large blooms. Messrs. H. Cannell and Sons, Swanley, had a group of the neat double white Tuberous Begonia Octavie (vote of thanks); and Messrs. J. Lee & Son, Hammer-

smith, showed small plants in pots of a variegated Cornus, well coloured and most suitable for decorative purposes.

#### PLANTS CERTIFICATED.

*Lælia Eyermanni* (Veitch and Manda).—Flowers of a soft blush purple, the wings of lip white, with a faint dash of yellow in the centre.

*Dahlia Centennial*.—A Cactus variety; rich purplish crimson, edged with maroon.

*Dahlia Beauty of Arundel* (Mr. Burburry, Castle Gardens, Arundel).—A Cactus variety, of a peculiarly brilliant crimson colour; the tips of the florets purplish.

*Dahlia The Mikado* (Charles Turner).—A neat Pompon, white tipped crimson.

*Dahlia Othello* (C. Turner).—A Pompon, of deep rich crimson colour.

*Chrysanthemum Lily Stevens* (Reid & Borneman).—A neat white Pompon with quilled florets, very free, and likely to be useful for cutting (Award of merit.)

#### RAPHIOLEPIS OVATA.

A SHRUBBY evergreen plant that is not too well known in gardens is *Raphiolepis ovata*, a flowering shoot of which is represented in the

FIG. 33.—RAPHIOLEPIS OVATA.

woodcut (fig. 33). In some situations the *Raphiolepis* will pass the winter safely out of doors, especially in the south of England, but it is useful everywhere in conservatories or cool houses, its bold vigorous habit and glossy green leaves always having a good appearance. When in flower it is still more attractive; the large heads of white flowers, being produced at the ends of the branches, are very conspicuous.

*R. ovata* is a native of Japan, and is nearly related to the *Photinias*, some of which are occasionally seen in winter gardens, but which are

rather tender for general culture out of doors except in favoured climates.

## THE LIVING EARTH.

(Continued from page 255.)

"MANURIAL value" is a term used by chemists to express the amount of nitrogen that may be present. Now I do not doubt the ability of chemists to make a quantitative estimation of nitrogen, nor their power of informing farmers of the extent to which they may or may not have been cheated when they purchase artificial manures. I would humbly suggest, however, that the real practical manurial value depends not only upon the amount of plant food present, but also upon whether the plant food is present in a form in which it can be digested and exhaustively utilised by the plant. For the latter information, which is of the highest importance, I would sooner apply to a practical farmer or gardener than to a chemist. A chemist, for instance, who had regard to his analyses and nothing else might tell us that nut shells had a certain dietetic value, but ordinary men and monkeys know better than that. He might tell us that gin was richer in certain dietetic ingredients than ginger beer, but we know that ginger beer is the better article of diet. Again, guano has a far higher manurial value than "rich garden mould"—such as is got by mixing earth with organic refuse—but if we do not dilute our guano to the same level, so to say, as our rich garden mould we may kill our plants. To declare that rich garden mould is of low manurial value is absurd, because we know that in it plants of all kinds reach the highest development which is attainable. Farmers and market gardeners will tell you that artificial manures have "got no bottom in them," that their use is, so to say, a speculation; and if climatic conditions are unfavourable when the artificials are applied, the money spent on them is lost for ever. With organic refuse, however, the case is entirely different, and the effect of the application of organic matter, especially of human origin, to the soil is plainly discernible for three or four years. Solid organic matter cannot be washed away. It nitrifies slowly, and doles out the nitrates to the roots of the plants in proportion as they are needed.

From every point of view—scientific, sanitary, moral, economic—I feel strongly that dwellers in the country should take warning by the towns. They should revert to the cleanly and decent habits of our forefathers, and keep the sanitary offices away from the main structure of the house, and not, as is the filthy custom of the present day, bring them almost into the bedrooms. They should keep solid matters out of the house drains, and see that they are decently buried in the living earth every day, and they should replace the drains by gutters and filter all the household slops by applying them to the top of a different piece of cultivated ground every day. Whether an ordinary watering pot, or a tank upon wheels drawn by a horse be necessary for accomplishing this latter object, will depend upon the size of the establishment; but only those who have systematically pursued this plan, as I have done, can know the vigour which is imparted to hedgerows, shrubberies, fruit trees, or forest trees, by a tolerably frequent dose of household slops. There is no difficulty in doing this, provided the will be present—the will, that is, to combine your duty towards your neighbour with an act which is profitable to yourself.

Finally, you dwellers in the country, whether squires, who are the owners of broad acres, or occupants of modest villas with a garden, or, still more, if you be cottagers with an allotment, where it ought to be, round your cottage, what I have to say to you is this:—

1. That sewage, being a nuisance, although a necessity, it is to your interest not unnecessarily to increase its quantity or its offensiveness.

2. Keep solid matters out of the drains, for by doing this you will prevent the putrefaction of the solid, and you will find the purification of a liquid by filtration through the earth is affected with ease, which is proportionate to the thinness of the fluid.

3. Remove all solid matter every day from the immediate neighbourhood of the house, and bury it in the top layer of cultivated ground. Pour the household slops on to the surface of the garden, and do not make the mistake of attempting what is known as subsoil irrigation. If these directions be followed I feel sure that by no possibility can you be troubled by sewer gas, and I also believe that you may drink the water from your surface wells with safety.

I am, as some of you know, no mere theorist—I practise what I preach, and have now some nine years' experience, experience which has served to strengthen my opinions, and enables me unreservedly to exhort others to pursue a similar course with myself. In Hampshire I have a garden, and adjoining it are twenty cottages, which I also own, inhabited by about a hundred persons. These cottages are scavenged every day, and the scavengings are buried in the garden. The caretaker's first duty is to the cottages—to remove filth and bury it, to whitewash, paint, and to keep decent. His second duty is to the garden, where he acts as under gardener. In the garden, which has an extent of about  $1\frac{1}{4}$  acre, I am obliged in self-defence (what a hardship!) to raise the biggest crops possible. This garden not only supplies my London house with a variety of fruit, flowers, and vegetables (Cabbage, Potatoes, Carrots, Turnips, Parsnips, Beet, Salsafy, Lettuces, Artichokes of both kinds, Peas, Beans, Asparagus, Seakale, Peaches, Plums, Apples, Pears, Figs, Strawberries, Currants, Raspberries, &c.), which I doubt if I could purchase for £50 a-year of the neighbouring greengrocer; but the over-

plus, which is marketable, just about pays the wages of the caretaker and under gardener. I cannot help thinking that the combination of market gardening with cottage owning in country places opens up the possibility of an industry which is at once profitable and advantageous to all concerned, and affords a good chance of solving a sanitary difficulty.

I am addressing myself to dwellers in the country, but I should like to say to town dwellers that complete sanitation is impossible unless cultivated land be brought into tolerably close relationship with the dwelling. At present our sanitary arrangements are magnificently begun and seldom completed, and while we almost uniformly leave a most dangerous loose end to our sanitary measures we shut our eyes to it, and blow the trumpet of self-satisfaction as if the sanitary millennium had begun. The Allotment Act, as affording an outlet for organic refuse, ought not to be without its effect upon sanitation, and it is to be hoped that the masses will some day wake up to the great importance, from the moral and sanitary standpoint, of providing every dwelling with an adequate outlet. As things go at present I have very little doubt that the agricultural labourer, with his cottage and garden and 12s. a week, is infinitely better off than the town artisan on 25s., who pays dearly for pigging it in overcrowded rooms, in which a cleanly and decent existence is impossible.

I have been reading the last volume of our transactions, and in it I find a very interesting paper by Dr. Sykes, who quotes Dr. Corfield, who, in his turn, is quoting Sir Henry Acland, to the effect that the disappearance of the great cities of antiquity was due to pestilence, rather than war. We must all admit the possibility of such an assumption, and certainly no one can ponder upon the disappearance of Egyptian, Babylonian, Assyrian, Greek, and Roman civilisation without speculating upon the cause, and without applying the lesson to ourselves, and asking ourselves how much longer is our British civilisation to continue? Nationalities seem as mortal as the individuals which compose them. If great nations are destroyed by neglect of sanitary laws, and if prolonged national life is indicative of sound sanitary measures, there is at least one race upon the globe which is worthy of profound study by all who concern themselves with public health. This race is the Chinese, who have seen all the great nations of antiquity in and out, who were probably a great people in the days of Moses and before, and whose thrifty myriads are even now successfully contending with the Anglo-Saxon race in America and Australasia. The Chinese, as is well known, have had to contend with national calamities of a most stupendous kind. In our own days we hear of floods and famines which claim their millions of victims, and yet the race continues to increase in such a way, and to overflow its natural boundaries to such an extent, that it is certain, even without the exact returns of a Registrar-General, that the birth rate must very considerably exceed the death rate, and must have done so in an average way during the 3000 or 4000 years that the Chinese nation had existed. I think there is no doubt that the Chinese will see us out, as they have seen the other great nations of the world out, and the reason, I believe, is obvious. The Chinese are the most thrifty nation in the world. In China nothing is wasted, and all organic refuse is ultimately returned to the soil. Agriculture is in China a sacred duty, and the Chinese have got a firm grasp of the elementary principle that if the fertility of the earth is to be maintained we must constantly replenish it. The nineteenth volume of the Health Exhibition literature contains a most interesting series of papers on China by Surgeon-General Gordon, Mr. Hippisley, and Dr. Dudgeon of Pekin. The papers by Dr. Dudgeon are especially worthy of study, for many years of residence among the Chinese have impressed him with the fact that we have much to learn from them. I have not the pleasure of Dr. Dudgeon's acquaintance, but were he here I am sure he would give a general support to the propositions I have laid before you.

This question is a national one, and concerns us all. Every country squire ought, in these matters, to set a good example to his tenants. If he does not set the example of increasing the fertility of the soil by the daily addition to it of all the organic refuse of his country mansion, he cannot command our sympathy when he goes without his full rent. If a landowner embarks on a great building scheme he ought to keep the sanitation in his own hands. If a well-known landowner has done this—if he had preserved his autonomy on his own estate, and if he had, by a rational use of the railway, transferred the daily scavengings of his valuable city estate to his broad acres in Bedfordshire, perhaps his right of way on his London estate would not have been confiscated, and perhaps he would not have been obliged to remit 25 per cent. of his Bedfordshire rental. As it is, he allowed the vestry to do his sanitation for him, and by so doing lost his autonomy. Who can see how far the process of confiscation which has set in will ultimately reach? This question has an immediate personal interest for all who derive their income from the soil. I feel sure that the clergy would do well to enforce by example as well as by precept the old injunction to "replenish the earth and subdue it." If they do not they must expect to go without their tithes. Improvement in this direction is only to be attained by rousing the public conscience. So soon as the majority of individuals is impressed with the fact that it is wicked to foul our streams and starve the soil, and that our individual responsibility does not end, even though the fouling and starving be done by a "Board," so much the better will it be for the public health and national wealth. Parliament has compelled us to hand over our responsibilities to public authorities, with the consequence that the individual has lost his liberty and independence, and is drifting into a condition of sanitary imbecility.—G. V. POORE, M.D.

## PROTECTION FOR THE ORIGINATORS OF NEW PLANTS.

How the originators or introducers of new varieties of plants can be protected in what seems to be clearly their right to some special proprietorship of their productions is a subject that has often been discussed. At the late American Convention of Nurserymen the fact was emphasised that very few persons in this country who had originated valuable varieties of fruit had received any direct benefit from it. As an illustration it was stated that Mr. Worden, who brought out the Grape named after him, and which many people esteem, all things considered, as the best black Grape grown in America, is now a poor man, and never made 500 dollars from this valuable introduction. If inventors are protected by law against the piracy of ideas which have cost them labour and study, it would seem just that a man should be able to reap some reward for having brought out after much thought and experiment a new fruit which may add to the wealth and comfort of millions.

Different plans for patenting plants have been often advocated, but the essential objection to them all was well stated by Professor Bailey more than a year ago as follows:—"It is exceedingly doubtful if a patent could be secured for varieties which spring up from a chance seedling, and most of our varieties come in this way; but if the patent were granted there are innumerable cases in which no jury of experts could agree concerning the distinctness of varieties." Few cautious persons would be willing to swear to the identity of a given Strawberry or Rose, and it would be difficult to prove in any given instance that the flower or fruit in question was not a new one closely resembling an older variety.

Mr. A. L. Bancroft of California has also suggested a horticultural register wherein separate plants like Roses, Chrysanthemums, Ferns, Apples, Grapes could be kept and numbered on a system similar to that adopted in the various herd books where choice live stock is registered, but we then pointed out that a herd book was devised for a purpose quite distinct from those which it is proposed to secure by a system of plant registration. Individual animals are registered so that they may be identified, that their pedigree may be established, and that purity of blood may be maintained in a given breed or strain of live stock. In the case of plants, where the registration of one individual must stand for an entire class, and where the parentage is often unknown and always of secondary importance, it is difficult to see how such a list would prevent a duplication of names for the same plant or the selling of different plants under the same name. Mr. Bancroft's scheme has been carefully elaborated since then, and a plan of registration has been adopted by the California State Horticultural Society. We have no space here to go into the details of the plan, but as it was discussed it seemed to the nurserymen in their convention that it was too cumbersome to be practical and effective.

There is, however, considerable protection already given to the originator of a new fruit in the copyright law. Mr. Hoyt, of New Canaan, Connecticut, stated that he had taken out such a right on his label of the Green Mountain Grape, and had been instructed by eminent legal authority that no man could use this title on a label to a Grape Vine and sell it without his consent. It is true that if anyone should buy a plant of Mr. Hoyt he could propagate it as largely as he chose for his own use, or could sell the Vines under another name, but there would be little temptation to a grower to sell a really valuable variety under a name which would conceal its identity. The name is the very thing the plant-pirate most wants, and he often sells nothing else but the name of a good variety, attaching it to an entirely different plant from the one it really belongs to. This registered trade mark has proved of value too in preventing the sale of spurious plants under the label so registered, so that copyrighting assists in preventing the sale by unauthorised persons both of genuine plants and their counterfeits.

It is hard to see how much greater protection than this can be secured by a horticultural register. The plan of registering new plants has, however, many merits in other directions. It would be of interest to have an accurate description of any new plant filed in some public office, with its portrait and parentage so far as known. We should like to compare a plant and berry of Hovey's Seedling Strawberry as grown to-day with a preserved specimen of the original plant and its berry, or accurate portraits and descriptions of them, to see if any variation from the type had taken place. In questions of identity the register might give some assistance, but the inherent difficulties of accurate varietal description would remain. An organised effort to secure registration would be of value, too, in enlisting the co-operation of all horticulturists to secure to originators their rights, for although no system yet devised can add much to the protection now given by the trade mark laws, this protection would be much more effective if it had an active and united public sentiment behind it.

Of course this protection to the introducers of new plants would make such plants more expensive for a time, just as patented machinery and copyrighted literature is more expensive. But although this increased price might be considered a burden upon horticulture the advantages gained would be positive and important. Chief among these would be the encouragement offered to careful experiments in hybridising. When growers can feel sure that they will reap some reward from discoveries in this field we may entertain a reasonable hope that the breeding of plants may be reduced to something like a system or a science.—(*American Garden and Forest.*)

### HARDY FRUIT GARDEN.

**APPLES.**—These are ripening fast, and most of the earliest culinary varieties may safely be gathered and stored. The Codlin varieties have been much interfered with by blackbirds, and other comparatively soft varieties have suffered similarly—wasps finishing what the birds begun. It is therefore a relief to find the seeds of any variety of Apples, either culinary or dessert, browned, as then the time has arrived for gathering and storing. If this stage of ripening is anticipated—that is to say, if the fruit is gathered before the seed is browned, it will keep badly, shrivelling being the sure consequence. All ought to be very carefully handled, as they bruise easily, and none but the sound fruit should be given the best positions in the fruit room, the rest being either put on one side for present use or converted into cider.

**PEARS.**—It is the wall trees that are principally furnished with fairly good crops of fruit this season, and as these can be easily covered with nets there is even less excuse for gathering the fruit before it is fit. As a rule such varieties as Williams' Bon Chrétien, Victoria, Beurré d'Amanlis, Doyenné Boussoch, Louise Bonne of Jersey, Gansel's Bergamot, Pitmaston Duchess, Fondante d'Automne, and Comte de Lamy are ripening even earlier than usual, and early storing may in these cases be resorted to. On no account, however, should Doyenné du Comice, Marie Louise, Beurré Clairgeau, Beurré Diel, and other varieties that are generally fit to eat in November or thereabouts be dragged from the tree prematurely, or their quality will be impaired thereby. It would be a still greater blunder to gather Josephine de Malines, Glou Morceau, Winter Nelis, Madame Millet, Ollivier de Serres, and Nec Plus Meuris before they either part from the tree freely when lifted out of their natural positions or the seeds are nearly or quite brown. These late varieties if gathered before they are ready inevitably shrivel badly and are never fit to eat.

**STORING APPLES AND PEARS.**—It is not often there are extra large quantities of dessert Apples to store, but those who fortunately are somewhat favoured in this respect should take good care of the fruit, as it will be valuable this season. There is no necessity to store them very thinly, but they ought to have a clean sweet position, where no cold currents of air can reach them, and where they can readily be protected from severe frosts. The fruit really keeps longer and plumper when stored in deep boxes and hampers, and this plan of storing is especially to be commended where there is no fruit room proper. The less valuable culinary varieties may be stored in heaps and covered first with straw and then about 6 inches of soil, or much as Potatoes are pitted. Thus treated they keep surprisingly well, but the quality is never so good as when they are kept in a dry cool room or shed. Pears both keep well and ripen beautifully in drawers located in a cool dry room, or they may be stored in shallow boxes in single layers stalk end uppermost. If there is a fruit room well fitted with latticed shelves storing and keeping Pears is a comparatively simple matter, and if each sort is kept separate and duly labelled the owner's visits to the fruit room will in many instances be more pleasurable. A dry heat is objectionable, and the other extreme, cold and damp, must also be guarded against. If the temperature of the room seldom exceeds 55°, and rarely falls below 40°, the fruit will keep well, and if more heat is required to ripen Pears these should be moved to a warm house or kitchen according as they are required, this being the best method of bringing out their true flavour and of prolonging the season of each variety.

**RENOVATING FRUIT TREES.**—Once more the time has arrived when work of this description may safely be taken in hand. Those trees standing most in need of this renovation, and which well repay for the trouble taken, are fine old wall Pears, Peaches, Nectarines, Apricots, Morello Cherries, and in a lesser degree Plums. When the roots have gone from the surface down into an uncongenial subsoil the health of the tree is greatly impaired, and the quality of the fruit, if any, is also much inferior to what it should be. Undermining the tree, cutting the deep running roots, bringing all those reserved much nearer the surface, and relaying in fresh loamy compost, soon alters the character of the tree for the better, and in most instances answers more satisfactorily than destroying old trees and planting new ones. The work should be done thoroughly, but not in a reckless manner. It is also wiser to extend the operation over two seasons, one half of the roots being done at a time, as to completely lift and prune the roots of a large tree at a single operation might lead to its being so badly crippled as not to recover from the check for several years, if ever. Supposing a large Pear tree is to be operated on, a trench about 2 feet wide, and as much, or rather more, in depth, according to the nature of the ground, should be cut at about 9 feet from the stem, and only half way round. Next gradually fork away the soil from the roots, and to within about 3 feet of the stem, from which distance the tree could be quite undermined without disturbing the ball of soil about the stem. All large deep running roots should be cut or sawn cleanly through, and those more pliable, after having all broken ends cut off and bruised pieces cut away, can then be relaid in nearly, or quite all, fresh soil. A little partially decayed manure or old

Mushroom bed material, and half-inch bones and charred garden rubbish, may well be added to fresh loam, turfy if possible, and a portion of fresh garden soil can also be mixed with the heap if need be. The old roots will probably form some fresh fibres this autumn, and freely next summer, the rest of the roots being lifted and relaid in fresh soil in the autumn.

**ROOT-PRUNING YOUNG TREES.**—When young and not over-pruned trees are growing rankly and produce few or no fruit, this is a sure sign they want checking at the roots. Even those that are fairly fruitful will frequently be benefited by partial root-pruning, this checking undesirable deep root action, and tends to keep their roots more active near the surface. The method of procedure may be much the same as that advised in the case of older trees, and if the trees are fairly large one side only should be done this season, the other half being left for next autumn. Those that have only been planted two or three years may be worked completely round, these having fewer extra strong deep running roots to cut through. Nor do the latter require any fresh soil, but a little turfy loam will not be wasted on the comparatively large trees. If any flag badly after the root-pruning, syringe frequently, and shade from bright sunshine.

#### FRUIT FORCING.

**FIGS.**—*Early Forced Trees in Pots.*—Examine the roots of these, and as it is not advisable to increase the root room, particularly in the case of large trees, remove a few inches of soil from the base, cutting back the roots, and supply fresh fibrous loam, adding a sixth of old mortar rubbish, and a sprinkling of steamed half-inch bones. Good drainage must be provided, the soil being well rammed in the pots. Remove the loose surface soil and supply the above compost, adding a fourth of well decomposed manure. Afford a good watering, and place the trees where they can have plenty of air with shelter from heavy rains and frost. When it is desirable to increase the size of the trees, or young trees necessitating larger pots, it is necessary to remove the old drainage to cut back the straggling roots, loosening the sides of the ball, shortening the roots a little, removing the surface soil, and after draining the pots efficiently, sprinkle over the crocks a few crushed bones, repot firmly, ramming the soil well. Afford a good watering, and stand the trees in a cool rather dry place safe from frost.

*Planted-out Trees.*—Keep these drier at the roots, but avoid extreme dryness, and a drier condition of the atmosphere will tend to promote the ripening of the growths. Nothing contributes more to perfecting the growths and a good show of fruit in the coming season than keeping the points of the shoots well up to the light; therefore allow the growths to have their points exposed to light and air, those on roof trellises, which are much the best, being permitted to point towards the glass, the nearer they are to it without touching the better. As soon as the latest trees are cleared of their crops keep the soil drier at their roots and the houses well ventilated in favourable weather, cutting out all useless wood, exposing that left to air and light. Trees that grow too luxuriantly should be lifted directly the leaves begin falling, reducing their rooting area, shortening long roots, especially that are bare of fibres, cutting off those that strike straight down, rectifying the drainage where defective, adding some old mortar rubbish to the soil if deficient in calcareous matter, and making the soil firm, the roots being laid in evenly and well up to the surface. Give a good watering, keeping the atmosphere dry, and freely ventilate the house.

**VINES.**—*Houses Cleared of Grapes.*—Vines from which the Grapes have been cleared should now be divested of laterals down to the principal buds, which are to be retained for next year's fruiting, doing so, however, without injury to the old leaves, as upon their preservation depends the maturity of the buds, which should be plump and well ripened. The shoots, however, must not be reduced too much, allowing in each case a few buds or joints beyond the pruning buds to remain as an outlet for any surplus sap, and so prevent undue excitement or premature development of the pruning buds. A free circulation of air is necessary, and in the case of young Vines, or in those that are unduly vigorous, or where there is the least doubt about the thorough maturity of the wood, fire heat will be necessary. When the laterals have been removed, the old mulching or surface dressing should be cleared away, the border pointed over lightly, but not interfering with or damaging the roots, giving a top-dressing of turfy loam, with a sixth of sweetened horse droppings or farmyard manure, and a sprinkling of bonemeal. If the Vines do not make firm wood omit the manure and afford a good handful per square yard of bonemeal along with the turfy loam. If the roots have not penetrated the mulching or last year's surface dressing, remove the soil down to them, and give fresh compost, but do not cover them deeply, 2 or 3 inches depth is quite sufficient. Follow in the case of inside borders with a moderate watering, and allow those outside to have the benefit of October rains, and instead of adding manure to the loam mulch the surface with 2 or 3 inches of fresh horse droppings, covering with dry litter or bracken by the end of October or early November. Now is a good time to add a breadth of 2 feet to the front of borders only partly made, using fresh collected materials, all clean and sweet, also in good working condition, choosing dry weather if possible for work of this kind, mulching with horse droppings, and covering with leaves and a little litter to prevent their blowing about.

*Late Grapes.*—Evidence of finish in these will not always bear close scrutiny. Make sure that the berries are finished quite up to the stalk before withdrawing the needful aid from fire heat. Alicante invariably finishes well, and Lady Downe's always better than Mrs. Pince, which requires more heat and a longer time to perfect its berries, and it is not as good a keeper as Lady Downe's, the last

being the best of late-keeping Grapes, neither shrivelling nor losing quality or colour like the others. Gros Guillaume well done is quite as noble in appearance as Gros Colman; both have soft or fleshy footstalks, and though the berries colour perfectly they are not good keepers, the footstalks failing to keep the requisite consistence, often failing before the berries. Of the two Gros Guillaume is the better flavoured, but its bunches are too large for everyday use, and Gros Colman allowed to hang some little time parts with much of its disagreeable earthiness. Its noble appearance and usual deep colour and delicate bloom always command admiration. Syrian, Trebbiano, and Calabrian Raisin have enormous bunches, which detract from their usefulness, militating against good finish, and however well grown they are, with all white or yellow-skinned Grapes, more susceptible of damage from damp than black Grapes. Like all thick-skinned Grapes, they require a long time to mature after they are apparently ripe, consequently a temperature of 55° should be assured, with a rise of 5° to 10° by day, and a circulation of air until the foliage is giving indications of falling, when a temperature of 50° will be sufficient. The inside borders must not be allowed to become too dry. Water if necessary early on a fine day, and cover with a dry mulch as a safeguard against damp and to avoid a repetition of the watering. Outside borders will not require watering, as they usually at this season are damp enough; but it is essential to the sound and plump keeping of the Grapes that the soil be moist, lack of moisture at the roots being a chief cause of shrivelling when it does not arise from imperfect finish. If in a proper state of moisture they should be covered, preferably with lights, or some other means must be employed to throw off the wet, as saturation repeatedly from heavy rains is destructive of the roots, besides reducing the temperature of the soil needlessly.

*Late Muscats.*—If these are not now perfectly finished continue rather sharp firing in the daytime, with a free circulation of air and enough at night to prevent the deposition of moisture upon the berries. There is danger of the Grapes shrinking if there be a deficiency of moisture at the roots, and when water has to be given to inside borders where the Grapes are in an advanced stage of ripening, there is danger of spot, though it may be prevented by a free circulation of air, and covering the border with dry material. Indeed, moisture must be kept down by a buoyant atmosphere, pent-up air with a sudden increase of warmth from sun being sure to induce moisture to condense on the berries; which will cause spot, and then the Grapes will speedily decay. The inside borders should be covered with clean dry straw or matting to prevent moisture arising. When the Grapes are thoroughly matured a gradual reduction of temperature must take place, about 50° at night being necessary for Muscats after they are matured.

*Late Black Hamburgs.*—These finish and colour at a late period better than the thick-skinned varieties. Those that are now colouring and advanced in ripening should have a temperature of 60° to 65° at night, and 70° to 75° in the daytime, with a circulation of air constantly, not allowing the border to become dry, but giving a good watering if they are only partially advanced in ripening, and mulch with rather short dry material. Hamburgs like a good spread of foliage, therefore only restrict the laterals to prevent overcrowding; but after the Grapes are finished further extension must be avoided, yet not reducing the foliage much, as this assists Hamburgs to keep their colour. When ripe a temperature of 45° to 50° must be maintained, and air freely admitted by day whenever the weather is favourable, never allowing the temperature to rise considerably before air is admitted, as moisture will then be condensed by the cooler surface of the berries and their tissue be destroyed, the epidermis parting from the flesh.

*Houses of Ripe Grapes.*—Black Hamburgs and all the thin-skinned black Grapes lose colour by hanging. Nothing preserves them better than a good spread of their own foliage, and where this is scanty or only moderate some herring net doubled over the roof lights will materially assist in the Grapes keeping colour. A moderate amount of air moisture is beneficial to the foliage and not inimical to the Grapes, only the air is not stagnant, and air is given early enough to prevent the sun heating the atmosphere, and causing moisture to be deposited on the berries. In too dry an atmosphere the Grapes are liable to shrivel, especially when the Vines are dry at the roots, it not being uncommon to see Vines with their roots entirely inside ripening their foliage and the Grapes shrivelling, whilst Vines in outside borders have fresh foliage and plump Grapes. That in the same house. The Grapes should be looked over frequently for the removal of decayed berries, damp being their greatest enemy.

*Young Vines.*—Those planted last spring or early summer will need every encouragement in keeping the foliage clean and healthy; also keep the laterals away from the principal leaves in order to their free exposure to light and air, especially those at the base of the canes, so that the buds to which the Vines are to be pruned may be thoroughly ripened, and the wood at that part thoroughly firm and stored with food. A genial warmth in the pipes by day will assist the wood to mature, and ripening will be induced by throwing open the ventilators at night. Although a somewhat dry condition at the roots is desirable it must not be persisted in to the extent of causing the soil to crack.

#### PLANT HOUSES.

*Allamandas.*—The growth of plants that have been used in the conservatory has nearly ceased. If these are removed at once where the night temperature ranges to 60° they will soon start into growth again, and continue to yield flowers until Christmas. Fully expose them to the sun and supply stimulants liberally if the pots are full of roots. Plants that flowered early may be induced to rest by placing them in a

temperature of 55°, where water can be gradually withheld. Do not ripen them prematurely, or the wood will eventually shrivel instead of remaining firm and plump. Two months' rest is ample for these plants, and if rested now they may be pruned and started again early in December.

*Clerodendron fallax*.—Select two or three of the earliest plants and allow them to flower where the atmosphere is moderately dry and a circulation of air can be provided daily, seed will then be produced freely. When well grown this *Clerodendron* is very ornamental in the stove or intermediate structures during the next two months. Insert plenty of cuttings of *C. fragrans*, they will be useful for flowering in small pots early in the year. The cuttings should be inserted singly in thumb pots, and when well rooted place them into 3-inch pots. They flower freely when confined at their roots. If given liberal root room they grow too luxuriantly and fail to flower satisfactorily.

*Ixoras*.—Select a number of growing shoots that are moderately soft, and insert them in sandy soil in 2-inch pots. These will be useful for decorative purposes in spring, and carry one fine truss each. Young plants that are well rooted and growing freely may be placed into 4-inch pots. Press the soil firmly, and grow the plants on a shelf close to the glass in a warm moist atmosphere. They will make greater progress if gentle bottom heat can be provided for a time. Fully expose them to the sun. Large plants that have become woody through being confined at their roots are flowering freely the second time, and others will not be long before they yield a supply of trusses for cutting. Young plants growing into specimens should have the points of any shoots removed that are taking the lead. Keep the plants free from mealy bug by examining them frequently, and syringe at once with a solution of tobacco water, or fumigate the plants with tobacco smoke if thrips become established upon them.

*Aralias*.—Plants of *A. Veitchi*, *A. Veitchi gracillima*, *A. leptophylla* and others that are large enough for table decoration may be placed in a temperature of 50° to 55°. They will remain in good condition, and growth will be very slow. In brisk heat they run up quickly, and soon become useless. Plants that have been raised from portions of stem and are growing freely may be placed into 4-inch pots, and grown in brisk heat. These do well in loam, sand, and one-seventh of manure. Where there is a plentiful supply of fine peat a little may be mixed with the loam.

*Crotons*.—Plants that are highly coloured and large enough for table and other forms of decoration should be prevented making further growth. Fully expose them to the sun, and place them where the night temperature can be kept at 55°. Admit air daily, and gradually increase it. This prepares the plants for room decoration better than when removed from a warm moist atmosphere. Plants that are fully exposed to the sun, highly coloured, and their pots full of roots are liable to be attacked by red spider. Be careful the soil does not become dry at the roots of the plants, and syringe them liberally. The plants are greatly benefited by being syringed once or twice weekly with soot water perfectly clear. Assist plants in a backward condition by keeping the house warm and close, closing the ventilators early, so as to run up the temperature considerably in the afternoon. Insert in small pots all highly coloured side shoots that have been produced by plants from which the tops were removed some time ago.

*Paneratiums*.—The earliest of these are growing freely, and as they cease flowering must be kept close, moist, and shaded from the sun, with abundance of water and occasional stimulants. Any plants that need larger pots may be attended to at once in a compost of loam, sand, and one-seventh of decayed manure, a little charcoal may be added. It is not advisable to break up the plants in their present stage of growth. The check would be too serious, and prevent the plants making good growth afterwards. Plants that need division should be left as they are until February, or just preceding growth.

*Vincas*.—Pinch the shoots of plants in 5-inch pots for the last time; they will be useful in the stove during the dreary months of winter. The shoots are also useful for cutting; in warm rooms they will continue to develop their flowers for a long time after they have been severed from the plant. Cuttings may be inserted in small pots for early spring flowering. Large plants that have ceased flowering may be placed in a moderately dry atmosphere where the temperature ranges about 55°, and gradually withhold water.

*Dracæna gracilis*.—This is probably the most useful of all *Dracænas* for room decoration. It will stand in almost any position for a long time. Large plants may be removed to the greenhouse. In this position avoid cold draughts striking upon the plants. Those that have grown too large may have their heads removed and rooted in 4-inch pots. Those raised from heads are very useful for single vases, while those from the stem are the most serviceable for table decoration. They are lighter through the foliage being only about half the width of those that have grown strongly.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

WE have now reached the time when honey gathering in normal seasons ceased, but this puzzling season is an exception, and bees

are still working and hives are increasing in weight, the weather continuing fine. The 12th inst. was the best day they had, although the following days were rather windy, which is against bees flying and the secretion of honey. On the evening of the 18th September the lightning gleamed across the hill tops, which often indicates storms, but the morning following was one of the finest we have had, and we expect the bees to still add to their stores, as there is plenty of Heather in fine bloom. Taking everything into consideration we have been agreeably disappointed, and feel sure it will not be only interesting but instructive to give a brief summary of our management.

#### HOW WE PREPARED OUR BEES FOR THE MOORS.

As is well known I never allow my stocks to be low in stores nor to indulge in fanciful and unnatural feeding in driblets. Unlike many seasons we have experienced when we had to feed the whole summer, the middle of July found our bees with a fair quantity of honey, and so crowded that had the weather settled many supers would have been filled. At this season, even with large stores, bees are liable to draw their brood, and if not prevented all hopes of a yield of Heather honey are gone. To prevent brood drawing and to encourage breeding, I fed most stocks with 5 lbs. of sugar, the exceptions being the Cyprian blood, done for the purpose of keeping up their reputation as good honey gatherers without feeding; these, however, were the only stocks that drew brood, and which driblet or stimulative feeding would not have prevented. The preparation and management in this respect are in no way different from spring management.

Our hives require only a few minutes to prepare for the journey of fifty miles and eighteen hours' imprisonment, an ordeal no bees could stand in the state ours were in the ordinary hives of the day; but in our safety hives not a bee was lost, although the day on which we took them was the hottest of the season. The Thyme was profuse and fragrant, and in one hour after the bees were released they had taken to their supers, and as the body of the hives was filled with brood would have been filled and completed in a few days. The fine weather lasted, however, but one day longer, with the results already explained. For a month the rivers and rivulets were in flood, and although we had three or four more dry days during the month than in 1889, the rain and cold were excessive, and entirely at variance with the meteorological reports some twenty miles distant.

#### DRONE EXPULSION.

During this period drones were expelled, which is a great advantage not to be going on during honey gathering. Young bees hatched, but none was drawn unless in the hives mentioned, and those belonging to other people who had neglected to feed them. By the time the weather improved supers were abandoned, and although some colonies take to them on account of so many empty combs in the body of the hive the greater part of the honey gathered has been stored there.

#### HOW SUPERS MIGHT HAVE BEEN SECURED.

Had the weather settled sooner, or had I had any idea that it would have continued as it has, I would have removed the under body box for several days. This would have compelled the bees to cluster in the supers, and comb building would have begun. By this plan a more saleable article would have been secured, but a less quantity, which from a commercial point of view in so scarce a year would have been the least profitable.

#### ATTENDANCE TO HIVES.

To secure the greatest results at the moors it is absolutely necessary to be in almost close attendance with the bees, as in spite of all precautions (unless having young queens) and bad seasons bees will swarm. During cold weather entrances require to be contracted to prevent extra consumption of food and robbing, then as the honey is getting less plentiful robbing is greater, and a narrow doorway is the only safeguard, while it keeps up the heat inside as

it declines with the season, and enables the bees to carry up and seal all honey.

#### WEIGHT OF HIVES.

Our bees will have to be at home before I can give the quantity of honey gathered, and the result of the six varieties of bees. I cannot yet say which have gathered most, but I am glad to say that I can with one exception corroborate all "A Hallamshire Bee-keeper" has said of the Punic bees. I am sure it will please him to learn that those he sent me are not in the rear, and it will neither surprise him nor me should they prove to be the heaviest hives on the moors. They have one feature that "A. H. B. K." has never explained, and it is a good one—viz., they have shorter abdomens than some of the imported races, which brings their load and centre of gravity well forward under their wings, and power of flight is increased, and they can brave storms that longer bees cannot.

I trust the foregoing explanations will assist bee-keepers in the future, and enable all who carry out the system to their satisfaction and advantage securing a large yield of honey in the midst of many hives that, according to what their owners explained lately, have not gathered as much as will keep the bees alive during the winter, and I have examined many that have gathered much less. Fuller particulars will be had when at home from—A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Netting (E. H. B.).**—Your complaint appears to be well founded, for if your measurements are correct you have less than 33 square yards.

**Pentstemon W. E. Gladstone (J. F.).**—The spikes sent were very fine, and the variety is evidently a handsome one, but the flowers had all shaken off the stems when they reached us, and had consequently nearly all withered.

**Seedling Richardia (H. E.).**—Both the leaves and spathe were withered on arrival, but such a plant as you describe bearing miniature spathes abundantly would be an acquisition, and a good flowering example sent to the Floral Committee of the Royal Horticultural Society would receive attention. The present is not the best season for displaying the character of the plant. The spathes of Richardias usually increase in size with the strength of the plants and high culture. The specimens you send are certainly very small, and the name "Little Gem" seems appropriate.

**Protection for Fruit Blossoms (W.).**—There is no objection to any of the materials you mention for protecting blossoms from frost, but netting is not nearly so good as canvas, for the blossoms are injured by damp or rendered more susceptible to damage than when kept dry. The stouter thicknesses of scrim canvas and tiffany are good, but we prefer Hessian or scrim canvass, both of which are 1½ yard wide and can be had of varied stoutness, which influences the prices. With care the materials are durable, not being so much affected by wet as cotton fabrics. They are made of hemp, and have a certain openness favouring a circulation of air; we find them excellent protection. Wool fabrics are, of course, the best, but they are double the price or more.

**Destroying Thistles on a Lawn (J. M.).**—The ground we presume is efficiently drained. If not it should be done to a depth of 3 to 4 feet, as Thistles are deep rooters, and are much checked by draining. After this they yield more readily to pulling or cutting, either of which will destroy them, especially if a little salt or nitrate of soda be dropped into

the holes, or in cutting them off a little sulphuric acid placed on the cut part will act more effectively, and usually is efficacious at the first dressing, but should be persisted in as necessary. The sulphuric acid is best applied with a stick notched at one end, and the liquid placed in an old blacking bottle with a piece of stout wire twisted round the neck, so as to form a longish handle. The acid must be used very carefully, only allowing it to touch what is to be destroyed, keeping it from the hands and clothes.

**Select Peaches and Nectarines for Early and Late Houses (L. J. A.).**—For early Peach house:—Peaches: 1, Waterloo or Alexander; 2, Hale's Early; 3, Condor; 4, Royal George; and of Nectarines, 5, Lord Napier; and 6, Elruge. Late house:—Peaches: 1, Grosse Mignonne, but Belle Beauce is finer though ten days later; 2, Alexandra Noblesse; 3, Barrington; 4, Princess of Wales; 5, Walburton Admirable; 6, Sea Eagle; and Nectarines, 7, Improved Downton; 8, Rivers' Orange; 9, Pinc Apple; and 10, Victoria. A Cherry tree is not suitable for growing in the same house as Peaches, for when the Cherries are ripening the fruit must be kept dry, and unless you can insure that we do not advise the practice. If you decide to have a Cherry you could not have a better than Early Rivers.

**Transplanting Fruit Trees (G. J. A.).**—In lifting and transplanting the Pear trees no difference need be made in the pruning. As they, however, are to remain on the spot, the trees may be lifted carefully, not allowing them to suffer through being out of the ground long. The chief cause of red spider is want of nourishment, but it no doubt spreads rapidly, and can only be kept under by forcible syringings and the application of an insecticide. The trees should be dressed this autumn directly the leaves fall with a solution of softsoap, 4 ozs. to the gallon of water, applying with a brush, washing them thoroughly in every part. Give a good mulch of manure over the roots, and keep them well supplied with water and liquid manure during dry weather in the growing season. Gather the beans when quite dry, and place them in stone jars in layers with salt alternating, enough salt being used to cover them.

**Pruning Old Lilacs (An Ignoramus).**—The old Lilacs will be the better for having the suckers thinned, but leaving some of the best in strength and place, cutting back any of the old that are long and bare; but unless overgrown the old stems should not be interfered with, as Lilacs flower more freely on the older branches. Privets may be cut-in to any extent, but if you want them to flower they must not be cut hard back, merely shortening irregularities. Golden Elders will bear cutting to any extent, but they, where space permits, are best only kept from straggling, shortening irregularities of growth during the winter season. Pruning is best performed in autumn, directly the leaves begin falling; or they may be cut back now, so that the growths left will have the benefit of the autumn sun. It may, however, be done any time during the winter, preferably in mild weather, always before the buds begin swelling.

**Peaches on Walls versus under Glass (A. N.).**—In the majority of cases Peach growing is very uncertain against walls, and it is to do away with the uncertainty that glass is recommended by most growers for sale. Trees, however, well protected and managed are grown profitably in many localities against walls, but that is beside the question, as it is not a matter of successful culture against walls, but whether erecting a wall or a glass structure for the cultivation of Peaches and Nectarines for sale would be the most economical and profitable. First cost and after cost, or wear and tear, as well as cost of production, have to be considered, and where they have been the glass structure has afforded the most certain and highest dividends on the outlay. Indeed, some walls occupied with Peaches and Nectarines, though paying what was considered a fair per-centage of profit on the labour and means expended upon them, afforded very much better results when covered with glass, the house being erected over the whole border, and trees grown in front as well as on the wall. Where a wall exists, and Peaches and Nectarines can be grown satisfactorily, to cover it with glass without affording accommodation for more trees cannot be expected to pay, but where the climate is cold to cover the wall with a case insures certain and finer crops of fruit. Growing fruit for home consumption and for sale are very different, requiring consideration from their respective standpoints. From a sale point of view Mr. Rivers is no doubt right.

**Walnut Trees Coming into Bearing (S. B.).**—There is a great difference in the soil and locality in respect of the age at which the trees come into bearing. Trees on silicious soils and calcareous soils produce fruit sooner than trees on rich and moist soils. The mode of raising also affects the age at which the trees bear; those grafted come into bearing in about half the time that those raised from seed require. Trees of the common Walnut 6 to 10 feet high, and grown thinly as well as frequently transplanted, will usually bear in three to five years after being placed in their permanent quarters. The earliest-bearing is Dwarf Prolific, which bears abundantly at 6 feet high, affording good-sized well-flavoured nuts, and is a variety that reproduces itself from seed. It, however, requires a warm soil and situation. Ordinary varieties of the common Walnut which are usually raised from seed do not afford profitable crops until of the age you name—viz., thirty or forty years. The only thing likely to cause trees of that age to bear is to root-prune them, which should be done as soon as the foliage turns yellow or is beginning to fall. In order to secure more fertile trees, scions should be taken from trees that are noted for fertility and good quality, grafting the stocks from seed so as to secure earlier bearing and a certain character. For elevated and northerly localities the Yorkshire is very desirable.

**Plants for Conservatory (A. N.).**—As climbers you could not have anything better than drooping plants, which always have a graceful appearance; but your roof being low they would occasion much cutting, therefore plants that are neat in growth would perhaps suit your purpose better. Of compact growers *Lapageria rosea* and its variety *alba* are superb. The roof covered with these would be extremely chaste, and for a small house nothing could be better than something distinct. *Rhynchospermum jasminoides* and its variety *variegata* are also good and sweet. Those are what we recommend of the neat growers. For depending, *Acacia Riceana*, *Passiflora Impératrice Eugénie*, *Solanum jasminoides floribundum*, *Tacsonia insignis*. Foliage plants suitable for your purpose are—*Dracaenas australis*, *congesta*, *rubra*; *Eurya latifolia variegata*, *Ficus elastica*, *F. elastica variegata*, *Farfugium grande*, *Grevillea clegans*, *G. robusta*, *Lomatia elegantissima*, *Phormium tenax variegatum*, *P. Colensoi*, *Rhopala clegantissima*, *Yucca aloifolia* and *Y. quadicolor*, *Isolepis gracilis*, *Coprosma Baueriana variegata*, *Aralia leptophylla*, *A. Sieboldi* and its variegated form, *Aspidistra lurida variegata*, and *Veronica Andersoni variegata*. A few Palms also would be useful, such as *Phoenix reclinata*, *P. sylvestris*, *P. tenuis*, *Corypha australis*, *Areca rubra*, *Chamærops excelsa*, and *Rhapis flabelliformis*. Also Ferns, such as *Nephrolepis Duffi*, *Adiantum cuneatum*, *A. Williamsi*, *Asplenium dimorphum*, *Cyrtomium falcatum*, *Davallia Mariesi*, *D. tenuifolia stricta*, *Lastrea aristata variegata*, *Lomaria gibba*, *Nephrodium molle corymbiferum*, *Pteris cretica albo-lineata*, *P. serrulata* and *var. cristata major*, and *Selaginellas formosa* and *Wildenovi*. For the pillars you could not have anything better than *Abutilons* and *Heliotropes*.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. G.*)—1, Cackle's Pippin; 2, Calville Blanche; 3, Alfriston; 4, Kentish Fillbasket; 5, Sturmer Pippin; 6, not known. (*J. H.*)—1, Vicar of Winkfield; 2, Doyenné Boussoch; 3, not known; 4, Duchesse d'Angoulême; 5, not known; 6, Napoleon.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens should be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. B.*)—1, *Helianthus multiflorus*; 2, *Senecio pulcher*; 3, *Aster amellus*; 4, *Rudbeckia purpurea*. (*H. T.*)—1, *Polygonum cuspidatum*; 2, *Nycterinia selaginoides*; 3, *Kniphofia Uvaria*; 4, *Lagurus ovatus*; 5, *Herniaria glabra*.

SEED CORN.

THE temptation to knock out enough corn from any nearest to hand for sowing now will be greater than usual, because the weather is so fine and the entire strength of the farm is absorbed on the land, from the very natural and praiseworthy desire of every sensible farmer to turn this splendid autumn weather to full account for cleaning the land. But do let us remember that good and pure seed is indispensable, and that nothing short of the best seed will answer if we would have a full crop well above the average. What does the low average corn yield point to but bad practice? It is not by any means so dependant upon seasons as many would have us suppose, but is rather owing to inferior seed and inferior cultivation generally. There can be no doubt that very much of the inferior corn so recklessly used for seed in the past contained a large quantity of weed seeds, and that in a great measure accounts for the serious spread of Charlock and Poppy, for those who would use tail corn for seed are unlikely to be particular in other matters.

We want now for the autumn sowing Winter Oats, Beans, Peas, and Wheat, and there should be no difficulty about having them pure and clean. The seed sample should be just as clean as a market sample, and that is only to be managed by repeated screenings, and no old second-hand corn screen will answer. Every farmer should have a corn screen approved by judges at one of the Royal Agricultural Society's Shows, or from a local maker of repute. This is an investment that is certain to repay one, and it ought to do so in a single season. Dirty and foul samples are the corn merchant's and miller's grievance. Cultivation has its influence, but the final result depends so much upon quality, that brightness, weight, purity, and cleanliness all tell, and to all these a good corn screen contributes very materially. It is, therefore, obvious how important thorough screening is both for sowing and for sale.

Equally important is selection, and now is the time to decide whether we have corn sufficiently pure to thresh for seed, or whether seed must be purchased. In the latter case it may frequently be had from a local grower at a slight advance on market prices, failing which it may be had through a cornfactor for a fair price. Much greater attention has been given to seed selection during the last few seasons, and the great specialists in seed corn have the unanswerable argument in reply to complaints of their high prices, that they have no difficulty in selling, so keen are growers to improve their stock, which shows that we are speaking to a recognised fact rather than pointing out a fault.

Is the full importance of selection and improvement recognised as fully in Ireland as in the other part of the British Isles? The question occurs from the suggestion that had due attention been given to planting sorts of Potato of approved merit, and seed that had suffered no exhaustion from wasteful premature sprouting, the

risk of loss from disease would have been much lessened this season. We merely record the thought as it occurs to us, for though it is a little wide of our subject, it is nevertheless intimately connected with the home farmers' interests, and now is the time to select seed Potatoes, and so to store them that when the planting season comes round again they may be firm and plump, with short sturdy shoots as thick as one's little finger.

Having given due care to seed selection, let us be equally discreet in our preparation of the seed bed, and see that it is both clean and fertile. The safe standard of fertility is that which ensures robust growth from the first, and nothing short of this is to be regarded as sound practice. If there is a doubt in the matter it is better to make certain by sowing chemical manure with the seed. Here is the formula:—Half cwt. nitrate of soda, quarter cwt. steamed bone flour, quarter cwt. mineral superphosphate per acre. The hundredweight per acre of nitrogenous and mineral manure is a cheap safeguard against poverty of soil, and the expenditure involved of some 6s. or 7s. upon it points to an increase in bulk of yield, the value of which even at present prices will cover it and the spring dressing, pay the rent, and leave a handsome balance towards the cost of tillages. We like a strong robust plant in our winter corn, so that it may come away quickly in spring, and are willing to run the risk of a slight loss of nitrogen to secure it. This risk of loss sinks to a minimum if the manure is drilled with the seed, as it is then close to the roots, which are certain to absorb most of it. If sown broadcast before the drill and harrowed in it is so distributed over the entire surface that much of it may be washed down to the subsoil by heavy rain before the roots can reach it. The dressing of manure may be applied to Rye as well as to Wheat and winter Oats. Rye is usually sown for an early supply of green fodder for horses and cattle, as well as for folding ewes and lambs. We want it early and plenty of it, both which depend very much upon fertility of soil. In poor soil the Rye plant is always weak and backward; in rich soil it is strong and forward.

#### WORK ON THE HOME FARM.

On mixed soil farms where Wheat-growing is still well to the fore early sowing is all-important. We like to begin in the present month, and to get through in October. When the Wheat area extends to some hundreds of acres this is only possible by having the ploughing well in hand, and the drill going by the third week in September. Rye, too, and winter Oats and Beans must also be got in early, and a first sowing of Tares made by the end of the month. Much of the second crop of Clover is being folded by sheep, as the flower heads are so barren of seed, and the ploughs follow the folds closely for Wheat, which is soon got in. We shall also follow some Cabbage and early Turnips with Wheat, as both have been folded with sheep, and the land is in such good heart that there is no question about fertility, and no expense about manures this autumn.

What a boon to the farmer is a flock of well-bred healthy sheep! Here have we been folding white Mustard, Cabbages, Turnips, &c., since the lambs were weaned, leaving the land so rich in fertility that a full crop of corn is a certainty. No manure bills, but a delightful per contra of plenty of sheep to spare, and a certainty of high prices whenever we wish to sell. This gives a spirit and go to farming such as it has not had for several years, and the sight of our fine herd of home-bred store cattle is equally cheering, for there's money in it, sir! Our neighbour, Brown, who has made his pile on the Stock Exchange, says cattle are a snare and delusion, for the store cattle his man purchased a year or more ago after faring sumptuously upon pasture, hay, corn, and oilcake were sold recently at the local auction mart for less money than he gave for them. Nor does he receive our advice to try home-bred stock with a good grace, for he has had abortion rampant among his cows. We have no doubt that both his cows and store beasts suffered much from exposure last winter, for they were out on a cold wet pasture daily, and have no suitable yard or lodges for shelter or warmth. Brown has built magnificent stabling for his carriage horses, replete with every modern appliance and decoration, but his cowsheds near them are a snare and delusion, and he certainly has no just cause of complaint at the failure and annoyance resultant from such mismanagement. We mention this because many a gardener having charge of the home farm has to struggle on with inadequate means, and is blamed for losses and failures which it is out of his power to prevent.

#### THE HOP CROP.

We have delayed issuing our report this season about fourteen days beyond our usual time that we might be in a position to say what effect the hot weather that set in about that time would have upon the crop.

We have now finished a most careful personal survey of the Hop-growing districts of England, and we are sorry to have to report the extreme heat has not, on the whole, been beneficial; it has certainly to a limited extent helped the Colgates and late Goldings, but has done great harm to many of the early Hops, especially those on dry soils, almost all of which have gone off with "red mould;" vermin has also made its appearance in the cones in many gardens, and we fear many will not be fit to pick that are left over until next week. Fresh fly can be found in them; this is bad, as it foretells an attack of aphid next spring. In making an estimate of the growth on as liberal a scale as possible we should say that 10,000 acres will not produce a Hop, 20,000 acres may produce 3 cwts. per acre, 15,000 acres may produce 6 cwts. per acre, 5,000 acres may produce 8 cwts. per acre, 3,000 acres may produce 10 cwts. per acre, and 2,000 acres may produce 15 cwts. per acre.

We are pleased to say that the best growths will be very grand indeed, and will be of such splendid quality that have hardly, if ever, been surpassed; we should think these Hops will produce something like 70,000 cwts.; there will also be about 100,000 cwts. of fair copper Hops picked, and the remainder will be of very indifferent quality, which in ordinary seasons would not tempt brewers, but this season will all be taken for mixing with good sound old Hops, and will be very useful for this purpose. Even at this late period of the picking it is not quite safe to say that 250,000 cwts. of Hops will be picked, as it is probable that many of the gardens that are left unpicked this week may be completely destroyed by red mould and vermin. The Weald of Kent and Sussex Fuggles have withstood the ravages of vermin and mould best this season, and some of the best growths will be found amongst these Hops.

The Continent will not produce more than half of last year's, when every bale went into consumption. America will grow about as many on the Pacific Slope as last year, but the New York State crop will fall short by at least one-third; last year, although America imported nearly as many Hops as she exported, every bale of their 1889 crop had gone when this season opened. This year it is not likely she will import a bale, as in the first place Germany will have none to spare, and in the second the import duty, which has just been raised to 70s. per cwt., added to the very high prices now ruling at Nuremberg, will put them out of the market, consequently America cannot spare a bale of Hops for England, and if many of the Hops that have been contracted for already should be shipped here, there will be the greatest famine in Hops in America ever known, as the consumption of beer there increases at an enormous rate, the increase this year over last being nearly 2,000,000 barrels.

The position of affairs is unique. America and the Continent produce just enough for their own consumption and no more. England, with an annual consumption of 700,000 cwts. may, if every Hop that is hanging on the poles be picked, grow 250,000 cwts.; to meet this deficiency there may be 70,000 pockets of sound old English Hops, which, if reckoned as three equal to one pocket of new Hops, will add 30,000 cwts. to the 250,000 grown in England (the Continent has already commenced preparing old Hops for the English brewer, and several thousand bales have arrived marked 1888, which are nothing but worthless Hops of the years 1885, 1886, and 1887 growths, that have all been mixed up and manipulated and repacked. The attention of the Government should be drawn to these packages; the same trickery was practised in 1882, when worthless Hops of ten years of age were repacked and sold as 1879's. Brewers would do well to refuse to buy any repacked Continental Hops).

Long before the 1891 crop can be secured there will be the greatest famine in Hops all over the world ever known, and lucky indeed will be those consumers who secure their twelve months' consumption while there are some Hops on the market, as it is now certain that even the old beds of Germany will be turned out to keep the brewers going until the next crop can be secured.—MESSRS. W. H. & H. LE MAY, 68, Borough High Street, London, S.E. (in *Andover Advertiser*).

#### REMARKS.

14th.—Bright throughout. 15th.—Bright and warm. 16th.—Bright and warm.  
17th.—Bright early; thin cloud and haze in morning; generally overcast in afternoon; heavy rain in evening.  
18th.—Rain in small hours, and generally cloudy till 11 A.M.; then fine and bright till 3 P.M., and cloudy again after with rain at 5 P.M.  
19th.—Bright morning; generally cloudy afternoon.  
20th.—Rain in small hours; fair morning, with occasional sun; bright afternoon; spots of rain in evening.  
The rain on the 17th ended a drought of twenty days. The nights have been considerably warmer than in the previous week, and the temperature on the average has been considerably above several weeks in July and August.—G. J. SYMONS.

## FRUIT TREES IN AUTUMN.

NATURALLY the desire of owners and cultivators of fruit trees is to see them laden with fruit. To the great majority this pleasure is denied this year, but there are exceptions. Here and there trees may be seen very much overladen with Apples, and have, in consequence, made little or no growth beyond the production of small leaves. Such examples are, however, exceptional, and, as a rule, fruit trees that are not too old or exhausted have made unusually free growth, while the young and inherently vigorous have, to use a familiar simile, grown like Willows. It is the same with trees generally which are systematically allowed to make all the growth that can be forced by unrestricted roots in the summer for cutting out in winter in the process of what is known as pruning. A great deal of this kind of pruning has been done in the past, and will probably be done in the future, the direct result being, as it always has been, must be, and will be, the prevention of fruit.

A few years ago the readers of a popular newspaper were satiated with advice from correspondents on the subject of "What to do with our boys?" Whether they did any better with, or for, the boys in consequence of the discussion is perhaps a moot question, for sometimes good advice is given which by one section of the community cannot be followed, while those who might profit by it fail to do so for various reasons, such as lethargy, stupidity, incredulity, and assumed superiority. That, however, is not the fault of those who strive to be useful, and it may be fairly presumed that there are a few who are apt in turning to account published hints and suggestions that are applicable in their case. A question of interest to many at the present time who are endeavouring to grow fruit is almost a counterpart of the boy question—namely, "What are we to do with our trees?" In many, if not in most, cases that question would probably not be very difficult to answer if the exact condition of the trees could be made clear to an experienced cultivator, together with the surrounding influences, and the treatment to which the trees had been subjected. With this information before them, there are plenty of men who could form a very good opinion of what it would be desirable to do to render the trees as satisfactory as seasons and circumstances permit.

No one who is admitted to possess a fair knowledge of fruit culture needs to travel far, or visit many gardens and orchards, before being driven to the conclusion that by far too many persons who have trees do not know what to do with them. A certain number of these persons do nothing, and they occasionally succeed quite as well as do others who are always doing something, but often doing wrongly. Intelligent readers of the gardening papers to whom practical men contribute have learned much during recent years on the management of fruit trees, and improvement is manifest in many gardens; but there are thousands of trees in the care of persons who either do not read, or skim the papers without thinking, that are a disgrace to a civilised nation—crowded, filthy, moss-encrusted, and starved on the one hand, or young, vigorous, and clipped in like Privet bushes on the other. They are alike pitiable to see. The former may or may not crowd themselves with blossom and worthless fruit, and the latter grow with unwonted vigour for the knife or shears in autumn to put them into shape. Of fruit these latter kind of trees bear little or none,

but the pruner never dreams of that being his fault. If asked why they do not bear he will perhaps tell you the sorts are wrong, the soil bad, or that some stupid man did not plant them right at first. There seems no end to the ingenuity of a man who fails in covering the cause of his failure, and it is deplorable to observe how many either fail in fruit-growing or only succeed in having good crops by chance.

There comes a time in the life of a tree when it is practically beyond renovation. It has had its day and done its duty as best it could under the circumstances, but there are vast numbers of trees that become practically useless too soon because they have been either neglected or mismanaged. The present is the time to afford aid to more or less exhausted fruit trees, the time also to assist effectively others which are not exhausted. Let us take a few typical examples, and see what is best to be done with them. There is not the slightest necessity to draw on the imagination for such trees, for they exist in every county, and in many orchards and gardens in each.

Here is a plantation of very old trees. The most ancient of them were planted at some remote period by somebody's grandfather, of whose pomological work there is no record. In the course of time one here and there, and now and then, has either died or been blown down, and another has been "stuck in" to fill the blank created. This became old before its time, as trees are apt to do under such circumstances. Without any doubt the Anglo-Saxons are an intensely conservative people, and, in rural districts especially, appear loth to depart from the habits and customs of their forefathers in the provision of fruit. Once an orchard always an orchard, would appear to be the unwritten law that has governed the actions of men through many generations, if not centuries; and the old custom of filling up blanks in old Apple orchards with young Apple trees is still in force in many localities. It is utterly bad, but we are bound to recognise its existence, much as the fact is to be deplored. If it is necessary—or, whether necessary or not, thought desirable—to continue a fruit plantation on a site which has become historical, let the blanks in an ancient Apple orchard be filled up with Plums, and in a Plum orchard with Apples, and a much better return may be expected, and will be realised, than if the ancient custom of filling up the ground with the same kinds of fruits which have grown and died thereon from time immemorial. Now, while the leaves, if not fruit, are still on the trees in old orchards, is the time for a critical examination, because at no other time is it possible to arrive at such a correct decision as to which of the trees should be marked for removal and which for renovation.

Many fruit trees, which if left alone, can only be regarded as cumberers of the ground in the future, may be made to yield usefully by judiciously pruning, cleansing and manuring till young trees, planted on a fresh and suitable site, produce what only young trees and good soil can produce—a full supply of superior fruit. When old trees have arrived at a state of decrepitude that they cannot without aid of the nature indicated be serviceable, young trees should always be planted, not among the old, but apart from them, for it is evident that the end of the former is near, and not until the young trees have arrived at a profitable bearing state should the old be wholly destroyed where a continuous supply of, we will say Apples, is essential. More than one young gardener has erred, and suffered for his error, by too hastily uprooting old fruit trees, and thus creating a blank in the supply of fruit, which has been more than inconvenient, pending the time that the young trees he may have planted of the best varieties have become substantially productive. The safe course to pursue is to make the best of the old trees for a time, and it is wonderful how many can be improved by the thoughtful use of the saw and knife now, with the application of the scraper and lime for cleansing the branches, and the generous use of strong liquid manure to the roots at any convenient time in winter or early

spring. So long as a tree which has been neglected can be made with a little attention to bear, if not high class, yet useful fruit, it will be safe to follow the advice of Mr. G. Bunyard, as given in one of his practical papers in the words of the old song—"Woodman Spare that Tree."

The present is the time, and the best of all times, for relieving exhausted trees of the useless parts, and thus concentrating the sap on the more useful, and imparting to them new life and vigour. Weak, crowded, worthless branches should be removed at once. Their true character can be seen now, and it can be determined at a glance which can be advantageously removed and which retained; but only men of long experience and experts in the work can decide with the same accuracy how to proceed with the work when the branches are bare in winter. Moreover, the wounds made by the removal of branches now, and duly pared smooth, heal far more freely than when they are made when the sap is in its most dormant state. In affording assistance to old trees in the manner suggested it is a golden rule to thin out—remove entirely—worthless branches instead of merely shortening them, and neither to remove nor shorten any which, if not strong, are clean and healthy through the direct action of the sun and air on the foliage in summer. These will be the extremities of the branches on the outsides of the trees, and there let them remain. Do not thin them too much, but remove the interlacing branches from the interior of the trees, which can be of no service, but are the reverse, in diverting the sap from the extremities where alone, in the case of such trees, serviceable fruit can be produced.

Passing from orchard standards to established bushes what do we find? Trees in various parts of the country planted twenty, thirty or more years ago. They afforded good crops of fine fruit for a few years, or until they attained the height at which it was intended to keep them, 7 or 8 feet, or as high as a man could reach, and after that they grew "nothing but wood," long, strong shoots in summer, closely cut back in winter after the manner of pollarding Willows. Yet the complaint is they bear no fruit. It would be little short of a miracle if they did, for the spurs below were spoiled by the summer growths above, and these cut away before they could produce spurs in turn. Anything more thoughtless and even barbarous than such practice it would be difficult to imagine. If trees are to be kept dwarf, yet fruitful, exuberant summer growths must be prevented by free cropping in fruitful years, or root-pruning in fruitless seasons. In that way, and no other, the finest of fruit can be produced and handsome dwarf trees, of which owners and cultivators may be proud. But it is not the way to obtain the most fruit from a given space of ground. When that is the object in view there must be no violent restriction with the knife while the roots are left to ramble where they will. A few years ago a gentleman had an avenue of bush Apple trees in his garden; they were 6 feet in diameter and 7 in height. He would not have those dimensions increased on the ground that the cropping of the land would be interfered with. The trees made summer growths between 3 and 4 feet long—a thicket of them, closely cut back in winter. As might be expected the trees gave next to no fruit for years. The owner did not know what to do with them. He had tried manuring (which was worse than useless), he had tried root-pruning (but the work was not half done). He was advised to let a stated number of the strong summer shoots, a foot apart, remain unshortened, removing all others, and where new growths pushed from the cut back parts in spring to rub them out by the sockets. The first summer afterwards the 3 to 4 feet growths were studded with fruit buds, the second they bore splendid fruit, the next the crop was a crowded one, and luxuriant growth of necessity ceased. The trees yielded more fruit in those two years than in the ten preceding, and with a little thinning of the branches as requisite they continued as productive in subsequent years as could be desired. From profitless they were turned into profitable trees, and no further objections were heard about their interfering with the cropping of the land.

Trees that are neither worn out or nearly so by age, nor neglected, or wrongly treated should equally have attention now in the removal of breastwood or lateral growths from the main branches instead of leaving them till winter or spring. A young shoot may be left where there is space for a new branch a foot from the others, and the main branches thus thinly disposed should be well furnished with blossom buds, and eventually laden with fruit. These remarks apply to established trees, for the shoots of young trees should be cut back for the first two or three years for ensuring a strong foundation and producing the requisite number of growths for well furnished trees. This shortening may be deferred till the leaves fall or till spring, according to circumstances; but early autumn pruning generally is of more importance than is recognised by many owners and managers of fruit trees.—  
J. WRIGHT.

### HARDY FLOWER NOTES.

SEPTEMBER has just come to a close, and it is impossible for the lover of flowers to think of the close of the month with equanimity. It seems but yesterday—and yet it is three years ago—since, on the 29th of September, the morning dawned mild and showery, and all was bright and full of bloom, but ere night the wind had veered round to the north-west, our most dreaded wind, and when day broke once more, blackened flowers and stems and bleak desolation everywhere spoke all too eloquently of the power of that pitiless icy wind. I had only the previous day been in a garden where a long walk presented a picture of beauty; long lines of Begonias on either side, with Dahlias in the background, while tall Hollyhocks, and some of finest Ricinuses I have ever seen, broke the regular lines of White Queen and Glare of the Garden. Need I say what this was like on the morning of the 30th? Words cannot depict it, and I leave it to the reader to imagine the scene. With such a bitter gale the hardiest flower had to succumb, and too many were doomed untimeously to depart.

"To see their mother—root . . .  
Where they together  
All the hard weather  
Dead to the world, keep house unknown."

I have no doubt that some who read this will utter a malediction upon me for sounding these notes of evil warning, but their motive is a good one, warning all to keep a good look-out, and by a little timely reflection, save some of our late favourites from being "nipped i' the bud." A worthy neighbour of mine has a late Chrysanthemum which she carefully covers with a cloth when signs of frost appear. This late Chrysanthemum—a late purple Pompon—is one of the hardiest I have ever seen. I do not know its name, but it grows from year to year a true herbaceous perennial, which needs, and receives, no protection or propagation. But enough of winter awaits us without dwelling too much upon it, and let us while they are with us think of the glories of the present.

If there were no Sedums worthy of growth but the one now in flower, *S. spectabile*, often known as *S. Fabaria*, the family would deserve gratitude at our hands for producing such a useful flower. There is something so bright and cheery in its fine large flat heads of pink flowers that we cannot refrain from admiring it. This Stonecrop is sometimes used with good effect as a bedding plant, but grown as such much of its beauty of form is lost, but when grown in single plants of moderate size it is much finer. It has a singular property of intoxicating or stupefying bees, and I have no doubt that "A Lanarkshire Bee-keeper" will agree with me in recommending that the plant should be grown very sparingly where bees are kept. I have heard of one humane lady who carefully lifts bees off her beds of the *Sedum* and lays them on the grass to recover. *Cenothera taraxacifolia* is still flowering away, and although it appears to prefer a light sandy soil, seems also to luxuriate in a moist season. It is perfectly hardy with me, and my plants are fast increasing in size. In my last notes I made mention of some of the *Colchicums* in flower. Others have now come into bloom, and two that I have flowered for the first time are worthy of special note. The first, *C. chionense*, is, as the specific name denotes, a native of Chios, and is, I think, one of the finest of all the chequered varieties. The shape is starlike, and the colour, when the flower is in its early stage, is more crimson-like than *C. variegatum*, the commonest of the chequered varieties. This is one of the *Colchicums* known to Miller and the old authors of works on gardening. The next is *C. veratrifolium*, which is almost equal in value to *C. speciosum rubrum*, but is not of such fine form. Several others, including the double white, are also in flower. I have been anxiously looking out for flowers of autumnal Crocuses, but the

ever welcome *C. speciosus* is the only one which has as yet favoured us with a display of its beauty.

Some of the Tritomas are as fine as when I wrote last, and the late Asters are coming well into flower. One fine seedling, which grows about 6 feet high with me, is very good at present. It forms a pyramid of lilac flowers, clustered, like most of the others, so thickly as to hide the foliage. *A. amellus*, the neatest and best of all to my mind, is coming well into bloom, and several others have opened a few flowers. Many have a considerable resemblance to each other, but when seen at a little distance the points of difference are more noticeable. The Mossy Saxifrages are assuming the beautiful greenness which renders them so valuable throughout the winter months, the finest in this respect at the present time being *S. tenuifolia*. *Rudbeckia Newmanni* remains unapproachable for beauty by all others among the host of yellow composites. There is something exceedingly attractive in the bright orange rays and intensely dark centre. The queen of the early Chrysanthemums, Madame C. Desgranges, with its yellow sport *G. Wermig*, lightens up the border. I have not as yet grown Mrs. Burrell, but hope to test it another season. Gladioli are nearly past, the later sorts being comparatively useless with us in the north, and the garden is beginning gradually to assume a more sombre hue.—S. ARNOTT.

### OUTDOOR TOMATOES.

I ONLY venture a line on this subject because I have not seen any outdoor Tomatoes this year or last, even in good gardens, that had such fine crops as my own. I do not pretend to teach, but as my practice seems to be successful perhaps an outline of my cultural routine may be worthy of note.

The season has, of course, been unfavourable. I have not gathered ripe Tomatoes out of doors in June as I did last year; but my plants have done well. We have for a considerable time had as many as we wanted, and to-day (Sept. 25th) I have gathered 37 lbs. of fine sound thoroughly ripe fruit\* from just that number of plants, not cutting any which were not completely and thoroughly ripe. Only three of these plants are on a south wall, the remainder being on a larch paling, and mostly facing W.N.W. A large amount remain to be gathered.

I venture to suggest those who fail in the outdoor culture of this popular fruit do not give it sufficient attention. I have been surprised to see a quantity of green growth on plants in other gardens, even as late as this date, whereas I (not pretending to be an authority, but speaking only as one who seems to be successful) allow no stem or leaf growth whatever after the end of July at latest. My variety is Suttons' Main Crop. I do not at all say it is the best for the purpose, but as it serves me well and I know its "manners and customs" I am satisfied. My plants are raised as near the glass as possible to make them short jointed, and kept in a similar position when removed to a cooler house. They are put out about the same time as bedding plants—say the middle of May for an average, and I do not think much of a plant that has not by this time a bunch of flowers, sometimes with the fruit set—planted against the paling in firm soil, well trodden with no manure, and watered occasionally but not too much. They need now, as soon as they begin to grow, a good deal of attention, and should be gone over carefully at least three times a-week, thinning the foliage severely, and cutting away perhaps a good portion of each leaf left if it is so large as to shade the plant. The one-stem system is rigorously adhered to, and any side shoot is rubbed away at once. If left only for a short time it will weaken the stem above it. The very large trusses of bloom are thinned, and any leaf growth from the bunch stopped at once. The plant is carefully nailed or tied up, and the bunches of fruit supported in some manner, or their weight will soon bend and bruise the stem of the truss. About the middle or end of July, according to the season, all growth is stopped for the year; there should then be from six to eight good bunches of fruit or blossom buds on each plant. Now for the first time liquid manure is given, but cautiously; not if the weather is cold and wet. The swelling fruits are tied apart from each other as much as possible. Some (always the biggest) are sure to rot in wet weather, especially if they touch one another or wet remains long upon them; but I do not think we have ever had any of the actual disease.

I find seedlings as good as cuttings, and have not experienced any advantage in growing them in plunged pots to restrict the roots. As English Tomatoes are better than imported, so I imagine (but it may be my fancy) outdoor ones gathered perfectly ripe are best of all. When taken indoors unripe and coloured (I

will not say ripened) in a kitchen or hothouse they always seem to me very poor things.—W. R. RAILLEM.

THERE are many crops of our gardens on which the unfavourable season has had a serious effect, but there is none, I believe, more disappointing than the outdoor Tomato crop. The acquired taste for these fruits is undoubtedly steadily increasing each year, for most salesmen declare that no garden produce meets with so ready a sale. Growers for market are fully alive to this demand, and in endeavouring to meet it secure good profits. I have more than once heard it said that Tomatoes prove the most remunerative of market crops, and any sheltered sunny spot available outdoors, and not otherwise appropriated, is accordingly given up to these fruits.

Probably more plants were raised and forwarded under glass for planting outdoors this year than ever before, and the prospects gave bright hopes at the earliest period, but the frequent rains and humid atmosphere proved fatal to the setting of the fruits. Plants grew well and produced vigorous flower trusses, but unless protected were unable to effect an early set. The unusually early appearance of the Potato disease brought with it great terror to the Tomato grower, who had hoped for fruit on the later formed clusters, but the disease, as was expected, communicated itself to these plants on walls, affecting stems, leaves, and fruit alike. In some cases the attack was so severe as to necessitate the entire removal of the plants without any crop to repay the trouble of the several previous months, and others left presented but a sorry figure. Such experiences may not be known to all, but of the various gardens I have visited I know but one where a good crop is forthcoming outdoors, and that is under the care of Mr. W. Iggulden. On the low front wall of some forcing houses, and on the more lofty Peach wall, both having a southerly aspect, there are numbers of plants carrying excellent crops of large size, and many of the fruits have been cut, and others are ripening on the earlier perfected clusters.

Several varieties are planted, but all are not alike free. Those that are bearing the greatest amount are the crimson Mikado, Ham Green Favourite, Chemin Red, Conference, and The Peach. The first-named is a selection from the original introduction, and differs from that only in colour, and if possible better form. Ham Green is a very free bearing sort, and now has a good reputation, but Chemin Red is not so generally known, though there is a possibility that it may prove a rival for that previously mentioned. In appearance it closely resembles Ham Green, but the quality, which is the chief essential, is said to be superior, and that is saying a good deal. It was sent out, I believe, by MM. Vilmorin of Paris, by whom many excellent garden products are distributed.

The Conference has been referred to several times this year and last autumn as being the best flavoured Tomato yet sent out, this being decided, I think, at Chiswick last year, when so many sorts were grown on trial. This quality, combined with great fruitfulness, will no doubt secure for this the premier position among these popular fruits with all save perhaps exhibitors, for with these Perfection must still hold sway, on account of the large size to which it may be grown. The Peach produces small or medium sized distinct looking fruits in abundance, on open walls at Marston, in company with those before named.

Mr. Iggulden attributes his success mainly to the great warmth of the site occupied by these plants, the walls of the forcing houses being naturally warmed through from the hot-water pipes within, as they pass along the whole length in close contact. As might be naturally conceded, the pollen has greater chances of becoming dry in such favourable quarters than is possible when more fully exposed.

Disease, although present, is not nearly so violent as with most growers in the district, and as yet but little inconvenience has been experienced in this matter. The attack of *cladisporium* has been very common under glass, but it is a somewhat new experience to find that it thrives in the open air, but not to such an extent as to cause any alarm; still it would be more satisfactory if the past opinions of respected authorities could be true, namely, that it could not live or spread outdoors.

Another item that has contributed largely to the production of so good a crop is firm and not rich soil. That in which they are growing is a narrow enclosed border from which a similarly heavy crop was taken last year, with only a slight top-dressing placed on in the spring for the benefit of some Lily of the Valley roots, which are part occupiers of the soil, rather than for the Tomatoes. In such a firm medium the growth becomes sturdy, and large clusters of fruit are seen, almost touching the ground in some instances.

One of the most shy bearers that I could find at the time of my visit was the yellow fruited Golden Sunrise, which was rather disappointing, this being one of Mr. Iggulden's first favourites on account of the quality of the fruit. Sutton's Golden Queen with

\* Query, fruit or vegetable? I think "Punch" puts this question in the mouth of a customer at a restaurant, with the waiter's answer, "Neither, Sir, it is a hextra!"

us is the most abundant cropper of all among our plants outdoors, Daniel's Crimson Queen and Ham Green showing secondary favours.

It would be most interesting if other readers would give their experience of the season with regard to the outdoor crop of these popular fruits. Reports, so far as I have noticed, have not been favourable this year, but there are possibly some districts in which Potatoes are not so badly or so early disease-stricken where good crops are the rule, at any rate it is to be hoped that it is so. It would be considered a boon if good returns were general among poor as well as the more wealthy, for they are undoubtedly becoming a luxury. Failure of the outdoor fruits and consequent higher prices charged, will prevent many from investing in them.—W. S.

#### DENDROBIUM SCHNEIDERIANUM.

PART 103 of Messrs. B. S. Williams & Son's valuable "Orchid Album" gives good coloured illustrations of *Vanda teres candida*, *Zygopetalum crinitum cœruleum*, *Miltonia Bleuana splendens* (which has been described and figured in this Journal, but unacknowledged in the references accompanying the description), and *Dendrobium Schneiderianum*. Concerning the last we extract the following interesting particulars:—

"The genus *Dendrobium* is now a very large one, and the number of species and varieties which adorn our stoves are both numerous and beautiful. The one whose portrait is here produced is most chaste and elegant, arguing well for the rich combinations which we may hope to see when the many seedlings which now are in their infancy have arrived at a flowering stage. Natural hybrids amongst the species of this genus would not appear to be common, but some examples have from time to time appeared to which a hybrid origin has been ascribed. These, however, have been collected in sufficient quantities to cast a doubt upon this supposition; and they have, moreover, been collected in wide and distant localities. Our specialists at home have produced a few very beautiful kinds, but it must be confessed that this genus has not received the attention at their hands which the *Lady's-slipper* family has done. The first hybrid *Dendrobium* was obtained by an old and respected friend of ours, Mr. Dominy, when engaged in the nursery of the Messrs. Veitch at Exeter, and it very deservedly bears the name of *Dominianum*. It is a very bright and cheerful flower, raised between *D. nobile* and *D. Linawianum*, the latter being then known under the erroneous name of *D. moniliforme*. Since then we have had *D. Ainsworthi* and *D. Ainsworthi roseum*, raised by Mr. Mitchell, the last-named variety being figured in these pages, t. 20. The same forms were also obtained by Mr. Osborne when gardener to H. J. Buchan, Esq., at Southampton. Grandier forms of the same cross have also been obtained by Mr. Seden at Messrs. Veitch's, in *D. splendidissimum* and *D. splendidissimum grandiflorum*. *D. Leechianum* is also a superb form, raised by Mr. Swan when at Fallowfield, Manchester. This also is from the same parents as the above. Sir Trevor Lawrence has also been a successful hybridiser of *Dendrobiums*, and we have seen some exquisite flowers in his garden at Burford Lodge, Dorking, which we hope to be able to figure, and lay before our readers in the early future.

"The plant, however, whose portrait we here lay before our subscribers, is the result of a cross between *Dendrobium Findlayanum* and *D. aureum*, and is at once beautifully chaste and very distinct. The plant was fertilised in the collection of Oscar Schneider, Esq., of Fallowfield, Manchester, and the seedlings were raised by Mr. Holmes, gardener to C. Moseley, Esq., at Grange-thorpe, Rusholme, Manchester, and it is through the kindness of Baron Schroeder, The Dell, Staines, that we have been afforded the opportunity of laying its beauties before our readers.

"*Dendrobium Schneiderianum* is a plant having much the character and appearance of its first-named parent, *D. Findlayanum*, in habit of growth, and its flowers are large and showy, mostly produced in pairs on long pedicels. The sepals and petals are sub-equal, having the ground colour creamy white, tipped with rosy purple. The lip is half rounded at the base with an acuminate point, which is also rosy purple, behind which is a white zone. The base of the lip is downy, rich orange yellow, bearing numerous veins and streaks of orange or purple. The plant is deciduous in habit, losing all its leaves before flowering;

but so freely are the blooms produced that one does not appear to notice the deficiency. The plant appears to be somewhat strong in constitution, and will doubtless become stronger as it increases in age. It should be planted in good peat fibre and sphagnum moss, using some moderate-sized nodules of charcoal to keep the whole open and free. This soil requires to be made firm, and the drainage must be perfect. We have found it to thrive best when treated as a basket plant, and hung up near the glass. During the growing season it requires an ample supply of water to its roots, and moisture in the atmosphere, but after the pseudo-bulbs are mature and the leaves begin to fall less heat and less water will be necessary; indeed very little water should be given during winter. At the latter part of winter or early in spring the plants should be watched for the pushing out of the flowers, and upon these becoming visible gentle waterings should be given, and the temperature in which the plant was wintered may be raised a few degrees."

## GROWING AND SELLING FRUIT.

(Continued from page 267.)

### BLACK CURRANTS.

AS regards profit, this is the next fruit on the list, and will grow in any situation, although it is not advisable to plant it in a poor dry soil. It does best in a rich deep loam which is moist, but not too stiff and heavy.

PLANTING.—This should be done in the autumn, as for other fruits. The plants should have been grown two years in the nursery from the cuttings, and will then yield a nice lot of fruit the second season after planting. They are easily raised from young shoots about 9 inches long, put in the ground firmly any time between September and March, in rows  $1\frac{1}{2}$  foot apart, and 4 inches between the cuttings. After severe frosts they will require pushing into the ground tightly again to make them quite firm, or they will not make roots. In the following autumn they should be transplanted to 2 feet between the rows and 1 foot from plant to plant. The next autumn they should again be lifted, and planted 3 feet between the rows and 18 inches apart, and after another season's growth they will be ready for their permanent quarters; but as a rule, bush fruit trees may be bought in quantity from 10s. to 15s. per 100, and it is often the cheapest in the end to buy plants large enough for planting at once, instead of waiting to grow them from cuttings. They should be planted out when large enough in rows 5 feet apart each way, or if the ground is rich 6 feet apart will be the best. The plants should be "angled"—that is, the plants in one row should form the point of a triangle with the two plants in the next row. By planting them opposite the centre of the space, instead of opposite the other trees, they may be planted among standard Apples or other fruits, and will give good crops, although not so much as when they have a plot of ground to themselves. The cost of plants and planting will be about £12 per acre.

PRUNING.—In this operation it must always be borne in mind that the Black Currant fruits best on wood made the preceding summer; it is therefore best to encourage a free growth by cutting out the old wood after it has borne for two or three seasons, and training young branches up in its place. To secure this end it is not advisable to grow Black Currants on short stems, as is often done with Red Currants, as they are all the better if they throw up strong young shoots from the roots occasionally. In pruning young plants raised from cuttings they should be cut back until five or six good strong shoots are obtained to form a tree. These should then be left full length, and any small shoots cut back to one bud. After this all shoots that cross others may be cut out yearly, and the weakest shoots cut close so as to obtain a nice even shaped tree, with an open centre like a teacup. All branches that droop down lower than 18 inches from the ground should be cut off, as fruit that gets splashed with dirt is of no use in the market, and only fit for wine-making. All old wood that is becoming weak should be cut out, and if a plantation begins to fail from old age it may be cut down to the ground and given a heavy dressing of manure. One year's crop will thus be quite lost and part of another, but the fruit will be much larger afterwards on the young shoots which spring up abundantly from the old roots. After pruning is over the ground between Black Currants should always be forked over, putting manure on first if the ground is poor. Black Currants are sometimes pruned as "great or piecework," at about 1s. per hundred trees.

MARKETING THE FRUIT.—In districts where large quantities of this fruit are grown they are generally gathered by women at 4d. to 8d. per half sieve (about half a bushel), according to the crop. They should not be allowed to get soft before gathering, or

they will smash when travelling to market. The half sieves when full should weigh 24 lbs. nett, and before the fruit is placed in should be lined with paper. In the fruit-growing counties what is called "fruit paper" is used; if this cannot be had "cap paper" will do, but is not so cheap. A sheet should also be put over the top of the fruit, and the package finished off as recommended for Apples. If gathered when thoroughly dry Black Currants will not spoil so soon as some other fruits, but all these soft fruits should be sold and used as soon as possible after gathering. Those sent to Covent Garden are generally sold again within twenty-four hours from leaving the plantations. Prices vary from 2s. to 4s. 6d. per stone of 14 lbs., according to quality and time. Those sent to London markets are sold by the half sieve at about the same rate. An acre of trees that are four years old should give about 600 lbs., increasing rapidly to 5000 lbs. in an ordinary season, and double this quantity when there is a heavy crop, and under the highest cultivation without a "top crop"—that is, standard Apples, &c., above them.

**VARIETIES.**—Lee's Prolific, Black, Naples, and Carter's Champion are the best; the latter has by far the largest fruit.

**CULTIVATION.**—The plantations where Black Currants are grown should be forked over annually after pruning, and all weeds should be destroyed during the summer before they get large. A liberal dressing of farmyard manure once in three years will be of great benefit in promoting the size of the fruit.

**ENEMIES.**—With the exception of birds this fruit has nothing to interfere with its success; even frost in spring seldom takes any effect on it.

#### GOOSEBERRIES.

This is a good fruit to grow for sale, as they can either be disposed of green—in which state they often give the best returns—or they may, in the case of the red varieties, be left until ripe. In Kent, where large quantities are grown, they are generally gathered by women and girls, who earn good wages at the rate of 4d. per half sieve for green ones, and 2½d. to 3d. for ripe fruit.

**PLANTING.**—The best time for this as for all fruits is when the leaves begin to change colour; but any time between October and March will do if there is no severe frost or snow at the time. Gooseberries may be raised from cuttings in a similar way to Black Currants, except that Gooseberries are best grown with a stem, from 6 inches to 1 foot high, to allow of digging, &c., underneath, and to keep the fruit from the ground, also to prevent so many strong shoots growing in the centre of the tree. The cuttings should, therefore, be not less than 9 inches in length, as 3 inches should be put into the ground and trodden in firmly. All the buds should be cut off Gooseberry cuttings except three or four at the top, to prevent suckers springing up from the root. The distances for planting should be the same as for Black Currants. The Gooseberry will thrive in a stony soil better than Currants. The cost of planting per acre will be about the same as for Currants.

**PRUNING.**—For young bushes this consists in selecting six or eight main branches springing out evenly not far from the top of the stem. Thus, if the cutting throws out three or four shoots the first year they may be cut back to within 4 inches at pruning time, when each one will throw two or three good shoots the next season, and enough may then be selected to form the future tree, keeping the centre open and cutting always to buds that point in the right direction for the branch to grow. Some varieties, and especially Warrington, persist in bending over towards the ground, and require pruning back well to get the main branches as upright as possible. All strong roots in the centre of the tree should be cut clean out and the small side branches cut off within an inch of their base, leaving one almost full length occasionally in the thinnest parts of the tree, and always leaving a good leader at the point of the main branches until they get 4 feet in height. Summer pruning is also of great benefit to the Gooseberry. This consists in cutting out all young shoots in the centre of the tree and elsewhere which would otherwise be cut out at the winter pruning. By cutting them out in summer as soon as the fruit is gathered the remaining buds on the main branches get a better chance to ripen and store up nourishment for next year's crop. The work is also much better done in mild weather than in the winter. In the Kent plantations Gooseberries are pruned by the "tree cutters" in "piecework," during the short days of winter at about 1s. 6d. per 100 trees, according to size.

**CULTIVATION AND MANURING.**—Like all other bush fruits, Gooseberries pay well for an application of manure about once in two or three years. Night soil is often given to them in Kent, and materially assists in bringing very heavy crops of fruit to perfection. The soil is removed from under the bushes early in the spring, forming a basin-shaped cavity into which half a pailful of night soil is poured, and next day the earth is put back again which had been removed. Large quantities of London manure is also

brought down the river in barges, and after partial decay is applied during the winter months before the plantation is dug over, but there is no manure so good as that from a cowyard when it can be got. The plantations should be kept perfectly clean by hoeing and hand-weeding if required, and the ground should always be dug roughly in the winter after the bushes are pruned.

**VARIETIES.**—Whitesmith for gathering green, Crown Bob either green or red, Warrington for late red fruit. A new variety called Early Kent has lately been very highly spoken of for its earliness, which is a great consideration in Gooseberries for market.

**GATHERING AND MARKETING.**—Gooseberries, if *early*, pay well for gathering and sending to market green, and for this purpose Whitesmith is the best among the older varieties for early work. But Early Kent is said to be much earlier. The early sorts should be planted in the warmest part of the ground, in order to get the full advantage of the early prices, and all of the "White" Gooseberries should be gathered in a green state for market, as they do not sell well when ripe. Some of the Crown Bobs may also be gathered green, or all of them if prices are good. Warrington generally pays best when ripe. I say *ripe*, but ripe Gooseberries for market must only just be red. If allowed to get quite soft they are apt to split in damp or showery weather, and there is thus a risk of great loss, which is avoided by gathering earlier. Also they will not stand handling at the market if overripe; neither will they travel so well; but if required for sale near home, the wishes of the buyers must be considered. Green Gooseberries should realise from 2s. to 3s. per stone at the market, ripe fruit 1s. 6d. to 2s. 6d. An acre planted 5 feet apart each way should yield the first year about 40 stones of green fruit, or 60 stones when ripe, worth £4 to £5 clear of expenses, and this will increase yearly as the trees grow (if the crop is not spoiled by frost), until at six or seven years after planting they should have reached a full size, and give a crop of 5 tons per acre, worth £50 at a low estimate clear of expenses. It is possible to have double this amount occasionally by high cultivation and getting the best prices in the market. As Gooseberries may be grown among standard Apples and other fruits, they will add considerably to the returns, although it is not possible to grow such large crops of under fruit in mixed plantations. They should be packed for market in half sieves containing 2 stones, or 28 lbs. nett, and finished off as advised for Black Currants.

**ENEMIES.**—Birds are very troublesome to the Gooseberry grower, both when the fruit gets ripe (at which time they must be scared off by shooting), and also by eating the buds off when the trees are in a dormant state. It is at this stage when most mischief is done, as every bud eaten then means the loss of two or three Gooseberries. Strings of white cotton crossed in various ways over the trees by twisting them round four of the most prominent branches is one of the best methods of frightening them away. When damage from this cause is expected the trees should be pruned, and cotton put on them before January, as pruning is not easily done after the cotton is on. Bullfinches and sparrows are the most destructive among the buds. All of the former should be destroyed, as they do no good to the fruit grower to counterbalance the mischief. Sparrows do some amount of good in summer by devouring caterpillars, and must not all be destroyed, or the remedy may be worse than the disease. The Gooseberry caterpillar often does a vast amount of damage if not destroyed as soon as it appears. Handpicking is the best and safest remedy for these. Dusting the bushes with white hellebore powder is often recommended, and is very effectual, but it is a dangerous poison, which should only be used with the greatest care. All traces of it should be washed away with clean water a few days after.—  
W. H. DIVERS.

(To be continued.)

#### HOLLYHOCKS.

ONE of your correspondents, Mr. George Steel, Cornhill-on-Tweed, is devoting considerable attention to Hollyhocks, and has one of the best collections in the kingdom, and I hope that shortly we shall, through the Journal, hear from him the result of his experience in culture and the disease to which the Hollyhock is unfortunately liable. I have not the pleasure of his personal acquaintance, but he is a frequent correspondent on matters relative to the Hollyhock, Pansies, and Violas, and a few days ago he sent me a small box of Hollyhock blooms by post, which were a glad-some sight, for in size and quality they vividly recalled the good old Hollyhock days of close upon forty years ago, when those glorious old flowers, Lizzie, Beauty of Cheshunt, Glory of Cheshunt, Model of Perfection, White Globe, Pourpre de Tyre, Safranot, and many others were so popular and so fine.

It is fully evident that the Hollyhock is rapidly becoming again a popular flower, especially in the midlands and north, and cultivators will confer a great boon if they will freely convey through the columns of the gardening papers their experience of the disease and remedies for cure or prevention. Mr. Steel sent me blooms of a dozen varieties, and remarked that "blooms are of course small now, and as they do not seem to travel well I have sent you buds so that you can see their colours, and perhaps travel better." The following are the varieties:—

*Pride of Layton* (Finlay).—A flower of the finest quality, rich salmon colour, large, and very full high centre, and good guard petal.

*Grace Darling* (Thompson).—Shaded pale salmon, a very fine flower, very close high centre, large, and with excellent guard petal.

*Walter Scott* (Steel).—A seedling of 1890, pale salmon buff, a very fine flower of a bright shade of colour, large, and very full high centre, and capital guard petal.

*Mrs. Joseph Oliver* (Steel).—Seedling, 1890; shaded pale flesh and rosy lilac, very close high centre, and medium guard petal, and distinct.

*Favourite*.—Very light pink, shading to a lighter colour, a beautiful blending of colours, large, close, high centre, and good guard petal; a very fine flower.

*Mrs. George Steel* (Steel).—Seedling, 1890; bright shaded salmon tinted pink, a very refined flower, close well-formed centre, and perfect guard petal; a grand flower.

*Vesta* (Chater).—A deeper shade of colour than Mrs. G. Steel, having a more decided salmon shade in it, but rather rough in outline, and pockety, still a telling flower in a stand.

*Nobilis* (Chater).—Very pale buff tinted with primrose, a distinct and very fine flower, grand in high close centre and guard petal.

*Agnes Royle* (Oliver).—Pale yellow, a grand flower in every respect; extra fine.

*Octoroon*.—Deep maroon, tinted crimson, a very fine flower, and telling in a stand.

*Leviathan* (Chater).—Light scarlet, a beautiful flower in every way, with plenty of centre.

*Robert Royle* (Oliver).—Lighter in colour than Leviathan, and very close high centre; a very fine flower.

*Perfection* (Chater).—Mottled or shaded pink and lilac, tinted white; a distinct flower of first-rate qualities.

*W. Dean* (Downie).—Bright salmon rose; a flower of refined quality, with excellent guard petal, and close high centre; very fine.

*Maggie Bain* (Thompson).—Bright deep rose; a grand flower in every respect.—W. DEAN, *Sparkhill*.

## NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 155.)

I HAVE long had in contemplation an essay or article upon the benefits England has received from Scotland, which could be proved to be neither few nor unimportant. The annals of British gardening during last century, for instance, would show that South Britain was greatly indebted for its horticultural progress to a number of natives of the northern part of the isle who migrated to the nurseries and establishments in or about London, and some other towns. Dr. Johnson would probably have growled disapprobation, and complained that they took the bread out of the mouths of honest Englishmen, but the laddies set a good example, displaying Scottish prudence, patience, and perseverance, which might well be copied by their fellow workers. Possibly they were a trifle too conservative, over-cautious in adopting improvements or changes, but when the utility of these was seen the Scotch gardeners never failed to turn them to the best account. A writer upon the subject of horticulture in the reign of George III., when cataloguing the sins of gardeners, seems to consider slovenliness the greatest, and this, I think, is seldom the fault of a Scotchman.

That the Scotch folks generally were slow in the introduction of new plants appears from the statements of travellers, who express surprise that when even in the gardens of English cottagers there was to be found a number of vegetables, those of the better class in Scotland often showed only varieties of the Cabbage, Onions, and Potatoes. Again, Cromwell's soldiers are credited with having planted in Scotland some hedges of Hawthorn, and pointed out to the people there how great were the advantages derived from the protection hedges give to fields or gardens, but a hundred years after they were seldom to be seen, and indeed to this day there is a scarcity of hedges both in Scotland and the northern districts of England. If these may spoil a prospect sometimes, they soften the grim outlines of an uninviting landscape,

and many a garden would be improved by being thus screened from cutting winds. I may note in passing, that I find there are still persons who object to hedges on the ground that they afford shelter for insects—a mistaken notion. Indeed, in the case of fruit trees it is likely that some caterpillars, which would otherwise attack them, are left to settle upon the Hawthorn and Sloe when they are used for hedging. One thing that existed in Scotland during the infancy of horticulture, of which there is no trace in England, was a series of small lodges or societies of gardeners, who met from time to time for the exhibition of plants grown, and the interchange of ideas. Many of these were chiefly composed of mechanics or small tradesmen who devoted their spare hours to flower culture, the taste being traceable, not to English influence, but to that of French weavers, who settled at Paisley, Edinburgh, Glasgow, and other places. The Edinburgh Botanic Garden originated about 1680, made only small progress till 1767, when it was enlarged, and extensive ranges of conservatories or hothouses erected under the direction of Dr. Hope, and in the middle of that century a large botanic garden was formed by the Marquis of Bute, which attracted much notice. But special honour belongs to Mr. James Justice, as one who, by personal exertion, and through his travels on the Continent in the reign of George II., brought into view many new species and varieties. His father was a merchant, and having dealings with the Dutch, they offered him bulbs unknown in England, some of which he bought, and this, 'tis said, led his son to become such an enthusiastic amateur, that, though a lawyer, he was tempted to an outlay upon his garden at Crichton, by which he got into difficulties. He had the first Pine stove seen in Scotland, and he was presumed to have had one year the largest collection of Auriculas in Europe. A book containing the results of his many years' experience was published in 1754, and, not to limit its sale to the Scotch, he called it the "British Gardener's Director." It was apparently the first standard work of the kind brought out north of the Tweed, and contained valuable information about the whole range of outdoor gardening as then practised, also on greenhouses and stoves.

About the middle of the eighteenth century the man styled by Cowper the "omnipotent magician Brown" began to exercise a great influence upon horticulture, and his fame was for a time unrivalled as a designer of flower gardens and pleasure grounds. People called him "Capability" Brown, from his frequent use of that word when he was describing the plan he meant to pursue in forming a new garden or remodelling an old one, but his name was Lancelot, and though not Scotch, he was a borderer, hailing from Northumberland. Brown made his start as a worker in the kitchen garden at a house near Woodstock, and afterwards he attained to the position of chief gardener at Stowe. Lord Cobham becoming his friend, by this peer's recommendation he got the appointment of gardener to the royal Palaces of Hampton and Windsor, which brought him to the pinnacle of his popularity, but in fact there was nothing particular about his methods. His gardens were even more formal than those of the older style, and showed less variety, yet there was hardly a nobleman or gentleman who did not consult Brown at some time or another. From Scotland and Ireland also he received pressing invitations, and he sent pupils to those countries. He himself never left England, though he had tempting offers even from Russia. His ideal of a flower garden, if he had space sufficient, was to have it gently sloping to an artificial stream at the bottom, and beds on each side of the lawn which it divided corresponding formally with each other, in the middle of every one a tree or shrub. Around the whole garden ran an upper walk with a background of trees or tall shrubs, amongst which Roses were sometimes placed for effect. His favourite method of planting trees was in circular clumps, large or small, and in belts; which led Sir W. Chambers to remark, that if Brown's mania was generally followed there would ere long not be half a dozen trees in a row left standing in England. Some of his rivals greatly ridiculed what they called his "kitchen garden" manneism, arising, they hinted, from his early career. But he was always ready with an answer, as when they criticised a place he had laid out at Latimers, Bucks, cramming there a number of beds and shrubs into a narrow valley; this he defended, saying it was a "playful style," though the expression seems incongruous. We must regard him as one who did little to advance horticulture, except indeed by showing what ought to be avoided.

We have referred to Kent, one of Brown's predecessors in the art of landscape gardening, and mention should be made of another of that name, Charles Kent, who was attached to the English Embassy at Brussels in the reign of George II. He had previous to his residence abroad taken no special interest in gardening, but while in the Netherlands he made a study of the matter during some tours, and was surprised at the diligence the Flemings exhibited. He drew up a report upon the Flemish methods, dealing specially with their skill in selecting and applying manures to the

land, which he presented to the House of Commons in 1766. Upon his return to England he made further investigations upon the character of soils, as ascertainable from the plants that would naturally flourish upon it. For instance, he pointed out that it was always good land where Oaks grew, or the Meadow Foxtail and Cocksfoot Grasses.—J. R. S. C.

#### NOTES AT CARDIFF CASTLE.

THERE are two kitchen gardens at Cardiff Castle about four acres in extent each. Both may be regarded as suburban gardens, as they are only divided from the town of Cardiff by a wall, and I state this as my subsequent remarks will indicate that it is possible to grow first-rate Apples and Pears in such situations. Each garden contains a great many fruit trees, both on the walls and as standards. The latter line the walks everywhere, and many are also grown in lines through the vegetable quarters. The majority were planted about twelve years ago. The growth they have made since is of the most satisfactory description. Those who have read Mr. J. Wright's book on "Profitable Fruit Culture" will find some of these trees illustrated therein, and they may well be shown as examples anywhere. All tendency on the part of the trees to become crowded has been rigidly frustrated. Each branch stands clear of its neighbour, but they have been allowed to ascend to about 12 feet, thus giving an average of growth of 1 foot per year. Every branch is furnished throughout with luxuriant foliage, and bristles with well developed buds. They are in the best of health and exceedingly clean. They indicate the most careful training from the first, and must receive the greatest care at the present time. The branches of Lime, Sycamore, and other trees come very near drooping over the garden wall, and are not many feet from the wall trees. The foliage of these, as is common at this season, is much overrun with red spider and other insects; but none of them appear to have gained a footing on the fruit trees, and the line of distinction is clearly marked. The Apples are chiefly growing on the free stock. A few on the Paradise are not regarded with favour. The soil may be described as a light loam; the walls have no coping, and no attempt is made to protect the blossom in spring, and the fine results secured can only be attributed to high culture.

At present the crops are most remarkable both for their extent and quality. Many of the branches, particularly on the Apples, have had to be staked and tied up to prevent the weight of fruit breaking them down. The most fertile are of Apples—Ecklinville Seedling, Lord Suffield, Lord Grosvenor, Keswick Codlin, Pott's Seedling, Annie Elizabeth, Beauty of Hants, Wellington, Nelson's Glory, Emperor Alexander, Alfriston, New Hawthornden, Beauty of Kent, Worcester Pearmain, King of Pippins, Nonpareil, Sturmer Pippin, Court of Wick, and Devonshire Quarrenden. Some of the specimens of Ecklinville were upwards of 1 lb. in weight, and owing to the enormous crop of this size they gave one the impression of being the best of all; but none of the others were far behind it in their respective merits. Pott's Seedling was an excellent clean sample, and the old Keswick Codlin was hardly recognisable in its excessive development; but size was not their only recommendation, as the quantity was there too, and it was computed that many of the trees not yet in their teens were carrying from 1½ cwt. to 2 cwt. of fruit. I would make special remark of Ecklinville Seedling for the benefit of your South Wales readers, as being a variety admirably adapted for their locality, for apart from the success at Cardiff Castle it is an invaluable sort with Mr. Stephen Treseder, and several other growers in the neighbourhood of Cardiff and South Wales.

The best of the standard Pears are Pitmaston Duchess, Jargonelle, and Williams' Bon Chrétien. The same kinds are also excellent on the walls, as well as Marie Louise, Beurré Rance, Beurré d'Amanlis, Easter Beurré, Beurré Clairgeau, Glou Morceau, Beurré Bosc, and Beurré Diel. The fruit of Pitmaston Duchess takes the lead here as much as the Ecklinville Seedling amongst the Apples, but the produce of all the others is remarkably fine, being large in size, clean, abundant, and evenly distributed all over the carefully trained and most vigorous branches. Considering that none of these trees were protected while in bloom, and the most ungenial season they have had to contend with, the results are marvellous, and although there are many striking features in the gardens at Cardiff Castle none do Mr. Pettigrew more credit than the Apple and Pear trees.

#### MELONS.

No matter what time of the summer we visit Cardiff Castle we are sure to find a fine crop of Melons. I have seen them year after year, and much as I have been struck with their superiority in former times I do not think I ever saw them better than they are at present. The plants are grown in a loftier span-roofed house than is generally devoted to Melons. They are planted in the side beds, which are about 1 yard in width and 1 foot in depth. Top and bottom heat is provided. The plants stand at a distance of 4 feet from each other. The distance from the soil to the trellis is a little over 3 feet, and a thick bare stem, like a Vine rod, occupies this space and then branch out over the trellis, which is from 10 to 12 feet high. The whole trellis is covered with a luxuriant mass of strong healthy shoots and huge green leaves absolutely destitute of the slightest trace of disease or insects. The fruits are evenly distributed over the trellis, and the size was much in excess of what we are accustomed to see. The chief variety grown is Carter's Holborn Favourite; this is one of Mr. Pettigrew's raising, and it does

him much credit, as none of the fruits would be under 6 lbs., some would reach 10 lbs., and the average would be 8 lbs. They were beautifully formed, prettily netted - in fact, most handsome, and as the flesh is a greenish white and the flavour much above the average the fruit, although some might be inclined to think them too large, are admirable in every respect. Another new variety raised and grown here, but not yet in commerce, is the result of a cross between Holborn Favourite and Longleat Perfection. It, too, is a large Melon, with a partially netted beautiful skin and most pleasing flavour; indeed, no one could see the Melons at Cardiff Castle without pronouncing them perfect; but Mr. Pettigrew does not believe in the drying-off system, not even on the eve of the fruit ripening, and he attributes his unusually handsome fruit to copious waterings and the great luxuriance of the plants. A round earthenware ring or collar about 1 foot in diameter encircles each stem; no water is ever given within this circle, but the other part of the bed is watered almost daily, and the roots, plants, and fruit testify to the soundness of this practice.—M.

#### A PECULIAR GLOXINIA.

FLORAL freaks have seemed to be somewhat frequent this year, for we have had a number submitted to our notice, and amongst them

FIG. 34.—A PECULIAR GLOXINIA.

several Gloxinia flowers have been sent at different times. That depicted in fig. 34 is remarkable for the fact that two or three flowers were received identical in formation. The ordinary corolla was of the usual form and colour, but there was a thickening towards the base, and five even segments the same colour as the tube were strongly recurved, alternating with the lobes of the calyx. At first glance it would be taken for an enlarged calyx, but that organ is quite of its normal form, and its lobes can be seen in the sketch. Varieties of this kind are not usually ornamental, but in this case the flower had a rather pleasing appearance, but it is doubted if the freak could be perpetuated.

#### ROYAL HORTICULTURAL SOCIETY.

THE following is the official list of awards made by the Committees at the recent Grape and Dahlia Conference at Chiswick:—

##### AWARDS OF THE FLORAL COMMITTEE.

*Silver-gilt Banksian Medal.*—To Messrs. Paul & Son, for Dahlias; Messrs. J. Laing & Co., for Dahlias, and also for Begonias; Messrs. J. Cheal & Sons, for Dahlias; Messrs. Keynes, Williams & Co., for Dahlias; and to Mr. Charles Turner, for Dahlias.

*Silver Flora Medal.*—To Mr. Geo. Phippen, for Dahlias; Messrs.

Rawlings Bros., for Dahlias; Mr. J. T. West, for Dahlias; Mr. T. S. Ware, for Dahlias; and to Messrs. H. Cannell & Son, for Dahlias.

*Silver Banksian Medal.*—To Messrs. Dobbie & Co., for Dahlias; Mr. Geo. Humphries, for Dahlias; Messrs. Saltmarsh & Son, for Dahlias; Messrs. Heath & Son, for Dahlias; Messrs. H. Cannell & Sons, for Begonias; and to Messrs. Harkness & Sons, for hardy flowers.

*Bronze Banksian Medal.*—To Mr. J. Tranter, for Dahlias; Mr. W. Salmon, for Dahlias; Messrs. Reid & Borneman, for Chrysanthemums; and to Messrs. J. Peed & Sons, for Dahlias.

*Awards of Merit.*—For Chrysanthemum (Pompon) Miss Lilly Stevens, from Messrs. Reid & Borneman; and Lælia Eyermann, from Messrs. Pitcher & Manda.

#### DAHLIA CONFERENCE.

Certificates of merit were given to the following blooms, as shown in the stands of the various exhibitors:—Centennial (C.), from Messrs. J. Cheal & Sons; Melita (C.), from Mr. T. S. Ware; Comedian (F.), from Messrs. Keynes, Williams & Co.; Beauty of Arundel (C.), from Mr. Burbury; Eldorado (S.), from Mr. C. Turner; Othello (P.), from Mr. C. Turner; The Mikado (P.), from Mr. C. Turner; A. W. Tait (C.), from Messrs. H. Cannell & Sons; Daisy (P.), from Mr. J. T. West.

The following varieties, which have been under trial in the gardens, also received certificates of merit:—

*Caetus vars.*—Honor, Panthea, Juarezi, Empress of India, A. W. Tait, and Mrs. Hawkins from Messrs. Keynes, Williams & Co.; Juarezi from Mr. C. Turner; Mrs. Hawkins, Henry Patrick, Charming Bride, and Lady Kerrison from Mr. T. S. Ware.

*Pompon vars.*—Darkness, Brunette, Millie Wood, Fairy Tales, Whisper, Middle. V. Facourt, Gem, Red Indian, The Khedive, Janet, Rosetta, Rosalie, Lady Blanche, E. F. Junker, White Aster, Fashion, Isabel, and Mabel from Messrs. Keynes, Williams, & Co.; Ernest, Isabel, Fanny Weiner, Anna Zachman, Dove, Princess Sophie Soficla, Cupid, Lady Jane, Admiration, and E. F. Junker from Mr. C. Turner.

*Single vars.*—Miss Linaker, The Sport, Sunningdale White, Mr. Kennett, Alfonso, Lady Monckton, Cetewayo, Formosa from Messrs. J. Cheal & Sons; Florric Fisher, Miss Henshaw, and Kate from Mr. T. S. Ware.

*Bedding vars.*—Yellow Pet, Marguerite Bruant, and Flora Macdonald from Mr. C. Turner.

*Show vars.*—Condor, J. B. Service, George Rawlings, Ovid, Mrs. Gladstone, Cyprus, Royalty, Primrose Dame, Leah, Goldfinder, Royal Queen, Diadem, Toison d'Or, Mrs. Glasscock, Statesman, Mrs. Harrison, and Pioneer from Mr. C. Turner.

*Fancy vars.*—Grand Sultan, Queen Mab, and General Gordon from Mr. C. Turner.

#### GRAPE CONFERENCE.

Certificates of merit were awarded to the following varieties, as shown in the different collections:—Black Monukka, from H. Balderston, Esq., and the Royal Horticultural Society; Canon Hall Muscat, from Mr. W. Roupell; Muscat of Alexandria, from Mr. G. Wythes; Muscat Hamburgh and Alwick Seedling, from the Royal Horticultural Society; Gros Colman and Gros Maroc, from Mr. Hooking; Muscat of Alexandria, Muscat Champion, Alicante, and Black Hamburgh, from Mr. J. Loudon.

Certificates of merit were also accorded to Messrs. T. Rivers & Son, for a collection of Frontignan Grapes; to Mr. J. Wallis for a collection of Grapes. The silver-gilt cup for examples of packing Grapes for private use went to Mr. Dawes; and certificates of merit in the same class to Mr. J. Hudson, Mr. S. Castle, Mr. C. J. Waite, and Mr. Hookings.

Silver-gilt Banksian medals to Mr. W. Roupell for collection of Grizzly and Frontignan Grapes. Silver Banksian medals to Messrs. T. Rivers & Son, to Mr. St. Clair, to Messrs. Parrot Brothers, to Mr. Peter Kay, and to Mr. Sweet, for collections of Grapes.

#### HARDY FRUIT TREES.

FRUIT trees of nearly all kinds have been late in making their growth. The ravages of caterpillars and other pests early in spring retarded the growth of the trees, so much that many varieties of Apples are only now in active growth. The caterpillars and aphides had early in May taken possession of the trees to such an extent that the prospects of a crop of fruit seemed hopeless. They devoured the flowers before they expanded, and had curled themselves safely into the young shoots and leaves. We anticipated seeing the trees leafless in a short time, but fortunately succeeded in checking these pests beyond our expectations.

The wall trees were hand-picked, as well as many of the bush trees, and this proved the most satisfactory of the methods tried. It takes considerable time, which is its main objection, but it appears to be the only certain method of destroying caterpillars if neglected until the insects cause the leaves to curl round them. If the trees are syringed or sprayed liberally with hellebore powder and water when the insects are first hatched their destruction is certain. We used the powder at the rate of three 2-inch flower pots full to four gallons of water. Heavy rains soon clear the powder from the trees, and it is necessary to renew the application, for the caterpillars continue to hatch over a considerable period. This mixture is not so good as 8 lbs. of soft-soap, the same quantity of quassia chips, and tobacco paper, boiled together and then strained. This quantity will make 100 gallons.

The trees syringed with this were quickly freed from aphides, and the caterpillars soon turned yellow and died. One dressing of this solution cleared one flat of bush Apple trees that were very badly attacked. No doubt the majority of the eggs were hatched, or did so very soon after the application, and were consequently destroyed as soon as they commenced feeding. It appears to me feasible, that if this, or some similar mixture, that will stick to or dry upon the leaves, was applied before the pests established a footing, injury to the trees and the destruction of the crop of fruit would be averted. I have in view bush and pyramidal trees of moderate size only, standards and large examples are much more difficult to deal with. Merely spraying the trees may prove effectual if repeated at short intervals, but where the trees were thoroughly soaked the most complete destruction followed.

My object, however, is to call attention to the condition of the trees of the present time, and the treatment necessary to overcome as far as possible the evils of spring, and give them every chance of perfecting bold fruit buds for another year. It is a mistake to leave wood in the trees that is not really wanted for another season. Bush and pyramidal fruit trees in too many gardens are too crowded with branches, which exclude light and sunshine, and weak puny fruit spurs are the result. Fruit buds in this condition, even if the fruit sets, are often poorly formed, small, and inferior in quality at the end of the season. Trees crowded with branches may appear perfect examples of manipulation during winter when divested of foliage, much more so than trees that have their branches thinly disposed. Once the trees have been crowded with branches purposely to have shapely specimens, they are often disfigured by the removal of branches afterwards, but this is only of secondary importance. The primary object of all cultivators should be fruit of the first size and quality. This can be accomplished, and shapely formed trees into the bargain, if the knife is used carefully and judiciously from the first. It cannot be impressed too forcibly that every branch of bush and pyramidal trees should be so disposed that the sun has free access to every leaf and spur. If the main branches of the trees are thinly disposed, and the current season's growths are allowed to crowd the interior, the evil is as bad if not worse than crowding the trees with main branches.

Trees that are properly managed are pinched while the shoots are tender, so that a large amount of foliage has never to be removed at one time, the leader that is required for extension only being allowed to grow until the required length has been attained. All the growths that issue along the branches need not be left more than three inches in length when first stopped. This necessitates going over the trees again in August, and cutting back closely all growths that are made after the first pinching. Trees that are thin then devote all their energies to the development of the fruit and the perfection of spurs for another year, instead of wasting their energies on wood that is eventually to be cut away. Where the lateral growths are allowed to extend throughout the season not only is the fruit deprived of light and support, but the fruit spurs as well. Trees that are gone over twice during the season of growth are in a satisfactory condition until the fruit has been gathered. Further thinning is then necessary, and all wood that is not required should be cut clean out, so that light and air has free access to the fruit spurs. As soon as the fruit is gathered the trees should have their final pruning, except perhaps old trees that are crowded with spurs. Much may be done in thinning these, but the final thinning is best left until the foliage has fallen. All wood unneeded from late varieties is cut away as soon as the fruit has been cleared from the earlier fruiting varieties.

Early pruning is not only beneficial to the trees, but is much more pleasant now than during the cold short days of winter. This is not all. Early pruning allows of cleaning the fruit garden in autumn long before it could be done if pruning was delayed after the foliage had fallen. Trees that are crowded should have their main branches thinned directly the fruit is gathered. The distance the branches of bush and pyramid trees should be apart cannot be given here, for so much depends upon the growth of the tree and the size of its foliage. For instance, the branches of large foliage kinds, such as Warner's King, Blenheim Orange, Betty Geeson, and others, need to be further apart than such varieties as King of the Pippins, Kerry Pippin, and others of similar growth. Some judgment is needed in thinning out the main branches of a tree, and only the experienced can determine their proper distance after the foliage has fallen, and even then may easily be deceived. While the foliage is upon the trees there is no difficulty. Shoots that are needed for the extension of main branches may be left from 6 to 18 inches in length, according to their strength and degree of ripeness. A good many of ours were pinched when only 2 inches in length, and consequently are being cut close back. Lateral growths may be cut back to two eyes if needed for furnishing the branches eventually with spurs, if not they should be cut out. It is much better not to prune the trees after the first few years of planting than to allow them to become overcrowded with branches.

There are no reasons of any weight that can be adduced why pruning should not be completed simultaneously with the gathering of the fruit, or as soon after as possible. Raspberries may have the old canes removed as soon as the last fruit has been gathered, and all young canes cut away that are not wanted for bearing fruit the next season. The tops of the canes may be removed after the middle of September. Currants are better pruned during that month than two or three months later. The same may be said of Gooseberries, commencing early in September, and completing the operation as the fruit is gathered. Cherries and Plums may be finally pruned as the fruit is cleared from the trees, and Pears as well. Morello Cherries are frequently left until

winter, but they are better thinned as the fruit is removed, and thus give the wood every chance of ripening.

We have long since followed the practice of close pinching during summer, and final pruning during late summer and early autumn, with the best results. The thinner we have kept the trees, and the earlier they have been pruned after it is certain the shoots will not break again into growth, the bolder the fruit buds and finer the fruit. The thinner the trees in northern or shaded positions the more satisfactory they are likely to prove.—WM. BARDNEY.

**EVENTS OF THE WEEK.**—The chief horticultural event next week will be the Fruit Show in the Guildhall, London, held under the auspices of the Fruiterers' Company. In another paragraph full particulars are given concerning this Exhibition, which will be held on Monday, Tuesday, and Wednesday, October 6th, 7th, and 8th. The Crystal Palace annual Show of hardy fruits will be held on October 9th, 10th, and 11th, and a good display is expected, as numerous entries have already been received.

— **THE WEATHER.**—Fine weather has prevailed in London during the past week; little rain has fallen; the days have been bright and the nights clear, but only in a few low districts has slight frost been experienced. Tuesday night was rather stormy, but without rain. Yesterday the rain began to fall.

— **THE GUILDHALL (LONDON) FRUIT SHOW.**—We understand that the Exhibition of fruit, promoted by the Worshipful Company of Fruiterers, and which opens under Royal and distinguished patronage on Monday next, is likely to be as successful as could be expected during a season when the fruit crops are proverbially scant. The entries, we are informed, have exceeded the anticipated number, and produce will be staged from several of the best cultivators in the kingdom. It is thought, however, there will be ample space for all the collections, as in addition to the main building, which is larger than the vinery at Chiswick, in which Apple and Pear congresses have been held, the old Council Chamber and further rooms will be placed at the disposal of the Committee by the City authorities, who are most generously affording all possible facilities in promoting the object in view. The attendance will be very large and influential, as some thousands of tickets have been distributed amongst the Aldermen and Common Council, Stock Exchange, Lloyds', Society of Arts, City Companies, Bank Directors, the Royal Horticultural, Agricultural, and Botanic Societies, the Linnæan Society, British Fruit Growers' Association, Crystal Palace Company, and various other corporations, who either are or ought to be interested in fruit culture in the kingdom. No charge is to be made for admission, and tickets can be had by applicants at the Guildhall on the second and third days of the Show. Sir James Whitehead, Bart., the Chairman of the Executive Committee, is working with great zeal, and is being well supported by his colleagues in completing the arrangements for what ought to be a noteworthy event in the fruit world. A. H. Smee, Esq., with Mr. O. C. T. Eagleton (the Clerk of the Company), and Mr. J. Wright are appointed Directors of the Show, and Mr. R. Dean as Manager. The Exhibition will be opened by the Lord Mayor in the afternoon of the first day, and will close at five o'clock, and not six, on the third day.

— **FINE CYCLAMENS.**—Mr. William Mowbray, Fulmer Gardens, Slough, sends us some very fine Cyclamen flowers with the following note:—"The blooms I think are good. The one with double row of petals appear to be a novelty; the plant has thrown up six blooms, and they are all exactly the same; also, the other blooms are showing similarly. Most of the plants are in 24-size pots, the plants 16 inches through the foliage, and will be a mass of bloom by the end of December. The seed was sown in the middle of October last and the plants have been in a cold pit all the summer." [We have seen several double Cyclamens, but the one alluded to is the finest that has come under our notice. The flower is 3½ inches across, and the corolla is divided into eleven broad segments, carmine at the base, shading to rosy purple. The flower stalk is 11½ inches long and very stout. The other varieties are also good, and the specimens bear the stamp of superior culture.]

— **POTASH FOR VINES.**—Messrs. Alexander Cross & Sons write in reference to our reply to "J. S.," on page 61, relative to potash for Vines, and state the manure they advertise contains an unusually large per-centage of potash, and think gardeners would do well to give it a trial.

— **THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The annual dinner of the above Society takes place on October 23rd, at 5.30 P.M., at the Cannon Street Hotel. Mr. E. R. Cutler will preside. The Secretary is Mr. W. Collins, 9, Martindale Road, Balham, S.W.

— **MR. T. LAXTON** sends us flowers of **SWEET PEA CARMEN SYLVA**, a new variety with blue and rose-tinted flowers, but the specimens had suffered too much in transit by post to show their characters to the best advantage.

— **CHISWICK GARDENERS' ASSOCIATION.**—We are desired to state that the Committee of the above Association are organising a grand concert in aid of the Gardeners' Orphan Fund, to take place on October 29th next, in the Vestry Hall, Chiswick.

— **MANY** of your readers will regret to learn of the death of **MR. JAMES HOTHAM**, late fruit foreman to Earl Brownlow, Belton House, Grantham, where he has been for three and a half years. The deceased was a young man of promising abilities, was well known and highly esteemed. Deceased was interred at Nafferton, W. Driffield, Yorks, on September 20th.—A. M.

— **GARDENING APPOINTMENT.**—Mr. Charles Turner, late foreman at Old Warden Park, Biggleswade, has been appointed head gardener to J. B. Firth, Esq., Barningham Hall, Norfolk.

— **CORDON PLUM SUCKER OR SEEDLING—HOW TO TREAT.**—A Plum sucker or seedling has come up beside the wall of my garden—N.E. aspect. I removed the head, and it has well branched in cordon style on each side, the growths this year being about 2 feet long. I have been told I must graft it, but would like to know is that absolutely necessary to get fruit? Would some experienced correspondent say what treatment is most judicious to produce fruit? Would lifting and root-pruning and less rich soil than that of the vegetable garden be desirable, and if so, would November be the best time for this purpose? I should have said the tree is vigorously healthy, and about five years old.—W. J. MURPHY, *Clonmel*.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR LAST MONTH.**—56 feet above mean sea level. Mean temperature of month, 57.8°. Maximum on 5th, 77.7°; minimum on the 30th and 31st, 37.4°. Maximum in the sun on the 8th, 127.1°; minimum on the grass on the 31st, 28.7°. Mean temperature of the air at 9 A.M., 59.3°; mean temperature of soil 1 foot deep, 59.3°. Nights below 32°, in shade none, on grass two. Total duration of sunshine in month 142 hours, or 32 per cent. of possible duration. We had one sunless day. Total rainfall, 2.15 inches. Rain fell on fourteen days. Wind, average velocity, 8.5 miles per hour; velocity exceeded 400 on one day, and fell short of 100 miles on five days. Approximate averages for August:—Mean temperature, 60.2°. Sunshine, 149 hours. Rainfall, 2.52 inches. A cool month, without any really warm weather. The rainfall was below the average, but the last ten days were rather showery.—JOSEPH MALLENDER.

— **EXHIBITION POTATOES.**—A Birmingham gardener, Mr. Burden, is a good cultivator and exhibitor of vegetables, and in looking through his gardens recently he was moving out his crops of Potatoes, so that I had an opportunity of seeing what they are as croppers, and the following varieties were remarkably good and clean—viz., Sutton's Satisfaction—A main crop variety, a flat kidney, and an excellent cropper. Sutton's Abundance.—A cross betwixt Magnum Bonum and Fox's Seedling, both rounds and kidneys being produced as the type, a kidney not being fixed in the growth here. It is an excellent main crop, almost as late as Magnum Bonum. Windsor Castle.—A second early kidney, and a great cropper and short haulm; a first class variety, and so far disease resisting. Sutton's Noncuch.—A flat round main crop variety and excellent cropper, and of good quality and a first-rate cooking kind. Sutton's Matchless.—A second early round, some of kidney form; a very first-rate table variety of medium size, dwarf haulm, and a great cropper. In the same garden I noticed a very fine Pea, Sutton's Matchless Marrow, with ten peas in a pod, and exhibitors will be glad of such a variety.—W. D.

— WHEN paying a visit to PICTON COTTAGE, THAMES DITTON, the residence of C. F. Howell, Esq., I was much pleased to see this now popular vegetable the Tomato extremely well cultivated. The plants were in 12-inch pots, and the compost used at the time of potting being a mixture of light and heavy loam, and they were helped when fruiting by sprinkling a little of Thomson's Vine manure on the surface. There were in all three dozen pots, the size of the house being 20 feet by 14 feet, with a span roof; other plants, such as Pelargoniums, Fuchsias, Lilliums, &c., being grown in the house as well, and scarcely any peat had been used. At the time of my visit (the middle of August) they were well worth going a long way to see, the plants all doing well, and carrying a heavy crop of fruit, some of the specimens being 1 lb. in weight, plenty of others fully  $\frac{3}{4}$  lb. The varieties grown were Suttons' Reading Perfection and Waite's Glenhurst Favourite, with a few pots of Carter's Perfection, the two former being much alike, the distinction if any being in Waite's Glenhurst Favourite having slightly deeper fruit.

— ON again paying a visit a few days ago I found them still in a flourishing condition, the gardener (Mr. Kent) informing us that he should think at least 200 lbs. had been gathered during the season, a dish from which had easily secured premier honours at the late Show of the Ditton Horticultural Society, held in July last. In addition to the above it might be mentioned that Mr. Kent secured first honours for a very prettily arranged group of miscellaneous plants. The gardens at Picton Cottage are not extensive, but whatever is attempted is well grown and satisfactory to its popular owner (C. F. Howell, Esq.), who takes a great interest in his garden; and it is creditable to his gardener, Mr. J. Kent. Orchids are also well represented—Cattleyas, Odontoglossums, Cypripediums, and Dendrobiums especially in great variety.

— NEAR there are the beautiful grounds attached to MANOR HOUSE, Thames Ditton, the residence of Hannibal Speer, Esq., under the management of Mr. H. Farr, who was the winner of the bronze medal presented by the Royal Horticultural Society at the above Show for the largest aggregate amount of money prizes. One plant specially worthy of note at the time of my visit was a beautiful specimen of *Lilium auratum*. The stem came very much deformed, especially towards the top, and it was thought that the flowers would not come perfect, but contrary to all expectations, the buds all expanded into perfect flowers, and formed a sight once seen never to be forgotten, as there were no less than forty-three good sized flowers open at once, filling the conservatory with fragrance. The Chrysanthemums, of which about 200 are grown, looked well, and no doubt later Mr. Farr will have a grand display of bloom.—P.

— I HAVE forwarded to you a sample of selected PERFECTION TOMATOES as grown here, and shall be glad of your opinion of the same. They are not the largest we have grown this season, having gathered many fruits weighing upwards of a pound, one specially fine fruit weighing 22 ozs. Our plants are confined to single stems, and have a very limited root run, the majority of them growing in boxes of various lengths, but only a foot wide by 6 inches deep, the plants standing a foot asunder, and we have taken a heavy crop of fruit from them. We always use the brush to assist the setting in the earlier stages, and invariably secure a good set, but I find as we discontinue the use of the brush we secure but little addition to our crop as regards quantity, the plants devoting their strength to swelling the fruits which we have assisted them to set, and being generously treated to liquid manure and a sprinkling of fertiliser, they acquit themselves in a very satisfactory manner.—T. CROSSWELL, *Homewood Gardens, Eden Park, Beekenham.*  
—[Four magnificent fruits were received, weighing respectively 13 ozs., 15 ozs., 15½ ozs., and 19 ozs., a total of 62½ ozs., or an average of 15½ ozs. each. They were well formed, even, and handsome, such as are seldom seen.]

#### ORIGIN OF THE FLORISTS' DAHLIA.

THE opening paper at the Dahlia Conference at Chiswick on Tuesday was by Mr. Shirley Hibberd, the subject being "The Origin of the Florists' Dahlia." Instead of reading in the customary manner from written or printed copy, Mr. Hibberd entered upon a free extemporaneous discourse; and with the aid of a series of drawings was enabled to interest his auditors in a subject that appears not to offer many points of general interest.

He divided his subject into two parts, the historical and the biological. The earliest description of the Dahlia extant is in the "Treatise on the Animals and Plants of New Spain," by Francisco Hernandez, published at Madrid in 1615. From this time there was no more heard of the flower for 150 years. It was again heard of in 1787,

when Nicholas de Menonville was sent from France to Mexico to obtain, by any means, the cochineal insect and the plant on which it fed. This explorer reported having seen in the gardens great Asters on stems 6 feet high with leaves like those of the Elder tree, and this augmented the desire in Europe for the possession of the floral wonder. The desire was gratified in 1789, when a parcel of seeds was sent from Mexico city by Vincent Cervantez, to be grown by the Abbé Cavanilles, in the Botanic Garden at Madrid. Of these England secured a share through Lord Bute, who was at that time in Madrid, and secured a few, which he sent home to Lady Bute, who grew them in her greenhouse, so that in the year 1790 the living flowers of the Dahlia were actually seen in this country. But the nature of the plant being misunderstood, it was soon lost to cultivation; it was, in fact, killed by kindness, for the pet idea of that time was that all exotic plants required a high temperature and a stifling atmosphere.

The year that followed was the first in the proper history of the plant, for then Cavanilles, in his *Icones*, gave it a name as *Dahlia coccinea*, the generic name being a compliment to Andreas Dahl, author of a treatise on the Linnæan system of botany. This name was subsequently set aside by Professor Willdenow in favour of Georgina, in compliment to Professor Georgi of St. Petersburg; but in 1832 the original name was restored on the sole ground of priority, and from that time has been generally used.

The formation of the florists' Dahlia began in the year 1813, when Donkelaar, at the Botanical Gardens at Louvain, obtained a series of double flowers, which were freely distributed. But from about the year 1800 the French had been assiduously cultivating it, though but little was heard of their operations in this way, owing to the influence of politics in every department of public intelligence. But the advancement of the flower in French gardens was revealed when the Allies entered Paris in 1814, for the English amateurs found single and double varieties in profusion, and it seems that the credit for all this was due to Donkelaar, who had first persuaded the plant to display its variability, and had freely distributed his improved varieties. Thus the Dahlia came in with the French Revolution, and it attained to the dignity of a florists' flower concurrently with the downfall of Napoleon, who was the "child" of that revolution.

Turning to the biological history, the figures of *Dahlia coccinea* ("Botanical Magazine," t. 762) and of *Dahlia variabilis* ("B. M.," t. 1885) were contrasted with the flowers in the Exhibition to show that although the several forms of Dahlias were known eighty years ago, the interval had been one of continual progression, the earliest doubles being so unlike those of the present day that one might say that their relationship was botanical rather than floral. The progress of the flower in all the qualities that are valued and sought by the florists was continuous until about the year 1850, the golden time being from 1830 onwards, when the prices of the new varieties ranged from 20s. to 30s., and the Dahlia supported publications of its own, one of its ablest advocates being the "Dahlia Register." In those golden days the principal trade cultivators were Wheeler of Warminster, Brown of Slough, Heale of Calne, and Glenny of Isleworth. In one of his advertisements in the year 1836 Mr. Glenny announced that the selection he had made represented the best amongst 3000 seedlings. For some time after this date Mr. Charles Turner of Slough, and Mr. George Rawlings of Bethnal Green advertised their new varieties at 15s. each, but after 1850 there was a visible decline in the popularity of the flower. The years 1860 to 1870 was a dark time in the history of the Dahlia, but in 1870 the National Dahlia Society commenced operations, and accomplished a genuine revival, and this was the more gratifying as it was on the broad basis of recognising the single and the Cactus varieties that were then coming into favour, the first Cactus variety, Juarezi, of recent times being shown by Mr. H. Cannell in 1872. Previous to this, however, the Cactus group has been prefigured in Brown's "Glow-worm," 1836, a portrait of which Mr. Hibberd presented to the meeting.

The Dahlia was described as the most variable flower known, and a detailed account was given of the changes that take place in the development of the single to the double flower. The dissection of the flower revealed the differences between the florets of the ray and the florets of the disk, not only as to outward form, but as to their relation with the sexual systems, one direct tendency of the doubling process being to sterilise the flower. Some very interesting particulars were given on the seeding of show Dahlias and on the limits of variation in this variable flower. Of the extent of its variability Mr. Hibberd was enabled to discourse the more freely when he announced his belief that all our Dahlias, save and except the South American *Dahlia imperialis*, are representatives of one species. Thus he fuses *frustranea* with *superflua*, and even *glabrata* he regards a miniature form of *variabilis*, which name for strictly technical purposes he considers should represent the one species of which the other reputed species are but geographical forms. His reasons for those views would occupy more space than we can afford for them, but as the full text of the discourse will appear in the Society's journal, those who are curious on this part of the subject have but to wait for the publication to satisfy their curiosity.

#### CLEMATIS STANLEYI.

THE engraving (fig. 35) has been prepared from a drawing made at Kew about a month ago, and faithfully represents a distinct and little known member of the genus *Clematis*. It cannot be claimed as a novelty for it has been known at least half a century, having been

found in Natal by a collector employed by Lord Derby, whose name it bears in the specific title, and not that of the modern African traveller, as some might suppose.

some genus, and deserves to bear the name of that nobleman Lord Derby, through whose liberal patronage of natural history the plant is made known to us. Its discoverer remarks that it forms a shrub

FIG. 35.—CLEMATIS STANLEYI.

The plant was figured in Hooker's "Icones Plantarum" in 1843, and accompanying the Latin description are the following remarks:—"This is, assuredly, the handsomest species of an extensive and hand-

(apparently several feet in height), everywhere clothed with silky tomentum, so as to have a good deal the appearance of the silky variety of the North American Anemone patens. The flowers are as large

as those of our Corn Poppy, and, judging from the dried specimens, purple."

Last year seeds were sent to Kew from the Transvaal, and this summer the plants raised have flowered both under glass and out of doors. It is a dwarf compact shrubby plant not exceeding 3 feet in height, and has flowers about 3 inches in diameter, varying in colour from a pale tint to purple. Flowers are produced freely, and with the elegantly divided foliage give the plant an attractive appearance. It has fleshy roots, and loses its stems annually.

#### THE LATE MR. WILLIAM HOLMES.

It was with very deep regret that I read in the Journal of 25th ult. the sad news of the death of Mr. Wm. Holmes. It is now six years since I made his acquaintance on the occasion of the annual show of the National Chrysanthemum Society in 1884, when I asked his advice in the organisation of the first show of the Hull Society, which advice he readily gave, and many times since have I had the pleasure of talking Chrysanthemum matters over with him and received the benefit of his experienced judgment.

Only a short ten months ago Mr. Holmes was in Hull on the occasion of the second provincial show of the N.C.S., and I feel that the following words, which appeared in the report of the Hull Society, may be fitly reproduced here, where they will be more widely read, as they bear testimony to the unvarying courtesy with which Mr. Holmes conducted the business of the N.C.S.

"The Committee take this opportunity of putting on record the fact that the whole of the negotiations between this Society and the National Chrysanthemum Society, in connection with the joint Show, were conducted throughout by the members of the Executive Committee of the National Chrysanthemum Society with the greatest liberality and fairness, and the readiness with which they adopted the actions of the Executive of the Local Society was most gratifying to the latter, leaving, in consequence, nothing but pleasant memories of the second Provincial Show of the Metropolitan Society."

Mr. Holmes may be said to have made the National Chrysanthemum Society what it is, and it is no disparagement to others to say that the Society which he loved so well will find their loss difficult to replace, the shows will not seem the same without his presence. The N.C.S. will doubtless wish to form some lasting memorial of their late Hon. Sec., and I would suggest that the affiliated societies be allowed to join such a movement. If a sufficient sum were subscribed it might be possible to institute a "Holmes' Memorial Prize."—R. FALCONER JAMESON, *Chairman Hull and East Riding Chrysanthemum Society.*

#### THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE next two or three months will constitute an important and critical period in the history of the above Society. It is true the general programme for the Centenary Festival is prepared, and the preliminary arrangements are practically completed, but much will depend upon the actual execution of the details, and it will be impossible to devote too great a care and consideration to the work. Happily Miss Holmes, the sister of our late Secretary, has undertaken to continue for the present the duties she has for some time so well performed as assistant to her brother. Being so thoroughly conversant with all the details of the clerical portion of the secretarial work, this is a most valuable offer, and will be highly appreciated by all members of the Society. The Chairman of the Committee, Mr. R. Ballantine, who had been for years one of Mr. Holmes's most intimate friends, and who has assisted greatly in the past both by suggestions and taking a good share in the work, has also promised to devote as much time as he can spare from business to general supervision. This, with other ready and able help in the management and arrangement of the Show itself, will effectually remove any fear of a collapse, and this explanation of the position of affairs will no doubt be welcomed by many from whom I have had letters expressing concern as to the prospect of the exhibition and the Society.

It is felt by the majority of the late Mr. Holmes's friends that no better course could be adopted at present than to do their utmost to insure the success of his special project—the Centenary Festival. The least that can be done is for the officers and members of Committee to co-operate heartily with this object in view, and if petty dissensions and jealousies are suppressed, success will be insured. It was proposed that the November gathering should be taken advantage of to call a general meeting to discuss propositions for next year, and upon one of the last occasions I spent in the company of Mr. Holmes this matter was discussed at some length. He evidently thought as others have, that following such a season of activity there would be corresponding depression and a tendency to a decline in public interest unless fresh

projects were prepared. With the aid of the numerous affiliated societies something might be effected in this direction, and in any case no harm could be done by inviting suggestions at the conversazione it was intended to hold on the day the prizes are distributed.—LEWIS CASTLE.

#### CHRYSANTHEMUM BELLE PAULE.

IN "taking" the buds of this variety on strongly grown plants all the shoots which cluster about the bud should not be removed at once, as is usually done with other varieties, but one should be left to draw off the sap until the bud has thoroughly formed and is seen to be swelling. On strong plants many buds go blind, and I know of no other reason for their so doing than that this variety needs assistance in perfecting its buds in the manner described. The fact of weakly grown shoots setting their buds freely, as named by "G. P.," points to the reason for non-setting and the remedy here advised also.—E. M.

#### ASHES.

WHEN any part of an organised substance is reduced by thorough combustion there remains a fixed residue or ash. This contains several metallic and non-metallic elements. The most important of the former are:—Potassium, sodium, calcium, magnesium, aluminium, and iron; and of the latter the chief are chlorine, phosphorus, sulphur, silicon, and carbon. These are combined together in varied amount and form in plants, and are derived by the plants from the soil. The characteristic elements of the leaves differ from those of the fruit, therefore an examination of the ash of plants leads to important conclusions as to the most suitable manures to employ for enriching the soil.

Ashes as generally available for cultural purposes are but limited in quantity; the most abundant are coal ashes. These have some manurial as well as mechanical value. The manurial properties are confined to sulphate of lime and potash, and carbonate of lime unless sulphate of iron is admitted to have manurial value. Coal ashes also contain carbon, silica, alumina, and oxide of iron, carbon being of considerable importance. Coal ashes are usually recommended as most useful to heavy soils. When they contain many cinders they are peculiarly suitable for lightening them, the benefit being mostly mechanical, as the staple is rendered more open, therefore permeable by air and rain. Rough ashes should always be reserved for heavy soil, and the finer for light. It is a great mistake to act on the principle that ashes are not a useful application to light soils. Lime in any form is beneficial as a binder, though it may have a decomposing disintegrating effect on organic matter. That does not imply the uselessness or even impoverishing tendency of lime when applied to light soils. In any form lime has a strong affinity for water, and binding as the effect of lime is it must improve light soils, acting as an absorbent and retainer of moisture. When reduced to dust or white ash coal ashes may be used as a dressing to light soils to the extent of half an inch thickness, and form good manure for Peas, Beans, Potatoes, and an excellent dressing for grass. Rough ashes, however, do more harm than good to light soil, and on heavy soil they can hardly be applied in sufficient quantity to alter the staple, but it may be overdone. An inch thickness mixed with the top spit will effect wonders as to working clay soil, and the air the ashes admit must act beneficially. Coal ashes are also excellent as a medium wherewith to mix blood, night soil, cesspool cleanings, and similar substances, for which purpose they cannot be too fine and dry.

WOOD ASHES.—There is always a quantity of woody matter in gardens, the result of trimming hedges, pruning trees, &c., as well as rough weeds, all of which reduced to ash contain various substances more or less valuable as manure. They contain sulphates of potash and lime, chloride of sodium, carbonates of lime, potash, and magnesia, besides other constituents, the most important component being potash, which often amounts to one-half or more of the ashes. On the amount of available constituents depends the value of wood ashes as manure. Salts are removed from soil through cropping, and it is necessary to restore these to the soil, as the aggregate amount in a few years will so far impoverish the soil as to prevent profitable culture. The ashes of plants containing the elements required by the various crop plants they can scarcely be applied wrongly. It is found, however, that sulphates and carbonates of potash act similarly to sulphate and carbonate of lime on the texture of soil—viz., that they have a binding effect. That, however, may be due to the ashes containing lime having no connection with the potash; but by whatever agent it is effected the continued application of wood ashes to clay soils is found to be attended with small benefit, whereas their continued application to light soils improves their staple, augments their retentive power, and enhances their producing value.

In the limited quantity that wood ashes are procurable in this country as compared with the supplies where wood is used as fuel, there is little danger of any soil being other than benefited by

their application. There are two conditions which must not be overlooked—viz., in their burning. Bakeries or brick ovens reduce the wood to a perfect ash, or nearly so, a similar result attending the thorough combustion of woody or vegetable matter on a hard floor or earth, whereby the whole by “stirring up” is reduced to ash. This is a kind of the greatest value, and there is this about this ash—viz., it must be kept dry, but if left to get soaked with rain a semi-lye is formed, and the potash vanishes correspondingly with the saturation. It is very useful for dusting over Peas, seedling or young vegetable crops of all kinds in the morning or evening whilst their leaves are damp as a safeguard against slugs and birds, besides value as manure. It is, however, one of the best fertilisers for every description of crop. I have mostly a store of this substance, and whenever seeds are sown, whether on the flat or in drills, give the ground a good dusting before covering with soil. I do not think there is a crop of any kind grown in gardens to which I have not applied this form of wood ashes, and invariably with beneficial results. All plants like it, as might be expected, as all soils contain potash, lime, and soda, therefore enter into the construction of plants. Of course, elements may be in a soil without plants making use of them, but those are as essential to plants as the “staff of life” is to man. They are not delicacies, but their everyday necessities. For fruit trees they are invaluable. If farmers would take care of the ashes resulting from their wood fires, and scatter them about their orchards, the moss would disappear from the grass, and the fruit trees would outgrow their gum and canker, especially if the precaution were taken to keep the ashes dry and take care of the blood when hogs are slaughtered, which mixed with the ashes is perhaps the most powerful of all manures for fruit trees, with an equal quantity of superphosphate added, though it is first-rate without. Gardeners are requested to give it a trial on Vines. A good handful per square yard will serve the Vines better than a foot thickness of stable manure, and both substances are let waste or expend themselves on a luxurious growth of Nettles. Figs like it, and all fruits, applying it some little time in advance of growth, for what is passed into the tree will pass into the fruit, and the more they have the more chlorophyll they will store on condition that the foliage has full exposure to light and air, and is not prevented assimilating the food elements for lack of ventilation. The more potash in the fruit with corresponding lime and phosphorus the larger it will grow, and the characteristic malic, citric, and other acid will come, with pectose in due course, and the colour of Grapes will be as is the chlorophyll stored. A peck per square yard (30½ square yards) is a suitable application, distributing evenly, and the fresher the ashes are the better, or they must, as before stated, be kept dry; but even then they lose value through the affinity of lime for water, therefore keep as dry as possible.

There is another property of wood ashes which must not be overlooked—viz., their value for applying to over-rich soils. Some soils—they are not very common in gardens nowadays—have so much manure that they do not produce crops correspondingly, in fact they become sour and unprofitable, the crops clubbing, grubbing, mildewing, and doing everything bad. The soil also becomes cold. A dressing of wood ashes corrects the sourness—more, it supplies the essential elements needed by the plants to harden their cell wall, balance or counteract the flushing tendency of the organic matter, whereby the plants are given stamina and staying power; in a word, usefulness. Dust ashes are not so good, however, as those that are rough, containing more carbon—i.e., charcoal.

Coarse wood ashes are generally any garbage—coarse weeds, remnants of vegetable crop, with enough wood or clippings and pruning to ensure their combustion, a slow process, whereby there is a considerable amount of charred matter, wood being converted into charcoal of a sort. These ashes and charred refuse are valuable for applying to heavy soil, as they contain a considerable amount of silica and lime with lessened proportions of potash and soda, although they may contain more when the leaves of vegetables are consumed than is present in the ashes of thoroughly consumed wood, as twigs and leaves contain more potash and soda than wood, and less lime. This charred material may be used at double the quantity when there is not much earth mixed with or holding it before burning, but when there is much earth it may be used in four times the quantity of the fine ash with very beneficial results on stiff soils, and to light does good, only the rougher parts are best taken out by passing it through a half-inch sieve. In this state the ashes may be used on light soils in the same proportions as for heavy soil. I like to have a good heap of the ashes at hand, particularly when the soil is stiff, having it damp for covering seeds with after sowing. I use it for everything sown in the way of vegetables, covering those on the flat with a similar thickness the seeds would otherwise be of soil, and fill the drills level where those are drawn. It serves to keep vermin from the

germinating seeds and their underground stems, also from their stems above ground, as no predatory slug cares to travel over it, and insures immunity from weeds to a great extent, especially as regards drills. It entails some trouble, but it is of a kind that pays, at least I found it difficult to get anything upon a stiff soil before I took to this plan. There are other ashes, but I do not think gardeners are troubled with more than the two kinds mentioned, therefore they are passed.—G. ABBEY.

#### NOTES ON SOME NEW ROSES.

WE have had some fine new Roses sent out within the last three years, the majority of them of British raising, and they seem to increase not only in quantity but also in quality as time goes on. Two belonging to 1887, which ought to be remembered as the Mrs. John Laing year, are only now becoming known, and these are Germaine Caillot, H.P., and L'Idéal, N. The former is a very fine show Rose, but will never be extensively cultivated, as it is one of the worst of growers, of the dwarf robust type. A maiden plant makes a shoot of 6 or 7 inches, and then produces its fine bloom. What are you to do? If you cut it to show you must take very nearly the whole plant, and thus very much weaken it for the future; and if you leave it it will not make more than two or three weakly autumn shoots with poor flowers. The first bloom is very good, but is the game worth the candle?

In L'Idéal, N., we have a strong grower, quite capable of climbing a wall. I have been a little disappointed with the flowers, which seem to resent any rain; but if “caught right,” and especially if shown in a bunch or in company with W. A. Richardson, it is very attractive. It seems much more vigorous than its popular buttonhole rival, and I think is more likely to help it by contrast than to weaken it by rivalry.

The year 1888 was not strong in H.P.'s. Monsieur Trievor seems a good deal like Comtesse d'Oxford, but I have only seen a few blooms. Sir Rowland Hill is a lovely colour, most distinct, effective, and useful. I have not yet succeeded in getting really strong growth or large blooms from it, and it is weak in centre and a bad laster. A midland rosarian told me he had found it revert to Charles Lefebvre, but it has not done so with me. Ernest Metz, T., redeemed the year in the Tea classes; a fine large well-shaped, and lovely flower, a good grower withal, and I have been surprised to see it shown so seldom during the past season. It is sure to come to the fore as the stock increases.

I wish Messrs. Dickson had not sent out Lady Castlereagh, T. As seen with me it certainly spoils their most excellent record, generally coming with a green eye, and as flat as a pancake when it does not. 1889 was also stronger in Teas than in H.P.'s.

The two good French Roses of the year, Gustave Piganeau, a very large strong growing red H.P., and Augustine Guinoisseau, a nearly white La France, I have had no experience with, but I have had Messrs. Dickson's two H.P.'s. Of these, Lady Arthur Hill, a seedling from Beauty of Waltham, is of excellent quality and form; the colour is charming, and though I should have liked it a little larger it is as good in that respect as the seed parent. James Brownlow is quite big enough, and not so coarse as I expected from its parentage, Marquise de Castellane and Paul Neyron; the wood and foliage are very similar to the latter Rose, but it has been a very bad bloomer with me, the majority of the shoots coming blind.

Three very fine Tea Roses were sent out this year, of these Cleopatra is grand. I saw some magnificent blooms at Mr. B. Cant's in June, and feel confident that this Rose will make its mark. It cannot be called a vigorous grower, but it will “answer to treatment” as doctors say, and do best I expect as a standard. This and Ernest Metz will, I have no doubt, be reckoned among our best Teas. Mrs. James Wilson is a very pretty Tea with good and most distinct growth; the flowers are like pale, very delicate Marie Van Houtte in colour, with good pointed centres, and though not of the largest size it is quite good enough to show among other Teas.

Souvenir de S. A. Prince has well maintained its reputation in every way as the best white sport of Souvenir d'un Ami. I had one this year, at least a Souvenir d'un Ami of mine produced white flowers throughout the season, one of which I took up to the Crystal Palace to show to Mr. Prince, but they were not quite pure in colour.

This year, 1890, two Roses from Messrs. Dickson seem likely to be heard of in future. My plants of these varieties have not bloomed, but I saw one flower of Jeannie Dickson at Birmingham, and believe it to be very good, and I heartily hope that T. W. Girdlestone will prove worthy of the name it bears.

And 1891 will surely be a noteworthy year; there are the three Roses shown at the Crystal Palace—Salamander, Mrs. Paul and Captain Hayward—on which I have no further criticisms to offer; Bruce Findlay at Manchester, Mrs. Arthur Wilson from Madame Luizet, and, above all, Margaret Dickson at Birmingham. Its parentage simply describes the latter Rose, a cross between Lady Mary Fitzwilliam and

Merveille de Lyon, and that is just what it looks like. A very happy thought, Messrs. Dickson, and what is more, a very happy result; a grand broad white Rose with the point of Lady Mary in the centre of the cup of Merveille, just where it was wanted. It certainly looks as if this was going to be our best white H.P., at all events for show purposes.

To look even further, Mr. B. Cant has kindly sent me some specimens of a sport from Madame Faloot, which he is testing. It seems a decided improvement upon the original; stouter, fuller, and larger. One at least of the blooms sent was quite good enough in centre, fulness, and shape for "the likes o' me" to show in a Tea class. If Mr. Cant decides to send this out I think it may be fully relied on. "D., Deal," has remarked, in giving lists of new French Roses, that to a certain extent we have to trust at first to the reputation gained by the raisers as to how their Roses have turned out and answered their descriptions in other years. Mr. B. Cant has sent out one Rose, Prince Arthur, and it will be remembered, I think, that he originally did not announce it as a show Rose at all, yet it has turned out to be one of no mean quality.

I have also been favoured by Messrs. Harkness with a specimen of their striped sport of Heinrich Schultheis. It was a poor bloom in itself, sent only to show the colour; there was a fair specimen, I hear, among their Roses at Tibshelf, and they inform me that they have had it really fine and good. Now, again, when a comparative stranger tells us he has had such a Rose fine and good, we naturally think to ourselves what is his ideal and knowledge of what is a good and fine Rose? but of course such an inquiry is unnecessary in this case, for if Messrs. Harkness do not know what a fine Rose is, who does? But I confess I do not like striped or parti-coloured Roses, they look to me tinselly, meretricious, clown-like, bizarre among self-coloured blooms, like the lady who appeared in the park the other day with sleeves, &c., of different colours. The tints of this sport are very much like those of the old so-called York-and-Lancaster, and the flower is, therefore, at least brighter and more cheerful than Pride of Reigate, which, in my private opinion, is sufficient to spoil the appearance of any stand; but taste, as Mr. Squeers said of "Natur," "is a rum thing," and it is wise to keep to the old rule—*De gustibus non disputandum.*—W. R. RAILLEM.

#### FRUIT FORCING.

**PINES.**—To maintain the sturdy healthful appearance of young plants free ventilation is necessary, the plants being afforded ample space, maintaining the bottom heat about the roots at 80°, watering the plants whenever they require it, employing weak liquid manure always, and avoiding the use of the syringe too frequently, merely damping the paths morning and afternoon daily will suffice. Fire heat must be resorted to to maintain a night temperature of 60° to 65°. Newly potted plants should have a bottom heat of 90° to 95°, with a view to the roots speedily penetrating the soil. Recently started suckers should, as soon as the roots are plentiful, be raised near the glass, it being essential that those intended to be wintered in small pots be brought on gradually.

When the suckers started this autumn are rooted pot them without delay, draining the pots well. Employ the fibry part of turfy loam, and do not tear it up too fine, but use it in lumps proportionate to the size of the pots. The strongest plants may be transferred to the fruiting pots at once, the size of the pots being proportionate to the robustness of the varieties. Jamaicas do not require large pots, 9 or 10 inches are quite large enough, as they go too much to leaf when more pot room is given them. Queens do well in 10 or 11-inch pots, Smooth-leaved Cayennes are accommodated in 11-inch pots, or 12-inch pots at largest, and Providence, of which it is desirable to grow some on account of its fine appearance, do well in 12 or 13-inch pots, which will afford fruit of the largest size, the cultural treatment being good. To get fine fruit the plants must be given plenty of space, and be kept well up to the light so as to form a sturdy thoroughly solidified growth and well developed base. Where smaller plants and fruit are required pots an inch or two less in diameter will answer. Plants not of a size fit for transferring to the largest pots can be shifted into 8-inch pots, in which they may be kept until spring, and then be transferred to a larger size. Fruiting plants should have a night temperature of 70°, 80° to 90° during the day, closing at 85°.

**CUCUMBERS.**—The autumn fruiters must have every attention, affording weak liquid manure whenever water is required. Syringe only on bright afternoons at closing time, which should be soon after midday so as to command a good sun heat. Pinch out the growing point one or two joints beyond the fruit, examining the plants at least once, better twice, a week for that purpose, retaining no more foliage than can have full exposure to light. Remove all staminate and surplus pistillate blossoms, and pinch off tendrils early. Earth up the roots as the plants advance in growth from time to time, and take care that the soil, also water or liquid manure, is given at the same temperature as the bed. Pot the seedlings raised at the beginning of September for

winter fruiting directly they are large enough, not allowing them to become stunted, plunging the pots in bottom heat until the plants are established, then raise them well up to the light, keeping near the glass. Maintain a temperature of 70° at night, 75° by day, with an advance from sun heat of 10° to 15°. Where fermenting materials are used for bottom heat they must be in course of preparation for forming the beds. For producing fruit in January onward through the spring months a sowing should be made at once, the plants being kept sturdy by keeping near the glass.

Plants in dung-heated frames or pits will continue to afford good fruit for some time, only the linings are renewed as required, the foliage kept rather thin, all bad leaves removed, exhausted growths being cut away, and the shoots stopped to one joint beyond the show of fruit. No more water should be given than to secure healthy moisture for the roots, discontinuing syringing or damping overhead. If mildew appear dust with flowers of sulphur, and arrest canker by dusting with quicklime. Afford the protection of mats over the lights on cold nights.

**CHERRIES.**—These are not seen under glass to anything like the extent they deserve. They succeed admirably in any light well ventilated structures without heat; but they force readily only they are not hurried in the early stages. They may be grown in pots or planted out in bush or pyramid form, and they succeed admirably trained to trellises. It is essential to success in forcing that the roof lights be moveable, as the Cherry is liable to over-maturity of its buds when subjected to early forcing in consecutive years. The best time to plant trees under glass is when the leaves begin to fall. The most eligible are those trained four to six years against walls, and subjected to annual or biennial lifting. Trees from the open answer well, only they have been lifted so as to move safely, and are free from gum. Trees that have been grown in cool houses are the best of all; but they can seldom be had in trained trees, and that is no drawback, as they succeed very well planted out in bush or pyramid form, or they can be grown in pots, whereby the house is liberated for Chrysanthemums in autumn. The Cherry succeeds best outdoors in a silicious soil, but indoors it requires a more retentive soil. Good turfy loam, inclining to be strong rather than light, four parts, one part each old mortar rubbish and road scrapings thoroughly incorporated, form a suitable compost, the border being 24 inches deep over 9 inches of rubble secured with a layer of old mortar rubbish, and about 6 feet wide is ample for trellis trees. The very finest varieties are Early Rivers, Empress Eugénie, May Duke, Black Tartarian, and Large Black Bigarreau. Of the light coloured varieties, Early Jaboulay, Governor Wood, and Elton are excellent. In planting, the soil should be made firm, a good watering given, and the surface mulched with an inch of short but rather fresh manure. The lights having been removed some time from houses that are regularly forced they need not be replaced for a month or six weeks, the old surface soil being removed without injury to the roots and replaced with fresh compost, that above-mentioned answering with the addition of a fourth of manure. A handful of steamed bonemeal or ground coprolites may be given per square yard. Trees in pots required to be shifted into larger pots should be attended to at once, and those not required to be so treated should be turned out of the pots, removing a few inches of soil from the base, cutting back the roots, and supply fresh loam with a sprinkling of half-inch bones, good drainage being provided. The surface soil should be removed, supplying the above compost, adding a fourth of decayed manure. The soil should be made firm. Afford a good watering, and place the trees where they can have plenty of air. If stood outdoors they should be plunged over the rims of the pots.

**STRAWBERRIES IN POTS.**—Autumn fruiters afford acceptable dishes of fruit, their bright appearance affording a pleasing variety at dessert. All the varieties forced are not good autumn fruiters, but the early forciers, as La Grosse Sucrée, Vicomtesse Hericart de Thury, and Sir Harry, are most suitable through their quality being higher than the larger fruited varieties. Plants that have been forced in spring, shaken out, repotted, and grown on are excellent for autumn and early winter fruiting, or if planted out and duly attended to they can be lifted at the end of September, potted, and placed in a frame. After the fruit begins to swell they should be encouraged with weak liquid manure, guano water being suitable, and where the plants are weak they may have an occasional dose of nitrate of soda, half-ounce to the gallon of water. Early autumn fruiters with the fruit approaching maturity should be placed in frames with abundant ventilation, which will assist the fruit to ripen, improving its colour and quality considerably. Any autumn fruiters not required to fruit for some time yet may be retarded by placing them on a north border, assigning them plenty of space on a hard bottom.

The earliest intended for early forcing should now be selected, taking with the most promising crowns, well developed, and plumped, giving them plenty of space, so that they will become well matured in their growths, and before heavy rains place them in frames plunged to the rims of the pots in ashes, and well up to the glass, so that with that perfectly clean they will be assured plenty of light, and air must be afforded abundantly by keeping the lights tilted in rainy weather and withdrawn when the weather is mild and fair. The plants must not lack water at the roots. A loose surface for Strawberries in pots prevents the soil leaving the sides of the pots, and admits of the water passing equally through the ball and moistening it thoroughly. A little dried horse droppings or cowdung rubbed through a half-inch sieve applied to the surface will keep all right there. Remove all runners as they appear, also weeds, and do not allow the plants to suffer through insufficient supplies of water. The plants should have plenty of space

for the full exposure of the foliage to light and air, which is essential to sturdy growth and plump well developed crowns. Late and weakly plants may be assisted with weak liquid manure, but stimulants must not be given strong plants or it may cause them to push the flower buds, which if only partial splits up the crowns into a number of parts derogatory to a good show of trusses when placed in heat.

#### THE FLOWER GARDEN.

*Carnations and Picotees.*—A showery season has been favourable to the rooting of the layers generally, and abundance of strong plants ought now to be available. Newly rooted plants of choice varieties, as a rule, are potted and stored in cold pits and dry frames, though whether in many cases they would not do better planted out is a moot point. Supposing the layers are plentiful, both plans might well be resorted to, a failure being thereby guarded against, and it may be the foundation of a greater success than usual be laid. Those to be potted should be separated from the parent plants with a moderate amount of soil about the roots, and be given well drained 3-inch, or rather larger sizes if need be, and a compost of turfy loam, a little old Mushroom bed manure, and plenty of sharp sand. Pot rather firmly, water, and set in frames near to the glass. During the winter they ought to have abundance of light and air, and on no account to be subjected to much fire heat, mats and other coverings being the best safeguards against severe frosts.

*Planting out Carnations.*—No time should be lost in getting either seedlings or plants, raised from cuttings or by layering, into their flowering quarters. A damp or low position does not suit them. They thrive best in slightly raised beds, to the soil of which has been freely added a good thickness of sandy loam and a little short sweet manure. These beds ought really to have been prepared for some time previous to planting, in order that the soil should be well sweetened and pulverised. Nor should planting be attempted in wet weather, as it is of importance that the soil be well pressed about the roots without causing it to bind badly. Slightly raised beds 6 feet wide may hold five rows of plants put out about 12 inches apart. A sharp look-out must be kept for slugs, frequently stirring among the plants serving to keep these down, and if the frosts loosen the plants, as they often do, then must the soil be as often pressed about the roots again. Much of this upheaving may, however, be prevented by mulching the beds with either leaf soil, spent tan, or old Mushroom bed manure.

*Pinks.*—These also should be planted out in beds directly they are sufficiently well rooted to bear removal with a trowel. Raised beds may well be formed for trees, the soil being prepared much as advised in the case of Carnations. A distance of 9 inches apart is ample. New plantations are by far the most satisfactory, the very old beds producing a larger number of flowers perhaps, but of a very inferior description. They do not fill up so rapidly as do Carnations, and a bed may be said to be at its best when about three years old. If no steps have been taken to strike a number of cuttings for planting out now, old plants may be pulled to pieces, and the divisions, whether furnished with roots or not, be deeply dibbled out into well prepared soil. All should be sunk well up to the young leaves, the plants rarely doing well if any portion of the old stems are exposed.

*Pansies.*—Seedlings grow and flower the most freely, and if the plants are large enough to put out into raised beds before wintry weather sets in the chances are a grand display will be had early next season. Plants raised from either seed sown or cuttings inserted at this late date ought to remain under glass till the spring, and these will afford an early summer display. Pansy cuttings strike very freely, and now is a good time to insert them, these being selected from young flowerless shoots, and otherwise treated similarly to what will be advised in the case of *Violas*.

*Bedding Violas.*—These have done remarkably well this season, plenty of moisture being what they stand most in need of during the hot weather. Of late years this beautiful class of bedding plants have been enriched by the addition of several charming varieties, and seeing how easily many hundreds can be wintered with very little protection they ought to be even more extensively grown than they now are. The simplest way of raising and wintering the requisite stock is to prepare garden frames for their reception. If these are shallow they may be set on an old hotbed, or a bed may be formed of exhausted heating materials, no bottom heat whatever being either required or desirable. Some rough soil should be placed in the bottom, or enough to bring the 5 inches of sifted sandy soil placed on the top of it well up to the glass. Deep frames can be set on bricks or flower pots at each corner, a few barrowloads of old heating material being placed firmly in the bottom, and then rough and fine soil on the top, finishing off in this and the other ease with a surfacing of sand. The best cuttings are those just springing from the centres of the old plants, and failing these the tops of old growths will do nearly as well. Shorten to about 3 inches in length, and insert them that distance apart each way all over the bed. A watering should be given, the lights put on, kept shaded in bright weather, and close for some time, abundance of air being given after they have commenced to form roots. A very little protection will suffice to preserve them from severe frosts.

*Calceolarias.*—These again have done very good service this season, and abundance of good cuttings are to be had. The firmest or most short-jointed flowerless shoots ought to be selected for making into cuttings, the soft undergrowth being discarded as much as possible. Cut just below the third joint, and trim off the lowest pair of leaves. In most other respects *Calceolarias* ought to be treated very similarly to *Violas*, no bottom heat being given them. Not being so hardy they will

require more protection during the winter. If a few dozen plants only are needed these may either be struck and wintered in handlights or in boxes kept in cold frames. *Calceolaria amplexicaulis* is alike the most delicate and the most beautiful variety of all for bedding purposes, but even this must not be unduly coddled, fire heat, unless a little only is turned on in cold weather, being most injurious to this class of plants. *Calceolaria* cuttings may be put in any time before December, but if long delayed severe frosts might spoil them.

#### KITCHEN GARDEN.

*ONIONS SPROUTING.*—As we anticipated, the Onions not being well matured this season many of those drawn up about a month ago are sprouting again in the open shed where they were spread out to dry. It is chiefly those with thick necks that are doing this, and all the growths should be broken off them, and they should be the first used. Do not store them in a warm place, but keep them as cool as possible. On wet days the whole of the Onions may be examined. Remove the loose necks and skin, and store the sound bulbs in an airy loft for winter and spring use.

*SPRING CABBAGE.*—These have grown well since they were planted in their permanent quarters. The first planted are now ready for earthing. Some think there is no advantage in this operation, but it keeps the plants firm, and prevents their shaking about in the wind, which they otherwise do when the heads become heavy. They are also more hardy and robust in winter if the roots are growing in a firm soil, and before earthing tread round each plant until the soil is as firm as a road. This we have frequently proved is a sure way of securing compact plants, which are always the most desirable.

*LATE KIDNEY BEANS.*—Runners were unusually slow in podding in summer, but they have been uncommonly prolific since. Some late rows that are beginning to form pods will prove useful in October and November if they escape frost. Those that have been bearing all the season are of little use for a late supply. Late Dwarf Beans in the open that are about to flower must have frames and glass lights placed over as many of them as can be protected. Place the lights over them every night and when it is wet, but remove them on fine days. If the plants are crowded they will hold too much moisture amongst the leaves to fruit well, and some of the plants should be thinned to avoid crowding. Where Kidney Beans are desired at Christmas a quantity of seed of *Ne Plus Ultra* should be sown in small pots at once. Place them in a cold frame, let them remain there until they are ready for transferring into larger pots, and then place them into a warmer pit or house where the atmosphere is not too close.

*YOUNG POTATOES IN WINTER.*—It is surprising that those who devote much attention to the production of choice vegetables in and out of season do not grow Potatoes more generally for a supply at Christmas. Last October we made up a hotbed to hold a dozen lights or frames, placed soil into them, planted early Potatoes as if it was the spring crop, and we had many choice dishes at midwinter. The position must be sheltered and sunny, and the bed and frames should stand at a sharp angle to catch the sun and escape damp. *Shaibe's Victor* has succeeded well with us in autumn.

*SALADING.*—The Lettuce plants for the winter supply are now ready for transplanting. Some of them should be placed into frames at a distance of 6 inches apart, but do not protect them until it is necessary. They will soon establish themselves in good soil, and they can readily be protected from frost. At the same time plant a quantity at the bottom of the garden wall, or anywhere that shelter is afforded. Endive may be treated in the same way, and in mild localities a quantity may be planted in the open garden. Winter Radishes of the China Rose and Black Spanish types now showing should be thinned to 2 inches apart. Mustard and cress will not grow in the open now, and must be sown under protection.

*WINTER SPINACH.*—We never had this more promising. It is a useful winter vegetable, but those who have the plants crowded and without thinning will find it suffer much more from frost than when it is thinned in good time, so that each plant stands clear of the other. These will furnish more useful leaves than a crowd of plants.

*LATE SOWN CARROTS.*—In common with many others, when our Carrot crop sown in April was badly attacked with the grub in July the prospect of having our usual supply of Carrots in winter was not bright, but by adopting our usual practice of sowing again when a crop is failing we have now a large quantity of clean healthy young Carrots. They are not so large as the April roots would have been, but they are of a most useful size, and we are seriously considering whether in years to come it would not be better to be less anxious to sow the main crop in April or May. July sown crops rarely suffer from grubs, and there is no doubt as to their gaining a useful size by October. This matter is worth the consideration of growers.

*VACANT GROUND.*—Lifting Potatoes and clearing of Peas and other crops will leave some vacant quarters. These are often allowed to remain with the old stems and roots in the ground until midwinter or later, but this is a bad plan, and the best way is to clear all refuse off or burn it on the ground, and dig it roughly immediately afterwards. This gives the garden a good appearance, and is also most beneficial to the soil.

#### PLANT HOUSES.

*Gladiolus The Bride.*—Plants that flowered during the early part of June in the greenhouse and have since been standing outside should be repotted before they start into growth. If this is done at once the old soil can be shaken from the corms, and then placed thickly together in

5-inch pots, and covered with about half an inch of soil. After potting they may stand outside or be placed in cold frames, where they will soon start into growth. If placed outside plunge the pots in ashes, and just cover the surface of the soil with the same material that has been passed through a fine sieve.

*Lilium candidum*.—Bulbs that were potted a short time ago and have started into growth should be placed in cold frames; they will be perfectly safe in this position until it is necessary to force them. When the flower spikes appear they should have greenhouse treatment; nothing is gained by hurrying them. As their flower stems lengthen a sharp look out must be kept for aphides.

*Lilium Harrisii*.—These may still be potted, and placed in cold frames until they start into growth. Be careful that the soil is in an intermediate state of moisture. When placed in frames fill in between the pots, and cover the rim to prevent watering with cocoanut-fibre refuse. Directly they show through the plunging material they should be lifted out at once, and if required in flower early it will be necessary to place them where they will be safe from frost. They delight in standing on a moist base, and must not be hurried before the flowers are formed, when a temperature of 60° will do no harm. Until they reach this stage a temperature of 50° should not be exceeded.

*Epacris*.—Remove these from frames to give room for Cinerarias, Calceolarias, and other plants. Select for Epacris a light position, where they can have abundance of ventilation. Stand the pots on ashes or some other moisture-holding material. Be careful that they do not become dry at their roots, or the material upon which they stand. Syringe the plants lightly on fine days in the morning and afternoon.

*Solanums*.—The earliest plants will have a number of coloured berries upon them, and should be placed in cold frames or in the greenhouse at once. Whichever position is selected the base should be a moist one, and the plants liberally supplied with water. Soot water is very beneficial, and will impart to the foliage a fine dark hue. Later plants in pots that have set a good number of berries should be placed under cover. Lift those that are planted out, and place them for a week behind a north wall, give a good soaking of water, and syringe several times daily until they commence rooting afresh, when they may be placed in frames.

*Callas*.—Where these are grown in pots, and if required in bloom as early as possible, place them at once in the greenhouse or any other light airy structure. Small plants in 3-inch pots that are well rooted should be placed into 6-inch. Lift all that are outside, and place them in pots according to their strength. No harm will result from reducing their roots considerably provided the roots are preserved. If treated the same as advised for Solanums they will soon be sufficiently established in their pots for any position. In case of frost protect them with tiffany.

*Salvias*.—Those that have been grown in pots may be placed into 10-inch if large plants are desired. Do not pinch them again. Lift those that have been planted out, and place them in various sized pots. They will soon become established if given the treatment advised for Callas.

*Bouvardias*.—Do not leave longer in cold frames; remove them to a light house where the temperature at night can be prevented falling below 55°. Give the plants weak stimulants every time they need water. Large trusses will result, and be produced in succession for a long time.

*Begonias*.—Plants that are still in frames should be placed in a light house where a free circulation of air can be given by day, and where the night temperature will not fall below 50°. Keep the atmosphere as dry as possible. Tubercous Begonias that have done flowering may be allowed to go to rest; dry then gradually, or the tubers are very liable to decay. Seedlings and those raised from cuttings that have attained fair size and have commenced flowering will continue to do so in the conservatory for a long time. Later plants should be given gentle heat, and they will soon commence flowering and yield suitable blooms for cutting for some weeks. Start into growth a few plants that have rested of *weltoniensis* and others of a similar nature. Repot young plants that need more root room.

*Azaleas*.—These are frequently at this season outside and in various positions in consequence of their different stages of growth. No time should be lost in training those that have been closely tied in; the foliage will then turn to the light before winter. Arrange the whole of these in their winter quarters. Examine them for thrips, and if any are found wash the plants in a solution of tobacco water, 1 oz. of softsoap to the gallon, and a piece of common washing soda the size of a Cob Nut.

sheltered soil is still quite dry a little way below the surface. No tree or shrub ought to be moved in a dry state at the roots. A basin should be formed, opening out the soil near the stems in extent according to the size of the ball to be removed, and after this has been filled with water a few times the soil will be found well moistened to a good depth below. Never drag a tree or shrub out of its position. A good trench ought always to be opened out with forks around it, and the tree well undermined, nor should a very large ball of soil about the roots be aimed at, these very frequently breaking away in large pieces. Pick away with a fork all unoccupied surface soil, and flatten the ball underneath while it yet rests on a small pedestal of subsoil. It can then be safely slipped on to a strong board or barrow, and carried to a fresh site, and which ought previously to have been well and deeply dug. Mix leaf soil or spent manure with the surface soil, and plant rather above the level.—W. I.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### HOME.

AFTER two months' absence I am home again, but how glad would I be could I say that Leadhills was my home. It is truly a country for bees during June, July, August, and September, and what a resort for health and pleasure amongst the hills and dales. The welcome home was agreeable; heaps of literature and letters awaited me, and from some of my correspondence I must beg a little indulgence.

After being shut up for forty-five hours the bees reached home safely. A partial covering to keep off the rain for a few days until the manipulations are past will be given, and a thorough covering will be supplied later on. To prevent robbing our strong stocks have not more than 1 inch of doorway, no ventilation.

#### WEIGHING THE STOCKS.

I have not had time yet to weigh all my stocks, of which with one exception, a nucleus, all are good, and have during the month of September risen in weight about 50 lbs. This will give a small surplus from each hive, but the exact quantity will not be known until further on. I have, however, selected two, my best Carniolian and the second best Punic, and I am pleased to say that the greatest weight has been gathered by the Punic. They are my two heaviest hives, the second best one scoring 9 lbs. more than my best Carniolian. The other I have not weighed yet. The nett weights of the two contents of these hives are 70 lbs. "A Hallamshire Bee-keeper," in a private letter, states, "That unlike other breeds the pure Punic bees are the best honey gatherers." Can he help us to secure the number of queens that may be wanted? The test they have been put to is a fair one, and will be remembered. The Punic were mere nuclei in the spring of the present year, so that although first at the last were really last at the first.

The temper of these bees appears to be very mild, and although I have not as yet seen nor tasted their honey, I will not be long until I do, as I have it for the taking. They were the first, if not the only ones, that secreted wax for comb building in the super, which the untoward season alone prevented. I have other remarks to make, which must be held over till a future occasion.

#### VENTILATION.

It is well known that since I made public my method of ventilation, both British and Continental bee-keepers have taken the hint, but some of them, recommending a method most injurious to bees, by advising a very wide doorway, which creates a severe draught, and brings on dysentery on the bees, the cause being attributed to honey. When hives are ventilated in any manner so as to expose the contents of the hive to the direct action of the air, the honey is liable to ferment, and the odour at all times attract robber bees. This, together with a wide doorway, causes the bees inside to cluster closely, and the robber bees have an easy task to enter without opposition, and despoil the hive of its valuable contents. A narrow entrance, with an insensible under and upward ventilation, is how to winter bees successfully. I often give my

TRANSPLANTING EVERGREENS.—Conifers and various evergreen shrubs can be moved safely at this time of the year, and for several reasons we prefer to do as much as possible of the work of transplanting now, forming new shrubberies and re-arranging the old ones. At this time of year it often happens more men can well be spared from other work than is the case in the spring, and, moreover, the state of the ground favours the operations. When a tree or shrub is carefully transplanted thus early in the autumn they have time to partially recover from the check, and very frequently form fresh root fibre before cold weather stops all active growth. If placed in a good position, and always, if possible, in rather better soil than they were previously rooting in, they rarely experience a great check, and form good growth the following season. We find that not enough rain has fallen to well moisten the soil near the stems of the trees, and much

bees the benefit of the draughty ventilation from below during very warm weather, but I immediately close it on the first approach of a lower temperature, and very often every evening.

At two miles distance from where my bees stood at the moors are fifty hives which have had their ventilators open all the time, with the result that there is not a single hive with sufficient bees to stand the winter and come well out in the spring. Nearly every hive has a bin of dead bees in front, equal to an ordinary swarm. The particles of wax, and the odour of the hives, passes through and attracts stranger bees, which keep up a constant raid on the inmates and contents of the hive. These hives have done little good, and will require two or three to be united to be of any value. My own hives are a contrast, not one but I could form two colonies from. I trust that the hint will deter others from falling into a similar error.

#### QUEENS' CAGES.

I have observed "A Hallamshire Bee-keeper's" remarks (pages 169-70), but I am not sure whether I understand their meaning. I remember some time since seeing in a contemporary a statement to the effect that Mr. Benton was the originator of these cages, and in another I observed an editor also claiming them. As I had sent queens many years previous to Benton's time in similar cages I simply mentioned the fact. The centrebit was not invented to make queens' cages, but is useful in many ways.

I have before me a standard work on bees of American production containing a vast amount of matter as original that appeared first in the pages of this Journal, and British publications are not free from the same practice, which does not injure much, but is unfair.

The article at page 260 is no doubt meant as a burlesque, and to be amusing, but it entirely loses its humour when other than facts are stated. Few will agree with him that the bee is either "fussy or disagreeable," neither is it an "impostor," nor does it assume to "teach," nor can they be taught, nor will they enter flowers "six times over." We do not expect people to work themselves to death, although bees to a certain extent do so, but many of their actions are worthy of emulation. We have never known bees poison themselves, though some insects destroy them when at work on certain plants. It would be better for us all if our laws were as stringent as the bees are in defence of their property. Bees will find out their hive, weather permitting, although it be moved many yards. Do not many of us store up more than is necessary for our wants? A bee's life is full of pleasures, even when robbed of their last drop of honey they seem full of happiness. Drones are not at a discount so long as they appear to be useful.

#### BEEs AND POPPIES.

Will you kindly say in your next week's Journal whether Poppies grown near bee hives will have any injurious effect on the bees, or if there is any honey in the Poppy which the bees can extract and poison themselves? A solution of this question will be gratefully received.—G. H.

Poppies have only one injurious effect upon bees when growing near their hives. If right in front of them they seem to annoy them, and the bees attack the scarlet flowers, tearing the petals. Syrians are the most determined in this respect. Poppies afford much pollen in the morning before Mignonette, and are specially useful for the bringing forward of nuclei; but they do not yield much if any honey, but certainly they are not injurious to bees.

I prefer a good strain of French Poppies for variety and bees. I have grown for the past forty years a white Poppy, tipped scarlet on the outer edges of their petals, which always came true until this year. They have shown a decided departure from the true type to that of the French, or nearly so, with one exception. The flower is preserved as in the original, but the foliage is that of the common Poppy, and lacks the bristles of the original. I have a pretty cross between it and another sort which comes true, being higher in the colour than the mother; but none suits the bees so well as the French type.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

A. M. C. Jongkindt, Coninck Dedemsvaart, near Zwolle, Netherlands.—*Trade List of Plants.*

G. G. Rumsey, Wrotham, Kent.—*Catalogue of Roses.*

E. Webb & Son, Wordsley, Stourbridge.—*Catalogue of Seed Corn, 1890-91.*

Hooper & Co., Maida Vale.—*Bulb Catalogue, 1890.*

Daniels Bros., Norwich.—*Dutch Flower Roots (illustrated), 1890.*

Yokohama Gardeners' Association, Nakomura, Yokohama, Japan.—*Japanese Trees, Shrubs, and Plants.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Colonial Appointments** (*Inquirer*).—We should advise you to write to the Curator of the Royal Gardens, Kew, stating your objects, and it would probably be desirable for you to spend a short time in the establishment named.

**Transplanting Peach Trees** (*F. S.*).—The trees will move quite safely if care is taken to lift them without damage, preserving all the roots practicable, and if possible keeping a ball. That, however, is not very important only the fibres are preserved, and there is no delay in planting after lifting. The transference is best made when the leaves have for the most part fallen. Cut away any long bare roots, and pare the ends smooth that are damaged in taking up the trees. Make the soil firm about the roots and give a good watering, mulching the surface as far as the roots extend with a little rather fresh manure. With protection for the blossom there is no reason why the trees should not succeed admirably against a south wall.

**Lord Palmerston Peach** (*J. F.*).—The fine fruit you sent was not in condition when it arrived for testing the quality of the variety. It was overripe, and also much bruised. We have tasted fruits of this variety that were very good indeed, and others the reverse. It seems variable, and is more affected by soil and other influences than are some other varieties. It appears to succeed well with you, and we are glad to learn gives satisfaction. You can obtain all requisite particulars on sending specimens to the Fruit Committee of the Royal Horticultural Society by writing to Mr. A. F. Barron, R.H.S. Gardens, Chiswick, London, W. We think the next meeting is on the 14th inst. If the Peach buds are swelling, the ties may be "eased" now.

**Thickening a Grass Lawn** (*J. W.*).—Give a good dressing of well decayed manure or rich compost in autumn, disposing it evenly, and in spring rake off the rough portions, sowing early in April grass seeds of the finest mixture at the rate of half a pound per square rod, or more if the grass be thin. Rake over lightly, and roll well. This will cause the grass to thicken. Lose, therefore, no opportunity of rolling it well in moist weather. If you have some short manure or compost at hand it may be applied now, raking it well in, and then sow the grass seeds, rolling well afterwards. The present grass will shelter the tender seedlings, and they will fill up better than if the sowing were deferred until spring.

**Tomatoes Diseased** (*Old Subscriber*).—We have neither received the samples nor the letter to which you allude as having sent some time since. The fruit now before us is affected with the disease *Peronospora infestans*. It is most difficult to eradicate, but can either be prevented or the attack minimised when the plants are grown in glass structures heated artificially. A dry buoyant atmosphere can then be maintained and the air impregnated with sulphur fumes from the hot-water pipes. The disease occurs when there is an excess of moisture in the soil and atmosphere, and the opposite conditions are what you must endeavour to produce. Keep the soil so dry that the leaves turn flaccid before giving water, and the atmosphere of the house as dry as you can make it by heating the pipes (if your house is heated) and judicious ventilation. You give no particulars of the treatment to which the plants have been subjected, or we might possibly have indicated more definitely the cause of the attack.

**Shortening Growths of Black Hamburgh Vine** (*F. I.*).—It is a capital plan to cut back the laterals after the Grapes are cut, or when growth ceases, so as to develop the buds, and by admitting more

might assist the wood to mature. The old rods should be cut away close to and even with the main rods. There will not be any bleeding, and the earlier it is done the less likelihood is there of its taking place when the Vine starts into growth next year. You are quite right as to the cropping of Vines and other fruit trees not being overdone when fresh growth issues from stopping, laterals and sub-laterals being produced concurrently with the fruit swelling and perfecting. The wood being ripe, air may be admitted constantly day and night, but it is not desirable to do this until the wood is thoroughly brown and hard. An occasional syringing will benefit the foliage by cleansing it of dust, but it will hardly be necessary at this time of year. Dryness is most desirable.

**Verbena Cuttings Damping** (*Inquirer*).—The coloured fungus is one of the moulds assumed by fungologists to be only an early stage of fungi, more complex in structure when matured, and have the power of producing spores that when lying in fluid which contains sufficient food, cause a ferment. This they may obtain in the soil used for inserting the cuttings, which, containing leaf soil, may afford a fermentable substance; but the fungus exists on plants the leaves of which remain damp. The germs exist in the soil, and then it is not possible to prevent their growth in damp places when they find a suitable host. We can only suggest that the cuttings be inserted in pure sand (drift, *i.e.*, road sand, river, or sea sand), using no soil whatever in striking them, but keeping the sand thoroughly moist. The sand used hitherto probably contains carthy matter, but it is not unlikely the fungoid germs are on the cuttings when inserted, and then germinate through the damp being regular and prolonged. Have you tried a fresh stock? It often proves satisfactory both in growth and freedom from disease.

**Forming Privet Hedge** (*J. W.*).—Dig or trench the ground fully a yard wide, mixing with the soil some well-decayed manure. Plant in November bushy specimens of the evergreen variety with good roots 6 inches apart. Cut it down in spring to within 6 inches of the ground when the buds begin swelling, trimming in the sides. This will cause the plants to branch freely and become dense at the base. Trim the sides a little in August; in fact, cut them back so as to form a base of not more than 9 to 12 inches width, slightly tapering upwards, and in September cut off the top, the mere tops only, so as to form an even height. This will be determined by the lowest parts, which will probably be 18 to 24 inches high. The following year the hedge will advance rapidly, and may be treated as in the previous year, when a hedge will be had about a yard high, but it is well not to let it grow too tall without heading, otherwise it will be weak. About a foot height is sufficient to gain in each year after the first up to a height of 3 feet, and then 6 inches gain each year until it is of the height required. A hedge may be had quicker by planting 2 to 3 feet bushy plants, merely trimming in their irregular side and top growths.

**Apples for Planting** (*Balbriggan*).—If you can not only remove a foot in depth of the clay, but lay a drain along the bottom of the trench, which may be 4 feet wide (with outlet into a deeper drain), and over this place 6 inches of rubble or broken stones, to be covered with turf before filling in with good soil, you will have an excellent station for Apples; but if you cannot provide the drainage as suggested, merely digging out the clay would be practically making a tank for the water to collect in, and rather than do that it would be better to let the clay alone, plant in ameliorated soil, the trees to stand on slight mounds with the roots covered about 4 inches deep, and the soil over them mulched with rather open manure, not a wet pasty mass. A mulching of this kind will be quite as useful in summer as in winter, as if the good soil near the surface is kept moist the roots will ramify in it, but if it gets dry in the summer they will strike down to the clay in search of moisture. We have excellent Apples grown in the manner described in soil over a bed of clay. You say you have room for "eleven trees, and require half to be dessert and half culinary." We will try to oblige you with 5½ each, or an equivalent. For your exposed but not cold position the following may be suitable:—Dessert: Devonshire Quarrenden, Worcester Pearmain, King of the Pippins (Golden Winter Pearmain), Cox's Orange Pippin, and Wyken Pippin. Culinary: Lord Grosvenor, Keswick Codlin, Ecklinville, Warner's King, and Bramley's Seedling. To make up the required number plant Duchess of Oldenburg, and use the fruit either for dessert or culinary purposes as you prefer.

**Manuring Flower Borders** (*J. W.*).—They are best manured in autumn, as the manurial matter is assimilated and absorbed by the soil ready for being taken up by the roots when fresh growth takes place, whereby a good growth is assured and the plants flower more profusely. Nightsoil and soot are powerful manures, and should not be used excessively. Soot is more speedy in its action, and should not be supplied until it is required by the plants, applying it to flower borders in spring during moist weather when the plants are commencing growth. It is good against predatory vermin or slugs, &c., and may be given at the rate of a peck per rod (30¼ square yards), distributing it evenly on the surface, and unless thrown on the plants in excessive quantity will not injure them. It should, however, be kept from those with hairy leaves. During March or early April is a good time to apply soot, repeating in June, or it may be given during summer in liquid form to any plants requiring stimulation, a tablespoonful to a gallon of water is sufficient. Being rather difficult to mix it should be formed into a paste with sufficient water, and then it mixes readily with water. Nightsoil mixed with dry fine ashes or dry soil may be applied at the rate of a bushel per rod for general dressings, the ashes or soil used not being more than an equal quantity of the night soil; but when the

soil is poor it may be applied at double the rate named, and should be pointed in. This should be done in autumn or some time in advance of growth in the plants. It will be rendered very powerful by adding urine to form a paste and dry wood ashes to form it into a dry powder. This kept in a dry place is little inferior to guano, and can be applied to any crop with material benefit. A good handful per square yard is a sufficient dressing to apply at once, and before cropping or a little in advance of the plants requiring assistance in accelerating their growth or enlarging their parts.

**Indian Figs—Cochineal** (*T. G.*).—You are quite right in saying the fruit of *Opuntia vulgaris* is so called, but it is not that species that supports the cochineal insect. *O. vulgaris* has been naturalised in the south of Europe, where, in Sicily, it has spread over expanses of volcanic sands and ashes where not a particle of vegetable soil exists. The fruit is about the size of a Fig, and red on the inside. It is very much relished by some, but varies in quality according to the climate in which it is produced. The Sicilians grow it extensively, and esteem it one of their most valuable esculents. It forms an important article of diet with the inhabitants of that island during three months of the year, though strangers generally consider it insipid. In the countries where it grows the Prickly Pear is, on account of its rapid growth, much used for the formation of fences round lands and dwellings; and the quickness with which it grows, and its long stout spines, speedily render it such a formidable enclosure that neither man nor beast can penetrate it. *O. Tuna* also makes strong fences, and when the island of St. Christopher was divided between the English and the French three rows of the Tuna were planted by common consent between the boundaries. Sir J. E. Smith states that the long and slender stamens of the flower are very irritable, and that if a quill or feather is thrust through them, in the space of two or three seconds they begin to lie down gently on one side, and in a short time become recumbent at the bottom of the flower. The fruit yields a rich carmine pigment, which is used at Naples as a water-colour. *O. cochinchinensis*, or Nopal, is the plant on which the cochineal insect feeds and breeds. It is in Mexico where the production of cochineal is carried on to the greatest extent, but it is also produced in the Canary Isles and in Java. The insect is the *Coccus cacti*. A number of the females are preserved during the rainy season. After the rains have ceased they are distributed over the plants, and having deposited their eggs speedily die. The eggs are hatched by the heat of the sun, and give rise to innumerable insects, the males of which are only in the proportion of one to a hundred or two hundred females, and being provided with wings they move about and fecundate the latter. After this period the females which before moved about attach themselves to the plant, and increase rapidly in size, so that in the end their legs, antennæ, and proboscis are scarcely discernible, and they appear more like excrescences on the plant than distinct animated beings. They are now gathered by scraping them off by means of a blunt knife, or brushing them off with a quill, a feather, a squirrel's or deer's tail, a few being left to continue the race. They are destroyed by dipping them in hot water, or by the heat of a stove. In the former case they are afterwards dried in the sun.

**Maggot in Wood** (*E. G. G.*).—The caterpillar in the wood is the larva of the goat moth (*Cossus ligniperda*). As is stated in Miss Ormerod's "Manual of Injurious Insects," the moth lays her eggs in crevices in the bark commonly at the lowest part of the tree, and the caterpillars which hatch from these eggs feed at first in the bark, or between the bark and the wood; as they grow stronger they eat their way into the wood, and form chambers and galleries of various size and width, some as large as a man's finger. The caterpillar has the power of exuding an oily fluid from its mouth with a remarkably pungent goat-like smell, whence the name of the moth. Infested trees may often be known by this disagreeable smell, and sometimes by heaps of dirt or wood-dust thrown out by the caterpillars lying below the entrance of their burrows. During the winter they lie quiet, otherwise they feed for a period of three years, and when ready to change form cocoons of little bits of wood roughly spun together just inside the entrance of their burrows, in which they turn to a reddish-brown chrysalis. Shortly before the moth is ready to emerge the chrysalis forces itself partly through the cocoon, where the empty case remains sticking out from the tree, and is a useful guide as to infested timber. The moths are heavy and sluggish, and may be taken easily by hand as they rest quietly during the day on the bark of the tree out of which they hatched. The caterpillars sometimes leave the trees, and may be found straying about in May and in the autumn, and in such case they should always be destroyed; but generally (as above mentioned) they change to chrysalids at the entrance of their burrows, and where trees are known to be infested these reddish chrysalids should be looked for during June or early in July. Any mixture that can be laid on the tree, so as to prevent the moth laying her eggs on the bark is useful, and a thick coating of clay and cowdung has been found to answer well. The caterpillars may be diminished in number by crushing them in their holes with thick strong wire; a glance at the state of the end of the wire when it is withdrawn from the hole will show whether the caterpillar has been reached or not. If the direction of the hole admits of the caterpillar being dragged out by a finer wire doubled at the end, so as to form a kind of hook, this plan is also serviceable. Paraffin injected by a sharp-nozzled syringe with as much force as possible into the holes where the caterpillars are working is a good remedy, and any fluid poisonous to the caterpillar, or which would make the wood of its hole poisonous or distasteful to it for food, would be serviceable, such as tobacco water or a solution of softsoap. The fumes of sulphur blown into the hole are also effective.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores.

COVENT GARDEN MARKET.—OCTOBER 1ST.

MARKET quiet, with no alteration.

FRUIT.

Table listing fruit prices: Apples, Lemons, Melons, Oranges, Peaches, Plums, St. Michael Pines, Strawberries.

VEGETABLES.

Table listing vegetable prices: Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Cabbage, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Potatoes, Rhubarb, Salsafy, Scorzonera, Seakale, Shallots, Spinach, Tomatoes, Turnips.

CUT FLOWERS.

Table listing cut flower prices: Arum Lilies, Asters, Bouvardias, Carnations, Calceolaria, Chrysanthemum, Cornflower, Dahlias, Eschscholtzia, Eucharis, Forget-me-not, Gardenias, Gladiolus, Gypsophila, Iris, Lapageria, Lavender, Lilium, Marguerites, Maidenhair Fern, Mignonette, Pansies, Pelargoniums, Pinks, Primula, Roses, Moss, Red, Tea, White, Yellow, Stocks, Sweet Peas, Tuberoses.

PLANTS IN POTS.

Table listing potted plant prices: Aralia Sieboldi, Arbor Vitae, Asters, Calceolaria, Chrysanthemum, Climbing Plants, Dracena terminalis, Erica, Euonymus, Evergreens, Ferns, Ficus elastica, Foliage plants, Fuchsia, Geraniums, Geraniums Scarlet, Heliotrope, Hydrangea, Lilium lancifolium, Lily of the Valley, Lobelia, Marguerite Daisy, Mignonette, Musk, Myrtles, Nasturtiums, Palms, Pelargoniums, Rhodanthe, Stocks, Tropaeolums.

MICHAELMAS THOUGHTS.

"FARMS are still to be had worth the money," were the words with which a leading East Anglian farmer recently wound up his report of the condition of agriculture in his district.

Corn growing even in the eastern counties is gradually being contracted, while there is a proportionate extension of the area of land under crops for live stock. Flocks increase faster than herds there, for the simple reason that wet or breeding flocks have long been established on corn farms, and their enlargement under present high prices was a foregone conclusion—a simple case of cause and effect.

In this, as in everything else, one sees the wisdom of not trusting entirely to one crop. The men who have passed best through the agricultural depression are precisely those who have kept steadily to a system of well-balanced cropping, with such enlargements or curtailments of certain crops as could be managed easily and quickly.

Well, the loss of income is serious both east and west; but the western landlords have still the best of it.

A radical change, which must do good, is the rearing of home bred cattle by farmers generally. Cattle dealers have shot their rubbish into British markets quite long enough to open the eyes of the most easy-going farmer. The Board of Agriculture is doing its utmost to stamp out infectious disease among cattle, and to prevent its re-introduction by foreign cattle. Let us do our part by the avoidance of imported cattle, and the rearing more and more really well-bred stock. Is it not the action of a fool to go and purchase store beasts upon which one is morally certain no profit is possible? Yet this has been done again and again, and what is even still more strange, the simpletons discuss results as though they deserved the sympathy of their friends.

There are farms to be let this Michaelmas, as there always will be, but there is nothing like a glut of farms in the market or on offer in any market. Wide circulation has been given to a report of the increasing number of vacant farms in Sussex and Kent, but the statement was erroneous and misleading. Hop farms are on offer, and with Hops at from £15 to £20 per cwt. they ought not to go begging. The statement that two East Kent growers in partnership expect to realise between £60,000 and £70,000 for their Hops of this season, and another puts his profits at £12,000, is certainly tempting, but pray do not forget the lessons of the past few years, and avoid putting all your eggs into one basket.

#### WORK ON THE HOME FARM.

Most favourable has the weather been for autumn cultivation, and we never had the land in better order by the end of September. There has been some rain, but not enough to hinder work at all, and the clearing and sowing has gone on without a hitch. The last field we put a plough into had a lot of Charlock in bloom, but there were no other weeds, and this last turn of the ploughs has left it quite ready for sowing. The new layers are all remarkably full of growth, the Clovers being nearly a foot in height, so freely have they grown since the corn was carted. This abundance of food has induced us to break up a field of Sainfoin which was becoming very foul, but which had we wanted it would have given us some useful fodder next year. There was a lot of Dock plants in it which were got up by hand before the ploughing was done, and we shall have very little trouble with the other weeds. We must have clean land at any price, and prefer a little extra outlay for labour than the serious exhaustion of the soil by weeds. This Sainfoin had been eaten off by sheep in folds, so the land is in good heart, and will come to hand quickly for other crops.

Root crops have improved wonderfully all through September, and we shall soon have the Mangolds in clamp now, each clamp being close by a hard road to facilitate carting when the roots are required for use. As we are so forward with our work generally, and carting is so light now, enough Mangold will be carted and clamped near the yards in readiness for use early in the new year. Carrots are taken at once to the root house, as we shall begin using them for dairy cows as soon as they come off the grass into the yards. We have also an ample supply of fine Cabbages quite ready for use, and they are an excellent addition to our cow dietary in moderation a little later on. Green Maize is now being used freely for all yard stock, but there has been no carting of it upon pasture for store cattle this autumn, so abundant has been the feed. We do not like to venture far into October before using up this most useful auxiliary green crop, as we have so often had it browned by early frosts. Cattle will go on eating it even then, but it cannot be so good for them. Anyone having an empty silo may turn any large surplus of green Maize to account by passing it through the chaff cutter and storing it in the silo for winter or spring use.

#### FISH-KEEPING.

A POND without fish is like a garden without flowers. Any piece of water, no matter how it is situated, is rendered desolate in aspect when it is barren of finny forms. It is choked with vegetable and minute animal life, but offers a rich feeding ground for the fish it lacks. But this state of things may be easily remedied by the exercise of a little trouble and the expenditure of a comparatively small sum, for at short notice fish can be imported and deposited in the pond. Its size and physical conditions must decide the question as to the number and species of fish desirable for introduction, and having satisfied oneself on the subject the fish chosen can be obtained of a pisciculturist and planted at any time without difficulty. Sometimes the conditions of the pond are so far satisfactory that trout can be introduced, and provided sporting strains are selected, the owner may depend upon obtaining a certain amount of fishing, sufficient, perhaps, to enable him to practise in

his spare moments. Thus, from the insignificant position which the pond previously occupied it rises to a high degree of importance and value, while it becomes an ornamental adjunct to the garden or grounds in which it is situated. It would be thought that all owners of ponds or waters were desirous of stocking them with fish, and yet I know many to whom the idea has never occurred, or if so, it has not been entertained because of doubts as to carrying it out successfully. No such doubts need exist in the face of the fact that any waters, no matter what may be their physical characteristics, provided they are not polluted, can be stocked through the art of fish culture with one species of fish or another. It is needful, however, that advice be gained previous to planting the fish in order to ascertain the species best suited to the water, and the nature of the food contained in it.

Being desirous of gaining some practical information on the subject of stocking ponds, I journeyed to Malvern Wells to seek an interview with Mr. Burgess at the Midland Counties Fish Culture Establishment, the well known fish breeding station. Here I saw the fish at home in their various habitats, and noted the wonderful rate of growth which they achieved therein through an excellent and perfect system of propagation. On one hand were the buildings wherein the eggs of the fishes were hatched, and on the other the nurseries where they were reared. But I came not with the intention of diving deeply into the process of hatching and nursing the fish, as that would have taken too long, while after all I should not, probably, have comprehended all the phases of the art so ably carried out and explained by Mr. Burgess, but I desired more particularly to ascertain the method by which ponds were stocked and planted. It so happened that whilst I was there a consignment of live trout was being got ready for despatch to Cornwall, and I therefore had an opportunity of witnessing the operations connected with it. In the first place the fish were taken from a pond and carefully sorted and counted, each fish being examined previous to selection. They were then deposited in carriers made by Mr. Burgess, and having been placed on carts were driven rapidly away to the railway station and placed in the train.

The time and trouble expended in the operation are considerable, and, as great care has to be exercised throughout, it becomes a laborious process. But when that is over and the fish entrained no further trouble is experienced, and on arrival at their destination the carriers have only to be taken to their destination and emptied. I had an opportunity of inspecting a large number of ponds, and noting how the fish lived therein, thus enabling me to see for myself how readily Salmonidæ become naturalised to enclosed waters or ponds, and how great is their capacity for thriving therein. Of course the needful conditions under which that desideratum can alone be acquired must be present, the two most important being ample food and running water. Both these conditions can often be acquired if non-existent by artificial means, and if not there is the alternative of planting some of the coarser fishes which are adapted to still waters. I obtained some valuable hints coupled with practical demonstrations which gave me a deep insight into the whole process of fish-keeping. The establishment is the largest in England, and by reason of the natural adaptability of the site the fish are supplied with an abundance of pure water thickly charged with all kinds of food of such a character as is most conducive to physical development.—W. A. C.

#### REMARKS.

21st.—Bright morning; generally cloudy in afternoon; showers in evening.  
22nd.—Bright and fresh till 10 A.M., then frequently cloudy, and slight shower at 11.30 A.M.  
23rd.—Cloudy, with occasional sun in morning, slight shower at midday, then fine; some sunshine and thunderstorm from 4.30 to 6 P.M.  
24th.—Brilliant till 11 A.M., then overcast; distant thunder in afternoon.  
25th.—Fine, with much bright sunshine.  
26th.—Overcast all day; bright night, with lunar halo.  
27th.—Overcast till 11, then fine and bright.  
Another fine and warm week. The thunderstorm on the 23rd was not severe here though it is reported to have been so in the west of London.—G. J. SIMONS,

**A**FTER the remarkable display of Apples and Pears this week in the historical building indicated it will be impossible for anyone to sustain the allegation that British fruit of the first size, colour, and quality cannot be grown in British soil. In no fruiterer's shop in London, where the best obtainable specimens are procured from various parts of the world, could such Apples be found as those represented in hundreds of dishes at the Exhibition in question. No doubt a few of the most striking specimens, such as Mr. Samuel Barlow's magnificent Peasgood's Nonesuch (the finest ever seen at a show), were grown with the aid of glass, but leaving them entirely out of comparison there was more than enough of genuine outdoor-grown fruit to prove to demonstration that the resources of this kingdom are equal to the production of hardy fruits of the highest order of excellence, and with which the most exacting critics could find no fault.

Only a very few years ago such an exhibition as the one under notice could not have been provided either in the London Guildhall or anywhere else in this country, and it is clear that earlier efforts in improving the supply of home-grown fruit are beginning to tell. It is most gratifying to observe the advance that has been made, and we look forward hopefully to its extension over every part of the kingdom in which the requisite concrete conditions exist for the profitable culture of useful fruits. The improvement already effected, though distinctly marked, is mainly limited to gardens, nurseries, and fruit farms managed by skilled cultivators. This is only what might be expected under the circumstances, and is satisfactory as proving what can be done by good management.

We trace the better production of Apples to the Congress held in the Royal Horticultural Society's Gardens at Chiswick in 1883. As the immediate result of that event, large numbers of trees of well chosen varieties were planted; but only professional men, with trifling exceptions, either visited the great national display of Apples on that occasion, or benefited by the information given in the report, and through the gardening press. We are convinced that the Royal Horticultural Society never did more good than by its fruit congresses and conferences, and the Society must be acknowledged as the pioneer in the improvement of fruit culture in the United Kingdom. But its influence could not, for obvious reasons, directly reach a large section of the community who might grow fruit with advantage to their families, instead of either going without or buying the produce of other lands, for it is an astounding fact that the inhabitants of many country towns and villages have during recent years been practically supplied with imported Apples. We have done all that was in our power to disseminate the good work of the Society, and shall hope to do more, and we shall similarly render what aid we can to other agencies that well and worthily engage in a movement that is calculated to be of benefit to individuals and the nation at large.

When Sir James Whitehead was Lord Mayor of London last year he made fruit culture a theme of many eloquent discourses. He was the first Lord Mayor who gave the weight of his high authority to the subject; the first also, we believe, who imposed the condition that the presentation of fruit in accordance with ancient custom from the Fruiterers' Company at the Mansion House should consist entirely of home-grown produce, and a splendid contribution it was. With the object of continuing his efforts

as effectively as possible in the cause of hardy fruit culture in the homesteads of the United Kingdom, he joined the Livery of the Fruiterers' Company, and was elected to the position of Master the first year. He then took up the idea that had been considered by Mr. H. R. Williams and friends of having a great show of home-grown fruit in the City, a project that was well received by the civic authorities. He believed that by showing the wealthy citizens what could be done in the growth of fruit he would enlist their sympathy, and so gain an accession of strength and influence to the Guild, which is not like some other City companies—rich. Taking as his basis of action the promotion of hardy fruit culture in the cottage gardens and homesteads, he obtained the patronage of Her Majesty, and other distinguished persons. He also sought the co-operation of practical men, and the outcome of their efforts was a show that may fairly be described as extraordinary. Not only was the noble building filled with fruit, but the art galleries were crowded, and the old city council chamber with corridors had to be requisitioned. Upwards of 7000 square superficial feet of tabling were occupied, and 4500 plates used. The display exceeded the most sanguine expectations, and the throng of visitors will not soon be forgotten by those who were in the crowd. Every portion of the space was packed, and hundreds could not gain admittance when the Lord Mayor in state opened the Show on Monday afternoon. All day on Tuesday the Show was similarly thronged, and so it continued to be till the hour of closing on Wednesday evening.

Generally speaking the fruit was of high excellence, and in some of the classes the competition was very severe. In the class in which the gold, silver-gilt, and silver medals were offered 600 dishes were staged. Mr. Barlow had the champion dish, his five Apples of Peasgood's Nonesuch weighing 8 lbs. 14 ozs., yet he failed to win one of the medals, but was awarded an extra prize. This will indicate the superior character of the exhibits. In the south-eastern zone alone there were twenty-six entries of twelve dishes of dessert Apples, thirty-four of twelve cooking Apples, and forty-four of three dishes of dessert and three of culinary. There were nineteen collections of fruit from nurserymen, which made an imposing display, and a remarkably good and very interesting collection from the Royal Horticultural Society. We publish the prize list as supplied to us officially, and such notes of the fruit as could be obtained under circumstances of difficulty.

The weakest part of the Show was in the cottagers' and tenant farmers' classes, and this proves the necessity for the effort being made in their interests. They, however, staged between 300 and 400 dishes, and some most creditable samples of Apples and Pears. The Show is calculated to do a great amount of good in the direction intended, and it was most pleasant to see the countenance given to it by the Royal Horticultural Society, the respected Secretary of the Society and Superintendent of Chiswick being both exhibitors and Judges. This is the best answer to the somewhat undignified and absolutely groundless suggestions that the undertaking was in some way antagonistic to the Society. The Royal Horticultural Society is doing as much as it can do, and both it and the Fruiterers' Company will each, in their way, and in mutual friendliness, do a great deal for fruit culture in gardens large and small over the length and breadth of the land.

We give on page 315 an illustration, speedily prepared, of the Guildhall Fruit Show, also a portrait of Sir James Whitehead, Bart., the Chairman of the Executive Committee, this latter being supplied to us with the compliments of Mr. H. Cannell, as prepared by him on the occasion of a visit of Sir James to the nursery at Swanley.

The present is, we believe, the third occasion on which the Guildhall has been occupied by horticulturists, the first being by a flower show, which led to the establishment of the United Horticultural Benefit and Provident Society in 1866; and the second, by a banquet in connection with the International Horticultural Show also in 1866. The City authorities and various Guildhall officials gave

ready and valuable aid in the preparations, and thus largely contributed to the success of the Show to which these notes refer. Mr. G. W. Cummins and assistants worked willingly and well in staging the fruit, and the judging was completed by the appointed time.

## FLOWER CULTURE FOR PROFIT.

### RICHARDIAS.

At present there are no signs of any abatement in the demand for this popular plant, nor is there likely to be while church decoration is practised on the same elaborate and expensive style as during the past decade, and memorial wreaths and crosses are so much in request. Richardias would really appear to be indispensable for these purposes, nor is this to be wondered at, seeing how serviceable it is. Those who are favoured with numerous orders for wreaths and crosses must find the spathes most profitable, and even those who market or sell at wholesale rates have not much cause to complain. At the festivals of Christmas and Easter the best prices are obtained, ours not unfrequently being sold locally at the rate of 9s. per dozen, and for rather less sums, or from 6s. to 8s. when sent to large towns. At other times, unless wanted for a special purpose, the price per dozen is about 4s. clear. Seeing that numbers of plants can be grown in positions, perhaps, which would not be otherwise utilised, such as newly started vineries and Peach houses, as well as the stagings of greenhouses and the conservatory beds, they may be said to pay very well even if the lower figures only were reached.

The best methods of culture have been so often discussed that there is not much necessity for enlarging upon them afresh, though I cannot avoid touching upon the principal facts. I have tried preparing the plants in the pots in which they are to flower, and also by planting out and potting in due course, and I am of opinion that the latter plan is both simpler and better. We have numbers that were started early in 8-inch pots being intended to flower in December, and so doubtless they will, but those planted out have already commenced flowering, and are by far the most vigorous. At the same time I must protest against the assumed necessity for preparing Celery-like trenches for Richardias, in our case at any rate it is not required. It is not huge plants and great coarse spathes that are wanted, but rather a greater profusion of medium sized to small spathes, and the plants to produce the latter can be had with little trouble. Where many err is in too long delaying the planting out. There is no necessity to keep the plants in pots nearly or quite without water for several weeks in order to force them to rest, the better plan being to turn them out of the houses directly they have ceased flowering, and to take the first opportunity of pulling them to pieces, roughly trimming off the old leaves and planting out.

A lumpy soil is unfavourable, as the plants start feebly in it, and cannot be well lifted out of this, but a breadth of well-pulverised ground that would grow Carrots and other root crops well is equally suitable for Richardias. Plant the divisions 1 foot apart in rows 2 feet asunder, keep the ground clean, mulch with strawy litter or manure, and little further trouble need be taken unless the summer be exceptionally hot and dry, in which case a few good soakings of water will prove beneficial. All ought to be potted before a frost cripples them, 4° or 5° being enough to seriously injure them. This season the lifting was safely deferred till the end of September, but there have been seasons when they had to be lifted a fortnight earlier. There is no need for lifting a great ball of soil with the roots, but every care should be taken of the roots. Whether they are placed singly in 7-inch or rather larger pots, or three in 9-inch pots, or in still greater numbers in larger sizes, ought to depend upon circumstances, the smaller sizes being handy for house and church decoration, and convenient for small or light stages, but if the plants have to be set on the floors or beds of houses they seem to do best when from nine to twelve strong plants are placed in 15-inch or rather larger pots. The drainage ought to be good, and any fairly rich compost suits them well. They flag but little in full sunshine in spite of the rough treatment given them, a good soaking of water and a few syringings soon putting them right. All should be housed on the first symptoms of a frost.

A staly position under glass will not do for these plants, as the nearer the glass or the lighter the quarters they are kept in the sturdier and more floriferous they become. Therefore, give them good room, plenty of light and water whenever the soil is at all dry, though there is no necessity for or wisdom in standing the pots in saucers or pans of water. Liquid manure of some kind is needed frequently after the flowering period has commenced. They are comparative failures in cold houses, or those heated only when frosts are imminent, and high temperatures are equally objectionable. Under the former conditions spathes are sparingly

produced till warm spring weather is experienced, this being when they are frequently a glut in the market, while a forcing temperature causes a spindly growth and an attack of aphides. A little fire heat ought always to be provided, and air admitted freely whenever the weather is mild. I never look at the thermometer except during very frosty weather, but should say our houses, in which Richardias are principally grown, are, during the winter and early part of the spring, seldom above 55°, and not often lower than 45°, the night temperature on an average being nearer 50°. Green fly is frequently very troublesome, and once this pest is allowed to gain a good foothold it is very difficult to exterminate. Yet this must be done, or the spathes will be of little value. Fumigations with tobacco paper directly the aphides are seen, or better still in anticipation of their visits, will keep the plants clean.

The spathes keep better off the plants than they do left uncut, but it is a mistake to keep them long after they are fully grown, or many of them will have lost their freshness and value before they reach their destination. In anticipation of the extra demand and better prices at Christmas and Easter, the flowers with a good length of stem should be kept in jars of water placed in a cool dark room. The stems being cut over frequently the flowers will keep fairly fresh for about ten days. Their own foliage is required with them by decorators, an extra charge sometimes being made for these. We are content to give the leaves, and believe the spathes sell the more readily in consequence. All should be cut with long stems, and packed closely and flatly in long shallow boxes lined with clean moss, clean tissue paper being placed over them, and sufficient cotton wool on this to keep the flowers from shifting, the lids closing tightly on this.—M. H.

## ASPHALT WALKS.

As from time to time I have been asked by gardening friends who have called on me how we make the asphalt for our walks here I venture to hope that the plan I am about to describe may be of use to some of the readers of the Journal who are desirous of having a good hard walk at as little expense as possible.

Everyone will admit there is nothing to equal in appearance a well-made gravel walk, whether in the kitchen garden or elsewhere; but when that kitchen garden happens to be on a sharp slope they will also admit it is annoying to have to wheel all the gravel from the bottom of the garden to the top after every thunderstorm, so that the advantage of asphalt in a case like this is very apparent, as when once it is properly laid it requires very little expense to keep it in good condition.

There is, however, one drawback which perhaps it would be as well to state at once, and that is it is a work that requires to be done in the summer, when, as a rule, gardeners have little time to spare for extra work of this kind; yet when we come to consider the labour and expense of keeping ordinary walks clean the extra labour entailed is but trifling, and we have all the winter before us to collect materials and prepare the walks to be operated upon.

In preparing an old walk for asphaltting, if there is any doubt about the drains being in perfect order they should be examined, and if necessary taken up and relaid some time in winter, as then there will be plenty of time for the soil that has been moved above the pipes to become solid again, so that there may be no chance of it sinking after the walk is made. If edging tiles are used they should be looked to and placed down firmly, so as to have a straight and tidy appearance when the walk is finished. Materials may also be collected and everything prepared, so that there may be no delay when the fine weather arrives.

The ashes I have found to answer the best for mixing with the tar are those made from steam coal, such as comes from locomotive engines (they can be obtained from almost any railway company at a very cheap rate). These should be passed through a half-inch screen, the coarser particles answering well for placing in the bottom of the walk, or if there is sufficient ballast in the walk, say 4 inches, it will not be necessary to disturb it more than to take off sufficient of the surface to allow for about 2 inches of the tar to be placed on when the walk is being made.

The remainder of the work must be done in fine dry weather. The sifted ashes should be spread out thinly in a sunny spot, and turned over occasionally for the moisture to evaporate; also procure some lime, old mortar rubbish, or gas lime, very dry, and screened like the ashes, as if this is applied at all lumpy it will sometimes spoil the surface of the walk by raising the tar and breaking it.

When the materials are dry, add one barrowload of the lime (or lime rubbish, as the case may be) to two of the sifted ashes. Mix well, make a hole in the centre of the heap, and pour on sufficient tar cold, so that when mixed it will be of the consistency of mortar. Care must be taken that there is no water added to the heap with the tar, as this will spoil it.

All being in readiness for laying down the walk, sprinkle some

tar over the surface of the walk to be made, and lay on the mixture so that when pressed down it will be of an uniform thickness of about 2 inches. Draw it down smoothly as the work proceeds with the back of a wooden rake, scatter on a little dry road grit over the surface, sufficient to keep it from sticking, and pass a light roller over it.

The walk will be rendered more solid if, after the rolling, it is gently beaten down with wooden rammers, especially along the edges. If there are any walks running into the one that is being operated on, a piece of board 1 inch thick should be let into the ground across where the walks meet, to form an edging to keep the asphalt from being pressed out by the roller.

After a day or two the walk should be firm to the feet; then choose a fine day and pour some cold tar over the surface, brushing it gently with a broom, and allow it to soak in. This will fill up all spaces, and render the walk sound and durable.

If at any time the surface should show signs of wearing, a little tar poured over the surface before it is too bad, and brushed in, will soon improve it, and make it quite firm again. I have tried various experiments, both by boiling the tar and using it cold, also with different materials, but the above is the most simple and economical plan I have been able to discover, and answered here admirably. I could not perceive any advantage in boiling the tar; it is a very disagreeable business, and one I was very glad to find I was able to dispense with.—C. O. S.

ROSE ANALYSIS, 1886—1890.

THE Crystal Palace Exhibition of the National Rose Society proved this year in one respect the most satisfactory the Society has yet held. For, as recently pointed out in this Journal by "J. H. P.," on no previous occasion has such a large proportion of the blooms exhibited retained their freshness throughout the entire show day. But then this show day was no ordinary one, being, without exception, the coldest day of the past singularly cold summer. The preceding night was also cold and extremely wet, thus allowing the flowers to reach the Exhibition in most cases in the same condition as when cut from the plants on the previous evening. Those Roses which, owing to their want of substance or the fleeting nature of their tints, are generally difficult to stage in exhibition form, were consequently for once especially favoured. On the other hand, the weather proved too chilly and damp for most of the thin petaled varieties. Fortunately for our analysis the Rose season of 1890, although not nearly so forward as about midsummer day it promised to be, was nevertheless again an unusually early one, so that in the present analysis the later flowering Roses are better represented than has hitherto been the case.

From the short statement given below it will be seen that nearly ten thousand Roses have been altogether tabulated during these five years, all, be it remembered, Roses which have appeared in first, second, third, or fourth prize stands.

	HYBRID PERPETUALS.	TEAS AND NOISETTES.
1886 .....	1038	509
1887 .....	1130	642
1888 .....	1247	854
1889 .....	1176	778
1890 .....	1396	631
	5987	3414

Throughout the accompanying tables the established kinds find places according to the average number of times they were staged at all the five exhibitions. As, however, it would not be fair to the comparatively new Roses if they were placed on precisely the same footing as those which have been in general cultivation for a number of years, the following scale, which is similar to that employed in former years, has been adopted. The positions of varieties sent out in 1883 are dependent upon their averages for the last four shows, those of 1884 upon their averages for the last three shows, and those of 1885 on their averages for the last two shows only. In the case of the still newer sorts, their 1890 form has alone been taken into consideration.

The Hybrid Perpetuals which were shown in the greatest number of prize stands at the first four exhibitions were as follows:—In 1886 and 1887 Madame G. Luizet appeared in forty-seven and

thirty-eight stands respectively; in 1888 A. K. Williams and Madame G. Luizet each in thirty-six stands; and in 1889 Captain Christy in forty-two stands. Ulrich Brunner has, however, this year eclipsed all previous performances, having been shown in no fewer than fifty-seven prize stands. Other varieties which were much more frequently staged than at either of the four preceding Metropolitan Exhibitions were La France, Marie Baumann, François Michelin, Charles Lefebvre, Etienne Levet, Marie Verdier, Prince Arthur, and Heinrich Schultheis. Among well known sorts very indifferently represented may be mentioned such fine weather beauties as Captain Christy, Marie Rady, Duchesse de Vallombrosa, Monsieur Noman, and Reynolds Hole.

Madame Gabriel Luizet still continues to take the lead of all the Hybrid Perpetuals as an exhibition Rose, a position this variety has held throughout the whole five years. Nevertheless another light pink variety, Mrs. John Laing, sent out ten years afterwards, promises when more largely grown to become a serious rival, possessing as it does so many good qualities, not only as a flower but also as a plant. Her Majesty, first distributed in 1885, stood last year in the position now taken up by Mrs. J. Laing, but has this year, doubtless owing in some measure to the unfavourable character of the season, fallen to the ninth place on the list. 1886 is represented by Viscountess Folkestone, a large flower of an exquisitely delicate shade of pale salmon, but somewhat loose and rough in the petal. This is tabulated for the first time, and will be found at No. 44. Mrs. John Laing, the leading flower of 1887, has already been referred to. Earl Dufferin, sent out in the same year, has improved very little on its 1889 form, being now at No. 24 instead of No. 25. Lady Helen Stewart on its first appearance just manages to secure a footing at the bottom of the analysis, while Sir Rowland Hill (1888), another new comer which may be described as a rich plum coloured Charles Lefebvre, takes up its position at No. 53. Now there is a very remarkable circumstance which must be mentioned in connection with these six new Roses, and that is that we are not indebted to the continental growers for any of them, four having been raised in England and the remaining two varieties in Ireland.

Turning our attention to the table of Teas and Noisettes we find that the positions of the three leading flowers—Catherine Mermet, Innocente Pirola, and Comtesse de Nadaillac—remain altogether unchanged since last year. The effect of the cold, wet, and unless weather previous to the Show is, however, clearly traceable on many other varieties; for instance, Caroline Kuster, Jean Ducher, Etoile de Lyon, and Madame Angèle Jacquier have all lost more or less ground since the last analysis, whereas those flowers which are less susceptible to humid conditions of the atmosphere—such as Madame Lambard, Marie Van Houtte, Rubens, Souvenir d'un Ami, and Jules Finger—appeared in unusual force. Francisca Kruger was also well shown, but on the other hand there were but few Maréchal Niels or Edith Giffords.

Like 1888 this was another Lambard year, but we have to go back to the Jubilee year in order to find a show in which Maréchal Niel appeared in nearly every prize stand. During the last two seasons this, by far the finest of all the yellow Roses, has scarcely been seen at all, whereas in the first three analyses it stood only second to Catherine Mermet.

The following are the only three new Teas on the list:—The Bride, a lemon-white sport from Catherine Mermet, and the sole representative of 1885, has gone down one step since last year; the position now accorded to it is, however, still a very honourable one (No. 5). Madame Hoste (No. 25), introduced in 1887, finds a place in the table for the first time; the colour of this variety, a soft creamy yellow, is one much wanted, and no doubt in a warmer season it will be more freely exhibited. The only other new Tea is Souvenir de S. A. Prince, a white sport from Souvenir d'un Ami, which, although only sent out last year, already stands as high as the Rose last named.

I have in conclusion to thank those kind friends who this year assisted me in taking down the names of the Roses at the show.

For the benefit of beginners and others I again submit a select list of varieties which can be recommended for general cultivation.

HYBRID PERPETUALS.—*Light-coloured Varieties.*—Madame G. Luizet, La France, Merveille de Lyon, Captain Christy, Marie Finger, Baroness Rothschild, and Mrs. J. Laing. *Medium Reds*—François Michelin, Ulrich Brunner, Marie Verdier, Marquise de Castellane, Camille Bernardin, Comtesse d'Oxford, Dupuy Jamain, Heinrich Schultheis, and Suzanne Marie Rodocanachi. *Reds.*—Marie Baumann, A. K. Williams, Alfred Colomb, Prince Arthur, Earl of Dufferin, E. Y. Teas, Ferdinand de Lesseps, Senateur Vaisse, Victor Hugo, Earl of Pembroke, and Madame Henri Pereire. *Dark Varieties.*—Charles Lefebvre, Louis Van Houtte, Horace Vernet, Duke of Wellington, Duke of Connaught, and Sir Rowland Hill.

TEAS AND NOISETTES.—Innocente Pirola, Souvenir d'un Ami,

Caroline Kuster (N.), Marie Van Houtte, Madame de Watteville, Hon. Edith Gifford, Madame Lombard, Anna Ollivier, Francisca Krüger, Rubens, Jules Finger, Madame Hoste, Perle des Jardins, Souvenir de Thérèse Levet, Souvenir de S. A. Prince, and L'Idéal (N.).

HYBRID TEAS.—Grace Darling and Viscountess Folkestone.

BOURBON.—Souvenir de la Malmaison.

CLIMBING ROSES.—William Allen Richardson (N.), Gloire de Dijon (T.), Bouquet d'Or (N.), Belle Lyonnaise (T.). *Summer-flowering Varieties*.—Blairii (H.C.), Charles Lawson (H.B.), Coupe d'Hébé (H.B.), Bennett's Seedling (Ayr.), Félicité Perpetué (Evergreen), and Madame Plantier (H.N.).—E. M., *Berkhamsted*.

## HYBRID PERPETUALS.

Position in Present Analysis.	Average Number of Times Shown in the Five Years.	Number of Times Shown in 1890.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	37.0	40	Madame Gabriel Luizet .....	1877	Liabaud .....	Light silvery pink.
2	36.0	36	Mrs. John Laing .....	1887	Bennett .....	Light pink.
3	35.0	45	La France .....	1867	Guillot .....	Silvery rose.
4	34.0	57	Ulrich Brunner.....	1881	Levet .....	Cherry red.
5	33.4	44	A. K. Williams .....	1877	Schwartz .....	Bright carmine red.
6	33.2	40	Marie Baumann .....	1863	Baumann .....	Soft carmine red.
7	28.0	34	François Michelon .....	1871	Levet .....	Deep rose.
8	27.2	28	Merveille de Lyon .....	1882	Pernet.....	White.
9	27.0	21	Her Majesty .....	1885	Bennett .....	Pale rose.
10	23.2	12	Captain Christy .....	1873	Lacharme .....	Delicate flesh.
11	22.8	30	Alfred Colomb .....	1865	Lacharme .....	Bright carmine red.
11	22.8	34	Charles Lefebvre .....	1861	Lacharme .....	Purplish crimson.
12	21.4	34	Etienne Levet .....	1871	Levet .....	Carmine rose.
12	21.4	16	Marie Finger.....	1873	Raimbaud .....	Light salmon rose.
13	21.2	15	Lady Mary Fitzwilliam .....	1882	Bennett .....	Rosy flesh.
14	21.0	6	Marie Rady .....	1865	Fontaine .....	Bright carmine red.
15	20.8	29	Louis Van Houtte .....	1869	Lacharme .....	Deep crimson maroon.
16	19.4	33	Marie Verdier .....	1877	E. Verdier .....	Pure rose.
17	18.2	24	Duke of Edinburgh.....	1868	Paul & Son .....	Scarlet crimson.
18	17.8	21	Baroness Rothschild .....	1867	Pernet.....	Light pink.
19	17.0	28	Comtesse d'Oxford .....	1869	Guillot .....	Carmine violet.
20	16.4	13	Xavier Olibo .....	1864	Lacharme .....	Dark velvety crimson.
21	16.0	19	Horace Vernet .....	1866	Guillot .....	Purplish crimson, shaded.
21	16.0	23	Prince Arthur .....	1875	Cant .....	Bright crimson.
22	15.8	19	Marquise de Castellane .....	1869	Pernet.....	Clear cherry rose.
23	15.6	19	Camille Bernardin .....	1865	Gautreau .....	Light crimson.
24	15.0	15	Earl of Dufferin .....	1887	A. Dickson & Son...	Deep crimson.
25	14.3	27	Duke of Wellington .....	1864	Granger .....	Vivid crimson, shaded.
26	14.2	18	Beauty of Waltham .....	1862	W. Paul & Son .....	Rosy crimson.
27	13.8	19	Dr. Andry .....	1864	E. Verdier .....	Bright crimson.
28	13.6	21	Dupuy Jamain .....	1868	Jamain .....	Bright cerise.
29	13.4	12	Le Havre .....	1871	Eude .....	Vermilion red.
30	13.2	25	Heinrich Schultheis.....	1882	Bennett .....	Delicate pink rose.
31	12.6	18	E. Y. Teas .....	1874	E. Verdier .....	Bright carmine red.
32	12.4	18	Ferdinand de Lesseps .....	1869	E. Verdier .....	Shaded crimson.
33	12.2	4	Duchesse de Vallombrosa .....	1875	Schwartz .....	Pale flesh.
34	11.6	20	Général Jacqueminot .....	1853	Rousselet .....	Bright scarlet crimson.
35	11.4	10	Abel Carrière .....	1875	E. Verdier .....	Crimson maroon.
35	11.4	14	Duke of Teck .....	1880	Paul & Son.....	Crimson scarlet.
36	11.0	0	Monsieur Noman .....	1866	Guillot .....	Pale rosy pink.
36	11.0	19	Pride of Waltham .....	1881	W. Paul & Son .....	Light salmon pink.
37	10.8	15	Madame Victor Verdier .....	1863	E. Verdier .....	Clear light crimson.
38	10.6	13	Sénateur Vaisse .....	1859	Guillot .....	Bright crimson.
39	10.4	7	Star of Waltham .....	1875	W. Paul & Son .....	Carmine violet.
40	10.0	16	Prince Camille de Rohan .....	1861	E. Verdier .....	Crimson maroon.
41	9.8	9	Fisher Holmes .....	1865	E. Verdier .....	Shaded crimson scarlet.
41	9.8	1	Marie Cointet .....	1872	Guillot .....	Light pink.
42	9.6	13	Duchess of Bedford .....	1879	Postans .....	Light scarlet crimson.
43	9.2	10	Countess of Rosbery .....	1879	Postans .....	Carmine rose.
43	9.2	6	Marguerite de St. Amand .....	1864	Sansal.....	Clear rosy flesh.
44	9.0	9	Viscountess Folkestone .....	1886	Bennett .....	Creamy white, shaded pink.
45	8.7	11	Victor Hugo .....	1884	Schwartz .....	Bright crimson, shaded.
46	8.6	14	Duchesse de Morny .....	1863	E. Verdier .....	Silvery rose.
46	8.6	1	Reynolds Hole .....	1873	Paul & Son .....	Deep scarlet maroon.
47	8.4	2	Violette Bouyer .....	1881	Lacharme .....	Tinted white.
48	8.2	7	Charles Darwin .....	1879	Laxton .....	Brownish crimson.
48	8.2	12	Madame Eugène Verdier .....	1878	E. Verdier .....	Light silvery rose.
49	7.8	6	Queen of Queens .....	1883	W. Paul & Son .....	Pale blush pink.
50	7.4	6	Madame H. Jamain.....	1871	Jamain .....	Pale flesh.
51	7.2	8	Comte Raimbaud .....	1867	Rolland .....	Clear crimson.
52	6.8	11	Magna Charta .....	1876	W. Paul & Son .....	Bright pink carmine.
53	6.0	8	Auguste Rigotard.....	1871	Schwartz .....	Cherry red.
53	6.0	6	Sir Rowland Hill .....	1888	Mack .....	Deep velvety plum.
54	5.6	3	Comtesse de Serenye .....	1874	Lacharme .....	Very pale rose, shaded.
54	5.6	8	Madame Isaac Percière (B.) .....	1880	Margottin, fils .....	Bright carmine red.
55	5.4	4	Rosieriste Jacobs .....	1880	Ducher .....	Dark velvety red.
56	5.0	5	Lady Helen Stewart .....	1887	A. Dickson & Son ...	Bright scarlet crimson.

TEAS OR NOISETTES.

Position in Present Analysis.	Average Number of Times Shown in the Five Years.	Number of Times Shown in 1890.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	40.7	42	Catherine Mermet .....	1869	Guillot .....	Light rosy flesh.
2	38.6	41	Innocent Pirola .....	1878	Madame Ducher ...	White, slightly shaded.
3	35.7	35	Comtesse de Nadaillac .....	1871	Guillot .....	Rosy flesh and apricot.
4	32.6	34	Souvenir d'un Ami .....	1846	Belot Defougère ...	Pale rose.
5	32.0	31	The Bride .....	1885	May.....	White, tinged lemon.
6	31.4	30	Souvenir d'Elise Vardon.....	1854	Marest .....	Yellowish rosy cream.
7	30.8	36	Marie Van Houtte .....	1871	Ducher .....	Yellowish white, tinged rose.
7	30.8	28	Niphetos.....	1844	Bougère .....	White.
8	29.2	18	Caroline Kuster (N.) .....	1872	Pernet.....	Lemon yellow.
9	29.0	19	Maréchal Niel (N.).....	1864	Pradel.....	Deep golden yellow.
10	27.0	24	Madame de Watteville .....	1883	Guillot .....	Cream, bordered rose.
11	24.4	15	Jean Ducher .....	1874	Madame Ducher ...	Salmon yellow, shaded peach.
12	23.4	24	Madame Cusin .....	1881	Guillot .....	Violet rose.
13	19.6	10	Honourable Edith Gifford .....	1882	Guillot .....	Creamy white, shaded flesh.
13	19.6	23	Madame Lambard .....	1877	Lacharme .....	Salmon, shaded rose.
14	18.2	31	Francisca Krüger.....	1879	Nabonnand .....	Coppery yellow, shaded rose.
15	17.8	17	Madame Bravy.....	1848	Guillot .....	White, flushed pale pink.
16	17.2	18	Anna Ollivier .....	1872	Ducher .....	Pale rosy flesh, shaded buff.
17	16.6	24	Rubens .....	1859	Robert .....	Creamy white.
18	15.6	7	Etoile de Lyon .....	1881	Guillot .....	Bright sulphur yellow.
19	13.2	10	Souvenir de Paul Neyron .....	1871	Levet .....	Creamy white, tinged rose.
20	12.8	14	Princess of Wales.....	1882	Bennett .....	Pale rosy yellow.
21	11.4	2	Madame Willermoz .....	1845	Lacharme .....	Creamy white.
22	10.2	0	La Boule d'Or .....	1860	Margottin .....	Golden yellow.
23	7.8	12	Jules Finger .....	1879	Madame Ducher ...	Bronzy rose.
24	7.4	6	Devoniensis .....	1838	Foster.....	Creamy white.
24	7.4	4	Madame H. Jamain.....	1869	Guillot .....	White, shaded yellow.
24	7.4	3	Madame Margottin .....	1866	Guillot .....	Citron yellow.
25	7.0	7	Madame Hoste .....	1887	Guillot .....	Pale lemon yellow.
25	7.0	7	Souvenir de S. A. Prince.....	1889	Prince.....	Pure white.
26	5.6	0	Madame A. Jacquier .....	1879	Guillot .....	Light pink, shaded yellow.
27	5.0	0	Belle Lyonnaise .....	1869	Levet .....	Deep lemon.
27	5.0	2	Perle des Jardins .....	1874	Levet .....	Bright straw colour.

GROWING AND SELLING FRUIT.

(Continued from page 289.)

RASPBERRIES.

THIS is another fruit which pays well for growing as a rule, and is easily cultivated. Large fields of several acres in extent are grown in Kent for jam, and for the London markets, but there is generally a good demand for Raspberries near any country town.

SOIL.—This suits them best if cool and moist all through the summer, and what is generally termed “stiff loam,” such as grows strong wild Briars to perfection, is sure to suit them. They should not be fully exposed to the noonday sun. A piece of ground sloping to the north is best, although they will grow and ripen a moderate crop in almost any soil or position, unless very dry.

PLANTING.—They should be planted at the same period as other fruits. The young suckers or shoots sent up from the roots a short distance off during the preceding summer are the best for planting, and it does not matter about the tops being weak if they have plenty of good fibry roots. They should be planted in rows 5 feet apart and 2 feet between the plants, or single rows may be run through at intervals in a mixed plantation, as the inclination of the planter may direct. The cost of plants and planting at 5 feet between the rows would be about £24 per acre.

PRUNING AND TYING.—Early in the spring, following planting, the tops should all be cut off to within 2 inches of the ground, as they ought never to bear any fruit whatever the first year, or the plants will die. They should not be cut down until all danger of severe frost is over or the whole plant may be killed. After this during the first summer they will throw up from one to four shoots, which should be reduced to two as soon as it is possible to see which are the strongest. These should be encouraged to grow as strongly as possible by watering and mulching during the summer, and early in the following spring before they commence leafing they should have their tops shortened. The length they are

to be left will now depend upon the system they are to be grown under. In many very large plantations it is the custom to cut them back to 2½ or 3 feet in height, and not to use any supports for them; but smaller quantities pay for attention in this respect, and are best secured by placing stout larch poles at intervals of every 20 feet up the rows. If these poles are dipped in creosote or gas tar they will last much longer. They should stand 5 feet above the ground, and go from 1½ to 2 feet below the surface. Galvanised wire should now be fastened the whole length of the row to these stakes by means of small staples, putting one wire within 4 inches of the top and another about 3 feet from the ground in places where the Raspberry is quite at home and grows to a good height; but if the canes are not likely to grow high enough to reach 4 inches above the top wire it must be fastened to the stakes at a less height from the ground to enable them to do so after about 1 foot has been cut off from them. They should be tied to each wire with twisted raffia, leaving room when tying for them to grow larger. As soon as all the fruit is gathered the old fruit-bearing canes should be cut out close to the ground, and any weak shoots also, leaving enough for tying-in 6 inches apart all along the wires. All shoots that are more than 4 inches on each side of the original sets or row should be chopped off when very young unless required for forming fresh plantations.

GATHERING AND MARKETING.—If required for dessert purposes or for cooking, Raspberries should be gathered in flat 1 lb. punnets like Strawberries, and sent to market in a large box as described for that fruit; and if for preserving they should always be gathered without stalks, and put into glazed jars or crocks, and at once securely fastened up and sent to their destination. When the fruit is ripening, advantage should be taken of every fine day when the fruit is perfectly dry to gather all that are coloured before they get too soft. This fruit is one of the most difficult to market in good condition, and to prevent any of them being spoiled by rain. When gathered with the stems they should be worth 6d. per lb. wholesale, and for preserving purposes 4d. to 6d., according to the season and the crop. A piece of ground under my charge gave a crop last year (1888) at the rate of 1 ton 13 cwt.

per acre, worth £68 10s., at the rate of 4d. to 6d. per lb., which is the price they fetch here. Cost of gathering a similar crop would be about £14 per acre. The season was a very bad one, a large quantity getting spoiled with the wet, and this result was only obtained under the highest cultivation—viz., plenty of good manure, and the plants tied to posts and wires 5 feet high, so that half the above produce would be about a correct average from an acre under field cultivation, and grown without stakes.

**CULTIVATION.**—A plantation of Raspberries should last at least twenty years; with good cultivation and manure when requisite in poor soils they will pay for a supply every winter—about 20 tons per acre—stronger and richer land will not require it so often. They should also be kept strictly clean and free from weeds, and especially from Bindweed or wild Convolvulus, which is very difficult to kill when once it gets established, and which often does much mischief by growing over the fruit and young shoots. Raspberry plantations should never be deeply dug, as they root very near to the surface. A light forking over, therefore, in the winter is all they require—just enough to bury the manure under the surface if any is given, and to cover in any weeds that may be growing among them. If the soil is of a dry nature a good mulching over the roots, as recommended for Strawberries, will be of great benefit in dry summers, and will double the weight of the crop if put on early before the ground gets dry.

**ENEMIES.**—Birds, and especially blackbirds, are the worst foes the Raspberry has, and must be destroyed or frightened off in the usual way if the plantation is open. Hares and rabbits will sometimes do a great deal of mischief in severe winters, and wire netting must be put round to protect the plants.

**VARIETIES.**—Only the red ones are of any use for market. Two of the best are Fastolf and Baumforth's Seedling.

#### RED CURRANTS.

These do well in a mixed plantation, and under standard Apples, if not too much shaded. They will grow in drier and warmer soils than Black Currants; but where the latter will thrive they are, as a rule, the most profitable.

**PLANTING.**—Young plants may easily be raised from cuttings exactly as described for Gooseberries, but much time is saved by purchasing three-year-old plants. Where nothing else is to be grown on the same plot they may be 5 feet apart each way when put in their permanent positions, and at this distance will require about 1740 plants per acre; the cost of plants and planting will be about £12 per acre. They should be planted about the same time as Gooseberries or Black Currants, and the other details of cultivation are the same, with the exception of pruning.

**PRUNING.**—In this respect the requirements of the Red Currant are very different from those of the Black, as the latter bears best on the young wood while the Red answers best if the young wood is cut off almost close to the main stem at pruning time in the autumn, leaving only about an inch in length unless it is desirable to extend the number of branches or the size of the tree. Young trees should be encouraged to form six or seven main branches, keeping the centre of the bush open all the time like a basin, until the trees reach their full height, about 4 feet. The leading shoots should have only about one-third of their length cut off, and when the tree gets to its full height they may be cut at the points as in other parts, thus keeping the old main stems, which by this time will be full of buds their whole length and bear very freely; it is well to encourage a young branch to grow up if any of the others show signs of weakness from old age, and thus to gradually replace them. Summer pruning is also very beneficial to Red Currants, cutting all young wood back to about 3 inches as soon as the fruit is gathered if it is not required for extending the tree, and reducing the pieces left to 1 inch in length at the winter pruning. Red Currants are pruned by the Kent "tree cutters" at 1s. to 1s. 6d. per hundred, according to size.

**GATHERING AND MARKETING.**—As with other bush fruits, the gathering is generally done by women and children in the large fruit-growing districts, who are paid about 3d. per half sieve. This fruit also requires gathering before it gets over-ripe if intended to be sent a long distance, otherwise it will smash, and in that state is useless in any market. If for disposal in the neighbourhood it may get riper before gathering. Packing is the same as for Black Currants, and prices range from 1s. to 2s. 6d. per stone. The quantity grown per acre will generally be rather more than for Black Currants.

**CULTIVATION.**—Same as for Black Currants.

**ENEMIES** are fortunately not numerous. Caterpillars will sometimes eat the leaves, and should be picked off by hand and destroyed if numerous. Birds, and especially robins, are very fond of the ripe fruit, and must be frightened away.

**VARIETIES.**—The Scotch is grown very much for market, being firm and large. Red Dutch is also a good hardy variety.—  
W. H. DIVERS.

(To be continued.)

#### TRANSPLANTING LARGE SHRUBS.

FROM time to time we have heard much upon this subject, and the results of experience have varied as much, if not more, than the different localities from which they have written; added to which, soils and subsoils have a material effect upon all transplanting operations. I have met with some who strongly advocated that there can be no better period of the year for carrying out improvements and alterations about the grounds of any residence than early in the autumn. They base their argument principally upon the fact, that during the summer months the earth becomes heated to a much greater depth than it is in the other months of the year, and assert that moving a certain portion of earth cannot be done without fully exposing it all to the action of the air, even if the time which the operation takes is very limited; that in many instances shrubs will, under these conditions, begin to emit fresh roots in the course of ten days or a fortnight after their being removed; and that they will often, after being so removed, start in the following spring quite as fresh and vigorous as those which have not been removed.

This is one side of the question, and I imagine those who advocate this mode of proceeding reside upon gravelly soils or chalky formations, where the drainage is naturally good, and where the soil never becomes saturated with stagnant moisture, which is sure to cause young and tender roots to become ruptured and ultimately decay.

Strong soils never answer well for transplanting large shrubs or trees, and I consider it by far the best policy in all such to have quite young plants. They may look very diminutive for a time, but it is far better to bear with this than to endeavour to give effect at once with much larger specimens. I have seen these have all the care and attendance for a season which could be bestowed upon them, by mulching the ground above their roots, and likewise giving them copious supplies of water; but after all, many of them would soon become little better than sticks, not half clothed with leaves.

After a season or two, notwithstanding every precaution, it would be found necessary to supply healthy young plants. These may, and often will, for a season or two, almost stand still, not growing more than a few inches. Nevertheless, they will generally retain all their freshness; though a few of them may lose most of their leaves, still they never present that unsightly and skeleton-like appearance which is sometimes seen as the result of planting much larger specimens in strong soils.

From having had to operate in different soils in various parts of the country, I may safely state that it is difficult to transplant large specimens in strong soils; but in those which are light and open, especially when the subsoil is of a similar character, I have repeatedly transplanted large shrubs in the middle of summer, and when the weather was a little showery for a week or two they never lost a leaf by the operation. In a soil of this character I a few years ago assisted at the removal of many Oaks from 30 to 45 feet high, and the operation was generally very successful. The trees were cut round at some distance from the stem eighteen months before removal; all the roots which were put forth where they were cut were carefully preserved, as well as the ball of earth; but no practical man would recommend this being done in strong adhesive soils, however desirable it might be to produce an immediate effect. I consider it safest to use young and healthy plants, and these, in the long run, will give the greatest satisfaction.—D.

#### THE WALNUT TREE.

I MAY in the first place observe that the Walnut is seldom considered as in the list of cultivated fruits, its growth and bearing being generally left to chance. There is an old distich coupling the Walnut with a spaniel and a wife, to the effect that they are all the better for being well beaten. Now, this advice is, I confess, all that I have read about rendering the Walnut tree fruitful; and vulgar though it be, and often regarded as an unmeaning couplet put forth by some sarcastic individual, I am far from denying it some merit, for the beating of the tree with long poles to knock down the fruit in autumn, is never accomplished without breaking off a number of small shoots, thereby effecting a sort of rude pruning, and so rendering the tree more fruitful the following season; and as the rougher the usage the more shoots are broken off, it is not unlikely that a greater proportion of fruit may follow the year after. This,

however, is not always the case, for other influences also operate on the crop. An unfavourable spring is fatal to the setting of the young fruit, or it may be an ungenial autumn refuses to prepare the embryo buds, or other causes may tend to produce a failure similar to that which all other fruit-bearing trees are liable to.

Now, although but little can be said about the proper treatment of the Walnut tree, I fear the severe root-pruning given by some cultivators is the cause of much of the fruit falling at an early stage, and of the remainder being poor and imperfect, as most likely the tree would have borne a fair crop of useful fruit but for that pruning which deprived it of its most important food. It is possible, however, that next season, or the one after that, the tree may be benefited by the operation, especially if it is young and vigorous; but in general we would not advise root-pruning Walnut trees unless they are in that condition, for Nature usually points out when a tree ought to commence bearing, and if it begins to do so when very young, and is allowed to carry heavy crops, it seldom arrives at a great size. To begin bearing early is, in a certain sense, a token of disease or a too early maturity. Pinuses which commence bearing cones early rarely become large trees, and the same may be said of Walnuts. Patience, therefore, must be observed, and the best results will usually follow when the tree has been allowed to have its own way in everything save in the site chosen for it, which ought to be dry, hard, and stony, avoiding the deep, rich, cultivated soils of old gardens, and the damp situations to be met with elsewhere. The most fruitful Walnut trees are very often those occupying a public place on some hard road or thoroughfare, or some dry meadow, the tree receiving no further attention than a good beating when it produces fruit. At all other times letting alone is, perhaps, the best treatment the tree can have.

It may here be remarked, that although there is only one recognised species of fruit-bearing Walnut in general cultivation, the kind called French being only a sort of enlarged English, still, like every other hardy fruit, it differs to a certain extent when raised from seed; the variation takes place in the quality of the fruit, so that certain trees produce better nuts than others similarly placed. This fact is well known amongst the rustics, who have for many years made it a point of duty to taste the produce of all.

A similar sport or variation is observable in the Sweet Chestnut, and other trees also raised from seed. Some are known to produce excellent nuts, others indifferent, and some cast them before they arrive at perfection. Other instances might be given, but in most cases I would advise the Walnut tree to be left alone, and when Nature has done her part by expanding the tree to something like the proportion of a timber tree it will afterwards become less anxious for enlargement, and direct its energies to the production of fruit.—J.

#### ODONTOGLOSSUMS.

SHADE should be gradually dispensed with for *Odontoglossums*, the blinds being drawn down for a few hours only during bright sunshine. As much light as possible should be admitted, and where the shading is of a permanent nature lose no time in washing the greater portion of it off. It will not be safe to remove all at once or injury may result if bright weather follows. Shading of this nature is not, however, advisable for Orchids. Considerably less moisture will be needed in the atmosphere, and also about the roots of the plant, but on no account allow the atmosphere of the house to become dry, or the soil at the roots of the plants. Press down the moss if it has grown above the base of the pseudo-bulbs. Wash the pots in which the plants are growing, as well as those upon which they are elevated. Slugs can frequently be found when turning over the plants. Wash the glass and woodwork of the structure in which they are grown, and limewash the walls. Do not allow the temperature to fall below 50° at 6 A.M. Artificial heat only will be needed during cold nights for some weeks longer.

#### CYPRIPEDIUM INSIGNE.

Plants that have been kept in heat are showing their flower spathes. Remove the plants to the *Odontoglossum* or any cool structure, but do not allow cold draughts to strike direct upon the plants. These plants can be retarded for some time, and they will be much more useful some weeks hence than if allowed to come into flower.

#### CALANTHES.

These need shade no longer unless very bright weather ensues. Do not remove the blinds, but use them only for a few hours when the weather is very warm and bright. Arrange these plants close to the glass, so that their pseudo-bulbs will become thoroughly matured. Supply weak stimulants every time they need water. Free the plants from scale if any exist upon them by means of a sponge with softsoap and water. Do not allow the temperature at night to fall below 65°. Provide a circulation of air daily whenever the weather is favourable.

#### CŒLOGYNES.

The earliest of these have completed their growth. Place them for a time in a cool house, and expose them to light and a good circulation of air. The plants will then mature their pseudo-bulbs thoroughly, and in due time flower profusely. Frequently when left in heat they start again into growth, and a few flowers only are the result. Keep those warm, close, and moist that are still in active growth, and push them forward as rapidly as possible.

#### ONCIDIUM INCURVUM.

Although the flowers are small and insignificant individually, this produces long spikes of bloom. It is well worth growing in baskets for cutting purposes; its long arching spikes are very attractive in glasses where light arrangements are required. This plant does much better in the cool house than where a high temperature is maintained. It is a long time unfolding its flower spikes.

#### PHALÆNOPSIS.

These should be rooting abundantly and throwing up their flower spikes freely. Do not allow any weak plants to flower, pinch off the spikes as soon as they appear, and thus give the plants every chance of gaining strength and establishing themselves. These plants flower so freely that they are frequently weakened considerably by allowing them to flower when they are small. It is a mistake also for the spikes to remain upon the plants too long. Keep these plants shaded from the sun, and be careful that the material about their roots does not become dry. They should be syringed twice daily. Watch for thrips, and if they establish themselves upon the plants sponge with weak tobacco water.—ORCHID GROWER.

### WATERING VINES.

A FEW years ago the borders in which Vines are grown were not given the liberal supplies of water that we administer to them now. Well drained borders, it has been said, cannot be easily over-watered, and only recently we noted in these pages from the pen of a well-known cultivator that Madresfield Court was frequently given too little water. Two or three times a day for this Vine grown in pots was thought not to be too much.

I believe that more Grapes have failed to set, stone, colour, and keep well through over-watering than by insufficient supplies. Shanking and pithy wood are certainly the outcome in many cases of wet and therefore cold borders. We all know that Vines require liberal supplies of water, but in many localities and under many conditions the quantity poured upon the borders is far in excess of what is needed. Much depends upon what are termed well-drained borders; a border that some would call well drained is often sadly over-drained, and if the border is composed of light sandy soil, with perhaps a liberal addition of broken bricks or other similar material, it would perhaps be difficult to give too much water. Pouring water on to borders of this nature does little more harm and not much more good than pouring it into a sieve, for it passes through the border almost direct to the drain. Unless the application is repeated at frequent intervals the Vines are certain to suffer by drought. The evils that attend such systems of culture are as great if not greater, than if the Vines were growing in borders insufficiently drained. It cannot be good either for the Vine or the lasting properties of the border to be continually pouring water into it. The same applies to Vines grown in pots, and we cannot help thinking that something is radically wrong when two or three applications are needed daily. Our experience with plant growing in pots tends in the opposite direction. The longer the soil about the roots of the plant can be kept in an intermediate state of moisture without recourse to the water-pot the better. Even that water-loving plant, the Strawberry, when grown in pots can have too much water; the fewer the applications, provided the soil remains moist, the better is the flavour, and the finer the fruits. This we demonstrated during the season of 1889, when some hundreds were plunged to the rim to prevent evaporation, while equal numbers were grown without to test the value of the two systems.

It has been generally believed that red spider on Vines is solely the outcome of drought, or at least when the atmosphere of the structure becomes dry as well as the border the leaves are certain to be attacked. This we do not doubt to be the case, because a check is brought about and the Vines at once become a prey to this particular pest. They are, however, equally liable to an attack when the borders are too wet, and when they can be dried until they are in a normal condition red spider will disappear. This will undoubtedly be questioned, but I have ample proof which need not be entered into just now.

Too generally has water been given to Vines with a free and liberal hand without taking into consideration the drainage of the border and the nature of the soil of which they are composed. One example has been given of where liberal supplies could do little or no harm, and even those in this condition may be over-watered after the decomposition of the fibre. But the soil of which Vine borders are composed varies so widely that much judgment is needed. Where the soil is close and tenacious few applications suffice, the drainage of the border and nature of the soil should be the sole guide in this matter. If instead of adopting a general practice judgment and sound common sense were exercised fewer Vines would be ruined. Well drained borders are necessary, but not over-drained ones, the heavier the soil and the closer it is likely to go together after it has been in the border a few years the more liberal should be the drainage and the less frequent the supplies of water. Borders of this nature need most care or they are sure to become too wet, the Vines flag and fail to grow when they should bear the full force of the sun and be growing luxuriantly.

Shanking may arise from a variety of causes, but is frequently due to a severe check to the Vines, which prevents their bringing up the necessary supplies at the proper time. The lack of suitable food during the stoning period often results through the roots being in wet borders. Active roots are formed in quantity only very late in the season, and these die after the foliage falls, so that there is an insufficiency of active feeders until the mischief has been accomplished. The roots in wet cold borders are naturally late in starting into growth, and shanking follows. This can be largely remedied by careful watering and an increase of surface roots without recourse to lifting. Rich surface dressings are the best means of encouraging roots near the top, and thin mulchings of manure, heavy mulchings when the borders are composed of heavy soil are an evil, and prevent necessary evaporation and warmth. A very thin layer of manure will keep the soil beneath moist for a long time, and the daily sprinklings of the border can be dispensed with.

The supply of water in gardens generally is much better than it used to be, and the evils arising from the overwatering of borders are far more frequent.—W. BARDNEY.

#### HASSOCKS GATE NURSERY.

BUSINESS took me to Messrs. Balchin & Sons' Nursery some days ago, and I saw much that was both interesting and instructive. The glass houses are well built, well stocked, and are kept as clean and orderly as any gentleman's houses. We find a large span-roof house devoted to *Leschenaultia biloba major*, which is a speciality. Hundreds are grown in all sizes, and no better evidence of the purity of the air of Hassocks and the correctness of the treatment could be afforded than by the fact that they grow like weeds. The next thing that took my attention was the enormous quantity of Palms, *Phoenix reclinata*, *Latania borbonica*, *Scaforthia elegans*, and *Areca lutescens* in large numbers in all sizes, and of *Kentia australis* thousands, and it is surprising how regularly they grow, almost every plant having the same number of leaves. Many of these are sold in a small state for furnishing those small vases and ornaments so troublesome to many gardeners, but the great bulk are grown into plants of 18 inches or 2 feet high. Palms, of course, play an important part in ballrooms, and other decorations undertaken by this firm in Brighton and neighbourhood. About 5000 *Chrysanthemums* are grown. *Madame Desgranges*, *Mrs. Burrell*, and *George Wermig* are largely grown for cutting. The great bulk are such popular sorts as *Fair Maid of Guernsey*, *Lady Selborne*, *Source d'Or*, *Peter the Great*, *James Salter*, *Hiver Fleuri*, *Elaine*, and the neat little incurved *Mrs. Geo. Rundle*, *Mrs. Dixon*, and *Geo. Glenny*. But all the best are grown in smaller numbers. The plants are good, and they show less signs of loss of bottom leaves than is generally the case this season. A lean-to house is devoted to *Tea Roses* in pots. *Niphetos*, *Isabella Sprunt*, *Madame Falcot*, and *W. A. Richardson* are grown in large numbers for cutting. Almost everything that will produce choice flowers, especially white flowers, are grown in quantity. *Eucharis*, *Stephanotis*, *Lilium Harrisi*, *Lapagerias*, white *Azaleas*, *Bouvardias*, and *Tuberoses*. The latter have special attention, and are well grown. Nearly 2000 are now coming on for autumn and winter blooming. They are started in comparatively cool quarters, but are moved into a little warmth as soon as they begin to throw up. A necessary adjunct to their cut-flower business is *Maidenhair Fern*, *Adiantum cuneatum*, of

which they grow thousands, and never get enough; also useful sorts for decorative purposes, such as *Pteris tremula*, *P. serrulata*, and its crested varieties. Amongst other popular plants well grown were *Erica hyemalis*, *Cyclamen*, *Cinerarias*, *Hydrangea Thos. Hogg* (in a forward stage, and just being placed in their largest pots), and *Solanums*. *Roses*, fruit trees, hardy herbaceous plants, *Coniferae*, and hardy shrubs are also grown, but my time did not permit a further inspection. The few I have just mentioned, and the fact that the same firm has two large conservatories, and another nursery with a great extent of glass, together with a seed business in Brighton and Hove, will give some slight idea of the nature of the business.—R. I.

EVENTS OF THE WEEK.—To-day (Thursday) the Crystal Palace Hardy Fruit Show will be opened at Sydenham, and it will close on Saturday, October 11th. On Tuesday, October 14th, the Royal Horticultural Society's Committee meetings will be held in the Drill Hall, Westminster, at 12 noon. The following day (Wednesday, October 15th) there will be an Exhibition of fruit and *Chrysanthemums* at the Royal Aquarium, Westminster; the Floral Committee of the National *Chrysanthemum* Society meeting at 12.30 P.M. A meeting will also be held in the Library at 4 P.M. to consider the proposed Holmes memorial, and following this at 5.30 P.M. the British Fruit Growers' Association will hold a Conference on Apples, to be introduced by a paper read by Mr. G. Hammond of Brentwood.

— THE WEATHER IN THE METROPOLITAN DISTRICT has continued fine for the greater part of the past week, Tuesday being the only exception, rain falling heavily during the day. Very slight frosts have been experienced in some districts, but generally the temperature has been high and the atmosphere clear.

— THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—As will be seen on reference to our advertisement columns an addition is to be made to the pension list of this admirable institution, and that candidates must send in their applications to the Secretary on or before November 8th.

— WE regret to announce the death of Mr. WALTER DARKIN, which took place quite unexpectedly at an early hour on Monday in last week. Mr. Darkin was proprietor of "Bell's Weekly Messenger," "Mark Lane Express," and "Farm, Field, and Fireside." He was able, energetic, enterprising, and gained a good position in the newspaper world.

— B. S. WILLIAMS' MEMORIAL.—We are informed that, although a considerable list of promises of contributions has been secured, the total amount promised is still insufficient to carry out the recognition that forms the basis of operations. It is hoped that friends of the movement will renew their efforts to augment the list, the more especially as the Fund will be wholly devoted to the sustenance of the orphans of gardeners and the encouragement of excellence in the cultivation of plants. Those who have promised and not paid are requested to forward their several amounts as early as may be convenient, as the Treasurer desires to advertise all contributions in the order in which they are received. The Chairman of Committee is Mr. Shirley Hibberd, Kew; Treasurer, Mr. H. J. Veitch, 544, King's Road, Chelsea, S.W.

— THE death of a celebrated French author, ALPHONSE KARR, was announced by the London daily papers on October 2nd as having occurred at Saint Raphael on the previous day. M. Alphonse Karr was principally known to amateur horticulturists in this country as the author of a most interesting book, "A Journey Round My Garden," which has been translated into English, but has had a large sale in the original French. M. Karr had for some years engaged in the cultivation of plants, and it is said that he had inscribed over the door of his unpretentious cottage the words, "Alphonse Karr, Gardener." He was the author of several successful works of fiction and dramatic works. He was in his eighty-second year, and his death is due, it is said, to a severe cold contracted by superintending some work in his garden during a recent heavy rainstorm, and refusing to change his clothes for some time afterwards.

— THE total RAINFALL AT CUCKFIELD, Sussex, for September was 0.82 inch, being 2.31 inches under the average. Total for the nine months, 20.79 inches, or 0.52 inch above the average. The heaviest fall was 0.31 inch on the 17th; rain fell on seven days. The highest temperature was 72° on the 10th, lowest 36° on the 1st. Mean shade temperature, 66°; mean night, 49°. Partial shade readings, 3.4° above the average.—R. I.

— AT a recent meeting of the BRITISH FRUIT GROWERS' ASSOCIATION at the Hotel Windsor, Mr. T. Francis Rivers in the chair, twelve members were elected, and it was stated as an indication of the interest taken in the work being performed by the Association that within the past five months the number of members had been increased by seventy additions. It was resolved to contribute a collection of fruits from the members of the Association at the Guildhall Show, also if possible at the Crystal Palace and the Royal Aquarium. At the latter place it was arranged that Mr. G. Hammond of Brentwood should read a paper on "Apple Culture" on October 15th at 5.30 P.M.

— I AM sending you a few varieties of TUBEROUS BEGONIAS gathered from beds outside. The tubers were planted on May 27th, and from that day up to this, October 3rd, they have been our most attractive beds in the flower garden, and have been much admired. I hope to plant largely another season. We suffered severely from winds and rain early in the season, which caused havoc and rank growth among Pelargoniums and Calceolarias. The Begonias have been fresh and bright throughout; I can strongly recommend them to amateurs for bedding out purposes.—ALFRED SKINNER, *Christchurch*. [The flowers sent were as bright and fresh as possible, all of good varieties.]

— THE WEATHER LAST MONTH.—September was the driest month of the year so far, and with the most sunshine. We had four clear days and six others partly so; splendid weather for the harvest, also checking the Potato disease very much (we have the finest crop here that I have seen for several years, and only a very few diseased). Wind was in a westerly direction twenty-two days. Barometer, highest 30.48 at 9 P.M. on the 25th; lowest, 29.66 at 9 A.M. on the 22nd. Total rainfall, 0.68 inch, which fell on ten days, the greatest daily fall being 0.25 inch on the 21st. Highest shade temperature was 79° on the 8th and 9th; lowest, 31° on the 1st; lowest on grass, 29° on 1st; mean temperature of the month, 59.20°. The garden spring ran 13 gallons per minute on the 30th.—W. H. DIVERS, *Ketton Hall, Stamford*.

— LAYERING CARNATIONS.—Mr. F. Hardy, in his excellent paper on the Carnation, says, page 226:—"After the soil is placed round, the layers should have a slight watering, and the business is completed until they are rooted." In showery weather, doubtless, this one watering would be sufficient; but if it should not set in dry (as was the case here this season) I think it is important that the Carnation layers be well attended to in the matter of watering. A mound of light sandy soil soon becomes dry, and the layers do not root so freely as if this is kept moderately moist. Indeed I have reason to believe that I once saw a large number of Carnation layers totally ruined through neglect in this respect, and this is why I am writing this note, and not for the mere sake of picking a hole in Mr. Hardy's paper.—T. S., *Henbury Hill*.

— THE WEATHER DURING SEPTEMBER, 1890.—The weather during the past month here has been delightful, and it has been the driest September in the past three years. The bright sunshine, of which we have had an abundance, has done much in well ripening the wood of our fruit trees, thus giving us the possibility of a crop of fruit next season. The temperature has for the most part remained very steady, the highest point reached by the thermometer being 74° on the 5th; the lowest 33° on the 1st. Rain fell upon six days, against ten of 1889. Maximum in any twenty-four hours 0.10 inch on the 19th; minimum, 0.02 inch on the 3rd; total during the month being 0.39 inch against 2.11 inches of 1889.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Hert.*

— THE *Kelso Chronicle* says:—"Mr. Archibald M'Kellar, of the gardens at Floors Castle, has been appointed head gardener to their Royal Highnesses the Prince and Princess of Wales at Sandringham, and from what we know of Mr. M'Kellar there is every reason to believe that he will worthily fill this high and important position. Although yet in his prime, he has been in some of the most notable Scottish and English gardens, gaining in his day a large experience, and during his nine years of duty at Floors Castle it is admitted by all those

who ought to know that the well-known and famous gardens there have never been in better order. The loss of Mr. M'Kellar will be felt by their Graces the Duke and Duchess of Roxburghe, but while this is the case they will no doubt be gratified at this his latest advancement."

— EARLY SCOTCH GARDEN LITERATURE.—On page 290, your able contributor, "J. R. S. C.," in one of his interesting and valuable articles on Early English Horticulture, notices Justice's "British Gardeners' Director," and says it was apparently the first standard work of the kind published north of the Tweed. It may be of interest to know that an earlier work, which ran through at least two editions, was written by John Reid, Gard'ner. The second edition, which is in the possession of a friend, and which I have seen, is called "The Scots' Gard'ner," and was published in Edinburgh in 1721. It is, however, chiefly devoted to the laying out of land, and forms somewhat curious reading. If Justice published an edition of his work in 1754 under the title of "The British Gardeners' Director," part of the issue, or a separate edition, was published as "The Scots Gardiners' Director." I saw a copy of this a few days ago, and I have a copy of the second edition of "The Scots Gardiners' Director," published in 1759, and containing the dedication of the first edition. This second edition is of more value to the student of early horticulture than the first, which contains little but cultural directions, while the second gives descriptions and names of many plants.—S. ARNOTT.

— ALLEGED FRAUDS AT A NURSERY.—At Worcester last Wednesday, Edward Ray, a timekeeper in the employ of the well-known firm of Richard Smith & Co., nurserymen and seedsmen, Worcester, of which city Alderman Richard Smith Carington is Mayor, was charged on a warrant with obtaining £10 4s. 6d. by false pretences. The Town Clerk (Mr. S. Southall) prosecuted, and explained that defendant, besides being a timekeeper, was overseer of piecework and had to call over a roll of workmen. At certain periods of the year several extra men were employed, and a separate time book was kept for these. The cash book was made up from the time book. Defendant had at various times called at the office and received money for two men, whose names were given as Hall and Barnes, representing that it would be a convenience to these men to have their money before the ordinary pay time. In this way he received the amount named in the charge. On September 20th defendant took the time book to the office, but before the time for the cash to be arrived the defendant was discharged, for reasons not connected with this case. When the cashier called over the names of Hall and Barnes, no one answering to those names appeared, and consequently the fraud was discovered, as it was found that the men in question had not been employed since March last. Evidence in support of the charge was given, and it was stated that defendant had offered to pay the money back and leave the city if he were not prosecuted. He was committed for trial at the quarter sessions.

— HINTS TO FRUIT GROWERS.—Orchard fruit generally has been a short crop this season, but the care given by growers to greasing and washing has very sensibly diminished the plague of caterpillars and aphides. The trees look far more healthy than for many years, while the heavy rains of the past summer have kept them growing freely, and much wood has been built up, and ripened by the glorious sunshine of the past three weeks. Therefore, subject to the usual "if's" incidental to fruit culture, and without prophesying, we may infer that 1891 will be a fruitful year; foliage is good, buds are plump, wood is ripened, and the roots are in good order—four necessary conditions. In case of a heavy crop only the finest samples can sell freely at a good price, and I venture to suggest to growers that they should at once have their old orchards examined; all crossing boughs should be removed and the heads of the trees be opened so that a man can readily get his head and shoulders between the branches; all dead wood should be cut out, as it can be detected easily now that the leaves are on it. Boughs over 1 inch across should be smoothed over with a sharp knife, and these cuts will partially heal before Christmas. Should old trees be overfull of fruiting spurs they can be thinned from the under boughs, and all prunings should be gathered in a heap and burnt at once to kill eggs of moths, which generally choose loose bark and cankered spots to lay in. By these means trees will still further perfect their growth, and the crop will become larger in size and clearer in the skin than where these precautions is not taken, and growers will secure a better price, while the strain being less on the pruned tree than on one that is not pruned, and consequently full of useless wood and foliage, the chance of a crop in 1892 is enhanced.—GEORGE BUNYARD, *Ma'ldstone*.—(*South-Eastern Gazette*).

— THE PORTSMOUTH FLORICULTURAL SOCIETY AND CHRYSANTHEMUM SHOW.—The Portsmouth Chrysanthemum Show is an annual event looked forward to with much interest. From comparatively small beginnings it has grown to be one of the largest Exhibitions in the country, and it owes its development in no small measure to the energy of Councillor F. Power, who has been Honorary Secretary of the Show since its establishment. The organisers of the Show have formed the Portsmouth Floricultural Society, an institution for encouraging the cultivation of fruit and flowers generally, and Chrysanthemums in particular. The Mayor for the time being will be President of the Society, and the first to hold office is Sir William King. The Committee for the first year consists of the Mayor, Alderman G. E. Kent, and Councillors G. Ellis, Ward, Winter, Corke, Barnes, Fulljames, and Power, who will have the assistance of four professional gardeners—namely, Messrs. Penford (Leigh Park), Collins (Waterlooville), Kimber (Borough Asylum), and Hatch (Victoria Park). The first Show under the auspices of the newly formed Society will be held in the Volunteer Drill Hall, Alfred Road, on November 5th, 6th, and 7th, when prizes of the total value of £250 will be offered for exhibits of Chrysanthemums, other flowers, and fruit. Schedules are now ready, and can be obtained from Mr. Power. The principal prizes offered are that known as "The Jubilee," for eight show plants, the total value of this being £22; the challenge vase, valued at £25, and £23 in money prizes for forty-eight cut blooms; and (in the fruit list) £10 for fifty dishes of Apples and Pears.

— AN ECHO FROM GUERNSEY.—TOMATOES FOR PROFIT.—The excellent paper on Tomatoes read at the British Fruit Growers' Brighton Conference has attracted some attention here among Tomato growers, especially as it came from Mr. W. Iggulden, whose practical book on Tomatoes and their culture has had a fairly good sale among the growers. As to the Tomato being overdone, we do not here think there is much chance until the English nation can supply itself with this wholesome vegetable, and the foreign fruit is no longer needed. Prices may fall for early grown fruit, but the demand, increasing as it certainly is among the masses, will provide an outlet for the increased supply. While on the subject of foreign goods it will be news to some of the British fruit growers to learn that the majority of the population of the Channel Islands are English—not foreigners—and I maintain that the constant quoting of Channel Islands produce as foreign is unjust to the growers here, and shows a lack of knowledge of these islands and of the nationality of their inhabitants. As Mr. Iggulden remarks, there are crops produced here that would be an "eye opener" to many smart professional gardeners. I last week saw a span-house 260 feet long 45 feet wide (cool house) that had yielded a crop of 8 tons of Tomatoes, and the plants are showing flower now, so that if heat could be applied there would be fruit until Christmas. The variety usually grown is a good strain of Large Red. The Perfection and other kindred varieties do not meet with much attention from growers for profit, and only a few have persevered in keeping one or more small houses especially for this variety. The Cladsporium has created great havoc and loss here, as on the mainland, and as yet we have not discovered any really effective means of checking its ravages. Medium sized houses properly heated, with careful attention to culture, will as a rule insure a fair crop if not a heavy one, and the fruit in this case will swell up to full size. The output next year from this island will be enormously increased, as more houses are being erected than has ever been known before at one time, and consequently builders and timber merchants are working at high pressure. As these houses will be utilised for growing Tomatoes it is to be hoped the British public will favour fruit grown by British subjects, and in an island free from cholera and contagious diseases.—SARNIAN.

### THE GUILDHALL FRUIT SHOW.

OCTOBER 6TH, 7TH, AND 8TH.

THE history and scope of the remarkable Exhibition of fruit organised under the direction of the Fruiterers' Company in the Guildhall, London, this week are dealt with in the article on page 305, and it is therefore unnecessary here to refer to the origin of the gathering. It will be necessary, however, to describe as briefly as possible the general characters of the Show, and to give particulars of the more important exhibits. In a display of such magnitude and comprising so much that is noteworthy it is difficult to make a selection of the more important, and a detailed report would require a large portion of the Journal to do the matter full justice. With regard to the positions taken by the successful competitors, the official list of awards appended to these remarks supplies all the information needed, and we will endeavour to give a general review of the Show

as likely to be of most interest to our readers. To give the names of all the varieties shown in the prizewinning collections would involve the repetition of many familiar names, as except in the trade and large collections the varieties represented were not very numerous. It was, however, a subject of common remark amongst the experienced fruit growers present on the three days that few could have expected in a season like the present to see so large a number of entries and such good even quality as characterised the Show under notice. It is true that nearly all the best fruits staged were from private gardens, and that they were selections in many cases from numerous trees, and consequently could not be taken as average samples, yet they proved that even in a season of general scarcity there is still plenty of good fruits to be obtained in England. In size and colour the majority of the Apples shown left little to be desired, and though the Pears were necessarily wanting in the tints which render the Apples so attractive, some extremely fine fruits were included, especially from the south-eastern gardens.

The classification of the exhibits in geographical districts was instructive and interesting; it was also fairer for the competitors to have only to contend with the contributions from growers working under the same climatal conditions. Until the principle adopted was thoroughly understood it was, however, somewhat perplexing to visitors, and even to experienced showmen, for the same class numbers were repeated three times, and after seeing the prizes and entries in a certain class at one part of the Show it was rather puzzling to find the same class repeated in other widely separated apartments. Perhaps a word of explanation may be useful as indicating the plan followed in the arrangements.

The first section, comprising six classes, was appropriated to cottagers, defined as "persons of the working class who do not employ professional assistance or paid labour in the cultivation of their gardens or allotments." The exhibits in each of these classes were then classified in three "zones" as follows:—

(1) Northern Zone.—The Counties of Northumberland, Cumberland, Westmoreland, Durham, Yorkshire, Lancashire, Cheshire, Derbyshire, Nottinghamshire, Lincolnshire, Staffordshire, Shropshire, Leicestershire, Rutland, Flint, Denbighshire, Carnarvonshire, Anglesea, Merionethshire, Montgomeryshire, Cardiganshire, and Radnorshire. (2) South-Western Zone.—The Counties of Cornwall (and Scilly Islands), Devon, Somerset, Dorset, Wilts, Gloucestershire, Monmouthshire, Herefordshire, Worcestershire, Warwickshire, Pembrokeshire, Carmarthenshire, Glamorgan-shire, and Brecknockshire. (3) South-Eastern Zone.—The Counties of Hants (and Isle of Wight), Sussex, Kent, Surrey, Berkshire, Middlesex, London, Essex, Norfolk, Suffolk, Cambridgeshire, Huntingdonshire, Northamptonshire, Bedfordshire, Buckinghamshire, Oxfordshire, and Hertfordshire.

This system was applicable to sections 1 to 4, thus increasing the nominal number of classes (19) to 57, as prizes of equal value were offered for exhibits staged from the respective "zones." There was a great difference not only in the number of entries in each class but in the divisions of those classes also, except in the cottagers' and tenant farmers' sections, neither of which were largely represented. In the amateurs' and gardeners' section, especially from the south-eastern zone, the competition was extraordinary, reaching as many as forty-four in one class, and the quality all round was superior there to either of the other geographical districts, though nearly equally fine examples were staged by some exhibitors in smaller numbers from the south-west and north.

It will not be necessary to take the classes in the order of the schedule, as prominence must be given to the gold medal class as the great feature of interest in the Exhibition. This was for "a collection of fruit, to consist of thirty varieties of Apples and twenty varieties of Pears, five specimens of each," and were to be shown only by amateurs or gardeners in the United Kingdom, the prizes consisting of a gold medal, a silver-gilt medal, and a silver medal, without money prizes. The twelve exhibits in this class, comprising 600 dishes of fine fruits, occupied two tables 6 feet wide, extending from the dais at the end to the centre of the Great Hall, and constituted one of the most handsome classes of competitive fruit ever seen in England. The remaining two tables, extending from the centre to the opposite end of the hall, with some side tables, were occupied with the trade exhibits, and the table across the hall above the dais, shown as the extreme boundary in the engraving (fig. 36) was occupied with the 300 dishes of fruit from the British Fruit Growers' Association. To these exhibits we shall have to refer again, but returning now to the fruit class, it must be said that the gold medal was well and easily won by Mr. G. Woodward, gardener to Roger Leigh, Esq., Barham Court, Maidstone, who had magnificent Apples both in size and colour, fully equal to the Barham Court records of previous years. The varieties were as follows:—Apples: Warner's King, Alexander, Claygate Pearmain, Belle Dubois, Royal Russet, Yorkshire Beauty, Stone's, Golden Spire, Cox's Orange Pippin, Brabant Bellefleur, New Hawthornden, The Queen, Flower of Kent, Bismarck, Ribston Pippin, Northern Greening, Minchull Crab, Gascoigne's Scarlet, Peasgood's Nonesuch, Lady Henniker, Alfriston, Lord Derby, Mère de Ménage, Reinette de Canada, Cox's Pomona, Grenadier, Washington, Tower of Giamis, Bedfordshire Foundling, and Calville Malingle. The Pears also were very fine, but, of course, owing to the want of colour they did not form so bright a part of the exhibit. The varieties were General Todtleben, Emile d'Heyst, Marie Louise, Doyenné de Mersode, Easter Beurré, Brown Beurré, Doyenné du Comice, Louise Bonne of Jersey, Hacon's Incomparable, Pitmaston Duchess, Vineuse, Glou Morceau, Catillac, Beurré Hardy, Doyenne d'Alençon, Beurré Diel,

Conseiller du Cour, Beurré Superfin, Nouveau Poiteau, and Marie Benoist. The second honour — the silver-gilt medal — was accorded to Mr. Davies, The Mote Park, Maidstone, who had

Waltham Abbey, Dumelow's Seedling, Bismarck, Melon Apple, Cox's Orange Pippin, Warner's King, Fearn's Pippin, Mère de Ménage, Blenheim Pippin, Cobham's Pearmain, Summer Thorle, Cox's Pomona, Lord

FIG. 36.—THE GUILDHALL FRUIT SHOW.

handsome fruits, especially amongst the Apples. The varieties were—Apples: Peasgood's Nonesuch, Queen Caroline, Worcester Pearmain, Gloria Mundi, Gascoigne's Scarlet, American Mother, Stone's,

Derby, Alexander, Ecklinville, Ribston Pippin, Alfriston, King of the Pippins, Lord Suffield, The Queen, Lemon Pippin, and an unnamed variety. The Pears were Doyenné du Comice, Emile d'Heyst, Comte de

Flandres, Durondeau, Beurré Hardy, Brown Beurré, Beurré Clairgeau, Hacon's Incomparable, General Todleben, Pitmaston Duchess, Urbaniste, Beurré Diel, Colmar d'Été, Beurré Bachelier, Doyenné Boussoch, Glou Morceau, Marie Louise, Marie Louise d'Uccle, and two or three unnamed varieties. Both these were Kentish exhibitors, and it showed the necessity of the zone system, for if that plan had been adopted in this class it would have given several other exhibitors places in the competition. For instance, Mr. Goodacre, Elvaston Castle Gardens, Derby, was awarded the silver medal for a good collection, and S. Barlow, Esq., Stakehill House, Middleton, had an extra prize for fine fruits, including exceedingly large and handsome Peasgood's Nonesuch, probably the finest dish of Apples in the Show. Both these were northern exhibitors, and with Mr. J. McIndoe, Guisborough Hall Gardens, Yorks, could scarcely be expected to compete on equal terms with the Kentish fruit. Other competitors who showed meritorious collections were Mr. Cummins, gardener to A. H. Smee, Esq., Wallington; Mr. G. Reynolds, gardener to the Messrs. Rothschild, Gunnersbury Park; Mr. T. Turton, Maiden Erleigh; Mr. J. C. Dean, Titsey Place Gardens, Limpsfield; Mr. J. Nicholson, gardener to W. Melles, Esq., Sewardston Lodge, Chingford; Mr. J. Rose, gardener to Lord Wantage, Lockinge Park, Wantage; and Mr. W. Dance, Gosfield Hall Gardens, Halstead.

Referring briefly to the remaining exhibits in the Great Hall, it may be said that the general quality was satisfactory, though in the majority of cases not less than fifty dishes were shown by each exhibitor. As already stated, the table on the dais was devoted to the British Fruit Growers' Association (Hon. Sec., Mr. Lewis Castle). About 300 dishes were staged from thirty exhibitors and fifteen counties in the following zones:—Northern.—Northumberland, Cheshire, Salop, and Lincoln. South-Western.—Wilts, Gloucester, Hereford, and Worcester. South-Eastern.—Surrey, Sussex, Kent, Middlesex, Bucks, Essex, and Herts. The principal exhibitors were the following:—Mr. G. Harris, Alwick Castle Gardens, Northumberland, who sent representative northern fruits from Alwick; also from Messrs. D. Inglis, Howick Hall; R. Henderson, Chillingham Castle; J. Thompson, Shawdon Hall; and A. Burgess, Doxford Hall. Other northern exhibitors were Brownlow Tower, Esq., Ellesmere; Messrs. Dicksons of Chester; and Mr. W. H. Divers, Ketton Hall Gardens, Stamford. From the south-western zone the contributors were Mr. H. W. Ward, Longford Castle Gardens, some fine Pears; Mr. G. Cole, Evesham, orchard and local Apples; English Fruit and Rose Company, Hereford, and Messrs. Jefferies & Son, Cirencester. The south-eastern zone included exhibits from Mr. G. Hammond, Brentwood; Mr. Goaring, gardener to J. W. C. Tower, Esq., Weald Hall, Brentwood, an excellent collection; Mr. W. Roupell, Brixton; Mr. E. Butts, Streatham Hill, and others showing suburban garden fruit; Mr. R. Smith, Yalding, orchard fruit; Mr. C. Herrin, Dropmore Gardens, Maidenhead; Mr. C. Goldsmith, gardener to W. Waterlow, Esq., Redhill; Mr. R. Merritt, Harpenden; Mr. A. F. Brown, Chertsey; Miss Flintoff, Mitcham; Messrs. Cheal & Son, Crawley, cottagers' fruit; and Mr. W. Butts, Poulett Lodge Gardens, Twickenham. The object of the collection was to show fair average fruits from private gardens, orchards, market gardens, and cottage gardens in the principal districts of England under good cultivation. Samples were also staged from neighbouring orchards to show the effects of attention and neglect in the culture of trees. Mr. Smith of Yalding stated that in his district this season, "Thirty bushels of Apples had been taken from one tree of Northern Greening, and twenty bushels from one tree of Blenheim Pippin. The produce of six standard trees of Colonel Vaughan variety in the same district had realised £20." Mr. Herrin also stated, as showing how the crops vary in different places, that at Dropmore they have "the best crop of orchard Apples secured for some years."

Mr. Harris's collection was very interesting, coming from the extreme north of England, and a statement accompanying the fruit was to the following effect:—"Pears are very scarce in this district, except those sent, which are mostly cropped heavily, all of which are good here. The choice Pears do not succeed in the open in this climate except on walls, therefore we have not so many varieties as more favoured places in the south. Of Apples I have sent only one dish of a variety, all of which are among the best to produce good crops. Mr. Inglis speaks highly of Peck's Pleasant and Queen Caroline, and Mr. Henderson of Chillingham knows nothing so delicate when cooked as Carlisle Codlin. Speaking generally, the largest fruit are from the Paradise stock, and from trees planted from two to eight years. If fairly sheltered, with good land, useful marketable fruit can be grown on the Paradise stock. Several of the varieties begin to fruit the first year after planting. We have had several of the varieties which are sent from trees planted in 1888, bearing from 3 dozen to 3½ dozen fruits. This was a very unfavourable spring. One friend reports 27° frost in March, 17° in April, with cold winds after setting."

The framed certificate of the Fruiterers' Company was awarded for this exhibit, and several awards of merit were granted for the fruits shown.

A similar recognition was accorded to the Royal Horticultural Society for a collection of fifty dishes of fruits from the Chiswick Garden. These comprised some excellent Apples and Pears, together with Aubergines, fruits of the Tree Tomato and Currant Tomatoes, which attracted much attention. The trade exhibitors contributed largely to the beauty of that portion of the Exhibition in the Great Hall, as the majority displayed considerable taste in the arrangement, highly coloured varieties being placed in imposing mounds, or disposed on dishes with a garnishing of suitable leaves. We cannot particularise

these exhibits in the present issue, but the names of the exhibitors, with the awards granted, are given in the official prize list at the end of these notes.

From a cultural and competitive point of view perhaps the most interesting section of the Show was that formed by the exhibits from the south-eastern zone, which were arranged in the art galleries, first entered from the road. Here there were some cottagers' and tenant farmers' exhibits, but they do not call for special mention. In the amateurs' and gardeners' section, however, the competition was extraordinary, and it is doubtful if it has ever been equalled before at any exhibition. The first class of the section was for twelve dishes of dessert Apples, distinct varieties, five fruits in each dish, and the twenty collections staged were of high merit throughout, rendering the judging extremely difficult, as after the first two were passed there were seven or eight of nearly equal value. Mr. G. Woodward succeeded in gaining the first prize with bright and beautiful fruits of the following:—Worcester Pearmain, Queen, Cox's Orange Pippin, Colonel Vaughan, Wealthy, Cox's Pomona, Washington, Calville Rouge Précoce, Mabbot's, Braddick's Nonpareil, American Mother, and Ribston Pippin. Mr. J. Turner, gardener to R. W. Combe, Esq., Pierrepont, Farnham, was placed second, being only a few points behind the first. His varieties were American Mother, Cellini, Worcester Pearmain, King of the Pippins, Cox's Pomona, Claygate Pearmain, Emperor Alexander, Duke of Devonshire, Baumann's Red Reinette, Wyken, Cox's Orange Pippin, and Kerry Pippin. Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, was a good third, staging fine fruits of Cox's Orange Pippin, Wealthy, Herefordshire Pearmain, Washington, Ribston Pippin, Worcester Pearmain, Queen, Gravenstein, Blenheim Pippin, Peasgood's Nonesuch, King of the Pippins, and Cellini. Mr. T. Turton was placed fourth, and an extra prize was adjudged to Mr. F. Miller, gardener to J. J. Friend, Esq., Northdown, Margate.

The next class, for twelve dishes of cooking Apples, distinct varieties, was the most remarkable in the Show as regards the competition, for there were forty-four entries, and of these no less than forty exhibitors staged their fruits. The majority of the Apples were of great size, fine, clean, even samples, and this especially applies to Mr. Woodward's premier collection, which comprised the under-mentioned varieties:—Gascoigne's Scarlet, Emperor Alexander, Golden Spire, Warner's King, Stone's, Belle Dubois, Peasgood's Nonesuch, Cox's Pomona, Lord Derby, Brabant Bellefleur, Annie Elizabeth, and Flower of Kent.

The northern and south-western exhibits were included in the Council Chamber, reached from the Great Hall by the corridor, where the Grapes, Tomatoes, and some miscellaneous exhibits were staged. Cottagers, tenant farmers, amateurs, and gardeners were again represented here under the two zones, and in each of the eighteen classes provided in the schedule. The exhibits were not so numerous, however, as in the other section, and they were as regards the northern Apples, with few exceptions, deficient in both size and colour.

Passing the cottagers' and tenant-farmers' exhibits in both the northern and south-western sections, which, however, included some fine fruits that cannot be referred to this week, we come to the amateurs' and gardeners' contributions from the northern counties, and there the leading exhibitors were Mr. Crawford of Coddington Hall Gardens and Mr. Ingram of Belvoir Castle Gardens with Apples, and Mr. Hunter of Lambton Castle Gardens with Pears, all three showing extremely handsome fruits. In the corresponding classes of the south-western zone Mr. S. T. Wright, Glewston Court Gardens; Mr. T. Parker, Moreton Court Gardens, Hereford; and Mr. W. Iggulden, Marston Gardens, Frome, were the leading prizewinners, and some of these exhibits ran the Kentish Apples and Pears closely in point of merit.

Suburban fruits were not largely shown in the class specially provided for them, but Mr. Roupell took the lead with twelve dishes of capital Apples, Sir James Whitehead, Bart., being second with slightly smaller but very good specimens.

The Grapes were not very numerous, but some fine bunches were staged. For six bunches of black Grapes, distinct varieties, Mr. Allan, Gunton Park Gardens, Norfolk, was placed first, showing Black Hamburg, Gros Maroc, Alwick Seedling, Alicante, and Lady Downe's, good in size of bunch and berry, and of excellent colour. Mr. J. Reynolds was second with Lady Downe's, Alwick Seedling, Mrs. Pince, Black Hamburg, and Gros Maroc, especially fine. Mr. Iggulden, gardener to the Earl of Cork, Marston House, Frome, following with Black Hamburg, Gros Maroc, Gros Guillaume, Alicante, Lady Downe's, and Gros Colman, notable for their excellent colour. An extra prize was awarded to Mr. Goodacre for three bunches of Gros Guillaume and the same number of Gros Colman, much the largest bunches in the Show, but he was excluded owing to his not having the requisite number of distinct varieties.

In the white Grape class Mr. Crawford won first honours with good examples of Golden Queen, Muscat of Alexandria, Mrs. Pearson, and Royal Vineyard. Mr. Iggulden was second, showing Muscat of Alexandria, Foster's Seedling, Mrs. Pearson, and Golden Queen in capital condition. An extra prize was again accorded to Mr. Goodacre for extremely large bunches of White Tokay and Muscat of Alexandria.

The exhibits of jams, bottled fruits, and jellies were notable in one portion of the Council Chamber, Mrs. Smee of The Grange, Wallington, being very successful in three of the classes, taking first honours for admirable examples of well-prepared jams, jellies, and whole fruit. Amongst the non-competing exhibits Messrs. T. W. Beach & Sons had a

notable collection, well staged and effective. The other exhibitors are noted in the prize list.

Mr. J. Reynolds contributed twenty-four fine Melons, beautifully netted, for which a framed certificate was awarded. Messrs. J. Carter and Co., High Holborn, also sent a collection of fine Tomatoes, for which awards of merit were granted. The Tomato classes were not, however, well represented. Mr. J. Clarke of Farnham had thirty bunches of Grapes grown without fire heat, and was awarded a framed certificate. There were also several other meritorious exhibits, which must be passed for the present.

There was a large attendance of visitors on each of the three days, the galleries, rooms, and Great Hall being crowded from morning to evening. The following is the official list of the awards as supplied to us by the manager of the Show.

#### AWARDS OF THE JUDGES.

##### SECTION I.—COTTAGERS.—NORTHERN ZONE.

Class 1.—Three dishes of five cooking Apples, one variety in each dish.—First, 30s., John Wilson, Latham, Ormskirk. Second, 20s., John Cope, Hermitage, Rugeley, Staffordshire. Third, 15s., R. Heard, Freshfield, Formby, Lancashire. Fourth, 10s., J. S. Baron, Leyland, Lancashire.

Class 2.—Single dish of five cooking Apples.—First, 15s., T. J. Pullett, 82, Russell Street, Loughborough. Second, 10s., J. S. Baron, Leyland, Lancashire. Third, 7s., G. Berrington, Julian Road, Ludlow, Shropshire. Fourth, 5s., C. Leeson, Melton Road, Wrawby, Brigg, Lincolnshire; R. Weatherell, Skelton, Penrith, Cumberland.

Class 3.—Three dishes of five dessert Apples, one variety in each dish.—First, 30s., T. J. Pullett, 82, Russell Street, Loughborough. Second, 20s., J. S. Baron, Leyland, Lancashire. Third, 15s., J. Cope, Hermitage, Rugeley, Staffordshire. Fourth, 10s., R. Weatherell, Skelton, Penrith, Cumberland.

Class 4.—Single dish of five dessert Apples.—First, 15s., T. J. Pullett, 82, Russell Street, Loughborough. Second, 10s., J. S. Baron, Leyland, Lancashire. Third, 7s., J. Weatherell, Skelton, Penrith, Cumberland. Fourth, 5s., R. Weatherell, Skelton, Penrith, Cumberland.

Class 5.—Three dishes of other hardy fruit (which may include Pears, Medlars, Quinces, Nuts, Walnuts, Plums, Damsons, and any other hardy fruit not named above), one variety in each dish.—First, 15s., R. Weatherell, Skelton, Penrith, Cumberland.

Class 6.—Two dishes of five Tomatoes, one variety in each dish.—First, 15s., withheld. Second, 10s., C. Leeson, Melton Road, Wrawby, Brigg, Lincolnshire.

##### SECTION I.—COTTAGERS, SOUTH-WESTERN ZONE.

Class 1.—Three dishes of five cooking Apples, one variety in each dish.—First, 30s., John Copp, Brimley, Tainmouth. Second, 20s., Allan Williams, Bodenham, Leominster. Third, 15s., H. J. Hooper, East Coker, Yeovil. Fourth, 10s., Wm. Yates, 15, Whitefriars Street, Coventry.

Class 2.—Single dish of five cooking Apples.—First, 15s., A. Williams, The Moor, Bodenham, Leominster. Second, 10s., S. French, Marstow, Herefordshire. Third, 7s., W. Yates, 15, Whitefriars Street, Coventry. Fourth, 5s., H. J. Hooper, East Cottage, East Coker, near Yeovil.

Class 3.—Three dishes of five dessert Apples, one variety in each dish.—First, 30s., S. French, Marstow, Herefordshire. Second, 20s., A. Williams, The Moor, Bodenham, Leominster. Third, 15s., W. Yates, 15, Whitefriars Street, Coventry. Fourth, 10s., H. J. Hooper, East Cottage, East Coker, near Yeovil.

Class 4.—Single dish of five dessert Apples.—First, 15s., S. French, Marstow, Herefordshire. Second, 10s., A. Williams, The Moor, Bodenham, Leominster. Third, 7s., H. J. Hooper, East Cottage, East Coker, near Yeovil. Fourth, 5s., W. Yates, 15, Whitefriars Street, Coventry.

Class 5.—Three dishes of other hardy fruit (which may include Pears, Medlars, Quinces, Nuts, Walnuts, Plums, Damsons, and any other hardy fruits not named above), one variety in each dish.—No competition.

Class 6.—Two dishes of five Tomatoes, one variety in each dish.—First, 15s., W. Yates, 15, Whitefriars Street, Coventry. One competitor only.

##### SECTION I.—COTTAGERS.—SOUTH-EASTERN ZONE.

Class 1.—Three dishes of five cooking Apples, one variety in each dish.—First, 30s., Wm. Jacob, High Street, Petworth. Second, 20s., W. Waghorn, Allington, Maidstone. Third, 15s., Hy. Newman, 2, Ocklinge Road, Eastbourne. Fourth, 10s., J. Fasham, Northdown, Margate.

Class 2.—Single dish of five cooking Apples.—First, 15s., W. Jacob, High Street, Petworth. Second, 10s., W. Pulling, Hill Top, Tillington, Petworth, Sussex. Third, 7s., J. Ewer, Woolmer Green, Stevcnage. Fourth, 5s., W. Waghorn, Allington, near Maidstone, F. Marsh, The Bow, Nettlestead, Maidstone.

Class 3.—Three dishes of five dessert Apples, one variety in each dish.—First, 30s., W. Pulling, Hill Top, Tillington, Petworth, Sussex. Second, 20s., W. Waghorn, Allington, near Maidstone. Third, 15s., W. Jacob, High Street, Petworth.

Class 4.—Single dish of five dessert Apples.—First, 15s., G. Baynes, East Street, Rochford, Essex. Second, 10s., W. Jacob, High Street, Petworth, Sussex. Third, 7s., J. Sheppard, Wolverstone Park, Ipswich. (?) Fourth, 5s., G. Phillips, Moleside Cottage, Brookham Green, Surrey.

Class 5.—Three dishes of other hardy fruit (which may include

Pears, Medlars, Quinces, Nuts, Walnuts, Plums, Damsons, and any other hardy fruits not named above), one variety in each dish.—No competition.

Class 6.—Two dishes of five Tomatoes, one variety in each dish.—First, 15s., W. F. Breach, Gubert House, Eastbourne. Second, 10s., Jno. Mudge, 8, Kingswood Road, Penge, Surrey. Third, 7s., H. A. Grimrod, St. Stephens, Tunbridge, Kent.

##### SECTION II.—TENANT FARMERS, NORTHERN ZONE.

Class 7.—Six dishes of five cooking Apples, one variety in each dish.—First, 40s., J. Doncaster, Halloughton, Southwell, Nottinghamshire.

Class 8.—Three dishes of five cooking Apples, one variety in each dish.—No award.

Class 9.—Three dishes of five table Apples, one variety in each dish.—First, 20s., J. Doncaster, Halloughton, Southwell, Nottinghamshire.

Class 10.—Three dishes of five Pears, one variety in each dish.—No competition.

Class 11.—Three dishes of other hardy fruit (which may include Quinces, Medlars, Plums, Damsons, Nuts, or Walnuts, or any other hardy fruit not named above), one variety in each dish.—No competition.

##### SECTION II.—TENANT FARMERS, SOUTH-WESTERN ZONE.

Class 7.—Six dishes of five cooking Apples, one variety in each dish.—First, 40s., J. Davies, Bunhill, Bodenham, Leominster. Second, 30s., W. Morgan, Denmore, Hereford. Third, 20s., J. Hyde, Calderwell, Bodenham, Leominster.

Class 8.—Three dishes of five cooking Apples, one variety in each dish.—First, 20s., J. Davis, Bunhill, Bodenham, Leominster. Second, 15s., W. Morgan, Denmore, Hereford. Third, 10s., J. Hyde, Calderwell, Bodenham, Leominster.

Class 9.—Three dishes of five table Apples, one variety in each dish.—First, 20s., J. Davies, Bunhill, Bodenham, Leominster. Second, 15s., J. Hyde, Calderwell, Bodenham, Leominster. Third, 10s., W. Helyar, East Coker, near Yeovil.

Class 10.—Three dishes of five Pears, one variety in each dish.—First, 20s., J. Davis, Bunhill, Bodenham, Leominster.

Class 11.—Three dishes of other hardy fruit (which may include Quinces, Medlars, Plums, Damsons, Nuts, or Walnuts, or any other hardy fruit not named above), one variety in each dish.—No competition.

##### SECTION II.—TENANT FARMERS, SOUTH-EASTERN ZONE.

Class 7.—Six dishes of five cooking Apples, one variety in each dish.—First, 40s., R. Webb, Beenham, near Reading, Berks. Second, 30s., R. Cawthorn, The Grove, Fordham, near Soham.

Class 8.—Three dishes of five cooking Apples, one variety in each dish.—First, 20s., R. Webb, Beenham, near Reading, Berks. Second, 15s., H. Manser, Omers Farm, Northdown, Margate. Third, 10s., R. Cawthorn, The Grove, Fordham, near Soham. Extra, W. Bull, Bishops Ramsden, Billericay, Essex.

Class 9.—Three dishes of five table Apples, one variety in each dish.—First, 20s., R. Webb, Beenham, near Reading, Berks. Second, 15s., R. Cawthorn, The Grove, Fordham, near Soham. Third, 10s., W. A. Medhurst, Chobham Farm, Chobham, Surrey.

Class 10.—Three dishes of five Pears, one variety in each dish.—No awards.

Class 11.—Three dishes of other hardy fruit (which may include Quinces, Medlars, Plums, Damsons, Nuts or Walnuts, or any other hardy fruit not named above), one variety in each dish.—First, 20s., W. W. Bull, Bishops Ramsden, Billericay, Essex. Second, 15s., R. Cawthorn.

##### SECTION III.—AMATEURS AND GARDENERS, NORTHERN ZONE.

Class 12.—Twelve dishes of five dessert Apples, one variety in each dish.—First, 40s., Mr. J. Crawford, gardener to Colonel Thorpe, Coddington Hall, Newark-on-Trent. One exhibitor only.

Class 13.—Twelve dishes of five cooking Apples, one variety in each dish.—First, 40s., Mr. W. Ingram, gardener to the Duke of Rutland, Belvoir Castle, Grantham. Second, 30s., Mr. H. Price, gardener to B. C. Roberts, Esq., Oldfield, Upton, Chester. Third, 20s., not awarded.

Class 14.—Three dishes of five cooking, and three dishes of five dessert Apples, one variety in each dish.—First, 30s., Samuel Barlow, Esq., J.P., Stakehill House, Castleton, Manchester. Second, 20s., Mr. H. Price, gardener to B. C. Roberts, Esq., Oakfield, Upton, Chester. Third, 10s., not awarded.

Class 15.—Twelve dishes of five Pears, one variety in each dish.—First, 40s., Mr. James Hunter, gardener to the Earl of Durham, Lambton Castle, Durham. Second, 30s., Mr. William Ingram, gardener to the Duke of Rutland, Belvoir Castle, Grantham. Third, 10s., Mr. John Crawford, gardener to Colonel Thorpe, Coddington Hall, Newark-on-Trent.

Class 16.—Six dishes of five dessert Pears, one variety in each dish.—First, 30s., Mr. James Hunter, gardener to the Earl of Durham, Lambton Castle, Durham. Second, 20s., Samuel Barlow, Esq., J.P., Stakehill House, Castleton, Manchester. Third, 10s., Mr. John Crawford, gardener to Colonel Thorpe, Coddington Hall, Newark-on-Trent.

Class 17.—Six dishes of five cooking Pears, one variety in each dish.—First, 30s., withheld. Second, 20s., Mr. Jno. Crawford, gardener to Col. Thorpe, Coddington Hall, Newark-on-Trent. Third, 10s., not awarded.

Class 18.—Six dishes of other hardy fruit (as in class 11), one variety in each dish.—No entry.

## SECTION III.—AMATEURS AND GARDENERS, SOUTH-WESTERN ZONE.

Class 12.—Twelve dishes of five dessert Apples, one variety in each dish.—First, 40s., Mr. S. T. Wright, gardener to C. Lee-Campbell, Esq., Glewston Court, Hereford. Second, 30s., Mr. T. Parker, gardener to Mrs. Evans, Moreton Court, Hereford. Third, 20s., Mr. S. Kidley, gardener, East Coker, Yeovil.

Class 13.—Twelve dishes of five cooking Apples, one variety in each dish.—First, 40s., Mr. Thos. Parker, gardener to Mrs. Evans, Moreton Court, Hereford. Second, 30s., Mr. S. T. Wright, gardener to C. Lee-Campbell, Esq., Glewston Court, Hereford. Third, 20s., Mr. S. Kidley, gardener, East Coker, Yeovil.

Class 14.—Three dishes of five cooking, and three dishes of five dessert Apples, one variety in each dish.—First, 30s., Mr. S. T. Wright, gardener to C. Lee-Campbell, Esq., Glewston Court, Hereford. Second, 20s., Mr. W. Iggulden, gardener to the Earl of Cork, Marston, Frome. Third, 10s., Mr. Thos. Parker, gardener to Mrs. Evans, Moreton Court, Hereford.

Class 15.—Twelve dishes of five Pears, one variety in each dish.—First, 40s., Mr. W. Iggulden, gardener to Earl of Cork, Marston, Frome. One competitor only.

Class 16.—Six dishes of five dessert Pears, one variety in each dish.—First, 30s., Mr. W. Iggulden, gardener to Earl of Cork, Marston, Frome. Second, 20s., Thos. Parker, gardener to Mrs. Evans, Moreton Court, Hereford. Third, 10s., Mr. S. T. Wright, gardener to C. Lee Campbell, Esq., Glewstone Court, Hereford.

Class 17.—Six dishes of five cooking Pears, one variety in each dish.—No competition.

Class 18.—Six dishes of other hardy fruit (as in Section II.) one variety in each dish.

## SECTION III.—AMATEURS AND GARDENERS, SOUTH-EASTERN ZONE.

Class 12.—Twelve dishes of five dessert Apples, one variety in each dish.—First, 40s., George Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Second, 30s., Mr. J. Turner, gardener to R. H. Coombe, Esq., Pierrepont, Farnham, Surrey. Third prize, 20s., Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, Kent. Fourth, T. Turton. Extra, Mr. F. Miller, gardener to J. J. Friend, Esq., Northdown, Margate.

Class 13.—Twelve dishes of five cooking Apples, one variety in each dish.—First, 40s., Mr. G. Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Second, 30s., Mr. W. S. Skinner, farmer, Beresford, Boughton, Kent. Third, 20s., Mr. C. Ross, gardener to Col. Eyre, Welford Park, Newbury. Fourth, Mr. F. Bridger, Penshurst Place, Kent. Extra, Mr. A. Waterman, gardener to A. H. Brassey, Esq., Preston Hall, Aylesford.

Class 14.—Three dishes of five cooking, and three dishes of five dessert Apples, one variety in each dish.—First, 30s., Mr. F. Bridger, The Gardens, Penshurst Place, Kent. Second, 20s., Mr. T. Turton, gardener to Jno. Hargreaves, Esq., Maiden Erleigh, Reading. Third, 10s., Mr. E. H. Caterer, gardener to Thos. Arnall, Esq., Brookside, Heddington Hill, Oxford. Fourth, Mr. C. F. Prangnell, Holloway Gardens, Virginia Water, Surrey. Extra, Mr. W. Goaring, gardener to C. J. H. Tower, Esq., Weald Hall, Brentwood. Extra, Mr. A. Waterman, gardener to A. H. Brassey, Esq., Preston Hall, Aylesford.

Class 15.—Twelve dishes of five Pears, one variety in each dish.—First, 40s., Mr. Geo. Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Second, 30s., Mr. Chas. Blick, gardener to Martin A. Smith, Esq., Hayes Common, Hayes, Kent. Third, 10s., Mr. T. Turton, gardener to Jno. Hargreaves, Esq., Maiden Erleigh, Reading. Fourth, Mr. G. Trinder, The Gardens, Dogmersfield Park, Winchfield, Hants. Extra, Mr. T. Dunn, gardener to Sir F. W. Truscott, Oakleigh, East Grinstead, Sussex.

Class 16.—Six dishes of five dessert Pears, one variety in each dish.—First, 30s., Mr. Wm. Allan, Gunton Park, Norwich. Second, 20s., Mr. R. Smith, gardener to A. Cox, Esq., Presdales, Ware, Herts. Third, 10s., Mr. C. Blick, gardener to Martin R. Smith, Esq., Hayes Common, Hayes, Kent. Fourth, Lady F. Fletcher, Kenward, Yalding.

Class 17.—Six dishes of five cooking Pears, one variety in each dish.—First, 30s., Mr. G. Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Second, 20s., Mr. W. Dance, gardener to Mrs. Lowe, Gosfield Hall, Halstead, Essex. Third, 10s., Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Carshalton, Surrey.

Class 18.—Six dishes of other hardy fruit (as in Section II.), one variety in each dish.—First, 30s., Mr. J. Sheppard, Woolverstone Gardens, Ipswich. Second, 20s., Mr. G. Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Third, 10s., Mr. G. Trinder, The Gardens, Dogmersfield Park, Winchfield, Hants.

## SECTION IV.—NURSERYMEN AND TRADE GROWERS IN THE UNITED KINGDOM.

Class 19.—Collection of hardy fruit of all kinds, at the discretion of the exhibitors, each collection to cover not more than 15 feet run on tables of 3 feet width.—For these collections money prizes were not offered, but the Judges awarded for those which are meritorious the framed certificate of the Worshipful Company of Fruiterers. Northern Zone, certificate: No award. South-Western Zone, certificate to Mr. Henry Berwick, nurseryman, Sidmouth Nurseries, Sidmouth, and John Watkins, Pomona Farm Nurseries, Withington, Herefordshire. South-Eastern Zone, certificates: Messrs. G. Bunyard & Co., nurserymen, Maidstone; J. Cheal & Sons, Crawley; J. Peed & Sons, Streatham;

T. Rivers & Son, Sawbridgeworth; A. J. Thomas, Sittingbourne; Jas. Veitch & Sons, Chelsea; J. Laing & Sons, Forest Hill; J. Clarke, Albion Nursery, Farnham. Awards of merit: Balchin & Sons, Hassocks Nursery, Sussex; Paul and Son, Cheshunt; Wm. Paul & Son, Waltham Cross; A. Wyatt, Hatton, Middlesex; W. Tay'or, Hampton.

## SOCIETIES AND MISCELLANEOUS.

Framed certificates were also awarded to the British Fruit Growers' Association for 300 dishes Apples and Pears; to the Royal Horticultural Society, Chiswick, for fifty dishes Apples, Pears, and other fruits; also to Mr. Reynolds, Gunnersbury Park Gardens, W., for a collection of fine Melons.

## SECTION V.—AMATEURS AND GARDENERS IN THE UNITED KINGDOM.

The silver medal of the Fruiterers' Company and money prizes.

Class 20.—Six bunches of black Grapes, distinct varieties.—First, silver medal and 60s., Mr. Wm. Allan, gardener to Lord Suffield, Gunton Park, Ipswich. Second, 60s., Mr. George Reynolds, gardener to the Messrs. De Rothschild, Gunnersbury Park, Acton. Third, 40s., Mr. W. Iggulden, gardener to the Earl of Cork, Marston, Frome. Extra prize, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derbyshire.

Class 21.—Six bunches of White Grapes, three Muscats, and three other White varieties.—First, silver medal and 60s., Mr. John Crawford, gardener to Col. Thorp, Coddington Hall, Newark-on-Trent; second, 60s., Mr. W. Iggulden, gardener to the Earl of Cork, Marston, Frome; third, 40s., not awarded; extra prize, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derbyshire.

Class 22.—Six dishes of five Tomatoes, one variety in each dish. First, 30s., withheld; second, 20s., H. H. Hurnard, Esq., Gurney's Manor, Hingham, Attleborough, Norfolk; third, 10s., R. Hill, gardener to H. B. Bower, Esq., The Brae, Minchinhampton, Gloucester. Extra prize, Mr. C. J. Waite, gardener to Col. the Hon. W. P. Talbot, Glenhurst, Esher, Surrey.

## SECTION VI.—AMATEURS AND GARDENERS IN THE UNITED KINGDOM.

Class 23.—Collection of fifty dishes of fruit, to consist of thirty varieties of Apples and twenty varieties of Pears, five specimens in each dish.—First, gold medal, Mr. George Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone. Second, silver-gilt medal, C. Davies, The Mote Garden, Maidstone. Third, silver medal, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby. Extra, Samuel Barlow, Esq., J.P., Stakehill House, Castleton, Manchester.

## SECTION VII.—AMATEURS AND GARDENERS WITHIN A RADIUS OF SEVEN MILES FROM THE ROYAL EXCHANGE.

Class 24.—Twelve dishes or less of hardy fruit at the discretion of the exhibitors, one variety in each dish.—First, 40s., William Roupell, Esq., Harvey Lodge, Roupell Park, Streatham Hill, S.W. Second, 30s., Lady Whitehead, Highfield House, Catford Bridge, Kent. Third, 20s., Mr. F. Minchiner, Park House, Avenue Road, Penge, Surrey.

## SECTION VIII.—JAMS AND PRESERVES, TRADERS AND MANUFACTURERS.

Class 25.—Collections of Jams, Jellies, and Preserves of various kinds at the discretion of the exhibitors, made of British-grown fruit only, each collection to cover not more than 6 feet run on tables of 3 feet width.—Certificate, Messrs. Barnes & Co., Fishmongers' Hall Offices, for Bottled Fruit; The Britannia Fruit Preserving Company, Kelvedon, Essex, for Bottled Fruit; Messrs. Chivers & Son, Histon, Cambridge, for Bottled Fruit and Jam; Messrs. Beach & Sons, Ealing Road, Brentford, for Jam; Harrod Stores (Ld.), Brompton Road, London, for Jam; Goodhew & Son, Borden, Sittingbourne, for Jam.

## SECTION IX.—JAMS AND PRESERVES, COTTAGERS AND AMATEURS.

Class 26.—Four jars of Jam, distinct sorts.—First, 40s., Mrs. Smee, The Grange, Carshalton, Surrey. Second, 30s., Mrs. Emma Wood, 70, Gloucester Street, Warwick Square. Third, 20s., Mrs. Goodacre, Elvaston Castle Gardens. Fourth, 10s., Mrs. S. H. Goodwin, Mereworth, Kent.

Class 27.—Four bottles of old Fruit, distinct sorts.—First, 40s., Mrs. Smee, The Grange, Carshalton, Surrey. Second, 30s., Mr. John Taylor, Hoole Hall, Cheshire. Third, 20s., Mrs. Goodacre, Elvaston Castle Gardens, Derby. Fourth, 10s., withheld.

Class 28.—Four bottles of whole fruit preserved in syrup, distinct sorts.—First, 40s., Mrs. A. J. Budden, 65, Freshfield Road, Brighton. Second, 30s., Mrs. Goodacre, Elvaston Castle Gardens, Derby. Third, 20s., Mrs. G. T. Barnes, Stoodley, Tiverton, Devon. Fourth, 10s.—Not awarded.

Class 29.—Four bottles of Fruit Jellies, distinct sorts.—First, 40s., Mrs. Smee, The Grange, Carshalton, Surrey. Second, 30s., Mrs. Sheppard, Woolverstone, Ipswich. Third, 20s., Mrs. Nicholson, Sewardstone, Chingford, Essex. Fourth, 10s., Mrs. J. Macdonald, Clyde Villa, West Hill Road, Wandsworth.

## JUDGES APPOINTED FOR GUILDHALL SHOW OF THE WORSHIPFUL COMPANY OF FRUITERERS.

Section I. and II., Classes 1 to 11.—Dr. Fotherby, A. H. Smee, Esq., Mr. John Wright, and Mr. Geo. Paul.

Section III., Classes 12 to 18.—H. R. Williams, Esq., Shirley Hibberd, Esq., Mr. Joseph Cheal, and Mr. Lewis Castle, Hon. Sec. B.F.G.A.

Section IV., Class 19.—Sir James Whitehead, Master; Mr. S. T. Wright, Dr. Robert Hogg, LL.D., and Mr. G. Woodward.

Section V., Class 20.—G. J. Brocklesby, Esq., Upper Warden; Mr. Brooks. Class 21.—Mr. A. F. Barron, R.H.S.; Mr. Coomber. Class 22.—Mr. Geo. Wythes.

Sections VI. and VII., Class 23.—R. S. Mason, Esq., Rev. W. Wilks,

### STOKEHOLES AND BOILERS.

NOTHING connected with horticulture under glass is of so much importance as the heating appliances; hence the reason that all such should be found in perfect order ere the frosty nights are upon us, for then the work can only be very incompletely performed by reason of the hurry and bustle to have things in working order at the moment they are required. Moreover, when it is done at the last moment

FIG. 37.—SIR JAMES WHITEHEAD, BART.

F.R.H.S., Samuel Barlow, Esq. Class 24, Mr. T. Francis Rivers and Mr. George Bunyard.

Section VIII., Class 25.—Henry Martin, Esq., Renter Warden; Messrs. Fortnum & Mason, John Barker, Esq., Mr. W. Warren.

Section IX., Class 27.—Baroness Burdett-Coutts and Lady Whitehead. Class 28 and 29.—Mr. T. W. Beach.

Experts for awarding certificates of award.—Chairman, Dr. Robert Hogg; Messrs. T. Francis Rivers and Joseph Cheal. Secretary, Mr. George Bunyard. Superintendent of the Exhibition, Mr. Richard Dean.

in many instances has to be repeated or patched up before long; while another reason for having such work done when fires are not needed is because hot-water engineers are invariably taxed to their utmost later in the season. In those instances where fresh stokeholes have to be made this constitutes an important item, particularly in those districts having a deep subsoil of gravel overlying a stratum of clay, for not unfrequently the construction of the stokehole in such places is a serious item, not to say troublesome, and a continuous worry if they are not properly made in the first instance, and if the first chance is lost it is an expensive matter to deal with afterwards when the boiler has been

fixed in position. In this respect lucky are those that are not troubled with wet stokeholes, and those that are not have drawbacks in other ways to contend with. Damp or wet stokeholes are directly opposed to economical heating, and equally opposed are they to getting up a sharp brisk heat, for where the stokehole is damp the boiler and flues will be proportionately so, as no fire can burn freely or economically that first has to dispose of superfluous moisture such as this. I have in mind several localities where the making of a good stokehole is a rather expensive item, on account of the gravelly subsoil and the land water in winter time coming so near the surface, and I have known as much as a hundred pounds spent on a stokehole with a view to keep the water out, but which has ended in a complete failure, owing to some little whim having been very carefully carried out; but the pressure of land water is rather great in some districts in winter time, and will admit no whims or fancies being adopted, and nothing short of solid, honest work can stand against it.

Some six years ago in this neighbourhood (West Middlesex) a stokehole was constructed at nearly the cost just named, and by the adoption of a little fad has never kept the water out, with the result that it has proved necessary to put down three new boilers this season, one of the old ones (if a six-year-old may be termed such) having given way. Apart, too, from so sudden and serious an expense is the fact that the stokehole has been a great trouble in winter time to keep the water out, and in case of heavy rains could only be left four hours day or night without pumping, in order to keep the fires from being put out. Such a state of things all wise and prudent gardeners will endeavour to avoid, though at times even experienced men are deceived. A change of situation may and frequently does involve a variety of new experiences, and in this way I have known nurserymen driven by degrees from London to the suburbs to do battle with foes which to them did not exist because unseen. Many have taken out the hole for their boilers, and finding the base dry have never provided for the contrary. But let me advise all who sink stokeholes in gravelly districts never to trust to anything but a thoroughly watertight foundation, for no soils are more treacherous, and when the water comes in you have no further control in the matter.

The whole of the stokeholes which are sunk in this neighbourhood have to be made in strong cement concrete—*i.e.*, if they are to remain perfectly dry, and it is no unusual thing for 3 tons of best Portland cement to be used in one of them. The usual way they are constructed is this: In excavating, the soil is removed about 1 foot deeper than that required for the boiler and connections, and the bottom being perfectly dry a concrete is formed of four parts clean rough stones to one of cement, and being well mixed is placed at the bottom of the hole to the depth of 1 foot or thereabouts, leaving the surface level. This is allowed to settle for a couple of days, by which time it is quite hard, when it is surfaced over with clean sharp sand (river grit is the best that can be used) and cement, the proportion being much the same as that used for the concrete. Of this from 1 to 2 inches thick is floated over the surface, and again allowed time for setting. Such is the material, then, that invariably constitutes the stokehole bottom in this district, and while giving every satisfaction in keeping the water back, affords an excellent foundation for the boiler itself to rest upon. In constructing the side and end walls, cement and mortar are generally used together, the strength about six to one. With such a foundation below no footing course is employed, but as a precautionary measure against water forcing its way in at a weak point the first course of bricks is generally bedded on with neat cement; the bricks all being soaked in water as the work proceeds prevents a too rapid absorption ensuing. The walls are then carried up with rough joints, inserting on the reverse side a 9-inch pier here and there for strength. After the walls are completed they must be faced with sharp sand and cement to a thickness of three-quarters of an inch, composed of about four and one—some prefer to employ it at six and one—and finally skim over with neat cement. The former, however, makes an excellent job.

It is in such stokeholes as these that boilers are enabled to do their work and give satisfaction; not so, however, when handicapped as they undoubtedly are in damp or wet stokeholes; for in these they rust away at more than double the rate of fair wear and tear, particularly is this the case where the water is also allowed to remain in the boiler when not in use. Many hundreds of people have no alternative but to allow the water to remain in the boiler, simply because to empty the boiler would mean also to empty the pipes, a serious item where the water for refilling has to be carried in. Much of this may be avoided by inserting an extra pair of screw-down valves in the main near the boilers, for then the boilers alone could be emptied without interfering with the general run of piping; it adds but a trifle to the original cost, while the advantages accruing from such an arrangement are considerable.—J. H. E.

#### FALLING LEAVES.

THE falling leaf has been from time immemorial a theme of the poet and sentimentalist. Nor can any, save the colour blind, be coldly callous to the warm tints of beauty which diffuse themselves in autumn through the vegetable world. Nature's blush, as she puts off her robe of living green to doff her winter garb of poverty, merits our most respectful regard. Yet the notion that autumn is a time of general decay adds but another to the myriad popular fallacies which it is the function of science to dispel. The fall of the leaf, in fact, despite all

the tender moods of poetry and the sighs of the love-lorn, is a token and a result—not of death, but of life. The vital processes involved in the forming of the reddish-brown heaps that rustle and crackle around our feet in an October walk are as definite and wonderful as they are oft entirely overlooked.

To appreciate these we must learn, as science would ever teach us, to look beneath the surface of mere seeming into the heart of Nature's realities. Nor does the beauty of the distant landscape suffer any loss at all from our knowledge of the biological history of leaves and flowers close at hand, or of the grass beneath our feet. The case before us is one especially concerned with that constant struggle for existence, which our eyes are now opened to see going on wherever life is known. The acknowledged uncertainty of our climate detracts nothing from the general certainty of a definite and abiding difference in temperature between summer and winter. We who live in these "temperate" zones must accustom ourselves to variations and extremes of season changes which are wholly unknown in tropical regions; and the vegetable world, no less than the animal, has to learn to face these realities—in fact, plants are said to be even more sensitive to variations in temperature than animals.

Thus, from the rustle of the drying leaves, even before they fall, we hear once more the old story of that adaptation to environment which characterises all life. Trees, as well as men, must find how to endure through winter if they would luxuriate in summer. Spring's apparently new created vigour, and the seeming decay of autumn are, after all, only the natural steps whereby the transition from one adapted condition to another is gently broken. Plants are, moreover, in a somewhat worse case than animals, seeing that they have no power to transport themselves from one region to another. The genus, or even the species, may gradually migrate to pastures fresh through the kindly free portage of seed by wind or insects; but the individual plant or tree must live or die where it stands rooted in the soil. Without a root there is for it no life, but with the root no travelling.

In these days we know happily how easy animal locomotion permits the debilitated city merchant and the weary brain worker to seek bracing air by the seaside. The consumptive patient can prolong life by removing his bodily apparatus to Grand Canary or Madeira. Not so the plant. It must remain *in situ*. The tonic or preservative of change of clime cannot enter into its pharmacopœia. Whatever comes or goes it must face all in patience. It must adapt itself to environment or cease to be. This brief biological preamble is really necessary to our present study, for it conveys the essential principle of that whole phenomenon before us which most people so easily ascribe to death and gravitation. As a matter of fact the latter has next to nothing, and the former quite nothing to do with it. The falling is a mere trifle in the matter, and the process is entirely a vital one, the decay of the separated leaf being but a following accident, which may here be left out of account. Before the separation it is so genuine a case of *cuthanasia* as to refuse to be worthily called death. There are, at least, three distinct vital processes concerned in falling leaves, and these are based upon a definite principle which is nowhere in nature more wonderfully and instructively exhibited.

The principle is one of economy. The processes are those which effect (1) the avoidance of loss of valuable material; (2) the actual removal of an organ no longer profitable to the tree; (3) the protection of the tree from injury at the points of removal.

We will glance briefly at these, concerning ourselves now only, of course, with trees that we know are "deciduous." Everyone understands to-day how entirely the vegetable world is dependent upon chlorophyll. Thanks to the modern diffusion of scientific knowledge there are but few who have no idea of this fact. Not everyone, however, apprehends in this connection the supreme importance of leaves to the trees that bear them. That they are the true functional representatives of both lungs and stomach, is a fact only dimly grasped by very many of those who are "fond of flowers." Nor would they probably be disposed at first to admit that the leaf is a more highly organised structure than the flower, and of much more value to the parent organism. Yet so it is, though here we must assume rather than stay to prove. Now we are almost all aware that a certain temperature must be maintained in the animal stomach if digestion is to take place happily. The exception is apparently found in the case of those who flood themselves inside with cold water by way of commencing dinner. A better prescription for the sure acquisition of dyspepsia could hardly be invented. And the harm is not, as is sometimes thought, in the "dilution of the gastric juice," but in the reduction of the temperature. Thus Dr. Beaumont observed that the introduction of a single gill of water at 50° Fahr. into the stomach lowered its temperature upwards of 30°, and its natural heat was not restored for more than half an hour. And when a bottle containing food and gastric juice—easily digested at 100° Fahr.—was exposed to cold air, scarcely any digestion at all took place. So much for the practice—as sensible as any other item of fashion—of taking ice and iced cold water with a meal.

To return to chlorophyll. It is found that its important functions can only be discharged at a temperature varying between 6°—40° C., or 40°—90° Fahr. This manifestly requires direct sunlight, and an absence of cold winds, frost, &c. Now whatever doubts we may have concerning to-morrow's weather, we know well that between any autumn and the following spring we shall have more or less of the latter, with a great deal less of the former. Hence, very little, if any, assimilation could be carried on in the leaves by the chlorophyll, even if they hung on all the winter through. The tree, therefore, is very

much in the position of some of our modern houses of business, which during the season put forth branches at the various watering places, and do a thriving trade; but when winter drives custom away they find it pay best to withdraw their "staff" and stock, and close until the next season. It is no less plain that if all leaves remained *in situ* through the winter the balance of profit would turn against the parent tree instead of for it. Those which, during summer's sunshine, are the great source whence the tree draws its supplies and grows thereby would have themselves to be supplied whilst winter's cold prevailed. The cost of such nourishment and repair through the cold dark months would have to be subtracted from the proceeds of summer work. The tree would be by this so much the loser that plain principles of economy, working in nature according to the law of each organism's being, not by caprice as in human nature, demand their removal.

(2) But even this called-for removal is done economically. As the business firm which closes its season shops takes good care first to remove all valuables, so before the leaves are dropped off their respective branches, they are previously drained of their precious contents by processes which collect, transform, and transport them into persistent reserves in the parent organism. Thus, when winter once more melts into spring, and the vital mysteries of spring energy begin to express themselves in renewed growth, there are materials at hand to work upon, so that forces from within and from below may combine to produce the new buds whence are to come the twigs, branches, and leaves for another season's ingathering.

To describe in detail the draining processes referred to would require no little space. It must suffice here to note that it varies in different trees. In the Vine the form of the chlorophyll corpuscles is first destroyed, then the colour goes. In the Elder and Poplar the form and colour of these minute bodies melt away together after the earlier disappearance of the starch. In the Horse Chestnut all seem to go about the same time. The main point to be observed is that there is a definite emptying by means of colligative changes in the chlorophyll bodies. And it is to these changes, with their results, that the well known hues and tints of autumn are due. Thus (i.) in place of the real green and definite form of the chlorophyll corpuscle there are found in autumn leaves before they fall numbers of yellow oil drops, with still larger quantities of very small yellow granules. Their colour and substance are quite distinct from the etiolin which precedes the appearance of chlorophyll. They are, moreover, often embedded in red sap, whence arises the beautiful colouring which some leaves exhibit. (ii.) The means by which this economic work is done will be easily apprehended by all who bear in mind what is known as the fibro-vascular system. This is far too complicated to admit of detailed description here. Any good book upon botany, moreover—*e.g.*, Prantl and Vines—will supply the requisite information. Perhaps the best possible illustration of this system is found in those specimens of the "veins" of leaves, which are often obtained by maceration of the softer parts. These so-called veins when examined microscopically exhibit a series of tubes and vessels, the function of which is exceedingly difficult to define in detail, but which amply suffice to afford channels whereby food materials may be transported. It is not needful, therefore, to step aside here and decide the mixed puzzles of histology and biology. That (iii.) the emptying process referred to does take place can be shown to conviction in several ways. First, by micro-chemical testing, which shows that in the just fallen leaf there is scarcely a trace of starch, whereas the vigorous leaf abounds with it. Or, again, it may be demonstrated by testing carefully the chemical constituents of the ash of a leaf in full vigour, as compared with that of one naturally fallen. The presence in the former and absence in the latter of potash and phosphates is manifest and sufficient.

(3). The drained leaf-skeletons being then obviously of no service to the parent organism during the following six months, it is highly desirable that such should be removed. And in considering how this comes to pass, we are brought face to face with another of those marvels of anticipation in Nature which so deservingly astound us, and land us ultimately in life mysteries which laugh at all our theories of biology. What, for instance, do we know of the processes whereby, in the dark and under water, the eyes of *Libellula* are fashioned, with their 24,000 facets? We can only say, with Topsy, that we suppose they grow. And it is a no less remarkable work of Nature which underlies by anticipation the autumnal leaf-fall.

Long before the leaf shows any signs of dissolution there are internal indications of a coming change. These consist in the development of two new cortical features at the base of the petiole—*viz.*, periderm and the absciss layer. The latter is a layer of special cells—smaller, more rounded, and more loosely coherent than the ordinary cortical parenchyma—which is formed immediately beneath the base of the leafstalk. This is not always equally easy to make out distinctly, yet it may be plainly observed in the following:—*Aesculus Hippocastanum* (Horse Chestnut), *Robinia pseudacacia* (Bastard Acacia), *Populus dilatata*. If access to *Gymnocladus canadensis* (Kentucky Coffee-tree) be possible it is a specially suitable subject for illustration, and may be experimented on. Thus if strong leaves are placed in the dark or damp an absciss layer is formed at once under the base of the leaflet-stalks, so that in about two days the leaflets drop off on the slightest touch. Almost equally good subjects for investigation are *Ailantus glandulosa*, *Fraxinus excelsior*, and *Juglans regia*. For ordinary students the Horse Chestnut is best, both because of its easy accessibility and plainness of demonstration. When the absciss layer is fully developed the leaf drops

off with a very small amount of mechanical disturbance, thus especially through the force of the wind.

Sachs also interestingly states how temperature effects a similar result. The cells of the absciss layer being loose and rounded allow of the presence of more water than usual in their interstices. Thus with the first frosty nights of October a thin plate of ice is formed as a plane of separation from the parent branch, underneath the base of petiole. The well-known expansive power of ice acts here as elsewhere, consequently the leaf and its stalk are gently all but severed from the tree, and when the sun arises there is in its rays sufficient heat to melt the ice film, whence, in the morning, leaves drop off in great numbers.

(4) But the anticipative power of Nature is still more manifest when we consider the means adopted for prevention of injury at the points left bare by the removed petiole. Ordinarily, of course, the fibro-vascular threads which ramify through the leaf blade are collected together into a string or bundle, passing down the leafstalk and joining others in the parent branch or tree; but whilst the absciss layer immediately precedes the fall of the leafstalk there is much earlier a remarkable formation (on the inner side of where it afterwards appears) of what is known as periderm.

To make this intelligible to non-technical readers it must be pointed out as tersely as possible that plants require a "skin" as much as animals. They can no more afford to have bleeding spots without a protecting cuticle than we; hence they are provided with an epidermis, which in all trees and large plants involves more or less of cork. Generally the epidermis serves three functions—(1) prevention of excessive evaporation; (2) protection from injury; (3) strengthening. Here we are concerned with 1 and 2. It must be remembered that what is properly termed cork really involves several distinct layers of cells, histologically considered. The most important is a layer of actively dividing cells, known as phellogen or cork cambium, from which are formed externally cork proper or phellem, and internally phelloderm. The whole of these is included in the name periderm.

Now, it is of great importance that a corky shield should protectingly cover up for the winter the spots which are left naked by leaf-fall; but this can only be done from within. Nothing can grow out from the external cork to form a covering. As a matter of fact the periderm is formed long before leaf-fall, even whilst the fibro-vascular bundles are in full discharge of their functions, hence they pass right through this growing plane of periderm, and their broken off ends at first project when the petiole is actually removed, and it is to these the peculiar marks are due, which are seen in every "leaf scar."

When the leafstalk drops off, carrying the absciss layer with it, there is left behind at first apparently some greenish parenchyma cells on the outside; but the foregoing section shows that under this veil of parenchyma there is already prepared a layer of periderm, with its plane extending beneath the whole, except through the fibro-vascular bundles; but now it begins to develop through these also—that is, right across the roundish area left bare, consequently the outer cells just mentioned dry up, and ultimately a completely closed layer of cork is formed over the recently exposed tender spot; this increases somewhat in thickness until the branch is effectually protected against the coming storm and cold of winter, thus the tree remains adapted to its environment until once more spring draws on, and the daily increasing amounts of heat and light indicate that it is safe and profitable to put forth again buds and leaves. Then recommences that fixation of carbon with evolution of oxygen, whereby the tree itself is nourished and the healthful balance between the vegetable and animal world is so wondrously maintained. It seems to me impossible to attribute the marvellous inter-working of all these processes, reasonably to mere fortuity.—REV. F. BALLARD, M.A., B.Sc. (in *The Journal of Microscopy for October, 1890.*)

#### CHRYSANTHEMUMS IN THE SOUTH.

THE time is now fast approaching when growers will become anxious as to their chance of success at the forthcoming exhibitions; they will be comparing their plants with those of their neighbours to ascertain if they are likely to be too early or too late, too weak or too strong, and so forth. Each grower has fancies of his own in these respects; and as everyone has not the opportunity of inspecting for themselves the collections of plants belonging to exhibitors in the past, and would still like to know how their probable opponents are "looking"—a familiar term amongst growers of Chrysanthemums—I will note what I saw in a hurried run through some gardens a short time since.

Messrs. W. & G. Drover's nursery at Farcham, during the last few years especially, have devoted much attention to Chrysanthemums for large blooms, and with excellent results. Many new varieties have been tested to discover their worth for exhibition. The greater part of the space in the nursery is covered with glass houses devoted to the flower trade. The plants are arranged in blocks, the lines running north and south parallel with the glass structures, and one very long row of Japanese is arranged in front of a lean-to range of houses on the edge of the path.

The number of the plants grown this year for large blooms cannot be less than 700. Many others are cultivated to supply cut blooms in quantity later on. The plants look remarkably well, just the wood, foliage, and buds to produce blooms; and Mr. Adams, the grower, may well feel proud of his charge. The plants are tall and exceptionally strong, but the growth is well matured; the leaves have a bronzy hue from the base upwards, which betokens gradual ripening. The buds are what most experienced growers would call "about right," being "taken" at various times to prolong the display as late as possible. Very promising were Stanstead White, Sunflower, Madame Bacco, Boule d'Or, Etoile de Lyon, Mr. H. Cannell, Mrs. C. Wheeler, Baronne de Prailley, and its sport Carew Underwood, Belle Paule, and M. Bernard. I have never seen such stems as the first named had, over 1 inch in diameter, and quite brown. New Japanese were represented by Marvel, one of Délaux's varieties; J. Bourne, a reflexed Japanese, rich yellow, from Messrs. Elliot, Jersey; M. E. A. Carrière, Veil d'Or, Mrs. J. Clark, W. W. Coles, and Mrs. Alpheus Hardy. Much has been written against this novelty as to its manner of growth, but judging from plants of it here it is partly the fault of the cultivator. No doubt the rapid propagation to which it was subjected last season has much to do with its general weakness this season.

The incurved varieties are grown in masses of one sort rather than a number, merely for the sake of variety. Whole rows of the "Queen" family ranged from 7 to 8 feet high, of splendid proportions—Princess of Wales, Lady Carey, Prince Alfred, Novelty, and a capital stock of its sport Alfred Lyne, which is thought highly of here. The "Tecks" were full of promise, all the buds being "taken." One point in the appearance of the plants generally to which I attach much importance is the manner in which the flower stems were swelling; they were fairly "bulging" out a couple of inches or so below the buds. The size of the pots in general use was smaller than is usually employed, many being rather less than 9 inches in diameter; many plants also were growing two in one pot—of large size of course. By the appearance of the plants large pots are not a necessity. No doubt many of them derived assistance from the manner in which they are top-dressed. A collar 2 inches deep made of zinc is fitted inside the rim of the pot, and gives much more space, not only for additional feeding material in top-dressing, but provides space for a greater water supply.

#### ROOKSBURY PARK.

Until last year Chrysanthemums were grown here in but small numbers, but upon the change in the management it was not to be expected that Mr. N. Molyneux could rest content with a score or two of Chrysanthemums after the numbers grown at Swanmore Park, where he received his early training in this phase of horticulture. He has increased the number of plants here until he has now under his care the usual 500. Those persons who saw the plants in the early part of July would scarcely believe they were the same that are now to be seen, so wonderful is the change in their appearance since that date. Owing to the pressure of other duties at that time, the Chrysanthemums did not progress quite so well as could have been expected, but by close attention they now look as well as it is possible. Their wood is perfectly ripened, and cannot fail to produce blooms of high quality. The plants are arranged on each side of the kitchen garden paths, some running north and south and others east and west, which allows of some of the plants having the sun upon them the whole day. Some of the varieties, notably Madame C. Audiguier, Belle Paule, Carew Underwood, and Baronne de Prailley, have "run up" exceptionally tall; but they are stout also, and betoken fine flowers, judging from the manner in which the buds are swelling. Such early Japanese as Frederick Marrouch, Avalanche, Edwin Molyneux, Mdlle. Lacroix, George Daniels, and J. Délaux, by the manner in which they are opening their flowers give an indication of what is to follow in the later and better timed buds. The "Queens," of which there is one long row, promise right well, and so do the "Tecks." An opportunity here will be obtained of proving whether the new varieties, John Doughty and Mrs. S. Coleman, are an advance upon their parents or otherwise. The plants of these promise well. As Mr. Molyneux has a capital place to show off the flowers to the best advantage when they are fully developed—a large conservatory near the mansion—he will, no doubt, have a fine show of blooms, about which more may be heard later on.

#### HINTON HOUSE, PORTSMOUTH.

This is the residence of T. Edgecombe, Esq., whose gardener, Mr. Adams, has recently made himself renowned for the Chrysanthemums cultivated there under somewhat adverse circumstances. It is indeed a real town garden, being surrounded by numerous tall trees, that the quality of the plants to be found in this garden came upon me as a surprise, and not only shows what an accommodating plant is the Chrysanthemum, but proves what can be done under difficulties by a painstaking gardener. Mr. Adams grows about 300 plants upon the tall system, presumably for large blooms. Good "bushes," which are much prized here for conservatory decoration; and capital plants in 6-inch pots, mainly of single varieties, which are very effective when employed, as they are here, to hide the pots of the taller plants when in bloom in groups in the conservatory. Those plants intended for large blooms are strong yet not gross, have fully developed leaves and nicely ripened wood, the buds are swelling kindly, and promise to develop handsome flowers. Some finely half-developed blooms of Lady Lawrence I noted in one of the vineries, showing what a substance of petal this variety possesses when seen in good condition.

#### VICTORIA PARK, PORTSMOUTH.

Mr. Hatch, the Superintendent, labours well here to obtain success in the growth of the Chrysanthemum, which this park has of late obtained a name in the neighbourhood of this busy town. About 200 plants are grown on the tall system, half that number on the cut-down plan, which is found very serviceable here in the low-built houses in the park; about fifty bushes, and as many singles. At the Portsmouth Show Mr. Hatch invariably stages the best blooms of this section, the equals to which I have not seen anywhere, and by the appearance of the plants similar results may be again expected. Taken altogether the plants give promise of future development quite up to the previous standard, and perhaps superior to many found in places with much more convenience.

#### SWANMORE PARK.

In connection with southern Chrysanthemums a note on their appearance here will not be out of place in a passing notice on this subject. Although Mr. Molyneux has not taken an active part in competing during the last two years, nevertheless the number of plants grown have not diminished, more attention being given now to the growth of new varieties. No less than seventy are on trial this season from all sources. One variety, Bouquet de Dame, already gives promise of future excellence, it is very much after the style of Avalanche in formation, having flat florets, a full flower, a dull white in the earliest blooms, later ones promise a pink tint on the outer side of the florets.

Several new French and American varieties are under trial; one point which they possess and is very marked is their dwarf character, which is a decided step in the right direction. Experiments are being tried with a view of dwarfing the growth of some sorts, and proving whether it is possible to do this without depreciation of quality in the flowers. If success should follow in this respect a decided gain will be the result. The tall growth of many does far more to bring adverse criticism upon the method of culture now so largely practised than anything else. Many of the Queen family are now but 4 feet high, with their buds "taken;" although they are so dwarf the plants have not been subjected to the cutting down plan to attain the object in view. Etoile de Lyon, which was shown so well from here last year, is rather largely grown this season to further test its capabilities.—VISITOR.

#### THE FORMATION OF CHRYSANTHEMUM SOCIETIES.

Now that the number of Chrysanthemum societies is so much on the increase in all parts of the country, it seems a fitting time to discuss their formation and constitution. Frequently floral societies fail through supineness on the part of their promoters, who seem to have an idea that so long as they have a schedule of prizes printed they may then rest on their oars, and, like Mr. Micawber, wait for something to turn up; but, as a matter of fact, issuing the schedule is merely the commencement of the work, after which every move has to be thought out as carefully and thoroughly as if it were one's private business on which wives and families are depending.

Let us suppose that we are in a town of some size. First obtain a good representative working committee, who will not only attend meetings and give advice, but who have the success of the movement at heart, and will use every exertion to attain that end. Then comes that all-important person, the secretary, upon whom depends to a considerable extent the welfare of the society. Secure if possible an enthusiast who is independent of party clique—one who will work for the sheer love of the thing, and give such services as cannot be obtained by payment.

It is very essential to form a good backbone consisting of annual subscribers. This is one of the most onerous, but at the same time most important tasks in the organisation and maintenance of a Chrysanthemum society; frequently it is left to two or three, instead of being, as it should be, the business of every member of the committee. What is laborious for a few is comparatively light and easy for the many, besides which the interest in the society is spread over a wider and more varied area, this doubly ensuring its stability. With an ample list of annual subscribers the committee feel, to a certain extent, independent of the weather on the show days, and other vicissitudes, and are enabled to launch out more boldly than they would otherwise feel justified in doing; they therefore secure a better show, and thus please their subscribers and the public. In Chrysanthemum shows, as in most other things, it is very true that success begets success.

In the formation of the schedule, cater for all sections of growers, so far as funds will allow, and if either the society or some generous individuals offer some cups in addition to the money prizes—such cups to go to the employer—it will be an inducement to the latter to allow their gardeners to compete.

There is a growing tendency among Chrysanthemum societies to attach too much importance to cut blooms, and neglect other sections of the show; but though a fine display of cut blooms may gain notoriety for a show in the horticultural world, it does not do so to such an extent among the money-paying public, and public taste must be considered, or failure will inevitably ensue.

Firstly, in the cut bloom section offer a few large prizes to attract first-rate growers, whose exhibits will form object lessons for those less expert, inciting the latter to improvement, and thus to become eventually themselves among the mainstays of the show. Do not at first make the conditions too stringent. Remember that to stage, say, forty-eight blooms, half incurved and half Japanese,

all distinct, is not a light task. Rather let it be "not less than eighteen varieties of each," at any rate for a commencement, and in course of time the regulations may be made more strict. Encourage local talent by limiting a few classes to exhibitors residing within a certain radius. Then the amateurs employing no gardener should not be forgotten; at first their productions may not be of the first order, but amateurs are generally enthusiasts, animated with a desire to excel, and before long will doubtless take a more prominent position.

Not much need be said as regards plants, but by all means have a class for groups, as to the general public they are amongst the greatest attractions of a show. If interspersed with foliage plants the beauty of the groups is greatly enhanced, and it allows of the edge being brought down to the ground instead of being, as is frequently the case, a wall of unsightly sticks and stems. The shape of the groups must depend upon circumstances, but it will be found that ovals or half-ovals have a more graceful effect than circles or half-circles. If a rule is made that the groups shall be finished the day before the show, it will be of advantage to the exhibitors themselves, as well as to the officials.

Lastly, but by no means least, I come to classes competed for by ladies only, which I do not recollect having seen in any Chrysanthemum Society's schedule except that at Hull. Though these classes absorb a good deal of money, they are well worthy of it; firstly, by reason of the usually beautiful character of the exhibits, also on account of the interest they excite among the families and friends of the competitors as well as the general body of visitors. The classes which may be provided for in this section are dessert or dinner tables (the former are the prettier), bouquets, dress-sprays, baskets, and other arrangements executed with Chrysanthemum flowers and any kind of foliage. The size of the dessert or dinner tables should be not less than 8 feet by 4 feet, though, if space will allow of it, 16 feet by 4½ feet will afford greater scope. The tables should be ready for the use of the ladies on the day before the show, and if they can be shown by gaslight the effect will be more pleasing.

For judging, procure the services of the most experienced men available—men who are not only first-rate judges of this particular flower, but are also experienced in the actual work of judging; men whose names and standing will inspire confidence in the accuracy of their decisions and carry the Society safely through in the event of a serious dispute. Remember a man may be an excellent judge of a flower, but a very bad adjudicator if he is inexperienced in the work.

The committee must not fail to bear in mind, that to the general public there is a certain amount of sameness between one Chrysanthemum show and another; they will, therefore, do wisely to provide other attractions, in the shape of music, &c., which may be varied from year to year.—R. FALCONER JAMESON, *Hessle, Hull* (in "*Castle's Chrysanthemum Annual*.")

#### FRUIT FORCING.

**VINES.**—*Early-forced Vines in Pots.*—These always mark the advantage of bottom heat at starting by breaking well. Provided there is a bed about 3 feet deep and 4 feet in width, the pots may be raised upon bricks in pillar fashion, so that their rims are slightly higher than the pit edge, and so that the pots will be in the centre of the bed. Leaves being placed in to fill the pit, a gentle warmth will be afforded, and the roots will pass from the pots into the leaves. The temperature at the roots ought not to exceed 75°, and in the atmosphere 50° to 55° by artificial means, until the buds swell, then gradually increase it to 60° or 65° when they are breaking. Press the canes to a horizontal position to secure their breaking regularly. Damp the house and canes in the morning and afternoon. To have Grapes ripe in March the Vines should not be started later than the early part of November.

*Early-forced Houses.*—Vines that are to be forced to furnish ripe Grapes in March or early in April should be started by the middle of November. It is not advisable to start permanently planted Vines so early where there is convenience for growing some in pots, as it is a great strain on the energies of the plants through their having to make their growth at the dullest period of the year, and to rest at the hottest. The house after pruning should be kept cool and dry, and the outside border protected from autumn rains by covering them before the ground is chilled. A good covering of dry leaves, with a little litter to prevent the leaves blowing about, is an effective protection, and if tarpaulin is employed to throw off heavy rains and snow, nothing need be done to outside borders, and they need not be covered until they have been well moistened by the autumn rains, yet before they become soddened and much reduced in temperature. Where, however, fermenting materials are available they are a great aid in forcing operations, and especially so for placing inside the house to generate and maintain a genial condition of the atmosphere, without recourse to so much fire heat or sprinklings

from the syringe. The materials need not be used until the house is closed, but they will need to be thrown into a heap a week or ten days, previously turned and moistened if necessary. Three parts of Oak or Beech leaves to one of stable litter will give a more suitable warmth and ammonia vapour than all dung. Mix the materials well together when thrown into the heap, damping if dry, turning when getting warm, again damping if necessary, and when warmed through they are fit for placing in the house.

*Young Vines.*—When those have a disposition to keep on growing to a late period they may be checked by stopping the shoots moderately and facilitating the ripening of the wood by a high and dry temperature by day, shutting off the heat and keeping the ventilators open by night.

*Late Grapes.*—These will be thoroughly ripe if they were assisted in spring by fire heat, which is much preferable to having to maintain a forcing temperature after October comes in to secure the ripening of the fruit. In the latter case the temperature must not be less than 70° to 75° by day, and 65° at night, falling 5° through the night, allowing an advance of 80° to 85° from sun heat, continuing this until the Grapes are ripe—at least, until the wood is brown and hard. The fruit being thoroughly ripe—in which state only can the Grapes be expected to winter satisfactorily—and the wood being well matured, all sprays or laterals may be removed down to the main buds, ventilating freely on all favourable occasions. Fire heat will then only be necessary to prevent the temperature falling below 50°. To prevent dust settling upon the berries raking or sweeping must not be practised. Mats or clean dry straw laid over the inside borders will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. The outside border must be covered if the Grapes are to keep satisfactorily. Glass lights are best, wooden shutters good, and tarpaulin over dry bracken or straw answers well. A thick thatch of straw or bracken is very serviceable.

**MELONS.**—Water must be given very carefully, but the latest plants with fruit swelling must not be allowed to become dry at the roots. Keep up moderate moisture by damping every morning and at closing time, earthing the plants as required. Remove all superfluous growths as they appear, and maintain a temperature of 65° to 70° at night, 70° to 75° by day, up to 85° or 90° with sun. Keep the bottom heat at about 80°. Fruit ripening will be the better of a little extra heat and a little air constantly; a dry state at the roots, but not so as to cause the leaves to flag, accelerates the ripening process. To insure quality at this season—indeed, at any time—the foliage must be kept thin, all superfluous laterals being cut out, so as to afford the principal foliage the benefit of the autumn sun.

In manure-heated pits and frames no water will be required after this. Keep the frames well lined, admitting a little air constantly, which, with the fruits raised well above the surface of the bed, will do much to impart flavour. Any fruit it is wished to keep for a time should be cut when changing with a good portion of stem, and be kept in a dry airy room or house; or if wanted to ripen at once they may be placed in a warm house in the full sun, and they ripen better than in frames or pits devoid of artificial heat, and although they may not be as full flavoured as those ripened on the plants in a good heat, they are welcome additions to the dessert.

#### APIARIAN NOTES.

##### YIELD OF HONEY.

It is gratifying to learn from many persons, particularly on the west coast, that their bees have done well, and from some, "This is the first year we have had honey." I have been an eye-witness to many of the supers secured, and they could not be finer, the yield from each hive being nearly 30 lbs. Their owners are pupils of my own. Some bee-keepers near the successful ones referred to have not secured 1 lb. A Renfrewshire bee-keeper's hives have in some instances given three supers of the Stewarton type sealed out, and his bees are independent of feeding. Such cheering news, in what appeared a disastrous year, makes many of us hopeful of the future; but before September brought us bright and summer-like weather it was not, as we have been told, "the worst year for bees in the remembrance of man." Frequently in past years we have had to feed our bees during the whole summer to keep them alive, whereas this year no such thing was necessary beyond what was required to keep up the breeding for the Heather. That we have had excessive rainfalls with a very low temperature no one can deny. In addition to many worse years, I remember in 1844 that during July and August there was not a dry day, and

very few before and after these dates, while in June and July heavy showers of rain fell.

#### PREPARING FOR WINTER.

No time should be lost in getting all stocks prepared for standing the winter, well furnished with stores, defended from internal and external moisture, and secured from being blown over by the wind. An iron rod or wooden stake driven into the ground close to the hive and secured by a cord or tying wire is all that is necessary to prevent the highest hive from being blown down, and is at all times neat and handy.

#### VENTILATION.

My mode of ventilation is well known. The greater part of my plan appeared in the pages of this Journal about thirty years since, in the same part as Langstroth's method appeared, which was similar to mine, but dwelt principally on insensible upward ventilation, as essential to-day as it was then, even with our method of under ventilation. It is perhaps necessary to state these facts, because an apiarian has asserted that insensible upward ventilation is unnecessary since he has adopted the "3-inch eke" and not more than "1-inch entrance." If he would simply cover that eke with perforated zinc it would make the arrangement perfect; but why does he advise that plan to be adopted when a short time since he recommended wintering bees in hives with "wide entrances?"

#### A TEST.

Cover your hives well upon the top with dry meadow hay with or without the improved method of under insensible ventilation. Place close upon the top of the dry hay any waterproof material, and note how short a time elapses before it becomes thoroughly saturated with damp and mould. But try the opposite, and raise the waterproofing a little above the dry material, and then examine and see how dry and comfortable the bees must be beneath so dry a covering.

The perforated floor allows all debris to fall away from the bees, and rids them of parasites and moths, and the plan advised by Mr. McConnel of Annan of placing dry peat beneath the zinc prevents the condensed moisture on the floor rising amongst the bees on the slightest increase of temperature, keeping the bees comfortable, free from disease, and at rest during the most trying time of their existence, which ultimately proves profitable to those who cared for them. Neither relinquish the one form of ventilation nor the other, but let both go together, and you will all soon learn why there are so many different methods and opinions in the management of bees.

#### BEEES INTOXICATED.

This is a subject to which I intended to have turned my attention had the summer been a fine one, as I have frequently witnessed a half-dormant bee upon many different flowers, and have often observed humble bees in a sleepy state upon some that the hive bee visited with impunity. Writers often classed both sorts together. I am inclined to the belief that there is something else that stupefies the bees seen upon these flowers than the plant or flowers the intoxicated bees are seen upon. I have observed the remarks by Mr. S. Arnott at page 266. Although I grow two varieties of *Sedum Fabaria*, I have never observed an intoxicated bee upon any of them, but have done so upon the yellow flowered Stonecrops. The first mentioned are in flower with me at present. As soon as the stormy weather abates, and bees are again working, I will watch their proceedings upon these *Sedums*.

#### CURE FOR FOUL BROOD.

Formic acid, as a certain cure for foul brood, has been advocated for some time past, and discussed in various journals, and as might be expected with a new thing, old cures are condemned. We hope it will be efficacious. The Canadians have passed an Act of Parliament for the purpose of having the disease suppressed. It appears the foul brood inspector has been busy

for several months overhauling diseased colonies, and applying remedial measures under the Act, which authorises diseased colonies "to be destroyed by fire;" but he has not done so, finding it unnecessary, as he cures "by a simple hygienic process, and without the aid of the chemist, the druggist, or drug doctor." I am sure it will please none more than the Editor of this Journal to learn that "the method of cure is briefly the starvation plan, the only one in our large experience which we practised with success." Like other good things, and modes of good management, it appeared first in the pages of this Journal, and was known as the "purgatorial process" by "A Renfrewshire Bee-keeper," and as a further immunity from the disease our method of ventilation as described above. Sometimes much hangs by a little, and a very little stroke of mismanagement will ruin a whole apiary.

#### ROBBING.

A meddling bee-keeper commenced manipulating amongst his bees at an improper time for profit to himself, and although the best honey days of the season, and unlikely time for bees to rob, they set to it, and but for my presence some of my best hives would have been destroyed by the careless and imprudent act.

#### SHORT STORES.

No matter what time of year it is, colonies with short supplies of meat dwindle away until they are so much reduced as to be worthless. What appeared to be fairly strong colonies situated a little distance from my own at the moors, which I saw daily, from being under supplied dwindled gradually until they were either robbed out or unable to gather any honey when the weather improved. At a little distance from their hives dead bees lay in great numbers upon the stone dykes, the ground, and upon flowers. My whole experience is simply what I have taught, and which Art will neither forward nor frustrate. Nature and the weather are the controlling factors. So much has been said about swarming and its prevention that it is needless to repeat further than in some localities bees swarmed in September almost to a hive, the exceptions being those having young queens. But there are exceptions to this rule which I hope to explain in a future article.—  
A LANARKSHIRE BEE-KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Grapes Falling (R. H. R.).**—If you turn to page 261, our issue of the 18th ult., you will find a reply given to "J. S.," which appears exactly applicable to your case. Relative to your other inquiry, *Stephanotis* flowers are not in season now. On turning to the market list, published in May, we find the prices quoted 3s. to 5s. per dozen sprays.

**Retarding Chrysanthemums (Novice).**—We do not know that you can do better than carry out the practice you are adopting of placing the plants in the coolest position you have on warm days. The development of the blooms depends more on the weather than on "feeding," and unless the temperature is unusually high during the

present month, we think most, if not all, the blooms may be kept in good condition till the time you require them.

Two Peaches for Forcing (H. C. B.).—All points considered there are not, perhaps, two better Peaches for forcing than Hale's Early and Royal George.

Coe's Late Red (W. B.).—Dove Bank is an earlier and larger Plum; yours is Coe's Late Red, also known as St. Martin and St. Martin Rouge, which is thus described in the "Fruit Manual:—"

White Mould in Mushroom Bed (J. W. C.).—We suspect you have dried the manure too much. Read carefully what is said on this subject in the sixth edition of "Mushrooms for the Million."

Iceland Poppies (W. E.).—Sturdy plants, the result of thin sowing, or early thinning, usually pass the winter if transplanted early in firm well-drained soil.

Pruning Fruit Trees (St. Julien).—The advice given not to cut back the leaders of oblique cordon trees is sound. There is much more likelihood of the buds pushing fruitless growths if the leaders are shortened than of the stems being bare if not cut back.

Peach and Vine Border Making (J. R.).—The turf is a dark loam, evidently of vegetable origin, containing little silicious or calcareous matter. We should therefore mix 1 ton of quicklime with every ten cartloads of the turf when in good working order, mixing thoroughly.

clay, as finely divided as possible, and these thoroughly incorporated will form a suitable compost for the Vine in your case. Half a ton of crushed bones may be added to the fourteen cartloads and 15 bushels of charcoal, but they are not necessary, especially the bones, which are best given as dust at the surface, or along with wood ashes as advised for the Peach border, doubling the proportions.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores.

COVENT GARDEN MARKET.—OCTOBER 8TH.

MARKET quiet, with no alteration.

Table with columns: FRUIT, s. d., s. d. Items include Apples, Lemons, Melons, Oranges, Peaches, Plums, St. Michael Pines, Strawberries.

VEGETABLES.

Table with columns: s. d., s. d. Items include Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Cabbage, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Potatoes, Rhubarb, Salsafy, Scorzonera, Seakale, Shallots, Spinach, Tomatoes, Turnips.

CUT FLOWERS.

Table with columns: s. d., s. d. Items include Arum Lilies, Asters, Bouvardias, Carnations, Chrysanthemum, Cornflower, Dahlias, Eucharis, Forget-me-not, Gardenias, Gladiolus, Gypsophila, Lapageria, Lavender, Lilac, Lillium, Marguerites, Maidenhair Fern, Mignonette, Pansies, Pelargoniums, Pinks, Primula, Roses, Sweet Peas, Tuberoses, Violets.

had never even heard of Winter Oats, and had never seen a crop of Sainfoin, Green Maize, or Trifolium incarnatum. He is, nevertheless, a successful farmer, and why he is so remains to be told in some future paper.

It is not to be expected that pasture will be lightly broken up, but it is certainly a mistake not to have enough arable land to produce sufficient food for home consumption, and it will be well this Michaelmas to consider if any particularly poor and unprofitable meadow might not be ploughed early in winter, sown broadcast with Oats early in spring, and subsequently turned to account for any of the green crops we have mentioned. A crop of winter Tares might follow the Oats, and if they could be spared to be consumed in folds on the land by sheep, the land would be much improved, and the sheep would be withdrawn from the pasture to the advantage of the other live stock.

Co-incident with plans for the production of more food for live stock should be others for weeding out unthrifty animals, and their speedy disposal at any price. Keep no inferior animals, and pray do avoid overstocking. In most parts of the country green food and roots are so abundant and cattle are so cheap that the temptation to purchase a few more is very great. Better, far better, is it to keep well within our means, to have a surplus of food rather than a scarcity, and above all things avoid the annoyance and loss of having to part with live stock at a sacrifice from the food supply failing at midwinter.

WORK ON THE HOME FARM.

October has come in with high wind and pelting showers, and the cold air under the gloomy storm clouds was a reminder of the speedy decline in temperature which we must now expect. We are quite ready for the change, with the yards and lodges all in good order, plenty of litter at hand, and an ample store of winter food. Yet, according to the views which the ordinary Leicestershire farmer embodies in his practice, very much of our care and its attendant expense for the comfort of live stock in winter is as uncalled for as it is unnecessary. No matter how inclement the weather, his cows, aye and his young stock too, are out on the pasture with no other shelter than hedge or coppice affords. On most farms there is really no choice in the matter, for a hovel or two comprise the sum total of outbuildings. We do not hesitate to say both custom and practice are at fault here, and results prove us to be right; for we have heard a sad account of losses from a variety of ailments, and especially from abortion. Let us look into this matter closely. The Stilton cheese season will soon be over, butter making will follow for a few weeks, and then most of the cows will become dry and continue so for nearly three months, as they are timed to calve in spring about the beginning of the cheese season. The terrible exposure to which they are subjected in the depth of winter very frequently proves so exhaustive that abortion is quite a common thing, and yet it is termed a mystery.

Readers of the Journal who are managers of home farms, do all in your power to protect your stock from exposure to cold and wet, for both are pregnant with evil, and both cause much suffering. By all means see that all your stock have pure water, pure air, plenty of exercise, wholesome food, and, to crown all, efficient shelter. As the nights become colder gradually bring stock into the yards, till they are at length settled down for the winter. We have held upland grazing as much in reserve as we could for the sheep in winter, and doubt not our sheep shelters will tend as usual to promote the comfort and health of the flock.

REMARKS.

28th.—Fine and bright, especially in afternoon.  
 29th.—Brilliant early; overcast after 9 A.M. 30th.—Brilliant throughout.  
 Oct. 1st.—Overcast and squally, with occasional spots of rain in morning; showers from noon to 1 P.M., and at 2.50 P.M., otherwise fine and bright in afternoon and evening. 2nd.—Almost cloudless throughout, but colder.  
 3rd.—Brilliant throughout. 4th.—Cloudy early; unbroken sunshine from 8.30 A.M. The fifth consecutive week with a temperature above the average. Practically rain less, and with an exceptional amount of bright sunshine.—G. J. SYMONS.

MICHAELMAS THOUGHTS.

FARMERS of arable land have now to thoroughly consider their scheme of cropping for another year, and well will it be for them if fodder crops enter largely into it in view of reducing the area of land under corn crops, of reducing labour, and of increasing their flocks and herds. What to grow and how to do it become increasingly important every year, and it is most certainly the business of every farmer to make himself master of the best and latest information in a matter of such vital importance.

We are writing this article in a Leicestershire farmhouse very early in the morning, for we like rising with the lark, and we heard the rattling of the milk carts at daybreak, when the worthy farmer and his assistants were off to the milking on an outlying pasture. This farm is entirely in permanent pasture, not a single field is there under the plough. A couple of heavy carts, and a light milk cart, with implements for mowing and milking, is all the farming plant required out of doors. Indoors the making of most excellent Stilton cheese is in full swing, and it is to its production that most of the farm is devoted, and much care and skill are brought to bear upon the entire process from the making to the ripening of the cheese.

With the farm in permanent pasture results are much affected by weather, and complaints of a shortness of keep caused by a dry September are general in this district. On this farm most of the sheep are, in local phraseology, "mobbed out" by cows and cattle, and they have been sent away upon hired keep for awhile. Here it is that one sees the evil of laying down the whole of a farm to permanent pasture. Anything like useful auxiliary crops is then an impossibility, and yet it is a certainty that a fair proportion of such crops enables a farmer to keep more stock to combat a drought successfully, and to avoid sending away animals upon hired feed. It does more; it enables him to afford his stock a more liberal diet, so that cows give more and richer milk, and young stock are maintained in the very pink of condition, which is assuredly the most profitable. When this cannot be managed, the animals have to endure a series of trying alternations of abundance and scarcity. Calculations based upon a full bite upon pasture are upset by a drought, and then animals go short, and there is a falling off in condition and a serious curtailment of the milk yield. If stock is sold on such an emergency it is done at a sacrifice, which might have been avoided if there had been such crops as Lucerne, mixed seeds, Tares, Green Maize, and Cabbage to fall back upon. A field of Winter Oats harvested in July and prepared for use at once by thrashing the corn and chaffing the straw as it was carted from the field, would have given a fine store of most wholesome nutritious food to fall back upon all through the autumn. Mention of this to our Leicestershire friend brought to light the curious fact that he, though born and bred a farmer,

SCARCELY has the bustle of the fruit season subsided when attention is turned to the floral favourite of autumn—the Chrysanthemum, and active preparations are in progress for a still busier period. With a renewed and ever-increasing pleasure our eastern friend is welcomed, especially in towns, and it is difficult to imagine now what the horticultural November would be without the attractions it provides. It is not surprising that societies and shows devoted to the Chrysanthemum flourish and increase, for the plant stands without a rival in regard to the time of year when its flowers brighten our gardens, houses, or exhibitions. Comparisons are said to be odious, but the Chrysanthemum has often been compared with the Rose in popularity and variety, and has been generally entitled “The Autumn Queen” with good reason; but had the Chrysanthemum produced its flowers in June and July it would never have attained its present position in public favour, and would have ranked far below the acknowledged queen of summer—the Rose. Happily there is no need for rivalry, and we must be thankful to have the dullest and most depressing month in the year rendered bright and busy by the beauties and interest of Chrysanthemums in their numerous variations of form and colour.

Ample reason exists for the continued popularity of the Chrysanthemum in the fact just mentioned, and we find the number of societies concerned with it steadily increasing annually. There are not less than 100 societies in Great Britain now devoted to the encouragement of cultivators of the plant, and if to these are added the societies being formed in the Colonies, on the Continent, and in the United States (the latter of which are advancing rapidly), the total would probably be more than doubled. It is satisfactory, too, to observe that the majority of the shows held by these societies in our own country are well supported, and as regards the more important displays the attendance is considerably larger than is obtained at summer shows. Examples of this have been afforded both in the north and the south—at Hull and Portsmouth, where 10,000 persons have been admitted during the three days of the respective exhibitions. This is encouraging alike to the officials connected with the societies and to the exhibitors, and, moreover, a useful public service is being performed in drawing attention to so accommodating a plant for towns.

The increase of societies and the liberal prizes offered for plants and cut blooms, have done much to stimulate the culture of Chrysanthemums, for it has afforded many growers an opportunity to recover a portion of the expenses incurred in the production of exhibition specimens. Competition, too, excites a keener interest, and induces further efforts on the part of the defeated ones, thus tending to materially advance the cultivation. The result is that as the growers become more numerous every year the general system of culture improves, and the competition becomes keener at all the principal shows where the most substantial prizes are offered. It is not uncommon to find ten or twelve exhibitors in one cut bloom class now, when ten years ago it would have been difficult to secure three; in some cases indeed as many as twenty have staged in one class where only four prizes were offered. This leaves no chance for inferior productions, and the average character of cultivation has in consequence been raised far above that of a few years since. Perhaps there is some

truth in the statement that advance in size of bloom has been more marked than improvement in quality, but it applies with greater force to the incurved than to the Japanese. It is much more difficult to combine the two characters of size and quality in the former than in the latter, and unusually large incurved blooms are very apt to be coarse and deficient in the refinement so essential to their perfect representation. It must be admitted as a fact, which all florists will deplore, that the incurved varieties of Chrysanthemums are not advancing in the same degree as the Japanese, indeed it appears that some decadence has occurred. This can be partially explained by the consideration of two or three matters, one being that the Japanese are more easily grown to fair condition, they are more reliable, there are more varieties to select from, and they afford a greater range of colour variation. With so many qualities to recommend them it is not surprising that the Japanese Chrysanthemums have advanced so rapidly in public favour, outdistancing their older rivals.

This brings us to the consideration of an important matter outside all exhibition interests, and that is the value of the Chrysanthemum in nearly all its types for decorative purposes in conservatories or for homes. This has helped the Japanese varieties greatly, as they are of conspicuous value for grouping or general decoration, either as plants or cut blooms, and the demand of recent years has increased in this way so enormously that the importance of an easily secured supply at a dull season cannot be over-estimated. The uncommon and fantastic forms of the Japanese have rendered them favourites with many, and the general brightness of moderate-sized blooms better adapts them for ordinary floral decoration than most of the other sections. An exception must, however, be made of the single varieties, which are charming for vases and stands in almost any position, but they are not yet fully appreciated either by cultivators for home displays or by exhibitors, and it is regrettable that some of the societies do not give more encouragement to these varieties. I have seen stands of the “singles” set up both on the exhibition and private tables with the best possible results, the gracefulness of the flowers and their soft colours eminently fitting them for the work.

The season which will commence in the course of another fortnight will be an unusually busy one for all who are concerned with societies and shows, and many intending competitors are anxiously watching the progress of their plants and blooms. Much after success will depend upon the weather experienced in the next week or two, and cultivators are in some degree at the mercy of the elements. The season up to the past month was not satisfactory, the prevalence of wet sunless days tending to excessive, succulent, immature growth, by no means calculated to give good results. Happily the weeks of bright sunshine we have now had have aided greatly in correcting former evil influences, and the growth has ripened admirably in most cases. Judging by the collections that have come under my observation and by letters received from many correspondents, the tendency is, or rather was, to a somewhat late flowering, but this prospect has been changed as regards some of the hardy growers in the south by the high day temperatures experienced recently. Fearing a sudden severe frost in such clear weather many have hastened to house their plants, and the effect of a summer sun has been to forward the bloom buds rapidly. A continuation of this warm weather for another week or two will considerably disturb the calculations of several would-be exhibitors.

It is most difficult to generalise in such matters, however, and an example of this was afforded by a journey last week amongst a few of the noted Chrysanthemum gardens. In two establishments particularly, three or four miles apart, in the same county, and equally well situated, a great difference was noted in what may be termed “the time” of the buds. One series of plants could not have been less than a fortnight later than the other, if left unaided by special attention, but while in one case the grower will do his

utmost to hasten the due expansion of the flowers, the other will be equally engaged in retarding those under his care. In both instances there is danger of bad results, but the former is the more serious, and will need the closest attention to avoid mishap. When a cultivator has entered for a particular show, and he finds his blooms are late, he will probably, if a novice, become nervous, and in endeavouring to bring his blooms up to time will employ too much heat and keep his houses too close. This is a great mistake, and must inevitably lead to disaster, the flowers opening weakly, thin, and irregular, as well as being much more liable to that mysterious malady "damping" than if they expanded under cooler and more airy conditions. The Chrysanthemum will not submit to forcing, as usually understood, and I have in past years seen some most promising collections spoiled by undue haste in this respect. This is a note of warning that is not so likely to be needed this season as regards the southern growers, but there are some exceptions, as already mentioned, and nothing is ever gained by inconsistent hurry. "Hasten slowly" is a motto equally as well adapted for Chrysanthemum growers as it is for the affairs of life generally.

Retarding the blooms for the earlier shows will be difficult if warm bright weather continue, but it will not be so serious if the weather remains dry. In the metropolitan district the unwelcome fogs have already made their appearance, but the buds are not yet sufficiently advanced to be injuriously affected. As the blooms expand slight shade for an hour after the fog disperses has been proved to be beneficial in several instances that have come under my notice, and has assisted in preventing scalding, which is often the precursor of "damping." Another matter which assists in preventing blooms keeping well is having them too near the glass where they are subjected to sudden and frequent fluctuations of temperature, which must affect such a delicate structure as the florets of any section of Chrysanthemums, but especially those termed "large exhibition" varieties, which are most in danger of being grown too luxuriantly.

Some curiosity is being expressed as to the behaviour of the novelties which were brought into notice last year, and it will not be surprising if a few of them are a little disappointing, not from lack of merit themselves, but because they have been propagated so extensively that the constitution of the plants must have been weakened to some extent, and tests the skill of the best grower to produce good results from a weak cutting. A few blooms of Mrs. Alpheus Hardy have been seen, but not at their best, though it will probably appear in many of the exhibition stands this year. A pink sport or form of this is already talked about, and it is rumoured that a series of forms of the same type may be expected. Many will be desirous to see how the variety Robert Cannell preserves the characters it displayed when first shown, and the resolution not to send it out this year was undoubtedly a wise one. Really meritorious additions to the incurved list come, however, so slowly that they are the more urgently sought. It is doubtful if there will be many novelties from the Continent of sufficient value to supersede any of those already in cultivation, for every year it becomes far more difficult to obtain any advance on those previously sent out. The seedlings raised from seed saved in this country will be watched with much interest, especially as one of the parent varieties is Edwin Molyneux. Seedlings from imported seed are numerous, and may be expected to yield something good, though the prizes are necessarily small in proportion to the blanks.

Though all the principal societies are offering good prizes, and have provided comprehensive schedules, the great event of the year will be the centenary celebration by the National Society, and it is confidently expected that the available space in the buildings devoted to it at Westminster will be taxed to the utmost. The several other attractions of Conference, banquet, and conversazione, are also likely to induce a large gathering of Chrysanthemum admirers. At this and all the shows the officials charged with the arrangements have a formidable task to perform, and

a good deal of mutual forbearance and consideration is necessary to ensure a smooth execution of details. Exhibitors can help by sending in their entries early, and by staging their exhibits in good time on the morning of the Show. Having the arrangements completed promptly for the judges to commence at the appointed time is important, for more mistakes are caused in this and other matters by hurried work than in any other way. The calm men, whether show officials, exhibitors, or judges, invariably do the best work, and this opinion is formed on a wide experience amongst all classes. It is a character that is worth cultivating, especially by those who are just entering the Chrysanthemum ranks in either of the capacities named.—LEWIS CASTLE.

## THE CULTIVATION OF APPLES FOR MARKET.

[A paper read by Mr. G. Hammond, Brentwood, at the British Fruit Growers' Meeting, October 15th.]

It is not without considerable hesitation and diffidence that I appear before you this evening to read a paper upon this subject, knowing as I do that many older and abler men than myself have already dealt with it, and I can hardly expect to say anything new. Still I am aware that instruction in the cultivation of fruit as in other things must be line upon line, precept upon precept, here a little and there a little; and as it is possible that I occupy a somewhat different position, and therefore see things from a different standpoint from many who have preceded me, I hope it may not be altogether wasting your time in listening to what I have to say upon the matter in hand.

I wish it to be understood at the outset that my remarks refer to the cultivation of Apples for profit, therefore of course for market, as distinct from the growth of extra large fruit for the exhibition table, or the growth of a large number of sorts for the supply of the gentleman's table and kitchen for the longest possible time. With regard to the cultivation of the Apple one thing has been clearly proved by the recent Show at the Guildhall—viz., that this fruit can be grown, and well grown, over a very much wider area than has been generally supposed, and that although our esteemed Kentish friends may have led the van they can by no means claim a monopoly of either suitable soil or favourable situations for the growth of this fruit, but as in the case of the queen of flowers so also with the most useful of fruits. Although some soils and situations may be naturally better adapted than others, still with a wise selection of sorts, combined with careful and attentive culture, it is possible to succeed almost anywhere between the Channel and the Tweed; nor do I forget that most useful fruit is grown beyond the border, and some of our most useful kinds have come to us thence. Our Secretary also, and his companion in travel, have convinced us that the Apple at least can be profitably grown with care and attention even in the Emerald Isle, and we may hope that some of the labour hitherto spent upon the Potato may be diverted to the growth of the Apple, with the best results of bringing more money into the pockets, better health to the bodies, and greater comfort and contentment to the homes of our Irish friends.

Now the first point in the successful culture of the Apple undoubtedly is "the thorough preparation of the ground before planting." It is not enough simply to make a hole in otherwise unbroken ground just large enough to thrust in the roots, but the whole field, or portion to be planted, should be well stirred to a depth of not less than from 12 to 18 inches. I myself in this matter prefer not to bring up the subsoil to the surface, nor do I think it necessary to insist upon the ground being double-trenched. In my opinion a good preparation may be made at less cost, either with the "steam digger" or by a good ploughing with a subsoil implement of some kind following the plough, and breaking up the bottom of the furrow. This process should, if possible, be repeated, and if the second ploughing or digging can be done crosswise of the fruit so much the better. If the soil be poor a good coating of manure should be carted upon the land before the first ploughing; if the soil be in good condition this may not be necessary.

Having well prepared the ground, the next thing to be done is to mark out the lines in which the trees are to be planted, and at this stage it will be advisable to decide as to what shall be done with the ground—whether it shall be laid down with grass or planted with other fruits, as more room should be given in the case of orchards than in gardens, as I will presently show. The ground should be marked out both lengthwise and crosswise, and may be done either with a marking line and hoe or by an implement made for the purpose, such as may be often seen in the county of Kent. The trees will then, when planted, be equidistant, and straight in every direction.

The selection of the trees will follow next in order, and this depends, both as to the class of trees and also as to the kinds of fruit, upon the decision made as to the future of the ground. If for orchards, then standard trees only should be planted, and these upon the Crab or free stock, and of kinds that can be best recommended by the nurserymen for this form of tree. If the ground be intended for continual cultivation, then in my opinion the best form of tree is what is generally known as "half-standard." These are not so much exposed to the wind, are much more convenient for the gathering of the fruit, and can be grown in a greater variety of sorts, and also upon various stocks.

If the trees are to be well fed and cared for, then I think the best stock will be one of the freer-growing Paradise; these will, I think, best attain the desired end in fruit culture—viz., to grow a fairly good tree while also bearing a large quantity of fruit. But if what is known as the starving process is to be followed—i.e., plant the trees and take no further trouble about them—then by all means avoid every kind of Paradise stock, as trees upon the Crab, however vigorous, will be none too much so for such a method of treatment. I prefer to buy two-year-old untrimmed trees, and to make my own personal selection, so as to secure the kind of trees which I desire.

Having secured the trees (which should always be obtained from some well-known and established nurseryman) it is of all things most important that they be properly planted. First let the roots be seen to, and all injured ones cut back, and also all long straggling roots; then have a hole made—not deep, but of sufficient space to allow of the roots being spread out their whole length, not cramped into a heap, and then filled in with the earth made as fine as possible, so that it may shake well into the roots; then tread tolerably firmly with the foot, according to the state of the ground, and let the ground when finished be slightly higher round the trees than elsewhere.

If the trees be standards they will need immediate staking, or they will soon be displaced and injured by rough stormy winds. This should be done carefully and well, otherwise much harm may come to the trees by chafing against the stakes, a result which I saw some time ago in the case of a young plantation. If the trees be "half-standard," or two years old, such as I have described, they will not need staking, except in a few cases where the roots are few and feeble, and this not until some time after planting, at least such is my experience and practice.

We come now to a part of the subject upon which I am aware a great diversity of opinion exists, greater perhaps than in any other. I mean that of pruning. In this matter I wish to give my own experience and belief, in no dogmatic way, but with an honest open mind, willing to believe that others may have found some other practice to be preferable. It is my practice with trees such as are to be obtained generally, to cut back severely, the same season as the planting takes place, and I have rarely failed to secure good shoots with which to form the basis of the trees. Often these require nothing more in the way of pruning beyond the thinning of the branches and the removal of shoots that cross each other, but where the growth is weakly I cut back a second time. But when once a tree is properly furnished with an evenly balanced head, the best thing to do is to let it alone, that it may bear fruit, which it never will if the pruning knife is constantly used. In this matter the habits of the different varieties of Apples must be studied. Some will bear more pruning than others, while some apparently will not bear any.

With the approach of spring (or even at the autumn planting) the trees will be greatly benefited by some manure being spread round the stems of the trees, and remaining upon the surface. This will help to exclude the dry penetrating winds, and will also tend to encourage surface rooting, which is much to be desired.

I have thus dealt with the preliminary stages in the cultivation of Apples, as being the all-important time upon which the success or failure of after years to a large extent depends. If the land be intended for orchards, it will be better to defer sowing the seeds for at least two years, and planting the ground with other crops, such as Potatoes or roots, so that the trees may become thoroughly established, when the grass seeds may be sown and afterwards fed off with young stock or sheep, or if cut for hay care should be taken to replenish the soil so that the trees may not suffer.

In the case of trees upon land under constant cultivation much more may be done in the management of the trees where a tree shows signs of running to wood. If upon the Paradise stock it may be lifted and replanted, or if upon the Crab it may be root pruned with very good results, whilst those that appear weakly may be encouraged by stirring the soil and by surface dressing. So far I have said nothing upon the distances at which the trees should be planted. This will vary very much indeed, for while 30 feet by 20 may not be found too much for orchard standards of vigorous

kinds, 18 feet by 12 or 15 will be found ample for many sorts upon the Paradise stock.

It may be expected of me to give a list of sorts that I consider most profitable. I therefore append a list, not as being in any way complete, but rather as types of all classes to which they belong, always remembering that any one kind of Apple will not succeed equally well in all soils and in all districts, and that in making a selection regard should be had to the soil and situation, and to plant those sorts that seem best to succeed in each particular locality.

For kitchen use I should advise the following:—Early Julien, Lord Saffield where it succeeds, Keswick Codlin, Yorkshire Beauty or Red Hawthornden, Stirling Castle, Duchess of Oldenburg, Lord Grosvenor, Ecklinville, Jolly Beggar, Lord Derby, Grenadier, Small's Admirable, Warner's King, New Hawthornden, Stone's Apple, Tower of Glamis, Bismarck, Lane's Prince Albert, Bramley's Seedling, and Wellington where it succeeds.

For dessert or table use I would suggest the following—viz., Red Juneating, Mr. Gladstone, Yellow Ingestrie, Devonshire Quarrenden, on soil that suits it; Lady Sudeley, Worcester Pearmain, which has more money in it than any table Apple I have yet seen; Duchess's Favourite, King of the Pippins (if in orchard Blenheim Orange), and Cox's Orange Pippin. The last named will, I think, be generally found to answer best upon the Paradise stock.

I purposely pass over the cost of planting, which may be easily ascertained by reference to catalogues of fruit trees, and by a little calculation. I would like, in closing, to emphasise a few points. First, do not plant a few trees of a large number of sorts, but first ascertain what is best for each particular locality, and then plant a large number of those sorts. Give preference to those which can be gathered from the trees and sent direct to market. If possible plant a whole field, or at least several acres when planting. Avoid all patchwork business. Do not force growth too freely when young, but as the trees advance in age, and heavy crops have checked their vigour, let them be well fed and cared for, which expense and trouble they will well repay. Remember that "whatever is worth doing at all is worth doing well," but that it is impossible to do anything well without attention.

## HARDY FLOWER NOTES.

FROST is still holding off, but by the stormy Solway another enemy seeks to work havoc among our late flowers. Boreas seems to take pleasure in levelling to the ground our tall plants, and even our Crocuses and Colchicums are not safe from his rude breath. The stoutest stakes well driven into the ground too often prove powerless to uphold tall Asters and Chrysanthemums. In this light soil the stakes are shaken until they become loose, and the plant they are intended to support finds its stake affords but little aid. A few days' absence from home allowed the enemy full scope, and on my return I found some of my flowers in all manner of positions—some bent gracefully, others were at an angle which would have made the leaning tower of Pisa tremble for its laurels, while others (too proud to stoop or too weak to contend) grovelled in what should have been the dust, but was only damp earth. Fortunately some of these flowers seem to have a toughness of stem quite valuable, and a little work soon set them to rights. But after all, what is there to write of now? The dwarfier plants have mostly ceased to produce their flowers, Hypericum reptans being perhaps the best among the few alpine in flower. There is a charm about the bright green carpet of leaves formed by this little plant which endears it to me; but to see it bearing profusely its pretty yellow flowers about an inch across—yellow above and buff beneath—makes it doubly dear. Another long bloomer is *Potentilla nepalensis*, a plant which sends out long trailing stems, which produce bright cherry red flowers in great numbers for some months.

Bulbous plants still help to give variety to the garden. *Lilium auratum* is still in flower, but from its magnificent flowers it is a long stretch to look to the Crocuses and Colchicums. *Crocus speciosus* is now past, but its fine dark variety *C. s. transylvanicus* is still in flower, while *C. nudiflorus* and *C. zonatus* are blooming away. *C. Boryi* is going to disappoint me this year, but some others are coming rapidly forward. The double white Colchicum is very fine at present, and another pale but little species, *C. Bertoloni*, is in bloom with a few others. Some bulbs of *Hyacinthus azureus* (Musari) obtained last month have chosen to flower just now instead of waiting until their normal time, January or February. Newly purchased bulbs of many kinds which have been lifted and dried frequently act in this erratic manner. This Musari, or Hyacinth, for it is known by both names, is a very pretty little flower, of a colour which is well described by the specific name *azureus*. It is a little disappointing, however, to

find it anticipating its usual period of flowering, as this will likely mean its failing us in spring.

The Tradescantias are old-fashioned plants which are apparently again coming somewhat into favour. They are beginning to re-appear in good collections. I have grown several varieties, and seen some others, and had I to make a selection of four I would choose *T. virginica* (blue), *T. v. alba*, *T. congesta* (light blue), and one which I have under the name of *T. atro-rubens*, the brightest of all. They are almost continuous bloomers, and this damp season appears to have suited them well. Some of the perennial Sunflowers are still in full bloom, and looking over them I do not see any to equal at this season *Helianthus multiflorus maximus*. I much prefer it to the double varieties, not even excepting *Soleil d'Or*, the subject of so many criticisms. From all I have seen of it I feel bound to say that generally speaking it is distinct from the ordinary double *Helianthus multiflorus*, but that its value varies in different gardens. I have seen it very good, but last week I saw it in a Lanarkshire garden, and then it was very poor indeed, and not equal to the ordinary form. *Chrysanthemum uliginosum* is now in full flower, and despite its strong growing propensities is of great value as a succession to the other hardy species. A gardener of my acquaintance was in the habit of cutting these down when about 18 inches high, and this had the effect of reducing their height, although it also retarded the bloom. It is a little surprising in going through gardens to see so many worthless perennial Asters. I have seen but few I should care to add to my collection with the exception of a tall, large-flowered one named Robert Parker and one named *Galatella linifolia*, which is very bright, and is covered with flowers, which are, however, not of good form. I expect this is synonymous with *Aster linariæ-folius*. I have a considerable number of these Asters, some of which can hardly be considered among the *élite* of hardy flowers, but are useful for cutting, and help to give interest to the garden in dreary days. Too soon, however, we shall have to say with Bryant:—

“ on the hill the Golden Rod, and the Aster in the wood,  
And the yellow Sunflower by the brook in autumn beauty stood,  
Till fell the frost from the clear cold heaven as falls the plague on  
men,  
And the brightness of their smile was gone from uplands, glade, and  
glen.”

—S. ARNOTT.

### STRAY NOTES.

THE article by “I. M. H.” on Violets in the Journal of September 18th was an excellent one. He gave the solution to a problem in culture which seems perplexing to a novice:—viz., You must cut off all runners as soon as they form in summer and autumn, and yet your fresh plants in the spring must be young ones, and not the actual old crowns. The answer to this puzzle is that a few runners here and there are very short, and form plants that do not reach much beyond the margins of the clumps, and also some early cut-off runners, I think, form plants close in to the old stools. One naturally leaves these in cutting off the thin string-like runners round the plants, and in the following spring, when breaking up the stools for fresh planting, it is not difficult to choose these instead of the worn out centres. Cutting off the runners is very important; it is by constant care in this respect that great strong clumps are formed which bloom in extraordinary profusion nearly round the year. It is a troublesome job, especially late in the season, when leaves and flower buds, neither of which should be injured, are mingled with the runners all round the plants; but a neglect of it is one of the first causes of failure. A second, and more important fault, is the adding of manure in any shape; the ordinary groom and gardener thinks “a dressing of muck” will do good to anything, but it will ruin Violets unless you want fine leaves, and them only. I was rude enough the other day, in sending a large bunch of Violets by post to a friend, to say that I had not enclosed any leaves, as his own plants, I knew, could furnish them. And a third source of failure is the delaying till too late in the spring to make the fresh plantation; it should be done early in April as soon as the blooms are practically over and the new leaves begin to grow; and the plants should not be tucked in any odd place, but carefully planted in rows in a good open part of the garden. We very seldom block up the lights in the winter; they are altogether off if it is not actually freezing, or altogether on if it is. We aim at as much air as possible compatible with the warding off of frost. We have an Ivy screen close to the Violet frames, and use these leaves alone for Violets in the winter.

I think “T. M. H.” is right in keeping to the two sorts, Marie Louise and Comte de Brazza, and I have four times as many of the

former as I have of the latter, which are never so fine except in the leaf, and are of no use except in the spring. I see a Violet is advertised by a large firm which is “in every way to supersede” Marie Louise; but “as at present advised” it is the best Violet, and I for one do not want anything but the best. I picked a good bunch from my fresh plants about the middle of July. I made no note of the exact date, but it was before we had done Rose-showing. We have been picking ever since, and hope to do so till the beginning of next April. It is a grand large flower, and will take a lot of beating. The old Neapolitan Mr. Beachey recommends is a charming colour, but a very poor flower, and a great many are required to form a bunch. We do not want so many sorts of Violets, or Apples, or anything to the hindrance of the multiplication of the best.

Roses? Well, if we are exhibitors in the large classes we must have many sorts. The National Rose Society is of considerable service in pointing to the best, and in protection against duplicates; but even as it is, the mediocre varieties, which are too good to discard, and yet ought not to take up the room of newer and better sorts, are becoming rather a nuisance.

I see in the Journal that the Americans are starting a society to protect, as by patent, the raisers of novelties in horticulture—an excellent idea, especially if it will not only protect the raisers against the public, but also the public against the raisers, by insisting on everything patented being distinct and of merit. Is not that so, fellow students, of the merits of “Brown’s Bouncing Broccoli” and “Price’s Paragon Pea?”

How useful is an ever-ready supply of liquid manure! By putting solid manure into the soil you lose all control over it, whereas with the liquid you have your hand on the tap so to speak, and can put on the spurt when it is required. A neighbour’s Peach tree had no bloom to speak of, and no fruit at all; the soil was rich, and the shoots were thick, strong, and gross. My only Peach tree on a little bit of west wall is in poor soil; its shoots were small, thin, twiggy, and hard, but it had a fair amount of bloom, and set five dozen of fruit. They would have been very small, and perhaps a good many would have fallen off, but, commencing in July, we gave it two or three thorough drenchings of liquid manure, and had as fine a lot of Peaches as I could wish. It is the same with Tomatoes. I wish I had sold some of mine (I see inferior samples in the shop windows labelled at the same price per lb. as legs of mutton), or at least weighed all I have gathered out of doors. As I have not done so I will not estimate, for that is fallacious. I have at last found the disease on one plant, which I have carried away and carefully burnt. It is strange we have not had it before, if it is actually the same as the Potato disease, for that was upon us badly at an early period. I am trying to persuade the labourers about here that the best possible way to assist the Potato-disease is to do as they do, and always have done—viz., leave all tubers touched with it scattered about on the surface of the ground to rot gradually; but they do not see it, and as I cannot promise them they will have no disease if they do otherwise, they do not think much of my advice.

I have been reading somewhere an account of the fine gardens at Shrublands in Suffolk, as they are now, converted from the most rigid adherence to the bedding out system to a more natural and less artificial state of things. Tea Roses are extensively grown without winter protection, and the gardener, somewhat naturally, says that they are hardy. He is not alone in this statement. A professional Rose grower of note affirms the same in his catalogue, and the meaning of it is that his grounds and those at Shrublands are each on the top of a hill. If the gardener at Shrublands had to grow his Teas in the meadows below, by the river, as I have, he would, I think, alter his opinion. The difference is astonishing, and more than one would imagine, considering it is a matter of at most not more than 3° or 4° of temperature. The top of the hill, if you can, for Tea Roses, Apples, and everything that is likely to be injured by frost, but I do not think they thoroughly understood this in old times. We read of the sheltered valleys as being fruitful and flowery, and exposure was dreaded for half-hardy things, but we know now that low-lying valleys are dangerous, not because exposure to winds is necessarily desirable, but because frost is strongest and most hurtful in low localities, especially by the side of rivers, where there is much evaporation.

An article in last week’s Journal dealt with fish culture. It is true that this is much neglected, and perhaps also true, as some say, that more food per annum can be raised from an acre of water than from the same amount of land, but what I think is also overlooked is plant aquiculture. We ought to get more flowers, and more edible or useful vegetable produce from our water. Will not

some nurserymen make a more pronounced specialty of hardy aquatics? There are many amateurs who have more or less space occupied by ornamental water, but few who have any ideas beyond Water Lilies to grow in it. And what else is there for them to grow except, perhaps, Aponogeton? There are very few things, I fancy, of actual merit in the lists of hardy aquatics as seen in catalogues. We want something better than Butomus, Caltha, Sagittaria, or Typha, not that these things are not pretty or elegant, but that they are simply wild British plants. Have the waters of temperate climes in other parts of the world been really and thoroughly investigated for pretty flowers or useful or edible plants? For the latter purpose it would, I think, be hard to beat the common Watercress, but now that people are actually making bogs in their gardens for Irises, Orchids, and Osmundas, it seems a pity that true water plants, if there are any more good ones to be brought into notice, should not occupy more attention.

I suppose that, in an unusually warm and favourable autumn like the present one, the fly of the Carrot maggot manages to work in two generations in the year. My Carrots had rather a bad attack about midsummer, and I thought the crop was spoiled; but it seemed to pass away, the plants grew luxuriantly, and latterly only the worst spots here and there looked rather thin. On taking them up now (October 10th) every single root is infested, though the tops are still flourishing; the depredations have evidently only been commenced quite recently, and, I take it, these maggots are bred from eggs laid by the flies hatched two or three months ago. We ought to have worried those flies then if I had known how to do it; and the moral here seems to be lift your Carrots sooner if you have had the maggot in the early summer. I expect the Celery fly has profited in a similar manner by the fine weather of September. I saw its blisters on dock leaves in the roadside hedges early in June, and knew we were in for it before it appeared on the Celery. We ousted them out of that with soot, but just lately there has suddenly been another severe irruption on my plants. This is, no doubt, a second generation bred from flies which escaped on the plants or hatched in the hedges. So a fine early autumn seems to have its drawbacks as well as its advantages.—  
W. R. RAILLEM.

#### THE ROSE SEASON OF 1890.

It is related of Sir Walter Raleigh that when he was writing in prison his "History of England" a street row happened beneath his window which he himself saw; two of his friends came in to see him, and gave him an account of the transaction, but so different was their narration that he threw down his pen in despair, and said, "How impossible it is for me to give a correct account of things I have not seen when I cannot get a true account of that which has occurred under my own eyes." Some such despairing thoughts come across my own mind when I come to jot down my reminiscences of the past Rose season. I wished to supplement my own experiences with those of other Rose growing friends, amateur and professional, and wrote to many; but oh! the conflict of opinion and the diversity of experience. The points I was most anxious to obtain information about were general character of the bloom, mildew, orange fungus, and aphid; and it was quite clear from the replies I received that no general description would suit all and every case.

My estimate of the season has been formed from a tolerably wide experience. I have as judge visited many shows, and in going about during the season have also seen many gardens, both of exhibitors and non-exhibitors. I have endeavoured to regard it from the exhibitor's point of view, and also from that of the simple unambitious lover of the flower, who likes to grow flowers as good as those he sees on the exhibition table, but has no thought of "putting on the gloves" and entering into the fray. Every year gives fresh proof their number is increasing, and that their zeal is much increased by the magnificent proofs of successful culture they see at the Rose shows.

I must again record, as far as exhibitors are concerned, a disappointing season. In May everything promised well. This month, as well as the early part of June, was magnificent, growth was rapid, and except in some places frosts were absent; but then came a long spell of cold and wet weather. The early part of July was miserable in the extreme. Shows were held under the most depressing conditions. That of the National at the Crystal Palace was in striking contrast to that of last year, when a suffocating atmosphere destroyed everything. Happy was the society which secured a fine day, for on the first fourteen days we had in East Kent but one day without rain. The effect of this was very manifest, especially amongst the Teas, and it was not until later in the season that they came out in their full beauty, being much finer at

Birmingham than they were at the Crystal Palace for the same reason—excess of moisture. The smaller specimens fared badly, and very many "fell out" when the exhibition day arrived. This must ever be the case where a grower is dependant on a few plants, for however carefully he may shade there will be damage done by excessive wet, and hence we heard on all sides from the smaller growers of plants that they were out of the running altogether.

And yet with all these drawbacks it was a grand year for Hybrid Perpetuals, especially for the high coloured sorts. At every show there were magnificent specimens, which showed not only that the cool weather suited them, but that their cultivation was better known than it used to be, and I honestly think that if we could resuscitate the stands of bygone days we should be fain to confess that we had advanced. This has been most notably the case with Teas, and in a favourable season the immense strides made in this lovely class would be very clearly manifest.

As I have already said, there seems to have been a very unequal distribution of Rose plagues. One large and very successful grower tells me that he had to put on six extra men, who for three weeks did nothing but wash the trees; while another tells me he had no green fly, but was greatly troubled with maggot. In my own garden I never saw an aphid the whole season, and my plants never suffered so little from mildew. I fancy that the cooler weather checked it, and that its most productive cause is the alternation of heat and cold which we experience so often in the latter part of June and beginning of July. Very often, too, after the flowering season is over mildew sets in very severely, but with me it has not done so. Some of our Hop growers have a notion that when a garden once suffers severely from mould it never gets out of it, and I have seen acres in my own parish grubbed because of this persistent tendency, although in the very same field they do not suffer. I know, for instance, one Hop garden; there was a corner of it, about an acre, where year after year it was a failure from mould, and yet 3 or 4 acres of the same garden grew very fine Hops. Whether there was anything peculiar in the soil I know not, but Hop growers believe that the mould is in the ground, and attacks the plant from below. I find in many places the same conditions as in my own garden—an absence of aphides and mildew.

Those who regarded their Roses from a non-exhibition point of view had an immense enjoyment in them this year. Towards the close of July flowers came out in large numbers and of excellent quality; indeed finer flowers were gathered than perhaps in the earlier portion of the season. The absence of hot glaring sun kept many of them in flower a long time, just as it helped on wonderfully the staying powers of the cut blooms in the exhibition boxes; and then, what a glorious autumnal bloom we have had! Day after day during the lovely September weather we were favoured with grand blooms of such flowers as Marie Susanne Radocanachi, Ulrich Brunner, Gloire de Margottin, Violette Bowyer, &c., while Teas have been a perfect garland of flowers. Marie Van Houtte, Cleopatra, Ernest Metz, Souvenir d'Elise Vardon, Mrs. James Wilson, and Rubens have all been as fine as I have had them in the height of the season; but it has taken away the reproach from the H.P. of not giving us autumnal blooms, and even now (October 4th) there are numbers of buds which, with fine weather, we may hope for many flowers yet.

In one point of view the season has been a noticeable one—viz., in the production of new Roses. It is somewhat remarkable, more especially as they have been home-raised flowers, when it is recollected that the National, since its establishment in 1876, has previous to this year awarded only four gold medals, and that two of these have been for sports, and that this year it has awarded three gold medals. It may well be regarded as an "*annus mirabilis*." I need not say much with regard to these, as your correspondent, R. W. Raillem, has sweetly discoursed on them. I quite agree with him in thinking that Margaret Dickson will be the most popular of the three. Salamander is a form and colour which is always popular, but we have several Roses approaching it in both respects. Mrs. Paul is a grand addition to the Bourbons; but somehow the Bourbons are not in so much favour as the Hybrid Perpetuals; but Margaret Dickson, with its fine broad stout petals and its magnificent foliage, is sure as a very white Rose to be very widely grown, and will be largely exhibited when it comes into general cultivation, and its thick almost leathery foliage promises an immunity from mildew. There are some others which have laid the foundation of a good name, such as Miss Jeanne Dickson, Mr. James Brownlow, Cleopatra, Ernest Metz, and L'Idéale.

The National Rose Society has shown signs of increased vigour. Its exhibitions have been most successful; that at the Crystal Palace quite up to the average, and the provincial one at Birmingham probably the best the Society has ever held, while it has made a new departure in holding one for Tea and Noisette Roses at the Drill Hall on June 24th. This was due to a suggestion by Mr. T. W. Girdlestone, and although the Drill Hall (Baron Schröder's dustbin) was as unsuitable a place as could be found for these lovely flowers, an excellent Show was the result, the only regret being that so few persons came to see them. It was felt by all who were present that a most successful addition to the Society's operations had been made.

Probably the two most successful exhibitors have been Mr. E. B. Lindsell and the Rev. F. R. Burnside, the former the winner of the challenge trophy and a long array of prizes; the latter certainly the Tea Rose champion, having won the Tea challenge trophy, Mr. Boscawen's memorial cup, four silver medals, twenty-seven first, nine second, and two third prizes for Teas only—a most wonderful and

unprecedented record, which would have been impossible a few years ago, and which even now could only be made by one who lives in such a paradise of dwarf Teas as Mr. Burnside does.

It would be ungracious while writing on the past Rose season to omit to mention the loss the Rose world has sustained by the death of Mr. Henry Bennett of Shepperton, to whom we owe so many beautiful and valuable flowers. Heinrich Schultheis, Her Majesty, Mrs. John Laing, Princess of Wales, Grace Darling, Viscountess Folkestone, and Cleopatra testify to the zeal and intelligence with which he carried out his work. While doubting the value of his first introductions (and not one of them is in cultivation now I believe) I at the same time stated that I believed he was on the right track, and that we might expect much from his work. In this assuredly we have not been disappointed, and we can only regret that we are not to see any more fruit of his labours. As a raiser of new Roses he will ever be gratefully remembered by all rosarians.

Such are my views of the past, and now we are busy preparing for the future. Wood has so well ripened that many are even now talking of planting. Let us hope no disappointments await us in the future, but that all may be *couleur de Rose*.—D., Deal.

#### NEW ROSES.

I CAN supplement Mr. W. R. Raillem's interesting note on new Roses, as far as concerns Augustine Guinoisseau. I bought some very small but healthy plants from Mr. H. Bennett in the spring this year; they have grown well and flowered frequently, in fact wonderfully, considering what tiny plants they were in May. The flower is a fairly large one and richly scented, but I do not think it resembles much its parent La France, and it certainly will never be so good a Rose as La France. For all that I think it is worth having in a collection, as it seems to me a free grower, and may develop into a higher class Rose when well established.

Mr. Raillem's remarks about Lady Castlereagh I also endorse. It is a poor Rose, and it has not a single good characteristic to recommend it. I am glad to see my friend Mr. Benjamin Cant properly describes it as "form indifferent." It would be misleading to give it good name.—CHARLES J. GRAHAME, *Croydon*.

MR. RAILLEM'S remarks on Roses are always welcome and valuable. I venture to endorse most heartily what he says of Lady Castlereagh, in which Rose I fail to see a redeeming point. I was much struck with a midland grower's experience of Sir R. Hill reverting to Chas. Lefebvre. This year one of several plants of Sir R. Hill budded by myself has appeared in wood and flower to be exactly Chas. Lefebvre. I naturally concluded that I had by mistake inserted a bud of Chas. Lefebvre, but now I am inclined to believe that it is a case of Sir R. Hill reverting to the character of its parent. May I hope for any remarks of rosarians on this Rose, which, I must confess, with me is not a good grower, and singularly sensitive.—HENRY B. BIRON, *Lympne Vicarage*.

#### LOCAL ROSE EXHIBITIONS AND THE AMATEUR CLASS.

TAKING a review of the past Rose exhibiting season, I think the time has arrived when there should be something more definite as to the word amateur, as at present there seems to be no limit. There are gentlemen who grow and cultivate two or three acres of Roses; they compete in the amateur and open class against nurserymen at the same time and beat both, and yet they say they are amateurs. Again, there are growers who grow and cultivate not more than a thousand plants. Undoubtedly they are amateurs (according to the definition of Walker and Webster) because they cultivate their Roses without aid, but the large growers do not. But mark the difference of the two in a competition point of view; can anyone say that it is fair for these two amateurs to compete in the same class? I say decidedly, No, and maintain that anyone who cultivates more than half an acre of Roses ought not, especially those who cultivate two or three acres. If labour is employed in the cultivation of Roses, does not reason say, as a matter of necessity, it must be professional labour, or, in other words, one who has made it his business to practically understand Rose culture, and, as a matter of fact, partly or wholly lives by it? Such being the case, the word amateur is certainly out of the question if the exhibitor grows so large a quantity that he cannot cultivate them without assistance. Again, I ask, where lies his claim to exhibit as an amateur? My opinion is that there ought to be a class especially for large growers, but in the event of there not being sufficient funds to provide for an additional class, they ought to be classed with the nurserymen, with whom they are quite able to hold their own, according to their previous performances. I think it would be well for committees of local Rose exhibitions before they frame their schedules for the ensuing year to ponder over these observations, hoping they will see the injustice of the past, so that they may be enabled in future to frame them on a more equitable basis.—AN EXHIBITOR.

### GROWING AND SELLING FRUIT.

(Continued from page 310.)

#### NUTS.

A GREAT deal of money is often made from this fruit by the Kent growers, and it has an advantage over most other things, as it will grow best on warm dry banks on any soil containing limestone,

and will also grow in places that are too stony for other fruits to thrive to perfection. It is not advisable to plant too many of these north of London, unless the situation is warm and thoroughly exposed to the sun. In Kent they are often grown as an under crop among standard Apples, but further north they do not ripen in shady positions.

PLANTING.—The plants may be raised from cuttings, but are not so easily managed as Currants or Gooseberries, and take longer to reach a good size ready for planting out; it is therefore best to purchase them, as they are sold very cheaply in Kent. When planted in their permanent quarters they should be not less than 12 feet apart each way, and as they are five or six years before they bear much fruit Gooseberries or Currants are often planted between them, or the ground may be cropped with other things. Planting should be done between October and March, as for other fruits. Cost of planting an acre with Nuts only would be about £5.

CULTIVATION.—This consists mainly in keeping the ground clear of weeds, and digging it over with forks in the winter. Nuts do not, as a rule, require any manure, but it will do them no harm if applied to other crops growing among them. A plantation when once established will last for fifty years with proper attention.

PRUNING.—They are best grown on a clear stem not less than 1 foot in height, and trained with about seven main branches springing out evenly all round, so as to form a low spreading tree shaped like a shallow basin, not more than 4½ to 5 feet in height, the centre of the tree being kept open to give abundance of air to the crop. Every winter all strong shoots not required for extending the size of the tree are cut back closely to the main branches, leaving the small twigs, which are not more than 4 inches in length and about the thickness of straws; these bear small red flowers in spring, from which the nuts come in due time. A few of the catkins or male flowers should always be left where this is possible, or the flowers won't set, and no crop will follow. Branches of the wild Hazel with catkins in flower may be hung among the trees if they are scarce. They are pruned in Kent at from 4s. to 12s. per 100, according to size. Summer pruning is also of great service to them. About July all strong shoots should be taken out of the centre of the trees, and those springing up from the roots also. They are best twisted off with the aid of a small wooden mallet instead of cutting them, as they do not shoot out again so soon from the same place. Boys do this summer pruning in Kent at 2s. 6d. per 100 trees. Some fruit growers leave these strong central shoots until the autumn, when they can be used for making the sieves and half sieves for marketing the fruit, but it is better to remove them in the summer to prevent weakening of the other parts of the tree.

GATHERING AND MARKETING.—This crop is often gathered green, as soon as the nuts fill the shell, and they are then sent to market at once, but the bulk of the crop is left until September and October, and then come off the trees easily with a good shaking. They are then picked up by women and boys, and spread out in a dry room on a boarded floor about 9 inches thick, and are turned over occasionally to prevent moulding. They will keep like this for a length of time, but are generally all sent to market by the middle of December. Before sending them away they are looked over, and all small ones and black ones picked out. They are then sent off to market as required packed in "sieves" just as they grow with the husk on, and finished off at top as recommended for Apples. They fetch from 6d. to 1s. per lb. according to the market. An acre of trees in full bearing should yield in the best seasons from 15 cwts. to 1 ton, worth at an average price from £50 to £70, but it is only in very good seasons that a crop like this can be grown. Sometimes the frost in spring will destroy nearly all the crop by killing the flowers or causing the young Nuts to fall. Cost of gathering when ripe will be 20s. to 30s. per acre.

ENEMIES.—Squirrels and rats are the worst, and the only remedy is trapping or shooting them.

VARIETIES.—The true Kent Cob Nut is the best for general culture, being larger and more productive than the Filbert.

#### PLUMS.

If anything prevents Apples being grown as a "top crop," Plums will be the most profitable to plant in their place if the situation is not too liable to suffer from late spring frosts. Plums are rather uncertain croppers for this reason, but give a good return when a crop is secured.

PLANTING.—They may be planted as standard trees at 20 feet apart each way, and either Gooseberries or Currants grown between them; or if a mixture of all kinds of fruit is to be grown with vegetables, as explained further on, it will be best to plant them 30 feet apart each way, as for standard Apples; or if the situa-

tion is cold and exposed, bush trees may be grown instead of standards, and should be planted about 12 feet apart in the rows, and 16 feet between the rows, and will then allow a row of bush fruits being grown between them, or vegetables if preferred. They should be planted in the autumn as for other fruit. Cost of plants and planting per acre will be about the same as for Apples if planted at the same distances.

PRUNING is done on the same system as for Apples.

GATHERING AND MARKETING.—If the fruit has to be sent a long distance it must be gathered as soon as well coloured and before it gets soft, or it will not travel well, and consequently the returns will be small. They are generally sent from Kent in "half sieves," which are made to an even weight, and instead of putting straw or grass on the top nettles are generally used, as they are considered to preserve the bloom better. If only a small quantity is grown they may be packed for dessert fruit in shallow boxes, just deep enough to hold one layer, and are then sold at fancy prices by the box in the shops; but for ordinary fruit the price varies from 1s. 6d. to 3s. 6d. per stone, according to quality and scarcity of the crop. As much as 3 or 4 tons per acre might be grown in a good season, but half that quantity would be an average crop.

CULTIVATION.—Same as recommended for Apples.

VARIETIES.—Only the Victoria can be recommended for the small grower. Other varieties are more uncertain in cropping.

INSECT ENEMIES.—The "aphis" or "green fly" or "blight" is very troublesome in some seasons, and besides causing the fruit to be small through crippling the foliage it makes it very dirty, and also weakens the tree for another season's crop. The best remedy is to syringe the trees with softsoap water, 2 ozs. to the gallon, early in the season before much mischief is done.

#### DAMSONS.

These may be planted round the edge of the plantation, whether Apples or Plums are grown, as the "Cluster Damson," which is the only one recommended for general planting, is a small growing variety, and not likely to interfere with the other trees. In some parts of the country they will pay well for growing, but in some parts of Kent have already been planted too extensively to get a good market in London. They should be planted as standards about 16 feet apart, and require the same treatment as Plums in every other respect. The "Cluster" variety, called also the "Farleigh Prolific" and "Crittenden," is generally on its own roots. The young suckers that spring up should therefore be taken care of, and will eventually grow into bearing trees. This is the heaviest cropping and hardiest Damson known, and although not so good in quality as the other varieties it pays better for growing. The price obtainable varies very much according to the season, &c., but generally speaking is from 3s. to 10s. per half sieve (about 4 gallons). Price paid for gathering in Kent is about 3d. per half sieve. Price of trees and planting is about same as for Apples if planted same distances, but, as mentioned above, Damsons are generally planted about 16 feet apart. To plant an acre at that distance will cost almost double as much as Apples at 30 feet.

CULTIVATION, GATHERING, AND MARKETING.—Same as for Plums.

#### CHERRIES.

Except in a few places in Kent where plenty are grown in the immediate neighbourhood, this fruit is not recommended as a source of profit, as, unless grown in large quantities, it is impossible to preserve them from birds. They should only be planted where chalk or limestone abounds in the soil, as although they grow quite as freely in sandy and other soils, they fail to stone, and the fruit drops off in a small state. When they do succeed, enormous profits are sometimes made from them, £40 per acre clear of all expenses being no uncommon price. They are always grown as standards, planted about 30 feet apart each way, and the ground pastured underneath. It is, therefore, not a fruit adapted for the small grower and cottager, if he wants to grow vegetables and other things, as the Cherry objects to the soil being cultivated where it is grown. Most of the fruit-eating birds like Cherries, but starlings are the greatest plague in the Midland districts.

#### MISCELLANEOUS.

PEARS are not recommended as a profitable fruit to grow. As a rule they are too uncertain in their crop to pay the small grower a good return, except in parts of Worcestershire, &c., where the soil is peculiarly adapted for them. In such places they may be grown as standard trees instead of Apples, and require similar treatment.

RHUBARB may be grown between the standard trees, and will

pay well in some districts; but as a rule it is not advisable for small fruit growers to cultivate this, and not being a fruit, although used as such, its cultivation is not treated of here.

TOMATOES.—These pay well in warm districts in a good hot season, but as they cannot be raised without the aid of glass they are of no use to the majority of small cultivators; and although really a fruit, yet as they are used as a vegetable, their treatment would be out of place here.

#### ARRANGEMENT OF A PLANTATION FOR SMALL GROWERS.

As regards fruit culture the old proverb is quite true which says, "Don't put all your eggs in one basket." It is not a good plan to depend on one kind of fruit altogether for a crop, because in some seasons Apples, for instance, may fail to give any crop through late frosts killing the flowers, while Currants or Gooseberries may escape and give a good crop, and so on with other kinds. A mixed plantation is therefore best for the small fruit grower, as he cannot afford to wait a year or two without any returns; but for those who grow several acres it is best to keep each kind of fruit by itself as much as possible for convenience in gathering and cultivation. Thus half the plantation may be planted with Apples and Gooseberries, the other half with Apples and Currants, and so on according to the size; but the cottager and those cultivating less than one acre will be safer if they grow on the following plan, and can also grow vegetables and flowers for market or home supply at the same time.

No.1	†	.	Δ	.	Δ	.	†	.	Δ	.	Δ	.	†
No.2	.	.	.	.	.	.	.	.	.	.	.	.	.
No.3	.	.	.	.	.	.	.	.	.	.	.	.	.
No.4	.	.	.	.	.	.	.	.	.	.	.	.	.
No.5	.	.	.	.	.	.	.	.	.	.	.	.	.
No.6	.	.	.	.	.	.	.	.	.	.	.	.	.
No.7	.	.	.	†	.	.	.	.	.	.	.	†	.

The crosses represent standard Apples or Plum trees, or whatever is grown as a "top crop," at 30 feet apart; the dots Gooseberry or Currant bushes 5 feet apart; or rows 3, 4, 5 can be omitted, which will give 20 feet down the centre of each row for growing vegetables, corn, or Strawberries if any of these are required. If Nuts are likely to succeed they may be planted in the same row as the standard trees, as at Δ in row No. 1, leaving out the bushes close to Δ., planting the Nuts 9 feet on each side of the standard trees, and cutting out the intervening bushes when they get in the way of the Nut trees; or row No. 4 may be Raspberries, and the others Currants and Gooseberries with standard Apples, and the plan may be varied in many ways to suit individual tastes and requirements. If bush fruit are planted a row of Potatoes or Cabbage may be grown between each row of bushes for the first two years after planting, which will bring in a good sum of money if well attended to, but will cause extra expense in keeping the ground clean, as hand hoes will have to be used instead of horse hoes. If Strawberries are grown in place of rows 3, 4, and 5 one-fourth of the ground intended for them should be vegetables or corn each year that will come off early, so as to get the ground ploughed up, and the young Strawberry plants planted out by the end of August, and another piece of Strawberries that is three years old ploughed up ready for a crop of corn or vegetables, thus planting a quarter of the Strawberry ground afresh every year, renewing the old plantation of Strawberries once in three years in this manner, and giving the land a year's change of crop once in four years. Where manure is difficult to obtain, a crop of corn for feeding pigs might be grown for a change if vegetables are not required.

Around London large quantities of Wallflowers, Violets, and Daffodils are grown under and among standard fruit trees, and sometimes prove very remunerative. These might be grown under the standard Apple trees when they get too large for the bush fruit in rows No. 1, 2, 6, and 7; this will be about fifteen or twenty years after planting. Ordinary cottage gardens are too small as a rule to admit of any arrangement like this. Too often there is not sufficient room to grow the necessary summer vegetables and the winter's supply of Potatoes for the cottager's family; but standard Apples may be grown in such cases, and may be planted 30 feet apart each way. The lower branches should be cut off if they droop within 6 feet of the ground; it will then be quite possible to grow the usual vegetables if they are well watered in dry weather during the summer, and in very large gardens rows of Gooseberries or Currants may be planted 10 feet apart, and the trees 5 feet apart in the rows, and the space between may be used for growing vegetables and Strawberries, or if large enough the

whole garden may be arranged as in the above plan, leaving out rows Nos. 3, 4, and 5 for vegetable growing.—W. H. DIVERS.

(To be continued.)

## INSECTS OF THE FLOWER GARDEN.

(Continued from page 222.)

THERE is hardly a flower garden, however small, in which during the summer and autumn bugs are not to be found; that is, bugs proper, insects belonging to the order Heteroptera. Some of these are comparatively harmless, others are injurious to an extent, as they suck the juices of plants, and some may be accounted useful because they prey upon smaller insects. Our American friends apply the word "bug" to a variety of species, beetles included, but it belongs of right to the group allied to the familiar plant lice and scale insects, though somewhat different in structure and habit, certainly minor pests compared to those, and if larger in size fewer in numbers generally. These Heteropterous insects are active through all the stages of transformation, and when full-grown have four wings, the upper pair being partly horny, the under pair membranous and very delicate. The head is furnished with a proboscis, which is doubled down when at rest. In the predatory species this is short and strong. Behind the head is what is called a shield, or horny plate. Many of the species run with agility, some of them leap from place to place, and most of the land bugs give forth a disagreeable scent, which makes it undesirable that they should haunt flowers.

It is not needful to describe the aquatic bugs, which are rather numerous, singular sometimes in form, and a few of them possessed of the ability to walk upon the surface of water, snapping up little insects that may chance to settle there or fall in. Very few indeed of our garden bugs have received English names, so one is obliged to speak of them by their scientific designations. One little group, however, have oddly been styled "bishops," or "bishop's mitres," from the shape of the body, and some seasons they are abundant in orchards, especially amongst Cherry trees, to the annoyance of fruit growers. They are probably attracted to flower gardens by the fragrance of certain species. One of these "bishops," that puts in an appearance now and then, is *Asopus luridus*, the body of which is yellow and black, its head and the edges of the thorax dark blue, or bronzy blue. Akin to this is a common autumnal species we may see running over herbaceous plants, or airing itself on the topmost twigs of shrubs. It is named *Verlusia rhombea*, from the curiously widened and flattened abdomen. It is yellowish brown, with a dark brown head, and legs of a paler yellow, having small punctures all over the body. During the hours of sunshine it frequently flies briskly, making a hum nearly as sonorous as that of the humble-bee. A much smaller bug, *Stenocephalus agilis*, is also remarkably active and fond of the sun. This is yellow and brown, with a red spot on each shoulder. Though these insects certainly feed on the juices of plants, we seldom catch them in the act of sucking. Most of the bugs, it also should be noted, emit a secretion which is probably connected with the smell they give forth, and which makes them, I believe, distasteful to birds. One exception is a scarlet species, *Pyrrhocoris apterus*, rather scarce in Britain, but which sometimes occurs during autumn in little companies amongst fallen leaves, this throws off a scent that is mildly aromatic.

Perhaps the best known of the garden bugs is the *Pentatoma*, called *griseus*, the colour grey predominating, though it has some markings of black, yellow, and red. Many readers have doubtless picked these off flowers and leaves, and dropped them speedily on finding they exuded a fluid which left a brown stain upon the fingers. Another *Pentatoma* has been styled the Cabbage bug, from its haunting that vegetable. In this species, *P. rufipes*, the red colour predominates. It may be seen amongst the Cruciferous plants in borders. All the *Pentatomas* are believed to be partly carnivorous; some of them have been noticed in the act of piercing the skins of caterpillars. A funny, very active, but small bug, is that named *Cymus Resedæ*, from its occurrence on beds of *Mignonette*. It is only the fifth of an inch long, yellow, with a red head and shield. It lives probably by making tiny punctures in the stems of the *Mignonette*, and sucking its sap. Those also of the family *Capsidæ* are sometimes numerous. They are very soft-bodied, have long antennæ, and are of various colours, a few dark brown, almost black, and apt to conceal themselves.

My attention has been called this autumn to a familiar pest, allied to the bugs, but in the hemipterous order, and which spares neither fruit, flowers, nor vegetables. No season passes without its doing some amount of mischief. This is commonly known as the cuckoo spit, a singular name. I can hardly suppose it originated in an idea that the cuckoo produced the froth in which the insect envelopes itself, but it is more likely the allusion is to the fact that

this insect is abundant about the time when the cuckoo's cry attracts notice. "Froghopper" is another name given to it both in England and France, and though some have stated that the French fancied this foamy substance was the frog's secretion, I rather think this refers only to the leaping habits of the insect when full grown. Entomologists call it *Aphrophora spumaria*. Checked by the coldness and dryness of part of April, the cuckoo spit was late before it appeared in 1890, and, speaking generally, caused less annoyance than usual, but the cool character of the summer seems to have made it more injurious to some flowers by robbing them of their vital force. A friend reports that it was abundant upon some Roses, upon Dahlias and Chrysanthemums, and he inquires anxiously whether anything can be done to diminish its numbers in the future; for besides the harm that arises from this insect, it is very disagreeable to see our plants dotted over with frothy liquid, and get portions of it on our hands and clothes. Of course this envelope not merely screens the larva or grub from the sun's rays, which, owing to its structure, would otherwise cause its death on a bright day, but it must certainly protect this insect from various enemies, including birds. Of course the "spit" or froth is sap which the insect has pumped into its body, and then throws off again almost unchanged. The curious part of the matter is how the creature manages to fill these globules with air, for they are by this means prevented from drying up speedily. One of them, if examined by a magnifier, may be seen busy at the work of making bubbles or globules, having first filled itself with sap, and as each one comes out it is moved in position by the legs till the insect is sufficiently screened. Syringing or washing the plants clears off this froth, but unless it is effectual enough to bring off the grubs themselves, it does no good, as they can soon coat themselves again. Probably a solution of soap would be a useful application. This would prevent those moistened with it (and which have fallen) from returning to the plants. But the destruction of the females at breeding time is more important. There is little difficulty in shaking these from plants and shrubs, for when full of eggs they are sluggish, and thus easily distinguished from their more agile male companions, which can leap a surprising distance. In the perfect state *A. spumaria* is most abundant during August and September, a dull-looking insect of brownish hue, but should a moderate power be applied to the upper wings the surface is exhibited as a membranous network, covered with a host of circular dots placed in rows. If we could ascertain where the eggs are laid it might be easy to get rid of some of them in the winter, for they evidently remain unhatched from the autumn till April. I suspect they would be found near the earth upon the crown or lower part of the stem, from which afterwards the little grubs work their way up gradually.—ENTOMOLOGIST.

## AN OLD MULBERRY TREE.

A FINE specimen of the Black Mulberry (*Morus nigra*) exists at Brotherton Vicarage, Yorkshire, as a standard on the garden lawn behind the house. This aged tree is not only an ornament to the garden and venerable in appearance, but it annually produces abundant crops of delicious juicy fruits. As it appears to be a very general opinion that the Mulberry will not produce eatable fruit so far north as this, perhaps a short account of the tree is question will be interesting to the readers of the *Journal of Horticulture*. That the opinion is entertained that ripe Mulberries fit for dessert are only produced on standards in the more favoured southern counties of England is evident from the following quotations. Mr. Rivers, in his very instructive book, "The Orchard House," on page 166 makes a statement to this effect: "The cultivation of this fruit (the Mulberry) is entirely restricted to the southern counties;" and on page 477 of Thompson's "Gardeners' Assistant" it is said, "In the north of England this tree requires a wall with a warm aspect." There are exceptions to every rule, and, as has been already mentioned, the old Mulberry tree here seems to be an exception to the general experience.

The tree which forms the subject of this note was planted by the Rev. Charles Daubuz, a Frenchman, who left his native country in the year 1686 to avoid the persecution then directed against the adherents of the Reformed religion. He found an asylum in this country, and eventually became vicar of this parish in the year 1697. He died in 1717, so that the tree planted by him must be at present upwards of 173 years of age, computing from the year of his death to 1890. It is still a flourishing tree, and seems far from producing its last fruits. The present season, so adverse to all outdoor fruit generally, has suited it admirably. Never within the writer's memory, extending over a period of the past seventeen years, has this old tree produced such a crop of large juicy berries, with that deep purple-black colour indicative of perfect ripeness. It would be interesting to know whether another similar instance exists in

Yorkshire. The tree mentioned is growing on the magnesian limestone formation, and on somewhat similar soil as that at Milford and Sherburn, which produces the famed Winesour Plums, so much prized for preserving. The lawn on which the tree is planted is elevated and well drained, and the subsoil, as may be concluded, of a very porous nature. The water level, as calculated from the depth of the garden well, is about 54 feet below the surface.

Some of the finest berries, picked off the tree this morning, are herewith sent for the Editor's inspection. It is to be hoped, being fruit that will keep so short a time, that they will arrive in fair condition.—GEO. HASLAM.

THE WEATHER IN THE METROPOLITAN DISTRICT has been generally fine, but the morning and evening fogs have been rather dense, and in the immediate neighbourhood of London they have on several occasions continued nearly the whole day. Slight frosts have been experienced, and on Tuesday morning it was severe enough in several places to kill the Dahlias. Wednesday morning was brighter, but rain fell during the day.

— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The quarterly meeting of this Society was held at the Caledonian Hotel on Monday evening last, Mr. G. W. Cummins in the chair. The Society still continues to make steady progress, both financially and numerically. No death has occurred amongst the members during the quarter, and there is but one sick member on the funds. All members are invited to contribute to the convalescent fund, which was opened in July last. The fund is voluntary, and entitles members to a sum not exceeding 30s. for change of air after illness. Letters were read by the Secretary on various subjects, and the usual vote of thanks to the Chairman ended the meeting.

— THE LATE MR. ENOCH HARVEY.—Many were the expressions of regret when it became known that Mr. Enoch Harvey, head of the firm of Harvey, Alsop, Stevens, & Harvey, solicitors, Castle Street, Liverpool, had met with a fatal accident at the Mersey Road Station, on the morning of the 1st inst. Mr. Harvey was proceeding to business in Liverpool, and in crossing the line was caught by an express train and instantly killed. As an amateur Orchid grower Mr. Harvey was most enthusiastic, and in addition possessed a thorough knowledge of botany. Many were the fine plants he from time to time exhibited successfully at the Liverpool shows, even up to the Show held in August last, and his choice collection at Riversdale Road, Aigburth, was always worth a visit. He was Chairman of the Liverpool Horticultural Association for many years, and when the Royal Horticultural Society held their provincial Show at Liverpool in 1886 Mr. Harvey rendered most valuable assistance in many ways; and the twelve and six Orchids and a collection of fifty herbaceous plants contained many choice specimens, and formed a pleasing feature of the Show. His generosity and kindly manner will be sadly missed.

— CARDIFF GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The above Society opened their session on Monday, October 6th, in the Mission Hall, Castle Street. Mr. J. Clark occupied the chair. Seven new members were elected. Mr. Robert H. Pearson, of the Castle Gardens, then read a paper on "Gardeners and Gardening," which was well discussed. Any information relating to the Society can be obtained from Mr. H. Pettigrew, Hon. Sec., Castle Gardens, Cardiff.

— THE RECENT FRAUDS AT A WORCESTER NURSERY.—We recently reported the case of a dishonest time-keeper named Edward Ray, employed at the Worcester Nurseries of Messrs. Richard Smith and Co., of which firm the Mayor of Worcester, Alderman R. C. S. Carington, is the head. Ray entered fictitious names on his time sheets, from which the wages book was made up, and obtained upwards of £36 at intervals. The trial took place on Monday at the Worcester Quarter Sessions, before Mr. F. A. Bosanquet, the Recorder. Ray pleaded guilty, and it was stated on his behalf that he had been an honest and reliable servant till recently, when he had given way to gambling. He was

sentenced to six months imprisonment, hard labour being dispensed with in consideration of his previous good character.

— CHRYSANTHEMUMS IN LONDON.—The Finsbury Park Show was opened to the public on Saturday last, 11th inst., and the Southwark Park Show commences on Saturday next, 18th inst.; both will be opened daily at 10 A.M. for several weeks.

— MR. E. S. DODWELL.—Miss Dodwell informs us with deep regret that her father is critically ill with a severe attack of bronchitis, and Dr. Guinness orders absolute quiet and repose as the sole condition of his possible recovery.

— GARDENING APPOINTMENTS.—Mr. James Alexander has been appointed to succeed Mr. Alexander Blaikie at Revesby Abbey, Horn-castle. Mr. Charles Street, late foreman at Penrhyn Gardens, Bangor, has succeeded Mr. A. McKellar at Floors, Kelso, N.B.

— GLOXINIAS FIVE MONTHS OLD.—Mr. Allis, Old Warden Park Gardens, Biggleswade, submits a box of Gloxinia blooms cut from plants of which the seed (Messrs. Sutton and Sons' strain) was sown in May this year. They are excellent in size, texture, and colour. He informs us that the plants are vigorous and sturdy. This is a proof of what may be done in a very short time with these valuable plants.

— THE peculiar GLOXINIA figured and described in the Journal recently I have known for a long time. Many years ago when I had charge of the stove plants in Messrs. Veitch & Sons, Chelsea, they sent out two varieties distinct in colour just like that figured, one being marked with intense crimson, and the other blue. They were very peculiar and distinct, but we rarely meet with them in cultivation. The peculiar formation is, however, no beauty compared with the perfect forms and lovely varieties now in cultivation.—ALFRED OUTRAM.

— APPLE YORKSHIRE BEAUTY.—I am surprised to see that Yorkshire Beauty, better known in North Kent as Counsellor Apple, is not more frequently mentioned as a profitable variety for market purposes. During my stay here I have more than once been told by fruit farmers that this is one of their heaviest croppers, and when put on the market in December often realise fair prices, 10s. or 11s. per bushel being given for unsorted fruit. Although an Apple of the second quality, it seems very popular in London, and many old trees have been regrafted with it. Mr. Wright, in his essay on profitable fruit culture, places this variety at the end of his list of culinary Apples.—A. WELLS INGRAM.

— READING GARDENERS' ASSOCIATION.—The opening meeting of the autumn session of this Association was held at the British Workman on Monday evening last, under the presidency of Alfred Palmer, Esq. A large number of members were present. The meeting took the form of an Apple Congress, and some magnificent examples of Apples, of both culinary and dessert varieties, were exhibited. Mr. Turton staged fifty varieties, Mr. Lees and Mr. Dockerill each exhibited thirty varieties, and Mr. Pound showed several dishes of fine fruit. The specimens were clean and handsome, and all the leading varieties in cultivation were represented. Considerable discussion on details of culture took place, and much useful information was disseminated.

— EUCOMIS PUNCTATA.—I often wonder why this most useful plant is not more largely employed for decorative purposes and for greenhouses. We have several plants, among them two in 10-inch pots, each carrying four spikes or scapes from 2 to 3 feet in height, which have done duty in the house since July 15th, and with a little cleaning occasionally will continue to do so for another six weeks. If not pretty, they are attractive and grand for front halls, corridors, &c., where tender plants are soon checked and have to be replenished so often. It is a Cape bulb, of which there are about half a dozen species. They succeed well in a greenhouse temperature. I hope to give them a trial outside next season.—ALFRED SKINNER, *Highecliffe Gardens*.

— SEPTEMBER WEATHER IN NOTTINGHAMSHIRE.—The following summary of meteorological observations at Hodsock Priory, Worksop, Notts, is sent by Mr. J. Mallender:—Mean temperature of month, 58.6°. Maximum on the 8th, 76.2°; minimum on the 1st, 33.3°. Maximum in the sun on the 6th, 124.9°; minimum on the grass on the 1st, 27.0°. Mean temperature of the air at 9 A.M., 59.6°; mean temperature of soil 1 foot deep, 57.2°; fell below 32° on one night on the grass. Total duration of sunshine in month 142 hours, or 38 per cent. of possible duration; two sunless days. Total rainfall, 1.21 inch. Rain fell on

twelve days. Wind, average velocity, 8 miles per hour; velocity exceeded 400 miles on one day, and fell short of 100 miles on seven days. Approximate averages for September:—Mean temperature, 55.8°. Sunshine, 110 hours. Rainfall, 2.51 inches. A very fine and mild month. The mean temperature is higher than in any year since 1880; it is also higher than any month this year, except July, which was a few tenths higher. More sunshine was measured than in any of the previous nine years, except 1885.

— THE "KEW BULLETIN" for October contains an interesting paper on an edible fungus of New Zealand, which we reproduce at page 343. Chapters are also devoted to "Mexican Fibre, or Istle," obtained from species of Agave; "A Forest Plague in Bavaria," due to the attacks of a caterpillar (*Liparis manacha*) in the Pine forests, where it is estimated the loss to the revenue next year will be £40,000. 'Okro Fibre,' the produce of *Hibiscus esculentus*, is dealt with in a short chapter. "Cocoa-nut Butter," with a dissertation on "the Soil and Cultivation of Yoruba-land," concludes the issue for the present month.

— I HAVE read with interest the article by "J. H. E." on STROKE-HOLES in the Journal of 9th October, and have no doubt that the advice is on the whole sound. I think, however, I can suggest an improvement in the mode of building the walls. It is well known that bricks are to a certain extent porous, therefore water may pass through the full headers into the stokehole in spite of the inner facing of cement, which may get cracked and broken from various causes. Instead of the ordinary method build two distinct 4½ inch walls with no full headers, and with a space of half an inch between the two walls, which space fill in with cement as the work proceeds. This will keep any amount of water out, and the same system is equally efficient in building underground cisterns. Of course, cement should also be used between the bricks, or cement and mortar, as described by "J. H. E."—R. FALCONER JAMESON.

— MELONS AT THE BAGOT VINEYARD, JERSEY.—A visit to the Bagot Vineyard is always interesting to gardeners. Few men would have the courage to venture on so large a scale with one crop as an experiment as Mr. Bashford does; but courage, combined with sound judgment and perseverance, has made this vineyard famed throughout the world. The cultivation of the Melon to any extent at Bagot is quite a new venture; nevertheless, during last winter two new houses were erected for this purpose. One of them is 300 feet long by 14 feet, the other is 1178 feet long by 14 feet wide. This is, I believe, the longest house yet built for Melon growing. At the time of my visit on September 8th the crop of fruits (9000) had been cleared from these two houses, and winter Tomatoes planted that were just setting fruit; but another house of later-planted ones was in full bearing, and perhaps it is the most extraordinary house of Melons ever seen. It is a lofty span-roofed house 780 feet long by 45 wide, from which the Vines were removed last winter. When the Vines were cut out Peas were sown, and a grand crop was cleared in April. Then the work of preparing the house for the Melons was begun. The Melon crop was not the only object in view, as the house was to be planted with young Vines at the same time as the Melons were planted, and 4 feet only was reserved for them along each side of the house. The work of preparing the plants was commenced on May 3rd by sowing the seed in a vinery where a little fire heat was given; but beyond this on no occasion has any fire heat been used. By the first week in June the plants were strong and the pots full of roots, so the work of planting was begun. The plants were placed out in rows the full length of the house, 3 feet 6 inches apart, and 2 feet 6 inches between the plants in the rows. From this time until the plants were in full bearing, and many of the fruits had been cut, I did not see them; but at the time of my visit the appearance of the house was striking, and would doubtless startle many English gardeners whose experience of Melon-growing is limited to a two-light garden frame or a 12 feet house. All the plants have been grown as single cordons tied to an upright stake, and grown to the height of 6 feet or 7 feet, and stopped when the required number of fruits were set, the plants being allowed to carry from two to six fruits each, according to the sorts and the strength of the plants. Few varieties are grown, as Mr. Bashford does not grow much of anything until he has proved its worth. The bulk of the crop is from one of his own raising, and has fine netted fruit, much like Eastnor Castle. Taking the crop all through, the fruits are above the average size, many of them weighing from 5 lbs. to 7 lbs. each, and the largest have turned the scales at 8½ lbs.—HERBERT PARKER, *Jersey*.

## A ROYAL PRESENT OF FRUIT.

AS showing in the best manner available the appreciation of the Fruiterers' Company and of the Executive Committee of the Guildhall Fruit Show of the patronage graciously bestowed on it by the Queen, Sir James Whitehead, Bart., Master of the Company, proposed, with the permission of the exhibitors, that specimens from the different sections of the Show should be sent to Her Majesty. The proposition was at once accepted, and experts were appointed to select the dishes. On those chosen was placed the following printed notification:—

THE Master, Wardens, and Court of Assistants of the Worshipful Company of Fruiterers desire that this exhibit should be reserved for presentation to

Her Majesty the Queen.

Should this wish be complied with the Name and Address of the Grower will be forwarded with the Fruit to Her Majesty.

The exhibitors were delighted to leave the dishes on the tables, and they were collected and arranged in one of the Committee rooms. The collection was subsequently photographed and engraved by an artist (see next page), and he also engraved the largest Apple in the Show, a wonderful Peasgood's Nonesuch grown in an orchard house, and exhibited by Mr. S. Barlow (see page 341). Instructions were given for accurate representation, and it will be conceded that the specimen is a remarkable one. It weighed, we believe, 30 ozs., the variety not being by any means a heavy weighing Apple.

We publish the list, as officially supplied, of the names of the exhibitors and varieties, also the classes and sections from which the dishes were chosen that constituted the Royal collection of home-grown fruit. Mr. H. R. Williams had a copy of Mr. J. Wright's gold medal prize essay on "Profitable Fruit Growing" for cottagers and small holders of land, beautifully bound in morocco and sent with the fruit for Her Majesty's acceptance.

### FRUITS SELECTED FROM THE GUILDHALL SHOW FOR PRESENTATION TO HER MAJESTY.

*All the varieties named refer to Apples, except where otherwise mentioned.*

#### SOUTH-WESTERN ZONE.

- Class 2, Section 1.—Allen Williams, bootmaker, The Moor, Bodenham, Leominster—Warner's King.  
 Class 3, Section 1.—S. French, labourer, Marstow, Hereford—King of the Pippins.  
 Class 7, Section 2.—Jno. Hyde, Farmer, Calderwell, Bodenham, Leominster—Ecklinville Seedling.  
 Class 8, Section 2.—James Davis, farmer, Bunhill, Bodenham, Leominster—Peasgood's Nonesuch.  
 Class 9, Section 2.—W. Helyar, farmer, East Coker, Yeovil—Coker Seedling.  
 Class 12, Section 3.—S. T. Wright, gardener to C. Lee Campbell, Esq., Glewston Court, Hereford—Hormead Pearmain.  
 Class 14, Section 3.—Thomas Parker, gardener to Mrs. Evans, Moreton Court, Hereford—Tyler's Kernel.  
 Class 15, Section 3.—W. Iggulden, gardener to the Earl of Cork, Marston, Frome, Somerset—Pear Doyenné du Comice.

#### NORTHERN ZONE.

- Class 1, Section 1.—John Wilson, labourer, Hall Lane, Lathom, near Ormskirk—Tower of Glamis.  
 Class 2, Section 1.—John Wilson, labourer, Hall Lane, Lathom, near Ormskirk—Dumelow's Seedling.  
 Class 3, Section 1.—Thos. J. Pullett, cottager, 82, Russell Street, Loughborough—Cox's Orange Pippin.  
 Class 7, Section 2.—John Doncaster, farmer, Halloughton, Southwell, Notts—Bramley's Seedling.  
 Class 14, Section 3.—Samuel Barlow, J.P., Stakehill House, Castleton, Manchester—Ribston Pippin.  
 Class 15, Section 3.—Jas. Hunter, gardener to the Earl of Durham Lambton Castle, Fencehouses, Durham—Pear Pitmaston Duchess.

#### SOUTH-EASTERN ZONE.

- Class 2, Section 1.—Fred. Marsh, cottager, The Bow, Nettelstead, Maidstone—Lord Derby.  
 Class 3, Section 1.—W. Pulling, labourer, Hill Lop, Tillington, near Petworth, Sussex—Scarlet Nonpareil.  
 Class 8, Section 2.—Herbert Manser, tenant farmer, Omer's Farm, North Down, Margate—Lane's Prince Albert.  
 Class 9, Section 2.—Richard Webb, farmer, Beenham, near Reading, Berks—Cox's Orange Pippin.  
 Class 12, Section 3.—F. Miller, gardener to Jas. J. Friend, Esq., North Down, Margate, Kent—Cornish Aromatic.  
 Class 12, Section 3.—W. S. Skinner, farmer, Beresford, Boughton, Monchelsea, Kent—Worcester Pearmain.

- Class 12, Section 3.—J. Turner, gardener to R. H. Comer, Esq., Picrepoint, Farnham—Claygate Pearmain.  
 Class 12, Section 3.—A. Waterman, gardener to A. H. Brassey, Esq., Preston Hall, Aylesford—Ribston Pippin.  
 Class 13, Section 3.—Fred. Bridger, gardener, Penshurst Place, Kent—Emperor Alexander.  
 Class 13, Section 3.—Geo. Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone—Stone's.  
 Class 14, Section 3.—E. H. Caterer, gardener to T. Arnall, Esq., Brookside, Headington Hill, Oxford—Prince Albert.

- Class 16, Section 3.—William Allan, gardener to Lord Suffield, Gunton Park, Norwich—Pears Marie Louise d'Uccle and Doyenné du Comice.  
 Class 16, Section 3.—R. Smith, gardener to A. Cox, Esq., Presdales, Ware, Herts—Pear Emile d'Héyst.  
 Class 4, Section 1.—William Jacob, High Street, Petworth, Sussex—Lady Sudeley.  
 Class 4, Section 1.—Henry Norman, bricklayer, 2, Oeklynge Road, Eastbourne, Sussex—Dumelow's Seedling.  
 Class 4, Section 1.—W. Waghorn, cottager, Allington, near Maidstone—Stirling Castle.

FIG. 38.—GUILDHALL FRUIT—THE GIFT TO HER MAJESTY.

- Class 14, Section 3.—Thomas Turton, gardener to John Hargreaves, Esq., Maiden Erleigh, Reading—Mère de Ménage.  
 Class 15, Section 3.—Charles Blick, gardener to Martin R. Smith, Esq., Hayes Common, Hayes, Kent—Pear Magnate.  
 Class 15, Section 3.—F. Dunn, gardener to Sir Francis W. Truscott, Oakleigh, East Grinstead, Sussex—Pear Beurré Bachelier.  
 Class 15, Section 3.—Charles Ross, gardener to Lieut.-Colonel Eyre, Welford Park, Newbury, Berks—Pear Seckle.  
 Class 15, Section 3.—James Sheppard, gardener, Wolverstone Park, Ipswich, Suffolk—Pear Louise Bonne of Jersey.  
 Class 15, Section 3.—George Woodward, gardener to R. Leigh, Esq., J.P., Barham Court, Maidstone—Nouveau Poiteau.

- NURSERYMEN AND TRADE GROWERS IN THE UNITED KINGDOM.  
 Class 19, Section 4.—A. J. Thomas, fruit grower, Bargams Hill, Rodmersham, Sittingbourne—Pear Louise Bonne of Jersey.  
 Class 19, Section 4.—English Fruit and Rose Company (Cranston's), Limited, nurserymen, Hereford—Duchess of Gloucester.  
 Class 19, Section 4.—Jarman & Co., nurserymen, Chard, Somersct—Nelson Codlin.  
 Class 19, Section 4.—Paul & Son, Old Nurseries, Cheshunt—Transparent de Croncelles.  
 Class 19, Section 4.—Henry Berwick, nurseryman, Sidmouth Nurseries, Sidmouth, Devon—Frogmore Prolific.

- Class 19, Section 4.—Chas. Turner, Royal Nursery, Slough——Holland-bury.
- Class 19, Section 4.—Balchin & Son, Hassocks Nurseries, Sussex——Hoary Morning.
- Class 19, Section 4.—John Peed & Sons, Mitcham Nurseries, Streatham——Belle Pontoise.
- Class 19, Section 4.—Will. Taylor, Osborn's Nurseries, Hampton——Pine Golden Pippin.
- Class 19, Section 4.—A. Wyatt, market gardener, Halton, Middlesex——Fearn's Pippin.
- Class 19, Section 4.—W. F. Gibbon, fruit grower, Seaford Grange, Pershore——Golden Noble.
- Class 19, Section 4.—John Watkins, Pomona Farm Nurseries, Withington, Hereford——Warner's King, New Hawthornden.
- Class 19, Section 4.—Thomas Rivers & Son, nurserymen, Sawbridgeworth——Peach Lord Palmerston, Monarch Plum.
- Class 19, Section 4.—J. Laing & Sons, Stanstead Park Nurseries, Forest Hill——Bismarck,
- Class 19, Section 4.—J. Cheal & Sons, Lowfield Nurseries, Crawley——Crab Edulis, Pear Doyenné du Comice.
- Class 19, Section 4.—W. Paul & Son, nurserymen, Waltham Cross——Cellini.
- Class 19, Section 4.—James Veitch & Sons, Royal Exotic Nurseries, Chelsea——Sandringham.
- Class 19, Section 4.—Royal Horticultural Society, Chiswick, W.——Braddick's Nonpareil.
- Class 19, Section 4.—Geo. Bunyard & Co., nurserymen, Maidstone——Apple Washington, Pear Doyenné du Comice.

SELECTED FROM THE GOLD MEDAL CLASS.

- Class 23, Section 6.—James Nicholson, gardener to W. Malles, Esq. Sewardstone Lodge, Chingford, Essex——Pear Durondeau.
- Class 23, Section 6.—J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Borrowash, Derby——Lord Lennox.
- Class 23, Section 6.—Geo. Reynolds, gardener to the Messrs. de Rothschild, Gunnersbury Park, Acton, W.——Lord Derby.
- Class 25, Section 6.—Samuel Barlow, J.P., Stakehill House, Castleton, Manchester——Peasgood's Nonesuch.
- Class 23, Section 6.—Charles Davies, The Mote Gardens, Maidstone——Gascoigne's Seedling, Pear Marie Louise.

FROM THE BRITISH FRUIT GROWERS' ASSOCIATION.

- P. Crowley, Esq., Waddon House, Croydon——Bismarck.
- Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury——Pear Uvedale's St. Germain.
- Thos. Rivers & Son, nurserymen, Sawbridgeworth——King of Tomkins County, Rosemary Russet, Pear Pitmaston Duchess.

EXTRA.

- Mr. John White, Home Farm, Hampton, Prince's Risborough——Dumelow's Seedling.

The fruit was packed in two strong cases and sent carriage paid to Ballater, addressed to Her Majesty at Balmoral.

The Show was visited by upwards of 35,000 persons.

POTATO NOTES.

HARVEST came in with dripping skies and cold boisterous winds, a state of things disastrous to other crops as well as corn. Happily the bad weather was not of long duration, and before any real harm had been done the very best and brightest days in the whole year dawned upon us—days that made work a pleasure and put gladness into all hearts. The genial mellowness of a fine English September day is not to be equalled in any part of the world. Nature seems to be resting after her long exertions, and the sons of toil are on every hand gathering up the precious fruits of another year.

Stackyards are filled with golden grain—clean and free from storm stain, and work is rapidly progressing in all departments. The dry weather has much facilitated the cleaning of fallows and the digging of Potatoes. By-the-by, there appears to be no implement better fitted for tearing out twitch and other weeds than the rotary Potato digger. It fairly shakes off every particle of earth, and leaves the rootlets, bare and exposed, easy to gather up and to burn with the Potato tops. The digger makes far quicker better work if the tops are gathered off first, and this is an easy matter, and one quite worth the attention of the Potato grower.

Some rather interesting Potato experiments have been tried this year. The idea was to find out good croppers for general marketing, and of seventeen sorts grown only five are found to have any value for the ordinary farmer when marketed in the ordinary way.

*Queen of the Valley* proved the best and the soundest, but her rosy hue might not commend her to everybody. "Handsome is

that handsome does," be it pink or white. This was closely followed by

*Sutton's Seedling*, which was a good crop and fairly sound.

*Reading Russet*, good in quality, useful, but considerably diseased.

*Snowdrop* is a sound second early, but must be lifted early, as it is very liable to disease.

*Sharpe's Victor* is one of the earliest, but not at all a farmer's Potato, being too shy a cropper for field growth.

*Sutton's Satisfaction* is fairly sound and fairly prolific, beautiful in appearance, but at the present time, October 6th, not fit for culinary purposes.

These were all set in a field which was Red Clover mown, plentifully dressed with foldyard manure and 2 cwts. sulphate of ammonia per acre in addition; soil red cliff; season favourable save for three weeks of warm, muggy, disease-creating weather. In the same field the main crop was Sutton's Abundance, and as far as can be estimated the yield will prove something after this—deliverable Potatoes seven tons, seed three-quarters of a ton, and another three-quarters of offal; quality very good indeed, quite the Potato to set before a king, flavour not up to, say Emperor, but still very good. Half the field received, when Red Clover, 2 cwts. per acre of kainit, and that kainit has most certainly left testimony behind it in increased crops. Even to idle little boys pickers' work must have been pleasant this year, so clean, and dry and bright, no trudging home at night with soaked clothes and perished little bodies, it is difficult to estimate the blessings of a fine "back end."

In the same parish and under the same management is another large plot of Potatoes, grown on Wheatstubble. The soil is more or less cliff, but varies very much. This field had a good dressing of foldyard manure, and the half of it that was set with Magnums and Sutton's Abundance had in addition 2 cwts. of sulphate of ammonia and 2 cwts. of bonemeal per acre.

The Magnums have come up very clean, with no disease; the Potatoes are small, and the crop is below the average as regards bulk. Sutton's Abundance is slightly touched by disease, nothing that is of any consequence. The quality is most gratifying, and the yield fair. This, one would fancy, must be a good marketable Potato.

It was fully intended that the whole of the hand tillage should be used on the Magnum and Sutton's Abundance half of the field, but as a little was left over the adjoining first five rows of Emperor got the benefit, and it is certainly extraordinary what a difference there is between those five rows and the bulk of the crop. It certainly goes far to prove that Emperors do not require the amount of tillage that their more fancy brethren profit by. "Great bouncing 'taties,' and lots of 'em" is the report, and good as Emperors are it is quite possible to have them too big and gross. However, these great tubers keep up the weight per acre, and a use will doubtless be found for them, if not in the market perhaps in the steam house. The rest of the crop is good, sound, and saleable.

Many Potatoes have already changed hands in this district at prices varying from £22 to £24 per acre. This sounds a good price, but it must be borne in mind that the grower has to find all the labour, and will have out of that money to provide himself with seed and offals, and these offals often form an important article of food on a large farm, especially when there is, as will possibly be the case this year, a falling off of some of the root crops. Of course, again, there is a feeling of great relief, too, in thinking that the fluctuations of the market are of no moment to you, and that your money is earning interest. It is but poor slow work peddling out a great crop by two or three tons at a time, and there is always more or less waste in delivering from the stores. With keen competition on every side, and profit margins growing beautifully less, it is more than ever desirable that a successful grower should be a man ready to advance with the times, and by a judicious combination of capital and common sense place the best article in a rising market.—PARTS OF LINDSEY.

SYDMONTON COURT, NEWBURY.

THIS, the pleasantly situated residence of W. H. Kingsmill, Esq., lies between Kingsclere and Newbury, at about equal distance, and stands in its own park, which is well timbered, commanding extensive and beautiful views in the distant landscape. The dressed grounds, which are of moderately large extent, are enclosed on one side by park fence, and on the others by broad belts of shrubby plantations extending to the highway, forming an excellent screen for shelter. The famous Hampshire hills which run in close contiguity forming a portion of the extensive estate, lend a pleasant aspect to the general surroundings, for unlike so many such elevated sites the range is clothed with verdure of the richest hue. On the lawn are some fine Cedars of Lebanon, Robinias, and other trees, with the pretty church in

the foreground. The open sward is unbroken by flower beds, so common in many establishments, but these are provided for in a strip of turf laying between the broad terrace and house, a position that displays the well planted beds to advantage. One of the most striking plants employed in bedding is Begonia Princess Beatrice, a variety remarkable for continuity of bloom and uniformity of growth. The flowers are white with a pinkish hue pervading them, but this may be less pronounced in the earlier part of the season.

The glass structures are all conveniently arranged in an enclosed yard, at an easy distance from the house and closely adjoining the kitchen gardens, from which good crops of Peaches, Grapes, Tomatoes, Melons, Cucumbers and decorative material are produced in quantities and of the best quality. It is supposed that a monastery once existed here, a courtyard of those days being now a charming spot filled with herbaceous and annual flowering plants, the walls covered with Roses. The annuals are planted in circular beds cut out in the turf, and are drawn upon largely for the cut flower supplies. A beautiful specimen *Arundo conspicua* occupies a central position, the other beds being disposed equidistant on all sides. Although an excellent all-round gardener, Mr. Lye, who has charge of this department of Sydmonton Court, excels in the art of vegetable production, which reports of various shows frequently testify, his success during the current season being quite phenomenal. No less than twenty-six first prizes have been awarded to him, and only one third, which alone is sufficient guarantee of his ability and painstaking workmanship, for he has secured them in the best of company. The great event of the season with vegetable competition was at Reading, where a first prize of 15 guineas and five others of proportionate value were offered. This brought together, as was expected, one of the largest displays of garden produce ever presented in a single class, and it was a feat of no mean order to secure an easy first among some of the best growers of the day.

True, facilities are here presented such as do not fall to the share of many growers, and this is found in the natural soil and shelter, but, on the other hand, the most is made of it by judicious cropping, Mr. Lye being one of those far-seeing men who plans and prepares his ground in the autumn and winter for the next year's crop. Runner Beans are enormously prolific, represented by no less than three types of the Ne Plus Ultra strain, one of them grown on trial being apparently a good advance on the original. These are grown in heavily manured trenches, and planted so that they are in full light, and the seeds a foot apart in single rows. Onions, again, are of immense size, and many sorts are on view, but it must be understood these are not produced under the usual practice of sowing outdoors, but have as much care expended on them as required for early Celery. Carrots and Parsnips are of perfect shape, in fact as clean as though machine made. This fact alone is sufficient to indicate the nature of the soil. The most beautiful and extensive plantation of Parsley I have met with this year is seen here, the destructive root pest that has wrought such havoc generally being absent, a bed of Dobbie's Extra-curved being grand in the extreme.

Celery which was prepared for autumn and winter supplies is overtaken with disease, so virulent as to affect the whole of one large plantation, many of them succumbing under its influence. The leaves are thickly covered with red rust-like spots, the cause for which it is difficult to assign a reason for. This disease is quite new to everyone who has yet seen it as displayed at Sydmonton.

Violets are grown largely and well, mostly of the Marie Louise variety, and Mr. Lye treats a portion of the stock in pots with more than ordinary success. They are potted the end of September, and stood in a sheltered spot outdoors for a short time, and transferred when partially re-established to shelves in the vineries, where they invariably give good returns in high-coloured flowers. Chrysanthemums, which are grown in moderately large numbers, are cultivated on the large bloom principle, mostly in 8-inch pots, and look promising for a good display later on. Apples are abundant on standard orchard trees, but Pears do not crop so freely. Peaches protected by a coping of glass are doing well, some recently planted trees growing with remarkable freedom on a south wall. Altogether this interesting garden reflects much credit on its chief, who is well supported by Mr. Kingsmill in the various items connected with such an establishment, which cannot be otherwise than appreciated.—S.

## ROYAL HORTICULTURAL SOCIETY.

OCTOBER 14TH.

IN addition to the exhibits before the three Committees, which were numerous and interesting, a special feature was provided in a display of preserved fruits and jams. Medals and certificates were offered, and several were awarded for the best representative collections. At the afternoon meeting Sir Charles Strickland, Bart., read a paper on "Crinums," but owing to the foggy weather the attendance was not large. The floral exhibits were arranged on two central tables, the fruit, both fresh and preserved, being placed on side tables, and, with the groups of Chrysanthemums, there was not much unoccupied space.

**FRUIT COMMITTEE.**—Present: Sir C. W. Strickland, Bart., in the chair, and Rev. W. Wilks, Dr. Hogg, Messrs. T. F. Rivers, John Lee, G. W. Cummins, J. Denning, W. Bates, J. Smith, H. Balderson, J. Hudson, F. Q. Lane, A. H. Pearson, R. D. Blackmore, and G. Wythes.

Ripe fruits of Figue d'Agen, the latest Fig in the Royal Horticultural Society's collection, were placed on the table by Mr. Barron. The fruit

is medium sized, roundish, green, with clear white fissures. The flesh is red, juicy, and sweet. Its chief merit, however, consists in its ripening well so late in the season.

A seedling Apple named Chorister Boy was sent from Messrs. Keynes, Williams, & Co., Salisbury; it is a conical Apple, but as shown possessed no distinct quality, and as no information was communicated relative to the bearing of the tree or the keeping properties of the fruit it was passed. A seedling unnamed Apple was sent by Mr. J. Hazzard; it is of the Codlin type, but not equal to others in cultivation. Apple Duc d'Aumale was sent by Mr. Lewis Castle from Merton; it is a large firm Apple with a distinct aromatic flavour, but was considered rather dry, and no award was made. A seedling Apple was sent by Mr. G. Jones, Greenford Place, Sudbury, medium sized but inferior, and therefore passed. Mr. James Smith, Newark, sent a small Apple, not named; it was thought to resemble the local Yorkshire Apple Elmender, and did not merit any special mark of recognition. A dish of fine fruit of "D. T. Fish" Apple was placed on the table by Mr. H. Balderson, with the object of determining its identity with Warner's King or otherwise. It was unanimously declared identical with Warner's King. Mr. R. Fenn sent dishes of a medium-sized Apple from Sulhampsted, named "Pay-the-Rent." It was spotted in the skin, deepening into the flesh, and hence was passed. After all those failures in Apples a success was at last arrived at in *Beauty of Stoke*, from Mr. R. Doe, The Gardens, Rufford Abbey, Allerton, Notts. Fruits were before the Committee in December last year, Sir Charles Strickland being requested to test their cooking quality. He did so, and found it excellent. Mr. A. H. Pearson was also requested to inspect the trees at Rufford, and having done so and reported them as of good growth and productive, a first-class certificate was awarded. The fruit is large, somewhat conical, of a uniform brown russet appearance, and very heavy. The variety is of the Alfriston type, but distinct and of considerable promise.

A large oval shaped, well netted Melon was sent by Mr. A. Bishop, gardener to R. Burrell, Esq., Westley Hall, Bury St. Edmunds. It was named *Westley Hall* by the Committee for the purpose of recording the first class certificate that was awarded. It is a scarlet flesh, tender, and of rich flavour. Fine fruits of *Monstera deliciosa* were sent by Mr. G. Wythes from Syon House; they were exceedingly rich in flavour, and a cultural commendation was awarded. Mr. Wythes also sent fruits of a large red Banana, name unknown, for which a similar award was granted. Messrs. Jarman & Co., Chard, sent a small collection of Apples, for which a vote of thanks was awarded. Mr. James Hudson, Gunnersbury House Gardens, sent a box of Golden Noble Apples, uniform in size and good, and was accorded a cultural commendation. A collection of different kinds of fruit and Nuts were exhibited by Mr. Fenn, and a vote of thanks awarded; also for some home-made wines, which, however, had been treasured up too long. Messrs. Gayman & Son, Barham, Attleborough, sent a collection of Apples from Norfolk from which they make cider. A bronze medal was recommended. Messrs. Wm. Paul & Son, Waltham Cross, staged a large and valuable collection of Apples, for which a silver medal was unanimously recommended. Baskets of well-fruited sprays of October Red and White Raspberries were arranged with the collection.

Mr. Roffey, Croydon, was awarded a vote of thanks for fine seedling fruits of his selected Telegraph Cucumber, and a similar award was recorded to Mrs. Alexander Dean for interesting examples of jam and syrup preparations of Tomato, Carrots, Vegetable Marrow, and Beetroot, the first and last named, perhaps, finding the most favour with a majority of the members present.

**FLORAL COMMITTEE.**—Present: John Fraser, Esq., in the chair, and Messrs. B. Wynne, T. Baines, R. Dean, W. C. Leach, J. Walker, R. B. Lowe, T. W. Girdlestone, H. Turner, D. Jeffries, H. B. May, G. Paul, and Rev. H. H. D'Ombraim.

From E. Mawley, Esq., Rose Bank, Berkhamsted, came a most tasteful group of Roses, Dahlias, Chrysanthemums, and Begonias arranged in baskets, stands, and dishes. Ferns, Asparagus, and other foliage were employed with excellent effect, and the whole being disposed on a white cloth had a charming appearance. It was an innovation that might well be repeated, the award of a silver medal being amply merited. Mr. H. B. May, Upper Edmonton, contributed a handsome group of Crotons, Dracænas, Ferns, and other foliage plants, which occupied the whole length of one table. A silver-gilt medal was awarded. Mr. H. J. Jones, Hither Green, Lewisham, had two bright and tasteful groups of Chrysanthemums at the ends of the tables, for which a silver Banksian medal was awarded.

Mr. G. Fry, Lewisham, sent a plant of a seedling Fuchsia raised from triphylla and named albo-carminata. It had pale salmon drooping flowers, delicate, but not showy. Sir C. W. Strickland, Bart., exhibited specimens of a bright purple flowered Achimenes, said to have been obtained from an imported plant of *Epidendrum raniferum*. Mr. R. Mitchell, Orleans House Gardens, Twickenham, showed good blooms of Chrysanthemum Mrs. Alpheus Hardy. Mr. C. J. Salter, The Gardens, Woodhatch Lodge, Reigate, had three blooms of a bronzy yellow sport from the Japanese Chrysanthemum Mr. H. Wellam named Memoir. They were quite distinct in colour and the characters seemed well fixed, but the blooms were rather rough. Messrs. Pitcher & Manda also sent several new Japanese Chrysanthemums, one named Elliott F. Shepard having large bright yellow blooms like Peter the Great; Mohawk, in the way of E. Molyneux; and Clarence Bryant, a neat yellow reflexed Japanese.

Messrs. W. Paul & Son, Waltham Cross, contributed six boxes of

autumnal Roses, beautiful fresh fragrant blooms, such as are seldom seen at the middle of October (silver Banksian medal. Mr. C. Turner, Slough, had two boxes of twenty-four fine Dahlia blooms, the last of the season, for the frost of Tuesday morning at Slough was rather severe (bronze Banksian medal). Messrs. J. Veitch & Sons sent a box of the Javan hybrid Rhododendrons in many varieties. The flowers exceedingly bright, and the frequency with which they are shown throughout the year affords abundant proof of the usefulness of the plants (vote of thanks).

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq., and Messrs. S. Courtauld, J. Douglas, H. M. Pollett, J. O'Brien, E. Hill, J. Dominy, and Lewis Castle.

Mr. Alfred Sanders, 146, Camden Road, N.W., sent a plant of *Odontoglossum grande* with twenty-two large flowers. It was stated that in 1888 it had eighteen flowers, and in 1889 it had twenty-three flowers. The plant was in excellent health, and as an amateur's production especially meritorious. A cultural commendation was awarded. J. Crispin, Esq., Fishponds, Bristol, sent a large well-flowered plant of *Lælia Perrini* on a block (vote of thanks).

Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine), contributed a small group of choice Orchids, comprising three plants of *Dendrobium Phalaenopsis*, bearing three to seven large richly coloured flowers each; the elegant soft rose-tinted *Cattleya Fausta*, certificated in 1874; *Cypripedium Fairrieanum*, with six flowers; and *Cattleya Imschottiana* (certificated). The *Dendrobiums* were greatly admired, for rarely are such fine examples of this handsome species seen in cultivation.

In addition to *Bulbophyllum amplum*, for which a botanical certificate was awarded, Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, showed a plant of *Epidendrum radiatum fucatum*, having pale creamy flowers, the lip streaked with dark radiating lines. Messrs. Pitcher & Manda, Hextable, showed a plant of *Lælia Arnoldiana*, having crimson-tipped flowers clustered near the apex of a long spike in the style of *L. autumnalis*.

M. Linden, Brussels, sent a small group of Orchids, conspicuous amongst which were several plants of *Cattleya Warocqueana*, showing considerable variation in size and colour of the flowers. Two of these were selected for certificates as the most distinct and meritorious, but the opinion was that the series of forms under the type *Warocqueana* would prove useful as late flowering *Cattleyas*. *Lælia grandis vera* and *Aganisia cyanea* had been previously certificated, and *Mormodes maculata*, with peculiar dark flowers, was passed.

Mr. W. C. Atkinson, Aigburth, sent fair flowers of *Vanda cœrulea*; and Capt. Hincks, Breckenbrough, Thirsk, showed a flower and photograph of *Masdevallia Stella*, a hybrid from M. Harryana and M. Estradae, but it was not seen to the best advantage, as the flowers had a faded appearance. The sepals are pale purplish mauve, with a deeper rosy purple base, and long yellow tips.

#### CERTIFICATED PLANTS.

*Angræcum Kamballianum* (W. Vanner, Esq., Camden Wood, Chislehurst).—A botanical certificate was awarded for this plant, one of the small white flowered species; the lip like a diminutive *A. eburneum*, the sepals and petals very narrow and twisted.

*Cattleya Imschottiana* (Baron Schröder).—A pretty variety of the *C. aurea* type. The sepals and petals creamy white, the lip crimson veined gold.

*Bulbophyllum amplum* (Sir T. Lawrence).—A peculiar Orchid, with unusually large flowers for a *Bulbophyllum*, creamy yellow sepals and petals dotted with red, the lip broad, and of a maroon tint (botanical certificate).

*Catasetum Bungeirothi var. Randi* (Linden).—Distinguished from the type by the flowers being yellow, the lip having an orange centre (award of merit).

*Cattleya Warocqueana flammaea* (Linden).—A handsome variety with deep rosy sepals and petals, the latter broad and spreading; the lip is long, having an orange throat, and is streaked with crimson on a lighter ground towards the tip. Very strong and free (first class certificate).

*Cattleya Warocqueana amethystina* (Linden).—Flowers somewhat smaller than the preceding, but of better colour, the sepals and petals very crimson, the lip a rich magenta; very effective (first class certificate).

*Cattleya aurea var. Lindenii* (Linden).—A bold handsome variety, the sepals and petals bright yellow; the lip very broad, deep crimson tipped, and rich gold margins (award of merit).

*Cattleya Buyssoniana* (Linden).—Very distinct, with narrow, fleshy, creamy yellow sepals and petals; the lip narrow, contracted in the centre, pale crimson (award of merit).

*Richardia æthiopica, Little Gem* (Mr. H. Elliott, Jersey).—A dwarf variety of a well known plant, and likely to be useful for culture in pots. The berries and spathes are considerably smaller than the ordinary type, and the height of the plant shown in a small pot did not exceed 12 inches. It seems to be free, and the neat little spathes were pure white (award of merit).

*Bouvardia Purity* (H. B. May).—Flowers pure white, of great size and substance, the corolla lobes broad and rounded. The flowers are borne in large trusses and freely produced (award of merit).

*Chrysanthemum Annie Clibran, Pink Mdlle. Lacroix* (Jones and Ware).—Under the former name Mr. Jones of Lewisham had some good blooms of the pink sport from Mdlle. Lacroix, the colour of which is

most marked in the older blooms. They open very pale, and gradually deepen to a soft pink—a rather pleasing shade in a good light, but it looked dull at the Drill Hall. Mr. Ware's blooms were similar to the above, but were shown as "Pink Lacroix" (awards of merit).

*Cunilla Mariana* (Pitcher & Manda).—A member of the family Labiatae, known in North America as the Common Dittany. Gray mentions that it is found on dry hills south of New York and westward, flowering from July to September. The plant is about a foot high, bushy in habit, producing small tubular lilac flowers in profusion. The leaves are ovate, and the whole plant has an aromatic odour (award of merit).

PRESERVED FRUITS AND JAMS.—Amongst the exhibitors in this portion of the Show Messrs. Beach & Sons had an attractive stand of bottled fruits and jams, for which a silver Knightian medal was awarded. Other exhibitors who had interesting stands were Messrs. G. Chivers and Son, Cambridge; Margetts & Co., Kingsland Road; D. Macgregor, Edinburgh; and J. E. Austin, Kingston-on-Thames. Sir C. W. Strickland, Bart., sent good samples of wild Strawberry jam and Blackberry jelly. Mr. J. Edmunds, 10, Stonefield Terrace, Liverpool Road, London, had specimens of preserved Mangoes, Guavas, Vanilla, &c. Mrs. Shore, Newington Green Road, sent some jams; and the Mid-Kent Fruit Factory, Tonbridge, had a stand of jams and preserved fruits.

One of the most interesting exhibits was a collection of syrups, preserved fruits, candied fruits, dried fruits, sweets, also Tomato paste and Olives as used in Turkey from Messrs. James Veitch & Sons, Chelsea. These comprised the following:—Syrups: Orange, Madella Cherry, Rose, Raspberry, Verjuice (sour Grape), Strawberry, Mandarin Orange, Pine Apple, Cornel, Tamarind, Isnicola Raspberry, Grape treacle. Preserved Fruits: Arabian Apricots, Cornel Berries, Orange, Madella Cherries, Apricot, Quince, Broussa Peach, Pear, Apple, White Plum, Citron, Egg Plant, Walnut, Date, Peach, Strawberry, Jujube, Fig, Prunes, Raspberry, Rose. Candied Fruits: Pear, Apricot, Orange, Persian Pistiks, Almonds, Citron. Dried Fruits: Mecca Dates, Smyrna Pears, Arabian Apricots, Manna, Cretan Locust, Arabian Apricot paste, Madella Cherries from Kutajah Anatolia. Sweets: Vanilla, Black Cherry, Rose, Bergamot, Mastik (handed to guests to be taken by a spoon, with water afterwards), Tomato paste, Black Olives.

Common articles of food offered for sale on barrows in the streets of Constantinople: Baked Teblebee, unbaked Teblebee, baked Nuts, St. John's Bread (John the Baptist's Locust), baked Pistacio Nuts, American Earth or Butter Nut, Persice Apricot, baked Pumpkin seeds, Sunflower seeds, Stone Pine seeds, used for kitchen purposes, pastry, &c.

#### AMERICAN SHRUBS.

*Gordonia Altamaha* (*G. pubescens*) is flowering in the Arnold Arboretum, the first blossoms opening about Sept. 8th. The plant here requires covering in winter, but it is in a too exposed and rather unsuitable position for one of its kind. There are doubtless many sheltered gardens and nooks in the city of Boston and vicinity where it would survive our winters without protection and eventually become a good sized shrub. We are unable to grow the great evergreen or Laurel Magnolia of the south, but this *Gordonia*, or *Franklinia*, as it is often called, seems of a hardier nature, and is well worth a trial in favourable places. Our seasons are so short that the later flower buds do not develop into blossoms unless protected from early autumn frosts; but in any case enough flowers are produced to fully repay the little care given to it and the space it occupies. The beautiful, pure white, delicately fragrant, single Camellia-like blossoms expand 3 inches across, and the cluster of stamens within is bright yellow. The corollas do not persist long, however, and usually become detached and fall thirty-six or forty-eight hours after expansion.

*Clerodendron trichotomum* is another shrub which in this latitude would be worth growing in sheltered situations, and would well repay any care given to it. This is a Japanese plant belonging to the Verbenaceae family, and although it is a good many years since it was introduced into Europe, it is still very rare in America. In this climate the stems are often so severely injured in winter as to seriously affect the flowering. Last winter being less severe than usual, the branches were but slightly injured, and they now bear numerous cymes of sweetly fragrant flowers. This *Clerodendron* in its native habitat is a large shrub or sometimes a small tree. The branches are round, smooth, and stout. The leaves are usually large, ovate, or sometimes cordate, pointed, and more or less pubescent on both surfaces. When bruised they exhale a heavy and rather disagreeable odour. At a little distance the foliage resembles that of a small-leaved *Catalpa* more than any other familiar plant. The flowers are borne in large, much-branched cymes on the ends of the branches. The blossom is white or sometimes slightly rosy coloured, and expands about an inch across, and it bears four stamens and a slender pistil, which protrude about an inch from the mouth. The narrow, very slender tube of the corolla is about an inch in length, all the lower portion being enclosed in a loose, five-angled, purplish red calyx, which adds much to the showy effect of the flower, and which is conspicuous when enclosing the unopened buds as well as after the corolla has fallen. The flowers of a cyme open here in gradual succession, beginning about the first week of September. It is said that in Japan this plant grows high up on the mountains, and in rich soils produces panicles of flowers 18 inches or more in length. It is possible that by getting seed from the extreme northern limits or the highest altitudes where this species grows, we may secure a race better able to withstand

the severity of New England winters. Besides propagation by seeds, which will hardly have time to ripen in this latitude, this *Clerodendron* may be increased by cuttings from the shoots or roots.

other early writers, although reduced to the rank of a variety of *C. alnifolia* by Michaux. It is a hundred years since it became known in European gardens. Later botanists, however, seem to consider it as but

FIG. 39.—PEASGOOD'S NONESUCH APPLE, GROWN BY MR. S. BARLOW. (See page 336.)

An interesting plant for gardens is a *Clethra* from the Southern States, to which Lamarck, in his "Botanical Dictionary," gave the name of the Cottony *Clethra*, or *Clethra tomentosa*, a name which was preserved by De Candolle in his "Prodromus" and kept up by Loudon and

a mere form of the common Sweet Pepperbush (*C. alnifolia*), and we look in vain for any reference to it, either by name or description, in the last edition of Gray's "Manual." In some of the earlier editions of the "Manual," however, it is stated that "in the Southern States are

varieties with the leaves rather scabrous and pubescent or white-downy beneath."

Although the pubescent variety, which the earlier botanists knew as *C. tomentosa*, may not be entitled to specific rank in the botanical classification of to-day, it is nevertheless sufficiently distinct in the estimation of the horticulturist to merit some name which would indicate a difference from the ordinary typical *C. alnifolia*. In cultivated specimens in the Arboretum the leaves are larger than those of *C. alnifolia*. They are rugose above, and densely covered with a greyish white tomentum beneath. In typical *C. alnifolia* the leaves are more smooth above and smooth and light green in colour beneath, being quite destitute of any pubescence or hairs. The individual flowers, as a rule, are nearly twice the size of those of *C. alnifolia*, and they differ also in that the petals assume more of a bell shape, and do not spread out so widely. The slender, pointed, terminal racemes of flowers average considerably larger, and many of them are supplemented by three or four well developed; but smaller racemes, which, springing from the side near the base of the central one, come into bloom later than it does. To the horticulturist, however, the most important character lies in the time of flowering of the plants. Growing side by side in cultivation and under exactly similar conditions the first blossoms of *C. alnifolia* open in the last days of July (July 22nd in 1889 and 31st in 1890), while the first of those of what we may call *C. tomentosa* do not appear until three weeks later (August 12th in 1889 and 19th in 1890), by which time *C. alnifolia* is past its best flowering, although in woods and other cool places it is found much later. The latest buds of the tomentose variety are not expanded by the middle of October, so that they are usually destroyed by frost, and fruit is never matured. As this tomentose *Clethra* is only recorded from Virginia, Carolina, Alabama, and other Southern States, it is naturally not so hardy as our northern one. The flowers are quite as fragrant as those of *C. alnifolia*. On account of its extreme lateness in blossoming this southern variety, or form as it may be, seems likely yet to become recognised and valued by gardeners at least, and to find a place in every garden where shrubs of this class are prized.—J. G. JACK, *Arnold Arboretum* (in *American Garden and Forest*).

### CRYSTAL PALACE FRUIT SHOW.

OCTOBER 9TH, 10TH, AND 11TH.

FOLLOWING the Guildhall Show so closely, it might have been expected that the Sydenham Exhibition would have suffered by the contrast, but this was not the case, as while the best of the exhibits from the previous display were staged at the Palace, the better light there showed the fruits to more advantage. Four long lines of tables in the northern portion of the Palace were occupied with fruits, principally Apples, and Mr. W. G. Head, the superintendent, arranged them most effectively, the centre of the tables having dividing lines of small foliage plants. Vegetables and miscellaneous exhibits were placed on side tables, and also filled considerable space.

The exhibitors and their contributions were so similar to those at the Guildhall that it is unnecessary to repeat them here, and the following prize list will suffice to show the order in which the awards were made. It must, however, be mentioned that the non-competing exhibits formed an admirable portion of the Show, especially those from Messrs. J. Veitch & Sons, Chelsea; J. Cheal & Son, Crawley; G. Bunyard & Co., Maidstone; H. Cannell & Sons, Swanley; J. Peed and Son, Streatham; Reid & Borneman, Jarman & Co., Chard, and the British Fruit Growers' Association.

OPEN CLASSES.—For best exhibition of Apples, kitchen and dessert, six fruits of each variety, not to exceed 100 dishes (distinct), orchard house grown fruit excluded.—First, Messrs. George Bunyard & Co., Maidstone, Kent. Second, Mr. J. Watkins, Pomona Farm Nurseries, Wittington, Hereford. Third, Mr. C. G. Sclater, Devon Nurseries, Heavitree, Devon. Fourth, The English Fruit & Rose Co., King's Acre, Hereford.

For best exhibition of Pears, six fruits of each variety, orchard house grown fruit excluded.—Second, Mr. G. Woodward, Barham Court Gardens, Maidstone. Third, Mr. J. Watkins, Hereford.

For best exhibition of vegetables, arranged for effect, and not more than four dishes (distinct) of any sort.—First, Mr. T. A. Beckett, Cole Hatch Farm, Penn, Amersham, Bucks. Third, Mr. W. Palmer, gardener to the Right Hon. Hume Dick, Thames Ditton.

For the heaviest Gourd or Pumpkin, weight to be stated.—First, Mr. George Shepherd, Lower Street, Pulborough, Sussex. Second, Mr. C. Boatwright, Beckenham Place, Beckenham. Third, Mr. E. C. Gaseltine, gardener to E. Byron, Esq., Coulson Court, Caterham.

For a collection of Pumpkins and Gourds.—First, Mr. G. Sturgess, gardener to B. P. Fearon, Esq., Court House, Banstead. Second, Mr. C. Osman, gardener, South Metropolitan District Schools, Sutton. Third, Mr. C. Boatwright.

For a collection of Ornamental Gourds.—Messrs. C. Osman, G. Sturgess, and C. Boatwright.

AMATEURS.—Twenty-four dishes of Apples, kitchen and dessert, distinct, six fruits of each.—First, Mr. G. Woodward. Second, Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, Third, Mr. S. Barlow, Stakehill House, near Manchester.

Twelve dishes of Pears, distinct, six fruits of each.—First, Mr. W. Chisholm, Cap Harcourt Rose, Oxenoath Park, Tunbridge. Second, Mr. G. Woodward. Third, Mr. William Allan, gardener to Lord Suffield, Gunton Park, Norwich.

Twelve dishes of Apples, kitchen and dessert.—First, Mr. T. A.

Killick, Weaving, Maidstone. Second, Mr. T. Parker, gardener to Mrs. Evans, Moreton Court, near Hereford. Third, Mr. S. H. Goodwin, Mereworth, Kent.

Twelve dishes of vegetables, not more than two dishes of any variety.—First, Mr. R. Lye, gardener to W. H. Kingsmill, Esq., Sydmonton Court, Newbury. Second, Mr. W. Pope, The Gardens, Highclere Castle, Newbury. Third, Mr. C. J. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher.

SPECIAL PRIZES.—Messrs. James Carter & Co.'s prizes for the best dishes of Holborn Abundance Potatoes and King of the Russets Potatoes, nine Potatoes to form a dish, were won by Messrs W. Pope, Highclere Castle Gardens, Newbury; R. Lye, Sydmonton Court, Newbury; and F. J. Hazell, Rose Cottage, Histon Road, Cambridge. For the best six dishes of Potatoes by Messrs. R. Lye; W. Pope, Newbury; F. J. Hazell, Histon Road, Cambridge; E. S. Wiles, Edgecote Gardens, Banbury; C. J. Waite, and C. W. Howard, Bridge, Canterbury.

Messrs. Sutton & Sons' prizes for the best collection of vegetables, six distinct varieties, were won by Messrs. C. J. Waite, T. A. Beckett, W. Pope, and R. Lye.

### CELEBRATED FIG TREES.

THERE is not, perhaps, an animal or plant, and certainly there is not a star visible in the firmament, which has not been the object of worship, and to which poor human beings have not offered sacrifices. Trees have, perhaps, been worshipped more than animals. Each tree has its legend, often its special mode of worship, and this is not always without reason. A custom exacts, for example, that in certain countries a tree should be planted to celebrate certain events, and perpetuate their memory. Such is the origin of the Trees of Liberty, of which such use and abuse was made in 1848 and since. To other trees is attached the souvenir of certain historical facts, such as the Arles Love Tree, under which the good king René administered justice; the Oak of St. Louis, that of St. Vincent de Paul; but this does not constitute a worship.

Some of these celebrated trees have been described. Let us say a word about the Fig tree. In antiquity it enjoyed great celebrity. The peoples of Greece rendered it a veritable worship. Some regarded it as a gift of the gods, and consecrated it to Mercury, Saturn, and Bacchus; others employed it to crown most of their statues and adorn their brows at public festivals. There were some celebrated Fig trees more particularly worshipped. There was one in Rome at the time of Pliny where the assemblies of the people took place. It was religiously tended in memory of that under which Romulus and Remus were found by the side of the wolf, their nurse. A Fig tree also grew at the spot where Curtius had generously sacrificed his life. The Indians at the present day worship a Fig tree of their country the Pagoda Fig tree. The god Vishnu, having been born under its shade, it is a sacrilege to cut it down, or even break its branches.

Native of the meridional countries of Greece, the Fig tree is to-day naturalised in all the hot climates of Europe, Africa, and America. Its products are lucrative for the Provincials and the inhabitants of Bas-Languedoc, who cultivate it in fields like the Olive. It is asserted that it was imported into these countries 600 years B.C. by the Phocceans, founders of Marseilles. It grows in Provence to a height of 5 or 8 mètres.

The *Ficus cerifera* supplies the Getah Lahö, or Sumatra wax. *Ficus venenata* produces a poisonous juice, with which the Indians of Guiana poison their arrows. *Ficus tinctoria* of the borders of the Amazon is utilised against tœnia. Another species produces fruits in which are found certain properties for the cure of rheumatism. *Ficus religiosa* gives shelter to an insect which produces an esteemed lacquer.

The wood of the Fig tree is valueless in commerce. On account of its spongy nature it absorbs fairly well oil and fatty substances. The locksmiths use it to polish their work. It burns badly, but gives a rather light coal. Some twenty-five years ago a magnificent Fig tree of more than 2 mètres in circumference was a subject of admiration in a garden of Montpellier. Iron bands encircled it, to support its partially dried and divided trunk. It produced two abundant crops of Figs, and its owner let them at the rate of 50 francs per annum to a wholesale merchant. This tree, remarkable for the country, was far from attaining the dimensions of certain Fig trees of hot countries.

Dumont d'Urville described an immense Fig tree, the bushy branches of which cover a large space in the Bay of Anna Maria, at Nouka Hiva, in the centre of a village. This tree measures 25 mètres in circumference. The trunk is composed of thick interlaced stems; it preserves almost the same width to a height of about 13 mètres, then it divides, forms about fifteen thick branches, several of which are 2 and 3 mètres in circumference. These last spread themselves horizontally, so as to cover with their shade a circular space of nearly 100 mètres in diameter. The principal stream of the valley flows under this majestic tree.—COSMOS.

### THE FIG TREE OF ROSCOFF.

The Fig tree, as is known, does not thrive much under the climate of the north and of the centre of France; its fruits rarely ripen; but in Brittany and the Normandy Isles it grows well, on account of the relatively mild temperature of these countries. Fig trees grow generally in Brittany in places sheltered from the north and north-west winds; they hardly rise above the houses which shelter them. Their dimensions are about that of an Apple tree.

There exists on the road of Saint Pol-de-Leon at Roscoff near this last village, a celebrated Fig tree, the exceptional form and dimensions

of which are worthy of notice. This tree is hardly higher than other Fig trees of the same country; its height is from 4 to 5 metres, but it covers with its branches a considerable extent, which may be estimated at about 400 square metres. It is situated in the kitchen garden of a large farm; the single trunk, somewhat low and twisted, is partially buried in a thick enclosure wall, which fact renders the estimation of its size very difficult; the section of the trunk is, we think, about 15 square decimètres, corresponding to a tree of 40 centimètres in diameter. From this trunk, and at 1m. 80 about from the soil, run horizontally and in every direction, a considerable quantity of branches, some of which spread themselves to a distance of more than 15 metres from the trunk. These large branches serve as basis for a cluster of small branches which rise towards the light, forming a kind of roof of verdure.

We can easily understand that a tree arranged in such a way cannot support itself. The thick branches lean against the enclosure walls of two small kitchen gardens, and on thirty-eight granite pillars, each formed of a single stone about 2 metres high and 30 to 40 centimètres thick. Between the two rows of parallel pillars is a covered alley of about 25 metres long. Beyond the last range of pillars the branches fall as far as the ground. When for the first time I saw this tree in the month of September, 1884, it was covered with leaves still green, which formed a thick shade; the Figs seemed rather numerous and were beginning to ripen.

I was curious enough to ask the farmer for some information about this extraordinary tree. I give his answers, which unfortunately are rather vague. "About what age is the tree," I asked him. "Sir," he replied, "the old people of the country have always seen it as it is at present." "How many ripe Figs does it give yearly?" "As many as you like; in spite of plucking them every day there always remain some more." "But how many do you take every day?" "Several basketfuls during the season—that is to say, during two or three months." "Does this tree still grow?" "Yes, sir; it would cover all the property if it were allowed to grow. I am obliged to cut every year the ends of the branches which come out of the alley."

However vague these observations may be I fancied that they were interesting enough to be noted, the more so as the Fig tree of Roscoff, in spite of its reputation, has not to our knowledge been described in a complete manner. This tree, although very old, is still very vigorous, and bears excellent fruits in abundance; in spite of the disproportion existing between the dimensions of the trunk and those of the branches these last have still enough sap to continue to grow. A peculiarity which is rather strange is that the vegetation, rather rich in the environs of Norbaix and Saint-Pol-de-Leon, ceases so to speak where the Fig tree grows. Starting from the farm on which the tree is situated the sea wind scorches and lays the trees, which are stunted and thinly scattered over a soil arid and stony as far as the sea.—(La Nature.)

THE PINE APPLE.

DURING the last few years I have grown and ripened the fruit from the suckers in the same house. The last twelve months I have cut twenty-nine Pines, weighing 132 lbs. 14 ozs., the heaviest 10 lbs. 8 ozs., the lightest 2 lbs. 13 ozs. I cut the first Pine on October 4th, 1889, the last on September 20th, 1890. The house is span-roofed, 22 feet 6 inches long, 18 feet 6 inches wide, with side lights 2 feet high, and one entrance. The house is heated by four rows of pipes on each side and four rows of pipes under the Pines. The bed is in the centre of the house. It is 17 feet long, 7 feet 6 inches wide, filled with tan 2 feet deep. Fresh tan is added to the old tan in spring and autumn. The latter is drenched with hot water to kill the insects. We grow between fifty and sixty plants. The soil we pot the suckers in is fresh fibrous loam, adding bone meal, soot, and charcoal. The fruiting Pines are placed at the warmest end of the house, and the suckers at the other end. In the winter we avoid high temperature by day, not exceeding 70°. Great care is taken in the supply of water, and I find they are better dry than wet. Diluted cow manure and soot are supplied, but we do not use the evaporating trough for moisture, and only lightly syringe the Pines twice a day in the summer. We distribute plenty of water about the house in hot weather. The Queen and Smooth Cayenne I find the most useful varieties. Care is taken to prevent white scale attacking the Pines. Each side of the house over the pipes is employed for growing small plants, and we find the house a useful one. I am sorry to hear it said the Pine Apple is not worth growing now foreign fruits are so cheap.—WILLIAM KIPPS, Walton Lea, Warrington.

AN EDIBLE FUNGUS OF NEW ZEALAND.

HIRNEOLA POLYTRICHA.

FOR some years an edible fungus, a product of the New Zealand forest, has become an important article of commerce between that colony and China. The fungus belongs to the same genus as the European Jew's Ear (*Hirneola auricula-judæ*), a tough but gelatinous fungus, formerly in reputation as an ingredient in gargles. The New Zealand fungus now under notice (*Hirneola polytricha*) is well described by W. Colenso, Esq., F.R.S., in the Transactions of the Penzance Natural History and Antiquarian Society, 1884-85:—

"*Hirneola polytricha* was first made known to science by Montagne as belonging to this genus, and as being an inhabitant of the East Indies and Java, though, like our two other species, it was first published as belonging to the closely allied genus *Exidia*, there being but a very small

natural difference between these two genera. This species is thus briefly described by Berkeley (translated and abridged from Montagne): 'Sub-hemispherical, cup-shaped, expanded, lobed, densely villous externally with grey hairs, disk purplish-brown.'

"It is of various sizes and, I might almost add, of shapes; some measuring a few inches, and when wet filling a large teacup or small basin; a large specimen weighing only 2½ drams. It is found growing on the trunks of many trees, both on living and on rotten ones (especially on the latter while standing), particularly on *Corynocarpus laevigata* and on *Melicytus ramiflorus*, both of these trees being endemic as to genus as well as to species; the former tree is mostly confined to the seashore, where it often forms dense and continuous thickets. In such situations it is generally of small size, but when standing apart it is of much larger dimensions, and not unfrequently in suitable spots it wears an imposing appearance from its large green and glossy persistent Laurel-like leaves. The latter tree is scattered plentifully throughout the country, and the foliage of both being evergreen, are eagerly browsed on by cattle.

"The only market for this fungus is China. From official information obtained from Hong Kong, we find that it is largely used by the Chinese in soups with farinaceous seeds, and also as a medicine, being highly esteemed. The Chinese have long been in the habit of using another species of this same genus that is indigenous in North China, and also of importing another species from other isles in the Pacific; so that the use of this kind of fungus as an article of food is not new with them. Who can say in this article of food Western pride may not again have to learn something more from this ancient, highly civilised, and much-injured people?

"At first, and for some time, our New Zealand fungus was only exported in small quantities. The demand, however, rapidly increasing, and the article plentiful and obtained at little cost, save the easy and untaught labour of gathering and drying it, its export rapidly increased. The drying of it, if collected damp, was an easy matter—merely spreading in the air and sun till dry, which soon takes place, when it is roughly packed in sacks, and if kept dry keeps good and sound for a very long time. The price paid to the collectors for it was originally small, only 1d. a pound; at this figure it remained for some time. It is now nominally 2½d. in some places, which sum, however, is often paid in barter.\* It is said to be sold in the China shops at about 10d. or more retail. I am not aware of the actual price obtained by the exporter, but we find that its declared value at the Customs has ranged from £33 to nearly £53 per ton, which no doubt is much under the real value.

"During the last twelve years no less than 1858 tons of this fungus have been exported, valued at £79,752, as is more particularly shown in the following return, which I have compiled from sources published in the Government statistical papers:—

Years.	Quantity. Tons. cwt.	Declared Value.
1872	58 0	£1,927
1873	95 0	1,195
1874	118 0	6,226
1875	112 0	5,744
1876	132 0	6,224
1877	220 0	11,318
1878	103 0	5,178
1879	59 5	2,744
1880	183 12	6,123
1881	187 11	8,122
1882	339 17	15,581
1883	250 6	9,300
	1858 11	£79,752

"I should observe that the official entries show that those exports are confined to the northern island, and only from two ports there—viz., Auckland and Wellington, except some small lots amounting to seven tons, exported from Poverty Bay and Napier in the last two years, 1882 and 1883. The fungus, however, may have been extensively collected in the districts containing those two larger ports."

In order to test the value of the New Zealand fungus as an article of food a supply of it was recently obtained for Kew by Mr. Thomas Kirk, Chief Conservator of State Forests, Wellington, New Zealand.

A portion of this supply was submitted for analysis to Professor Church, F.R.S., who has been good enough to furnish the following interesting note:—

*Hirneola polytricha*.—A sample of this fungus, in the air-dried condition as received, was prepared for analysis by careful brushing and the removal of a few fragments of obviously foreign substances. It gave the following per-centages:—

Water	17.0
Albuminoids (calculated from total nitrogen)	6.8
Carbohydrates, digestible	70.5
Carbohydrates, indigestible	1.9
Fat (ether extract)	1.5
Ash...	2.3

A few remarks as to these figures will prove useful in appreciating

\* I should, however, mention that in the spring of 1883 a large party of Maoris residing on the West Coast, near Mount Egmont, who had for some time been collecting and storing fungus there, sold the lot to an Auckland agent and general dealer, but took the whole total sum, upwards of £425, in hard cash.

the food value of this fungus. First of all the nitrogen present does not all exist in the form of albuminoids. The coagulable albuminoids, as estimated by the phenol method, amount to 5.4 per cent.; the remainder of the nitrogen occurring chiefly as amides, is not nutritive. If this result be accepted, the proportion of albuminoids to digestible carbohydrates plus the starch—equivalent of the fat, becomes 1:13.7 instead of 1:10.9, as shown by the percentages recorded above. Anyhow, this fungus is singularly poor in albuminoid or muscle-forming substances, and differs remarkably in this particular from the numerous edible fungi of which analyses have been previously made. In these analyses we find at least twice or thrice as much albuminoid matters, often more.

The substance or group of substances which I have called "digestible carbohydrates," contains neither starch, nor inulin, nor cellulose. Its chief constituent is a gum-like body apparently allied to bassorin, and well worthy of further examination. It swells up greatly in water and is soluble in dilute warm solutions of caustic alkalies. Its solutions gelatinise on cooling. I have observed what seems to be the same compound in other species of fungi, and it is probable that it has been described under several different names. The fungus now been discussed contains so large a proportion of this body that it presents a very convenient material for its isolation and the study of its composition and properties.

The ash of this fungus is rich in potash and phosphoric acid. Of the former constituent the ash contains no less than 42.02 per cent.; of the latter 20.02. These proportions are exceeded in the ash of other species; moreover, the ash in one hundred parts of this *Hirneola* is much lower than that recorded for other fungi.—A. H. CHURCH (in *Kew Bulletin for October, 1890*).

### ASPHALT WALKS.

Your correspondent "C. O. S." (page 306) has described a cheap and simple method of making asphalt walks. I think there is nothing to equal them for kitchen gardens. They are clean and fit to walk upon in all weathers; no weeding nor weed-killer required. We have been laying down a little annually for several years, as materials accumulate and our limited assistance would allow. The following is our mode of procedure. The ashes from the horse are put through a half-inch sieve, and during the autumn and winter are stored in an open shed. The cinders are taken to the stokehole, with the result that the output of clinkers is largely increased. These, together with broken bottles, brickends, broken tiles or slates, in fact anything hard and of no other use, are put together in a mass, and as opportunity occurs are broken up rather small.

About the middle of April an old door is fixed on four posts driven into the ground, about 2 feet high, in the shed near the mass of dry ashes. When a wet day occurs from now till the middle of May the ashes are mixed on this door in the usual way with the tar as it comes from the gasworks, which costs about 1½d. per gallon. It is tossed into a conical mass, and if left, as it often is for days or weeks, is covered with old mats or sailcloth to keep the outside from drying too much. Additions are made to the heap from time to time till all is mixed. As the time for putting it down draws on the old gravel walks are simply roughed up a little with a pick, the clinkers—previously broken—laid on evenly, and rolled down to give an even surface to receive the ashes. The latter if it has laid in the mass for some time is apt to heat, and to a certain extent loses its moisture, and in this case it should be pulled out and some more tar poured on the top and turned once or twice, so as to get it all of one consistency. It is then laid on the walks in the way described by your correspondent, and similarly treated. I think it best to get a clean even surface by well rolling before applying anything to the surface, using a little water on the roller to keep the tar from sticking to it. We then give a liberal sprinkling of "Pea" brack, first passing a dry roller over it several times, afterwards using water on the roller to still further work the brack into the surface. This, I think, is still simpler and cheaper than "C. O. S.'s" plan, and we find that with simply the ashes from the house and tar a very good walk is made at the least possible expense, and mixing it on wet days during several weeks is a saving of time without disadvantage to the material.—R. I.

### FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House*.—The trees are at rest and promise well, the buds not being too large. That is a good sign, as Peaches and Nectarines subjected to forcing year after year are liable to have the buds swelled to a large size, and these not unfrequently fall when they should be starting into growth. Some kinds are more prone to this defect than others. Noblesse stands at the head in liability to cast its buds, then comes Grosse Mignonne, and both these have a marked tendency to form double or triple fruit buds without a wood bud at the same joint, also to form buds with two or three pistils in embryo, in due course developing into twin or triplet fruit. This is what is meant by over-maturity of the buds, and is

common to all the large flowered varieties of Peach and Nectarine, which probably arises from a prolonged season of growth, with a decided tendency to over-production. The remedy, therefore, is to keep the trees as cool as possible after the fruit is gathered consistent with their safety, and remove the roof lights when the wood becomes sufficiently firm. Where this has been done the borders have got thoroughly moistened to the drainage, and when that is the case, and the buds are not over-matured, there is no fear of their falling. The trees should be pruned, dressed with an insecticide, and the whole of the house thoroughly cleansed. The trees also should be tied to the trellis, everything forwarded so that a start can be made without delay when the proper time arrives. The lights should remain off until the time of closing the house, or if the lights are fixed, which is a great mistake, as it causes the house to be subject to alternating fluctuations and depressions both of heat and moisture; the border inside must not lack moisture, and air must be given to the fullest possible extent. No amount of frost will injure properly matured wood, and the buds are never damaged by frost until they commence swelling.

*Second Early House*.—The trees have for the most part cast their foliage; the roof lights will have been off some time, or if kept over the trees longer than usual, as sometimes is necessary when the wood is strong to mature it properly, they must now be removed. The ventilating lights both top and bottom may remain, so that the unfixing and refixing of them is obviated, whilst the trees have complete exposure to atmospheric influences. The exposure has an invigorating tendency, it insures perfect rest, and the rains do much to free the trees of insects, besides soaking the borders. When the foliage is all down the necessary pruning, dressing with an insecticide, and cleansing the house should be proceeded with, removing the surface soil down to the roots, and supplying fresh material, but not covering the roots deeper than 2 or 3 inches. In the case of fixed roof lights watering may be necessary. Under no circumstances must the trees be allowed to become dry at the roots.

*Midseason Houses*.—The trees in these are just in the proper condition for lifting. It should be done with dispatch, all the materials being in readiness. Provide efficient drainage, shortening back any strong roots, and bringing any that are deep nearer the surface, employing the compost moderately firm. Good loam, rather strong, with an admixture of a sixth of old mortar rubbish, and a bushel each of bone meal and charcoal dust to every cartload of loam, will grow Peaches and Nectarines perfectly. If the soil be light add a fourth of clayey marl, and if very strong a similar quantity of road scrapings; avoid manure, except at the surface; give a good watering, and the trees will soon get established in the fresh compost. Trees judiciously treated at the roots whilst they have foliage seldom fail to set and stone the fruit satisfactorily. Borders that have the soil a soapy mass, and it is not possible to remove it, may have a good dressing of quicklime (an inch thick is not too much), mixing it with the surface soil as deeply as the roots allow without much disturbance. Nothing, however, is so effectual as lifting and renovating the border.

*Latest Houses*.—Except from the latest varieties the fruit is all gathered. Trees from which it has been gathered should have the bearing wood of the current year cut out, leaving no more wood of the current year's production than is required for filling vacant space and affording fruit next year. The foliage should be thoroughly cleansed of dust or insect pests by a few good washings from the syringe or garden engine. After that the trees will not require syringing, dryness with thorough exposure of the wood to light and air being essential to the perfecting of the wood and buds. Where this is not effected the house may be kept rather close by day, so as to secure a good heat, there being of course enough to ensure a free circulation of air, and the house should be fully ventilated at night. Any trees that have too gross wood should have a trench taken out as deep as the roots, and about one-third the distance from the stem the trees cover of trellis, leaving it open a fortnight, then filling again firmly.

CUCUMBERS.—Place out the latest plants which are to afford a supply of fruit about the new year on ridges or hillocks, training with a single stem to the trellis, up which they may be allowed to advance about two-thirds, when the lead may be pinched. Those not having the convenience of a Cucumber house may secure fair supplies of winter fruit by growing the plants in pots or boxes, training the plants near the glass over pathways in stoves, fruiting Pine houses, or other heated structures. Plants in bearing should not be overcropped, or the fruit allowed to remain longer than it is fit to cut, removing all deformed fruit in a young state. Maintain a night temperature of 70°, 5° less in the morning, 75° by day, up to 85° with sun, admitting a little air at the top of the house at every favourable opportunity. The evaporation troughs should be charged with liquid manure, and the floor damped about 8 A.M. and 4 P.M., dispensing with the syringe. Reduce the supply of water at the roots, but not so much as to cause flagging. A few horse droppings sprinkled on the beds occasionally will benefit the plants through the waterings and the ammonia given off. Keep the foliage thin and the glass clean, so as to secure thoroughly solidified growth.

### KITCHEN GARDEN.

EARTHING UP CELERY.—Some gardeners earth their Celery as fast as it grows. Others do not earth it until it is of full size, or nearly so. The former is the better way with Celery that is required for immediate use; the latter the more suitable for Celery that has to be kept for a long time, as when it is not earthed until full sized the stems are much harder than when they are covered and blanched from the first. It is now, however, time that all Celery should be earthed. If severe weather

occurs the non-covered heads would suffer severely in having no soil to protect them. Celery for early winter use that has been previously earthed should now have final attention. That which has not been done yet must have the loose short side leaves cleared off, and the main ones tied together in a firm bunch. This will prevent the soil falling into the centre. The soil must be placed well round each plant, and pressed down firmly. When finished, the ridge should slope sharply from the top to the bottom, as this assists in throwing off the rain and preserves the Celery; untie each plant after earthing, and do not break the main leaves in handling them.

**STORING BEETROOT**—Beetroot is somewhat easily injured by frost. It will not keep well into next spring or summer if the frost touches it before being stored. It is therefore important that it should be stored before any severe frost occurs, and it is not quite safe to leave it out in many parts until November. Take it up and store it at once. In stiff soil it may be necessary to lift each root with a fork, but the root must not be broken at any time. Do not trim any of the rootlets off, and cut the leaves about 3 inches from the crown, as if the juice escapes from the main root its value will be greatly reduced. Place them in an open shed for a day or two until the soil adhering to them has dried, then store them in their winter quarters where there is no artificial heat or dry air. Sheds or cellars are suitable places, and each layer of roots, when formed into a heap, must be covered with a quantity of sand or fine ashes. These are placed on to keep the roots plump and fresh.

**ASPARAGUS**.—In many cases, as soon as the owners of an Asparagus bed see the heads becoming withered in appearance, they conclude they are of no further use to the root, and cut them off. This is a mistake, as the stems are not ready for cutting down until they have become quite withered, and this will not be until the middle of November, or later. Weeds that obstruct the light from the crown of the plants should be removed, as, unless the young growths that are now formed are fully matured, the produce will be poor.

**TOMATOES**.—The season for these is virtually over, and so far as open air crops are concerned it has not been a successful year. We have gathered many ripe fruits from our plants trained against the kitchen garden wall, but nothing like a full return. There are, however, many green fruits on them still, and many will be in this state throughout the country. Few will ripen now if left on the plants, but should frost occur the green ones may be blackened by it. This causes them to become soft, and then they will not ripen but decay. To avoid this and save the crops in good condition all open-air fruits should be cut off now with the stems attached and tied in bunches of from six to a dozen, and suspended in a dry airy room to ripen. If the fruit is wanted soon they may be hung in a warm place, but if not until well into November or December a cool place will suit it best. All plants from which the fruit is cut should be thrown away.

**MUSHROOMS**.—If woodlice or any insects are plentiful on beds that will come into bearing soon, pour boiling water round the bed, but do not allow any of it to fall on the centre. They can be destroyed with less injury to the bed now than when the Mushrooms are plentiful. If the heat has declined in any beds below 70°, cover the surface with a layer of hay to the depth of 9 inches. If the surface of the bed is rather dry, water it with water at 80° before putting on the hay, but we do not approve of watering beds very much before the crop appears, and prefer to keep the surface of the bed in a moist condition by making the atmosphere of the place in which the beds are humid. Collect more materials for more beds, and form these as fast as one, two, or three cartloads can be secured. Beds made up now will bear at Christmas and in January, times when the crops are greatly valued.

**LEEKs**.—Those intended for use during the winter should have several inches of soil put up round their stems. This will blanch them, and make them good for use. Those intended for spring should not be earthen up until after the new year. Very large Leeks never keep well, and the huge specimens should be used first.

#### PLANT HOUSES.

*Adiantum cuneatum*.—Plants from which all the fronds have been removed that are suitable for cutting should have all small fronds about the crowns of the plants cut clean away. Remove all loose soil from the surface of the plants, and dust them with soot if slugs have been troublesome. Keep the plants rather dry, and in a temperature 5° lower than that in which they have been grown. After a few weeks' rest the plants will start again freely into growth if introduced into heat. Expose all plants to the sun that are well furnished with fronds to harden them, so that they will stand well after they are cut. Admit air daily, and be careful that no water is allowed to settle upon the fronds. Repot young plants that would otherwise become root-bound before the close of the year. They will soon become established, and continue through the winter and spring to yield suitable fronds for cutting when they begin to be scarce on old established plants. Good fronds are generally scarce during February and March, but young plants placed into 4 and 5-inch pots now will continue growing slowly and push up large fronds during those months. Pot these in equal proportions of loam and leaf mould, with the addition of sand. If kept in a temperature of 60° the roots will soon take possession of the new soil.

*Small Ferns*.—Those growing in small pots may be placed into larger sizes as they need more root room. These plants in the temperature advised for *Adiantums* will continue to grow throughout the autumn and winter, and early in spring will be suitable for decoration. Repot those that are growing in boxes and pans as they become large

enough. Nothing is gained, but the reverse, by allowing them to become crowded before they are placed singly into small pots. Small Ferns are always useful, and a good stock in various stages should be kept on hand. Pterises and other greenhouse Ferns are amongst the most useful, as they can be employed effectively in large conservatories in many positions where flowering plants fail to do satisfactorily.

*Hardy Ferns*.—Many of the choice forms of *Athyriums*, *Polystichums*, and others are invaluable for decoration in a young state. Many of these in gentle warmth will continue growing throughout the winter. Even plants that have been grown in cool structures soon start again into growth when placed in heat; the old fronds can be removed as the new ones display signs of pushing up. Hardy varieties are not half so much used for decoration as they deserve to be; they can be had in positions where it is scarcely safe to place tender Ferns, and when they are shabby, after being employed in rooms for some time, are quickly restored again to health and beauty. Seedlings or young Ferns raised by various means may be subjected to the same temperature and treatment as Pterises and other greenhouse Ferns.

*Foliage Begonias*.—These are not to be despised for conservatory decoration during the autumn and winter months, in fact the better varieties when associated with Ferns at any season of the year are very effective. In positions where flowering plants fail to do well these *Begonias* are doubly useful. Young plants recently rooted may be placed into 4-inch pots, and in a very short time, if kept in gentle heat, they will be ready for the conservatory.

*Ficus elastica*.—Young plants that have been raised from eyes and cuttings, and are in a backward condition, should be pushed on in heat; they will continue to grow in a temperature of 60°. If potted moderately firm and exposed to light they will grow into sturdy specimens. The growth of young plants is very slow when subjected entirely to greenhouse treatment. Young plants that have recently been raised from cuttings in small pots, and are well rooted, may be placed into 4-inch pots in a compost of loam, sand, and one-seventh of manure.

*Epiphyllums*.—Plants that have thoroughly ripened their growth and are showing their flower buds may be arranged with *Adiantums*. In no position when elevated above these plants are the beautiful flowers of the *Epiphyllum* shown to greater advantage. It is not wise to arrange all the plants in this position where flowering plants are needed in succession. Keep all those that have completed their growth and are not showing flowers perfectly cool, but fully exposed to the sun. Water them carefully, and if worked do not allow them to suffer by an insufficient supply at their roots. It is a mistake to keep them dry until they shrivel.

*Palms*.—Young plants that need more root room should be potted. It is a mistake to keep them too confined at their roots where the object is to grow them on into larger plants. It is much better to turn out any plants that are in an unsuitable condition at their roots and repot them than to leave them in this state throughout the winter. Do not give these plants large pots, for the soil is liable to become sour before the roots take possession of it, and this must be avoided if the plants are to grow freely and retain a healthy appearance. Be careful not to overwater *Cocos Weddelliana*, and keep the plants in a temperature a few degrees warmer than the general stock. This Palm does best in peat and sand, while the stronger growing kinds do well in loam and sand. Where good leaf mould can be had direct from the woods of Oak or Beech equal portions of loam and leaf mould may be used with the addition of sand.

#### APIARIAN NOTES.

##### COLONIES HAVING YOUNG QUEENS SWARMING.

As many bee-keepers have experienced during this tantalising, abnormal, and exceptional season, bees have sometimes acted contrary to the general rule. According to instructions given in these pages some have fed swarms having young queens, but contrary to expectations these swarmed during July in the same manner and proportion as the prime swarms, which was puzzling, and created an opinion that our advice was not sound. The case was as follows. They knew the consequences that were certain to occur subsequent to feeding swarms having queens that had already laid their full number of eggs for the season. Relying upon our advice they fed prime swarms sparingly, but fed after swarms freely, with the result that they swarmed too, which appeared to stultify what had been said. The error was with the bee-keepers themselves, who failed to carry out the whole of the instructions, placing the bees into too small hives, and failing to increase the size of them as the bees increased in numbers.

Young queens are most prolific at their earliest stage of existence after fertilisation, and it is not correct, as was stated by an apiarian in a contemporary—"That queens had to be a few months

old before they became prolific." My nuclei at present have more bees than any of my unswarmed stocks, and such stocks never fail to give the greatest satisfaction provided care be taken to prevent an excess of drone comb.

#### PUNIC BEES.

These are still active and are giving satisfaction as good workers. I can detect no difference in the quality of their honey, but can in their combs. They are completely and compactly filled and sealed, and should this be a permanent feature in their habits, will add to their value.

#### BEES FROM IMPORTED QUEENS.

Some have been sent me by "A Hallamshire Bee-keeper," and appear very attractive bees; they were lively and of a rich dark plum colour, and while they seem quiet to their owners are determined in keeping robbers from their hives. I liberated two in the presence of several bee-keeping gentlemen in a restaurant in Glasgow. A bee was caught by each person and placed beneath a glass, when instantly the bees pounced at each other, and quick as thought one stung the other to death much in the same manner as queens do. This is also a lesson worth remembering when introducing queens and joining bees from two different stocks. The old method of sprinkling two lots of bees with peameal is a good plan, and quiets the bees, but if the day is chilly the practice is bad, as the bees may be chilled before their toilet is completed. Feeding the two lots of bees with one honey and locating them on frames from one hive, caging the queen to be preserved, and leaving both queenless for a time, is a certain and safe plan. If two lots are gorged with honey they may be shaken together quickly, and this is a speedy and safe method. When any odour can be conveyed to any bee that also has a good effect, but often some of the bees do not catch the odour, hence fighting begins, and in many cases continues, and not unfrequently the queen is killed or maimed. The great object of the bee-keeper is to prevent robbing or fighting, or exciting the bees in any way.

#### MAIMED QUEENS.

Maimed or mutilated queens seldom survive the spring, or if they do so are rarely prolific enough to be profitable. The same may be said of those that have been exposed to extreme cold and dampness. The latter and exhausted queens are those that leave their hives in spring, termed "hunger swarms."

#### QUEENLESS HIVES.

I predicted some months since that there would be a large percentage of queenless hives or hives having unfertile queens, and this is now being verified. In several apiaries fifty per cent. of the hives are either queenless or having unfertilised queens, and in every case where queens were older than one year the loss is greatest. Bee-keepers should make sure before it is too late that the queens are all healthy, and likely to continue laying until next May or June. After that young queens should supersede every old one, and no stimulative feeding should be given to queens of an older date than those of 1890. Leave all such until next season.

#### STIMULATIVE FEEDING.

The supposition that driblet feeding is effectual in forwarding bees is a delusion. In an apiary situated but a few yards from my own where driblet feeding was carried on all the summer, the bees do little more yet than half fill the body of the hive, while those in my own apiary having plenty of stores are strong.

#### MOVING HIVES.

Modern bee-keepers are beginning to discover that the old system of moving bees from one place to another, as the flora of the district invites, is more profitable than keeping the bees pent up in the home garden the whole year. They are also finding that the hives commonly in use are ill-adapted for the requirements of the bee-keeper, and are too unwieldy for moving about from one place to another to be easily managed or profitable.

#### THE STANDARD HIVE.

This has already lost favour because of the introduction of two sizes of frames for one hive, necessitated through the discovery

that the so-called standard hive was too small for bee husbandry, a mistake every practical bee-keeper saw from the first. Then the make of the hive disallows bees to be moved about with profit, and the double casing, which prevents the thorough evaporation of the moisture from the interior of the hive, hastens decay, and is inimical in every respect to the well-being of the bees and production of honey.

#### OUTSIDE CASES.

These are far superior to double cased hives, but they have a grave fault—viz., when the hive is removed the cases stand in the way as so much lumber, whereas the wrappings with outer oilcloths accompany the hive at all times, and they may be taken to every place; while, when at home, the curved sheet of galvanised iron as a roof and porch, are a thorough protection from external moisture, and no annual painting is required, as is the case with double cases, or outside cases. It is not because I despise neatness and attractiveness in the apiary that I discourage these things, but because it is neither economical nor justifiable to carry out a system prejudicial to the bee and unprofitable to the bee-keeper. The style of bee-hive architecture has been carried beyond the limits of usefulness, and entirely at variance to the requirements of the bees and their owners. The successes of so many of our pupils this year, while those near them working upon a different system with not a pound of surplus honey, will perhaps convince them that the loss in a good season will be in proportion to the present year's success and non-success of the two methods.—A LANARKSHIRE BEE-KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**China Roses (T. F. W.).**—We received a box half full of petals, not one bloom. This was in consequence of no suitable packing being used, such as damp moss, or green grass, or leaves. The Rose is either Cramoisie Supérieure or Fabvier, we cannot tell which; but you cannot err in planting both these most richly coloured of all China Roses.

**Raspberries Unsatisfactory (F. J.).**—In some soils Raspberries do not thrive, those which are very strong, cold, and wet, and others which are thin and dry being alike unsuitable. Even in good soils some persons have found it difficult to establish productive Raspberry plantations, mainly through a mistake made at the outset in not shortening the canes to within a foot or less of the ground when planting, or shortly afterwards, before they make their first season's growth. Long canes with few roots are planted, and the canes left their entire length, or nearly so, for fruiting. They may produce a few fruits, but this exhausts the plants so much that the roots become almost paralysed, and the suckers few and weak. This check at the outset often affects the plants for years. You will find the right method of procedure figured in the Fruiterers' Company's prize essay on "Profitable Fruit Growing," the second edition of which is now being issued from this office, 1s. 3d., post free. Carter's Prolific is a free and sturdy grower and scores of acres of it may be seen in the fields in Kent as fully exposed to the sun as your garden can be, but all the same, Raspberries grow well in partial shade. Rivers' Hornet, Superlative, Baumforth Seedling, and Prince of Wales are taller growers. It is not a good plan to dig deeply among Raspberries, but strong soils especially should be pointed over. Partially decayed manure and vegetable refuse are good for spreading on the surface when the plantations are put in order, and should be left to decay. Not knowing the nature of the soil of your garden, we cannot give a more definite reply.

**Cellini Apple (Idem).**—This is classed as a culinary Apple in the essay above referred to, also by Dr. Hogg in the "Fruit Manual," where it is described as of the "first quality." Many persons consider the quality good enough to entitle it to rank as a dessert variety. It is, like the Blenheim Pippin, used both for culinary and dessert purposes, and therefore exhibited in both culinary and dessert classes. Unfortunately the trees are liable to canker, and though they bear early and freely they seldom remain healthy and productive for many years.

**Grape Wine (J. B.).**—A very good wine can be made from Grapes

which do not attain their perfect maturity in the open air in this country. The fruit should be allowed to hang as long as it is likely to derive any benefit in the way of ripening, and when it is ready the bunches are to be gathered and laid carefully, so as not to bruise the berries. The berries are to be picked separately from the stalks, discarding all that are in any way decayed. Measure the fruit as it is put into the fermenting tub, and to every fifteen gallons of fruit add one gallon of soft water. Stir and bruise the fruit, and after standing for twenty-four hours, strain and press the fruit through a hair cloth or coarse canvas bag subjected to pressure. Now test the liquor by the saccharometer and bring up the gravity to 120 by the addition of sugar, every pound of sugar raising the density 35 or 36. Let the whole be well stirred, and add one ounce of argol to every three gallons of must. Stir the must every day, morning and evening, and when the density falls to 80, and the fermentation becomes languid, the cask is to be bunged up and the wine bottled off in the month of March following. Argol can be had from chemists, and perhaps a saccharometer too, or from Messrs. Cetti, Glass Merchants, Lambeth.

**Injured Cyclamens (P. C.).**—The grubs you send are the larvæ of the destructive weevil, *Otiorhynchus sulcatus*, a brownish black beetle-like creature, which eats Vines, Roses, Ferns, and most other plants, feeding at night and hiding in the soil and other obscure places in the daytime. The insects should be sought in spring with the aid of a light, and as many as possible caught and destroyed. They deposit eggs just within the surface of the soil in pots and borders, and the maggots resulting devour almost any kind of roots with which they come in contact. They are very difficult to destroy. You might make a few experiments with some with different insecticides, such as Lemon oil, Fir-tree oil, and petroleum solutions, of a strength that could be safely applied to the roots of plants. In the case of your Cyclamens, however, we suspect the only effective means of dealing with them will be to shake all the soil from them, well wash the corms and roots with a safe insecticide, apply bruised charcoal to the eaten parts, and repot in fresh soil free from the maggots. If there is the slightest suspicion of any being in the new compost, it should be baked sufficiently to destroy all grub life, then made properly moist before using. The heating to which the soil is subjected will not impair it, but, on the contrary, increase its fertility.

**Plum Trees not Bearing (W. E.).**—Many Plum trees produce blossom, but from various causes fail to bear fruit. Your trees, we presume, produce no blossom. They may have grown too luxuriantly and not ripened the wood sufficiently for blossom formation. It is not improbable, also, that you have been too free with the use of the knife, for the more some Plum trees are cut the less they bear. You do not indicate the form of the trees. If they are standards or bushes the pruning should be practically limited to thinning, not cutting back to spurs; if trained to walls or as espaliers the summer growths from the main branches should be pinched in June and subsequently, not allowed to grow until the autumn. It is evident, also, that the root action is too powerful, and if you dig a deep trench 3 feet from the stems, and undermine the trees, you will most likely find some strong roots striking down more or less vertically, and if so sever them, fill in the soil again with some mortar rubbish and wood ashes intermixed, and press it under and round the roots firmly. Do not dig the ground near the stems, but scrape some of the old soil away and add vegetable refuse for inciting a mass of fibrous roots near the surface, and the growths of the trees will then be more sturdy and fruitful in character.

**Pruning Fruit Trees (St. Julien).**—We are obliged by your letter and sketches and now understand the case. You state in your letter that we were wrong in our supposition on a former occasion. We ought not to be compelled to base replies on supposition, but inquirers should make clear each case on which information is desired. We were certainly not wrong in the principle embodied in our reply. If a bud dies through any cause, obviously it cannot grow, but if sound and good it will push the more strongly the more the stem is cut back. We are not satisfied now that the leader of your espalier was cut back low enough for insuring two side growths and a leader. You appear to have cut it to the wire, whereas, if your sketch is right, the leader was previously cut considerably below the wires. If one or two shoots push strongly near the top of a cut back leader the growths are apt to draw the sap from the buds below, and these remain dormant. We have no doubt, the tree being healthy, if the leader were cut back into the two-year-old wood, that fresh growth would issue, but we do not perceive the necessity for doing so, for if you cut back both the leader and the side branch to good buds on sound wood close to the wire, growths may be expected to push in the spring, one of which can be chosen for training to the right, the other to the left, and the third to extend, if you have other wires to furnish, if not, only two shoots are needed, and all others should be suppressed. We are now alluding to the tree represented in the larger sketch. If a shoot push very strongly from one side, and weakly from the other, pinch the strong when it has made four or five leaves, and make it start again, as it will, and give the weak a chance to extend. If more than one shoot push after pinching, reserve the most promising for extension, pinching the others as soon as they make three small leaves, also any after growths that issue to one leaf. When a branch on one side of a tree is not strong enough, while another on the opposite side is too strong, elevate the weak and depress the strong, more or less according to the disparity between them, and their strength will become more equalised. Now we turn to the small sketch. What you describe as the leader is correct, and as all the wires are furnished, it ought not to have been allowed to extend. Cut it out

at once close to the top horizontal branch, and permit no more vertical growths from the top of the tree. In respect to oblique cordon trees we say that, as a rule, more is lost than gained by shortening the leaders; but there are exceptions to every rule. For instance, a leader may be obviously unripe to the tip, or may terminate in a fruit bud, in which cases cutting back to a good wood bud is essential for the prolongation of healthy growth. This must be left to individual judgment. From oblique cordon trees planted two years ago fruit was exhibited at the late Guildhall Show, won a prize in great competition, and a dish was chosen from the collection and sent, with other superior examples, to the Queen. The same advice we gave in the management of the trees in question we have given to you, and now we hope have adduced proof that it was not very erroneous.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Dianthus*).—A, Dumelow's Seedling; B, Beauty of Kent; C, Mère de Ménage; 13, Hollandbury; the others not known. (*Eve*).—1, not known; 2, Fearn's Pippin; 3, Winter Greening; 4, Small Mère de Ménage; 5, Golden Winter Pearmain; 6, Fondante d'Automne. (*C. W. T.*).—1, Royal Russet; 2, Blenheim; 3, Golden Russet; 4, Hornead Pearmain; 5, Court Pendu Plât; 6, not known. (*G. Sims*).—1, Blenheim Pippin; 2, Colonel Vaughan; 3, Duchesse d'Angoulême. (*W. S., Frome*).—1, Flanders Pippin; 2, Hawthornden; 3, Stubbard; 4 and 5, probably local varieties. The Apple sent subsequently is Bess Pool, true and good. (*George Fairbairn*).—We think your seedling very promising, and worth sending a little later, say to the December meeting of the Royal Horticultural Society. (*R. C. Kingston*).—3, Court Pendu Plât; 4, Cox's Pomona; 5, Round Winter Nonesuch; 6, Dutch Mignonne; 7, Sykehouse Russet; 9, Cackle's Pippin. (*J. P.*).—Beurré Hardy.

COVENT GARDEN MARKET.—OCTOBER 15TH.

MARKET still very quiet, with supplies more than equal to the demand.

FRUIT.

### DAIRY AND FRUIT FARMING.

Two Shows were held in London last week; a Dairy Show at the Agricultural Hall and a Fruit Show at the Guildhall, both of them being ostensibly in the interest of farmers, though it must be owned if farmers do ultimately derive benefit from the fruit Show they will be greatly indebted to gardeners for such a lesson in fruit culture as they never had before. We saw both Shows, and may, we think, usefully record our impressions now, for both of them taught lessons of weight and moment which should tend to promote that progressive improvement which is steadily bringing prosperity to agriculture once more.

Taken as a whole, the thousands of plates of fruit were absolutely bewildering, but a mere glance at any part of the marvellous Exhibition was sufficient to convince one of the high degree of excellence to which fruit culture has been brought in this country. In more than one report of the Show in the daily papers exception has been taken to it as a gardeners' exhibition after all, as having missed its aim of promoting fruit farming, its tendency to show what skilful fruit cultivators gardeners are, and how unskilful are farmers and cottagers. But that is precisely the point of the whole thing. If the Show taught one thing more emphatically than another it assuredly was the high importance of careful selection and skilful cultivation. It has long been notorious how very much farmers have been wanting in both things, and they have now been told in no uncertain manner that the careful cultivation of the best sorts—especially of Apples—tends to insure a supply of really first-class fruit even in a season so remarkable for the scarcity of Apples as the present one is.

Readers of the Journal were told long ago of the process of cultivation applied to the Barham Court orchards, and the gold medal, won so easily by the magnificent fruit shown by Mr. Woodward last week, affords proof of its soundness. To farmers who intend planting more fruit trees this season we say then, See that the stations are thoroughly well done for orchard trees, that the whole of the land is trenched for plantations, that full attention is given to the drainage and fertility of the soil, and that the planting is well done, and the trees made fast to stakes or other supports at once. Do not forget the importance of shelter, and if you plant an orchard in an exposed place plant belts of fast-growing trees around it at the same time—not a mere line or hedgerow, but a belt of several rows, which will form an efficient barrier against cold north-easterly winds by the time the trees come into bearing, and also screen the trees from violent south-western gales when they are laden with fruit. It is these two cross winds that so frequently prove fatal to the fruit crops, and we must guard against them if we would succeed. One word more before we turn to the Dairy Show, and that word is an expression of our pleasure at seeing Mr. Wright's prize essay on fruit culture being sold at the Show. That certainly was like the application of a sermon, for there was the marvellous fruit, and there also was the manual which tells so clearly what to grow and how to grow it.

Pleased as we were with the Fruit Show, we must own to a feeling of being crowded out by the eager throng by which every coign of vantage was taken up. It was not so at the Dairy Show, for there was ample space to enjoy fully the full and very excellent display. The various breeds of dairy cows were well represented, forming a show indeed in themselves, and the show of dairy produce and appliances was equally attractive. There could be no doubt about the earnestness of farmers here, and there certainly were many instructive sights, of which none afforded more striking evidence of progress than the cream separators. There was the milk fresh from the cow poured in at the top, and a steady stream of cream flowing out below on one side, and the milk from which it

was extracted on the other. This useful implement is a fine example of the combination of practice with science; its inventor has simply turned his knowledge of the laws which govern centrifugal force to account, and here is the result. Inventors must be paid, but we wish so useful an appliance could be placed on the market at a price which every dairy farmer could afford, for then a hundred separators would be sold for every one now ordered.

Bacon, cheese, and butter were all attractive features, especially the latter, which was so good in texture, colour, and flavour that the judging could not have been an easy task. What are termed fancy butters were striking examples of elegant design and skilful manipulation. Maréchal Niel Roses in butter were so skilfully arranged with suitable foliage as to present a wonderfully close resemblance to natural flowers, the rosebuds and petals of full blown Roses being correct in every line and curve.

There was an important discussion on the second day of the Show on railway rates for dairy produce, and copies of a paper read by Mr. George Barham were ordered to be sent to the Board of Agriculture and every Chamber of Agriculture in the kingdom.

### WORK ON THE HOME FARM.

As autumn draws on live stock require especial care. If calves have been let out on pasture they should now be housed entirely for winter in any convenient building that is well ventilated by roof ventilation. Many an old barn is turned to account for sheltering live stock, and such buildings answer well enough if only the walls are sound, but many an old barn have we seen with its boarded sides so broken and time-worn that the interior of the building was draughty and cold. Now, we do not approve of a close warm atmosphere in buildings for cattle at any time, but when warmth and shelter for them is mentioned, it points to thorough protection from cold wind and rain such as a sound building affords. This forms the basis of successful winter management, and with it there must be perfect cleanliness, pure food, water, and air, and a clearance of all filth twice daily. Let the dietary be abundant without waste, clear out rack and manger after every meal; keep on the calf flesh by all means, at the same time avoid a plethoric habit and its attendant risk. Our aim should be the happy mean between poverty of condition and the other extreme of over-feeding.

We have had only an occasional wet day, and the weather continues most favourable for work on the land. Wheat sowing has been such an easy matter that it and all winter corn sowing ought to be finished early. Foul land has been ploughed and harrowed repeatedly, and it has been possible to burn twitch and other rubbish as it is collected. With harvest over long ago, corn sowing done, foul land cleaned, abundance of feed still on pastures, and root crops improved wonderfully during the last six weeks, the situation is certainly not an unpleasant one for farmers south of the Trent, but they have their grievance in the low price of stock just now. Other farmers have much greater reason to complain. Here is an extract from a letter written on the 6th inst., after a journey due south. "It was raining heavily all last week in Caithness. All the north of Scotland has had a lot of rain lately. As we came along in the train the floods we saw in the valleys were fearful; all the cornfields were under water, much corn that had been cut was swept away by the floods; the hay, too, which is not yet all carted, is covered with water."

While the land is so dry and firm all roots intended to be stored in heaps should be cleared off the land, as useful growth is now pretty well done, and the ploughing should be done early, in order that the soil may derive full benefit from exposure to winter weather.

### REMARKS.

- 5th.—Bright sunshine from about 11 A.M. to 3 P.M.; the rest of the day cloudy.  
 6th.—A little rain from 2 to 3 A.M.; generally bright from sunrise to 1 P.M.; cloudy afternoon.  
 7th.—Wet from 8 A.M. to 2 P.M.; overcast afternoon, and wet again in evening.  
 8th.—Bright sunshine throughout.  
 9th.—Fog (at times rather dense) till 10.30 A.M.; faint sunshine from 11 A.M.; bright afternoon and evening.  
 10th.—Bright throughout.  
 11th.—Misty early; brilliant day.  
 A fine week, cooler than the previous ones, but still above the average.—G. J. SYMONS.

PECULIAR PLANTS.

PRESENT day demands for plants of decorative value, or such as will yield a plentiful supply of flowers and foliage for cutting, have caused many of the curiosities of the plant world to be discarded, and the tendency is to consider them as the lumber of the vegetable world. There are, of course, sufficient exceptions to this to prove the rule, and it is occasionally the source of considerable pleasure to a real lover of plants to visit a garden of the olden type where some of the plant wonders are prized as well as those required by the utilitarianism of modern times. It is true that in the now popular Orchid family we have a combination of structural peculiarities with great floral beauty, but the Orchids possessing showy characteristics have gradually ousted from most collections such curios as are found in the Pleurothalluses and the smaller Masdevallias. One group of essentially peculiar plants, the Nepenthes, holds an important place amongst indoor garden plants, and most deservedly, for many of them possess a large share of unique beauty, though they cannot rank with ordinary decorative plants. In recent years also popular and scientific attention has been called to the insectivorous plants, the Droseras, the Dionæas, and others, with the result that a demand was at one time created for "carnivorous" plants, and the inspection of these vegetables being surfeited with nitrogenous applications to their leaves afforded quite a sensational amusement. These plants, too, have been regarded with a species of dread, which a precaution adopted at Kew has had the effect of materially increasing in the minds of the unbotanical visitors who assemble there on Bank Holidays. The portion of the shelves devoted to these, with Sarracenias and other plants, has been railed off, and wire netting is stretched across to prevent persons of an experimental turn of mind practically testing the peculiarities of the Dionæas more especially. This has, however, been frequently mistaken for a means of protecting the on-lookers from the voracity of such vegetable monsters.

Marvellous moving trees have been described by imaginative writers in daily and weekly papers, the Rain Trees have had a large share of attention, and more lately the Weather Plant has been popularised in a like manner. Still, apart from all these sensational plants there are numbers which possess no garden value as usually understood, and which yet furnish much interest to the thoughtful and observant amateur or gardener. Amongst these the succulent plants from tropical and arid climates supply a diversity of strange forms, often accompanied by equally remarkable flowers. To the Cactus family I drew special attention in a series of articles published in the Journal some years since, and reissued in book form, which was followed some time afterwards by other works, all of which have helped to increase the popularity of several genera that include extremely beautiful as well as singular plants. In the United States of America, and on the European Continent, these plants are much more generally patronised than here, indeed the curiosities of plant-life are studied and grown with more interest altogether than in this country. With the exception of the Botanical Gardens comparatively few amateurs now attempt to make collections similar to those which characterised most enthusiastic horticulturists' establishments earlier in the present century. Since the late Mr. Peacock's collection was dispersed it is difficult to point to one of any extent, and Mr. C. M. Major,

Cromwell House, Croydon, is almost the only gentleman round London who makes a special feature of these plants.

The house devoted to Succulents at Kew is the most remarkable of its kind that could be seen anywhere; for while a large number of distinct forms are included, many of these, as in the Euphorbias and Cereuses, are represented by specimens fully developed to show the leading characters of their respective types. They also convey a good idea of the appearance these strange forms of vegetation present in the countries where they abound. Huge, fleshy, leafless stems, often unwieldy and grotesque in the extreme, yet producing in numerous cases flowers that absolutely astonish one in the production of such seemingly unsymmetrical or even deformed specimens. It is singular that plants with abnormally fleshy stems are not confined to a few families, though more numerous in some than in others, and the development of a thick fleshy substance is a kind of protective arrangement adapting them for existence under conditions that would prove fatal to many plants.

But all the succulent plants are not giants like the Cereus of America or the Euphorbias of tropical Africa; some indeed are diminutive and unpretentious in their growth. Amongst these smaller curiosities may be placed the majority of the Stapelias as regards their growth, but in the size of their flowers, judged by that depicted in the engraving (fig. 41, page 359), they might rank with some of the most remarkable plants in cultivation. At the recent Westminster Show a plant was sent from Pendell Court, Bletchingley, the residence of Sir George Macleay, of *Stapelia gigantea*, and as it was the first time it has ever been exhibited in flower in this country it attracted a large share of attention, and perhaps a little admiration also. Fortunately it had been very carefully covered with a large bellglass, and its odour was thus confined to a limited space, for like so many of its relatives, its odour is much more powerful than pleasing. As far as I can ascertain Pendell Court is the only place where this extraordinary plant has flowered, for though it is found in several other collections we have no record of the flowering having occurred elsewhere. It first flowered in October, 1889, and has repeated the performance this year about the same time. The flower when fully expanded was 10 inches in diameter, but has had to be slightly reduced to bring it within the page of this Journal. It is said to attain an even larger size, and one drawing represents a flower 15 inches in diameter. The corolla has a pale yellowish ground colour with abundant reddish dots, lines, or bars, arranged in a concentric manner, and becoming very small and closely placed towards the centre, where there is a slight purplish tint. Sir Joseph Hooker describes it as "A native of Zululand, where it was discovered by Mr. R. W. Plant, a collector thirty years ago, and sent by him to the botanical gardens of D'Urban, whence it was introduced into England by Mr. Cooper."

This is the true *S. gigantea*, but another species is found in collections under this name, and has probably been generally distributed—namely, *S. grandiflora*. A specimen of the latter received as *S. gigantea* flowered a few days since in Mr. Major's succulent house, and though the flowers are much smaller than the other, not exceeding 6½ inches in diameter, they are in some respects equally as remarkable. The whole flower has a peculiar dark purplish hue, very distinct from most other Stapelias, and the inner surface of the corolla is covered with dense hairs fully an inch long, and forming a kind of velvety pile that has a very strange appearance, increased by the fact that the hairs towards the tips of the lobes are whitish, forming a fringe. *S. hirsuta* and *S. Planti* are somewhat like the one just described, and the latter, with its pale yellow transverse bars, may almost be considered handsome.

Many other species could be named that are interesting in all respects except their odour, and it is not difficult to understand in some cases how the term "Carrion Flowers" became associated with

Stapelias, for in colour as well as odour the flowers in certain instances depart so widely from our floral ideal that they are too suggestive of putrid meat, and attract flies in plenty. Great as this defect must be considered Stapelias have found some cultivators, students, and even admirers. Probably Mr. N. E. Brown, of the Kew Herbarium, is one of the most enthusiastic in this matter, and I know he has for a number of years been growing the plants and investigating their characters closely. It was said at one time that we might expect an elaborate monograph of the group from his pen, but the task is a heavy one, and he has contented himself with a contribution to Hooker's "Icones Plantarum," dealing with the species of Stapelias collected by Sir Henry Barkly, when Governor of the Cape of Good Hope, from 1873 to 1877. In this work, which was only published a few months ago, about thirty illustrations are given of the most distinct forms, together with descriptions of many others, and analytical botanical "keys" to the genera and species. Some remarkable plants are represented—not only Stapelias, but Carallumas and Huernias, while species of Piaranthus and Hoodia are described.

In notes on peculiar plants, Hoodia Gordoni, a near relative of the Stapelias, must not be omitted, and the first plant which flowered in England was sent by Sir Henry Barkly to Kew. It has large, columnar, fleshy, ribbed stems, resembling some of the Euphorbias, the ridges being rows of strong yellow prickles. The flowers are 4 or 5 inches across, rounded, somewhat concave or bell-shaped when first expanded, pale sulphur yellow, with a central circle of rosy dots.

Returning to the Stapelias again, a few of the more noteworthy are *S. asterias*, "The Star Fish," very dark, nearly black, with livid transverse lines; *S. Bufonis*, yellow and black; *S. Hystrix*, small, sulphur, with purple dots, and numerous fleshy projections from the surface; *S. variegata*, an old inhabitant of English gardens, known as *Asclepias aizoides africana* to the earlier writers; *S. barbata*, *S. hirsuta*, *S. verrucosa*, *S. reticulata*, and *S. campanulata*—some of which are placed under other sections or genera—are all distinct and peculiar, while their floral structure is well worthy of a little study. Most of these are easily grown, their chief enemy being damp or stagnant moisture. They prefer a dry, warm, sunny position in a house, and an open well-drained compost of loam and sand, with careful supplies of water at all times, but especially in dull weather.

The list of peculiar plants might be greatly extended, but enough has been said to show that all the interest of plant life is not found in the groups for decorative use.—L. CASTLE.

## GROWING AND SELLING FRUIT.

(Continued from page 334.)

### FRUIT TREES FOR THE WALLS OF THE HOUSE.

ALL walls of houses and outbuildings may be used for fruit growing, and will bring in a good return of money if properly attended to. What kind of fruit will pay best depends upon the aspect, that is the direction, or point of the compass, which the wall faces. I shall therefore treat of them accordingly.

**SOUTH WALLS.**—The most profitable fruit these will grow are Peaches and Apricots, but in the coldest parts of the country these fruits are very uncertain croppers. In all such places Pears should be planted instead, or Victoria Plums.

**WEST WALLS.**—In districts south of London Apricots will succeed, but if north of London Pears or Victoria Plums should be planted.

**NORTH WALLS.**—Morello Cherries.

**EAST WALLS.**—Pears and Victoria Plums. Walls that have a N.E. or N.W. aspect should be planted with Morello Cherries in cold districts, but if south of London Marie Louise and Pitmaston Duchess Pears will succeed, those facing S.E. or S.W. same as for west.

**PLANTING.**—All should be planted in October if possible. If the ground near the wall is good and has been under cultivation no extensive preparation will be required, in fact nothing beyond that recommended for orchard planting; but if an old road runs by the side of the wall this should be taken out so as to form a

border 10 feet wide and 2 feet deep, the bottom below this being well broken up to allow of the water escaping, or if it is very wet the soil must be taken out 6 inches deeper at the back and 1 foot at the front, where a drain pipe should be laid to take the water away. The floor is then to be rammed hard and 6 inches of broken bricks or rough stones put in, putting some small pieces on the top to prevent the soil working down through the chinks and thus blocking the drainage. Rough angular stones should always be used, not flat ones like slates or tiles, as these become fixed together with soil and prevent the water from soaking away; over this drainage turves should be placed with the grassy side downwards, or if this cannot be got a good layer of straw will be better than nothing. The border should then be filled up with good soil from a garden or field, and allowed a fortnight at least to settle down before the trees are planted. All such work as this must only be done when the soil is dry, or it will bind firmly together and the roots of the trees will not thrive in it afterwards. Apricots should always have a firm soil to grow in with plenty of stones in it, and for all fruit that have stones inside it is a good plan to mix old mortar rubbish with the soil, unless there happens to be plenty of small limestones in the soil, when nothing else is required. All fan-trained trees should be 12 feet apart.

### PRUNING AND TRAINING.

APRICOTS, PEACHES, PLUMS, and MORELLO CHERRIES should be trained dwarf fan-shaped—that is, the main branches must start from the stem like the spokes of half a wheel do from the centre. They require too much care in their very young state for the ordinary cultivator to bud and train them, and are best purchased as dwarf fan-trained trees from a respectable nurseryman. The price varies from 3s. to 5s. each, according to size and variety. Early in spring after planting the branches should be cut back about half their length, and any weak shoots cut clear out, leaving three or four branches on each side of the centre one, which should be cut back farther than the others to get more branches to start, and also to keep the centre of the tree always open like the letter V, until the side branches reach the top of the wall and the trees next to them. After pruning the young shoots the first year they may be secured to the wall by nails and shreds of cloth as usual, keeping their points spread out at equal distances from each other, and leaving a greater distance in the centre. As the tree grows larger year by year the width between the points of these main branches will increase, and there will be room for more of them, which should therefore be laid in during the summer, pruning from the sides of the older branches, as they are then easily bent into their proper position. They should always start from the upper side of the main branches—that is, the side nearest to the centre of the tree. When the leaves are all off the trees each season the young shoots may have their points taken off, about two-thirds of their length being left if properly ripened. This will induce the buds to grow at their sides and form fruiting spurs, and when the young growths are about an inch long in the spring all those starting from the front and back of the main branches should be taken off, leaving those springing from the sides, as they can be nailed in easily. In about a week some of these may be taken off, and in another week all which are not required may be taken away, doing the whole of this disbudding, as it is called, in three times, that the tree may not be checked in its growth, as it would be if all were removed at once. As those shoots lengthen which are left, they should be trained towards the wall in their proper places by placing young twigs about 9 inches long (cut from Privet hedges, or similar plants) behind one of the older branches at each end, so as to bend the young shoots towards their proper position and to keep them there. This is a very easy and simple operation, but does not appear so on paper. It is much better than nailing the young wood when in a growing state. The foregoing remarks as to disbudding apply only to Peaches, which bear best on strong shoots made the previous season. The shoots on other kinds of fruit trees should be left until about the end of July, and then all those not required for extending the tree should be shortened back to four or five leaves. It should always be borne in mind when pruning Peaches and Morello Cherries in the winter that the best way to get fine fruit is to cut out the old wood and train in the young, and to keep the tree of the same size, not to reduce it while doing this.

APRICOTS should be pruned soon after planting in the same way as Peaches and Morello Cherries, and spurred back in the summer, pruning to four or five leaves, to be shortened to about 1 inch at the following winter pruning, preserving those shoots entire at the ends of the main branches if hard and ripe, or taking about one-third off if doubtful.

PEARS should be grown as "cordon trees" on walls, and on wire fences. These are trained to one or two main stems, and the side branches spurred in to 2 or 3 inches in length. If the soil

is light and dry they should be budded on the Pear stock, as this is a stronger and deeper rooter than the Quince. The latter is the best for cold and wet soils. Cordon trees are easily raised by planting the stocks and budding them close to the ground in July or August; they may also be purchased as one year old or "maiden trees" at 8s. to 12s. per dozen. They should be planted about 2 feet apart, and trained diagonally—that is, at an angle of 45°, which may be found a simple way. If the wall or fence is 10 feet high take a piece of string 35 feet long, tie one end to the stem of the tree close to the ground, then take the string straight up the face of the wall to a nail at the top. This should be perfectly upright like a mason's plumb line. Next take the string after securing to the nail straight along to the top of the wall 10 feet to the right, and fasten to another nail; then bring the end back to the stem of the tree, and tie it where the other end is tied. This last piece will run at a true angle of 45°, and a piece of chalk drawn along it on the wall will show where the stem of the tree is to be nailed. Having one stem nailed in its place the others may easily be got right by keeping each one the same distance all the way up the wall from the one before it. During the second year's growth from the bud another shoot may be trained to the wall, starting on the upper side of the main stem, about 1 or 1½ foot from the ground, and training it in the same way, so as to form two main stems to each tree 1 foot apart. The wall or fence will thus eventually be covered with branches 1 foot apart from each other. The stems should not be bent on one side during the first two years from the bud, and only partly so the third year, as they do not grow so freely when trained in this way, which is the reason why they are treated thus, as the sap by this means is kept from flowing so freely to the top of the tree. Pruning of these cordon trees is very simple, and consists in shortening the side shoots to 3 inches in length early in August to strengthen the buds at the base, and at the winter pruning cutting still farther back to about 1½ inch. The leading shoot must always be left full length, and secured by nails and shreds to keep it straight until the winter, and then about one-third of its length may be cut off until the tree reaches the top of the wall, when the points may be cut back like the side shoots.

#### VARIETIES.

**PEACHES.**—Early Alexander for earliest crop; ripens in the midland districts third week in July. Dymond for midseason; Princess of Wales for late crops. In very cold districts the latter should not be planted.

**APRICOTS.**—Where Apricots do well in the neighbourhood Moorpark is the best variety to plant, but if they die off suddenly, as they do in many places, a hardier variety, such as Hemskirk or Breda, should be grown.

**CHERRIES.**—The old Morello is the variety that pays best.

**PLUMS.**—Victoria is the most profitable kind.

**PEARS.**—Early, Williams' Bon Chrétien; midseason, Marie Louise and Pitmaston Duchess.—W. H. DIVERS.

(To be continued.)

## PROFITABLE FLOWER CULTURE.

### INDIAN AZALEAS.

WHERE there is a good local demand for cut flowers these Azaleas pay well, and may be said to be indispensable, this being more especially the case with both single and double white varieties. The good old Fielder's White, and the still more common Alba are of excellent service, either when forced or allowed to flower naturally, and all who hold large plants of these should take good care of them. We have frequently cut flowers to the value of 15s. from moderately large freely grown plants of the latter, it being in great demand for memorial wreaths and crosses. Lady Poltimore, a much newer single white variety, is also of free growth, forces well, and is one of the best that can be selected. As a rule, however, the double or semi-double whites are the most serviceable, and should be the most extensively grown. These, in addition to being in demand for bouquets, wreaths, and crosses, are also largely used for church decoration at the principal festivals, and we have frequently sold enough flowers from plants the same season they are bought in to pay for the same. Deutsche Perle is perhaps the most valuable Indian Azalea in cultivation, this remarkably precocious double white variety generally commencing to produce flowers in October or early in November, and continues to yield more for at least three months longer. A moderately large stock of plants very gently forced in succession would afford a good supply of flowers throughout the winter, finishing well at Easter. This, then, should be the most extensively grown, but there are a few others that are also well worthy of a place in a

limited collection. Bernard Andreas alba is an exceptionally fine double white, and good alike for midseason and late flowering. It grows strongly, and never fails to set buds plentifully. A. Borsig is another good white, and possesses the additional charm of being sweet scented. Much the same description applies to Raphael, and if a good late double white form is desired it will be found in the very floriferous Souvenir de Prince Albert alba.

The greater number of these Azaleas are imported from Holland, the Dutch growers apparently being able to supply the British trade far more cheaply than the plants can be raised in this country. None that I have yet had under my hands the same season they were received in this country had their pots well filled with roots; in fact, I believe most of them are either newly potted from beds of peaty soil, or are lifted and sent across without being potted at all. Under these circumstances they require to be very carefully watered, the plants being in very light spongy material, drying very quickly, and more often than not get too little, rather than too much, water. Kept in a uniformly moist state at the roots, and in a warm greenhouse, they rarely fail to flower well, and during the growing season well fill the soil with roots. The best time for repotting Azaleas generally is just when they are growing strongly in the spring or early summer months, this being when root action also is most briskly going on. But if this is the best time for repotting, it does not follow it cannot be done with safety at any other time of the year. On the contrary, rather than the plants, whether large or small, should be in a sour state at the roots, this usually resulting either from overpotting, unsuitable compost, defective drainage, or worms in the soil, I would turn them out of the pots, prick away the worst of the soil, and repot whenever they are found in this bad condition. This drastic proceeding might hasten the death of some of the most neglected plants, but would undoubtedly save the life of the rest. Azaleas, in common with all other hardwooded plants, can be, and ought to be, kept in comparative small pots, large shifts in particular being always avoided, and above all clean, well-drained pots should be used. If very light fibrous loam is available, one portion of this may be used to three parts of good fibrous peat and one of the best sifted leaf soil, fine charcoal and silver sand being also freely added. In our case the loam is of a heavy or clayey nature, and consequently not a particle of it is used for Azaleas. One inch of space between the old ball of soil and roots and the pot is ample, and in this the fresh compost ought to be packed or rammed as firmly as possible, good space being allowed on the surface to hold water, too little water after repotting frequently leading to the ruin of the plants. As before stated, if the old soil is in a sour state, much of it is picked away from the roots, but when the balls are closely occupied by healthy roots, it is advisable to just loosen these only with a pointed stick.

Good care ought always to be taken of Azaleas after the flowering and during the growing period, whether they have been repotted or not. They should where possible have the benefit of gentle heat, and be syringed frequently. They also require a certain amount of shade, rolled glass suiting them well. A vinery being gently forced or kept say at about 55° to 60° in the night time, and from 10° to 15° higher during the day, will always be found a good position for the larger plants especially, these being stood either on boards, slates, or inverted flower pots. Nor ought the cultivator to be in a great hurry to clear the houses of Azaleas, thousands of plants being annually injured beyond recovery owing to the reckless manner in which they are bundled out into the open air. If they must be turned out the least that can be done is to wait till the buds are well set and plenty of fresh root fibres are formed. In our case the plants are never outside the houses, and they all flower remarkably well in spite of the severe pruning they have when the flowers are cut every season. Some old plants about 5 feet high have for the past three years been kept near the back wall of a late vinery, and these flower astonishingly well, a long succession of bloom being had from them. At the present time they are well set with buds, and the bulk of these will without any further trouble on our part be expanded at Easter. There is really no reason why back walls of vineries should not be clothed with Azaleas, the roots being confined to narrow peat borders. Those who must turn out their stock of plants into the open every summer should at least avoid setting them on a cold moist base of any kind, this in addition to being prejudicial to a healthy root action being nearly always attended by a plentiful stock of worms, and which quickly clog the drainage and sour the soil. They ought, therefore, to be blocked up in some way, boards, flower pots, and bricks all being available for the purpose. The plants must also have an awning of some kind of shading material strongly fixed above them, and be housed before cold autumnal weather sets in. Retarding can be more safely and effectively accomplished in cool airy houses than in the open, and everything, therefore, points to the advisability of keeping the

plants exposed to all weathers as short time as possible, or say not longer than the middle of September. None of them, whether large or small, should be wintered on a moist base, or otherwise the chances are that most of them will commence growing afresh long before their natural flowering period, and the flowers that do open be of much less value accordingly. Set the larger specimens on inverted flower pots, and the rest on dry greenhouse stages, and if the hot-water pipes are kept just warm any selection of varieties or a large stock of *Deutsche Perle* will give a long succession of bloom without any being actually forced. All should be kept carefully supplied with water, but no liquid manure ought to be given till after the flowering period, and then in a weak state, and to the strong root-bound plants only. A judicious use of liquid manure and an annual light top-dressing of either turfy peat or light fibrous loam and flaky manure well keep strong old plants in a healthy growing state for many years, repotting being unnecessary.

When used for wreaths and bouquets on the place Azaleas flowers may be taken without wood attached, as they keep nearly or quite as well mounted on wires, either singly or in bunches of three or more flowers. When sent to shops or to a distance or supplied to church decorators they must be cut with a short length of young wood attached, but the plants being healthy and kept in gentle heat to form fresh growth, plenty of young shoots are usually forthcoming from the shortened wood. I ought perhaps to add that formally trained Azaleas are not of much value for affording cut blooms, those more freely grown, whether as half-standards, bushes, or pyramids, being by far the best for the purpose. Shallow boxes are most suitable for packing the flowers in, these being either lined with clean soft moss or cotton wool, the material in either case being covered with tissue paper. Packing the flowers flatly, closely, and in a single layer, cover with more of the paper and enough cotton wool to keep all quite tight when the lid is shut down. Thus packed they will travel equally well by rail or post. At Christmas the doubles are worth from 2s. to 2s. 6d. per dozen sprays, and the singles usually 1s. less. Subsequently the prices may drop to as low as 1s. per dozen, but will revive somewhat at Easter.—M. H.

### TREE PLANTING.

NOTHING new have I to say to the veterans among gardeners and foresters who have been engaged in planting so long, that any detailed account of the process which has rendered them so successful and their work so satisfactory to themselves and their employers may appear altogether uncalled for. So it is for them, as the right way is the only one possible in their work; but please remember there are the young hands and amateurs to whom sound practical hints are of the utmost value, both as helping them to understand the why and wherefore of what they have to do, to avoid errors, and to render their success as full and thorough as possible.

That failure is often the highway to success for an earnest teachable man there can be no doubt, and in planting anything less than success entire and perfect should be regarded as failure. One of the most unpleasant incidents of my planting experience was the failure of a considerable number of young forest trees in a belt, for which the trenching and levelling came under my supervision as estate manager, but the planting was managed entirely by a young hand so brisk and energetic that his sole aim appeared to be to get over work at express speed, without giving heed to that thoroughness which is so essential to success. The failure of the trees was most probably owing to root dryness before planting, and looseness of soil about the roots. It was suggested that the trenching was at fault, but even if it had been no deeper than ordinary digging, instead of the sound two-spit work it was, that could not have caused the loss of the trees. The resolution then formed never to have anything more to do with joint management in such work is a safeguard which I commend to the attention of other planters.

There can be no doubt that much exposure to the air is most hurtful to the roots, and through them to the trees. This happens when trees are lifted for the planting and are embedded temporarily in loose soil, so loosely that the roots become dry and shrivelled, and the rootlets perish. This also happens in some degree when trees are laid out in long rows with the roots exposed to a brisk wind, and possibly to sunshine, for a considerable time before the planters reach them. Still more hurtful is it when they are so laid out during a frost, and are subsequently planted in half-frozen soil. No fanciful conception is this, for I have seen it, and have also seen evidence of its baneful effects subsequently in the numerous failures and sickly appearance of the survivors.

Not only should the manager of tree planting be thoroughly

proficient, but he must see that his orders are carried out to the letter, or it may happen to him as it did once to a friend of mine who ordered a trench to be opened along each side of a Yew hedge very early in the autumn, to sever all long roots and induce a free growth of rootlets before the trees were transplanted a couple of months later. The trenches were opened, but the soil was not replaced, so that his object was defeated, and instead of vigorous growth next season the ill-used trees had a struggle for bare existence.

There is more risk of failure with trees from a nursery than others, and the greatest possible care should be taken to thoroughly embed the roots in fine soil at once as the packages come to hand. If such soil cannot be had in a satisfactory condition damp sand or fine ashes answer admirably, as they envelope all the roots closely. If the weather is frosty the sand is well covered with litter till the frost breaks. In planting the roots are spread out at full length, fine soil packed closely about all of them, 3 inches of soil over the upper roots pressed gently but firmly down over the whole of the roots. A close watch must be kept to prevent injury to root, stem, and branch during this work. Every tree requiring support must have it at once, and this must be managed so that there can be no subsequent injury to the stem. Envelop the stem loosely with rabbit-proof wire netting, with the edges overlapping sufficiently to allow the netting to expand with the growth of the tree, and if the trees are out on pasture there must be a tree guard of some sort to keep off cattle.

Transplanting large specimens is always a questionable matter. It was with much reluctance that I recently condemned a lot of fine young *Pinus austriaca* some 8 or 9 feet in height, which are in the way of some garden extensions. A considerable number of this useful Pine are to be planted, but experience has shown that smaller trees answer best, for though the large ones may be transplanted the check to growth is not fairly overcome for four or five years, and by then the younger trees will have shot up past them and will keep the lead. The very natural desire for immediate effect has led to much costly work in the transplantation of large specimens, especially among Conifers, and when the work is insisted upon the certain result of arrested growth should be clearly explained, and then move the trees with as large a ball of earth as possible. If a large rectangular block of soil after the Elvaston method can be managed so much the better for the tree, which must subsequently be well secured with guy ropes or wires.

In planting fruit trees, the advice to prune at the time of planting given for Apples by Mr. G. Hammond, in his admirable paper on page 328, may be applied to all fruit trees; only take care to select healthy trees and plant carefully, and then prune at once to the buds whence growth is required next season, in full confidence that such growth will prove entirely satisfactory. Remember, success does not rest upon the pruning so much as upon the planting, and it is when this has been badly done that free growth has not followed; it is, of course, easy to lay blame upon the pruning.

Plant as soon as possible now, in order that the trees may make some root growth at once, and so ensure unchecked branch growth and a plentiful supply of sap direct from the roots next spring, Mr. J. A. Reeves' new sap theory notwithstanding.—EDWARD LUCKHURST, *Warrens, Harold Wood, Romford.*

### CULTURE OF CYCLAMEN PERSICUM.

ALTHOUGH the culture of the Persian Cyclamen has been frequently written about, yet the plant baffles the majority of private gardeners. I believe many failures may be attributed to having a poor strain of seed, as it is impossible to grow good plants from seed which has been saved from debilitated parents. Grow the plants how you will, they have an inherent weakness that you cannot remedy. Of course good culture will have to be combined with good seed, or satisfactory results cannot be expected.

Next to the seed the soil is the most important consideration. The Cyclamen appears to have a partiality for soil which has a fair proportion of lime in its composition, and where this is known to be deficient some old lime rubbish should be added. Sowing may be done at various times, but for producing good flowering plants by next Christmas twelvemonth, the present is a good time. The seed should not be sown in a haphazard manner, as on this operation success in the earlier stages of the plant's progress depends. Procure some ordinary seed pans, and half fill them with drainage. Over this place a layer of flaky leaf soil, and fill with equal parts of leaf soil and loam, with a good addition of silver sand. Press in rather firmly, and fill within a half-inch of the top. The next proceeding is to dibble the seeds in singly, an inch apart, and a quarter of an inch deep. This is exactly how the seed is sown by some of our largest growers, and is considered of particular importance to secure good results. The benefit of being an inch apart will be seen.

later on, as at this distance the seedlings do not require pricking off, consequently do not receive a check. After the seed is sown give a gentle watering, and cover each pan with a sheet of glass, and over this place a layer of moss, to exclude light and so stop rapid evaporation. The best position for the pans is a moist pit, where the temperature averages about 60°.

As soon as the seedlings appear remove the moss and glass, and place the pans near the roof, so as the little seedlings receive all possible light, or they will become "drawn." As soon as the second leaf appears, lift the seedlings out with a label with small balls of soil attached, and transfer into thumb pots. Pot rather firmly, just covering the small corms, but not the crown or stems, or the base of the leafstalk will become weak and the leaves fall over. The plants should then be placed on shelves near the glass, and stand on a base of cocoa fibre refuse kept moist, or if there is convenience plunge the pots to the rims. This keeps the roots healthy, preventing rapid evaporation. The soil must be fairly moist. Sprinkle the foliage on fine days, and as the sun gains power shade from bright sun, but expose to all the light possible. Early in April the plants should be ready for repotting into large 60's. The soil at this potting should consist of two parts fibrous loam, one part sifted leaf soil, and one part well pulverised cow manure, with sand and charcoal broken up fine, and also with the addition of some old lime rubbish broken up. Pot rather firmly, making the surface level, and return them to the same position; ventilate rather freely, but not so as to cause a draught or an arid atmosphere.

The plants will grow rapidly, and when they are well rooted transfer into 5½ inch pots. Use the soil in a rather rough state, but the leaf soil and manure should be sifted. Pot firmly, as this is very important, and elevate the crown of the plant just above the surface. In our case the plants are now placed in cool brick pits facing the south, within 6 inches of the glass, and are also half plunged in cocoanut fibre refuse. Keep the frame rather close, and shade with tiffany from bright sun. The plants should be sprinkled about 3.30 P.M., and the lights closed. The plants must be carefully watered, taking care to use soft water both at the roots and over the foliage. During the daytime the lights must be tilted at the back according to the weather.

Shade from bright sun, but during September the plants are only shaded to prevent injury. If they need shading, they receive it, as the foliage should not become limp whatever the season. No rule can be laid down, so the man in charge must be guided by surroundings. For instance, on account of our exposed position we cannot ventilate so freely, and the plants also require more shade than in a more sheltered garden. The first week in October will be time enough for housing, and this should be into a light span-roof. Here the temperature should range about 50° as a minimum. The blooms in this temperature should become fully developed. Just a word on watering at this stage. This must be performed carefully but yet thoroughly, taking care not to pour water into the heart, or a number of blooms will suffer by damp.

I have not yet mentioned insect pests. Green fly is about the only foe to contend with in an ordinary way. Some growers recommend fumigation, but I prefer dipping in a solution of quassia chips and softsoap. A large number of plants may be done in a short time, and the mixture reaches all parts. When fumigators are used the fly is apt to descend into the heart of the plant, and come out again in a day or two.—A. YOUNG.

CYPRIPEDIUM CONSTANCE.

At the meeting of the Royal Horticultural Society's Orchid Committee on August 26th, 1890, Mr. Drewett O. Drewett, Riding Mill-on Tyne, exhibited three hybrid *Cypripediums* that may be welcomed as useful additions to the list. One of these named Alice was raised from *C. Stonei* and *C. Spicerianum*, the dorsal sepal white suffused with pale purple; the petals are greenish yellow dotted with brown; the lip is in the style of *C. Stonei*; it is a delicate and pretty flower. *C. Alfred* is from *C. venustum* and *C. phillipinense*, somewhat like an enlarged and improved form of the seed parent. The third hybrid was named Constance, and was obtained from *C. Stonei* crossed with *C. Curtisi*. A flower of this is shown in fig. 40, and indicates the combination of characters cross as regards form. The dorsal sepal is broad

and white with purplish streaks, the petals are 3½ inches long, pale yellow with brownish purple dots, and a few marginal hairs. The lip resembles *C. Stonei* in shape and colour. The plant seemed to be of vigorous and free-flowering habit, and the success Mr

FIG. 40.—CYPRIPEDIUM CONSTANCE.

Drewett has attained should encourage him to make further experiments.—C.

#### PERISTERIA ELATA.

At Dove Park, the residence of Mrs. Cope, Woolton, near Liverpool, I recently noticed two fine plants of the Dove Flower in bloom. The largest was in a 10 inch pot, and had four fine spikes; the second in an 8-inch pot had two grand spikes, each carrying a large number of blooms. Mr. Carling, the gardener, evidently has the right system of culture. Plenty of heat and moisture, the latter judiciously applied, and a thorough season of rest when growth is completed, are the chief elements to its successful culture. It is so refreshing to see this Orchid when in flower that a note about it is always acceptable, for it is too often met with under indifferent conditions.—R. P. R.

#### ODONTOGLOSSUM ALEXANDRE.

WHERE the temperature was kept 50° to 55° throughout last winter flower spikes will be showing freely from the axils of the leaves at the base of the newly made pseudo-bulbs. Some care is necessary to protect these from slugs. A little cotton wool round the leaf and spike will often prove effectual, but it must be kept dry or is useless. Every time the plants are watered it must be renewed. If every care has been taken throughout the season slugs should not be numerous, and may be kept down by examining the plants soon after dark with a light, after damping well amongst the pots. A few tender Lettuce leaves may be laid down, and will prove a capital trap if inspected about two hours afterwards. If left until morning the slugs will feed and disappear again to their hiding places. Where slugs are very numerous the only certain remedy of protecting the spikes from their ravages is to suspend the plants from the roof.

#### ODONTOGLOSSUM ROSSI MAJUS.

The earliest plants are unfolding their flowers, and with judicious management will yield a supply until February. For cutting purposes this is one of the most useful Orchids grown. Plants

that are to flower late should be removed directly they have completed their growth. They will bear any cool shady position where frost can be excluded from them. In this position do not keep them too wet at their roots, and on the other hand do not allow them to become too dry. If kept wet the roots decay, and the tips of the foliage soon commence decaying. This Orchid grows freely, even luxuriantly, in small shallow pans, but often fails to do well when placed in large pans or baskets, which necessitates too much soil about their roots.

#### CYPRIPEDIUM SEDENI.

This is a useful Orchid, for a large plant is nearly always in flower, and is very effective in the structure in which it is grown. It is practically useless for conservatory decoration; but the individual flowers are useful when arranged in small shallow vases, partially filled with clean green moss and sprays of *Adiantum cuneatum* laid over it. The flowers of *Pleione lagenaria*, associated with this *Cypripedium*, are very telling; in fact, it is the only method of displaying to advantage these short-stemmed flowers unless they are wired.

#### DENDROBIUM NOBILE.

Plants that have well ripened pseudo-bulbs, and have been resting for some time, may be introduced again into heat, when they will be induced to flower. The flowers are always useful, and may with care and judgment be had over a lengthened period by pushing plants into growth at different periods. Plants that have completed their growth should be placed into a cool, dry, airy position after they have been carefully hardened. A late viney in which Grapes are hanging will be a capital place for them. Even in this position expose them to the sun, and give sufficient water only to prevent their pseudo-bulbs shrivelling. More harm than good is done if the plants are kept wet at their roots while in these positions.

#### DENDROBIUM DENSIFLORUM.

Discontinue the syringing of plants that have completed their growth. Keep the atmosphere drier, and gradually diminish the supply of water. Give sufficient to keep them fresh and plump. The object is to harden and ripen their pseudo-bulbs thoroughly before removing them to a cooler place. *D. thyrsoiflorum*, *suavissimum*, and others of similar habit of growth should be subjected to the same treatment where their growths are sufficiently developed.

#### DISA GRANDIFLORA.

These are constantly attacked by aphides if the conditions under which they are grown are not suitable. The plants should stand on a moist base at the coolest end of a cool house where they will be safe from frost. A circulation of air must be maintained daily. Although they enjoy abundance of air they should not be subjected to cold frosty air striking direct upon them. This does more harm than good. If the pans in which they are growing are well drained, give liberal supplies of water, and syringe the plants once or twice daily. They will grow luxuriantly under these conditions, and seldom be troubled with aphides. Carefully protect the foliage from slugs.

#### ODONTOGLOSSUM VEXILLARIUM.

Where these have been grown in the cool house and a low temperature only is maintained they must be removed to warmer quarters. The *Cattleya* house will suit them very well where the temperature of this structure for the winter ranges about 60°. If the *Odontoglossum* house is not allowed to fall below 50° at six o'clock in the morning during the winter, they will be safe at the warmest end, where temperature will average 55°. *O. Roezli*, and others that require a little more warmth will be safe under the same conditions.

#### ONCIDIUM VARICOSUM.

This and *O. Rogersi*, if grown in the *Cattleya* house, will be throwing up freely, and soon be in full flower. The flowers will be more useful some weeks later, and therefore suspend the plants in the *Odontoglossum* house, where they can be safely retarded for some time. Keep these plants rather dry.—ORCHID GROWER.

### TOMATOES.

I WAS very much interested in the notes (p. 287) of Mr. W. R. Raillem and "W. S." on outdoor Tomatoes. I have not been so successful as I hoped to be this year with outdoor crops, but still I have been able to pick a fair crop. I have tried outdoors a number of varieties and I find, as "W. S." reports, *Chemin Red*, *Ham Green*, and *Peach* are very good croppers for the open even when not having the benefit of a wall, for most of mine were staked out in the open in an exposed position. The *Peach* carries

a quantity of small fruit, and to my idea is worthless, although a dish now and again may be acceptable if the flavour is liked, but I have found few that appreciate it. *Chemin* I had from MM. *Vilmorin*, and I am very pleased with it both under glass and outdoors. It is a good cropper, free setter, beautiful heart shaped fruit of fine colour, and above all, in a monetary sense, profitable, for it is the heaviest Tomato for its size I know. The plants that were put outside were late ones and I hardly expected much, but I was agreeably surprised to find a very fair crop which I commenced to pick about six weeks ago. The earliest to bear outside and one of the greatest croppers, albeit the fruit are small, was *Prelude*. This is a really good variety and you are sure to procure ripe fruit any season off it, and if the fruit is small the flavour is unexceptionable. *Early Ruby* and *Table Queen*, which were sent me from New York, are both good, the former doing well outside, being early, a great cropper and dwarf growing, and I found it satisfactory under glass, although *Table Queen* is far better for that purpose. This is an enormous cropper, bearing large and very flat fruit of good quality, and I would not wish for a better Tomato if the colour were scarlet instead of crimson.

*Golden Sunrise* I found to be the same as I did last year, and I must own I was very much amused at one sentence of "W. S.," in which he speaks of it as being "one of Mr. Iggulden's first favourites, on account of the quality of the fruit." Last year Mr. Iggulden found fault with it, saying the flavour was too flat. I am afraid "W. S.," who I believe is a neighbour of his, has "let the cat out of the bag," and we now find Mr. Iggulden has learned to appreciate the "flat." I also tried two sorts, both called *Trophy*, grown extensively by two market growers. They were very dissimilar in appearance and growth, but both cropped well, one being the best fruiter I ever saw; but I am afraid I shall have to discard it, for whereas my other varieties had the leaves diseased, only this variety had a large quantity of the fruit badly diseased. Were it not so I would have no other variety for main crop. *Advancer* was only tried under glass, and found early and a great cropper, but the fruit too small. *Eclipse* outdoors had similar results. *Ham Green* was satisfactory under glass as outdoors, and the fruits are very handsome and of good quality.

Amongst others I received from Mr. W. Wright of Talygarn a selection from Glamorgan, which I have christened *Talygarn*, and this was the first to ripen fruit indoors. It is early and a good setter, with fruit of a bright scarlet. It is not beautiful, being corrugated, but it is highly useful, having a moderate growth, and carried off a given space more fruit than any but the so-called *Trophy* mentioned before. Some extra selected *Trophy* (true) which I tried was very unsatisfactory. *Tennisball* is too small, but crops well. *Glenlivet Favourite*, which I expected to turn out something extra, was disappointing, being with me a very moderate cropper, but the fruits were well shaped and of medium size. *Conference* was very useful, the appearance and flavour being very good, but I have come to the conclusion that for outdoor work nothing can beat *Prelude* and *Laxton's Open Air*, which never fails to ripen a heavy crop of good fruit, and for culture under glass *Table Queen*, despite its colour, *Talygarn*, *Ham Green*, and the market *Trophy*, with *Golden Sunrise* for a yellow, are most profitable and satisfactory. Mr. Iggulden has a very fine strain of the *Old Red*, and anyone who has it as good would not fail to grow it. *Chemin* might also be grown, and as I shall procure my seed of this earlier next season, I have no doubt it will prove itself equal to the others as a bearer of a great weight in a small space.—H. S. EASTY.

### TRANSPLANTING LARGE SHRUBS AND TREES.

IN the remarks of "D.," page 310, on the above subject he says, "Strong soils never answer well for transplanting large shrubs," he thinks it is the best policy to have quite young plants. Now from my experience, when a new garden is made or any part of an established ornamental shrubbery is renovated the general plan is to plant thickly for immediate effect. In a very few years, if the progress of the trees or shrubs is satisfactory, it is necessary to thin and re-arrange, or in a few years more there will scarcely be a presentable specimen. If the plan which "D." recommends were followed the whole of the plants in the shrubberies would have to be burnt or a greater part of them, instead of thinning by removing the surplus to other parts of the garden. This I fancy cannot very well be adopted by most gardeners, because just at that time shrubs of a large size are becoming interesting as they assume their true character. We have a bad soil to deal with; it is not actual clay but a near approach to it, being tenacious, and with it is freely mixed large flint, the whole binding together in one solid mass, which is most difficult to separate when dry and extremely "sticky" when wet. It is termed a "cold, unkind soil," and one in

which new roots are not quickly made after a shrub or tree has been replanted. In spite of this we annually thin many shrubs and trees so as to keep the shrubberies as presentable as possible. Plenty of shrubs and trees we move from 6 feet high to 12 feet high, and with excellent results, even the first year after removal. This month we have a good number to replant, such as *Thuia Lobbi*, *Thuia borealis*, *Picea Nordmanniana*, *Cedrus deodara*, *Abies grandis*, *A. Menziesi*, and many others of the same class and size. I hope to have the work done with as little delay as possible, as I find the present is the best time for such work. The trees are in a much better state to resist the searching winds we experience in March and April than though they were not replanted until that period. I would strongly advise all who have shrubs of the size named not to destroy them, but set about replanting in the manner I will describe, as a few hints on the practical method of shrub moving may not be out of place at a seasonable time like the present.

The first thing to do with any tree that has to be lifted is to tie up the lower branches with cords, so that they will not be in the way of those who have the soil to remove. The branches are made secure also from injury, as if left loose they might be broken or otherwise damaged. With four-pronged steel forks a trench is then dug in a circular form around the tree and 3 feet from the stem on all sides. A spade or small shovel is also required to remove the fine soil. By using forks the roots are not damaged nearly so much as if spades were used, in fact the latter tools are of little use here where so many large stones are encountered in lifting a tree or moving the soil in any manner. At a depth of 1 foot from the surface the soil is gradually worked out underneath the tree all round until a space of 2 feet under the centre of the tree remains. At this stage the tree will generally be ready to heel over by putting the forks underneath the "ball" of soil and roots at one side, lifting up the roots gradually; at the same time someone should gently bend over the stem of the tree.

When the tree is partly turned on its side we fix beneath the roots a part of what we call our lifting cloth, which consists of a square piece of sail cloth 5 feet over; the sides are double thickness, being strongly sewn together, forming a hemmed side. Eight ropes, 5 feet long and half an inch in diameter, are secured to the cloth by fastening them to sewn eyelets in it—one at each corner, and an extra one between those named. The cloth is doubled in the middle, so that when the tree is bent on one side to admit the canvas being placed underneath the tree, and then repeated on the opposite side, the remaining part of the cloth is pulled through with the ropes attached; the tree is then allowed to assume a natural habit of erection. If the tree is properly balanced on the cloth the ropes afford a capital means of lifting it out of the hole on to a low trolley if any distance is to be travelled. The ropes are then made secure around the stem in such a manner that the cloth prevents the soil falling from the roots on the paths. If the weight of soil and roots is very great a stout plank is used to assist in removing the shrub from the hole on to the trolley and off it again, as it is easier to slide the mass of soil and roots up a gentle ascent on a plank than to lift the whole by sheer strength. The position which the plant is to occupy in its new quarters having been settled, the hole is prepared before the plant is removed from its old site, so that the roots shall not become dry by exposure; these are kept covered as well as possible, which prevents shrivelling and check. For fully 1 foot around the roots the soil is removed, the bottom of the hole trenched 1 foot deep, which prevents water collecting.

Care is taken that all shrubs are planted so that the surface roots will not be below the original level of the ground. The soil is broken fine and carefully placed about and amongst the roots, making the whole quite firm. Six inches from the surface a layer of partly decayed manure is placed on and covered with soil. If the soil is at all dry, a good soaking of water is given to the roots, and a thick mulching of manure is laid over them on the surface, which prevents evaporation of moisture from the roots. Every tree that requires support is at once attended to. It is a bad plan to delay the staking of newly planted shrubs or trees; the wind loosens the soil about the stems so much that a check to a quick growth is almost certain to take place, and in some instances results in death. For a 12-foot tree two stakes should be used if in a windy position. These are driven into the soil at a distance of 1 foot from the stem of the tree, a small piece of old bag or a wisp of straw is wrapped tightly around the stem, to prevent the bark being rubbed by vibration of the whole tree. Stout Hazel wythes is the best of any method to secure the plants to the stakes; such wythes will last well for two years, and are much better than tar cord or thick string, which expands by exposure to the weather, which do not act upon the wythes in the same way, but they remain secure, and owing to their being stiff when twisted together, do not admit of the

plants rocking with the wind. For a shrub 12 feet high, a stake 5 feet out of the ground is long enough.—E.

My experience with shrubs is very different from that of "D." (see page 310). We have both very light and very heavy soils to deal with, and without exception the plants growing in the strongest loam and clay transplant the best. In every case the trouble of cutting back the roots is taken the spring preceding the autumn in which the shrubs are transplanted; we thus secure a capital ball of soil, the outside at least of which bristles with growing points.

I think it well to point out that your correspondent has not taken into account the following facts when condemning the practice of employing large shrubs instead of small ones. It sometimes happens that the employment of specimens is absolutely indispensable. I often have such cases, and have ere now been at some trouble in securing large enough specimens from nurseries to meet certain requirements. Three years ago such a case occurred, and again during the present year. I took the trouble to see that the shrubs were prepared a few months before removing them, and thus secured an immediate effect, which with ordinary shrubs would have taken at least twenty years.

Going back a dozen years, when the intensity of the frost destroyed many tender shrubs and killed others to the ground, we had bad backgrounds exposed which had to be concealed as quickly as possible. This was accomplished by removing large Yews, Portugal Laurels, and Rhododendrons from less important or overcrowded positions into these exposed spots. The result was immediate. What has followed where the injured shoots have made young growth has been to either remove the latter to other places requiring making up, or to take away the former and leave the old plants to fill their old positions.

I prefer to remove all shrubs subject to damage by severe frost, from places where they cannot fail without causing a serious blank, and leave the quite hardy shrubs to do duty for them. At the present time I await an opportunity of securing a number of old and large shrubs, many of which must be from thirty to fifty years of age at the least. They all occupy positions where they would require to be cut back to allow other shrubs room to spread, but by removing them to other places which are too thinly planted, or where decaying plants require renewing, we feel amply repaid for the extra trouble. As regards Conifers, it is decidedly objectionable to buy in large plants, but when it happens that specimens are being damaged for want of space, there is no good reason why they should not be transplanted, and with ordinary care in cutting in the roots some months before operating, and with care in removing, quite as fine shoots may be made as in ordinary seasons. I find that the season the roots are cut, the growth is not so good, especially if the weather be dry and no water given, but the next year growth begins to assume its normal state, and it is impossible to say from appearances that the specimen had been removed at all.—B.

#### MEMORIAL TO THE LATE MR. WILLIAM HOLMES.

A MEETING of the members of the National Chrysanthemum Society and friends, convened by special circular, was held at the Royal Aquarium on Wednesday, October 15th, 1890, to consider the expediency of raising a memorial to the late Mr. William Holmes.

Mr. R. Ballantine, Chairman of the Committee of the National Chrysanthemum Society, presided, there being a large attendance of sympathisers. The circular calling the meeting having been read, it was stated that letters expressing approval of the proposal had been received from Mr. John McKenzie, Linton Gardens, Staplehurst; Mr. J. T. West, Cornwall Gardens, Brentwood; Mr. J. C. Restall, Broad Street, Birmingham; and Mr. E. Wilson, Uffington, Stamford; and a letter was read from Mr. D. B. Crane of Highgate, making some suggestions as to the form the memorial should take.

The Chairman opened the meeting by setting forth the objects for which they were met, and invited suggestions from those present, both as to the expediency of raising a fund to provide a memorial, and also as to the form the memorial should take.

After some discussion it was moved by Mr. T. Bevan, seconded by Mr. Witty, and carried unanimously, "That in the opinion of this meeting it is desirable to raise a memorial to the late Hon. Secretary of the National Chrysanthemum Society."

Considerable discussion followed, and suggestions were offered by Messrs. Shea, Doughty, Broughton, E. Molyneux, E. Harland, and others as to the form the memorial should assume. It was then

resolved to raise a fund, to be called the William Holmes' Memorial Fund, and that a Committee be formed to obtain subscriptions to the same, and to consider suggestions and formulate a method of applying the Fund.

It was also resolved that the following should constitute the committee, together with the officers of the Society and the representatives of affiliated societies:—Messrs. E. Sanderson, E. Molyneux, J. Laing, T. Bevan, H. Cannell, L. Castle, Geo. Stevens, W. Roupell, W. Witty, N. Davis, C. E. Shea, E. Beckett, C. Gibson, G. Gordon, G. Prickett, B. Wynne, R. Owen, and E. F. Kemp.

Mr. Harland of Hull proposed that Mr. Lewis Castle be desired to act as honorary secretary, and consent having been given, the proposition was duly seconded and carried unanimously.

Mr. Molyneux's suggestion, which was most favourably received by the meeting, was as follows:—"That the memorial take the shape of a class or classes in the schedule of the N.C.S., to be called the Holmes' Memorial Class, to be competed for at the November Exhibition of the N.C.S., terminable at a period consistent with the amount of the funds forthcoming."

Mr. Shea's suggestion was to this effect:—"That the form the memorial to Mr. W. Holmes should take be that of a medal or medals given triennially, after the character of the Veitch Memorial Medal."

Several subscriptions have already been promised, and all communications should be addressed to Mr. L. Castle, Hotham House, Merton, Surrey.

#### THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE display of Chrysanthemums at the recent Westminster Show was surprising both in numbers and quality, and indicated that many plants are very early this season in flowering—rather a bad augury for the November shows. There can be no doubt that the National Society acted wisely in providing prizes at this time of year, as in previous seasons many handsome Japanese blooms have been lost before the end of October, and the date fixed (15th, 16th, and 17th inst.) was exactly suited for these.

With twenty-four Japanese blooms, not less than twelve varieties, there were fourteen competitors, Mr. C. Gibson, The Gardens, Morden Park, Mitcham, winning first honours with superb examples of Stanstead White, E. Molyneux, Mdle. Lacroix, W. Holmes, Elaine, Comte de Germiny, Peter the Great, Sunflower, Stanstead Surprise, J. Délaux, Golden Dragon, and Mrs. J. Wright. All these were beautifully fresh and of considerable size, Stanstead White being wonderfully good. Mr. J. Doughty, Cranbrook, followed closely, showing handsome flowers of G. Daniels, Madame de Sevin, Avalanche, Baronne de Prailly, and Margot. C. E. Shea, Esq., The Elms, Foots Cray, was third, having Avalanche, Etoile de Lyon, Mrs. F. Jameson, and Val d'Andorre in excellent condition. In the class for twelve Japanese blooms, distinct, eight competitors entered. Mr. C. Blick, gardener to M. R. Smith, Esq., The Warrens, Hayes Common, Kent, took the lead with fine specimens of Baronne de Prailly, G. Daniels, Val d'Andorre, E. Molyneux, Hamlet, M. Freeman, Etoile de Lyon, Avalanche, F. Marrouch, Carew Underwood, Belle Paule, and another variety. Mr. Shea was second, and Mr. W. Collins, gardener to J. W. Calile, Esq., Ashdene, Bayford, Hertford, third. For six white Japanese, one variety each, Mr. C. Cox, gardener to J. Trotter, Esq., Brickenden Grange, Hertford, was first amongst twelve competitors, showing grand, full, pure white blooms of Avalanche. Mr. C. Ritchings, gardener to W. Lindsay, Esq., Brandries, Beddington, was a close second, his blooms not being fully expanded, but in a few days they would have surpassed the others. Mr. W. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common, was third with Elaine.

At a meeting of the Floral Committee on October 15th, Mr. R. Ballantine in the chair, certificates were awarded for the following Japanese varieties:—W. H. Lincoln (Mr. E. Beckett), very handsome, bright clear yellow incurving florets, a first-rate variety; Puritan (Mr. E. Molyneux), pure white, excellent; Mrs. Falconer Jameson (Mr. Molyneux), generally known, brownish orange; Charlie Sharman (Mr. E. Beckett) rich purple, a fine variety; Annie Clibran, the pink sport from Mdle. Lacroix; and Anna Hartzhorn, a grand white variety, with incurving florets, from Mr. Davis.

#### EARLY FLOWERING CHRYSANTHEMUMS.

THIS season has been a bad one for the growth and perfection of the early flowering Chrysanthemums. The spring was good, inasmuch as there were not so many late frosts as usual. Then we had a fine warm May which forced some plants into bloom before their time, but after that came June, July, and August, wet and cool, with insufficient sunshine. September was a fine month for the later sorts, but it was then too late to restore the forward ones. There has also been more earwigs than usual, which, in many cases, destroyed the hearts of the shoots, causing many to be blind and crippled. The florets were so weak that the backs of the blooms faded before they were hardly open. All this told with great effect on the show at the Crystal Palace, for the plants were not equal to those of former years. There was nothing particularly noteworthy there except the appearance of a group from new exhibitors, Messrs. Reid & Bornemann of Trewsbury Road, Sydenham, S.E., who took the second prize.

The September Show of the National Chrysanthemum Society at the Aquarium, Westminster, on September 10th and 11th, was a remarkably good one. The display was extensive. For groups, Messrs. J. Laing

and Sons of Forest Hill, S.E., were first; Messrs. Reid & Bornemann of Sydenham, S.E., were second. In this exhibit was a very fine large white Japanese sort called by them "Sydenham," but there seems some doubt as to its origin, and it may be found to have another name; but if it should come as early, when not disbudded, which this plant was, it will be useful for early work. They also at this time showed a sort called Spiralis, which was a disbudded plant with about three flowers. There is some doubt, too, regarding this. There are two plants of the same name, and it does not seem certain if either of them is really early. Mr. N. Davis of Camberwell, London, was third. Mr. H. J. Jones, who has recently commenced business at the Ryecroft Nursery, Hither Green Lane, Lewisham, S.E., and with whom early flowering Chrysanthemums are features of importance, exhibited, not for competition, a fine group, for which he was given a silver medal, and a certificate for the new yellow Pompon Golden Shah.

The class for cut Chrysanthemums was filled with a more than usually great variety of sorts; Mr. R. Owen of Maidenhead being first with sixty sorts, among which was Miss Phyllis Broughton, exhibited for the first time, and the beautiful little white Pompon Miss Lily Stevens, for which he received a certificate. Mr. N. Davis of Camberwell was second. In this class, and exhibited for the first time, a new early sort, Mr. Harry Laing, a straight petalled magenta Japanese; and Ernest Bergman, a new crimson, both of which I have grown, but have not seen in condition to say what their value is, and it must be deferred till another season. They are both new French sorts of this season. Mr. E. F. Such of Maidenhead was third for cut flowers. In the class for twelve Pompons Mr. D. B. Crane, of 4, Woodview Terrace, Highgate, London, N., exhibited some flowers of Rosamundi, which I do not remember to have seen before at any early show, and if it will grow good flowers without disbudding it may be useful. I have grown one of this name this season, but it is late and evidently a difficult plant. I will grow the other next season and test its merits for myself. Of course, I do not consider because blooms of any sort can be shown in September that such a kind can be called early or semi-early, but only such as will do it without any buds being taken off, or forced in any other way except good cultivation in the open.

Though the season has been a bad one for the growth it has been a very good one for the extension of the culture in many directions. Many of those who have thought nothing of the early sorts find that it is to their benefit to grow them; but it is in the many good varieties that have come to light in this country that the season shows the most advance. We have not had to grow so many poor plants to discover good ones as we generally do, and besides there are several good English seedlings from English seed in view for next season.

Perhaps the best find of the year is P. Radaelli. This is a very beautiful early sort, blooming first in August on the crown bud, but afterwards shooting on and blooming during the following months. It will grow a flower 4 or 5 inches across without a bud being removed. It is white with a narrow reflexed petal with a rounded end. It has spare foliage, and grows to a height of 4 feet or more.

Arthur Crepey, certificated, is a very good early dwarf plant, blooming in September, perhaps another season in August. It is a primrose yellow varying to white; blooms about 3 inches across; height of plant 2 feet. It resembles Madame Desgrange, but the petals are rather broader, and the buds come naturally further apart, making it better for growing without any buds being taken off. It is of stiff habit, and can begrown without sticks. It seems to be a seedling of the above, and is likely in many places to be grown instead of Madame Desgrange.

Madame Léon Collin is an entirely new form and colour among the early sorts, being a bright light bronze, Japanese in form, with narrow, twisted, and eurred petals. It does well either disbudded or grown naturally. Flowers 3 to 4 inches across. Plant about 3 to 4 feet high. It is a charming addition to the early sorts, quite a new shade of colour, and has had a certificate granted to it. Blooms in September.

La Perle is a fine dwarf white, blooming at the end of September. It is a stout plant, and will come into competition with La Vierge, but while that is reflexed this is slightly incurved, has broader petals than that, and is considerably earlier. Grows 2 feet 6 inches high, with flowers 3 inches across.

There are several others which will probably come earlier another season in colours much desired—viz., crimsons, reds, and purples; but as they are not yet out (October 15th) sufficiently to be spoken of with certainty, and there are some promising novelties among them, I will try to write a little more on semi-earlies in a week or two.

Of the few new good ones of last year, I may say that Madame la Comtesse Foucher de Careil, which seemed a weak plant last season, turns out to be not so. It is a real good stout sort, being so dwarf (just over 2 feet high) that it can be grown without sticks. It is a very great acquisition because there are so few reds, which it is, and a very bright red, too. The ladies call it a terra-cotta, but it is very much lighter than a garden-pot red. It is a lighter colour than L'Amirable, besides being nearly a month earlier; in fact, there is no other like it. It stands alone as a red September reflexed Japanese beauty, and being so dwarf is excellent for front rows in decoration. As a cut flower it is striking and distinct both by day and night. It will probably be a great market sort in a season or two, both as a pot plant and for cut flowers. It has been certificated. I have one or two good seedlings from my own seed, and so has Mr. Owen from his own seed; but as they will not be sent out next season I shall reserve judgment upon them

till then. There are other good seedlings which I will refer to in the semi-early paper.—W. PIERCY, *Beadnell Road, Forest Hill, London, S.E.*

**CHRYSANTHEMUM CENTENARY.**—The number of the *Journal of Horticulture* to be published on the 30th inst. will contain matter of unusual interest relating to Chrysanthemums and Chrysanthemum growers. It is desirable that early application be made for copies of this issue to avoid disappointment in the supply, as the demand is certain to be very large. Secretaries of Chrysanthemum societies will oblige by making this known among their members and friends.

— **EVENTS OF THE WEEK.**—To-day (Thursday) the Holmes' Memorial Committee have a meeting in the Royal Aquarium, Westminster at 4 P.M. At 5.30 P.M. the fourth annual dinner of the United Horticultural Benefit and Provident Society will be held in the Cannon Street Hotel, Mr. E. R. Cutler in the chair. On Monday, October 29th, the National Chrysanthemum Society's General Committee will meet at 6.30 P.M. at Anderton's Hotel, Fleet Street. The Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet in the Drill Hall, James Street, Westminster, at twelve noon on Tuesday, October 28th.

— **THE WEATHER** in the metropolitan district has given an earnest indication of autumn during the past week, not so much in low temperatures as in the dull skies and fogs. Little rain has fallen generally, but in some districts rather heavy showers have been experienced.

— **THE GUILDHALL SHOW.**—We are requested by Mr. Geo. Bunyard (who arranged for the Judges at the Guildhall Show) to say that the following most kindly acted as additional Judges at a short notice, when it was found on the Show day that the entries in Section III. were so numerous:—Messrs. Begg (Bearwood), J. Hudson (Gunnersbury), J. Laing (Forest Hill), William Paul (Waltham Cross), Arthur Turner (Slough), and John Watkins (Hereford). Other willing helpers were—Mr. Chas. Ross of Welford Park and Mr. Miller of Northdown, Margate.

— **FRUITS PRESENTED TO THE QUEEN FROM THE GUILDHALL EXHIBITION.**—We are informed that the following were omitted from the official list published in the *Journal* last week. They were amongst the most interesting contributions, and some of them were grown within five miles of the Guildhall:—The Queen Apple was sent from Mr. W. W. Bull, Bishop's Ramsden, Essex; South-Eastern Zone, class 23, Wadhurst Pippin, from A. H. Smee, Esq., The Grange, Carshalton; class 24, Ribston Pippin, from Lady Whitehead, Highfield House, Catford Bridge; Peasgood's Nonesuch, from W. Roupell, Esq., Harvey Lodge, Stratham; and Worcester Pearmain, from Mr. F. Minchener, Park House, Penge.

— **DEATH OF MR. JULIUS NIEPRASCHK.**—We have received an intimation of the death of Mr. Julius Niepraschk, the Director of the Royal Garden "Flora" at Cologne, which occurred, after a short illness, on the morning of the 14th inst. Mr. Niepraschk was well known and held in high esteem by the horticultural community throughout the world.

— **ROYAL HORTICULTURAL SOCIETY.**—We are requested by the Secretary of the Royal Horticultural Society to publish the following announcement: Mr. Morris is about to resign the post of Hon. Treasurer to the Royal Horticultural Society, which he has held for such a length of time; indeed, at a meeting of the Council on the 14th inst. he formally tendered his resignation. Mr. Morris is about to sail to the West Indies on a Government mission, and as this will necessitate his absence from England for a period of three or four months he feels that under these circumstances he could not attend to the duties of Treasurer to the R.H.S. to his entire satisfaction. During Mr. Morris's term of office he has been most energetic in bringing the financial affairs of the old Society to a satisfactory state, and that he has succeeded and his services appreciated may be seen from the following resolution, passed by the Council:—"The Council of the R.H.S., in accepting with unfeigned

regret Mr. Morris's resignation of the post of Hon. Treasurer, which he has filled with such signal success and advantage to the Society, beg to express to him their grateful sense of the value of his services, of the judgment and discretion with which he has conducted his duties, and of the devotion with which he has in every way forwarded the interests of the Society."

— **CHISWICK CONFERENCES IN 1891.**—The Council of the Royal Horticultural Society intend to hold the following Conferences at Chiswick Gardens during the year 1891—viz., July 7th, "Hardy Mid-summer Flowers." July 8th, "Strawberries, Raspberries, Currants, and other Small Fruit." October 6th, "Hardy Autumn Flowers, especially Michaelmas Daisies, Perennial Sunflowers, Autumn Crocuses, &c." October 8th, "Conifers as Ornamental Trees and for Timber." The Council would be greatly obliged to anyone possessing good varieties of Michaelmas Daisies or of perennial Sunflowers if they would be kind enough to forward plants of them without delay to Mr. Barron, Superintendent R.H.S. Gardens, Chiswick, London, W., as they are very anxious to obtain a thoroughly representative collection of these charming flowers, with a view both to the selection of the best varieties and the correction of their nomenclature, which seems to be at present somewhat confused.

— **THE autumn Exhibition at the ROYAL AQUARIUM, WESTMINSTER,** last week was very satisfactory in all respects, cut flowers, fruit, and vegetables being largely shown in all the classes. In varied attractions and general interest it was one of the best yet held there.

— **MESSRS. F. SANDER & Co., St. Albans,** send us specimens of a very handsome variety of *LAPAGERIA ROSEA*, the flowers considerably larger and of more substance than usually seen, and the colour extremely rich.

— **GARDENING APPOINTMENT.**—Mr. Frederick Fulford, for the past eighteen months foreman in the gardens at Hallyburton House, Coupar Angus, Forfarshire, N.B., has been appointed head gardener to the Earl of Mayo, Palmerstown, Strattan, Co. Kildare.

— **THE meeting of the BRITISH FRUIT GROWERS' ASSOCIATION** at Westminster, on Wednesday, October 15th last, was very successful, and in some respects one of the best of this year's series. There was a good attendance of members, and Mr. G. Gordon took the chair at 5.30 P.M., opening the proceedings with a few introductory words. Mr. G. Hammond of Brentwood then read the practical and useful paper on "Apples for Market," which we published in our last issue. Considerable discussion followed, in which several important points were raised and debated. Messrs. Roupell, Cheal of Crawley, Ivatt of Cambridge, Cannell of Swanley, Luckhurst of Romford, Shea of Foots Cray, and Canham of Norwood, took part. Mr. Hammond replied generally to the various questions, and the proceedings closed with votes of thanks to Messrs. Hammond, Castle (Hon. Sec.), and Gordon (Vice-Chairman).

— **PANSIES.**—Amateurs and others will do well to look closely after aphides in the hearts of young Pansy plants before consigning them to their winter quarters. The spring and summer of 1890 will long be remembered for the plague of brown aphids, which not only played sad havoc with the blooms, but in many cases caused the destruction of the plants, and from what I hear from growers these insects are yet to be found in the plants. A decoction of tobacco water or an application of the insecticide "swift and sure," made according to printed instructions, should be prepared, and the young plants (not the roots) thoroughly washed in it. If this is done now, and they are examined through the winter, young plants can be secured in a clean healthy state for spring planting.—**AN OLD PANSY GROWER.**

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—An ordinary meeting of this Society was held on the 14th inst., the Rev. A. Lofts presiding. The membership steadily increases, and gives greater power to the Society by their influence. A capital collection of fifteen varieties of Pears was staged by Mr. R. Smith of "Presdales," Ware, and a very interesting exhibit was staged by Mr. Alexander of "Poles," Ware, in the shape of Onions in ten varieties. They were grand samples, and gave abundant evidence of the superior culture they had received. Apples and Chrysanthemums were also staged by other members. A paper was read on "Plant Stoves and their Occupants," by Mr. A. King, who treated the subject exhaustively. His remarks were followed by Mr. R. Smith and J. B. Riding, to which the essayist briefly replied. A cordial vote of thanks was passed to Mr. King for his paper.

— HORTICULTURAL CLUB.—The first dinner and conversazione for the present season took place on Tuesday evening Oct. 14th, when, notwithstanding the miserably foggy weather, there was a good attendance of members. The chair was occupied by Mr. John Lee, and there were present, amongst others, the Rev. W. Wilks, Messrs. Harry J. Veitch, Cousens, H. J. Pearson, Lindsell, Burrell, and Walker. The subject for discussion was the *Gladiolus* (hybrids of *gandavensis*), which was opened by the Rev. H. H. D'Ombrain, who, in opposition to some recent statements, showed specimens of bulbs to illustrate the correctness of his views, while Mr. E. B. Lindsell kindly contributed some beautiful spikes of flowers to illustrate the statements made. An animated discussion followed, which was joined in by nearly all present, and an interesting and profitable evening was spent.

— THE FRUIT EXHIBITION AT THE GUILDHALL.—As mentioned last week, at the close of the Fruit Exhibition in the City, the Master of the Fruiterers' Company (Sir James Whitehead) forwarded to Her Majesty at Balmoral two cases of English grown Apples and Pears, selected from the exhibits at Guildhall, with the view of illustrating what could with intelligent cultivation be produced in different parts of England, and showing the capacity of this country for the growth of much of the hardy fruit which is now imported. He also forwarded to the Queen a copy of an essay, "Profitable Fruit Growing," by Mr. John Wright, for which work the gold medal of the Fruiterers' Company together with a prize of twenty-five guineas was awarded last year. Major Sir Flectwood Edwards, K.C.B., in acknowledging the safe arrival of the fruit, stated that some of it had already been served at Her Majesty's table, and he was commanded to convey to the Fruiterers' Company the Queen's thanks for having been kind enough to forward the fruit, with the beauty of which the Queen had been struck. Her Majesty was also obliged for the copy of Mr. Wright's essay.

— IN the 103rd annual report of the ROYAL BOTANIC GARDEN, CALCUTTA, Dr. King says that the attention of the staff during the past year was devoted chiefly to the maintenance, in as high a state of efficiency as possible, of the various departments of the garden. Special attention was given to the herbarium, and a considerable number of new species were described. The sum of 1000 rupees having been granted in order that specimens might be obtained in Burmah and Assam, Dr. King was enabled to do more than usual in these provinces. Under a recent order of the Government of India this exploration will be extended. An official document relating to Dr. King's report, and issued by the order of the Lieutenant-Governor of Bengal, contains the following passage:—"The control of Indian botanical operations has been centralised in the Calcutta Gardens, and the Superintendent has been appointed Director of the Botanical Survey of India. The grants promised by the Administrations of Burmah and Assam will enable the collections to be made on a larger scale and more continuously. As this work will constitute a separate department, it has been ordered that in future years a separate report should be submitted on the subject."

— THE twenty-eighth annual report of the Government Cinchona plantation and factory in BRITISH SIKKIM, by Dr. King, has been issued. At the end of the financial year 1889-90 the plantation consisted of 4,682,401 trees of various ages, and of a nursery stock amounting to 264,000 seedlings. The crop collected during the year amounted to 304,705 lbs. The product of the factory were 1833½ lbs. of sulphate of quinine, and 6578 lbs. of febrifuge. The whole of the quinine and the greater part of the febrifuge were manufactured by the new fusel-oil process, and as the arrangements for working this process were quite completed during the year, the old acid and alkali method of manufacture has now been definitely abandoned. An additional year's experience of the fusel oil process confirms Dr. King's previously expressed opinion of its complete success. The quinine turned out by it is of excellent appearance and great purity, in the latter respect comparing favourably with most of the brands of the drugs of European manufacture.—(*Nature*.)

— KNOWSLEY COTTAGE, the residence of Thomas Pilkington, Esq., is within easy distance of Liverpool, and is approached from the main road by a short drive banked on each side by fine specimen Rhododendrons. The house, as well as the grounds, cannot claim much pretension to elaborate effect, but from the windows the banks of Rhododendrons skirting the lawn are grand in the spring time. The houses, eleven in number, are of various designs, the first entered being an intermediate house containing good plants of *Asparagus plumosus nanus*, *Bouvardias*, *Cyperus*, *Begonias*, *Poinsettias*, *Epi-*

*phyllums*, *Stephanotis*, *Bougainvillea*, and good batches of those useful Ferns *Adiantum euneatum* and *Pteris serrulata cristata*, all for decorative purposes. A general plant house filled with plants incidental to such structures was next visited, and then a propagating house containing fine young *Crotons*, *Pandanus*, *Eucharis*, and *Gardenias*, all in small pots for house decoration. The Cucumber house was just planted with its winter occupants, plants clean and robust of the old Telegraph. The Peach house contains four good trees on the back wall—viz., Hale's Early, Grosse Mignonne, Barrington, and Elruge Neetarine. They are the pictures of health, Mr. Simpson having worked out most of the old wood and taken up young shoots in their place, and with good treatment at the roots has practically renewed them. In the Muscat house the Grapes were cut, but the wood was all one could wish for. The second vinery, although occupied with old Vines, contained fine bunches of Muscats, Madresfield Court, Mrs. Pince, and Alicante. The Alicante house is 80 feet long, containing seventeen Vines, and has an east aspect. Each Vine carried ten splendid bunches, large in the berry, well coloured, of the largest size, and not a faulty bunch among them, in fact all fit for exhibition. We may rest assured that when Mr. Simpson gives his opinions on the cultivation of Grapes he is well able to do it, as evidenced by the Vines under his charge. The Camellia house is 75 feet long, and contains fine plants of the best varieties planted out and well set with buds. There is also a large roomy stove containing some very choice *Crotons*, Palms, *Dracenas*, *Pandanus*, Cycads, *Eucharis*, and *Pancreatiums*, the rafters of the roof being occupied with *Cissus*, *Stephanotis*, *Bougainvilleas*, and *Allamandas*. The conservatory is attached to the house, and was very gay at the time of my visit. The flower garden was effectively bedded out, particularly striking being two beds of Henry Jacoby *Pelargonium*, which does remarkably well in this part of Lancashire.—R. P. R.

#### SARRACENIAS.

It has often seemed strange to me that *Sarracenias* are not more popular. Perhaps some may say that they are difficult to manage, others again may say that they are not sufficiently showy, but to these excuses I answer that they are both showy and easily cultivated. Some of the species have been introduced to our gardens upwards of a hundred years, and yet how seldom do we meet with them, except in botanic gardens and a few establishments where large collections of plants are grown. A few years ago there were only about half a dozen species in cultivation, but now in addition some fine hybrids have been obtained by Messrs. Veitch & Sons of Chelsea. The great outcry at the present day is for new plants and Orchids; but if some of the new plants that are sent out annually were nearly as attractive as some of the *Sarracenias* we should not have room to complain. I have been a close observer at the great metropolitan exhibitions for this last few years, and have come to the conclusion that few new plants of really sterling merit have been sent out. If *Sarracenias* were an introduction of the present times instead of the past I am sure they would find favour with many plant-cultivators, for when well grown they are really ornamental.

Perhaps a few words on their cultivation will not be out of place to some of the readers of your Journal who may wish to give them a trial. I find that *Sarracenias* are very accommodating, not at all particular as to the house in which they grow. I grow mine through the summer in a light airy greenhouse well ventilated top and bottom, and in winter I place them in the coolest end of the stove. This is merely for my own convenience, for it is not absolutely necessary that they should be in heat in winter, as I have known some growers allow their plants to be exposed to frost for a considerable time. I have tried two or three composts for them, but what they like best is good fibry peat, chopped sphagnum, broken charcoal or potsherds, and plenty of silver sand. Some prefer potting their plants in autumn, others in spring. I prefer potting in spring before they make their spring pitchers. The pots should be washed and be filled about a quarter full with good drainage, or if large a little more drainage will be all the better; over this place a thin layer of moss, and then the potting proceeds. The crown or rhizome should be slightly elevated above the level of the pot, the plants being potted rather firmly, leaving sufficient space at the top for a good top-dressing of green sphagnum. After the plants have become sufficiently large pans are the most suitable to grow them in. In their native habitat *Sarracenias* are found growing in boggy or marshy ground, consequently they require a good amount of water both in summer and winter; in fact, they should never be allowed to become dry. The plants when growing should occupy a position near the glass and be fully exposed to the sun, for if shaded the colouring of the pitchers is not nearly so bright. It is very necessary to guard against the flies, for these intruders are very fond of the secretion produced by the pitchers when in a young state. If the flies are allowed to become entrapped in the pitchers in any quantity decomposition soon takes place, and causes the base of the pitcher to decay. I find that placing a small piece of cotton wool in the top of each pitcher, sufficiently far down to be unobserved, answers the purpose admirably.

The following are amongst the most useful and showy forms:—

*S. Drummondii*.—This is one of the best species grown. The pitchers

are quite erect, and from 1½ to 2 feet high, of a bright green colour, the upper part being beautifully variegated with red, green, and white.

*S. Drummondii alba*.—Another handsome form, differing very little from the typical species, except in the colouring at the top of the

*S. flava* and vars. *ornata* and *picata*.—These are all attractive forms, especially *S. flava ornata*, which produces pitchers of an enormous size, and remarkable for its bold and clear venation, which is of a dark purplish red. The flowers are large and handsome.

FIG. 41.—STAPELIA GIGANTEA. (See page 349).

pitchers; instead of being variegated, as in the last-named, it is nearly pure white.

*S. Drummondii rubra*.—This is very handsome, the pitchers being beautifully variegated with crimson.

*S. atrosanguinea*.—A strikingly beautiful variety. The pitchers are long and narrow, and of a greenish colour; the lid is heart-shaped, the lower part green, and upper part blood red with a satiny hue.

*S. purpurea*.—A good old species, quite hardy, and producing cup-

shaped pitchers about 6 or 8 inches long, and, as the name implies, are of a bright purple colour.

*S. variolaris*.—This is well worth growing, and should be in every collection. The pitchers are peculiarly hooded, growing between 1 and 2 feet long, and beautifully mottled.

*S. psittacina*.—Quite distinct from any of the former in habit of growth. Instead of growing erect it produces its pitchers horizontally or spreading; the pitchers are light green with crimson veining, and are curiously hooked at the end, much resembling a parrot's bill.

*S. rubra*.—Also well worth growing if only for its flowers, which are blood red and deliciously fragrant like Violets. The pitchers of this species are not so showy as in many of the others, from a horticultural point of view, but where a collection is grown it well deserves a place.

*S. Chelsoni*.—A beautiful hybrid of Messrs. Veitch's raising. It is much in the way of *S. purpurea*, which is one of the parents. The pitchers grow erect, of great substance, and very wide at the mouth, the colour being a bright red.—K.

### FRUIT FARMING FOR PROFIT—A CRITIQUE.

UNDER the auspices of the British Fruit Growers' Association much information has been diffused within the last few years on the profitable cultivation of hardy fruits. Conferences have been held in some of the most important fruit growing districts and centres of fruit consumption. One good effect of these conferences is that they tend to an interchange of views between practitioners. The papers, by experienced or eminent pomologists, are conveyed into every nook and corner of the kingdom through the instrumentality of the horticultural press. Sound reliable information is thereby conveyed to many minds, and although the teaching may be that of a lifetime it does not always carry conviction, for it must not be disguised that there exists a prejudice against preachers for profit, but it is a misfortune to become so blinded by prejudice as not to at least search into the facts if they cannot see or appreciate the work that is being done in behoof of the common weal.

Before me is Mr. Bunyard's work, "Fruit Farming for Profit,"\* papers read at various places, with prefixes, addendas, and illustrations, together forming a handsomely bound volume of 137 pages. In the introduction a survey is taken of foreign competition, and its bearing on British grown fruit, in which the whole thing is summed in a sentence—viz., in "Market growing for profit we shall have to grow such kinds as will pay. That is what the Yankees do, and what our colonists do—throw overboard their old ideas." But they do it in a very different manner to the old country folks. They know exactly what the consumer wants, and they set to work to meet that want. Instead of Ribston Pippins they place the glowing Northern Spy in the market, and supplant Goff's by Baldwins. They have found out that land that will grow a bushel of Crabs will grow three bushels of the choicest Apples. Yea, as Mr. Bunyard puts it, "we must have an eye to those sorts which crop freely and bear regularly. We should aim at quality and colour in dessert Apples and Pears, and weight or size in kitchen Apples," but why not aim at colour in kitchen Apples as well as weight and size? A fine looking Apple always takes the "shine" out of a sour looking one.

The author has a poor opinion of chalk as a sub-strata for fruit trees, and sandy soil is not recommended, yet a reservation is made in favour of a good depth of soil over chalk, and a brick earth sub-soil in the case of sandy soil. "Most of the land around Maidstone is on the lower greensand, and suitable for all kinds of fruit." That is a very interesting fact, as it shows the value of the fossiliferous formations to fruit growers, and equally is the further fact "that for general fruit nothing can be better than the very deep brick earth that is found in the valley overlooking the Medway from Chatham to Canterbury." In fruit growing there is nothing like a foundation. The greensand is rich in phosphates, the brick earth contains an inexhaustible supply of potash. Plums do well on the Kentish rag, indeed all fruits down to small fruits and Nuts. In the flinty lands of East Kent where the soil is rather heavy, fine Cherries and Apples are grown, and in "the heavy lands in the Weald of Kent, where there is a more or less loamy soil resting on the clay, we find some of their finest Apple orchards, the weight and colour of the fruit being remarkable." Indeed, the soil seems to team with fertility all through Kent; even "the stone slattery land in the neighbourhood of Orpington and the Crays, where it overlies and mixes with the gravel, is remarkably suitable for Pears, Apples, and Plums." Very wet land, but not flooded, will grow Black Currants, and the chalk will grow Strawberries. "The Boughton, Linton, Chart, and Sutton Hills are clothed with fruit. Well may the author say that "this fact stares us in the face—that with care and proper drainage fruit is grown" in this garden of England. Mr. Bunyard says, "As fruit succeeds in the garden while it fails in the orchard in the same soils, it appears in many cases only a matter of cultivation." That is just what makes all the difference. Some fail because the soil is bad, others through failing to drain it, all from bad cultivation, for there is not a soil in this country that will not, by drainage or other necessary improvement, grow some fruit profitably. "Soil that is naturally drained is even preferable to land that requires drainage, for obvious reasons, not the least is a saving of some £5 per acre;" but it does not necessarily follow that the naturally drained soil is as good for fruit culture as land requiring draining. Naturally drained soils are often the most unremunerative from their poverty and porosity, and the cost

in making and keeping them fertile with manure is far greater than investing in drains and opening up a mine of untold wealth. Bleak hills and uplands are to be avoided for fruit culture, and we are also advised not to plant too near a river, stream, or lake. Shelter is of such importance "that too much cannot be said. Hedges should be allowed to get up 6 to 10 feet;" but why such a ravenous earth grabber as the Wych Elm is recommended it is difficult to tell. Better far is "the fashion, and a good one, to plant the Cluster Damson." Land, it is stated, "which grew Birch, Beech, and other trees of low value," has given good results when planted with Plum, Damson, and Apple trees, Gooseberry and Currant bushes, Raspberry canes and Strawberry plants, which pay well." Then why bother with the profitless shelter? Damsons are as hardy as Sloes, and "these break the wind and screen the other trees, fruit heavily, and give a profitable return."

Manures are carefully and judiciously treated, and those are advised which are readily obtainable in the immediate neighbourhood of towns or from the coast. Wool waste, rags, fur clips, &c, sprats, London dung, shoddy, even road scrapings are laid under contribution; but the light manures are most in request, through the "readiness with which they can be placed on the land; being in bags one can be dropped here and there, and spread before the diggers." The first three are described as powerful manures or stimulants, decomposing slowly, and it is mentioned that "well-fed pigs, or sheep and lambs fed with oilcake, are a great help to free growth, and consequently good fruit." This, in "old orchards"—one more proof that poverty is at the root of decrepit trees.

A word of caution is given to those who have the means and opportunity to use a large quantity of manure when starting a plantation. Very often trees are manured at start, and when they begin fruiting, and their demands for nutriment are greatest, they are left to starve. Mr. Bunyard traces this to the too free use of stimulants in the early years, and mentions that trees forced into over-luxuriant growth have the wood unripe by winter, and it gets frozen, especially in Plums, and bough after bough has died off. The writer is "dead" on late growth. Caterpillar infestations lead thereto, that is one reason why they should not be allowed to infest the trees, "mildew sets in, and following the leafstalk to the eyes of the shoots forms canker, which eats into the boughs, and in a few years changes a smiling plantation into a miserable lot of cripples which never recover." That is another explanation of canker, which seems to thrive all the same in soils which there has been too free of stimulants, and where the trees are made do without manure; but how manures applied in July or August can act other than as stimulants to late growth it is difficult to explain, except that it is advised not to use too strong manure, which, though indefinite, qualifies everything.

Planting is treated very ably. Surface rooting is sought by planting high. "Surface roots being those that nourish fruit." It is mentioned that the chief mischief accruing to young trees arises from too deep striking of the large coarse roots, which, meeting with a badly drained or unsuitable subsoil, causes canker, and apparently healthy trees die back wholesale. Thus it seems the fruit grower has not matters all his own way, even in Kent. For all fruits planting in November is considered the best time, and though planting in holes is had recourse to to save expense, it is clearly set forth that the cultivator would be amply repaid by having all land intended for cultivation either steam cultivated or trenched.

Pruning receives a generous share of attention, and standard with half-standard fruit trees are not to receive any pruning at planting. In planting, page 19, it is recommended to "Shorten coarse roots slightly with a sharp knife, and any injured cut clean away;" but the head is not to be cut until a year after planting. There is to be, however, a thinning of the shoots if necessary, leaving from three to seven of the best situated for forming a good symmetrical head. The winter following, preferably in February, the shoots are to be cut back to five or six buds. This causes a number of shoots to push, and these in July are to be thinned, and in winter to be cut back to 6 inches. This is to be practised for a few years, when the trees begin to bear on the old wood. Practice of that kind is found necessary, "because some fruits, notably Manks Codlin, Stone's, and Lord Suffield if left uncut form a mass of fruit buds and come into bearing, and never afterwards get beyond a mop-sized head. Some Pears and Plums have the same tendency." "In planting Cherries I (Mr. Bunyard) strongly advise planters to let them stand the first year without cutting at all (except the roots, as advised for Apples)." But in planting "Plums (from the nature of their roots), if the planting is completed before Christmas, they may be pruned the first year of planting."

In the foregoing remarks on pruning the author is manifestly between two fires and knows not which way to run. Apples, Pears, Cherries, and some free-growing Plums have anything but fibrous roots on the free stock. In transplanting trees of all kinds I have invariably found that the larger their heads the more roots were lost in transplantation, and that to prune the roots, only leaving the heads entire, was to court failure. Hollies that may be thirty or more years old transplant splendidly if their heads are cut proportionately to the reduction of the roots in lifting. Old Laurels start grandly dug up with a mere stump of root if the precaution is taken to cut off the head correspondingly, but lift them never so carefully retaining the heads and they will look very seedy, mostly showing their detestation of the rude treatment by dying back considerably or collapsing altogether. The rationale of the whole thing is very simple—a tree checked in its growth by transplantation must have the balance restored between the roots and branches

\* Frederick Bunyard, Week Street, Maidstone.

before it starts into growth as freely as before the transplantation. This is seen in all transplanted trees, whether evergreen or deciduous, ornamental, forest, or fruit trees—the older they are and less frequently transplanted the longer time takes to recuperate. Standard Apple and other fruit trees have bad roots compared with those on dwarfing stocks, and because a tree has few roots many branches will enable it to recuperate is to me one of those things that “no fellow can understand.” If I plant a standard Apple tree with good roots and leave it unpruned it will make some wood growth besides forming fruit buds in the first year, and in the second it will blossom, affording some fruit, if a free bearer much; if a shy or non-early bearer little or none, and on the abundance or otherwise of the crop depends the wood growth. When I plant a Cherry against a wall and do not shorten its shoots at planting or soon afterwards it forms blossom buds or spurs at almost every joint, including the terminal, and gives a plentiful crop of Cherries the following year. A Plum, Apricot, Peach, or Nectarine behaves in a different way, making growth as well as forming fruit buds; but a Pear is just as liable to get stunted as an Apple or a Cherry. Unpruned they go at once to fruit in the free early bearing varieties, and become “mopsized,” practically useless. Mr. Bunyard is quite right in that, but labours at a disadvantage in writing for farmers. If they plant a tree it is in a hole on grass; if it bear in the second year they let it, and kill the goose that lays the golden eggs. Mr. Bunyard bravely puts an end to all that. Cut away the fruit for three years at least, and give the grower a tree that he cannot well spoil; but then our author advises the non-pruning at planting for all standard trees. “Plums, from the nature of their roots, may be pruned the first year of planting.” This is a philosophy that I can make nothing of, for if a tree has abundance of fibres it will feel the effects of lifting less than a tree will with poor roots. Trees with few roots and long shoots left unpruned are much in the same condition as Raspberry canes left their whole length at planting—evaporating their lives away instead of pushing fresh canes.

Valuable hints on pruning old and neglected trees follow, spurs not being forgotten. Chapters are devoted to Apples, Plums, Pears, Cherries, Walnuts, and Chestnuts (the “t” being left out), bush fruits, Kent Cob Nuts and Filberts, Strawberries, Rhubarb, extra fruits, packing, &c. Altogether a handy volume, full of information pertaining to hardy fruit culture, and though written evidently in the “farming” interest most of the teaching is of general application. We are told what to avoid as well as what to do to insure a profitable return on investments in fruit cultivation.

Though personally unknown to me, I take this opportunity of expressing my thanks to the author for his practical work.—G. ABBEY.

#### A WORD IN SEASON.

WE are to have a new Rose, Jeannie Dickson, this season; next year we are promised Margaret Dickson. Let me beseech the grower to be merciful, and not confuse our weak minds with all the members of the family. Which of us has not been inclined to use strong language about the numerous “Verdiere,” “Margottins,” and “Duchers,” &c., who have been immortalised by good, bad, and indifferent Roses?—DUCKWING.

#### LOCAL ROSE EXHIBITIONS AND THE AMATEUR CLASS.

MAY I venture to offer a few remarks in answer to the letter of your correspondent, “An Exhibitor,” in reference to the above-named subject? In the first place, he complains of indefiniteness respecting the word “amateur.” Surely it is clearly enough defined by the National Rose Society’s rule—viz., “That no person be allowed to compete as an amateur who sells Rose plants or Rose blooms.” This explanation of the word has, I fancy, been considered sufficiently definite by the majority of exhibitors. He next states that “there are gentlemen who grow and cultivate 2 or 3 acres of Roses,” which means that there are exhibitors who grow between 16,000 to 24,000 plants! this calculation being based on the fact that 2000 odd trees can be easily grown in a quarter of an acre. I have visited most of the amateur exhibitors’ gardens, and I am nearly certain that there is not one who grows more than 7000 odd trees (Teas and H.P.’s included), if so many. Your correspondent next complains of the unfairness of these leviathans showing against the smaller fry. But has it ever occurred when there are large classes available? If so, the exhibitor ought to be ashamed of himself for stooping so low.

If your correspondent would look at the schedules of the various Rose societies, he would see that the classes are so arranged to avoid this colliding of “whales and minnows.” And as to the question of employing labour in amateur Rose growing, I do not think for one there is very much in it, for it does not at all follow that because owing to the size of his collection an exhibitor is obliged to employ three or four men, or more, he therefore grows better Roses than one who perhaps has only one man. To my mind one can grow too many Roses. The consequence is the trees do not and cannot receive that personal supervision which a more reasonable collection obtains, therefore I do not

think your correspondent need be alarmed. If he grows a moderate collection of between 1000 and 2000 trees, and attends to them closely, he will find himself able to more than hold his own against amateurs, and very often nurserymen too, especially in Teas.—F. R. B.

I AM surprised at the letter of “An Exhibitor,” alike at his premises, his deductions, and his conclusions. His first complaint (and it is a very old and vexed one in every society or association) is that the word “amateur” is not sufficiently defined, that “at present there seems to be no limit.” The definition as given by the National Rose Society is, “No person shall be allowed to compete as an amateur who sells Rose plants or Rose blooms, nor any person in the employ of a nurseryman.” “An Exhibitor” may not see at first how this definition hinders an amateur from growing as many Roses as he likes, but I think he would soon find out if he attempted “2 or 3 acres.” In this extent he would probably have quite 4000 or 5000 maiden Roses every year, and what is he going to do with these plants or his cutbacks when autumn comes? Is he going deliberately to burn 4000 or 5000 plants? Giving them away would involve a great deal of trouble, and if he only grows enough maidens to fill up the blanks among his cutbacks he would find supply and demand would not always fit very well, and also that he had not nearly enough maidens for show in proportion to his stock. It would be a tyrannical interference, in my opinion, to limit a man’s title to be called an amateur by the number of Roses he grows.

The next idea is that “there are gentlemen who grow and cultivate two or three acres of Roses.” I thought I knew a little of most of the leading amateurs, but I am not acquainted with these gentlemen. Mr. Budd of Bath (who has not, I fear, met with quite his usual success this year) told us in the last number of the “Rosarian’s Year Book” the extent of his Rose garden, “about an acre,” and the number of his Roses, “between 8000 and 9000, and 1500 Briar stocks,” and this, I think (though I do not grow a third of that quantity), would make about as many Roses in a given space as could be grown to perfection. I should be astonished to hear that anyone now occupying a leading position as an amateur grows more Roses than this, and should expect to find that the majority, even of those at the top of the tree, have not nearly so many. Would it surprise “An Exhibitor” to learn that the gentleman, who has certainly beaten more nurserymen than anyone else in the last six years, grows about 3000 Roses, and has no gardener? I should very much doubt, however, if it is common, as “An Exhibitor” says, for those who cultivate not more than 1000 Roses to do so without aid.

Again, is “An Exhibitor” such a novice that he does not know that it is not my lord’s gardener, with his eighteen or twenty trained assistants under him, who wins big prizes, or is looked upon at all as a dreaded rival? Why it is just the man who does do everything himself—helped by his sisters or daughters perhaps—who is likely to win the amateur trophy, to beat good nurserymen, or to make three figures in prize money. And depend upon it such a one would do it easier with less than an acre than he would with three acres of Roses. I have no doubt that the man with 1000 Roses ought to be able to show, at his best, as good a twenty-four as the man with double or treble the amount.

“An Exhibitor” asks “Is it fair for these two amateurs to compete in the same class?” “There ought to be a class, especially for large growers.” “Committees of local Rose exhibitions should ponder this,” &c. I almost feel inclined to ask him if he has even the schedule of a Rose show. I can only think of one show, Manchester, where there are not protected classes for amateurs; that is just what he desires, special classes for large growers. At the National Metropolitan Show there are no less than seven classes, each entirely protected against all the others, and almost every local show that I know of, however small, has followed the example. Why should the small grower contend against the larger when there are classes especially protected for him? I fail entirely to see that there is any grievance, and think either “An Exhibitor” must very much have misunderstood matters, or I have very much misunderstood him.—W. R. RAILLEM.

IN reply to the letter of “Exhibitor” in the last issue of the Journal upon amateur classes at local Rose shows, it would probably be conceded that if his facts could be accepted as accurate, he would have some ground for his complaint of being swamped by “gentlemen who grow and cultivate two or three acres of Roses.” But this complaint is no new thing; it crops up every few years, and is founded on the fallacy that exhibitors in the largest amateur classes grow several acres of Roses and keep an army of skilled assistants to cultivate them. There may be such growers. There may be such gardens; and truly they would form an Eldorado, a Promised Land of Roses, and it would be worth a journey of any distance to see them; but where do they exist except in the lively imagination of “Exhibitor?” Birkenhead and Darlington in the north, and Hereford, Bath, and Exeter in the west, know them not. In the south Steyning sends her Roses from twenty or thirty poles of ground, and beautiful though the gardens of Reigate may be, the two or three acres of Roses are wanting both there and at Sunningdale. Nor can diligent search discover them at Havering or Ipswich in the east, or at Berkhamstead, Bedford, or Hitchin towards the midlands. To descend from these ideal visions of many-acre Rose gardens to prosaic facts, “Exhibitor” will perhaps recollect that there were six competitors in the amateur trophy class at the July Show at the Crystal Palace of the National Rose Society, and it seems reasonable to presume that some of these two or three-acre growers will be found among them; but speaking from personal knowledge of the gardens of

three out of the six, and from what has appeared in the pages of this paper and in the "Rosarian's Year Book" as to the extent of the other three, "Exhibitor" may be assured that all the plants grown by these six amateurs would go comfortably into four acres of ground; and further, that in at least two of these gardens nothing beyond labourers' assistance is available.

Should he still doubt, my modest half acre (a liberal estimate) is freely open to his inspection, and I venture to make the same offer on behalf of the other five amateurs to whom I have referred. As to the remarks of "Exhibitor" on the qualifications of an amateur, the best definition is, I think, given by Ogilvie in the "Imperial Dictionary"—"a person attached to a particular pursuit without regard to gain." This appears to precisely define the true amateur, and so long as he conforms to the explicit rule of the National Rose Society against the sale of Rose plants or blooms it seems immaterial whether he grows half an acre or 20 acres of Roses. Most assuredly the more he increases his number the less will be his "regard to gain."—E. B. L.

### PARK HOUSE, KINGSCLERE.

KINGSCLERE has associations amounting almost to national fame in its extensive and magnificent stabling, but the impressions on my mind, animated by a brief visit to this establishment, do not relate to horses but to gardening features, which, though not extensive in their ranges, are none the less interesting and enjoyable. Park House is the well-appointed seat of I. Porter, Esq., situated at the foot of the chain of Hampshire hills, which, together with the extensive expanse of corn-growing land at this season, thickly studded with neatly built ricks, makes the surrounding picture enviable in the extreme. A walk of about a mile brings one to the summit of this high elevation, from which a panoramic scene is presented not easily forgotten, the fertile and well-timbered country extending for many miles coming within view in varying and innumerable tints and scenes, and from here alone can the visitor become cognisant of the large extent of the establishment under notice.

As previously noted, gardening is not extensive in its attempt, but is exceptionally neat and well kept in every particular—lawns, gardens, and houses. On the former are flourishing specimens of handsome evergreen as well as deciduous trees, comprising *Cedrus deodara*, *Wellingtonia gigantea*, *Cupressus Lawsoniana*, *Pinus Pinsapo*, *Thuopsis dolabrata*, a good specimen Hornbeam, and Drooping Ash perfectly trained are noteworthy among many others equally beautiful; the deep green and rich colour which characterise their growth prove that the soil and situation are well chosen for their requirements. The flower beds occupy a prominent position in the front of the house, and are planted with much taste, especially a large circular one set in the enlarged gravel space by the principal entrance. This has a bold groundwork of the silvery foliaged hardy *Antennaria tomentosa*, having varied shaped devices tastefully arranged thereon. The value of such an arrangement is twofold, for a free and bold groundwork displays the coloured designs to greater advantage, and is economical as concerning the demand for tender summer plants as well as others to form the winter display. A piece of newly acquired land has been laid out for tennis courts, surrounding which are well-made gravel paths and a broad belt of shrubs for providing the requisite shelter from the winds, which descend with terrific force. This was sown with Grass seeds, and is now perfection itself to the eye and in practical utility. A costly pitch-pine structure serves as a summer house overlooking the lawn, and is fitted with a deep glass front in its entire length, the extended gable roof defying any intrusion from the sun to mar its coolness or comfort.

The glass structures are of medium size, and very conveniently arranged. Two excellent houses of recent date are devoted mainly to the culture of Orchids in mixed variety, and to flowering plants. I noticed some uncommonly fine pieces of *Dendrobium thyrsiflorum* and *D. Walkerianum*, the latter having stout and tall growths; *Dendrobium Dalhousianum*, *Jamesianum*, *nobile*, *Wardianum*, *albo-sanguineum*, and *primulinum*, among others being similarly well grown. *Cypripedium* in variety, also *Calanthes* and *Odontoglossums* are well represented, particularly *O. Alexandrae*, of which there are numbers of vigorous plants. *Odontoglossum ornithorhyncum* was furnished with some unusually strong pendant spikes, which are much appreciated for the agreeable fragrance freely emitted. *Laelias autumnalis*, *anceps*, and *albida* showed promises of a rich display later on, and a healthy specimen *Cattleya Gaskelliana* was finely in bloom. *Vanda Amesiana* is a precocious bloomer, quite a small plant sending up a strong spike, and is much prized. One striking feature with all except recent purchases was the freedom in growth of the sphagnum moss used as a surfacing, this proving so good a grower that frequent resort has to be made to clipping, so as to keep it from encroaching on the legitimate occupants of the pots. Not a few who have witnessed this moss growth have envied Mr. Norris, the gardener, his chances of supply, because his source, though restricted, is available in the neighbourhood, and thus he has an undeniable advantage over growers dependant on the dealer, who often supply it unavoidably in a dried condition. A span-roofed structure is devoted to Grapes in mixed varieties, of which Black Hamburgh and Madresfield Court have furnished unusually good produce, and the same remarks apply to that frequently abused Grape Mrs. Pinee. Night soil has contributed largely to the excellent growth and finish of the Grapes, and an attack of red spider was never known. Tomatoes in boxes occupied the sunniest end of the house, and gave the best returns

secured in the neighbourhood, disease never venturing to put in an appearance since Mr. Norris has been in charge of the garden. Peaches, Melons, Cucumbers, and other fruits are of the best in their season, and good demands are made for decorative material for room furnishing both in pots and as cut flowers. About 200 Chrysanthemums are grown, mostly on the large bloom principle, and they promise to give a rich display later on. Several of the newer sorts are on trial, together with most of the best standard exhibition varieties.

In the vegetable garden good provision is made for a large supply of the best quality, and Peas throughout the season have been abnormally prolific, and will continue until interrupted by severe frost. One long border sheltered by a thick hedge is filled with Roses, all of the best possible kinds obtainable, each one being distinctly labelled with its proper name, a fact that lends considerable interest to the viewing or gathering of the blooms to owners and visitors alike. Espalier trained trees are found the most profitable, because better adapted to the position of the garden. Fruit would have but little chance of perfecting on tall trees against the force of the west winds, which sweep across and down over the hill, the force of which was demonstrated beyond dispute on some rows of Runner Beans, whose leaves presented a blackened aspect, almost as if cut down by frost on the windward side.

Everywhere one sees the influence of an unstinting hand, the houses and other buildings being kept in good repair by periodic attention to paint, capital well invested. Although professional duties employ a great deal of time, Mr. Porter avails himself of all spare moments to visit his garden, which to him proves a pleasant recreation, and certainly great credit is due to him in the perfect condition of his estate and kindly thought for the welfare of his employes, none of whom appreciate more fully such sentiments than his gardener, Mr. R. C. Norris, who is prompted with the best of motives in furtherance of the commands of his esteemed employer accordingly.—VISITOR.

### THE HOLLYHOCK.

MR. DEAN, in his interesting notes on Hollyhocks at page 287, reminded me of a promise I made in these pages during the early part of this year—viz., to report my experience with an insecticide kindly sent for trial by Mr. Alfred Bishop. I may say it is an excellent preventive when applied double the strength recommended. It will keep the plants clean without in any way injuring their growth, which is not the case with some other insecticides I have been experimenting with it, but the application must be applied regularly and with great care. Syringing in damp weather or in the evening often causes the plants to damp in early spring, especially when not rooted; but well rooted plants seem to enjoy their bath. These were dipped carefully overhead in the preparation twice a week, the under parts of the leaves being thoroughly "caught" in this way. Plants thus treated, and with an occasional syringe during the season, have not been affected with the fungus. Thus from personal experience I can testify that if plants could be regularly treated with the preparation during the whole season we should hear very little of *Puccinia malvacearum*. The "Bordeaux mixture" is another excellent preventive; but instead of using it in the usual way, I have found it more effective when dissolving 1 oz. of softsoap in a gallon of soft water, dipping the plants in this, then dusting them with sulphate of copper bruised very fine. Sulphur used in the same way is perhaps more simple, and has the same effect; the leaves gradually wither and die, while clean healthy growths take their place. But can Hollyhocks not be grown without all this trouble? Yes. There are several growers who have no disease among their plants; but these are only reaping the reward of a hard-fought battle, and from them we hope to be favoured with a few notes through the Journal.

Although the fungus does not appear to attack the Hollyhock so virulently as it did when first introduced (it seems to have spent its energy, so to speak), it is, nevertheless, a great pest, and from my own experience I conclude that as long as Hollyhocks are grown *Puccinia malvacearum* will find its host. If the Hollyhock were the only plant affected by the fungus there might be some hope; but when we see so much of it on the Mallow family in a wild state there is, I fear, little hope of a perfect cure. Our plants might be quite clean this year, and next year we may carry it to our garden by visiting a friend's collection; or when passing the wild Mallow it might be carried on our clothes, or in some way that we cannot account for. I do not mention this to frighten beginners; on the contrary, to prepare them to use the greatest care; for although we may never be thoroughly free from this disease, yet we find Hollyhocks grown in many gardens now comparatively clean, and it is pleasing to relate that many amateurs are again growing their collections of Hollyhocks with marked success. For those who are about to commence their culture now is the time to prepare. Have the ground well trenched, well manured, and well dressed with soot and lime; then getting thoroughly pulverised with the frost it will be found in excellent condition for planting in spring. April is, perhaps, the best time

to plant, choosing a fine dry day when the ground is in condition. Clean healthy plants should, of course, only be planted. An excellent plan to secure young growth for propagation is to follow the course recommended by Mr. George Finlay some two or three years ago in the *Journal*—viz., to bury the old stools in clean soil in the autumn, when in spring the growths will be found coming through the soil as clean as *Seakale*. With cuttings or grafts such as these there is little fear of success. My esteemed friend, Mr. Oliver of Eslington Park, with whom this idea was, I believe, first introduced, sent me samples thus treated last year. These plants had no special treatment whatever; they were merely potted and kept in a clean frame by themselves until planted out at the usual time. Not a spot of fungus has been seen on these plants during the season.

Cleanliness is another important consideration. At this time of the year, when plants are being cut down, every leaf and stem ought to be carefully collected and burned. Whether fungus has been prevalent or not the greatest care ought to be exercised. We cannot always see where the germs are lurking about. Frames, too, where plants have been propagated and wintered, ought to be thoroughly washed and painted immediately the plants are cleared out. I generally add a little paraffin oil in mixing the paint. It is in frames and such places that fungi are often hidden for a time, and makes its appearance when least expected.

In a letter to hand this morning, when writing these notes, Mr. Mein, of the firm of Messrs. Stuart & Mein, Kelso, informs me that they have been very successful with Condry's fluid as a preventive of the Hollyhock fungus. I have not, however, tried this remedy myself, but as I understand this firm has been trying various experiments during the season, let us hope Mr. Mein will let us have the benefit of his experience through the *Journal*. I believe, also, one of their people gave a lecture on the Hollyhock recently. As I have not seen any report of it in any gardening papers, I hope this hint will be sufficient, and during the winter months others will, perhaps, take up the question. I may here state that I am preparing a list of the best exhibition Hollyhocks in cultivation at the present time, and I hope growers will, as soon as convenient, send me their lists of what they consider good exhibition sorts, taking them in their order of merit, with description of colour and raiser's name where possible. Now that the Hollyhock is receiving so much attention, it is really necessary to have a revised list of the best sorts true to name. It is very perplexing, after paying such long prices for plants, to find after growing them one variety under different names. Many of the sorts, too, are not admissible. I grow, perhaps, one of the largest collection in existence at the present time. Out of these not more than fifty varieties are admissible for exhibition. I do not, however, condemn many of the others, for as decorative plants they ought, perhaps, to find a place when true to name; but at present we shall only deal with exhibition sorts.

Will those growers to whom I have not written, and whose address I am not acquainted with, please accept this notice, and send their lists to the address as under?—GEORGE STEEL, *Heathers-law, Cornhill-on Tweed*.

#### QUEEN WASPS.

THESE troublesome fruit pests have been more than usually abundant in some localities this year, while in others but little inconvenience has been caused by them. The possible nests of next year can to a very large degree be reduced in numbers by thoroughly destroying the queens at this season, when they are searching for cosy corners wherein to pass the winter. Last year a correspondent writing on this subject advised readers having the opportunity to search among stacks of timber, which were found to be favourite winter resorts. It is an easy matter to catch and kill them now, as they will, if they have already found a place to their liking, be most likely in a stupid or sleepy condition, but quarters suitable to them may not be found in every garden. Last autumn I secured and destroyed about three dozen, and within the past month I have already killed twice that number, and still they come. In my case I have not far to seek, for the necessary daily visit to the fruit room at once reveals their whereabouts. This building was not erected for but adapted as a fruit store, and, unlike fruit rooms generally, has an unsealed stone roof, which evidently proves an attraction for these unwelcome creatures. Once admission is effected they are attracted by the window. Some conceal themselves between the frame and wall where slight spaces occur, others less concerned sleep quietly in dark corners, or suspend themselves to the rustic curtain employed for excluding light and frost.

The fact of so many queens being destroyed thus may account in some degree for our freedom from these pests among garden fruits in summer, for although no means are taken in excluding them from the vineries, not a single wasp has attempted to partake of this favourite dessert. Plums and Pears are the only outdoor fruits that have received any attention from them, and not to anything like a serious extent even among these, and it is more than probable that other gardens in

the district are affected by a similar freedom. Gardeners having any open sheds or similar buildings to that here mentioned would do well to make an occasional search now, this being a more economical mode of exterminating wasps than anything applied in summer for their prevention or destruction.—W. STRUGNELL.

#### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 14TH.

SCIENTIFIC COMMITTEE.—Present: Mr. W. T. Thiselton Dyer in the chair, Mr. McLachlan, Mr. Morris, Dr. Oliver, Mr. Veitch, Dr. Scott, Dr. Müller, and the Rev. G. Henslow (Hon. Sec).

*Plantain Fruit*.—Mr. Morris exhibited two large fruits of *Musa sapientum* var. *paradisica*, or the common Plantain, grown at Sion House. It is generally used before it is quite ripe as a vegetable in the tropics. It practically takes the place of the Potato, and is a very valuable food, especially in tropical America.

*Merulius lachrymans* (?).—Dr. Oliver exhibited an interesting specimen of the mycelium of some fungus which had grown between two sheets of canvas. It had spread in a radiating manner, covering a space of about 8 inches square.

*Antirrhinum majus, Monstrous*.—Mr. Henslow showed a flower of the yellow Snapdragon, with narrow ribbon-like yellow and white outgrowths from the calyx. Such enations are not uncommon from the outer surface of corollas, as in the fringed Cyclamen, Polyanthus, Gloxinia, &c.; but in the present instance they were detached from the inner surface of the calyx—i.e., by tangential chorisis.

*The Fog Report*.—Dr. Oliver read a report as to the scheme proposed at the preliminary meeting. A discussion followed as to the methods to be adopted, and it was suggested (1) that the Meteorological Society should be asked to lend a pump already used for the purpose of collecting fog; (2) to consult with Dr. Russell as to the construction of an absorbent apparatus; and (3) that a duplicate chamber with filters should be prepared for use at Kew. It is also proposed to re-issue circulars with an additional request as to the opacity of the fogs experienced.

#### VIOLAS.

SOME weeks ago I received from Messrs. Dobbie & Co., Rothesay, a box of Viola blooms, and amongst them were several which some of your readers will probably be glad to know something about, so I give a short description of each. Mrs. H. Bellamy is a rich violet purple with lilac-clouded top petals, and of fine form. Evelyn is an improved Duchess of Albany, brighter in colour and of fine form. Ariel has pale blue lilac top petals, the side and lower petals are white clouded with blue, a distinct variety. Glow is of a rosy-lilac ground colour, striped and marked with deep maroon, and distinct. Ada Adair, of a pinkish lilac colour with dark blotch, good. Queen of Scots, marked like the Countess of Kintore, but brighter in colour, and a beautiful variety. Rosebud, a pretty variety, closely resembling Ethel Baxter in colour and marking, the latter especially, a beautiful and distinct variety. Ardwell Gem, pale primrose, and a very free blooming and effective bedder. Delicata, white flushed with lilac, with darker markings. Joy, blush white tinted with lavender, with a purple belting on top petals. Acme, very much like Cliveden Purple, and no improvement on that variety. Topsy, rich dark violet purple. Ebor, rosy purple, of good form. Champion, a well-known old white variety. Lady Macdonald, white with dark markings in the centre of the flower. Bullion, deep yellow, a first-class variety. Daldowie Yellow, same shade of colour as Bullion. Lucy Ashton, bearing a close resemblance to Columbine, an old variety; white, with a broad margin of bright rosy lilac, very pretty. Royalty, yellow, with large dark markings. Sovereign, gold, with large dark markings. Lord Elcho, golden yellow, with dark markings. The Bride, white, with blue markings. Rosetta, an improved Mrs. Baxter, rich violet purple, with lighter coloured top petals. Mina Baxter, similar in colour and marking to The Mearns; the latter variety one of our best and most beautiful varieties, rosy purple, with lighter top petals. Crimson King, rosy purple colour, and of good form. Magpie, an old, well-known variety. Neptune, rich purple, with lighter top petals, style of Lady Amory, and not so fine a variety. Souvenir, pale blue, and worthless compared with others.

Many of these varieties I have grown, and it is scarcely possible to say too much in favour of these lovely hardy decorative plants, so rapidly rising in favour. As spring and summer decorative plants they stand boldly out amongst all others, and we now possess such excellent kinds in the Countess of Hopetoun, white without any markings whatever, and of dwarf sturly habit; True Blue, by far the best blue Viola known; Ardwell Gem, primrose yellow; Bessie Clarke, pale mauve; Bullion, deep yellow; Countess of Kintore, greyish purple, with large white blotch in each petal, everybody's favourite; Duchess of Albany, beautiful shaded mauve and lilac; Lady Amory and The Mearns, already alluded to, two very beautiful varieties; Marchioness of Tweedale, pure white; Sir Joseph Terry, very dwarf, rich black purple; Skylark, also Blue Cloud, both white, with a margin of azure blue; and Mrs. Gray, white, often flushed with lilac, a very fine blooming and fragrant variety for large masses. These are a few leading varieties, but there are many others of considerable beauty. I have not mentioned my collection, which comprises over sixty of the best selected varieties in cultivation, and amongst them are some very beautiful new varieties,

now being sent out from here for the first time, which will make their mark.

Either by themselves, or mixed with variegated-leaved Pelargoniums, or other plants, taking care to have pleasing contrasts of colour, Violas can be used to any extent; and they begin flowering in April and last until September and later.—W. DEAN, *Sparkhill, Birmingham.*

### GOLD AND SILVER FERNS.

AMONG the numerous handsome Ferns which now have a place in our houses, few are more generally admired than the Gold and Silver Ferns, as the species and varieties of *Gymnogramma* are appropriately designated. Having elegantly divided fronds, usually dark green on the upper surface, and plentifully sprinkled with a yellow or whitish powder beneath, being easily and quickly grown and readily propagated by means of spores, the plants possess ample merits to entitle them to popularity. It is therefore scarcely necessary to say much in their favour by way of inducing more extensive cultivation, for there are few lovers of Ferns who do not include in the smallest collections some specimens of these attractive plants. However, as there may be some who are unaware how easy it is to obtain such Ferns in good condition, a few remarks upon the treatment that I have found to suit them will possibly be of some utility.

*Gymnogrammas* are chiefly natives of tropical regions, the forms in cultivation being from the West Indian Islands and South America. One of their most important requirements is therefore a stove temperature, or such as is provided for tropical Ferns where a separate structure is devoted to them. During winter this should not be allowed to fall below 50° Fahrenheit, a range of 10° upwards being permitted; but too high a temperature at that time of year is inadvisable, as it tends to cause a weakened immature growth. In the summer the maximum should be about 80°. They need more exposure to light than many Ferns, the sunny side of a fernery or a slightly shaded position in an ordinary stove suiting them admirably. Abundance of water is required whilst they are growing and during hot weather, but as they are most impatient of any approach to stagnation the composition of the soil and the drainage must be carefully attended to. A compost of fibrous peat, light loam, abundance of sand with some small pieces of charcoal well incorporated, constitute a good soil, encouraging vigorous and healthy growth. The drainage should be regulated according to the size of the pot, placing the large potsherds at the bottom of the pot concave side downwards, filling up to the necessary height with small pieces and covering with a layer of moss. Upon this some of the compost described above can be placed and the plant potted rather firmly, allowing a moderate space from the rim of the pot to the soil to facilitate the supply of water. In some of the varieties the fronds are long and heavy with rather weak stems, necessitating the employment of a few light thin stakes, to which the fronds must be secured, or they are liable to be broken. Another point that needs attention is to avoid wetting the fronds, as the delicate silver and gold farina is quickly washed off and the chief beauty of the plants destroyed. This is one inconvenience that attends the introduction of *Gymnogrammas* into a plant stove, as unless they can be allotted a position where they will not suffer from the frequent syringing required for the other plants their appearance is never very satisfactory.

Gold and Silver Ferns are most readily increased by spores, as these germinate in a few weeks; in fact, they are some of the quickest to germinate of the whole family of Ferns. The best mode of effecting this increase is to remove the fertile fronds from the plant before the spores are fully mature, placing them in a dry warm house until they are ripe. Shallow pots or pans should be prepared by thorough drainage, upon which there should be placed a layer of sphagnum, filling up with very finely sifted loam and sand; and if the former has been baked it is better, though so much care is not needed with these as with more delicate or longer-germinating Ferns. It is one of the peculiarities of the genus that the young plants produced in this way are extremely variable both in the form of the fronds and the colour of the meal or farina, and it is owing to this circumstance that many forms, varieties, and probable hybrids have been obtained.

The following will be found a good selection:—*Gold*: *G. chryso-phylla*, *G. Lauchiana*, *G. L'Herminieri*, *G. Martensii*, *G. decomposita*, and *G. sulphurea*. *Silver*: *G. Calomelanos*, *G. tartarea*, *G. peruviana* and var. *argyrophylla*, *G. pulchella*, and *G. Pearcei*.—C.

### BERBERISES.

BERBERISES yield to no other shrubs in beauty, whether we regard the foliage, habit, or flowering properties. The foliage is peculiar in shape, of a bright glossy green; the habit is compact, and the flowers produced in profusion, of a beautiful yellow colour, and are followed by berries which make the plants handsome for a long period.

The common Berberry (*Berberis vulgaris*), is a native of this country, and is found in hedgerows and on wooded hills, where its fruit has refreshed many a rustic's palate. The flowers are produced in yellow racemes in April and May, are offensive to the smell if closely approached, but at a short distance their fragrance is very grateful. There is something very singular about fertilisation in a Berberry flower. The stamens are bent back to each

petal, the concave tips of the petals sheltering the anthers. Watch a bee come and plant its proboscis into the flower, sipping the nectar from the bottom of the cup where the filaments join the ovary; and immediately any filament is touched near the ovary, the stamen springs from the petal and shakes the pollen on the stigma. A pin or hair similarly brought into contact with the lower part of the filaments next the ovary produces the same result, but no shaking of the branch, nor any pinching or touching of any part of the flowers exteriorly, has any effect on this irritable flower. The fruit, about the size of a pea, succeeds the flowers, and when ripe makes an excellent preserve if one quart of fruit be boiled along with 1 lb. of loaf sugar. In its raw state the fruit is cooling and agreeably acid, and its juice is used for flavouring sweets, and in a dry state for making sugar plums. The bark of the tree is used even now as a cure for jaundice and affections of the liver.

*Berberis vulgaris*, and its several varieties—viz., *violacea*, *alba*, *nigra*, *lutea*, and *purpurea*, all named after the colour of their fruit, thrive in almost all soils and situations; but deep rich sandy loam suits them best, and an open sunny site or aspect is necessary to secure fruit. In woods, however, where the shrubs receive a moderate amount of light without much sun, I have seen them plentifully producing fruit, which seems to be well relished by some of the feathered tribe. As we begrudge a few Cherries and Strawberries for the songsters' invaluable nine-months picking of grubs out of our gardens, is it asking too much to request that a few Berberry shrubs be planted in the woods? They are an excellent cover for game. Nevertheless, their fruit grown in shade is never so highly flavoured as when exposed to sun heat, light, and air; therefore I by no means recommend planting Berberries in woods in hopes of obtaining their berries to increase the novelty of the dessert, and fill the preserve-jars in the store-room. Still the fragrance of the flowers imparts a charm to the woodlands in spring, and may help to keep the songsters from the netted Cherries.

As a hedge plant the Berberry has a few points to recommend it. It will bear any amount of cutting, grows rapidly and close, and is rather rough to face, its short prickles or spines not being pleasant. It is not so good, however, as a Quickset (Thorn) hedge, and at the very best is but a second-rate hedge plant. Irrespective of its claims as a hedge plant, in which respect it ranks with the Privet, it will be admitted on all hands that the Berberry is a highly ornamental shrub, whether planted in large shrubberies or by the side of woodland walks. Besides its peculiarly ornamental character it is of easy culture, requiring but little care after first planting.

Berberies may be best treated of in two classes—the deciduous and the evergreen.

DECIDUOUS SPECIES.—Of these *Berberis vulgaris* is the type. They are suitable for woods, where they form, as mentioned before, a capital cover for game, and for large shrubbery borders; but they are not suitable for planting in groups on lawns, for there plants should be as ornamental in winter, for the most part, as in summer, and this the deciduous character of the Berberries in a great measure prevents.

In planting them in shrubberies, it is necessary that the ground should be trenched deeply without turning up too much of a clay subsoil; and if that be wet, drains should be cut 4 feet deep and 21 feet apart, with a suitable fall and outlet. If the ground be poor, a liberal dressing of manure or leaf mould will contribute much to the prosperity of the shrubs; and a barrowful of fine, but not very rich, soil put a little under, around, and on the roots at the time of planting will materially assist the plants to form fibres and roots, and give them a start.

Half the height which any shrub attains is the proper distance to plant from a walk, and its full height the distance from plant to plant in the shrubbery. Most shrubberies, however, are faced with some of the undershrubs, or lower-growing kinds; consequently the taller kinds may be planted at a greater distance from the walk, so as to allow of those of low growth being planted in front of the border, so that, even when of full size, they will not need cutting back or clipping to prevent their encroaching on the path or space beyond their limits. Every tree or shrub should be planted at such a distance that it will never be made by crowding to assume an appearance contrary to its natural habits.

Were I forming a shrubbery I would have no duplicates in it, for no beauty can be pleasing unless it be varied. Shrubberies of the present time have no beauty beyond that seen at first sight, for such are mostly composed of the commonest shrubs purchasable, and have nothing to recommend them beyond cheapness, which is not commensurate with the interest lost. Were no duplicates admitted the shrubbery would afford an interesting field for study at all seasons, and take hours instead of minutes to inspect before all its beauties could be noticed.

I would distribute shrubs in mixed shrubberies, so as to present a good face to the eye; but, at the same time, with a variable yet harmonious aspect. But were the place large I would plant each natural order in groups, after the style of an arboretum; and with a view to this I would place the Berberidæ in the foremost rank. A group of Berberies on a lawn would be a beautiful object in May when our flower gardens are little better than fallow fields, and highly ornamental in autumn from the effect produced by their berries. Disposed of in that way, I should plant the deciduous kinds in the centre of the group and the evergreens chiefly around them, always taking into consideration the height of each species and their character of growth. I should not plant a straggling grower in front, but put it behind a compact grower.

In planting, however, ideas vary. Some would object to planting deciduous shrubs and evergreens together in groups, and it certainly detracts much from the beauties of evergreens when they adjoin deciduous trees, especially when seen on the same level with them. Therefore I would only employ evergreen Berberies for groups on lawns, unless I were forming an arboretum, when I might plant the deciduous and evergreen together.

*Propagation.*—Seeds of the common varieties, deciduous and evergreen, may be sown in sandy loam in the open ground on nursery beds in March or April, covering them with fine soil about half an inch deep; but seeds of the evergreen species, as *Berberis Fortunei*, *nepalensis*, should be protected in a cold frame until the seedlings are fairly up, and when of sufficient size to handle transplanted into nursery beds, and afterwards further transplanted annually or biennially, allowing more room each time between the plants, until they are of sufficient size to plant out finally. Seedlings are such a long time before they flower compared with plants raised from layers, division of the root or suckers, that it is not a very advisable method of propagation.—G.

(To be continued.)

### THE NORTH AMERICAN FORESTS.

THE visitor from Europe is particularly surprised at the extraordinarily long and numerous wooden structures which the railway train sets to vibrating in crossing the watercourses. In America the streams retain a freedom of movement of which they make full use; one year here, another there. From high mountains the bed of a stream looks like a broad white band of water and gravel banks, with green, wooded islands between.

Streams are a good indication of the state of cultivation of the surrounding country. Those which from year to year discharge their clear water into the sea, and through the year scarcely vary in their water-level, come from an undisturbed woodland. Their banks are held fast by the roots of the trees in the region of the headwaters, and in the mountains the water gathers slowly from the woods. Such streams one sees now for the most part in uninhabited regions only; in the island of Hokaido, in northern Japan, for example, I have found such.

Streams which during the rainy season or during the season of melting snow flow turbid, and during the rest of the time clear, showing in ordinary weather small variations in their water-level, rise in woodlands, and flow through arable land, part of the soil of whose roads and fields the rains wash into the streams. Of this kind are the streams of Germany and France.

Finally, streams which year by year flow with turbid water, or which, at least, through the rainy season rush through the cultivated plains to the sea with swollen floods, here carrying away soil, there heaping up gravel banks, come from an up-country in which the forest is almost entirely wanting, or the deforesting is under full headway. Such streams one sees, for example, in Ceylon, where the English, with plantations of Tea, of Coffee and of Cinchona, have begun the destruction of the forests and the woodlands of the mountains. Such streams are numerous in Japan, Spain, and northern Italy. There the streams are feared whenever it rains a few days longer than usual. The American streams approach this stage. In their unrestrained impetuosity they vie with each other in bringing ruin upon their bottom lands, which, as a rule, contain the best soil. That a change must have taken place in a river is clear when during the rainy season it undermines its banks covered with trees that have stood for centuries, and finally sweeps them away in its floods. Instances of this are numerous in America, and speak plainly to everyone who can and will see, more plainly than all the books upon the influence of the deforesting of the mountains and the plains upon the water-level of streams. The deforesting of the Adirondacks through fire and in useless attempts to take the mountains for agriculture, causes a perceptible change in the water-level of the Hudson, which during the dryness of the season is fed with the moisture of the earth in the Adirondacks. Formerly Peeksgill was a water station of the New York Central and Hudson River Railroad. This station had to be abandoned because during the dry season the salt water forces itself as high up the stream as Tivoli, and salt water is unsuitable for feeding locomotives.

Although the American engineer is familiar with the increasing variation in the level of the streams, one sees but few efforts to regulate their flow, which, indeed, would involve a mere waste of money, as

long as the average level of high water is yearly becoming higher. Moreover, many look upon the deforesting of the mountains with indifference, because they believe that the forest, with its beneficent influence, can be replaced upon a magnificent plan. Their idea is to fill enormous reservoirs with water during the rainy season, and then to permit the contents to flow throughout the cultivated lands. But for the filling of such reservoirs a considerable surface of soil which may collect the rain is necessary. It is to be hoped that the rain will be so gracious as always to fall with due regard for human safety, for the breaking of the reservoirs might have worse consequences than a cloud burst. To me it seems much safer that the great amount of money which permanent water works would require should be utilised in buying up the mountain lands and preserving their forests. This would be good policy even without taking into account the fact that these national reservoirs bring in money, while the artificial ones only swallow it up.

In spite of the outrageous management of the forest everywhere in the United States, I am inclined to believe that, partly of itself, partly with some little help, it will return to its beneficent condition, if in the future it should be possible to preserve it from fire. Danger from fire in the forests in the civilised parts of Europe has become a rare thing; at the least fire everyone hastens to put it out, and the Government has power to compel all to help.

In India the number of forest fires is lessened yearly, thanks to the energetic measures of the Government and the watchfulness of an efficient body of foresters, while young growth springs up on the protected plains.

In Japan, a smaller country, fire and axe have already nearly completed the work of destruction. The brave nation is labouring with the utmost zeal and with great outlay of money for the restoration of the forest on the shrub-covered mountain slopes, and for the preservation of what still remains.

In North America the practice of burning forests has become customary, even in cases in which it is entirely without reason. How can anything else be expected from the descendants of a nation that has no forest, and therefore knows nothing of the blessings of a forest? Closer study of the causes of the burning of the forests forms an instructive, if not an edifying chapter. We see what man can bring to pass in a country of such highly vaunted elbow room, in a country where the most complete individual liberty seems to be the chief principle, in a country whose laws for forest-protection are empty threats, because the ignorant and unprincipled cannot be compelled to obey them.

According to the report of Professor Sargent, 1,000,000 acres of forest were burned in a single year (1879-80), and with it 20,000,000 dollars' worth of property was destroyed. The causes of these fires have been ascertained as follows:—197 fires resulted from burning over pasture lands; in 1152 cases fires started in making forest clearings; 508 started from locomotive sparks; 628 from hunters' fires; 72 from camp fires; 35 from pipes and cigars; 12 from prairie fires; 9 from charcoal burning; 32 from lightning; 56 were kindled by Indians; 10 by lumbermen; 2 by tourists; 262 were kindled maliciously; in 2 cases fire is said to have been started by spontaneous combustion; 3 times woodcutters and 3 times unknown carelessness set the fire. This makes a total of 2983 cases.

Let us examine further the fires started maliciously and those caused by locomotives, hunters, and campers out, 1470 in all. The injury that the railway does to the forest interests is very serious. One who travels to-day in North America must grow accustomed to the charcoal heaps on both sides of the railway, if he would have any pleasure from the beauty of the landscape. From the railway the fire has encroached for countless miles upon the forest. Upon the oldest railways the danger of fire is reduced yearly by constant burning of the trees from the clearing on both sides of the road bed. Upon such clearings it would be an easy thing to cut off the fire from the forest with a safety ditch. It appears to me that there is no other expedient than to make a cleared belt along the tracks as soon as possible. At all events, this does more good than the spark arresters which the law prescribes, since, in spite of laws, the locomotives run without them.

A characteristic result of the boundless freedom of the individual at the cost of the people is presented in those cases in which hunters and tourists camping or travelling in the forest cause the fires. In the year 1880 they kindled 700. As far as my experience in western America extends, the sportsmen are careful to burn the under brush, which in the primeval forest contains generations of future forest trees, in order that they may be less hindered in their aim. In other regions the woods are fired in order that the game throughout particular districts may be driven together. Comment on this is quite unnecessary. Forest thieves, too, start fires, especially in the Government forests, in order to obliterate the traces of their theft.

With reference to the Yellowstone Park, the possession and the pride of the whole nation, H. Winsor says in his "Guide for Tourists:"—

"It is to be deeply deplored that because of the carelessness of campers out, many of them cultivated people, vast stretches of forest have been destroyed by fire. The fires have resulted from neglect of the simplest precautions as to camp fires. In consequence of this it is not at all unusual to be obliged to ride in the park for miles and miles between black tree stumps instead of in the refreshing shade of the green forest. This thoughtless destruction of the forest should be checked by severe punishment of the offenders."

It should be provided by law that anyone who causes a fire shall be held for the injury done, and the amount of damages should be equal to the value of the woodland destroyed. But the injury done to the

forests by overthrowing confidence in the security of forest property, by discouraging the investment of money in forest, by the destruction of the young growth, and by the effect upon the fertility of the soil, would still remain without mitigation.—(From "The Forests of North America," by Dr. Heinrich Mayr.)

### FRUIT FORCING.

**VINES.—Early Houses.**—Where late Grapes are not cultivated in quantity to maintain a supply to May, preparations must be made for early forcing. The Vines being pruned in September, the loose bark stripped off, the house may be cleansed, the border top-dressed, and the Vines dressed with a solution of softsoap, half a pound to a gallon of water, brought to the consistency of cream with flowers of sulphur, adding, if there be any scale, a wineglassful of spirits of turpentine, the composition being equally effective against mealy bug, killing all it touches. The whole being in readiness as advised in former calendars, cover the outside border with leaves and stable litter, so as to warm the border preparatory to employing fire heat. If there be the convenience for making up a good bed inside the house of Oak or Beech leaves, with about a third of stable litter, it will greatly facilitate the Vines breaking, and be more beneficial to them than fire heat alone. Therefore have them in readiness for placing in the house at the early part of next month.

**Early Forced Vines in Pots.**—These are much better than permanently planted Vines for very early forcing, say to afford ripe fruit late in March or early in April, selecting early varieties such as Buckland Sweetwater, Foster's Seedling, and White Frontignan in white Grapes, and of black, Black Hamburgs, Mill Hill Hamburg, Royal Ascot, and Madresfield Court. They should now be in position preparatory to starting early in next month.

**Renovating Vine Borders.**—Vines thrive for an almost indefinite period in a soil suited to their requirements, and where they have a good extent of rooting area, as may be seen in many places where the Vines were originally planted to cover a large area. Vines mostly have their roots confined to limited areas, and the natural outcome is that the soil becomes less favourable as a rooting medium if not defective in aliment, hence the desirability of renewing the soil, or such portion of it as will secure as many active feeders as possible. There is nothing perhaps equal to fresh soil as an encourager of Vine roots.

Where Vines are unsatisfactory, no time should be lost as soon as the leaves have effected their functions to the extent of perfecting the buds and wood, and whilst they are still upon the Vines, in removing the soil down to the roots and picking it from amongst them, so as to displace as much of it as possible with fresh. In case the border is very unsatisfactory, and the roots few and deep, it will be necessary to remove all the soil and renew the whole border, commencing with the drainage, which should be clear 9 inches to 1 foot thick, having a layer of fine material at the top, nothing answering better than old mortar rubbish 3 inches thick over 9 inches of drainage. The drainage must have a tile drain to carry off superfluous water. Two feet depth of soil is ample, and the roots should be laid out evenly in the top foot, encouraging those from the collar by laying any that proceed therefrom only just beneath the surface. The whole should be made firm, and the compost moderately dry. If the roots are inside and outside, one part may be done one year, and the other the next without any danger of loss of crop, care being taken to preserve the roots, and to keep them from the drying influences of the atmosphere, whilst the growth is in progress. Mulch the surface with a little short manure, preferably fresh horse droppings, and cover outside borders with a good thickness of leaves or other protective material. As regards soil, good turfy loam is best, but any ameliorated soil will grow good Grapes. Preference should be given to medium textured loam, that overlying clay being better than that overlying sand. The most suitable is a rather strong loam overlying the limestone formation, and interspersed with flints.

### THE FLOWER GARDEN.

**State of the Flower Beds.**—It is not often the beds present so gay an appearance during September and the early part of October as they have done this season. Only in very low positions have early frosts crippled the most tender plants, and the bright state of many of the beds, though very satisfactory in some respects, will greatly hinder the work of refilling for the winter. Advantage ought to be taken of a dry time for breaking up any of the beds not in an attractive state, refilling these with hardy flowering plants, shrubs, and bulbs, before rain falls on the newly disturbed soil and thereby quickly render it too sodden to work on. In some instances it may be advisable to dig the beds prior to refilling; poorer soils where possible being enriched by well decayed manure, but those of a heavy retentive nature frequently work more

freely and remain in a drier warmer state when not dug, the surface being merely cleared of rubbish, and the planting at once proceeded with.

**Spring Flowering Plants.**—The best display is made by plants established long before this in their flowering quarters; but if Wall-flowers, Forget-me-nots, Daisies, Polyanthus, Primroses, Violas, Saxifrages, Aubrietias, and Arabises, and such annuals as Collinsia bicolor, Limnanthes Douglassi, Gypsophila elegans, Nemophila insignis, Silenes, Saponaria calabrica, and Virginian Stocks have been well prepared, they transplant readily. This season they are exceptionally strong and healthy, and the sooner they are in the winter quarters the greater the likelihood of their doing well. In many districts the ground is in a comparatively dry state, and nothing therefore should be moved till the soil about the roots has been well moistened, one or two good waterings being given overnight. All ought to be lifted with a good ball of soil about the roots and carried in flat baskets or on hand-barrows to where they are required. Thin planting and mixtures are not recommended, masses of one or two colours arranged according to the known height of the respective kinds being most effective. Very few, if any, of the plants will increase in size before flowering time, and many will lose their outer leaves, consequently becoming smaller than when first put out. If therefore there are not enough to fill all the beds thickly do a limited number well, and cover the remainder with shrubs rooted, or branches and sprays only, with flowering bulbs among them. It is of the greatest importance that all the plants be firmly refixed, this causing them to become quickly re-established; frosts also being liable to upheave them considerably.

**Spring-flowering Bulbs.**—Old bulbs cannot be depended upon to flower freely, much the best effect being produced with the aid of a newly purchased stock. Luckily Hyacinths, Narcissi, Tulips, Crocuses, Scillas, and Snowdrops suitable for bedding out can all be bought at a comparatively cheap rate, and these should be put out in the beds, the choicer kinds and varieties being planted in herbaceous and other borders, where, if not often disturbed, some of them, notably Daffodils and Narcissi, will continue to increase and improve every season. Nor ought the bedding bulbs to be put out very thinly, or they will present a meagre appearance; and central masses of either Hyacinths, Narcissi, or Tulips, with broad bands of dwarf kinds, are much preferable to mixtures. Plant Hyacinths and Narcissi about 9 inches apart each way and 4 inches deep, Tulips going in the same depth, and not more than 6 inches apart. Triple lines or bands of Crocuses, Snowdrops, and Scillas are recommended, the bulbs being placed out from 3 inches to 4 inches apart each way, and 3 inches deep. Beds largely or wholly filled with bulbs might well have a temporary covering of sprays of such evergreens as Hollies, Box, Ivies, Aucuba, Portugal Laurel, common Laurel, and short pieces of Conifers, these being grouped and stuck in thickly, so as to resemble small plants. They will long retain their freshness.

**Shrubs and Conifers in Beds.**—The outlay in the first instance would be considerable, but there is no mistaking the value of various shrubs and Conifers for furnishing beds, borders, large vases, and window boxes during the winter. They can be had of any size, ranging from 6 inches to 6 feet in height; they move readily (beingspecially prepared for the purpose), and a beautiful and lasting effect is created in a few hours. Many of the Golden and Silver forms are quite bright enough for the summer arrangements, while all can be moved in May to the home nursery, and brought back to the beds in the autumn. Neat little specimens look well in a carpeting of dwarf flowering or coloured-foliaged plants, and mixtures also are effective. Quite small plants, however, ought to be in masses of one kind, or panels may be formed of different colours, with dividing lines of other species.

**Selections of Conifers and Shrubs.**—A visit to a good nursery would disclose the fact that there are numbers of plants admirably suited to the purpose of filling flower beds, foremost among these being such handsome Conifers as Cupressus Lawsoniana erecta viridis, lutea and nana glauca; Cupressus nutkaensis; Cryptomeria elegans; Juniperus tamariscifolia, Retinosporas ericoides, obtusa aurea, nana, plumosa argentea, squarrosa and plumosa aurea; Taxus baccata elegantissima, and Thuiopsis dolabrata. Quite dwarf plants can be had of any of these. Some of the most useful evergreens are variegated Hollies in variety; gold and silver variegated Box; gold and silver variegated Tree Ivy; Euonymus radicans variegata; Aucubas, Mahonia aquifolia, and the Myrtle-leaved Portugal Laurel. With these may be associated such flowering shrubs as Andromeda floribunda, Ligustrum japonicum, Rhododendrons daphnoides, myrtifolium ovatum and Wilsoni, herbaceous Ericas, and Kalmia latifolia. Berried plants of Skimmia japonica, the beautiful Pernettyas and Cotoneaster microphylla are also effective. Nor must the graceful Yucca recurva be omitted, and much also might be done with a few clumps of Iris foetidissima variegata, and which divide readily. Old plants of Golden Pyrethrum, Stachys lanata, Golden Thyme can be used up again, and small Beet will usually pass through a winter without being greatly disfigured.

**VIOLETS IN THE FLOWER GARDEN.**—A few rows or small beds filled now with strong plants of Russian Violets would most probably afford much pleasure to the owners. Showy they would not be at any time, but they would be handy for gathering from, and only a few flowers serve to scent the air near them. The Neapolitan forms, notably Marie Louise, will frequently survive the winter on raised beds, and these are quite showy in the spring.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### BEGINNERS' FIRST HIVES.

MANY people I know have this year commenced bee-keeping. Premising that attention has been given that each hive has not less than 20 lbs. of stores (better if it be 40 lbs.), and the bees occupying a hive large enough to allow space for the breeding powers of the queen, and that she be young and fertile, the beginner may rest assured that all will be well, and there will be no lack of bees within their hives when the spring arrives.

### THE EVIL EFFECTS OF DAMP.

Some have perhaps been feeding their bees. Now when bees are being fed the syrup ought to be much thinner than when the bees have it sealed for the purpose of enabling them to take it up rapidly, as thick syrup or thick honey is taken up very slowly. The right proportion is about equal weights of sugar and water, that proportion being much thinner, but better than is sometimes recommended, and the bees should rather expel the superfluous water than be necessitated to go outside in search of it to liquify the thick syrup. Expelling the superfluous water creates a damp inside the hive, particularly in the extreme angles, and upon the floor, which, if not removed, causes mould upon the combs, and induces the honey to ferment. At the same time it is slowly, but surely, extracting the heat from the bees and the hive, causing the bees to be restless, and consume more food than can be properly digested. The bee often becomes powerless and dies.

### THE BEST WAY TO PRESERVE BEES.

Keep them dry and free from draughts, so that no more heat is necessary to keep them alive than what the bees generate of themselves. Repeatedly I have had clusters of bees living between the outer wrapping and the dried grass covering the hive at the end of ten days. The longer bees can be sustained without feeding, and the less of it, the healthier will they be, and of course when extra meat is taken the reverse will be the case. The whole sanitation of the hive may be summed up as follows:—To have bees sufficient in number to be able to carry on the internal economy of the hive successfully without the brood nest suffering when a portion of the bees are abroad collecting water or pollen, or from any sudden atmospheric changes that may take place, and these bees located in a hive receptacle large enough for the demands of a prolific queen and an increasing population so provisioned that imminent want is never feared or known, and entirely free from draught or moisture. I have repeated the above so as to impress beginners with its importance.

If any beginner has been feeding his bees let him examine the interior of the hive, and he will at once see the moisture as described. Transfer bees and combs into a clean dry hive and the evils will to a great extent be averted, but not wholly, because as the bees consume more food during the winter if the hive is a non-ventilating one.

Water is condensed upon the extreme angles and floor of the hive, and the bees suffer in proportion. If an enamelled cloth lie close upon the top of the frames of a conducting nature condenses the vapour, which falls back upon the bees; but provide them with dry non-conducting porous material, with the ventilating floor and narrow doorway, then your hive is safe. When a hive is heated in transit through long confinement, water sprayed against the outside of the hive lowers the temperature inside the hive. Not unfrequently have we saved bees from suffocation by this simple but effective plan. Now, if a hive stands exposed whenever it becomes damp it has the same effect as when drenched with water, as stated above, and the bees suffer greatly from the lowering of the temperature. To avoid this we cover the whole exterior of the hive with dry and non-conducting material. We avoid double

cased hives because the moisture passes from the bees through the inner shell, and is condensed upon the sides forming the "dead air space," which also extracts the heat from the inside of the hive, and the hive soon decays whether the space has been filled or not. I know full well the advantages derived from "dead air spaces" proper, but a hive having the space filled with cork sawdust is not such a one, neither is it one so long as a hive must always have a doorway for the bees to pass out and in: the principle is destroyed. The foregoing is, perhaps, enough to enable the beginner to understand the evil effects of damp both inside and outside a hive, and how to avoid and prevent it. Never place any non-porous material close upon a hive, any more than you would close a chimney you wished to draw freely.

### THE SITE.

Next in importance to the hive and its coverings is the site, which is as essential for the well being of the bees to be dry as the hive and its coverings are. Never set hives where the surface is very damp, because when the bees alight upon it they soon get chilled, and there is always a coldness that renders the bees uncomfortable when inside their hives. A little labour will sometimes convert a very bad site into one of the very best, and there are few places that cannot be improved by judicious draining and planting. A carpet of Arabis is one of the best for bees to alight upon, and it affords both honey and pollen, but it answers a dry soil best. Without dictating too much or too far, leaving the beginner to arrange according to his fancy and means, but we cannot urge too far the importance of windbreaks either in the form of hedges, timber, or iron, avoiding eddies or lakes of water.

### THE KIND OF BEE.

I have been so well served and so highly pleased with the Carniolian that had it not been for the introduction of the Punic, apparently the best of all the foreign varieties, I would have had no hesitation in advising no other but the former, and may be it will be as well for beginners to be content with what they have until Punic queens are imported in numbers, which I hear from good authority will be before long.

### CROSSES.

As a rule crosses are the best for honey gathering, the Punic being an exception, the pure bees of that race being the most assiduous. It may, however, turn out that with certain varieties, crosses of that race may be the best. It is a pity that dealers have been so imprudent as to introduce into almost every country bees from another. By that injudicious act it is difficult to procure any race pure, and the same may be done with the Punic.

Very shortly after the introduction of the Ligurian bee crosses between it and the common bee found their way to this country as pure Ligurians. Complaints about that were loud and long. After a while Syrian and Cyprian races were introduced, and some of these after a while showed signs of being crossed. To remedy the cry against the more sombre Italians they were crossed with Syrians or Cyprians, and were sold as pure Ligurians, having "sometimes as many as five yellow bands." Out of a dozen Carniolian queens one only represented the true breed, all the others were simply crosses between pure Carniolians and Cyprians or Syrians. The greatest or most prominent distinction between these two races and Ligurians was the yellow saddle upon the thorax of the two former. There are other distinctive features that fully prove them to be distinct varieties, but I never saw a bee having five distinct yellow bands amongst the progeny of hundreds of queens.

I have never witnessed a pure Ligurian bee having the yellow band, and I emphasise this, because in "Gleanings" Mr. Doolittle admits the three varieties as distinct, but adds that "Italians showed this yellow (italics mine) shield fully as plainly as do the Cyprians, so that claim went for nought." From what I have seen and handled of all these races I never yet saw a pure Italian bee having the yellow shield. It was a trick of the dealers to produce

beauty at the expense of their dupes, and it is a pity that such errors should be propagated through ignorance. That it is as desirable to know the character of any race of bees as it is to have nothing but facts recorded will, I am sure, be the opinion of more than—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUE RECEIVED.

W. Drummond & Sons, 58, Dawson Street, Dublin.—*Catalogue of Dutch Flower Roots.*

United States Nurseries, Hextable, Swanley.—*Catalogue of Chrysanthemums.*

James Walters, Exeter.—*Catalogue of Roses.*

H. Cannell & Sons, Swanley.—*Autumn and Winter Catalogue.*

L. Späth, Berlin.—*General Catalogue for 1890-1891.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Blight on Apple Trees (*Beta*).**—Your trees are seriously affected with the American blight, but your letter arrived a day too late for being satisfactorily answered this week.

**Stock for Plum (*Plum*).**—The Mussel is perhaps the best stock for Victoria and all Plums grown as standards. It is free, without producing the grossness of the Brussels, and is not so prone to become stunted as the St. Julien and Damson stocks.

**Weed in Lawn (*G. F.*).**—The weed that, judging by the example sent, is so firmly established in your lawn, is *Prunella vulgaris*. Its unusual freedom of growth this year is no doubt the consequence of the showery weather during July and August. We suspect you will not find it easy to extirpate the weed.

**Fungus on Sycamore (*F. J.*).**—The substance you send is the mycelium of a fungus which has penetrated the bark and spread between that and the wood. It is probable that the tree was in an unhealthy condition, and perhaps decaying, before it took possession, but it would materially help to hasten the death of the tree if the attack extended over a large portion of the wood.

**Seedling Apple (*G. Fairbairn*).**—The Apples sent are far above the average of seedlings that are sent to us. As you say, the variety is an excellent keeper; it might, perhaps, be worth while sending specimens to the Fruit Committee of the Royal Horticultural Society, with a brief history of the tree—its age, habit of growth, and bearing character. If you do this you had better give the variety a name.

**Good Gladioli (*W. M.*).**—A dozen good varieties are *Amitié*, *Celimene*, *Crépuscule*, *Dalila*, *Enchanteresse*, *Flamboyant* or *Grand Rouge*, *Horace Vernet*, *Le Vesuve* or *Meyerbeer*, *Ondine*, *Pasteur*, *Sultane* or *Opale*. Another dozen may be made up by adding to these *Baroness Burdett Coutts*, *Bicolore*, *De Mirbel*, *Eugène Souchet*, *Fra Diavolo*, *L'Unique Violet*, *Mons. A. Brongniart*, *Pyramide*, *Sceptre de Flore*, and *Tamerlane*. If good corms are bought, they may be cut in two with great advantage. The best trade growers advertise from time to time, also exhibit spikes at the leading shows. It would be obviously unfair for us to recommend particular dealers.

**Vine Roots (*Bywater*).**—The roots, so far as we can detect, are not suffering from any disease but they have been dead some time. There is no doubt about that, nor of the border needing renovation when it produces such long fibreless roots. The roots have probably been destroyed by vegetable acids, induced by an excess of organic matter or humus, and too little of the mineral elements needed by Vines. The border evidently is too rich, and in a cold, wet condition; the roots consequently strike into the subsoil deeply. The sooner Vines with roots like those you have sent us are lifted the better, bringing the roots well up to the surface, affording sweet soil over good drainage.

**Cucumbers Turning Yellow at the End (*Plum*).**—The most likely cause is "the syringing every day," which at this season is

liable to cause the water to hang on the fruit and prevent evaporation, causing the fruit to become yellow. Except on very fine days the plants should not be syringed, a light sprinkling being all that is required, and then it should take place in the early afternoon. Where no air is given there is less necessity of syringing, sufficient moisture being generated by damping available surfaces other than the plants in the morning and early afternoon, or when the surfaces are becoming rather dry. The plants are certainly not in a very satisfactory state, but we think that by judicious care in keeping water from the fruit and maintaining a genial condition of the atmosphere that all would go well with the fruit.

**Pruning Fruit Trees and Bushes (*St. Julien*).**—The extension growths of espalier trees need not be shortened provided the wood is firm and ripe to the ends, and these do not terminate in fruit buds. We say this subject to the wise condition which you indicate of "not letting the higher branches outgrow the lower." This misfortune, however, cannot always be prevented by winter pruning alone, stopping luxuriant leaders in early summer and training weak branches obliquely for a time being more effectual. All winter pruning may be done as soon as the leaves can be shaken from trees and bushes, but in gardens where birds attack Gooseberry buds persistently gardeners find it advantageous to defer pruning the bushes till the spring, in the hope that the predators will have left a few buds out of the many for making growth and bearing fruit. Raspberry canes may be pruned now and the plantations put in order for the winter.

**Cutting Down Roses—Yellow-flowered Climber for Greenhouse (*W. W.*).**—We should not hesitate to cut down the too tall Roses to any desired extent, as if the plants are healthy, as we suspect they are, they will push growth freely from the cut-back stems. If there are young shoots strong and well ripened which spring from the lower parts of the plants, these might perhaps be bent down and coiled round for flowering. Early spring will be a good time for cutting back and starting the plants, as growths forced in the winter are usually weak. We have seen many Tea Roses cut down nearly to the ground grow luxuriantly afterwards and produce very fine blooms. You might, in addition, if you have room, procure a few smaller plants for affording early flowers. Though not strictly a climbing plant, inasmuch as its growths do not coil round wires, *Cestrum aurantiacum* would probably answer for your greenhouse as a companion plant to *Plumbago capensis*. The *Cestrum* is an excellent wall or pillar plant, and bears yellow flowers freely in the summer and autumn of the same character as *Habrothamnuses*.

**Amaryllis Belladonna (*R. I.*).**—The name given is that of your plant, and concerning it a correspondent wrote as follows some time ago:—What charming hardy bulbs the *Belladonna Lilies* are. The colour is beautiful, the veins and markings are distinct—a soft peach colour on a white ground—and the delicate fragrance is exceedingly refreshing. The plants carry as many as ten blooms on each spike; the flowers also last a long time in perfection either upon the plant or in a cut state. The great point in its successful cultivation is choosing a suitable position, preparing it, and planting the bulbs, draining the soil carefully that no stagnant moisture lies about the bulbs during the winter months. No position suits them better than at the foot of a hothouse wall facing south. Take out the ordinary soil 1 foot 6 inches deep, place at the bottom 6 inches thick of clinkers or broken bricks, over this some rough turf to keep the drainage intact, filling with a compost of turfy loam, peat, leaf soil, and some charcoal, about two quarts of the former to one of the latter. Cover the bulbs about 2 inches deep with the compost. During the growing season apply water freely, afterwards withhold the supply. The beginning of February is good time to plant.

**Eugenias—E. Ugni (*F. J. R.*).**—The specimen you send is a fruiting branch of *Eugenia Ugni*, which has been highly extolled as a fruit-bearing shrub adapted to the milder situations of this country. It is a native of Chili, and has been long known under the name of *Myrtus Ugni*. In Chili the natives call it *Ugni*, and the Spaniards *Murtilla*. The juice is expressed from the fruit and mixed with water, furnishing a very refreshing drink, with somewhat of the odour of Rosemary. The fruit is the size of a large Black Currant somewhat flattened, and of a brownish-red colour. The pulp is light-coloured, soft, and juicy, with singular mixture of a sweet and spicy flavour, which is very agreeable. It is cultivated in gardens and used in the dessert by the inhabitants of Valparaiso. Other species of *Eugenia* which yield fruits of some use are the following: The fruit of *E. pseudopsidium*, which grows on the mountains of Martinico, is held in great esteem in the West Indies, where it is called *Gouyavier batard*. A decoction of the leaves of *E. cheken* is said to cure diseases of the eyes. The bark is so astringent as to render a decoction of it of great use in cases of dysentery. The seeds of *E. tabasco* are used as a condiment. *Jamaica Pepper*, or *Allspice*, is the fruit of *E. pimento*, a native of the Carribbee Islands, and now cultivated also in the East Indies. It is a handsome tree about 30 feet high, with a straight trunk much branched above, with dense evergreen foliage. Soon after the trees have blossomed, the berries become fit for gathering, without being suffered to ripen; as, when ripe, they are moist and glutinous, and therefore difficult to cure, and, when dried, become black and tasteless. The berries are dried by spreading them on a terrace exposed to the sun for about seven days, during which time they gradually lose their green colour and become of a reddish-brown. They have a fragrant odour, which is supposed to resemble that of a mixture of Cinnamon, Cloves, and Nutmeg; and hence the name of *Allspice* by which they are known.

**Mildew on Vines (H. P.).**—The mildew referred to in the article named is the Vine mildew, *Oidium Tuckeri*, concerning which Mr. Barron gives the following account in his "Vines and Vine Culture :"—"This is a fungoid growth upon the young leaves and fruit of the Vine, and was not generally known in this country until the year 1847. Long prior to this, however, in the year 1831 or 1832, the Rev. M. J. Berkeley observed the appearance of this mildew in the vinery of Mr. J. Slater of Margate, which was under the care of Mr. Tucker, and suggested to him the use of flowers of sulphur, with which he readily complied, and succeeded in driving out the pest. An account of this was given by Mr. Tucker in the *Kentish Gazette*, hence it received the name *Oidium Tuckeri*. In America it had, however, been known to exist for many years previously, although, singularly enough, the American varieties of Grapes are not much affected by it. In this country it has caused great destruction amongst Grapes, both in vineries and in the open air, and in Vine-growing countries the entire season's crop is frequently destroyed by its agency. This mildew appears to the naked eye like a little powder only, resting on the leaves, &c.; but by the aid of the magnifying glass it is seen to be a true vegetable parasitical growth. It is a most insidious enemy, and requires extreme watchfulness, so as to observe its very earliest appearance. It vegetates very rapidly; from a small speck it will, in the course of a few days, spread over an entire house, and if not arrested in its growth, its threads will have penetrated so deeply into the tissues of the affected parts as to completely destroy them. The mildew itself may be arrested and killed, but its effects remain, the skin or cuticle of the berry being blackened and injured beyond recovery. It seems to render the berry incapable of distending further, so that it soon splits open and is, of course, ruined. The tissues of the leaves are also injured in much the same way."

**Roses Mildewed—Replanting (H. C.).**—The mildew would perhaps yield to syringing with bi-sulphate of calcium, or what is known by gardeners as sulphur water. It is made by boiling equal quantities of sulphur and quicklime in water for a quarter of an hour, preferably in an earthen vessel, keeping the mixture stirred all the time. Allow it to settle, then pour off the clear liquid, bottling, and keeping it well corked. A pound each of flowers of sulphur and quicklime are a proper quantity to use to three quarts of water, which in boiling will be reduced to about half a gallon. Of the calcium sulphide add half a gill to a 3-gallon watering-pot of water, syringing the Roses well with the solution. Now that the wood is firm they may be syringed with it at double strength, taking care to wet every part. Next month we should lift the Roses, and laying them in carefully, have the ground trenched, mixing with it, if strong, a sixth part of old mortar rubbish, or, if light, a similar quantity of chalk or clay marl, not using any manure. Failing either of those substances, give a dressing of quicklime at the rate of a bushel per rod (30½ square yards), but it must not be buried deeper than the top spit, in fact it must be mixed with that, or may be applied after the ground is trenched and forked in. Lifting will not prevent mildew, but it will enable the Roses to better resist the disease by tending to a firmer growth, and by hardening the outer covering of the bark and leaves the plants will be healthier. After syringing the Roses with the sulphide, you may dress the ground evenly, and whilst wet, with sulphate of iron at the rate of half a pound per rod, mixed with its own weight of dry sand to insure its even distribution. This will destroy fungoid germs, and its effect on the Roses will be the increasing of their substance, and their colour will be improved. The chief cause of mildew is a deficiency of lime, and, in some respects, iron, which fixes ammonia; and the roots in attacking the ammoniated iron abstract some iron, and the whole plant is strengthened. It would be best to treat the Tea Roses as you propose.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. **Apple from India (R. C. Lee).**—We are sorry the very fine Apple arrived perfectly soft; in fact, exactly as if it had been baked in an oven, and therefore we are quite unable to form an opinion of its qualities. It did not reach us till nearly a fortnight after your card of advice. It resembles a very large specimen of Warner's King, which is not a long keeping variety. (*G. Mant.*)—1, Cockpit; 2, London Pippin; 3, Cellini; 4 and 5, not known, worthless; 6, New Bess Pool. (*W. X.*)—Sorry we cannot identify either of the specimens with absolute certainty. (*F. H. K.*)—Worcester Pearmain. (*Robert Archer*).—Greenup's Pippin. (*Vesta*).—1, Sturmer Pippin; 2, Dume-low's Seedling; 3, Hawthornden; 4, Cockle's Pippin; 5, Selwood's Reinette; 6, Golden Winter Pearmain. (*T. S.*)—1, Beurré Superfin probably; 2, Marie Louise d'Uccle; 3, Cockle's Pippin; 4, Fearn's Pippin; 5, Reinette de Canada; 6, Manx Codlin. (*R. W. Ronayne*).—1, Brown Beurré; 2, Adèle de St. Denis; 3, Quite rotten; 4, Beurré Capiaumont. (*G. Foster*).—1, Bergamotte Esperen; 2, Beurré Diel. (*J. M.*)—1, Beauty of Kent; 2, Not known; 3, Local; 4, Kerry Pippin; 5, Local; 6, Beurré Clairgeau. (*F. Ashman*).—1, Bonne d'Ezée; 2, Beurré d'Anjou; 3, Not ripe; 4, Dr. Nelis; 5, Louise Bonne of Jersey; 6, Not ripe. (*G. C. C.*)—1, Not known; 2, Flanders Pippin; 3, Small's Admirable; 4, Lemon Pippin; 5, Northern Greening; the Pear is Bishop's Thumb.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers.

Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. W.*)—Neither of the Ferns you send is *Adiantum Sanctæ-Catherinæ*, which has much larger pinnæ. No. 1 is *Adiantum pubescens*, and No. 2 *A. pedatum*. (*J. Harding*).—We have no specimens of flowers of any kind awaiting attention, but all we have received have been named. (*R. T.*)—*Amaryllis Belladonna*. See reply above. (*J. A.*)—It resembles a species of *Mucuna*, but we cannot determine it from so imperfect an example. (*B.*)—The specimens reached us in very bad condition; 1, is *Hypericum calycinum*; 2, is *Spiræa filipendula flore pleno*; 3, is *Monarda didyma*; 4, unrecognisable; 5, is *Salisburia adiantifolia*. (*J. F.*)—The *Chrysanthemum* is too much like several other early flowering Japanese to be of value. (*E. H. T.*)—It is apparently a strong seedling form of *Chrysanthemum segetum*.

AT A BERKSHIRE HOME FARM.

It was only about a year ago that we were complaining of a general want of skill in building corn ricks among the workmen of East Anglia, and we had reason enough to complain, for we had

not one man able to build a first-class circular rick at either of the six farms we had then in hand. Since then frequent journeys through the midland and southern counties has enabled us to see many a goodly rick, and quite recently we have seen a considerable number at different farms in Berkshire, and at the home farm to which our title has reference we saw at the homestead some magnificent ricks alike remarkable for large size and symmetrical proportions. Every stack was built upon a timber stand raised upon stone piers some 2 feet or more from the ground, well out of reach of rats and damp, with the sides swelling outwards with a gentle curve upwards to the eaves of the thatch, which with the sides was clipped closely, not an ear of corn being wasted, and the stacks were literally damp proof and vermin proof. They were simply perfection, and if only such corn stacks were the rule and not the exception we should soon cease to hear complaints of the ravages of rats, aye and of mice too, for these "unconsidered trifles" do much mischief in the aggregate. It was at another home farm in Northamptonshire last year that we were standing near an old Wheat stack of such an exceptionally large size that we were curious to know all about what area of land the noble stack represented, and the quantity of corn it was supposed to contain. While these particulars were being discussed we called the bailiff's attention to a powerful odour of mice which came from the stack. The mice were certainly there in large numbers, and very muck corn must have been consumed and spoiled. It could not be helped, for the stack was built on the ground, but the wisdom of keeping over such stacks is as questionable as is the system of building them.

The homestead of the Berks farm had other especial attractions. The bailiff's house, a substantial building of brickwork and tiles, was well placed in a central position, whence speedy access could be had to the entire homestead, and the farm buildings were all sound, plain, business-like structures, every one of them being admirably adapted for its especial purpose. The entire floor of the barn was of asphalt, with brickwork carried up from the floor sufficiently high to exclude vermin, which were also kept out by well-fitting barn doors and good door sills, often the weak point of a barn. In making asphalt floors the ordinary practice of making the part which answers to the old threshing floor between the central doors 3 inches thick, and the remainder only half that thickness, answers very well if no heavy vehicles or horses ever go upon the thin part; if they do it soon becomes broken up, so that it generally answers best to have the entire floor of an uniform thickness of not less than 3 inches. One of the best floors we have had made was of Portland cement concrete 4 inches thick. If well done there is nothing more durable, and much experience of such work has led to the conclusion that it is superior to asphalt, wood, or hard bricks. The granaries were separate buildings with raised floors on piers, quite out of reach of harm from damp or vermin. Especial attention had evidently been given in this matter in all the buildings, and we may remark in passing that a damp-proof floor is not a difficult matter to contrive for a granary on the ground floor, and if the granary is made over stables or other buildings the floorboards should always be matched and tongued to prevent any subsequent trouble from shrinkage. It is really singular how frequently this simple but important matter is overlooked. Many a faulty old granary floor have we had to replace; weak joists and thin un-tongued boards both pointing to contracts, cheap or scamped work, false economy, and ignorant or careless supervision.

The swine were not confined in stys, but had the large commodious sheds which we have found to answer so well. None of the farm workmen are allowed to keep a pig at their cottages, but they have what pork they require at a very low price from the farm, and the various other privileges of which we were told showed that they had a kind and considerate master. The pigs were compact, well-bred animals, the only fault being in the sows, which were somewhat over-large and heavy. This is a general

fault worthy of attention, for an unwieldy sow so often smothers or crushes its pigs under its huge carcass that it is best fattened and sold.

The cattle were all out on some capital pasture, some twenty store beasts being brought on for stall feeding by having a certain quantity of dry food regularly out on the pasture. This was given them in tubs made by sawing paraffin casks in halves, a cheap and efficient substitute for the ordinary iron pans. For water they had the Thames flowing through the pasture, a limpid stream innocent of any of the foulness of its waters near London. No attempt had been made to finish the beasts on the pasture. The most forward in condition would go out for the butcher by Christmas, and the remainder in the following two months. They were evidently managed under a well tried and excellent system, and we parted from our friend, the able manager of the farm, with a feeling of pleasure, a sense of something gained, which the inspection of such a farm always affords.

#### WORK ON THE HOME FARM.

Corn sowing on heavy land has been hindered by drought, but enough rain has now fallen to set plough and drill going again, and the remarkable continuance of fine weather is much in favour of good and brisk work of all kinds on the land. We certainly enter upon another farming year with the land generally cleaner than it has been for several years, and all work well forward. A glut of Wheat in the market has caused prices to continue falling, but Michaelmas brings with it such urgent demands for money that it must be had even at a sacrifice.

Cows and store cattle are now taken into the yards at night, and complaints of a falling off in condition of forward beasts, through undue exposure on cold nights, show either a want of convenience or of care in affording the necessary shelter. Both cows and beasts will go out to graze on all fine days till about the end of the month, when they will have become settled in winter quarters. Cabbages are exceedingly good this autumn, and they will come into full use towards the end of the month as grass feed falls off. Such a supply of green food is then invaluable to prevent both cows and store beasts from a falling off in feeding, as they are confined more and more to yard and fattening shed. We have already seen some sheep folded upon Cabbages, which may be a sign of plenty, and of the predominance of sheep over cattle. Leading East Anglian farmers still declare sheep to be the farmer's best friend. They are wise, for many a man has cause for bitter regret just now over losses upon high-priced store cattle.

Potatoes are being lifted and stored in excellent condition, the percentage of diseased tubers being small, and the bulk of the crop is a bright fine sample. Magnum Bonums have certainly developed haulm, at the expense of tubers, which are, however, remarkably free from disease. Seed is being carefully selected for another season, and it will be placed thinly in a dry shed where it is safe from frost. No seed Potatoes should ever be placed in heaps and left there to sprout. Such abortive growth exhausts the seed and seriously affects the next crop, which suffers a proportionate loss in vigour and productiveness. It is a good plan to give a trial to some new sorts every year, for it is certain that the best way of keeping down loss from disease is to plant only sorts that are comparatively new and in full vigour.

#### REMARKS.

- 12h.—Bright and fine throughout.  
 13th.—Rather dense fog all morning, began to clear about noon, and bright from 1 P.M.; foggy again in evening.  
 14th.—Fog all morning; sunshine from 2 to 4 P.M., then foggy again.  
 15th.—Bright early; mild and showery from 9 A.M. to 1 P.M.; bright sun from 2 P.M. to sunset; heavy shower at 8.45 P.M.  
 16th.—Almost cloudless early; bright morning; high wind, frequent cloud and occasional spots of rain in afternoon; showers at night.  
 17th.—Generally overcast in morning; fair afternoon with some sunshine.  
 18th.—Generally overcast throughout.

On the whole a bright autumn week, though two days were foggy. Temperature at last just below the average, having been above it for six consecutive weeks.—G. J. SYMONS.

LAST year was evidently regarded by some authorities as the hundredth anniversary of the introduction of the present race of Chrysanthemums into this country. The plant first flowered on the Continent in 1789, and the Belgians were right in celebrating the Centenary last year; but it was not until the season following that the flower was seen in England, and therefore we believe the National Chrysanthemum Society to be quite correct in their fixture of the forthcoming celebration. The present year marks a distinct epoch in the history of this flower, and it is fitting that it should be the subject of special attention. A bright, cheery, joyous time the present Chrysanthemum season should be. In connection with the National Society, however, the joy must be tempered with the deepest sorrow by the lamented death of its laborious Secretary, the late Mr. William Holmes. It is sad that a promising life should be cut short at any time, but in this case doubly so, for all felt he was on the eve of the triumph that would have rewarded him for his unremitting work. He will not be forgotten, for his memory will be cherished, and his name kept in long and loving remembrance by hosts of friends.

Though this is the Chrysanthemum Centenary year, there is no precise date more appropriate than another for doing honour to the event. This must of necessity be governed by circumstances and controlled by convenience. The show days of different societies will naturally be the celebration days, and these, for obvious reasons, must differ. Foreseeing an unusually great campaign ahead of more than a hundred floral contests, and the consequent claims on our space, we have considered it the best, both for ourselves and our army of Chrysanthemum constituents, to be in advance of all the shows in recognising the services of officers and men who have done, and are doing, such excellent work in the Chrysanthemum world. This could not be done adequately after the shows begin and their demands for publicity, therefore we clear the decks for action.

It is not our intention to indulge in anything approaching sensationalism, but hope in a manner not inappropriate to produce a substantial memorial of an eventful year. The ancient history of the Chrysanthemum has been written and published repeatedly in these pages. In those matters, therefore, we shall not lengthily indulge on the present occasion, and while appreciating the researches that have been made in the direction indicated our pleasure now is mainly to deal with the work of the present generation and to portray a few of the workers of to-day—some as organisers of societies or secretaries of shows, others as exhibitors who have won high honours—all as representative men who assiduously endeavour to extend the cultivation of Chrysanthemums in the various districts of the kingdom.

To summarise an historical reference very briefly it may be said that the earliest recorded Chrysanthemum in this country of the types now so popular was a small flowered variety of *C. indicum*, which was cultivated by Philip Miller in the Chelsea Botanic Garden in 1764, but was subsequently lost, and can only be traced by a specimen preserved in one of the large herbaria. The large flowered varieties first made their appearance in England in 1790, and numbers of others were introduced in succeeding years, from which sprang still later the majority of incurved, reflexed, and Anemones, now such favourites. Then we come to an important

epoch, the introduction from China in 1846 of the Chusan Daisy and Chinese minimum by Mr. Robert Fortune, which in the course of some years resulted in the production of the neat and elegant Pompons. These, like many others of the family, we mainly owe to the French florists, for the "Chusan Daisy" was despised or ignored in this country until our continental neighbours had proved its capacity for variation and range of beauty.

To Mr. Robert Fortune, however, Chrysanthemum growers are still more deeply indebted, for to him are due the first Japanese varieties seen in this country, and there can be no question that the numberless richly coloured and strangely formed varieties since produced have done more to popularise the plant than all previous efforts. It was not until 1862 that Mr. Fortune's Japanese curiosities reached England, and then their fantastic appearance, so different from that of the varieties prized by the florists, excited much unfavourable criticism, and few could have thought that the "Dragons" and the neat little Laciniatum, still occasionally seen,

FIG. 42.—MR. ROBERT FORTUNE AT THE AGE OF 54.

would be the forerunners of so many fine seedlings and introductions. But again, we are largely indebted to our friends over the Channel for a large proportion of the varieties in cultivation at the present time. We have much pleasure in giving the prominence which is due to the portrait of Mr. Fortune as a Chrysanthemum pioneer. He died in 1880.

As a raiser of Chrysanthemums, one British name, however, stands out prominently, and must be mentioned here—namely, that of Mr. John Salter, who for nearly thirty years gave close attention to the improvement of the plant and succeeded in raising a large number of valuable varieties, many of which still hold an unrivalled position in the lists of incurved. In 1838 Mr. Salter took a nursery at Versailles, and from there, and subsequently at the "Versailles Nursery" at Hammersmith, his novelties were distributed nearly every year, the majority of which were noted at the time in the issues of this Journal frequently by the enthusiastic florist, Mr. Donald Beaton.

To the great army of cultivators who have performed such good service in the twenty years all plant lovers are very much indebted, for they have proved what great results can be

attained by continued perseverance and healthy rivalry. The societies, with their shows and prizes, have contributed largely to this advance, more perhaps than can be adequately gauged, and for this reason we have accorded some representative places in our gallery of portraits to-day.

In order to make our issue as complete as possible within the limits, we have thought it appropriate to illustrate a Chrysanthemum show. For this purpose we have necessarily had to choose one of the past, and therefore reproduce on page 385 an engraving of the Kingston Show, which first appeared in the *Journal of Horticulture* in 1886.

### CHRYSANTHEMUMS—EXHIBITORS' MISTAKES.

MUCH valuable information has been disseminated in the pages of the *Journal* for the benefit of Chrysanthemum growers and exhibitors, and for which many are thankful. I for one owe much to the many hints gained through that medium during my career in the exhibition field, which did not extend over a long period, but was most enjoyable, although it entailed much hard work. We are often told what exhibitors should do, but I do not remember having seen an article on "exhibitors' mistakes," which, as a rule, we do not care to chronicle. It is a weakness of human nature to hide defects, but from a chapter of mistakes it is very easy to gather valuable information. I purpose detailing a few striking incidents of my exhibiting career, that others may avoid committing the same errors.

One of the greatest mistakes which some exhibitors commit is that of boasting what they are going to do at a coming show. I once heard a well-known exhibitor give some excellent advice—which I will repeat in his own language—to a remarkably self-opinionated person, who was expressing his intentions loudly. The experienced exhibitor, who is remarkable for his quiet manner of speech, listened patiently, then placed his hand upon the shoulder of the vociferator, exclaiming, "My friend, never thou open thy mouth till thou seest card ont teeabel." I shall never forget that episode, which silenced the boaster effectually.

Some exhibitors have a disdainful way of speaking of a defeated opponent. This is a mistake, because no one can tell what may happen on the morrow. In company with several others on a long railway journey to an exhibition, in the course of conversation one of the party happened to say how many years he had been a grower of Chrysanthemums. The person alluded to, and who had defeated the other many times in competition, snappishly remarked, "Yes; you have grown at 'em," inferring that the cultural details were only partly understood. The same two persons have many times since stood in reverse positions on the exhibition tables. The despised one has lived long enough to attain a high position in the exhibition hall. Over-estimation is a mistake which experience will remedy.

Grumbling at the verdict is another mistake, for which some exhibitors have earned a reputation. So much is this the case that those who are acquainted with them always expect to hear complaints if they are compelled to occupy any other than the first position in the prize list, and in nineteen cases out of every twenty the grumbler has no cause for complaint. I have known men follow the judges about the show for the whole afternoon, pointing out the excellence of their exhibits, ignoring of course their deficiencies. Much better is it to take defeat gracefully. Another mistake some make when occupying a second or a third position is that of exclaiming, "Why I could have brought better blooms had I known, I have plenty at home." This invariably is what would be termed a "lame tale." Seldom, indeed, do exhibitors depend upon their second best quality when the results at stake are important.

Excitement is a weakness which the oldest of exhibitors cannot at all times control. It is, however, a mistake to give way to it, as it very often prevents the proper carrying out of duties necessary at a crucial point when a cool head and steady hands are of such advantage. I would remind beginners that the coolest persons generally do the best work, either on the exhibition table or at home, for the matter of that. Some persons allow themselves to be carried away by excitement, so much as to be perfectly helpless. I was once in company with a noted exhibitor who was arranging his blooms on the exhibition table in competition for a valuable prize. The moment his opponent placed his stand of blooms alongside, the exhibitor named was so excited at the prospect of winning, that in the absence of mind he suddenly took off his coat, threw it on the floor of the hall, walked to and fro in front of the stands, and as suddenly replaced his coat without attempting to do anything more. Afterwards he was so helpless that he was unable to

write a name or verify those on the stand, or to make sure the blooms were distinct, which is generally the last thing to do, to make sure a duplicate has not "crept in." In another case of excitement, an exhibitor was so elated over the prospect of winning a noted prize in the north of England, that on the strength of the information of one of the stagers who came out of the room where the adjudicating was taking place, informing the exhibitor that he was almost sure to win, telegraphed at once to his wife the happy event, yet when the verdict was authoritatively given this exhibitor occupied only the third position. Imagine his chagrin.

Mistakes are often made by exhibitors in preparing for and going to shows, also in not thoroughly examining the regulations and classes in the schedule, thereby bringing disqualification as the result of neglect. I have heard of persons making a mistake in the date of a show. One exhibitor blundered so far over this that he went with his blooms a week too soon. Another arrived a day too late. The most general mistake made is that of not allowing sufficient time to do the work necessary in a proper manner, rushing through it simply because an extra hour in bed should be obtained. Men have been known to have lost valuable prizes, which was distinctly traceable to want of time in preparing and packing the blooms. Much of this has to be done by lamplight, it is then that mistakes occur. The colours under this light are so deceptive that yellow blooms can easily be mistaken for white, and duplicate blooms are inserted. More often is a mistake made in this direction when duplicate blooms in say six varieties are allowed, but not more than two of a sort; three sometimes creep in instead—as for instance in the case of a noted exhibitor at the Aquarium, who lost the first prize a few years since in a leading class through making this very mistake.

The mistake most generally committed is that of deferring cutting the blooms till after dark. All blooms should be cut and carefully placed together in their respective classes during the day-time, when it is hardly possible to make a mistake in this direction. I once saw a valuable silver cup lost in the way stated. The winner was only two points in advance of the second prize man, and as the one to whom I allude was complaining of the justice of the award I remarked, "If you had taken the 'eye' out of that Queen and the same with that Peter, you would have won," which doubtless the Judges had taken into consideration. His reply was, "But I had not time." This was a mistake which proved of serious consequence. Many mistakes might be quoted which are traceable to "rushing," owing to want of time in not commencing earlier to make preparations, such as going away without taking the tweezers, forgetting a bloom that was put in the cellar to keep fresh. As, for instance, a new beginner last season left his "Gluck" behind in the same manner; when a hundred miles from home he remembered where this bloom was left. Forgetting the packet of labels may be a serious matter, as so much needless time is taken up at the show in procuring more labels and writing the names, when this time could be better devoted to arranging the blooms in the stands, and other duties.

It is also a mistake to depend entirely upon just the number of blooms required, not taking an extra one or two in case of accident. A celebrated northern grower was said to have lost a valuable first prize through having one of his blooms damaged in transit and not having another at hand to replace it. Always take two or three extra blooms. These should not be duplicates of those in the competing stand, because it is not known which bloom would be damaged, if any; but by making sure of an extra number of sorts the loss of one bloom is easily repaired. Many instances of wrong naming could be quoted which could be traced to neglect in ascertaining the correct names; for instance, when "Annie Fuss" is written for "Amy Furze," and "George Patney" for "Putney George," there can be no excuse.

I have seen many mistakes made in the transit of cut blooms, such as giving the boxes in the charge of railway guards and porters, who unknowingly turn them upside down, sometimes to be more convenient for conveyance from one train to another; having them jolted one against the other in the guard's van, instead of carefully handling the boxes yourself, and stowing them into the van also in such a manner that jolting is impossible.

Some exhibitors are very fond of staging their blooms very early at the show, in fact hours before it is necessary, the consequence is if the room being warm and so situated that the sun can shine upon the blooms, they fade, are covered with dust, and are on view to the eye of your opponent, that he has ample opportunity to detect the weak points and strengthen his own. Some exhibitors are too fond of showing off their exhibits to a certain class of admirers, that it is decidedly against their own interest for the reasons stated. One great mistake in staging the blooms is that of placing them too low upon the stands. The judges cannot examine them nearly so well, and, besides, the low position dwarfs the blooms considerably. If a beginner will take notice of this he will find it is not the successful exhibitors who make this

mistake. There are some who do not like to be told that this is a fault, and that makes the mistake a double one.

Some exhibitors make a mistake in staging varieties together which are too much alike, although they may be known to the owner as distinct, but if there is any doubt about their character not being quite clear it is unwise to run the risk of being disqualified for the reason stated. Far better is it to depend upon those sorts about which there can be no doubt whatever as to their distinctness.

One further reference only will I make—namely, on the subject of dressing the blooms. This necessary item in exhibiting is much decried by those who do not practise it as being everything that is bad towards spoiling the blooms. At a noted northern show I was inspecting the cut blooms, and found a stand of twelve incurved specimens of large size, but many of them having a fully developed "eye," especially in the "Queen family." I remarked, "They would be good blooms if they were dressed." A bystander, a stranger, rejoined, "If they had not been dressed they would have been good blooms." Now, it was apparent that the flowers were staged almost as cut from the plants, and it was a mistake to say that dressing would spoil them.

In conclusion, I would say that by a close study of what not to do, that which an exhibitor should strive to accomplish can easily be learnt, it being mainly a question of the proper use of what we all possess—viz., "brains, gentlemen, brains."—EDWIN MOLYNEUX.

### CHRYSANTHEMUM FLOWERS AND SEEDS.

RAISING Chrysanthemums from seed has become an important matter, and although the majority are obtained from imported seed saved in the south of France, Algiers, and other warm regions, yet it has been repeatedly proved that seed can be ripened in this climate. At the present time Messrs. Laing & Sons at Forest Hill have some seedling Chrysanthemums raised from seed saved last season, and as the seed parent was the distinct Japanese variety, Edwin Molyneux, the flowering will be watched with much interest. Several other nurserymen also have seedlings said to be from home-raised seed, and the matter is worth the attention of amateurs who are partial to making experiments. To assist in explaining the character of the flower, which is by no means generally understood, the appended illustration is reproduced by the courtesy of the Secretary, the Rev. W. Wilks, from the Journal of the Royal Horticultural Society (March, 1890). The accompanying remarks form a portion of a paper read by Mr. F. W. Burbidge at the Conference held at Chiswick on November 6th last year, which also gave an exhaustive description of the experiments undertaken by various raisers. The chief condition requisite to success appears to be that the seed should be set as early as possible, and that it be allowed a long period of ripening, at least two months, and no doubt saving immature seed has been the cause of many failures.

"The Chinese are a peculiar people, and in many ways different to the gardeners of the West. They are more insulated and self-contained. Less than a century ago China was the whole world to the Chinese. Although they live much nearer to the tropics than we do, they have not felt that soul-hunger for the plants of other and warmer lands than their own, which is such a characteristic feature in our horticulture of to-day. The mandarins, or nobles of China, allow the aristocratic Orchid to sway and flutter neglected on its native bough; but the one thing they do admire and value is their native Chrysanthemum, a flower which, with their neighbours the Japanese, they cultivate to perfection. It is the national flower of a great and powerful people, and not only of the conservative Chinese themselves, but of the more liberal Japanese, and also of the people of Siam. But what at the beginning of this paper I am anxious to emphasise is the broad central fact that the Chinese gardeners have gone out to their own waysides and hedges, and have brought into cultivation their own wild flowers. The Tree-Pæony, the Camellia, the Azalea, the Rose, and, above all, the Chrysanthemum, are a few only of their favourites, which may serve to illustrate what I

mean. Mr. Fortune told us, after his second return from China, that the Celestial gardeners did not care for any of the plants he took out with him from England, except for the scarlet Zonal Pelargonium; and certainly the faith and persistence with which these people have improved their own wildings is very remarkable, and I have sometimes thought that therein lies, by implication, the moral lesson to our British gardeners, "Go thou and do likewise." I am afraid, however, we are too fond of jumping to conclusions, too fond of rapid results, to take up the culture of our native Corn Marigold (*Chrysanthemum segetum*), or our great Ox-eye Daisy (*Chrysanthemum leucanthemum*), with anything like the long-suffering faith that must have prompted and animated the Chinese gardeners who first began the culture of the wild *Chrysanthemum* centuries upon centuries ago. It is not only possible, but extremely probable, that the *Chrysanthemum* was a popular garden flower in China when Egypt was in its prime, and in the future it is likely to remain the national floral emblem of a people who will either, as friends, help us to

keep our foothold in the East, or, as foes, they may possibly eat up the Russian Bear, and then reserve the eastern half of the world's loaf for themselves.

"We have now to consider the flower itself. I have reasons for believing that the small single yellow *Chrysanthemum indicum* (commonly cultivated in India, although only wild in Corea, China, and Japan) is the original wild type from which natural variation, and culture have evolved all larger growing and more highly coloured forms. All the botanists, from Linnaeus and De Candolle to Messrs. Forbes and Hemsley (*Jour. Linn. Soc.*, vol. xxiii., p. 437-8), have considered *C. indicum* and *C. morifolium* (= *sinense*) as two distinct species. I only believe in one species—the so-called *C. indicum* (of which *C. morifolium* (*C. sinense*) is, as I take it, a mere geographical variety), since I find that nearly every batch of seedlings exhibits a tendency to revert to this, as the primitive yellow-flowered type, although all sorts and sizes and conditions and colours, are obtainable from seeds gathered from the same capitule, be the seed-bearer Pompon (*C. indicum*) or large-flowered (*C. morifolium sinense*). When the weird forms, now known to have been of Japanese garden origin, were introduced by Mr. Fortune in 1862, we were very nearly led to believe in a third species (*C. japonicum*), so distinct and different were these flowers

to those previously known in Britain. Even supposing that there originally were two wild species of Chrysanthemum in China or Corea (a view from which I dissent), the result, as above stated, would tend to show that they must have intercrossed freely with each other; but all my observations go to prove that the weedy little single yellow Pompons, which so often come from the seeds saved from the finest and most modern of the large-flowered kinds, really imply reversion to first principles (ativism), and not the unmixing of two distinct wild plants naturally or artificially cross-fertilised.

“Botanically the Chrysanthemum is a glorified Ox-eye Daisy, trying hard to raise itself from a herbaceous perennial into an ever-green shrub. It belongs to the great natural family of the Daisy Flowers (Compositæ), and what we as gardeners call a ‘flower’ or a ‘bloom’ is really a flower head or capitulum (a) made up of 100 or more separate individual flowers, all neatly arranged into a bouquet-like group, and held in their places by a cup-shaped common calyx or involucre, as shown in this diagram (b). In fact, composite flowers are made up on what I may call the paint-brush principle, the florets representing the hair or bristles, and the involucre replaces the supports by which the hairs or component portions are held together, as here shown (b). The florets (c and d) are generally of two kinds, the outer or ray flowers being more or less ligulate (d), while the central or disc florets are tubular, as here shown (e). The outer or ray florets are female flowers having styles only, and no stamens, but the central or disc florets are hermaphrodite, being furnished with pollen-yielding anthers as well as with pollen-receiving bifid styles (e). The anthers (f) of

the Chrysanthemum, as of all the members of the composite order, are coherent by their margins or syngenesious, and they are, moreover, proterandrous—that is to say, the pollen is ripe and ready some days before the stigmas of the same flowers are fit for fertilisation. In a word, the Chrysanthemum had ages ago become naturally adapted for cross-fertilisation, and to that fact no doubt is due its variability in nature and in our gardens.”

EXHIBITION CHRYSANTHEMUMS.

IN submitting a tabulated analysis of the most successful varieties of the above I must apologise for the long delay which has occurred from circumstances over which I had no control.

Owing to a succession of severe frosts in October, 1888, the record for that year is abnormal and unreliable. Consequently the results obtained may be dismissed in but few words. Among incurved Empress of India still held pride of place, while Bronze Queen and Mrs N. Davis had both improved upon their previous position; Charles Gibson and Lord Eversley, the only successful novelties, standing at 36 and 41 respectively. In the Japanese section Madame C. Audiguier continued to lead, Edwin Molyneux being a good second, having advanced forty-two places since the previous season. Ralph Brocklebank also rose considerably and tied with Jeanne Délaux. Avalanche and Madame Baco, the latter's first appearance, scored twenty-six and eighteen wins each. Many old favourites have, however, lost ground heavily, notably Grandiflorum, while Bertie Rendatler, Comte de Germiny, Madame de

Sévin, and Peter the Great have also lost caste in prizewinning society.

Nothing very exceptional occurred in the weather of 1889. The summer was hot and the autumn fine, like the present season, which suited the growth of the plants. Cultural conditions were therefore normal.

For the first time since I have kept a record Empress of India has been deposed, and her throne occupied by her handsome offspring. Golden Queen, on the contrary, has, together with Barbara, Mrs. Heale, Mrs. W. Shipman, and Mr. Brunlees, experienced "betterment." As these are all old and well tried varieties their promotion is presumably due to sheer merit. Of the two novelties of 1888, Charles Gibson has greatly and Lord Eversley slightly, improved in position; but Miss Violet Tomlin, who merely tied with Angelina (48) in 1888, we now find at the fifteenth place, and included in twenty-five prizewinning stands. The most phenomenal success, however, is that of the *débutante* Miss M. A. Haggas, who in her first season has compelled "our only general" to share his laurels with her.

Among Japanese the changes are startling, amounting as they do to a social revolution amongst the "mums," Avalanche having in three seasons risen from the bottom of the list to the top, where

it now divides premier honours with Ralph Brocklebank, a recent upstart. Others novelties, such as Sunflower, Etoile du Lyon, and Sarah Owen have been equally triumphant, G. Daniells and Condor also proving themselves dangerous rivals to the older kinds. Indeed the fate of Jeanne Délaux, Madame C. Audiguier, and Comte de Germiny makes one inclined to moralise on the mutability of Chrysanthemum existence, and to exclaim sadly, "How are the mighty fallen!" A remark which also applies, though in a lesser degree, to Belle Paule, Fair Maid, Marguerite Marrouch, Thunberg, Yellow Dragon, and several others. While of former sure prizewinners Fernand Feral and Grandiflorum have now disappeared from the list altogether.

Duchess of Albany, however, again proves its sterling and reliable qualities by maintaining exactly the same position for three seasons out of four. Triomphe de la Rue des Châlets reappears, though in reduced circumstances, after enforced absence in 1888, owing to the frosts of that autumn.

In concluding my analytical remarks I cannot forbear adverting to the evidence afforded by these tables of how surely the new race of sturdy, "stocky," albeit somewhat coarse, growers are, in the struggle for show existence, ousting both the old "mop on a maypole" varieties and those with such miserable constitutions as Jeanne Délaux, &c.—B. D. K.

## CHRYSANTHEMUM NOTES.

## THE WILLIAM HOLMES' MEMORIAL FUND.

A MEETING of the Committee appointed to deal with the above fund was held in the Royal Aquarium, Westminster, on October 23rd, Sir Guyer Hunter, M.P., in the chair; when after consideration of the numerous suggestions as to the form the memorial should assume, the following resolution was unanimously adopted:—"That a portion of the fund raised be set aside for assisting the technical education in landscape gardening of the late Mr. W. Holmes' eldest son, and that the remainder be awarded as prizes or medals at the exhibitions of the National Chrysanthemum Society, and at those of affiliated societies."

Sir Guyer Hunter was appointed Chairman, and Mr. R. Ballantine Treasurer, with Mr. Lewis Castle, Hotham House, Merton, Surrey, as Honorary Secretary, to whom all subscriptions and communications should be addressed. Circulars and subscription forms will shortly be issued to all members of the National Chrysanthemum Society, the affiliated societies, friends of the late Mr. Holmes, and everyone who is desirous of helping in a good cause.

## AMONGST THE CHRYSANTHEMUMS.

FOR a dozen years or more I have made annual tours amongst all the best Chrysanthemum collections in the home counties and elsewhere, and it has become one of the most pleasant tasks of the year to visit old friends, compare the present condition of the plants with the past, to note the advance of younger growers, and to observe the respective merits of the various novelties as they appear. These excursions are usually performed a week or two before the rush of the shows commences, a time that most who are interested in Chrysanthemums select for similar inspections. All are anxious to know the prospects of the season, and intending rival competitors make frequent journeys to each other's collections with a mutual friendliness that is most commendable. Certainly, notwithstanding the keen competition now prevailing, there is less ill-natured jealousy in the ranks of Chrysanthemum growers than amongst some other groups of florists. The best growers and most successful exhibitors willingly relate their experiences and their failures to their rivals, and it is this generous feeling which has so greatly assisted in elevating the tone of Chrysanthemum societies and shows. There are, of course, instances to the contrary, but they are exceedingly rare, and I have no hesitation in asserting, from an intimate and extensive knowledge of the men so engaged and the modes adopted, that in strict honesty of competition the Chrysanthemum exhibitors will bear most favourable comparison with any horticultural or other shows.

Around the metropolis this year the plants are looking extremely promising, and not, perhaps, quite so early as in some previous seasons. Mr. Gibson, at Morden Park Gardens, has an excellent collection, and is strong both in Japanese and incurved, all the blooms looking clean and developing freely. Mr. Richings, The Brandries Gardens, Beddington, is likely to do himself substantial credit, for his blooms are of excellent quality, and the plants well grown. At the residence of Philip Crowley, Esq., Waddon House, Croydon, his gardener (Mr. King) has a fine houseful of plants, that will not, however, be at their best for a week or two yet. At Teddington Mr. W. Furze has the principal collection, but there are several others in the neighbourhood, also at Twickenham, concerning which something will be said later on. At Isleworth too Mr. Pears is making a speciality of the Chrysanthemum, and good results may be expected. The trade collections of Messrs. Laing & Sons, Veitch & Sons, N. Davis, G. Stevens, J. Carter & Co., R. Owen, W. Jones, and others will also attract many visitors, and some general notes respecting these and many others must be reserved for next week. It must suffice for the present to say that all the growers about London are hopefully expecting a capital season, notwithstanding "the damping," which is already beginning its disastrous work.—L. CASTLE.

## CHRYSANTHEMUMS AROUND LIVERPOOL.

THE season has arrived when most of our principal growers around Liverpool are watching with great eagerness the expansion of their blooms. I question if there is any part of England where the Chrysanthemum is more highly prized than it is around Liverpool, and it matters not where you go, in places large or small, you always find a certain amount of prominence given to the queen of winter. And rightly so, for what could we get at this dull season of the year to give us the wealth of bloom and infinite variety of colour? Liverpool growers have made their mark, and such men as Tunnington, Lindsay, Faulkner, Jellicoe, Fox, Roberts, and Mease, when with us, have to a great extent been pioneers in the movement which had for its object the higher cultivation of the Chrysanthemum. We have, in addition to those I have mentioned, many more equally as good, and on all sides energetic men are rising up who will in a short time be able to hold their own against all comers. The number of growers is increasing, and the general question at the present time is, "How are your blooms?" I think the year will be hard to remember when we have ever had a better promise of bloom than at the present. On every hand the one opinion is that they are grand. In many cases the plants are dwarfer than usual, the foliage is good, and mildew has not made its appearance to any great extent; but I am afraid the dense fogs we experienced during the early part of last week must have wrought some havoc, but as yet not many complaints have reached me. I have been privileged during the last few days to see some of the collections here, and as the area is so extended it is a difficult matter to see all. I am conscious that there are many collections grown where, if the gardeners were allowed to exhibit, their record would be excellent. I have also

seen some of the newer varieties, which promise to be acquisitions; but as this is only a preliminary note I shall reserve my notes on collections I have seen and newer varieties for a future issue.—R. P. R.

## THE CENTENARY AND THE AFFILIATED SOCIETIES.

THE Centenary festival to be held at Westminster on November 11th seems to me an opportunity which should be made the most of for further strengthening that good feeling now existing amongst the various societies. The provincial societies, as a rule, have much respect and admiration for the N.C.S., mainly on account of its spirited policy and the able manner in which its business is conducted. The continued increase in the number of affiliated societies and the success of the provincial shows are sufficient proofs of this, and there can be little doubt that so long as the popularity of the Chrysanthemum remains as strong as at present, and the management of the N.C.S. continues to be efficient, that success will continue.

What, then, I think now is required is that Centenary meetings should be rendered, as far as possible, a "gathering of the clans," or, in other words, a bringing together of the principal officials and Chrysanthemum growers from each affiliated society to take part in the celebration, and to meet together at a grand conversazione or conference, to be, if possible, presided over by the esteemed noble President of the N.C.S., supported by all its leading officials. Towards effecting this I would suggest that the Committee of the N.C.S. take into consideration firstly, the granting of a free pass for the exhibition and meetings to all fully accredited visitors from affiliated Societies; secondly, that the various railway companies be approached from the N.C.S. with the object of obtaining cheap fares to and from the exhibition; and thirdly, that something be done towards providing good and cheap lodgings, especially for such as are strangers in the metropolis, and who will wish to stay at least one night. Other matters there would be also to be considered which would occur to the Committee, such as arranging for sending a circular letter to each affiliated society stating what was thus being done, and inviting delegates from each such Society. I am of opinion such would meet with a hearty response, and would bring about such a meeting together of Chrysanthemum specialists as would most effectually serve to celebrate the Centenary, also causing pleasant recollections for many years to come.

## THE AFFILIATED SOCIETIES' CLASS.

THE following suggestions for the future working of what is known as "The Affiliated Societies' Class" at the November shows of the N.C.S. may be worthy of consideration. This very commendable class (which had its origin in the fertile brain of the late respected Hon. Sec., Mr. Wm. Holmes), is strongly commended by every one with whom I have conversed upon the subject. As at present it is but in its infancy, and being so entirely novel in character, it is scarcely surprising that it has not as yet proved the unqualified success its energetic promoter would wish to see it. To attain such success I believe the opinions and feelings of provincial growers and affiliated societies upon the subject requires to be obtained, and, as far as may be practicable, their ideas met. The *Journal of Horticulture*, circulating as it does amongst all the leading growers throughout the kingdom, is an excellent medium for bringing before them any new ideas upon the subject.

I would then suggest to the Committee of the N.C.S. that in the first place a circular letter be sent to each affiliated society, asking for opinions and suggestions, such, when received, to be fully considered by the Committee of the N.C.S. I am of opinion that the principal show of the N.C.S. should be of a character entirely distinct from any held by its affiliated societies, also that it should, as far as possible, represent the combined strength of such societies, and that to this end the class under consideration be made the most important one in the schedule.

One of the main causes which goes to prevent societies at a considerable distance from London sending exhibits and representatives to compete in this class is the expense to be incurred, and the doubts as to being recouped in such by prize money. I would suggest that none be offered, but that in lieu thereof the railway, and such other unavoidable expenses of each exhibitor as can be readily met, be paid by the N.C.S. The challenge shield might still continue to be the principal prize competed for, but that in addition there be at least three certificates, first, second, and third prizes, each to be well framed before presentation in a manner suitable for permanent hanging in the meeting room of the society winning it. The class also might be a little extended, in that a limited number of reflexed and Anemone flowers might be admitted, which would give to it really more of a representative appearance and character than at present.—W. K. W.

## FRAGRANT CHRYSANTHEMUMS.—MISS DAVIS.

IN a house which I have filled with the best varieties of October flowering Chrysanthemums, grown for stock purposes and for supplying cut flowers in quantity, and which are now a dense mass of bloom, many visitors have remarked the agreeable perfume, adding that they were not before aware that Chrysanthemums were fragrant. On making examination this afternoon as to which amongst the numerous varieties gave off this pleasant odour, I found it to be the new pink sport from Mrs. Cullingford, Miss Davis, which is with me most distinctly Violet-scented. Such is not the case with the parent variety, nor indeed with any of the other varieties now in flower in the same house. Irrespective of its sweet perfume, Miss Davis is a valuable and beautiful variety, standing out amongst the others as one of the most distinct, pleasing, and effective. The flower is the exact shape of Mrs. Cullingford, and a most pleasing shade of pink.

## CHRYSANTHEMUM PURITAN.

SEVERAL very promising novelties were exhibited at the meeting of the National Society's Floral Committee on October 15th last, and

so numerous, the merits of this one are so boldly marked that it will be certain to become a favourite. The florets are substantial, broad, somewhat incurved at the top, and of a peculiar glossy white colour,

FIG. 44.—JAPANESE CHRYSANTHEMUM PURITAN.

amongst them were handsome blooms of the Japanese Chrysanthemum Puritan from Mr. E. Molyneux, Swanmore Park Gardens, Bishops Waltham. A first-class certificate was unanimously awarded for this, an honour it well deserved, for though white Chrysanthemums are now

the surface having quite a polished appearance. The bloom is of good size, and the plant seems strong in habit. It is of American origin, and has been cut a year or two, but is not much known in this country.

## THE BECKETT CHRYSANTHEMUM CUP AND TUBE.

THE cup and tube illustrated in fig. 45 is an invention by Mr. Edwin Beckett, Aldenham House Gardens, Elstree, and possesses several important advantages. The following references will explain the construction and mode of action:—It consists of tubes A B C, shown in the accompanying sketch. The tube A is the water container; into and upon the top of A the tube B fits in such a manner as to prevent loss of water; inside B and outside cup C is formed a serew, C screwing inside B. The result of such an arrangement is the easy and effective regulation of

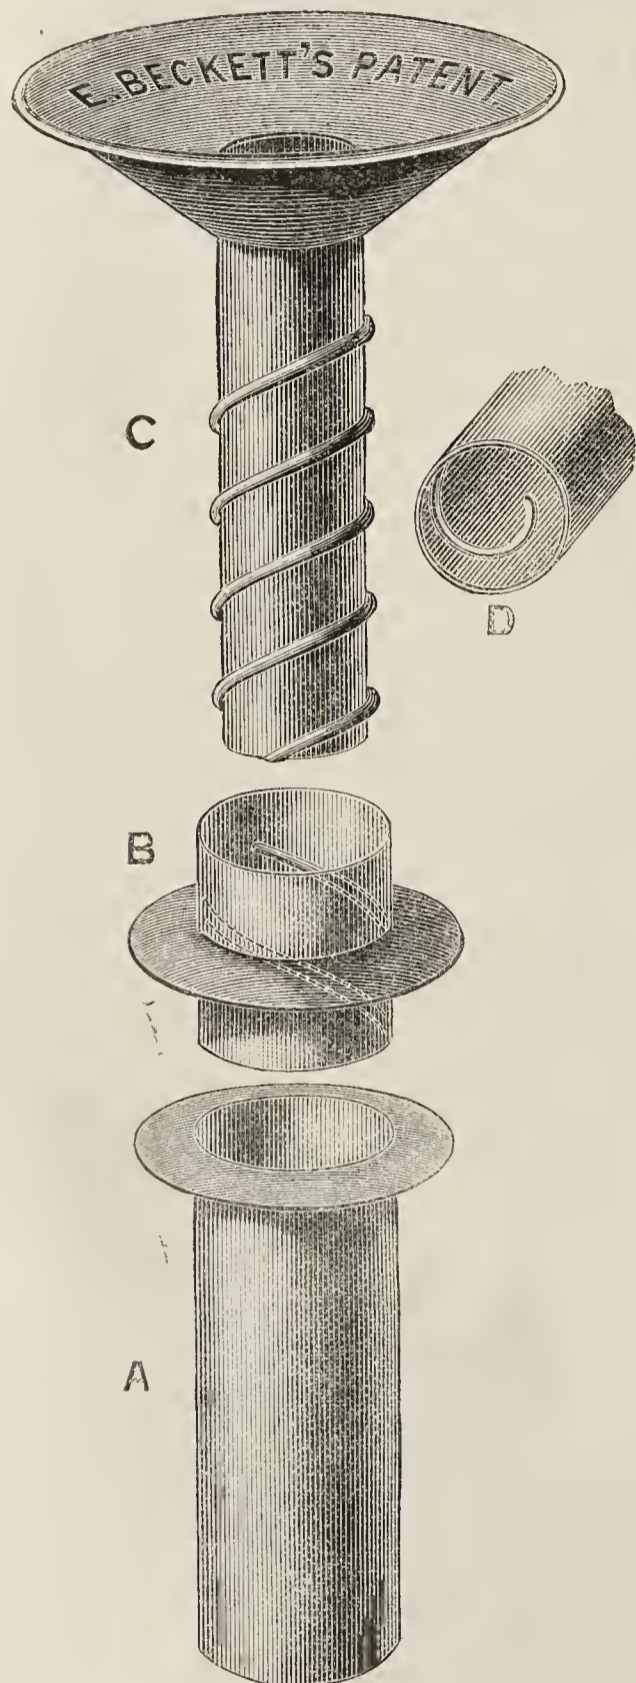

FIG. 45.—THE BECKETT CHRYSANTHEMUM CUP AND TUBE.

height of the flower cup C. At the bottom of the cup C is fixed a spring clip, a simple and effective method of securing the stem of the bloom as desired, plugging, &c., being thereby dispensed with.

## WREATHS OF CHRYSANTHEMUMS.

THE illustration on page 379, sketched by our artist at the National Chrysanthemum Society's Exhibition, St. Stephen's Hall, Westminster, last year, affords some idea of what can be effected by a tasteful disposal of Chrysanthemum flowers with Grasses and appropriate foliage. Japanese varieties, orange or red, look well alone or in combination with white varieties for this work, especially under artificial light.

EVENTS OF THE WEEK.—The Chrysanthemum Shows commence next week on Monday next, November 4th, at Ipswich, Brixton, and that at Blackheath by the Kent County Society. These will be followed on Wednesday, November 5th, by Portsmouth and Tooting, and on Thursday, November 6th, by Putney. The succeeding week will however, be the busiest of the season.

— THE WEATHER.—A decided change has occurred during the last few days, and winter has come at last. It is welcomed by growers of Chrysanthemum blooms for sale, for from all sides we have heard lately they "made nothing," because outside flowers have been so plentiful. They are over at last in the majority of gardens, as we hear of frost, snow, and hail from many districts. A Stirling correspondent states that no heavier fall of snow fell in the district all last winter than fell on Sunday last. There was a sudden change on Wednesday, which was quite mild.

— OVERMATTER.—This is a term which applies to articles in type that are crowded out of the number for which they were intended. Though the present issue of the *Journal of Horticulture* is devoted mainly to Chrysanthemums, we have still more awaiting publication with many other valuable articles on various subjects, the publication of which will not be long delayed. We thank all our coadjutors for their effective aid, and bespeak their patience, as well as their co-operation, during the Chrysanthemum season.

— FRUITERERS' COMPANY'S GUILDHALL EXHIBITION.—I have much pleasure in informing you that the Fruiterers' Company at their Court held on the 20th inst. decided to confer the freedom and livery of the Company upon the following gentlemen: Mr. George Bunyard, Mr. Joseph Cheal, Mr. Shirley Hibberd, Mr. T. F. Rivers, Mr. A. H. Smee, and Mr. J. Wright. This distinction has been conferred in recognition of the able services which these gentlemen have rendered to the Company as members of the Executive Committee having the management of the recent Exhibition, and has not been conferred on anyone except Sir James Whitehead during the past thirty years. This information will probably be of interest to some of your readers.—O. C. T. EAGLETON, *Clerk*.

— THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual dinner of the members and friends of this admirable Society was held at the Cannon Street Hotel on Thursday evening last, E. R. Cutler, Esq, presiding. The room and tables were beautifully furnished with plants and flowers contributed by Messrs. Cannell and Laing, and Mr. Chard's floral arches had a charming effect. We can only, for obvious reasons, refer to the proceedings in the briefest possible manner. Mr. Cutler met with a warm reception and fulfilled his duties in a manner which gave complete satisfaction. After proposing the loyal toasts he referred in terms of the highest approval to the Benefit and Provident Society, and highly commended it to the notice of gardeners and their employers. Amongst the other speakers during the evening were Messrs. H. J. Veitch, N. Sherwood, G. Bishop, J. Hudson, N. Cole, G. Anderson (of Sydney), Wright, Moss, Laing, Nutting, Wynne, and Collins, who either proposed or responded to the different toasts. Miss Mary Belval and her talented assistants met with warm applause as vocalists, and the ladies were presented with choice bouquets. About 160 persons sat down, and the gathering was regarded as the most successful yet held of this ever growing and most worthy Institution. Mr. George Cavendish was nominated by the Chairman to preside on the next occasion.

— PETROLEUM AND FRUIT TREES.—Mr. J. W. Ledger writes:—"I notice in last week's *Journal* an inquiry from "Beta" repeating American blight on Apple trees. My Apple trees had it badly last year, so much so that my then head gardener, an experienced man, since dead, painted them so with paraffin that he has killed some of the trees and greatly injured others. I fear they will not recover; so be good enough to warn your correspondent to be careful with petroleum." [We are obliged by this experience. We never advise the use of undiluted petroleum. The mixture recommended to "Beta" on another page is safe for trees in a resting state and effectual.]

— THE BIRMINGHAM GARDENERS' ASSOCIATION.—The Committee, in arranging their autumn fortnightly meetings, determined to devote a night occasionally to the exhibition of specimens, discussion, and answering questions, and the plan answered admirably. On the last meeting night, the 20th inst., there was a good attendance of members, and many objects of interest were exhibited, and much information elicited.

— RANUNCULUSES IN OCTOBER.—A charming display of these in October is somewhat of a novelty, and very beautiful they were, as seen at the meeting of the Birmingham Gardeners' Association, above referred to. Mr. Vertegans sent them, and the information was given that the roots were planted in July, covering to the depth of 1½ inch, and the damp weather of the latter part of the summer appears to have been very congenial to them. The usual time for planting is in February or March, but in this case planting was delayed until July. The orthodox plan of planting with our old florists in years gone by was an average depth of 1½ inch, in well prepared soil, and covering with good soil. In this instance very little preparation was made for planting.—D. S. H.

— ANTHRACITE COAL.—We are reminded by a circular on the Hendreforgan Anthracite Coal, which is being advertised from 23, Lime Street, London, of its great economic value for horticultural purposes, as well as of its smokeless character. This coal is being more and more used in gardens and nurseries as its merits become more fully known.

— VIENNA EXHIBITION AWARDS.—Messrs. J. Jensen & Co. (Ld.) write:—"We have the pleasure to inform you that at the Vienna International Exhibition of this year we have gained the highest award for all our exhibits—viz., guanos, cattle oil, medicinal, cod-liver oils, trade oils, liquid glue, &c., &c. We shall be glad if you will notify this in your next issue for the benefit of your numerous readers."

— LEICESTER CHRYSANTHEMUM CONFERENCE.—On Thursday evening last, at a largely attended meeting at Leicester, papers on the damping of blooms, also on dressing and staging them for exhibition, from Messrs. J. Wright, J. Udale, W. Tunnington, and others, were read by Mr. W. K. Woodcock. Some of these papers we publish this week, others being held over till space is available.

— CHRYSANTHEMUMS JOHN LAMBERT AND JOHN DOUGHTY.—A young exhibitor is anxious to know if the above varieties are considered distinct from the older forms of the Queen family. With him John Lambert is not distinguishable from Golden Queen, and John Doughty is lighter and of better form than Bronze Queen. What do old growers say to the young man?

— SWANSEA CHRYSANTHEMUM SHOW.—A show is advertised to be held at Swansea on November 19th and 20th, and we are requested to direct attention to the first schedule. We do so with pleasure, and pronounce it a very good beginning, the chief class, open, being for forty-eight blooms, with amounts of £8, £5, and £4 offered as prizes. There are other open classes. Messrs. T. Kneath and W. Roberts, The Uplands, Swansea, are the Honorary Secretaries. We wish the new Society success.

— STRAWBERRIES IN OCTOBER.—This autumn has indeed been a wonderful one, for we have enjoyed finer weather than any we have had during the summer. The effect of it on one variety of Strawberry alone has been that I have, during the last fortnight, been able to pick about a peck of fruit in an open exposed field. Had the weather continued mild I should have picked as many more, but the severe weather which has now (October 27th) set in will, I am afraid, stop all further picking. There is plenty of green fruit hanging, and three fine days would have coloured a good proportion of it. I grow several varieties, but one alone has flowered and fruited, and that is Vicomtesse H. de Thury. Noble, which is an earlier Strawberry, has not opened a single blossom, although in a more sheltered position. My crop of Vicomtesse will, no doubt, be considerably crippled for next summer. This is to be regretted, although the fruit has come in very acceptable just now, when we do not usually look out for Strawberries. I must say that picking the fruit to-day, with the wind so bitterly cold that I had to leave my occupation to put on winter flannels before I could finish, was quite a novel experience. I do not know whether others have had the same results with any variety of Strawberry at this season, but if so it would be interesting to learn the particulars.—H. S. EASTY.

— TESTIMONIAL TO MR. MCKELLAR.—Mr. McKellar's friends in and around Kelso gave him a dinner last Thursday in the Queen's Hotel, under the presidency of Mr. W. Thomson of Clovenfords, when a very handsome gold watch was presented to him, and a gold bracelet to Mrs. McKellar. The young men in the gardens at Floors Castle presented her with a silver cake basket, and the labourers with a silver dessert knife. Much regret was expressed by all present at the dinner that they were losing Mr. McKellar as a neighbour, but they were proud to think that he was the third gardener from Floors that had been selected by Royalty, and they felt certain that his management of the gardens at Sandringham would do him the same credit those of Floors had done. On the Wednesday evening a supper was given to Mr. Barnes, who has been Mr. McKinlay's foreman for some years, on which occasion a handsome silver watch and suitable inscription was presented to him in token of the respect entertained for him. Mr. Barnes is a native of Devonshire, and leaves Floors at the same date as Mr. McKellar.

FIG. 46.—A WREATH OF CHRYSANTHEMUMS. (See page 378.)

— FRUIT CULTURE.—Sir James Whitehead having been interviewed by a contributor to "Trade, Finance, and Recreation" on the subject of fruit culture in England, he explained that the chief idea of the Fruiterers' Company is to supply to farmers and cottagers the knowledge that will enable them to produce a variety of good Apples, Pears, and Plums from trees that are at present comparatively unproductive owing to the lack of instruction in such matters as suitable soil, situation and aspect, pruning and grafting. As a rule the trees are stuck in holes and left to take their chance. Sir James believes that the value of fruit as an article of diet is becoming recognised more and more every day. He finds that he can work on a fruit diet as well as on any other, though he is not a vegetarian. "England is the home of the Apple," he remarked, and the very best kinds can be produced here notwithstanding the outcry about climate. As to the mode of imparting the necessary instruction to small growers, he advocates the plan of giving lectures in different parts of the country, with practical illustrations of planting, pruning, grafting, &c. Annual shows, too, would tend to popularise the idea. But the crux of the whole question lies in the terms of land tenure. To meet this Sir James thinks that unless the landlords are prepared to give longer leases they themselves should plant the trees, making it a condition that the tenant should keep them in good bearing order. The Government is believed to be willing to make grants to agricultural colleges where horticulture is taught, as well as to horticultural colleges. That the nation has begun to make real progress is an article of faith with the worthy baronet, who believes, with many others, that nationally we eat far too much meat and not nearly enough fruit.

— THE general Committee of the NATIONAL CHRYSANTHEMUM SOCIETY held a meeting at Anderton's Hotel, Fleet Street, on October 27th, R. Ballantine, Esq., in the chair, when there was a good attendance of members. The principal business was completing the arrangements for the Centenary Festival at the Royal Aquarium, Westminster, on November 11th, 12th, 13th, and 14th. Lady Brooke will open the Show on November 11th. Lord Brooke will preside at the banquet on November 13th; and Sir Guyer Hunter M.P., with Sir Edwin Saunders, will preside at the Conference on the first and third days.

— DEATH OF MR. THOMAS CUBBON.—It is with regret that I report to your notice the death of Mr. Thomas Cubbon, gardener to G. H. Pinckard, Esq., of Coombe Court, Witley, on the 17th inst., at the early age of thirty-six years, after a few days' illness. He had been at the above place for the past fourteen years, during which time he had made a large circle of friends, by whom he was greatly respected. He was also a very successful exhibitor at the local shows, and by his death quite a gloom will be cast over the Godalming Chrysanthemum Show, where he had exhibited largely since the commencement, some six years since.—G. B. BASKETT.

— AMATEUR ROSE EXHIBITORS.—“F. R. B.” has perhaps sufficiently answered “Exhibitor,” but I want to ask him one more question. He says, “Large growers, being amateurs, growing say 8000 Roses, ought to be compelled to exhibit against nurserymen.” Now the largest number of Roses I have ever heard an amateur accused of growing, and I believe it to be a false accusation, is 10,000, and I ask “Exhibitor” what probable chance would that amateur have against nurserymen, growing above 100,000, early in the season? True, Mr. Pemberton and other amateurs have been successful later in the season. Never have I heard of an amateur beating the professional for 72, 48, 36, or 24 before 20th of July in any year. Remember, from June the nurseryman is cutting for sale blooms by the 1000 every day as well as for exhibition, and therefore he may occasionally be surpassed by an amateur without loss of reputation or less glory to his visitor. I do wish, however, that local, especially affiliated societies, would more strictly follow the model of the National Rose Society in arranging their schedules.—F. H. G.

— LOCAL ROSE EXHIBITIONS.—Replying to your correspondents with regard to the statement I made as to the number of plants and acreage cultivated by large growers, I regret to say from what has appeared that I have been strangely misinformed; but, however, by way of argument we will say if an exhibitor cultivates 7000 plants, are not the odds very great against the smaller growers who cultivate from 1000 to 2000? If so, then I say they ought to be protected by being fairly handicapped. This is the bone of my contention. If you take, as an instance, a race of any description you will find the competitors are fairly handicapped. Why ought it not to be so in the showing of Roses? The fact is the matter requires, in my opinion, to be carried out on a more equitable footing, and until it is there will be complaints. Mr. Raillem says there is protection in all the classes of the National Rose Society, but if he will look over the schedule again I think he will find a few discrepancies. It matters not how great a grower or how great an exhibitor he may be, it is optional if he think fit to infringe upon the classes allotted to the small growers. “F. R. B.” says that I complain of the unfairness of the leviathans showing against the smaller fry, and asks if it has ever occurred when there are large classes available, and adds the exhibitor ought to be ashamed of himself for stooping so low. I think I may venture to say that one of the greatest exhibitors who has taken perhaps more prizes than any other amateur exhibited a stand of six blooms at Birmingham when there were two classes of twelve available—one open, the other amateur; so I think it proves that the large grower chose to compete for six instead of twelve, it giving him a better chance for the prize than the small growers, who evidently cannot have so many to select from, and this provides loopholes sufficiently large for ambition to creep through. Again, Mr. Raillem infers that a man with 1000 Roses ought to be able to show at his best as good a twenty-four as the man with double or treble that number. I was never more surprised than by such reasoning. I think any schoolboy would say that three chances are better than one, and I take it that the object of growing a large number of Roses must be to have more to select from, and therefore this increases the chances in competing with smaller growers. Rose shows may be and undoubtedly are protected as a rule in the southern counties, but I do know from my own experience several places in the northern counties are not so.—AN EXHIBITOR.

## CHRYSANTHEMUM MEN OF THE TIME.

HAVING on a previous page referred to a Chrysanthemum pioneer, Mr. Robert Fortune, we now give a series of portraits, chiefly from recent photographs, which reached us in time for preparation, of men of action in the Chrysanthemum world, and as we expect more will be supplied to us for publication during the season, we clear the way for their insertion as opportunities occur. Those now given are of men who merit recognition for their zeal as officers or skill as cultivators. They are not chosen as exceeding in effort or cultural ability all other Chrysanthemum men of the time, and we know that every one of those portrayed would resent any such proposition. With the pressing claims on our space we can say little about them, but that little will show that they are workers who in their different spheres have done something in widening the interest in Chrysanthemums—making brighter the homes of rich and poor, and providing the public with autumn floral festivals, which are so highly appreciated, and can do nothing but good.

MR. E. DRAPER (Northampton).—As Secretary of the Northampton Society Mr. E. Draper has performed excellent service, and has infused much of his natural energy into the business and knowledge of the Society. Chrysanthemums are very popular in Northampton, and nearly everyone who can accommodate a few plants tries to do so, and soon becomes a competitor in some of the classes wisely provided by the Society for the encouragement of beginners.

MR. W. FURZE (Teddington).—When in 1889 Mr. W. Furze of The Roselands, Teddington, succeeded in winning the challenge vase at Kingston, there was considerable rejoicing in the district, and it is questionable if even the defeated competitors did not experience some satisfaction at the result. Chrysanthemums have for some years been admirably grown at The Roselands, and Mr. Furze has been ably assisted by his gardener, Mr. Coombs, for in the moderate space of a suburban garden Orchids under glass and Roses out of doors are as well cultivated as the Chrysanthemums. The example thus set of general horticultural enthusiasm has had considerable influence in the district, and the effects are rendered evident at the creditable summer and autumn Shows now held in Teddington.

DR. GEORGE WALKER (Wimb'edon).—With Mr. Lyne, late of Belvedere Gardens, Dr. G. Walker has for some time been associated as joint Honorary Secretary of the Wimbledon Horticultural Society; but Mr. Lyne has now removed to Chislehurst, and the duty has, therefore, devolved upon his colleague. Dr. Walker is not merely an admirer of Chrysanthemums, but he is also a cultivator, and his modest but interesting display attracts many visitors during the season. He is also a frequent visitor at the principal shows and gardens in the neighbourhood of the metropolis where Chrysanthemums are a specialty.

MR. LINNÆUS CUMMING (Rugby).—Mr. Cumming devotes all the time he can spare from his scholastic duties at Rugby to gardening, and is an earnest amateur, with all the enthusiasm that an educated man brings to bear upon such work. He is noted here because his position as Chairman of the Rugby Society has enabled him to encourage a love of Chrysanthemums and their culture, and at the dinner on the Show day he always has some cheery words for the Committee and the exhibitors. The Secretary, Mr. W. Bryant, who is thoroughly practical and experienced, has also assisted greatly in promoting the interests of this Society. In Mr. Cumming's town garden he grows alpine plants, Ferns, &c., remarkably well.

MR. F. POWER (Portsmouth).—Mr. Power is a great deal more than Secretary of the Portsmouth Chrysanthemum Society, for he is a Town Councillor, and in many ways has by his labours contributed to the improvement of the great seaport, and won the esteem of its inhabitants. He believes in the popularisation of flowers, and therefore brings the charges for admittance to the great Chrysanthemum shows, which he has been mainly instrumental in establishing, within the reach of the humblest toilers. The consequence is, that we believe the attendance exceeds that of any other similar exhibitions in the kingdom, and the Society is in a sound financial state.

MR. W. MEASE (Leatherhead).—In Mr. Mease we have an able energetic gardener, and unquestionably a first-rate Chrysanthemum grower. He has engaged in some of the keenest of the Liverpool contests, and won; also he is distinguished as the winner of one of the great challenge cups that are offered by a few Chrysanthemum societies. This was at Hull, and no man had finer losing stands of blooms to compete against than he had in those contests. He is now established at Leatherhead in Surrey, and made a good start last year at southern shows. He has proved himself a formidable antagonist, and if he takes part in the coming campaign the classes will not be weak if he is placed outside the circle of prizewinners.

MR. W. TUNNINGTON (Liverpool).—For many years Mr. Tunnington was a leading grower in the Liverpool district, where Chrysanthemums have long been produced in the highest excellence. It was only by years of persevering effort that he won the high position he occupied in the front ranks. He may fairly be regarded as a representative Liverpool grower, and there is no doubt whatever that the splendid incurred blooms which he brought to Kingston some years ago had a

stimulating effect on southern growers, and at the same time his eyes were opened on the capabilities of the Japanese, and these were subsequently grown as well around Liverpool as in the metropolitan district. Mr. Tunnington has done enough as an exhibitor, and retired from competition, and his services are now in demand as a Judge at shows.

MR. G. WOODGATE (Kingston-on-Thames).—At the death of Mr. Jackson, Secretary of the Kingston Chrysanthemum Society, which during his period of office had taken so high a place amongst similar societies; Mr. G. Woodgate, The Gardens, Warren House, Kingston, was unanimously appointed his successor. Perhaps no greater compliment could be paid to him than by recording the fact that he has well maintained the credit of the Society, and has won the confidence and esteem of all his colleagues. Mr. Woodgate is an experienced horticulturist with wide practical knowledge, he grows Chrysanthemums well, and keeps an extensive garden in admirable condition.

MR. NORMAN DAVIS (Camberwell).—As a Chrysanthemum specialist Mr. Davis has rendered his name familiar to growers throughout Great Britain, and he possesses an exceptional critical knowledge of the varieties cultivated within the past twenty years, for he has made them the subject of close study. Mr. Davis commenced as an amateur grower of Chrysanthemums when a mere youth, and had gained some years' experience before he made them his business. Even then the beginning was very modest; he gradually advanced, however, and at last removed to the Lilford Road, where he has grown all the varieties of each section that could be obtained. As many as 1400 varieties have been thus included at one time. Many excellent varieties have been sent out by Mr. Davis which are established favourites with cultivators.

MR. PETER BLAIR (Trentham).—Trentham is one of England's celebrated gardens, and Mr. Blair has in the past few years satisfactorily proved his ability to maintain its fame. Orchids, Chrysanthemums, and fruit are the specialties, but it was a surprise to many last year to find Mr. Blair a successful competitor at Chrysanthemum shows both north and south. The collection of Chrysanthemums is probably the largest in any private garden in this country, as considerable quantities of cut flowers are required for decorative purposes.

MR. R. FALCONER JAMESON (Hull).—The popular Chairman of the Hull Society could fairly claim to have exerted a greater influence upon the extension of the Chrysanthemum interest than any other amateur in the north of England, and mainly by his efforts the Hull Society was started, and the generous policy he advocated has resulted in a most gratifying success. The annual Show there has now become one of the best in the kingdom, and attracts a large attendance of visitors, rivalling Portsmouth in numbers. Mr. Jameson has been ably supported by the Hon. Secretaries, Messrs. Harland and Dixon, the former especially as the Hull representative on the Committee of the National Society, and all worked together most harmoniously to ensure the success of the National Provincial Show at Hull last year.

MR. J. HUGHES (Birmingham).—As Secretary of the Birmingham and Midland Counties Chrysanthemum, Fruit, and Floral Society, Mr. Hughes occupies a prominent position in the midlands. He is not an exhibitor, but a laborious worker in the interests of horticulture. He is a model Secretary, patient, courteous, and possessing a mastery of details that renders his services invaluable. He appears to spend all his spare time in the furtherance of objects that are instituted for the improvement of gardening and the well-being of gardeners. The Birmingham Chrysanthemum shows now rank amongst the most important, and the November exhibitions in their entirety are not surpassed by any in the kingdom.

MR. C. GIBSON (Morden).—An able gardener, a persevering worker, an excellent Chrysanthemum grower, and an unassuming man is Mr. C. Gibson. He is regarded as one of the most modest winners and best losers in the south. He neither boasts when successful, nor grumbles when defeated, but is "always the same." When, through an accident in staging at one of the National Shows, he lost the first prize in an important class, his integrity was recognised and a special honorarium granted. There are not many men who cut more exhibition blooms from the same number of plants than does Mr. Gibson, nor win more prizes with them. He always stages well, and has secured valuable prizes in the best classes at leading shows. The chief events in Mr. Gibson's career can only be briefly summarised. He commenced his career as an exhibitor at the Borough of Hackney Society's Show in the Royal Aquarium, Westminster, in 1879, where he won three first prizes. This success has been well followed each year until his record now is over 100 prizes, a large proportion being firsts. His best year was in 1886, when he won the Kingston cup, £10 at the Crystal Palace for forty-eight Japanese and incurred, the same amount at the Aquarium for forty-eight Japanese, and would have won the corresponding prize for forty-eight incurred at the same Show but for the unfortunate accident of showing four Golden Queens when not more than three of one variety were admissible.

MR. HENRY CANNELL (Swanley).—The Home of Flowers is famed for its Pelargoniums, its Tuberous Begonias, and for many other popular flowers, but at this time of year the special feature is formed by the

Chrysanthemums. To these Mr. Cannell has devoted much attention for many years, and has achieved a large share of success, for not only has he aided in drawing public attention to them generally, but he has introduced many valuable varieties, some direct from Japan, and others as seedlings or sports raised on the Continent or in England. A long chapter could be written respecting the important service rendered by Mr. Cannell in the Chrysanthemum cause, but space will not permit in the present issue, and we shall have something more to add on "men of the time," among whom Mr. Cannell is entitled to a high position.

MR. CHARLES PEARSON (Nottingham).—Chilwell, near Nottingham, is admittedly the great Chrysanthemum emporium of the midlands, and has been raised to the position it occupies mainly through the instrumentality of Mr. Charles Pearson, who may be termed the floral member of the firm that has there been so long established. The Chilwell collection of Chrysanthemums is one of the largest in the kingdom, and the plants are displayed to the best advantage in the large and lofty structures in which they are arranged. Mr. Charles Pearson is a great admirer of the flowers, and secures the best new varieties for comparison with the old. He has a keen eye for noting the characters of the varieties, and their adaptabilities for exhibition and floral decoration, and the papers which he from time to time writes are always fresh, instructive, and interesting. Assuredly he has plenty to write about, as will be readily acknowledged by all who find their way to Chilwell about the middle of November. The Show there is visited by thousands of persons during the Chrysanthemum month, and is worth a long journey to see.

MR. ROBERT OWEN (Maidenhead).—Mr. Owen is widely known in the Chrysanthemum world, for he has been a cultivator for many years, and has introduced many varieties into commerce. Numerous seedlings have also been raised at the Floral Nursery, Maidenhead, some of which, especially in the late-flowering type, have proved very useful additions to the lists of decorative Chrysanthemums. Mr. Owen has for some years taken an active part in the affairs of the National Society, being a member of the General and Floral Committees.

MR. GEORGE STEVENS (Putney).—In the St. John's Nursery, Putney, Mr. Stevens devotes a large proportion of space under glass to Chrysanthemums in October and November, not only as a display, but to furnish supplies of blooms for cutting. For this purpose he grows all the most effective and free-flowering varieties, and in addition has a large general collection. Mr. Stevens has been fortunate in raising numerous distinct seedling Chrysanthemums from imported seed, and intends following this method up more closely. He has been connected with the National Chrysanthemum Society for some years, and is a regular attendant at all the meetings.

MR. J. LAMBERT (Shrewsbury).—The Shrewsbury horticultural shows have become famous, not only for their magnitude, but for the extraordinary number of visitors which attend them from the surrounding district. Mr. Lambert has been one of the many successful exhibitors at those shows, and has also proved himself a skilful grower of Chrysanthemums by the blooms he has staged and the prizes he has won in high class competition. He may be fairly regarded as a representative cultivator in the district in which he has done such good work as a gardener, and whenever he exhibits his opponents have learned that it is necessary to put forth their full strength for placing him lower than themselves in the prize list. He is a thorough gardener and strives to do whatever he undertakes well, including the growing and also the staging of Chrysanthemums, for his blooms are always displayed to great advantage in the stands.

MR. E. MOLYNEUX (Swanmore).—When we published Mr. Molyneux's portrait on a former occasion, we stated that as a young man he had never been employed in a garden where Chrysanthemums were grown, except in the ordinary decorative way; but seeing the splendid flowers produced by the Liverpool growers, and being impressed with their excellence, he was animated with a desire to equal them, and well he has succeeded, in winning such a large number of prizes in the best competition, including more large challenge cups than any other man. This should be very encouraging to other young growers who desire to emulate him. He is a close observer of all small details in connection with the growth of the Chrysanthemum, never over-estimating his own produce. He has also been serviceable to many by his excellent work on Chrysanthemum culture.

MR. JOHN LAING (Forest Hill).—One of the most genial horticulturists of the present time, a practical, shrewd, and thorough man of business, a skilful hybridiser and cultivator, and a devoted gardener in the broadest sense of the term. Mr. John Laing, the founder of the Forest Hill firm, well deserves his popularity and success. Mr. Laing was born in October, 1823, in the parish of Carriston, near Brechin. His first instruction in gardening was gained in the gardens of Old Montrose, under the charge of Mr. Reid, and it was there he directed his attention to the study of Mosses and other cryptogamic plants, of which he ultimately acquired a considerable knowledge. The next move was to the gardens of Kinnaird Castle, the seat of the Earl of Southesk, and during the two years spent in that establishment he applied himself closely to his gardening duties, but still found time to pursue his

botanical studies. Removing to the Royal Botanic Gardens, Edinburgh, under Mr. McNab, he conducted himself with so much satisfaction to the authorities that he was honoured with an associateship. In 1847 Mr. Laing was appointed manager of the Onchan Nursery in the Isle of Man; thence he went to Chester, and took charge of the indoor department at Messrs. F. & A. Dickson's nursery. Remaining there for a short time he was engaged by the Earl of Rosslyn, as gardener at Dysart House, Fife, where he gained much fame as a cultivator. In 1860 Mr. Laing joined the firm of Downie & Laird, and proceeded to London to establish the nursery at Stanstead Park, Forest Hill. The firm was dissolved in 1875, as regards the London branch. Mr. Laing then took the business himself, subsequently admitted a partner, and until a year or two since, Messrs. Laing & Co. was the business title. A change was, however, effected recently, and the business is now confined to Mr. John Laing and his two sons, Mr. J. A. Laing and Mr. J. H. Laing. Mr. Laing dates his experience as a Chrysanthemum grower from 1849, and for some years he was a most successful competitor at Edinburgh. In late years he has obtained numerous valuable seedling Chrysanthemums.—(Extract, with portrait, from Mr. Lewis Castle's "Chrysanthemum Annual.")

MR. R. PARKER (Impney).—When Mr. Parker first came to the front as an exhibitor of Chrysanthemums and the winner of chief prizes in good competition his success created a feeling of wonder as to whether he would be able to maintain the position he so quickly won. He has done so, one of his latest achievements being the winning of the greatest prize ever offered for Chrysanthemums, and this in one of the closest and keenest of contests—namely, the forty-eight bloom class at Birmingham in 1889. The achievement is the more noteworthy since it was the fourth consecutive year in which he won the chief prize in the great midland city, and always against first-class competitors. Also in three consecutive years he won three cups at Sheffield, including the "National" for seventy-two blooms. That record of success alone entitles him to the distinction of being presented to our readers as "a man of the time;" therefore we reproduce his portrait which we had previously engraved.

#### CHRYSANTHEMUM BLOOMS DAMPING—CAUSE AND PREVENTION.

I HAVE pleasure in complying with the request from Leicester to contribute a "short paper on damping" for the purpose of eliciting discussion at a meeting of friends there—friends of myself and of the flower we think worthy of our solicitous care in cultivation and preservation.

As almost, if not every theory that has been advanced on the subject in question has been contradicted on some grounds, and it may be good grounds, as based on experience, I shall take a stand on what I think is a firm foundation, and challenge opposition to the following proposition—namely, that the cause of the evil—the premature decay of the blooms of Chrysanthemums known as damping—is either in the soil or the atmosphere, or both. A denial may be given to that proposition, but I shall be very much surprised if its falsity can be sustained. Though I know from evidence of the most convincing kind that the initial cause of hundreds of blooms decaying, even before their development, was in the soil, I suspect in the overwhelming majority of cases the origin of the evil has been above ground, not within it, while in not a few instances a combination of accidents or mistakes above ground and below has culminated in disaster.

I think it will be well to first get to the root—not of the question perhaps, but to the roots of the plants—in a search for the operating causes of the unwelcome visitation of mouldiness and decay that ruins so many blooms, and work upwards. In nine cases out of ten, when cause of the mischief is in the soil it is traceable, I believe, to the excessive application of ammoniacal manures. Several instances of damping arising from this practice has come under my notice, and one especially proved the case conclusively. An earnest young man, with the best intentions, was caught watering the plants in a large house with a solution of sulphate of ammonia. On ascertaining its strength it was found he was using the salt nearly at the rate of 2 ozs. to the gallon of water. He was told to stop forthwith, and not to give the remaining plants any stimulant whatever. The overfed plants were ruined, and the expanding flowers rotted on the stems, while those on the plants that were not "assisted" were as fresh and bright as blooms could be, all in the same house. On examining the roots of the former they resembled shag tobacco, and most of them were dead, while those of the latter were fresh and active. Obviously the crippled roots could not imbibe nutriment for the support of the plants, and drooping of the leaves with shrinking of the florets naturally occurred, followed by decay. But, it may be asked, why did they not shrivel without decaying? They might have done, perhaps, if the atmosphere of the house was as dry as a desert, but it was not, though it was not too damp to injure blooms that had due nourishment from active roots with moisture passing freely from healthy leaves in the important natural process of transpiration. In this case the sap was kept pure; in the other it of necessity became first stagnant, then putrescent, and the inevitable fungus, or mould, took possession. Clearly the damp in the house was not the initial, but only the secondary cause of the collapse, and the real origin of the evil was undoubtedly in the soil.

But someone may jump up and say, or say without jumping up, "That does not fit my case at all. My plants had no liquid manure, yet the blooms damped, and those were the worst that got the driest at the roots." With a considerable fluctuation of temperature and much

moisture in the atmosphere that is exactly what might be expected to occur. The florets of the plants which accidentally became too dry at the roots would shrink, though the shrinkage might not be visible, and these would, on that account, be the first to "go." As the strength of a chain is determined by its weakest link, so is the resisting power of Chrysanthemum blooms to adverse influences determined by the weakest florets, and I suspect no one will venture to say that those which shrink through any cause are then the strongest.

We are steadily working upwards, and I will now ask you to leave the earth for a few moments and follow me into the air. We may possibly all get up in a balloon together, but never mind so long as we come safely down again.

I am inclined to believe that where one Chrysanthemum bloom is ruined by damp through an accident to the roots of the plants, that ten are destroyed through atmospherical influences, such as extreme fluctuations of temperature and the condensation and precipitation of moisture on the flowers. It is not the moisture in the air in the form of vapour that causes damping, but that which changes to water by cold and falls on the blooms, or in other words the blooms will not "damp," so much in a moist plant stove in which a somewhat high, and especially an equable temperature, is maintained as they will in a greenhouse where the heat rises to above 70° by the sun in the daytime, and falls to, perhaps below, 40° at night. This is what sometimes occurs when the days are bright and the nights clear and frosty. The sun makes the blooms tender in the day, and when they become cold at night far more moisture condenses on them than if they were warmer. This is not a question of opinion but a matter of fact—the simple operation of a law of Nature, as evidenced in the formation of dew. Chrysanthemum blooms suffer under the conditions indicated; but, fortunately, if the injury cannot be prevented in all cases it can be minimised in many. A gauze-like blind or close net spread over the glass to break the sun's rays in the daytime will do something, but a thicker blind to prevent the radiation of heat at night will do more in preserving the blooms. This is because they do not become so cold, and it is a fact that the colder they become the damper they get, and the warmer they are the drier they remain, under similar hygrometrical conditions. It is not suggested that a higher temperature should be maintained than is good for the plants. That is not in the least necessary, but it is most desirable that an extreme range should, as far as possible, be prevented. I am positive that numbers of Chrysanthemum blooms have been spoiled by want of a reasonable amount of fire heat at night; and I will add in the daytime also when the temperature ranges abnormally low, as it does sometimes when there is a term of frost, rain, and sleet, a chilling wind and little sun.

It is under these conditions—a term of very cold days and nights, with now and then a sudden rise in temperature, or what is called a muggy or murky day, with more or less of mist or fog, that the blooms "go off" so rapidly. They have become cold—too cold—and the moisture in the warmer, and perhaps saturated atmosphere, condenses on them like a heavy fall of dew, and that is what it really is, and they in turn become saturated. Those the nearest the glass are the first to fail; those of the same variety and of the same age several feet below them being the last to suffer. At a critical period in the life of the blooms several may, under certain conditions, go off in a night, and those are the most likely to do so that have been generously fed with nitrogenous manures.

When are the falls of dew the heaviest? When the nights are the clearest and there is moisture in the atmosphere. That is because radiation is the greatest, cooling the surfaces of plants and blooms, and the moisture coming into contact with them is deposited—changed from vapour to the liquid form. When are dews absent? When the sky is overcast, the clouds not only preventing the radiation of heat from the earth and its vegetation, but often radiating it from the atmosphere instead. Dew then cannot form, because the surfaces of plants are not cold enough for the precipitation of moisture that is floating above them. When a screen or blind, instead of clouds, intercepts the passage of radiant heat from Chrysanthemums that are not too cold under glass there can be no deposition of moisture on them. What even a slight screen does in arresting radiation has been determined by experiment. A thermometer on grass exposed to the clear sky fell to 35°, another with a cambric handkerchief thrown over it ceased falling at 42°. An instrument against an exposed wall registered 38°; another near it, but with a piece of gauze stretched across 2 or 3 inches from it, registered 43° as a minimum. These facts are suggestive, and point unmistakeably to the desirability of maintaining, as nearly as is practicable, a moderate and equable temperature by the combined agency of fire heat (when needed), light screens on cloudless days, and thicker blinds on clear nights, when stars innumerable glitter in the firmament.

Oh, but that is all theory, some stern practicalist may say, who only believes in what he calls facts. If he will test the theory by practice, as I have tested it, he will have the facts; and he can do this in a very simple way. If he has a number of plants of any variety prone to "damp," that he wishes to retard, let some of the plants remain with their blooms not far from a glass roof on clear cold nights, after bright sunny days, when the temperature falls from, say, 70° or higher to 40° or lower, and others in a room, and see which keeps the best. He will find those in the room will, even if it is not a particularly dry one, because the temperature is much more uniform—cooler in the day, as little influenced by the sun, and warmer at night, inasmuch as there is little radiation. There may, and often is, a variation of temperature in one

case of 30° and not above 5° in the other ; but if the air is heavily, charged with moisture, no room or structure in which Chrysanthemum blooms are kept should get so cold and chilly as to give one a shudder,

Thus, as Professor Johnston has said, "in the cool of a summer's evening the grass plot is wet, while the gravel walk is dry, and the thirsty pasture and every green leaf are drinking in the descending

FIG. 49.—KINGSTON CHRYSANTHEMUM SHOW (See page 387).

but fire heat must be employed for preventing the condensation of moisture on the plants and blooms. The surfaces of these are colder than the stages are on which the pots stand, or of exposed soil.

moisture, while the naked land and the barren highway are still unconscious of its fall." No person who is the least observant can deny that, and if Chrysanthemum blooms get too cold, or much colder than

the surrounding damp air, they "drink in" the moisture that is deposited on them, and as what they cannot appropriate cannot quickly escape by evaporation they become saturated, hence decay; and the colder the house the less the evaporation, and the more quick and complete is the work of destruction.

I now pass to another cause of Chrysanthemum blooms damping. It reminds somewhat of the butcher who was searching long and anxiously for his knife, and found it in his mouth. Most persons have probably sought for something at some time or other that was all the time very near. Not many men have studied Chrysanthemums more closely than Mr. Pithers, the grower of one of the largest collections in the kingdom—Messrs. Pearson's of Chilwell. He is convinced that many blooms decay because the plants are left outdoors till the buds open and the blooms are partially expanded, as in showery weather the water must pass down between the florets and lodge in the capitulum, from which it cannot escape by evaporation, and especially in houses in which little or no fire heat is employed. That appears to be a common sense view of the matter. We all know that if Mustard and Cress is grown thickly, and freely sprinkled with water in a cold house at this season of the year, that it "damps off." This is because the excess moisture cannot escape by evaporation through the thicket of leaves. Damping is then bound to follow, and I think the suggestion of Chrysanthemum blooms damping by the same cause is worthy of consideration.

That view of the case, and probably others previously advanced, will be very likely opposed, on the ground that the blooms on plants grown in the open air, and therefore exposed to rain and extreme fluctuations of temperature, do not, as a rule, decay to anything like the extent that those do under glass. This is a fair practical argument to advance, and should be fairly met. I can only, in the few moments remaining to me for completing this paper, suggest in what way to meet it.

In the first place the plants grown in beds or borders are not highly fed with nitrogenous manure, and the florets are shorter, stouter, and hardier in consequence. In the next place the florets do not press on each other so closely and firmly, either in incurving or reflexing, as in the case of more highly developed blooms under glass, consequently air can pass between them the better; and, lastly, though the rain may pass into the open blooms readily it passes out of them the more freely when shaken by a brisk dry wind, and the evaporation of moisture from them is then more rapid than it can possibly be from closer blooms that remain stationary under glass.

Undue feeding for the production of large blooms, and consequently tender florets, with great variations of temperature, or allowing them to get too cold, so that on a natural and sudden return to dull damp weather moisture is condensed on them, are, I submit, the chief causes of the calamity that befalls so many blooms and brings dire disappointment to their cultivators.

I have seen water standing on the floor of a sunken house for weeks, and the stages filled with Chrysanthemums in flower, yet by maintaining an equable temperature with the aid of fire heat and blinds there was no damping of the blooms. They were not, however, fed up with ammoniacal manures for exhibition, but the plants were grown in a natural way for home decoration. The night temperature was not allowed to fall below 45°. If it had sunk below 40° and remained so for any considerable time the blooms would have "damped," as they did in previous years when fire heat was reduced to a minimum and screens and blinds were not brought into requisition.

I should like to say more on the subject with which I have been requested to deal, but all I can say at present is this: It is my wish that the whole matter be well considered; that everything I have advanced be opposed freely by friends who can point out the weakness of the propositions and adduce others more sound, for I shall be very willing to be proved wrong if by more sure and certain methods the blooms which have been worked for so long, and looked for so anxiously, can be preserved in all their freshness and beauty over the full term of their natural life, instead of being devoured, as it were, in their infancy by the dreaded ogre of Chrysanthemum growers—the "damp fiend."—J. WRIGHT, *Fleet Street*.

#### DRESSING AND STAGING CHRYSANTHEMUMS.

THIS paper is unfortunately written somewhat hurriedly on account of the small space of time allowed, consequently I feel that I shall not be able to say (and what I do say will be said imperfectly I fear) all that I would wish. My subjects, for they cannot be considered as one subject, are such as are properly open to various opinions and forms of practice, and therefore are very suitable for debate.

Dressing is necessarily the first to be considered, for the flowers must be made as perfect as possible before they are staged. Considerable variance of opinion exists in regard to dressing Chrysanthemums and other flowers when about to be exhibited in competition for prizes, and so long as judges make their awards according to the canons of perfection now and long in vogue, so long will it be necessary for competitors to render what manipulatory aid they can to bring their flowers as near as possible to the standard required.

Whether it would be better to exhibit flowers as grown need not here be discussed, but perhaps I might be allowed to say that, in my opinion, were the law to go forth that in future no flowers for competition shall be dressed, such law would be futile. By the term dressing many people imagine that some occult and secret process is implied, and that reflexed

blooms can be transformed into incurved by the aid of curling irons; also that a poor and badly grown bloom can be made as fine as one that could properly be called a good bloom. This is not the truth in the abstract and under such conditions; but given two blooms of equal quality and of the same variety—one flower to be dressed and the other not—the one that has been dressed is nearly always admitted to look much better, even by persons who are prejudiced against dressing. That a bad bloom can be greatly improved by dressing must be admitted, also that a really good bloom may be slightly improved, but as a rule the better and more perfect the bloom is the less there is to do in dressing.

I do not attempt to deny that the best blooms are occasionally placed second or third to those not quite so good, but which had been well dressed; but such cases are very rare, and during a period of ten years I have only once been a participator in such awards, and then an unwilling one, being one against two in making the awards. It is very hard on a man who has grown and exhibited the best blooms in an exhibition to place him second or third simply because he had not touched his flowers in the way of dressing; but, after all, is it harder than withholding the first prize from a man who exhibits a splendid horse or ox in dirty and untrimmed condition, or a bunch of Grapes containing seedless berries, or which has never been thinned?

Assuming, then, that dressing improves the appearance of Chrysanthemum flowers, and that therefore it is desirable, the question arises, How is a grower to proceed? He must first obtain a pair or two of tweezers that are made for the purpose of extracting deformed, short, or superfluous florets. Possessing these, it is as well to commence dressing, as the flower expands by extracting the florets just mentioned as they appear. This allows the bloom to develop symmetrically, whereas when such are left in until the last it not only takes a considerably longer time to dress the blooms, but sometimes the florets that have been pushed out of place by such deformed florets do not readily fall into their proper places, hence arises a tendency to roughness of appearance. Any staminate florets (yellow florets) that are seen at the base of the florets or in the centre should also be removed, and when the bloom is fully expanded, if it is a perfect bloom, there will be a number of short florets in the centre, and these must be removed by the aid of the tweezers, when the longer florets will fall into the centre and present a perfect bloom. A little courage is required to remove these short florets; they should be plucked out boldly and with a firm hand. When the blooms are cut preparatory to staging, they should be again examined for the purpose of removing any overlooked deformed floret, and then be cupped. After being pulled up so that the florets close well over the centre, they should be securely pegged. Then, commencing at the centre of the bloom, with the small end of the tweezers proceed to arrange the florets in an-imbricated manner smoothly and regularly, and radiating from the centre. In a good bloom there are numbers of florets having one or two underneath them; these should be carefully released, and placed in their respective places. Any floret that reflexes may be had into proper form again by stroking the inside with the smooth and rounded end of the tweezers; but some are very obstinate, and in such cases there is no alternative but to pull them out. To dress a large and good bloom well takes from twenty to forty minutes, therefore such work requires patience and a steady hand.

Having dressed the blooms the next subject is staging them, or more properly, arranging them in their stands; and here there is abundant scope for the exercise of the faculties of form, colour, proportion, and ingenuity. In the first place the stands when filled should appear as evenly balanced as possible, and likewise each row. Dumpiness and lop-sidedness must be avoided. Let the weight of the flowers be evenly distributed from end to end and back to front of the boards. The back row should be higher than the middle row, and the middle row higher than the front row, so that the whole of the flowers may, as far as possible and consistent with general effect, be seen to advantage. Sometimes it is necessary to have a flat flower in the same row as deeper ones; in such a case it should be specially raised to the level of the others in the same row, and this rule applies in all cases—viz., that all the flowers in the same row should be raised to the same level.

These are all aids to general effect; but I may here observe that competent judges are never deceived by any of these extraneous aids, but they are relieved of the trouble of raising flowers or taking them out of the stands for the purpose of seeing them properly; consequently good staging greatly facilitates the work of the judges, and all other conditions being equal, the best staged blooms would look the best, and therefore would rightly receive the first prize.

A proper arrangement of colours is also very important; harmony and contrast always to be borne in mind. Some people follow their own taste—or rather, the want of it—in opposition to all the rules of colour. Generally speaking, colours complementary to each other are the most easy of arrangement amongst distinct varieties of cut blooms of Chrysanthemums, and white agrees with any colour. In such an arrangement shades of the same colour should be separated, because they give either too light or too heavy appearance of that part of the stand. But I think horticultural societies have room for advancement in this particular. The stereotyped "Groups for effect" are about played out, and it is time something was done to advance a knowledge of the art of arrangement of colours. As a fact, very little advance has been made in that way.—JAMES UDALE, *Haverland Hall Gardens, Norwich*.

IN reference to dressing blooms, there is not so much art as supposed. The principal points are to grow the florets to the greatest possible

length, removing any irregular ones as the bloom develops, and when it is observed that the bloom is nearly finished, the centre should be taken out, and all the short florets. This will cause the longer plants to close inwards. On the other hand, if the centre was left in, they would grow outwards. Beginners at dressing often fail to take sufficient out of the centre before arranging the florets.

As to the damping, I have already told all I know on the subject. I may repeat, I do not think this is caused from the roots. It is, in my opinion, caused by the moisture that is carried in the atmosphere; this condenses on the florets. The least blink of sunshine, and the evil is apparent. Try tiffany as a permanent shade inside over the opening blooms, with a heavier shade outside on cold nights, also during sunshine. Keep the house closed during foggy weather, and ventilate freely, with sufficient heat in the pipes to keep the air of the house in motion. There will then be less complaints about damping. I had thought to have had a good struggle this year with damping. I do not show now, therefore I scarcely like to shut the light from my Peaches.—W. TUNNINGTON, *The Gardens, Calderstone.*

## LARGE CHRYSANTHEMUM BLOOMS.

SOME writers have declaimed against the size attained by the new varieties of Chrysanthemums. Where size has been obtained with the addition of coarseness they possess little attraction, and it would be unwise to place them in stands intended for competition if it can be avoided. The defective blooms may be quilled in their florets, others may be bad in colour, or they may have badly developed centres, points which tell heavily against them. On the other hand, where large blooms possess size with substance in the florets, well finished centres, and good colour they will undoubtedly tell better on the exhibition stands than smaller ones. Growers all value the smaller varieties for their several good points—it may be form, or colour, or beauty of florets, and in collections where the chief object is not competition more of these smaller varieties are grown with the large ones for variety, and there are few exhibitors I imagine but have favourites, which they grow for their own merits, and which are known to be useless for exhibition purposes.

The extraordinary popularity of the Chrysanthemum at the present time is due in a very great measure to the size attained by the blooms as grown by the method of culture now adopted, and also to the interest afforded by the new varieties.

It is apparent to all attending exhibitions which have the most attraction, for although groups and trained plants are much admired and add greatly to the exhibitions, as well as show the skill of the growers, the large cut blooms draw crowds of visitors round them, and it is the same at home displays. Several hundreds annually visit these gardens at this season, and whether they are old growers or persons new to the present state of Chrysanthemum culture, the largest blooms invariably receive the most praise. The public expect to see at exhibitions the very best productions, whether Chrysanthemums or other plants or flowers, arranged in their best form. But while I consider size to be preferred, other qualities being equal in the incurved and Japanese varieties, I think in the Anemone and Anemone Pompon only those varieties should be shown which tend to make the stand uniform, and as an illustration I may say that President when overgrown is quite out of character in a Pompon board. Much more could be written on this subject, but I must close my letter for the rapidly approaching Chrysanthemum season leaves little time for writing.—C. GIBSON, *Morden Park Gardens, Mitcham.*

LARGE blooms have been strongly condemned together with our whole system of cultivation by which such are produced. Some are evidently dissatisfied with the present state of things, and would have us return to the days when a few small Pompons and weedy straggling so-called bush plants of larger flowering varieties carrying thin weakly flowers but little larger than the Pompon varieties were met with in most good gardens.

Fortunately for the Chrysanthemum and its future popularity we have good grounds for knowing that the dissatisfied men constitute a small minority, whilst each succeeding year Chrysanthemum shows are growing in numbers, in popularity and attractiveness. How few now are the gardens where no disbudding is practised, and no attempt made to produce these large flowers compared with what was the case a few years ago. Where exhibiting is not allowed or thought of they still must be produced, as gentlemen possessing the necessary glass accommodation and employing gardeners are no longer content to be behind their neighbours in this respect.

In the dreary month of November what can be so enlivening as a fine display of these large well-grown and brightly coloured flowers? The introductions of the last year or two have certainly had a tendency to increase in size, especially so the seedlings from

America; but fortunately along with this enlargement has come a decided improvement in the habit of growth and foliage. I have only to mention such grand new varieties as Etoile de Lyon, Avalanche, Condor, George Daniels, Sunflower, &c., as proof of my statement. We have now no varieties introduced of the type of Madame C. Audiguier, which will oftentimes attain a height of 14 feet; and I am aware that this, with other such tall growing varieties, are gradually disappearing from collections to give place to others with dwarf habit, fine foliage, and large brightly coloured flowers. So long as this improved habit and foliage of the plant is accompanied by increased size in the blooms the raisers of new varieties need have no fear that their work will cease to be appreciated or that a ready market will not be found for their introductions.—W. K. W.

## THE KINGSTON CHRYSANTHEMUM SHOW.

As an example of the method of arrangement adopted at one of the most popular and successful autumn shows, we gave in 1886 an illustra-

FIG. 50.—MR. EDWIN MOLYNEUX. (See page 382.)

tion of the Volunteer Drill Hall at Kingston-on-Thames, where the annual Exhibition of Chrysanthemums is held, which is here reproduced. It is impossible in shows of this kind to avoid some formality in the disposition of the exhibits; every effort is made to relieve this as much as possible, and the result in this case is more than ordinarily satisfactory. Next to the walls of the building were placed the groups of miscellaneous plants and Chrysanthemums together, with specimens of the latter in several classes. The principal of these were, however, arranged at the end of the hall at the base of a small stage, as shown in the centre of our illustration, and in that position they had a most telling appearance. The most important among them were the very handsome plants from Mr. G. King, gardener to Mrs. Few, Esher, his half dozen specimens each 4 or 5 feet in diameter, and bearing hundreds of blooms, being worthily awarded the premier prize.

The centre of the hall was devoted to the cut blooms, three tables extending nearly the whole length of the building, and upon a third one, across near the entrance, were arranged the collections of fruit—Apples and Pears. In the centres of the tables, between the rows of cut bloom boxes, were lines of table plants, "berried" plants, Primulas, &c., the

first-named being especially useful for relieving the rather flat appearance of this part of the Show.

#### CERTIFICATED CHRYSANTHEMUMS, 1859-1890.

THE award of certificates to novelties of approved merit has now become a business of serious importance, and the circumstances are quite altered from what prevailed twenty years ago. Enormous numbers of seedlings are raised every year on the Continent, and too frequently, without adequate trial, are named and sent to this country for sale, leaving much the more important work of testing their distinctness and quality to our own nurserymen or private cultivators. The public have had some experience in recent years in this matter, and now require some kind of official recommendation before they invest in novelties they have not had the opportunity of seeing themselves. The Floral Committee of the Royal Horticultural Society and of the National Chrysanthemum Society have in consequence a grave responsibility, and how much may turn upon a verdict of this character was seen in a recent law case which attracted a large share of attention. The members of these Committees seem fully alive to their responsibility, and much greater care is now exercised in the awards than was the case a few years back. There was some excuse for the greater liberality in granting such honours when the novelties were much less numerous than at the present time, and it was desirable to encourage the production of worthy additions to the list. The result is that Chrysanthemums certificated within the past thirty years possess very different value, and may in consequence be taken as indicating somewhat of the historical progress accomplished. A descriptive catalogue of the varieties would, therefore, include the best of these in commerce at the different periods, and as this must possess some interest I have completed a list commenced several years ago, which will be published in this Journal from time to time.

The list will include all the varieties certificated by the Royal Horticultural Society and the National Chrysanthemum Society, with the principal of those honoured by judges at the leading provincial shows from 1859 to the present year. It will also give the date when the variety was certificated, the name of the exhibitor and raiser where obtainable, the chief characters of the flower and plant, and its general history.—L. CASTLE.

(To be continued.)

#### CHRYSANTHEMUM SOCIETIES AND SHOWS.

THE following list has been prepared at the request of numerous correspondents, who have supplied us with the particulars here given, and it will, no doubt, be found useful by many who are concerned with exhibitions during November. The name of the society, date of show, with the Secretary's name and address are given in that order.

Ascot, Sunninghill, Sunningdale, and District, Nov. 6th and 7th ; F. T. Patton, The Links, Ascot  
 Banbury, 19th Nov. ; H. F. Bennett, 46, High Street, Banbury  
 Bath, November 12th and 13th ; B. Pearson, 14, Neilson Street  
 Batley and District, Nov. 22nd ; John T. Booth, Batley  
 Bedford, Nov. 19th and 20th ; J. Sanders Clarke, 49, Linden Road  
 Birmingham and Midland Counties, Nov. 12th and 13th ; J. Hughes, Northwood Villas, Metchley Lane, Harborne, Birmingham  
 Bournemouth, Nov. 12th and 13th ; Charles Brown Carnarvon, Cavendish Road  
 Bradford and District, Nov. 7th and 8th ; George Taylor, 102, Godwin Street, Bradford  
 Brighton, Nov. 11th and 12th ; Mark Longhurst, 18, Church Road, Hove  
 Brixton, Nov. 4th and 5th ; W. Salter, Brixton Hill  
 Cardiff and District, Nov. 18th and 19th ; C. R. Waldron, 96, St. Mary Street, Cardiff  
 Chelmsford, Nov. 12th and 13th ; P. Edwards, 100 High Street  
 Cheshunt, Nov. 14th and 15th ; R. Archer, Hatton Road  
 Chorley, Nov. 21st and 22nd ; James Sargeant, 64, Market Street, Chorley  
 Cornwall Royal Polytechnic, Nov. 12th, 13th and 14th ; John P. Cregoe, 7, Tehidy Terrace, Falmouth  
 Crediton, Nov. 13th ; G. Lock, Belle Parade Cottage, Crediton  
 Croydon, Nov. 12th and 13th ; W. Beckett, 272, Portland Road  
 Crystal Palace, Nov. 7th and 8th ; W. G. Head  
 Dawlish, Nov. 13th ; H. L. Friend, 3, Priory Terrace, Dawlish  
 Derby, Nov. 14th and 15th ; G. Sutherland, Arboretum Square  
 Devon and Exeter, Nov. 7th ; G. D. Cann, 16, Queen Street, Exeter  
 Diss (Norfolk), Nov. 18th ; Rev. F. Page Roberts, Scole Rectory  
 Ealing, Nov. 5th ; J. A. Dawes and Geo. Cannon, 9, Drayton Green Road, Ealing  
 Eastbourne, Nov. 11th and 12th ; C. H. Simmons, Endlewick, Eastbourne  
 Eccles, Patricroft, and Pendleton, Nov. 14th and 15th ; H. Huher, 183, Worsley Road, Winton, Patricroft  
 Exmouth, Nov. 11th ; W. J. Godfrey, Rolle Street, Exmouth.  
 Finchley, Nov. 4th and 5th ; Edward Linfield, 19, Vernon Terrace, East Finchley, N  
 Green Street and District, Nov. 19th and 20th ; W. G. Ray, Mount Pleasant Nursery, Green Street, near Sittingbourne.

Hampstead, Nov. 12th and 13th ; Robert Frishy, 47, Flask Walk, Hampstead, N.W.  
 Hartlepool, Nov. 18th and 19th ; B. C. Laycock, 147, Studley Road, West Hartlepool  
 Havant, Oct. 31st and Nov. 1st ; A Chignell, West Street, Havant, Hants  
 Hayes, Nov. 7th and 8th ; W. Henry Burr, Dr. Triplett's Schools, Hayes, Middlesex  
 Highgate, Hornsey, and Finchley, Nov. 5th and 6th ; Thomas Press, 11, Victoria Cottages, Archway Road, Highgate, N.  
 Hitchin, Nov. 14th and 18th ; Pearson T. Harris  
 Hull and East Riding, Nov. 19th and 20th ; Edward Harland and James Dixon, Manor Street, Hull and 2, County Buildings, Hull.  
 Ipswich, Nov. 4th and 5th ; Rev. H. Berners, Harkstead Rectory  
 Isle of Sheppey, Nov. 6th and 7th ; James W. Fuller, 3, Alexandra Road, Marine Town, Sheerness  
 Kingston-on-Thames, Nov. 11th and 12th ; G. Woodgate, Warren House Gardens  
 Leicester and Midland, Nov. 14th and 15th ; H. F. Anthony and E. E. Waite, Knighton Church Road, South Knighton, and 12, Diseworth Street, Melbourne Road, Leicester  
 Lewes and District, Nov. 11th and 12th ; Geo. Stroud, 20, High Street, Southover, Lewes  
 Lindfield, Nov. 5th and 6th ; Clive Wheeler, High Street, Lindfield, Sussex  
 National Society.—Great Festival, Nov. 11th, 12th, 13th, and 14th ; R. Dean, Frampton Park Nurseries, Hackney  
 Norfolk and Norwich, Nov. 20th and 21st ; John E. T. Poilard, 7, Lady's Lane, Norwich  
 Northamptonshire, Nov. 12th and 13th ; E. Draper, 2, Primrose Hill, Northampton  
 Pembrokehire, Nov. 6th ; R. H. Treweeks, Main street, Pembroke  
 Portsmouth, Nov. 5th, 6th, and 7th ; F. Power, 36, Queen Street, Portsea  
 Putney, Wandsworth, and District, Nov. 6th and 7th ; John Moore, Upper Richmond Road, Putney  
 Ramsbottom, Nov. 15th ; H. H. Nutter, 14, Crow Lane, Ramshottom, near Manchester  
 Rugby, Nov. 19th and 20th ; William Bryant.  
 Scarborough, Dec. 2nd and 3rd ; Thomas Henry Pexton, 136, North Marine Road, Scarborough  
 Scottish Horticultural, Nov. 20th, 21st, and 22nd ; R. B. Ferguson, 6, South St. Andrew Street, Edinburgh  
 Southend-on-Sea, Nov. 13th and 14th ; John Brown, Recko House Hamlet, Southend-on-Sea, Essex  
 Swansea, Nov. 19th and 20th ; Messrs. T. Kneath and W. Roberts.  
 St. Neots (Hants), Nov. 10th ; William Ratchelous  
 Stroud, Nov. 6th and 7th ; E. C. Davis, 10, Rowcroft, Stroud, Glos.  
 Surrey, Nov. 3rd and 4th ; James Springett, 40, Maxted Road Beckenham.  
 Teddington, Nov. 13th and 14th ; David Anderson, The Nursery.  
 Tiverton, Nov. 20th ; R. P. Cosway, Lime Cottage, Tiverton  
 Tooting, Nov. 5th and 6th ; H. Brown, 39, Defoe Road.  
 Truro, Nov. 11th and 12th ; Alfred Blenkinsop, 11, Princes Street, Truro  
 Tunbridge Wells, Mid-Kent, and East Sussex, Nov. 12th and 13th ; Ernest Charlton, 37, Ye Pantiles, Tunbridge Wells.  
 Twickenham, Nov. 18th and 19th ; J. J. G. Pugh, 2, Heath Road.  
 Walkley, Nov. 7th ; M. Taylor, 9, Spring Hill, Sheffield  
 Wellington (Somerset), Nov. 14th ; Charles Tite, Shutes House, Wellington, Somerset  
 Wells (Somerset), Nov. 5th and 6th ; Albion George Andrews, St. Cuthbert's Lodge, Wells, Somerset  
 Westerham, Nov. 19th and 20th ; Frank George Remnant, High Street.  
 Wimbledon and District, Nov. 13th and 14th ; Dr. Geo. Walker, 12, Lingfield Road, and W. W. Thomson, The Nurseries, Hill Road, Wimbledon  
 Winchester, Nov. 13th and 14th ; Chaloner Shenton, 74, High Street, Winchester  
 York, Nov. 19th, 20th, and 21st ; J. Lazenby, 8, Spurriergate.

#### OUTDOOR CHRYSANTHEMUMS.

I SHOULD not like to let your Centenary number pass without saying a word for one of my favourite methods of growing the Chrysanthemum, though I am rather busy building and fruit tree planting in a new town garden. I am rather surprised your correspondent, Mr. W. Piercy, should consider "the season has been a had one for the growth and perfection of the early flowering Chrysanthemums" in his interesting notes thereon last week. Early flowering and outdoor Chrysanthemums may generally be taken as synonymous, as in any part of the British Isles there is no occasion to house plants before October. In the south of Ireland there is rarely frost to do them any harm before November. Here, up to the present, the best days of October, there has not been a degree of frost yet ; and my Pelargoniums, Dahlias, Vegetable Marrows, and other tender things are still untouched, luxuriating in the finest September and October within my recollection. The result is that my outdoor plants, at the base of a south wall and trained against it, as well as another lot on a western in another garden, are bursting rapidly into bloom, and the buds are among the fullest and most promising I can remember at a corresponding date. Passing over the usual

October bloomers, such as Madame Desgranges and its sports, G. Wermig and Mrs. Burrel, Alexander Dufour, Isidore Feral, M. Pynaert Van Geert, Simon Delaux, Sœur Mélanie, the very free and useful Elsie, and many others, I am cutting already others, such as Elaine—never finer, Lady Selborne, William Holmes, Sœur Dorothee Souille, Emperor of China, the hardiest Chrysanthemum in existence; L'Or du Rhin, James Carter, Amy Furze, M. Lacroix, and that splendid acquisition for any purpose, Avalanche. I should have named also M. Freeman, James Salter, and Bertie Rendatler, without including Pompons, which anyone can make a selection from, but I give a preference to fine varieties like those named. I must not be understood as confining my admiration to those early bloomers. I have 150 varieties, without including those in pots, in my greenhouse, and some varieties, like Goldfinder, Ceres, Ethel, and W. G. Drover bloom as late as January; but then I have crected over them a canvas-covered framework on hinges, that is raised by day and dropped down at night, which fairly answers its purpose, and gives me cut flowers for myself for wreaths, for church decoration, and for my neighbours, over Christmas.—W. J. MURPHY, *Clonmel*.

#### TAKING CHRYSANTHEMUM BUDS.

I MAY be rather late in expressing my views on this subject, but I have been led to pen these few remarks, as I find that growers still look for guidance. The "mystery" of bud taking, for such it is, as explained by some is very intricate. We are supposed to take a variety by a certain date to produce good blooms, and if this is not done it is hopeless to expect success. This is very perplexing to small growers, as they are at a loss what to do. For instance, many this season let the crown bud go as a supposed "freak," with the result that the next is a terminal; the blooms then, besides being late, are small and of little use for the exhibition board. The crown buds this season have generally shown early, and in our case these commenced in the last day or two of July, and by the first week in August numbers were showing. Acting upon the results of other seasons we took the crown buds as they appeared, and in a few cases allowed the shoot to run on to the next bud. The result is that the blooms from the crown buds are very good indeed, and likely to be in the second week in November, whereas the others are much smaller.

During the last week in July that superb variety Boule d'Or was showing; these were all taken, the result being that the blooms are likely to be very good indeed in every instance. About the time these were taken I read from the notes published at the time by one of our large growers, that the date would be too early for good results. I felt that we had made a mistake, but subsequent results reveal the fact that we were right. With many other varieties the results are the same. We are not exhibitors, but aim to have a good home show. From experiments with early varieties, rather too early for some exhibitors, I find that by topping the plants about March, and then running up a single stem, that the natural break is thrown much later. If buds are to be kept back, the plants must be manipulated upon during the early stages of their existence, either by later propagation than is usually practised, or by topping. In no other instance can the crown buds be made to show at certain dates or thereabouts. Small growers are in a maze with these published dates. When their buds show, if they are not about the time, they allow them to go by, the result being small blooms and late. It was only the other day that I saw a splendid lot of plants which had been allowed to run past the crown, and now the grower is bewailing his loss, as he can now see by what few crown buds that were taken the excellent results he would have had if all had been served the same.—A. YOUNG.

#### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 28TH.

THE Committee meeting in the Drill Hall on Tuesday last was not very well attended, owing probably to the keen weather. Chrysanthemums constituted the chief attraction amongst the exhibits, and in the afternoon Dr. M. T. Masters delivered an excellent lecture on "Trees and Shrubs for Towns," in which he reviewed in an able manner the principal points connected with this wide and important subject.

FRUIT COMMITTEE.—Present: Sir C. W. Strickland, Bart., in the chair, and Messrs. J. Lee, T. F. Rivers, P. Crowley, J. Cheal, J. McIndoe, T. F. Saltmarsh, G. W. Cummins, G. Wythes, J. Hudson, W. Warren, and Dr. Robert Hogg. From the Society's Gardens, Chiswick, came collections of Potatoes and Endives that have been tested there. Mr. William Smythe, Basing Park Gardens, Hants, sent a seedling black Grape with round black berries, which, it was stated, kept well until

March; it was, however, passed by the Committee. Mr. T. Laxton showed a white-skinned Jerusalem Artichoke, which is to be tried when cooked, and samples of the Chou de Bedford, which was thought to be no advance on Couve Tronchuda. Mr. R. Dean, Ealing, sent fruits of Grange's Winter Pearmain Apple and Nouveau Poiteau Pear, for which cultural commendations were awarded. Mr. Colbourn, Woolhampton, exhibited handsome fruits from a second crop of Strawberry Noble (vote of thanks). Mr. Hunt, Ashtcad Park Gardens, exhibited samples of a medium-sized Apple, named Ashtead Park Seedling, but no award was made. Mr. Wythes, Sion House Gardens, Brentford, sent even specimens of Cheltenham Green Top Beet (vote of thanks), and from Messrs. Carter & Co., High Holborn, came an excellent sample of Extra Early Autumn Giant Cauliflower (vote of thanks).

FIG. 51.—MR. JOHN LAING (See page 382).

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair, and Messrs. Herbst, R. Dean, B. Wynne, G. Nicholson, Lewis Castle, H. B. May, T. Baines, C. Jefferies, H. Turner, H. Cannell, C. Noble, J. Fraser, G. Paul, and the Rev. H. H. D'Ombrain.

From Messrs. J. Cutbush & Sons, Highgate, came a beautiful collection of Pernettyas, the plants compact and loaded with berries, the varieties rosea, atro-purpurea, rosea macrocarpa, alba, and purpurea being the most noticeable (silver medal.) Mr. R. Dean, Ealing, sent some good varieties of Pentstemons of bright colours, and an award of merit was granted for the strain. Messrs. H. Cannell & Sons, Swanley, contributed a large and handsome collection of Chrysanthemums, several of which were distinguished by awards of merit. Mr. Bridger, Peshurst Place Gardens, Tunbridge, showed plants of a border Carnation named Saccharina, flaked with rose on a yellow ground, and very free. Mr. G. Wythes had a stand of Chrysanthemum blooms very tastefully arranged with Fern fronds, small Palms, &c., for which a bronze medal was granted. Mr. R. Owen, Maidenhead, sent several new Chrysanthemums, and two obtained awards of merit.

It is not often that flowers of the Jerusalem Artichoke, Helianthus tuberosus, are seen in gardens or at shows, but Mr. A. Harding, Orton Hall Gardens, sent some small yellow flowers of the ordinary composite

character, but possessing no beauty. An interesting contribution came from the Royal Gardens, Kew, comprising flowers of the trumpet like *Solandra grandiflora*, the rosy *Ipomœa Briggsi*, the peculiar mauve coloured *Cleome heptaphylla*, the bluish *Solanum Seafortianum*, and *Philodendrons Simsii* and *dolosum*. Mr. T. H. Crasp, gardener to Lord Wimborne, Canford Manor, exhibited an imposing stand of incurved and Japanese *Chrysanthemum* blooms, arranged on a steep high stage (silver medal). Mr. W. Taylor, Isleworth, had a small leaved, silvery edged *Cyclamen*, and a number of the ordinary type with large abundant flowers (silver medal). Messrs. Paul & Son, Cheshunt, showed specimens of hardy trees and shrubs, amongst which *Berberis Thunbergi*, with bright red leaves, was very conspicuous. Messrs. J. Laing & Sons, Forest Hill, had a small group of *Chrysanthemums*, including several new varieties, for which awards of merit have been granted.

ORCHID COMMITTEE.—Present: Dr. M. T. Masters in the chair; and Messrs. J. O'Brien, C. Pilcher, J. Dominy, De B. Crawshay, H. M. Pollett, A. H. Smee, S. Courtauld, and J. Douglas.

Conspicuous amongst the Orchids shown were the plants and varieties of *Cattleya Warocqueana* from M. Linden, Brussels, the varied forms and colours proving this to be a useful and beautiful *Cattleya*. A

FIG. 52.—MR. R. PARKER. (See page 334.)

variety of *C. granulosa* named *Russelliana* was also shown, together with *C. Lindeni*, for which an award of merit was adjudged. Other plants and varieties of *C. Warocqueana* came from R. Young, Esq., Liverpool; W. J. Thomas, St. Helens; A. C. Coombes, Dudley; and W. C. Atkinson, Aigburth. Mr. R. Young also sent three racemes of *Vanda Sanderiana* with from seven to twelve flowers each produced by one plant. The flowers were dark in colour and of good size. Messrs. Seeger & Tropp, East Dulwich, showed flowers of *Lælia Perrini* in several varieties.

#### CERTIFICATED PLANTS.

*Berberis Thunbergi* (Paul & Son).—An effective shrub, the leaves of which turn to a brilliant red colour before falling.

*Chrysanthemum Duchess of Westminster* (R. Owen).—A Japanese Anemone with a dense centre of rosy bronze tubular florets, and rather thin guard florets, blush, or nearly white.

*Chrysanthemum Miss Anna Hartzhorn* (R. Owen).—A fine white Japanese, already noted.

*Chrysanthemum Eugénie Gait* (H. Cannell & Sons).—A Japanese variety, with flat florets, rich deep crimson, very effective colour.

*Chrysanthemum W. Tricker* (H. Cannell & Sons).—A Japanese, with broad pink florets, slightly incurved at the tips.

*Chrysanthemums Miss Violet Tomlin, Miss Haggas, Vivian Morel, and Madlle. Marie Hoste* (J. Laing & Sons).—Awards of merit were granted for the above varieties, the first two incurved, and the others Japanese, which have been previously described.

*Cattleya Lindeni* (M. J. Linden, Brussels).—A handsome and graceful *Cattleya*, with flowers of medium size, the lip of an intensely

rich magenta colour margined with gold, and veined with the same in the throat. The petals are of a delicate rosy mauve tint veined with white, the sepals pale blush or nearly white.

TUBEROUS BEGONIAS AND DAHLIAS.—Frosts have spoilt these as far as their beauty this season is concerned in most gardens, but the tubers being taken good care of will be available for next summer. Old tubers, or any three years and upwards in age, usually succeed very much better in the open beds than in pots under glass, and seeing that many of them can be split into several plants in the spring, none but tubers of inferior varieties should be thrown away. It is to be hoped the various seedlings have been duly marked, both the colour and habit of flowering being taken note of. Stored accordingly masses of one colour can be made next season, these quite eclipsing either mixed beds of *Begonias* or any other bedding plants near them. All ought to be lifted before very severe frosts intervene, a small portion of soil being left about the roots. Pack them closely in shallow boxes of fine moderately moist soil, remove decaying stalks when necessary, and keep cool and dry. Stored in a potting shed or outhouse it is advisable to cover the boxes with mats whenever a severe frost is anticipated. Dahlias keep well in a cool dry shed or loft, the roots being set rather closely together and well surrounded by fine and not too dry soil or sand. The more vigorous varieties, including some of the singles, will frequently survive an ordinarily severe winter left where they are. It is advisable, however, to protect the collars of the plant with a bank of ashes, and this should be done early.

#### FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forcing House*.—The trees having been at rest some time, the roof lights removed, the house thoroughly cleansed, the trees untied, pruned, dressed with an approved insecticide, re-arranged and tied on the trellis, the border surface dressed, and all prepared for a start when the time arrives, nothing further is required. If, however, the roof lights have not been removed, care must be taken not to allow the soil to become dry at the roots of the trees, as this is often a cause of the bloom buds falling. If the trees are weakly, or with a great quantity of buds, a supply of liquid manure whenever water is required will be of great benefit. The surface soil also should be removed down to the roots, not disturbing them, applying 2 to 3 inches thickness of good loam, and if the soil be light add a fourth of pounded clay or clay marl, with a bushel each of steamed bonemeal and wood ashes to every cartload of soil, thoroughly incorporated, making it firm, and giving a good watering. Borders that are rich in humus through heavy dressings of manure will be benefited by dressing with quicklime, a peck per rod being a suitable quantity, mixing with the surface soil as deep as practicable without disturbing the roots to any great extent, omitting the top-dressing before named. In treating borders, it should be practised on both the outside and inside. Lose no time in completing the pruning and dressing, cleansing the house, and admitting air to the fullest possible extent. The outside border being thoroughly moistened, it may be covered with a few inches thickness of leaves, with a little litter to prevent their blowing about.

*Second Early Forced House*.—The trees being leafless should be pruned after untying, dressed, and re-arranged on the trellis. This, with a thorough cleansing of the house, makes an end of insects before they became ensconced in the cracks and crevices of the structure. In pruning early forced trees it is not desirable to cut away much wood, but where weakly and crowded it should be judiciously thinned, removing any useless parts that have escaped the knife at thinning after the fruit was gathered, and any long unripened shoots may be cut back to a triple bud, making sure that the central bud is a wood bud, or to a wood bud on well ripened wood. Shoots, however, that are well ripened need not be shortened under any circumstances, having usually a few wood buds at the base and one at the extremity, the rest being fruit buds. It is, however, a great mistake to retain much wood, which weakens the trees in flowering, and there is not space to train in the young growths without crowding. Treat the trees in other respects as regards the house, and borders as advised for the earliest house.

*Succession Houses*.—The trees will be casting their leaves and should be pruned when they are all down, the house and trees being dressed. If the trees are too vigorous and do not set and stone the fruit satisfactorily they should be lifted, which is preferably done whilst the leaves are upon the trees, keeping the lights over the trees until the leaves have fallen. Where the roof lights are not moveable care must be taken to prevent the soil becoming dry.

*Late Houses*.—Where the trees are assisted in spring and as required during growth in cold periods, the wood ripening well, there will be nothing required but to admit air freely, but where green

leaves hang long it is an indication of unripe wood, and the roof lights must not be removed for some time longer, and if this condition prevails generally the trees should be lifted carefully and root-pruned. If this is performed judiciously it will not prejudice next year's crop, but it must be done whilst the foliage is still upon the trees, but with the wood firm, keeping the house rather close, the trees syringed, and the house shaded if the weather be bright. Under ordinary circumstances as to weather those precautions are not necessary. It is only when the trees are gross and the wood unripe that the careful treatment is requisite. In the case of young trees it will suffice to take out a trench one-third the distance from the stem the trees cover of trellis, and down so as to cut off all roots to the drainage, leaving the trench open for a fortnight, not allowing the soil in the radius to become so dry as to distress the foliage to a very severe degree of flagging, but not giving any water so long as the leaves maintain their persistence, and then the trench may be filled in firmly. With this check to the growth the wood and buds ripen satisfactory.

**Unheated Houses.**—In these ventilation must be given to the fullest possible extent, and the wood if necessary should be thinned to admit light and air freely to the growths. This ripens the wood, and where this is not sufficient over-luxuriance or a tendency to late growth is overcome by lifting, which must not be done until the wood becomes firm, and whilst the foliage is still upon the trees. Lifting and laying the roots near the surface and firm soil is the surest remedy for trees that fail to set and stone full crops of fruit. After the leaves fall the roof lights may be removed.

#### KITCHEN GARDEN.

**CUCUMBERS IN POTS.**—Open air Cucumbers have not been a great success this season. As a rule it has been too wet and sunless for them. They are now quite over, and those we have in frames are not active, indeed they too will soon be past, although fresh linings of manure have recently been applied. Like many others we have not extensive accommodation for the production of winter Cucumbers, but we have a number of plants in 12-inch pots. These are just beginning to fruit, and are likely to be exceedingly useful during the greater part of the winter. They are in a warm plant pit, but have no bottom heat, though the pots are near the hot-water pipes, and the plants are both clean and robust. As we only require a few fruits per week the supply will be ample, and those who have little space but who would still like to possess a few Cucumbers should grow their plants in pots. They are more easily accommodated in these than in a bed. They are easily kept going by giving liquid manure frequently when the pots are full of roots. The greatest mistake that is made in winter Cucumber growing is to allow the plants to make too much growth. If the main stem is taken up 2 or 3 feet and not more than 4 feet, the side shoots being closely pinched at the first joint, until the fruit there has formed, the results will be much better than if the side shoots were allowed to run out several joints. A crowded growth is produced then that is much against the formation of the fruit. It also exhausts the plant, and this must be avoided when the roots are confined to the small space of a 10-inch or 12-inch pot. When one fruit is formed at the first joint the shoot is allowed to grow anew to another joint, but no more, when another fruit appears, and in this way the plants are easily kept clean, robust, and fruitful. To allow many growths to run out and then cut them hard back, as is often done, is ruinous.

**MORE LIME FOR VEGETABLE QUARTERS.**—Experiments conducted for some years past lead us to assert that sufficient lime is not applied to vegetable quarters. Grubs have been unusually plentiful in Carrot, Parsley, and other quarters this season, but they have been much worse in some cases than others, and wherever lime was absent their ravages have been most destructive. Lime is an excellent preventive, while as a fertiliser it is equal in some soils to any manure. Old soil is especially benefited by it, and our crops generally have never been so robust and of such high quality as in the seasons succeeding the application of lime. We have resolved that none of our quarters shall go longer than three years without it, as most of the soil is very full of decayed leaves and other manure. The best way of dealing with it is to procure the lime quite fresh, place it in heaps of one or two barrowloads here and there on the vacant quarters, cover it over with soil as soon as it is deposited, allow it to remain covered for two days, then spread it on the ground and dig in at once. It may be applied at any time of the year, but at least a week should be allowed to pass from the time it is dug in until any crop is planted. We apply it at the rate of from 3 to 5 tons per acre, according to the condition of the soil.

**LATE CAULIFLOWERS.**—As usual Veitch's Autumn Giant Cauliflower is giving an ample supply. It is unique as an October sort, and the Self-protecting Broccoli succeeds it to an equally useful extent. None of them, however, will bear frost, as if the head is exposed it soon becomes brown and useless. When a quantity of these are ready and left exposed a few degrees of frost occurring unexpectedly will ruin them. It is therefore necessary to keep a look out that this should not occur. The plants should be examined twice or three times weekly, and all that have exposed heads should be cut and stored. If cut with a stem 6 inches in length, the bottom leaves cut off, only a few of the small ones left round the head, and the stem inserted in damp sand in any cool dry shed, they will remain fresh and good for upwards of three weeks. We generally fill a number of our cutting boxes with sand at this time and store the Cauliflowers in these, as they can be conveniently moved into any dry place.

**FORCING KIDNEY BEANS.**—These only make slow progress at this

season. Seed sown in small pots and that have now produced plants 6 inches or more in height, should be placed into 7 inch pots. Do not crowd too many plants into one pot, give them a rich soil and a temperature of 70°. They must be kept near the glass and fully in the light, especially as they begin to show flower. It is better to give a few dozen potfuls plenty of room than try to crowd a hundred or more into a small space.

**AUTUMN SOWN ONIONS.**—These have become unusually large, a severe winter would be apt to cripple them greatly. Distribute a quantity of soot over the plants and between the rows, Dutch hoe them soon afterwards, then tread them on each side of the rows as firmly as possible. This treatment braces them up for the winter better than anything we have tried. Where they are valued as salad the plants should be drawn from the parts that contain the most plants.

**STORED ROOTS.**—As we anticipated stored roots are not keeping well. There is much decay in Potato heaps, and to prevent further loss all Potatoes should be examined as soon as possible. Turn the heaps quite over in picking out the bad tubers, and if the position they have been resting on is damp remove them to a dry place. If sound tubers have become damp through being in contact with rotten ones let the former become dry before confining them again.

#### APIARIAN NOTES.

##### VENTILATING FLOORS.

A CORRESPONDENT ("G. H. D.") requires some information respecting the above, and as others may be desirous of having a knowledge how to proceed in completing a cheap but an effective hive of great utility, I will give a description of the work. It is quite unnecessary to give full details of every part of a hive, because one part must necessarily be made to suit another. There can be little doubt but that the storifying hive will be the hive of the future, as it has been so long the successful one of the past amongst advanced bee-keepers, and that its dimensions for many reasons shall be the same—viz., 14 inches inside measure both ways, and the thickness of the timber five-eighths, and the alighting boards held to the hive by wire dowls or brass hinges for handiness in transit, the boards either being removed or folded up, the latter being the better plan. The floor and the three divisions which forms the hive must be exactly of one size, only the former being 4 or 4½ inches deep instead of 6½ inches, as are the body boxes, and the alighting boards are fixed to the floor, the alighting board proper being about 4½ inches broad, and the gangway or ladder not less than 9 inches, also hinged to the alighting board proper.

A sheet of one-eighth perforated zinc forms the floor, or it may be that having club-shaped perforations the holes, although wider apart, are larger, and allow larger pieces of *débris* to fall through without bees escaping. It is better that this sheet of perforated zinc be laid loosely upon the stand, which may have feet of angled iron screwed to the inside extreme angles of the stand. Either way, a fillet of wood runs round the inner sides of the stand about half way up in the front, and the thickness of the shutter at the back of the hive. When the shutter is fitted into the recess, a wooden button at the back holds the shutter in its place, and two nails bent downwards or a second fillet holds it from falling in the front. The shutter or false floor, it will be observed, lies at an angle, highest in the front, and allows the water evaporated by the bees to run out at the back. The whole stand and shutter should be thoroughly tarred or painted with raw oil.

The shutter should have a little opening; 5 inches long by 1 inch broad is sufficient, and at least 4 inches clear from the back, so that a shutter 4 inches broad sliding in the bars of the false floor clears the opening when drawn back. A stopper prevents it being slid too far forward when closed. I have not witnessed a single cell of foul brood amongst my hives since I adopted this method of ventilation, and would not risk sending hives a distance without it. It is a good plan, several days before moving bees, to open the ventilator or sliding shutter, so that the bees become accustomed to the opening, and do not crowd upon it.

The sides of the hive must be accurately cut to the required length, and the front and back as accurately checked to receive them, and to form a bead or projecting bottle on the ends. The check or rabbet to receive the frames must have at least three-eighths lip, the same as the checks in the end, and half an inch deep, this being the thickness of the top bar, its breadth being  $1\frac{1}{4}$  inch. The cheapest and best distancers are the common tacket or shoe hobnail placed in the centre of the end piece which forms the frame, and to be clear of the top of the top bar at least quarter of an inch. Of course the end pieces should not be more than three-sixteenths of an inch from the inner sides of the front and back of the hive, and should have no bottom rail. When putting in the tackets open a vice to  $1\frac{1}{2}$  inch, marking where the dwong is then open to the required width to receive the partly driven in tacket, then turn the dwong of the vice to the place which forms the  $1\frac{1}{2}$  inch distance, which is the natural width bees build their combs; in lieu of a vice other guages may be used. Nine frames should measure  $13\frac{1}{2}$  inches, being half inch less than the width of the hive. Allow this extra space to the two outer combs, and the bees and bee-keeper will be satisfied. Now fasten each division together by means of  $1\frac{1}{2}$  inch back-flap hinges at the back, and hooks and eyes near the front on the sides, and the hive is complete, but do not neglect to have a groove on under side of the middle of top bar an eighth of an inch wide and deep. The end pieces are  $5\frac{3}{4}$  long, quarter thick, and have a square tenon let into a round hole. I trust the above hints will enable anyone to understand how to complete hives and why they are so made.

There is but one objection manipulators can have to shallow framed storifying hives—viz., the combs being in two or more divisions do not give the same facilities for inspection of the hive. It may be true, but the other advantages they possess far outweigh this, if it can be really so called, a disadvantage. Those who know how to manipulate a shallow framed hive properly, and a very little practice will enable anyone in a short time to do so, when he will realise the fact that any difficulty in that respect is more in name than practice. In point of economy alone they far supersede other sorts, and are not exposed to the danger of collapse of the combs when in transit or during a high temperature as are the combs in deep framed hives, neither is there any waste of comb when partial deprivation of honey takes place, and which, as a rule, is always free from pollen in the combs of the upper storey.

#### WASTE OF HONEY AND ENERGY.

Were we to accept the statements made by many writers that it takes 20 lbs. of honey to produce 1 lb. of wax we would be on the wrong track, and even as we do not believe the assertion without laying some facts before your readers we should be remiss in our duties, and as misleading as those who have repeatedly asserted what we know full well is not true. To make things clear I was asked to examine some hives according to the orthodox fashion of the "modern bee-keeper," whose belief amongst other errors is as stated above. The perfect impermeable quilt was there. The stimulative feeder and other objectionable things were also present, the direct cause of damp interior and rotten combs, which to replace the latter at least 20 lbs. of honey (according to the 20-lb. theory) would be required, and as a natural thing with spring comb-building would be drone comb, which the stores inside could not supply for its formation nor the rapid decreasing population of the hive be able to restore.

#### HIVES HAVING TRANSVERSE COMBS.

It has also been repeatedly asserted that bees always store their honey in what is termed "combination" hives furthest from the entrance. A few days ago I was asked to overhaul a number of these hives. In every instance the greatest quantity of the honey was stored above and in the centre combs, a position that at once pointed to the fallacy of the teaching and to the unsuitability of such hives for bee-keeping.—A LANARKSHIRE BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Chrysanthemum Show (W.).**—Since you say the Show referred to is produced "as an advertisement for cuttings or plants," the proper course is to do the same as other business people do—advertise it, and it would then have some claim to recognition. We have received the list.

**Heavy Soil (Sarnia).**—The sample you send is a marly clay, and we should not rely on it for growing any plants in its present state. If sweetened by exposure to the air it might be useful for mixing with light soils, and for any other purpose we should not think it worth digging from a depth of 8 feet. We find 8 inches quite deep enough for digging soil for potting purposes.

**Pyrus (Cydonia) japonica Fruit (W. M.).**—We have seen many such fruits as those you describe, and have heard of some having been preserved, also of persons who liked them, and of others who did not, these being in the majority. It is a question of taste. We are not aware that the fruit, preserved or not, has any market value, if that is what you want to know, for your postcard inquiry is as vague as it is brief.

**Exhibiting Pompons (Exhibitor).**—According to the National Chrysanthemum Society's catalogue the ordinary Pompons and Anemone Pompons are as distinct as are large Anemones and reflexed varieties, therefore are accorded distinct sections. It would be very unwise to mix them in a class unless the schedule clearly stated that this might be done, for committees can make what exceptions they like to general rules.

**Insects on Chrysanthemum (Sender).**—The insects are aphides, and so far as we know have no recognised specific name, and therefore may be appropriately referred to as Aphis Chrysanthemi. It is likely that the species is continued from year to year by hibernating females, which congregate about the root near the surface of the soil, or in dead leaves that may be about the stems, and produce young in spring. Preventive measures, as naturally suggest themselves in winter, may be expected to diminish the summer visitation of the species.

**Doubtful Chrysanthemums (Inquirer).**—We are not prepared to say whether a stand in which you place John Doughty, Bronze Queen, John Lambert and Golden Queen would be disqualified or not, because we are informed that cuttings have "got mixed" in some instances, and some blooms we have seen appear to support the proposition. Follow Mr. Molyneux's advice in another column, and never stage a doubtful bloom. That was his plan, and during his showing career he was never disqualified and not very often defeated. It is a very great mistake for exhibitors to stage blooms simply because the varieties are "new," regardless of their distinctness and merit.

**Blight on Apple Trees (Beta).**—The specimen you have sent represents one of the worst examples of injury by the American blight (Aphis lanigera) we have seen. All such branches should be cut out of young trees, even if this amounts to almost cutting them down, for the origination of healthy growths from below the swollen parts, which are the consequence of ruptured sap vessels. The prunings should be burned, and every part of the trees should be thoroughly washed with a petroleum and softsoap solution, made by dissolving 3 or 4 ounces of the soap in a gallon of boiling soft water, stirring very briskly in while hot half a gill of petroleum. Apply with a brush, forcing the solution into every fissure for reaching the insects. The surface soil should be scraped from under the trees, a good dressing of lime given, and fresh soil placed over it from another part of the garden. Order Gooseberry, Currant, and Filbert bushes at once, and plant them as soon as they arrive if the soil is in free working condition. If it is not, dig a trench, place the roots in it, and cover them well with soil till a favourable opportunity occurs for planting.

**Good Apples and Pears (H. C. B.).**—You ask for the names of two or three of the best early and the best late Pears; also of the best

early and late Apples. We have had too much experience with fruits, and noticed their variation under different circumstances, to commit ourselves so far as to name any two or three as absolutely the "best," which would mean that all others are inferior to them.

**Destructive Caterpillars (R. A.).**—These are the half-grown caterpillars of the great yellow underwing, Tryphæna pronuba, which has been abundant in many parts of England this autumn, though it is every season more or less troublesome to gardeners and farmers.

**Rose Heps (W. B.).**—These are not in any way injured by remaining on the trees to be frozen to some extent; indeed, it is questionable if severe frosts are detrimental to their germination.

**Fungus on Celery (Inquirer).**—The name of the fungus which covers Celery leaves with dark brown spots is Puccinia apii. Mr. W. G. Smith says:—"When seeds are sown which have been gathered from diseased Celery plants the youngest seedlings suffer from the same disease as the parent plants.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers.

Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp.

COVENT GARDEN MARKET.—OCTOBER 29TH.

NOTHING of importance to note. Business remains with no alteration, and supplies equal to demand.

FRUIT.

Table with 4 columns (s. d., s. d., s. d., s. d.) listing various fruits like Apples, Lemons, Melons, Oranges, Parsley, Peaches, Plums, St. Michael Pines, and Strawberries with their respective prices.

VEGETABLES.

Table with 4 columns (s. d., s. d., s. d., s. d.) listing various vegetables like Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Cabbage, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard & Cress, Onions, Parsley, Parsnips, Potatoes, Rhubarb, Salsify, Scorzonera, Seakale, Shallots, Spinach, Tomatoes, and Turnips.

CUT FLOWERS.

Table with 4 columns (s. d., s. d., s. d., s. d.) listing various cut flowers like Arum Lilies, Asters, Bouvardias, Carnations, Chrysanthemum, Cornflower, Dahlias, Eucharis, Forget-me-not, Gardenias, Gladiolus, Gypsophila, Lapageria, Lavender, Lilac, Lilium, Marguerites, Maidenhair Fern, Mignonette, Pansies, Pelargoniums, Pinks, Primula, Roses, Teas, Stocks, Sweet Peas, Tuberoses, and Violets.

PLANTS IN POTS.

Table with 4 columns (s. d., s. d., s. d., s. d.) listing various potted plants like Aralia Sieboldi, Arbor Vitæ, Asters, Calceolaria, Chrysanthemum, Climbing Plants, Dracæna terminalis, Erica, Euonymus, Evergreens, Ferns, Ficus elastica, Foliage plants, Fuchsia, Geraniums, Geraniums Scarlet, Heliotrope, Hydrangea, Lilium lancifolium, Lobelia, Marguerite Daisy, Mignonette, Musk, Myrtles, Nasturtiums, Palms, Pelargoniums, Rhodanthe, Stocks, and Tropæolums.

THE NEW "ROYAL" JOURNAL.

MUCH more valuable than any former efforts of his is another article on "Covered Cattle Yards," by Mr. W. J. Moscrop, in the new number of the Journal of the Royal Agricultural Society of England, because it goes so carefully into details, and is therefore

proportionately useful. Ventilation receives due attention, the different kinds of roofs are well illustrated by woodcuts, quantities and prices are appended, all structural points are explained, and the advantages of such structures are set forth as tending to the economy of food in conjunction with the health and well-doing of stock, the superiority of manure and economy in its application, and in the saving of litter, by all which the ingenious author quotes figures to show how, in his opinion, a saving and gain of £3 11s. 10d. per head of cattle is effected. He usefully gives point to his article by his closing paragraph, in which he says, "At the present time perhaps few ways are open to a landowner in which he can so readily and greatly assist his tenants, whilst indirectly benefiting himself, as by the equipment of his estate with covered yards. On many estates this has been done, and my parting word to the owners of those where it has not is, Lose no time in effecting a work that ranks so high in the list of farm economy, which judiciously carried out will prove a lasting benefit to the tenants, tend to an enhanced value of property, and thus become a sound investment of capital."

Though Professor Green's paper on "The Seed and its Germination" is unlikely to excite much attention on the part of practical farmers, it is nevertheless an important contribution to agricultural literature, as showing the reason why of a process of such vital importance, and it is surely something gained when men of science can say positively, as in this case, "We know."

Farming in Devon and Cornwall by Mr. F. Punchard marks time, and tells an interesting tale of the progress of these two remarkable counties. The account of fruit and vegetable farming in Cornwall is especially interesting just now, when general attention is being drawn to the subject; and an account of 300 tons of Strawberries, 4500 tons of new Potatoes, and 8000 tons of Broccoli sent by the Great Western Railway alone last year from the two counties to London, Manchester, Edinburgh, and other large centres, gives some idea of the extent of this trade, which now embraces Tomatoes, Raspberries, Gooseberries, and other bush and tree fruits. Rather full details of the cultivation of new Potatoes are given, but the writer is somewhat loose in his statements about the quantity of manure used, and the amount realised per acre. Devon live stock deservedly has an interesting chapter, and the fact is noteworthy that this county can boast of two native breeds of cattle (North Devon and South Hammers), four of sheep (Devon Longwool, South Hams, Dartmoor, and Exmoor), and two of ponies (Dartmoor and Exmoor). South Hammer cattle, we are told, have been much improved during the last fifteen years, and the cows are remarkable for their deep milking properties, 24 quarts a day being no unusual quantity for one of them to give.

The Devonshire water meadows and Devonshire cream each have a chapter, and an account is also given of the Prison Farm in the wilds of Dartmoor, where the tillage of 2000 acres is done entirely by the convicts, and the barren land reclaimed to such good purpose that one field in particular is mentioned as at one time being mostly rushes and now grazing a bullock per acre. The flock of Improved Dartmoor sheep at this farm must be remarkable animals, for the fleece of a ram is mentioned as weighing 27 lbs., and hoggets as averaging 14 lbs. to 15 lbs. per fleece, the price expected for the wool being 7½d. to 8d. per lb., or 18s. for the fleece of the ram!

A full report is given of the Plymouth meeting, and there are special reports of certain important features of the Show. No doubt the trials of light portable motors show improvements in construction and in economy of fuel, but this particular trial appears to us to take a flight quite out of the reach of ordinary farm requirements. Economy of fuel is all very well, but what is wanted for an ordinary farm is a cheap one-horse power motor within the means of an ordinary tenant farmer, say at about the price of a full-sized waggon, and the Society would certainly do well to encourage the production of such a motor, suitable for cutting chaff, crushing corn, and similar work.

With this copy of the Royal Journal nomination papers were sent out with an invitation for members to select judges for the next meeting. This was wisely done, so wisely that we are induced to hope members may eventually be asked in a similar manner to call attention to any want or possible improvement in agriculture which appears to them to fall within the far-reaching scope of the Society's work, and so add to its usefulness.

#### WORK ON THE HOME FARM.

Now is the time when a regular and full supply of eggs affords the best proof of skilful poultry management. The early pullets reserved specially for this purpose are laying tolerably well, and they must receive every advantage of draught and damp proof poultry houses, mixed food, a snug shelter by day open to the south, with plenty of dust and raised places, not perches, but low heaps of dry litter, or a platform raised a few inches from the floor; anything, in point of fact, which may help them to keep warm and dry. They should be shut in the roosting places at night, and not allowed to go out early at this time of year. They show plainly enough by their habits the sort of treatment they require. On a warm sunny day they are spread far and wide over the meadows; on a dull, cold, or wet day they keep as much under shelter as they can, many of them going up on the perches. Meal, crushed potatoes, kitchen scraps, and a little whole maize mixed with warm water is generally given now, no food being allowed to lie about, only as much as can be cleared up quickly being used each time. We prefer feeding ducks by themselves, for they are so greedy that they gobble up much more than their share if feed with other poultry. Now that turkey poults are required for table regularly, it is well to select the stock birds for next season, and mark them, or the best birds will be selected, till in the end there will only be inferior ones left for breeding.

We have begun curing bacon hogs for drying, as the store of bacon is running low, and there are complaints of its saltiness. We can manage some mild cured bacon during the winter and spring months, but for keeping in a sweet and wholesome condition throughout summer, it must be well salted and dried. An occasional porker of 60 or 70 lbs. weight is required for table, which can always be had, as we take care to have litters of young pigs in succession, upon the principle of breeding as often and as many as possible. Stubble pigs are now being finished and sold in batches of a dozen or two, and we find this plan better than keeping them for large jointers. Care is taken to keep stys and yards clean and well littered, both for the comfort of the pigs and to prevent disease.

#### OUR LETTER BOX.

**The Price of Mangolds (G. C.).**—The average price per ton for Mangolds may be placed at 15s. It is affected by locality very much. We have known them to be sold at 10s., and at various prices up to £1 per ton. The price in your neighbourhood is more likely to approach the higher than the lower rate, and if you require any considerable quantity it would be as well to ascertain prices on rail in some quiet district twenty or thirty miles farther from London for comparison with your local price.

**Windsor Beans for Pigs (G. A.).**—The Windsor Beans are an excellent addition to the food of pigs or any other animals of the farm. About a quart daily of whole Beans may be given to a full grown pig that is being fattened, and beanmeal may be mixed with advantage with middlings or pollard for porkers. For store pigs the Beans are not used, simply because other and cheaper food answers perfectly well for them. We hope shortly to deal fully with the entire question of pig feeding.

#### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

#### REMARKS.

19th.—Fine and dry, with cloudy sky.  
 20th.—Overcast throughout; occasional drizzle in evening.  
 21st.—Dull and rainy till 10 A.M.; overcast morning; generally bright in afternoon.  
 22nd.—Misty early; bright day.  
 23rd.—Fair and pleasant, though sunless.  
 24th.—Mild and generally dull, but occasional sunshine.  
 25th.—Mild, dull, and damp till 11 A.M., then cooler and wet till 3.30 P.M.; bright moonlight evening and night.  
 An average autumnal week, generally fine.—G. J. SYMONS.

“NOT quite all Chrysanthemums, if you please, Mr. Editor, nor even all fruit or all Orchids, Roses, Daffodils, or herbaceous plants. Something of each of these if you like, and a good deal of any of them at appropriate seasons, but do not forget there are trees.” Thus writes one who enjoys his garden and all that is cultivated in it, but he evidently thinks that the flowers of our stoves, greenhouses, and gardens receive the lion’s share of attention in these days, that the fruit “boom” is being sounded loudly, but that trees for use and ornament are not having a corresponding share of attention. We are inclined to think our correspondent is right, but in giving our adherence to the principle embodied in his short, terse note it is with no wish that there should be any cessation of interest in flower and fruit culture, but only that more attention should be bestowed on trees.

“Do not forget there are trees !” Those six words we suspect are intended to convey something more than a reminder—namely, a delicately suggested reproach, not to ourselves alone, or perhaps mainly, but to proprietors of many estates that might be improved and beautified by trees wisely chosen, well planted, and judiciously managed ; also to municipal and other authorities, on whom devolves the duty of providing and maintaining public parks, also of planting trees in and near towns for rendering them more pleasant to their populations. For ourselves we do not forget there are trees. We have of late had attention directed to their planting and management by able contributors, and we have much more that we think both interesting and useful to record in these pages. We have long regretted to see trees that have for years imparted grandeur to many a fine demesne going not gradually but rapidly to decay, and few or no attempts made to provide successors. Also it is not indicative of good management to see, as all who are in the least observant cultivators must see, the acres, even miles, of scrubby waste that might have been occupied with trees handsome or useful or both, for if the combination of beauty with utility can be seen anywhere, it is in thrifty plantations of appropriate trees. Many examples prove this in different parts of the country, for happily the neglect of arboriculture is not apparent everywhere, though unfortunately it is far too common.

Again, where planting has been done during recent years in public and private parks and gardens, it is nothing less than deplorable to see in so many of them what can only be fittingly described as the reckless method in which the work was done, and the subsequent ruin of thousands of trees. Obviously if the proprietor of an estate wishes to turn it into a jungle, he has a right to do so. He pleases himself for the time, but of necessity must leave a wild unproductive thicket behind him ; whereas he who proceeds on different lines, in accordance with sound principles, provides noble memorials of his thought and care to be enjoyed by succeeding generations. But even on the basis of private action—that he who pays the piper has a right to choose the tune—we have the right when the public finds the money in the form of rates for planting and maintaining public parks, to protest against the unscientific and unsystematic manner in which the planting has been in most cases done, and the subsequent spoliation of trees that has followed. “Bundle them in” appears in too many instances to have been the rule in the first place, and “let them alone” the policy afterwards. Incalculable benefit has been conferred on

communities by the formation of public parks in populous districts, but all the same, thousands of pounds of public money have been unwisely spent in them, on trees and shrubs to be spoiled, and in a few years’ time not one tree out of a hundred will be worthy of its name.

We do not in the least object to anything in the letter that has elicited these remarks. It is time that more attention was given to the planting of useful and beautiful deciduous trees, for beautiful many of them are which are little planted, as may be seen in those nurseries which contain rich collections. Conifers are handsome, and if judiciously planted effective, but in too many instances they have been so crowded into parks and gardens for “immediate effect,” and deciduous trees either excluded or spoiled, that the result is neither cheerful nor agreeable, but funereal. We are glad that the Royal Horticultural Society has at last determined to elicit information on the subject of trees, even if at present restricted to Conifers. It is quite large enough and important enough for a Chiswick conference, but we rest more firmly than ever in the belief that the Society does not do the best for the public by the slow production and restricted distribution of the information acquired at these conferences, and by lectures that few hear and which a comparatively small section of the horticultural community can ever see. Judging from the précis of Dr. Masters’ lecture on trees and shrubs in towns last week, it was most comprehensive, and could not be otherwise than full of instruction and valuable suggestions. Undoubtedly worthy of prompt and wide circulation, it must, under ordinary conditions, remain in obscurity for a considerable time, till the best planting season is over, and then it will not be seen except by a very small minority who might benefit by its teaching. That, however, does not concern ourselves. As above mentioned we have much matter on trees and shrubs awaiting publication. Among other competent men Mr. E. Luckhurst, who has planted trees extensively for use and ornament, and who is now engaged in estate improvement, writes thus on “Tree and Shrub Groups :”

“Taken in its literal sense of an assemblage of figures forming an artistic whole, the term group, as applied to an arrangement of trees and shrubs, is most expressive and appropriate. So pray remember, brother planters, that your grouping this season must be really artistic and not fanciful ; and if you are sensible that your work is more likely to prove an outcome of fancy, and not an embodiment of cultivated taste, then do not venture rashly upon it, for every error will become more conspicuous and offensive with tree and shrub development, many a fault that is unseen by an ordinary observer at first becoming so accentuated by growth as to afford tangible evidence that a thing of beauty in the wrong place is certainly not a joy for ever.

“But good taste may also make mistakes in planting by falling into the very common error of looking only to immediate effect, and planting much too thickly, with the inevitable result of crowding in the course of two or three years, when beauty of form and individuality are soon lost, and the clump becomes a mere thicket. If immediate effect is insisted upon, let it be clearly understood how soon thinning will become necessary ; then first of all plant the permanent trees, and afterwards proceed to fill in the intermediate spaces, taking especial care to afford the permanent trees ample space for root and branch growth. When shelter only is required for the permanent trees, Larch or *Pinus austriaca* answer well, preference being usually given to Larch because of its greater value when cut.

“Before planting at all the whole matter should have most careful consideration, and the results will very much depend upon the decision arrived at, as well as upon the execution of the work. First of all try to grasp fully what you have to do, and then do it in the best possible manner. Let it not be thought that I wish to see a garden or park with every tree or shrub standing out simply as plain and precise as the lay figures in an artist’s studio. There is

beauty—often great beauty—even in a thicket, but if you intend having a thicket, plant for it just as carefully as you plant for fine specimens, but neither should be the result of an accident. The individuality of a grove or thicket are as distinct, and often more telling, than that of single specimens, and both are attractive features in a garden. Here is a charming picture taken from an account of a visit to Herring the artist's Kentish home. 'White and red Rosebuds just bursting into bloom, clustered round the verandah, and from it the outline of the pleasant woods of Penshurst, which

“ ‘ Heard the sounds of Sydney's song,  
Perchance of Surrey's reed, ’ ”

was just visible in the drowsy distance. Partridges were feeding on the lawn, and scarcely caring to rise on the wing, or run behind the purple Beech at your approach; the deep coo of the wood pigeons as they perch on the Scotch and Silver Firs, which towered above the thickly interlaced grove of Holly and Laburnum, so vocal with its song of spring, was all in harmony with a painter's home.' How it breathes of the restful seclusion and quiet beauty of a home in the country! All is in harmonious repose, and the purple Beech, Firs, Holly, and Laburnum, and clustering Rosebuds all appeal to one like old familiar friends. There is an amount of character about every one of them that tells in a garden as few introductions of later date have done. Breadth of colouring always tells, and is far more satisfactory than a motley group that is more like a patch taken from a nurseryman's show borders than anything else. I once designed a garden which contained many raised banks with bold curves and deep nooks, each of which should have had its own peculiar features distinct in themselves, yet in harmony with the remainder. But unfortunately the planting was placed in the hands of a nurseryman, who simply crammed the whole of the borders with choice specimens, with a result of singular uniformity, utterly devoid of repose, and which was decidedly insipid after one inspection.

“ In contrast with this mistake take another bank crowned with *Pinus insignis*, which in some parts came right down to the bottom of the bank, sweeping thence upwards and along the slopes in graceful curves, in which was space for Silver Birches, Liquidamber, Scarlet Horse Chestnut, some of the best Maples, Scarlet Oak, Mountain Ash, Snowy Mespilus, and Acacia. Some curves contained two or three of these lovely deciduous gems, while others had only one of them. The effect was indeed most pleasing, and the scene grows in beauty year by year, so much so that I hope to repeat it elsewhere. One only regrets that *Pinus insignis* cannot be planted more generally, for where it does answer it is a veritable queen among *Pinuses*.

“ A much bolder effect upon a hillside was obtained by a free use of large masses of *Pinus austriaca*, Larch, Scotch Fir, Beech, Wild Cherry, Maples, Horse Chestnuts, Tulip Trees, Scarlet Oak, and White Birch. The effect during summer is exceedingly good, and in autumn it is lovely. This blending of deciduous with evergreen growth is always desirable, and is entirely satisfactory in skilful hands. It gives the planter scope for tasteful combinations, and imparts clothing and warmth to a landscape throughout the year.

“ How frequently has one cause for regret, both at unskilful grouping and the subsequent neglect of trees that are so generally planted too thickly. In my long journeys by road and rail it is quite an exception to meet with really well managed timber. Even hedgerow trees are seldom fine timber or flourishing specimens, and belts and clumps frequently have an air of neglect, which betokens all too plainly a lack of knowledge, to use no stronger term. Much caution is necessary in any attempt at the improvement of trees that have often been left untouched and uncared for during many years. I have occasionally been consulted about them, and am only too glad when judicious thinning and trimming prove to be possible.”

It will be conceded that our correspondent writes sensibly, and

the work he has done affords sufficient evidence of his capacity to teach sound doctrine on the subject in question.

### HARDY FLOWER NOTES.

THE weather, which for some days was exceedingly stormy, has again become more settled, and as usual, frost not having been so severe as further inland, flowers have not suffered much. We have still Dahlias in flower, and *Tropæolums*, among the first to suffer in frost, are yet in bloom. This being the case with such tender plants, hardy flowers were comparatively uninjured. The *Asters* are among the finest plants in the garden at present, and one is glad to find them becoming increasingly appreciated. I have of late been repeatedly asked by friends if I could give them pieces of such fine varieties as *amellus bessarubicus*, *novæ-angliæ ruber formosissimus*, *longifolius* var. *formosus*, and *diffusus* var. *horizontalis*. The latter has attracted much attention when in full flower, as it has been for a fortnight or more, and for neatness of habit and general gracefulness of appearance it is difficult to find a compeer. The flowers are very small—white, with red centres and somewhat reflexed petals. Individually, or when cut, these flowers are of little effect, but the plant when in flower is exceedingly pleasing, the deep green foliage and the multitude of flowers making it look like a bush sprinkled plentifully with snowflakes. With me it grows about 3 feet in height. I have had this species for some twelve or thirteen years, and am a little surprised to find some good hardy plant growers who have been until now unacquainted with it.

*A. formosissimus* well deserves its specific name, which means “most beautiful.” It is of good habit, grows with me about 4 feet, and produces many flowers of the finest colour. The fault of the varieties of *A. novæ-angliæ* is their ungainly habit and the comparatively few flowers produced for cutting purposes. It is, however, invaluable. *Chrysanthemums* are still aiding in the garden display, and we hope the increasing interest taken in October flowering varieties will add some more varieties which will prolong their season outside.

We have, as usual with mild weather in autumn, many unseasonable flowers. *Alyssum saxatile* has been in flower for about two months, but the appearance it presents is most forlorn as compared with its effect in spring. Instead of the masses of old gold covering the leaves as with a carpet of cloth of gold, a few stray spikes only are thrown up above the greyish leaves of the plant, and one longs for the time when its vernal robe will again cover it with beauty. *Auriculas* and *Primroses* must needs present themselves, while one or two of the giant *Thriffts* which with me are almost continuous bloomers, lift their tall wiry stems above their pretty tufts of grass-like leaves. Some of the *Aubrietias* have never ceased to flower all the season, but, like the *Alyssum*, they only present the shadow of things to come. *Erinus alpinus*, which is quite at home in my light soil, throws up many stray spikes of its pretty little flowers. Seedlings of this vary considerably in colour, some pale, some bright purple, and some bright rose. *Erysimum pulchellum* is bearing many little yellow flowers, which are borne on extremely short stems hardly rising among the foliage. These flowers are not nearly so freely produced as in spring, but as a set-off to this the spring flowers are carried on stalks which are then too long in proportion to the size of the flowers. I do not believe this will ever become a popular or useful border plant, nor do I think it will be thought one of the choicest of our rock plants; but I feel sure if more could only see it as it does with me, it would be more generally grown. I grow it on a narrow ledge of the rockery less than 3 inches across, and allow it to grow down over the front of a large stone, which is soon covered with a cushion of evergreen small Wallflower-like leaves. As a covering plant for an upright stone it has few equals. I wish, however, to be perfectly frank as to its defects, and thus have again to warn the reader that its spring effect is not so neat as one would wish. It seems to become better the longer it is established, as last year, after being four years planted, it was finer than ever. This Hedge Mustard (“popular” names are not always attractive) is easily grown from seed, and large plants are difficult to establish.

*Eucomis punctata*, spoken of on page 335 by Mr. Skinner, is quite hardy with us here, requiring no protection. My plant did not flower this year, having been robbed by another flower being too close, but it flowers well here and in some other gardens in the vicinity. It is well worth growing, and although dull in colour it is a plant which stands and needs careful inspection to appreciate thoroughly. What a harbour it is for small flies, attracted probably by the perfume, which is so powerful as to be hardly agreeable. I have never seen a bee on this plant. Can anyone state anything as to this point? *Anemones* are again beginning to flower. Last winter we had them in the open all throughout the winter with a

mat supported above them on hard nights, and this season I intend filling a frame with Anemones, as they are most valuable for cutting, lasting long in water, and many are of exquisite colouring.—S. ARNOTT, *Dumfries*.

### SYRINGING.

SYRINGING is a very important aid to successful gardening, possessing, as it does, the twofold virtue of assisting growth and keeping it in a clean healthy condition afterwards. But whilst a most useful agency when properly applied, what may be termed reckless syringing cannot be too strongly condemned. To syringe a plant or house a certain number of times in a day regardless of all conditions is enough to bring the practice into disrepute, and to condemn the use for causes which ought properly to be credited to the abuse, although, like most other implements, the dangerous qualities of the syringe are mainly brought out when placed in the hands of the inexperienced. When used to produce a genial atmosphere its combined influences are readily observed, and in like manner a house where there is a damp stagnant air or dry parched feeling noticeable, shows the effects only too plainly of the sins of omission or commission. Like everything else it produces good or ill results according to the skill or carefulness of the operator.

As a means of assisting growth the common practice of syringing Vines when in a dormant state is familiar to all who have had anything to do with their cultivation, and years of close observation prompt me to state that this is more frequently overdone than otherwise. At the time when this process is first called into action—generally in winter, when the chilly dampness of the external atmosphere influences the internal air to a great extent, as but little fire heat is used at the commencement of forcing—it would be most unwise to syringe with the same freedom that might be quite harmless at a later period, when the days are longer and warmer. And yet this is done with the frequent result of tender attenuated growths that bear a larger crop of tendrils than bunches. Even where the practice is not carried to the same extent as this it is questionable if a still less use of the syringe than is sometimes advised would not be of advantage. It is a well known fact that waterings over the foliage are not conducive to floriferousness or fruitfulness, and as fruit is the principal object for which Vines are grown, any means which might be the cause of thwarting that object ought to be used with extreme caution. The trainings of infancy have a great effect on the actions of mature age, and in like manner the early treatment of the bud influences the latter growth and its attendant fruitfulness. Good crops of fruit are had from Vines that are syringed in their early stages, and in some instances the practice is followed up until the ripening period has commenced, with fairly satisfactory results. But is it not probable that the crops would have been still more satisfactory without the assistance of the syringe? In my opinion—which is expressed with great diffidence—the less a syringe is used directly on the Vine the better, unless an occasion may arise for its services. If the Vines are thoroughly ripened, and in other respects properly treated, there ought not to be much assistance required from the syringe to start them into growth. If an occasional damping, sufficient to keep up a moist searching temperature, is not enough to start growth, I would try to find out the cause before using the whip—I intended to write syringe, but the terms in the sense implied are somewhat analogous.

Damping, as applied here, is not merely throwing water along the path, but syringing the walls and other exposed surfaces as well. It appears to be like a case of "will he, nil he" to see a Vine syringed a regulation number of times in a day, or in fact any plant where the pruning has not extended beyond the current year's growth, but if a plant has been pruned hard into the old wood the assistance of the syringe carefully used is productive of the most beneficial results. In the latter instance the treatment is unnatural, and is only done in extreme cases when extreme remedies are in common request. A plant that has overgrown its limits, or from continual cutting has been rendered unsightly, is frequently transformed into a fairly good specimen by being cut back into wood several years old. When this is done the assistance of the syringe as an incentive to growth is generally recognised. But unless at such times as these the direct action of the syringe on the plants it is intended to benefit is not generally its best mode of doing so. It has been observed that this practice is only following Nature, and the rains and dews are quoted to prove the truth of the observation; but who amongst practical gardeners waters his Vine borders with a syringe? yet the rain has first to fall on the tree before it descends to the roots, and there is no necessity to argue the fact that the dew is more closely imitated by the ascending moisture from sprinklings than by directly syringing water on to the plant.

It has already been observed that waterings over the foliage are not conducive to floriferousness, therefore softwooded plants which are not subject to the attacks of insects are generally better without syringing, but those of a more hardwooded description, and foliage plants generally, are difficult to keep clear of insects without its use. But there are different ways of using a syringe, and to dew a house of plants with a spray nozzle is not the method which is most successful in keeping plants clean. It is generally the under side of the leaves and the stem of a plant where the insects commence their career, and to check their action or prevent their gaining foothold those parts must have its action applied to them with a force sufficient to effect that purpose.—M. D.

### LETTUCES.

THIS summer I determined upon giving a good trial to several new and old varieties of Lettuces, to ascertain which were the best and most profitable, the latter point being a matter of importance to me, as indeed it is to most people nowadays. I sowed from seed received from New York, Sunset, New York, Big Boston, and Salamander, and from MM. Vilmorin, Blond Blockhead (what a name!), White Chavigny, and Trianon. Having thus put America and France under contribution, I turned to my native soil to provide me with Paris White Cos (which is French), All the Year Round, Sutton's Favourite, and Bath Cos. The latter are well known, and were simply grown to test the other varieties. I had forgotten Daniels' Buttercup, which, being the only new English variety, I will describe at once as a compact growing yellow Cabbage Lettuce, which hearts readily and is of good quality, but wants using at once, for the leaves being very soft they easily bruise, and the appearance is then spoilt. Sunset, a curled Cabbage variety, I found very good, but not extra good, and having found better I shall not grow it again, although it is better than many. New York is an exceedingly large Cabbage, of dark green colour, crisped and curled somewhat, hearting quickly, and when well grown will save much trouble in pulling, for one will easily take the place of four ordinary Lettuces. The quality is good. Being so large and solid it sells readily for a good price, which is another important point. Big Boston runs to seed in a hurry, and I never want to see it again.

Salamander is very similar to White Chavigny. It is a smooth leaved Cabbage, not running to seed but forming white hearts, the plants being compact and uniform in growth. This description will also cover White Chavigny, and if you grow one you will not require the other, for there is nothing to choose between them. Blond Blockhead, a fringed and crisped Cabbage variety, is a real beauty, and to my idea the best Lettuce I ever saw. The plants in a young state are green, but when the large round hearts—not flat round, but globular—are formed, they turn a delicate pale yellow, and are beautiful to the eye, and I may add to the palate also. It does not run to seed readily, but stands drought very well. Trianon is a Paris White variety, and is excellent. I grew it to a large size, and found it good in all respects. Sutton's White Heart, which I grew two years ago, I shall in future join with Trianon for Cos, and Blond Blockhead with New York for Cabbage varieties. These four varieties will supply me with all I want during the summer. Had I not unfortunately put out several hundreds of Big Boston, which all ran to seed, I should have been very pleased with my Lettuces this year. Where space cannot easily be spared, I find planting a row between the rows of newly planted Strawberries a good plan, and they invariably do better there than elsewhere, and being soon off the ground they do not affect the Strawberry plants injuriously.—H. S. EASTY.

### SARRACENIAS.

As a grower and exhibitor of these beautiful and most interesting class of plants, I should like, with your permission, to supplement the article of "K." in your Journal recently. I consider that watering and the annual repotting are the most important matters in their cultivation. I say annual, because as far as my experience goes, these plants cannot be kept in vigour if this is not done, and what I mean by the annual potting is shaking the roots out of the potting material and using fresh. As a rule this is done in the spring of the year, but it may be done any time, the roots being so pliable they are not, with ordinary care, readily injured. Plants are broken up at any time here when necessary for propagation, and the plants continue growing as if they had not been disturbed.

Water is freely used amongst them here; in fact, when potted in the material recommended by "K.," watering cannot be overdone. We deluge with water every day when the plants are growing, as dryness is fatal to the development of the pitchers. Water is given freely three times a week in winter when not growing.

As to varieties, your correspondent, "K.," mentions several that I have discarded, because superseded by better. *S. variolaris* gives way to that beautiful Lancashire hybrid *S. Wrigleyana*, the pitchers of similar shape, but larger, and the marking much brighter; and so does *S. psittacina* to that charming sort, *S. Courti*, the handsomest and most highly coloured amongst the dwarf growing varieties.

*S. rubra* is recommended by "K." for the fragrance of its flowers, but its pitchers are too small to be interesting; they are also wanting in colour.

The varieties below mentioned ought to be in every collection, because of the immense size and beautiful markings of their pitchers. *S. Williamsi*, pitchers 15 inches high, of a light green colour, with wide spreading mouth, ornamented by a lid 5 inches in width, with gold and crimson venation, a very handsome variety. *S. Flambeau*, a very highly coloured variety, the upper part of the pitchers of an intense crimson, with darker reticulation, the lid partially turned over the mouth; its height is about 15 inches. *S. Maddasoni*, of similar size and shape to the preceding, with green pitchers, and beautifully veined with crimson. *S. Tolliana*, pitchers green, with large open mouth, and correspondingly large lid, crimson and gold markings, height about 18 inches. *S. Stevensi*, another very handsome variety, pitchers about 20 to 24 inches, dark shining green, and heavily marked, with crimson venation, narrower at the mouth, has a large wide spreading lid, also beautifully marked. *S. Fildesi*.—This is unquestionably the largest and handsomest of the tall growing sorts, pitchers 20 to 30 inches high, of a light green, and richly marked with crimson, very wide mouthed pitcher, the lid of which I have measured 6 inches across.—A. J. A. BRUCE, *The Nurseries, Chorlton-cum-Hardy, Manchester.*

IMPORTED ORCHIDS.

THIS subject is one which is not thoroughly understood by all gardeners, though it is of the greatest importance to everyone interested in Orchid culture, and it is, moreover, a subject upon which very little has been written. Probably a few remarks may therefore be useful to some readers of the Journal.

It has often been asked, What becomes of all the Orchids that are annually imported to this country? Many thousands of plants from various parts of the world find their way into the English market from the numerous collectors employed by the leading nurserymen, such as Messrs. Veitch, Bull, Williams, Hugh Low and Co., Sander & Co., St. Albans, and many others, besides private gentlemen and others. Then it is again asked, What becomes of all these? The question has been answered by many, and by all in the same way—namely, that more Orchids are killed than are grown. Before Orchids were so well understood as they are at present thousands of valuable plants were killed owing to the collectors not furnishing the growers with sufficient information with regard to the temperature, climate, and altitude where the plants were found growing in their native habitats. If they came from the tropics it was thought they all required the same treatment, but experience has proved this to be a fallacy.

The trade that is known as Orchid-importing is rather a critical one, subject to great fluctuations and disappointments. It is very disheartening to both employer and collector, when a very valuable importation of Orchids has been received, to find on opening the cases that there is scarcely one living plant. The condition in which Orchids are received depends in a great measure on the time in which they are collected. This may be considered the most important point, for if the plants have abundant young growths the chances are against their arriving in this country safely. The best time for sending the majority of Orchids to England is when the season's growth is completed, and they have been subject to a certain amount of drying or ripening; but no rigid rule can be laid down for the guidance of collectors; much depends upon their own skill and judgment. Packing is another very important matter, for if Orchids are not well and securely packed they present a miserable appearance when taken from the cases. Each collector has his particular style of packing plants, as certain genera require to be packed quite differently from others. I need not go into details with regard to packing, for there is so much to be said in connection with it that a whole chapter may be written on it.

When Orchids are newly imported they present at the best of

times a rather sickly appearance; but with a little kind treatment they soon revive provided there is sufficient life and vigour in them to make fresh growth. Many are under the impression that when Orchids are newly imported all that they require is to be potted, placed in a high temperature, and given plenty of water to "freshen" them up; but it may be here remarked that nothing proves more fatal than such treatment. When the plants are received they should be thoroughly examined, taking care to remove any loose or decayed matter they may have about them. Of course different genera require different treatment, and I will take some of the principal that are of most importance to horticulturists, and give a few particulars respecting each.

**AERIDES.**—These are all epiphytes, and may be grown in either pots or baskets, baskets being preferable for many species. The present genus includes several very showy species, of which the following will be fair samples:—*A. crispum*, *A. Fieldingi*, *A. japonicum*, *A. odoratum*, and *A. quinquevulnerum*. They are always imported in dry boxes or cases. If the plants arrive in the best possible condition they have a slightly shrivelled appearance. Much depends on the time they have been coming. They should immediately be spread out thinly in a cool stove for a short time, placing them so that the foliage will not come in contact with any wet material. They should remain in this position for a few days until the foliage is becoming a little plump. Little or no water will be required on their roots or leaves, as the plants will take up sufficient from the atmosphere. Shade is essential to all newly imported plants. After the plants have plumped a little they may then be potted, using only broken potsherds and sphagnum. After they have commenced growing a top-dressing of sphagnum will be beneficial, watering them rather sparingly till they commence rooting.

**ANGRÆCUM.**—Angræcums of the *A. eburneum* type are rather difficult to import, for they generally lose a large number of their lower leaves. I find it a good plan to hang them up for a time to enable the leaves that remain to become firmer in texture, after which the plants may be placed in potsherds and sphagnum, watering rather sparingly till they begin to form fresh roots. *A. eburneum* and *A. sesquipedale* are the two most showy species, but there are several others that are extremely pretty and well worth growing.—L. C.

(To be continued.)

## GREEN-LEAVED DRACÆNAS.

IN those establishments where indoor decorations are carried out on a fairly extensive scale, green-leaved *Dracænas* take a prominent part in the display. Excepting perhaps the Indian rubber plant (*Ficus elastica*) *Aspidistra lurida variegata*, and a few Palms, no other plants that are used for this purpose withstand the rather rough usage better than the green-leaved *Dracænas*. They have also a very ornamental effect, and few plants look more graceful on the dinner-table than either well-grown plants of *D. gracilis* or *D. congesta*. *Dracæna rubra* may also be used for the same purpose, and with some people is a great favourite. For effect in the conservatory, what is more elegant than a well-grown specimen of *D. indivisa* Veitchi? *D. cannæfolia*, as its name implies, has some resemblance to the well-known *Canna*, although the style of growth is typical of a *Dracæna*. Either of the plants named may be grown in a cool conservatory or cool fernery, although whilst in a small state we grow them in an intermediate temperature to force them into size. Unlike other *Dracænas* the plants will retain their foliage for a lengthened period in comparatively small pots for the size of the plants. I kept a plant of *D. gracilis* in a rather dark part of a sitting room for upwards of nine months without the loss of a single leaf, much less colour, so this is evidence of the good qualities of the above named plants. When kept in a sitting room for a lengthened period watering must be carefully attended to, and the foliage sponged occasionally to keep it from dust, which injures plants as much as anything.

Although the propagation is somewhat different from that generally practised for the higher coloured varieties, there need not be the least difficulty on this point. *D. rubra* and *D. congesta* are propagated from the roots, or rather underground stems. To secure these the plants should be turned out of the pots, when the underground stems should be removed with a sharp knife. These could be cut up into lengths, and inserted singly in small pots or placed in fibre in a propagating frame, where growth will soon take place. In our own case we have several planted out in large baskets, when the underground stems push out all around. These are cut off when about 2 inches in length, and inserted in small pots. We have numbers which were taken off in the spring, and are now useful plants in 48-sized pots.

We have not the least difficulty in keeping up a good stock of *D. gracilis*. The tops taken off tall plants root readily if

inserted firmly in sandy soil in small pots, and these placed in a propagating frame. The old shoots are placed on a shelf in a stove, when the dormant eyes soon start into growth. These soon form useful cuttings, when they are taken off with a heel, and inserted like the tops firmly in small pots, and from these when well rooted into 48's. Equal parts of turfy loam and peat, with the addition of silver sand and charcoal, form a suitable compost. Vigorous syringing for young growing stock is very beneficial in keeping the foliage free from either red spider or thrips, which soon disfigure the plants when allowed to gain a footing.—A. YOUNG.

### LILY OF THE VALLEY.

It is somewhat surprising how little trouble is taken in the cultivation of this ever-popular plant, for though it would be a hopeless search trying to find a garden without it, just as every garden has its spot sacred to the Violet and the Rose, yet in how many gardens can it be said that due attention is paid to its wants? The bed or clump of Lily of the Valley may be likened to the brook of the poet—it goes on for ever. A change of garden government may see the overhauling of many things, but as a rule the most extreme reforms stop short at the spindly and antiquated plants, which do their very best to pay a quota of sweet-smelling sprays for the space they are allowed to occupy. This is not as it should be. Nothing pays better than improving Lily of the Valley by good cultivation. In comparison with most cultivated plants the labour involved is very small indeed, and the results, though not of a sensational nature, are nevertheless somewhat extraordinary. I presume most people are acquainted with the ordinary garden variety which produces, according to the want of care it has to submit to, spikes with from thirteen to fourteen down to five or six bells of small dimensions. Under a course of common-sense culture this common variety may be induced to furnish spikes with an average of twenty large bells, and occasionally with as many as twenty-four to twenty-five, and in one instance I have gathered a spike with twenty-seven expanded and unopened buds. As a rule nothing gives greater satisfaction than good quantities of common flowers, and if these are of a quality better than the ordinary run it gives great pleasure to the owner or his family to distribute them to friends. In this way Lily of the Valley pays well, but if it should occur that the inevitable "surplus" is required to find its way to market, then it will be found that good flowers will be easily disposed of at sometimes double the price of ordinary produce, while poor qualities will not sell at any price. Those unacquainted with this phase of the question will hardly credit the difference in prices betwixt good and poor qualities, especially when there is a good supply of any article. A salesman told the writer the other day he had just disposed of flowers of the same kind, but of varying qualities, at from 1d. to 4s. per dozen.

About the treatment necessary to secure Lily of the Valley of the best quality, it may at once be stated that there is very little in it. As generally grown Lily of the Valley is treated to the same contemptuous care as is accorded to Horseradish—that is to say, the dead leaves are raked off before winter, and the bed then left severely alone. It is one of the plainest axioms of good gardening that plants must be fed, and that the foliage must be allowed a free development, and in most cases the buds thinned out. It thus follows that an occasional change of ground may be advantageous, and that in any case the plants should be treated to periodical dressings of manure, and never be allowed to become too thick for the full development of the foliage. The present is a good time to replant. A thick dressing of cow manure should be dug-in and the plants put out in small clumps of four or five heads each in lines a foot apart, and about 6 to 9 inches from each clump. A surfacing of manure is of value spread thinly over the beds when the work is finished. If the plants are weakly they may be left without further attention save keeping free from weeds for the first year; but when the beds are in good cropping condition, beside the winter dressing of soil or cow manure, it will be found of the greatest benefit to spread a good coating of slag phosphate, of superphosphate, or of some good proprietary mixture between the lines during spring. The best time is when the buds are seen to be on the move. The quality of the spikes will be much improved, while the foliage will be much larger than if left undressed, the next season's crop, as a matter of course, benefiting to the full in increased length of spike and size of the individual bells. As to the length of time a bed should be allowed without breaking up and replanting, I do not think over five years should be allowed to pass. A portion should, of course, be done every year or second year, and thus a continued supply of fine-quality spikes will be secured, unless spring frosts should damage the crop. I have found a drenching of water in early May when the weather happened to be hot and dry do much good to the plants. When

the spikes are wanted extra fine, sashes placed over the beds and quite close to the foliage, with sides and ends open, secure them of the utmost purity.

As to the best variety, I grow a quantity of the true Berlin beside the common garden variety, and while the former yields finer bells and shorter though more equal spikes, it is much less prolific than the other, which produces a much greater number of spikes from a given piece of ground.—B.

### PIPTANTHUS NEPALENSIS.

THE Evergreen Laburnum is the popular name which has been not inaptly applied to this rare and little-known Indian shrub; but though it bears some resemblance to one of our most common and beautiful flowering trees, yet it can be easily distinguished from it at a glance by

FIG. 53.—PIPTANTHUS NEPALENSIS.

the most casual observer, and attractive though it be it cannot rival its more floriferous relative in effectiveness. Still it is one of those numerous old inhabitants of our gardens that deserve to be rescued from the obscurity and neglect into which they have fallen owing to the continued and extended introduction of novelties.

It is of branching habit, but not bushy, and seems to need support of some kind, as it has a rather straggling appearance. Trained to a wall it succeeds well, and is very pretty during May and early June, as it flowers abundantly when in good condition. In a few establishments it may be occasionally seen, but it is far from being common. It is quite hardy in most parts of England. It needs the protection of a wall in the northern or colder districts; but in the south it is rarely injured, even if planted in the open.

The name given above is the one by which it is best known, but it has several synonyms, *Baptisia nepalensis* being one that is occasionally seen, and more rarely *Thermopsis nepalensis* and *T. laburnifolia*.

CANNAS.—In favoured localities, and in dry sheltered positions, many of these will survive in the open, or where they are well established, but they require to have a good bank of ashes over them. As a rule the

safest course is to lift and treat very much as advised in the case of Dahlias. They keep exceptionally well on the floors of fairly light freely ventilated cellars, but commence growing again far too early if stored in close warm cellars. If packed closely together under greenhouse stages, as they often are, some method of warding off drip from pot plants above must be adopted, or otherwise either decay or premature growth will be the result.

### GRAPE GROWING AND GRAPE KEEPING.

A FEW words on the above subject at this season may not be out of place, and the method I am about to advocate may interest some of your readers, especially young gardeners who have lately taken on themselves the responsibility of a head place. I will commence with Vines which have been cleared of their fruit, and are intended to be started about the new year. These should have then had their shoots shortened as soon as the Grapes were cut, and this shortening should be continued at intervals up to the time the Vines receive their final pruning, by which means the eyes are strengthened and larger bunches secured. A good watering is also advisable at this period. Keep the Vines syringed daily, and should they be infested with insects syringe with the following in the evenings, washing the dead insects off in the morning:—Place 1 lb. black soap in a wooden, earthen, or tin vessel, add sufficient water to dissolve it; add 1 pint petroleum; mix all together, and when in a thick liquid add sufficient water to make 6 gallons.

The next point is the final pruning. Now no one cares to see long ugly spurs; but where Grapes are the principal object I advise that three, or even four, eyes be left, especially on old Vines. This gives choice of selection when the Vines are well started. Pruning completed, all cuts should be cemented in case of bleeding. This being done, commence removing the loose bark, not scraping the Vines, as is sometimes done, except in the case of insects; then it is necessary. Also the canes should be washed with the solution before mentioned, and dressed with a mixture of cow manure, soap, clay, sulphur, and petroleum, the house being washed previously. The rods may be tied in their proper places, except the Vines are young; then it would be necessary to tie them down to insure an even break. Commence now, and take all exhausted soil or manure off the border down to the roots, for if the borders have been properly treated roots will be near the surface, and if not the only way to bring them up is to supply a fresh soil, which ought to consist of fibrous loam, shells or bones, soot, and some lime—that is, if the soil does not contain sufficient. The border may be dressed with 3 inches depth of this, and it will then require a good dressing of cow manure, after which a thorough watering is essential. A little soil thrown over the manure gives the house a cleaner appearance.

We will suppose the new year has arrived. Commence by closing the house at night for the first week, in the second week close earlier still, in the third week about midday, and the following week introduce some long litter and leaves, which will maintain the temperature at from 40° to 60° by night, according to the weather. Ventilate by day very carefully from that time onwards, avoiding cutting winds or sudden falls of temperature. Close about 1 P.M., as by so doing in fine weather the temperature will rise to about 65°. When the fermenting material is nearly exhausted fire heat must be resorted to, the temperature requiring to be gradually raised, so that by the time the leaves are expanding it should not be below 58° at night and 65° by day. Admit air at 68°, allowing it to rise 75° to 80° by sun heat, and when the Vines are in bloom it will stand by night at 65°, by day at 72°. Admit a little air as early as possible. In mild weather run the temperature up to 85° or higher. Tap the bunches several times throughout the day, and give a good watering previous to flowering. Thin as soon as possible, and when the berries are stoning keep the temperature steady and the atmosphere drier, which will necessitate less fire heat. I never employ front ventilation until after the fruit is ripe. Still, I do not protest against others doing so; but think the method I adopt is the best. When the berries are colouring give another supply of water, also using Thomson's Vine or other manure, adding a good quantity of soot, which not only assists the colouring, but is also of great service to the foliage. Sometimes shanking is caused by too much water. I find that three thorough waterings, except surface waterings, are sufficient from the time the Vines are started until the Grapes are ripe; but supposing the borders were loose or shallow the above waterings would not suffice. Before entering on Grape keeping I must state that a Muscat of Alexandria house when in bloom should have a night temperature of 68° to 70°, day 70° to 75°, running up if possible by sun heat to 90°. Provided the canes are healthy the bunches will set as free as any other variety.

When the Grapes are finished, fire heat can be dispensed with in

the house started at the beginning of the year; but late houses will require some at times to prevent the berries damping, and the temperature must be kept as steady as possible. Many seasons Grapes can be kept better in a fruit room than on the Vines. A proper fruit room is so situated that the sun cannot strike on it after it is required for fruit, pipes being placed in it to supply heat if required and keep it airy; 45° to 50° is a good temperature to maintain. Ventilators should be opened at intervals, having a suitable heat at the same time in the pipes to avoid damp. I have known the late Mr. Tillyard, late gardener to the Earl of Yarborough, under whom I served as foreman, keep Black Hamburgs fresh in the fruit room from the month of October till March. Bottles filled with water and a little charcoal placed therein should be arranged ready. Cut the bunches with sufficient length of shoot to reach well into the water. A strict watch must be kept for berries damping, for one berry will soon ruin a whole bunch.

There are many points in Grape growing I have not touched upon; but what I have written I practise, and if any unsuccessful Grape grower will carefully follow what I have written he will find the results satisfactory.—S. SCOTT, *Belfast*.

EVENTS OF THE WEEK.—The Chrysanthemum shows are the special cause of horticultural activity just now, the present and succeeding week being remarkably busy ones for all concerned with exhibitions. To-day (Thursday) the Portsmouth Show continues, closing on Friday. There are also shows at Putney, Chiswick, Pembroke, Taunton, Stroud, Isle of Sheppey, Ascot, and Tottenham. On Friday, November 7th, the annual Show will be held at the Crystal Palace, Sydenham, which is expected to be of unusual interest, and there will also be a show at Exeter on the same day. On Monday, November 10th, the St. Neots' Society (Hunts), have their annual exhibition, one of the few held on that day. Tuesday, November 11th, is the opening day of the National Society's Show at the Royal Aquarium, Westminster, particulars of which are given in another paragraph. The Royal Horticultural Society's Fruit, Floral, and Orchid Committees meet on the same day at the Drill Hall, James Street, at twelve noon. The Kingston Show will also open on Tuesday, as well as Brighton, Lewes, Eastbourne, and Truro, all of which are two-day shows. Wednesday, November 12th, is another busy day, for besides those continued from Tuesday, shows will be held at Bournemouth, Croydon, Northampton, Tunbridge Wells, Birmingham, and Hampstead.

— THE WEATHER around London has been variable. Two or three days were extremely mild with continuous rains, but brighter weather has followed, though not cold for the time of year. The leaves are hanging late on many trees, but the first severe frost brought down all on the Mulberries, the Catalpas, and other tender trees.

— CHRYSANTHEMUM SHOWS.—We shall be obliged if secretaries or friends who favour us with reports of shows at which our representatives are unable to attend, will give the names of varieties in first prize stands in the chief open classes. We much prefer even very short accounts of shows written by officials or gardeners to lengthy newspaper reports, which can seldom be used. The co-operation that may be accorded in this matter will be much appreciated by the Editor.

— GARDENERS' ORPHAN FUND.—At a meeting of the Committee, held on Friday night last, it was decided to call a special general meeting of subscribers with the object of making a slight alteration in the rules, so that the financial year shall terminate at the end of December instead of at the end of June, for the convenience of subscribers and in the interests of the Fund. The meeting is to be held at the Cannon Street Hotel, London, at six o'clock P.M. on December 9th. It was also decided to close the Deal Memorial Fund on the 22nd inst. The response has been very good, but the Committee are anxious to raise a few more pounds for completing the sum they wish to raise for worthily

perpetuating the memory of an excellent man by placing a number of children on the list of beneficiaries. Any small amounts that can be sent to Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, for that good purpose will be thankfully acknowledged. Five shillings collected in fifty different gardens would fittingly close the Memorial Fund.

— CROYDON CHRYSANTHEMUM SOCIETY.—The Committee of this Society have arranged to have a stall for the sale of flowers and fruit in connection with their annual Show at the Skating Rink, Park Lane, Croydon, on Wednesday and Thursday, the 12th and 13th inst. The proceeds will be given to the Gardeners' Orphan Fund. Contributions of flowers, &c., will be gladly received by the local Secretary, Mr. G. W. Cummins, or Mr. W. Beckett, Secretary to the Society, at the Skating Rink, Park Lane, Croydon.

— PORTSMOUTH CHRYSANTHEMUM SHOW.—At the great Show held at Portsmouth yesterday, the awards in the twenty-five guinea challenge cup class were as follows:—First (£8) and cup holders, Messrs. W. & G. Drover; second (£7), Mr. N. Molyneux, gardener to C. Garnier, Esq.; third (£5), Mr. Penford, gardener to Sir D. Fitzwygram, Bart.; fourth (£3), Mr. Payne, gardener to Mrs. Smith. The cup is offered for forty-eight blooms, half incurved, and half Japanese, in not less than thirty-six varieties, and has to be won twice to become the property of the exhibitor. It was secured last year by Mr. W. G. Drover after two consecutive wins. The Jubilee prize of £10 for eight trained plants was won by Mr. J. Bushby, gardener to Captain Long.

— THE WILLIAM HOLMES' MEMORIAL FUND.—A circular is now being issued respecting the above to this effect—"At a public meeting at the Royal Aquarium, Westminster, on October 15th, 1890, it was unanimously resolved to commemorate the valuable services of the late Mr. William Holmes, the deeply respected Honorary Secretary of the National Chrysanthemum Society, by raising a fund for that purpose, to be termed 'The Williams Holmes' Memorial Fund.' The Committee appointed to carry out this object has carefully considered the numerous suggestions offered, and the following mode of applying the fund has been adopted. 'That a portion of the fund raised be set aside for assisting the technical education in landscape gardening of the late Mr. W. Holmes' eldest son, and that the remainder be awarded as prizes or medals at the exhibitions of the National Chrysanthemum Society and at those of affiliated societies.' Subscriptions and all communications should be forwarded to the Honorary Secretary, Mr. Lewis Castle, Hotham House, Merton, Surrey, from whom collecting cards can be had on application."

— A SUNDERLAND correspondent writes respecting the SEASON IN THE NORTH as follows:—"It has been a bad and busy season, and it is some years since I had so much labour for such scant return. The garden crops are very good, but the labour to keep all clean and healthy has been enormous. You will say it is just the old story of shorthandedness. This is just it. In a fine season we do very well, but a wet season flounders us. All was nothing to hay-making. I never before ran the risk of cutting all down at one time until this year, and it rained every day for over a week. You may guess the result."

— "WE have had a splendid crop of APPLES this season, some varieties exceptionally so. Of course Lord Suffield took the lead, as it always does, but we had also good crops of Warner's King, Cox's Pomona, Keswick Codlin, New Hawthornden. One Apple I weighed, 13½ ozs., not so large as the Peasgood's Nonesuch from Mr. Barlow, still it was not a bad production for us northern growers. Strawberries were plentiful, but the wet season spoilt a quantity of fruit. I think Waterloo will be a reliable sort for this district, or rather for this garden, as I think we have almost the most unfavourable spot in it."

— "I THINK it has been the most successful PEA SEASON I ever had in my experience. The growing season would have a good deal to do with that, but I think the varieties had quite as much. I had part of my seeds from Messrs. Veitch of Chelsea this season, and I had some varieties I have not had before. Whatever it was, the supply was marvellous. I tried a few new varieties of early sorts, but for here Backhouse's Selected William I. still leads the way, and we gathered Sturdy the last week in October, and shall get some more. Speaking of Chrysanthemums, I may say that I have not had such a show for bloom since 1887. They are all housed, and the conservatory is full at present of the Desgranges family and some others. The later sorts are all well budded, and look well for bloom. Of course I do not grow from one

to three blooms upon a plant as is done for exhibition, but as many dozens for conservatory show. What splendid weather we are having at present; dry and fine! It is as well so, as we have a heavy fall of timber here, and we are busy at present. There were 1100 trees marked; not a bad fall for our few acres."

— THE total RAINFALL AT CUCKFIELD, Sussex, for October was 1.51, being 2.44 inches below the average. The heaviest fall was 0.36 inch on the 7th. Rain fell on ten days. Highest temperature 61° on 4th, lowest 24° on 28th. Mean maximum 55.2, mean minimum 40.2. Mean temperature, 47.7°. Partial shade readings, 4° above the average. Remarkably fine month; nothing injured by frost till the 28th; up till then flower beds as gay as at midsummer.—R. I.

— COLLECTIONS or groups of TREE AND SHRUB SPECIMENS are too seldom seen at horticultural meetings or shows, and this rendered the contribution from Messrs. William Paul & Son of Waltham Cross, at the recent meeting of the Royal Horticultural Society, all the more valuable. It comprised a general selection of the most effective hardy shrubs and trees, among the former being *Berberis Thunbergi*, the leaves of which turn a bright reddish colour before falling. A certificate was awarded for this plant and a medal for the group.

— CHISWICK GARDENERS' ASSOCIATION.—The third annual concert in aid of the Gardeners' Orphan Fund took place at the Vestry Hall, Chiswick, on October 29th. It was most successful, the Hall being crowded. Mr. George Cannon, manager of Messrs. C. Lee & Son's nurseries, Ealing, sang well, and his daughter, Miss Louisa M. Cannon, a silver medalist of the Royal Academy of Music, ably presided at the piano. The platform of the Hall was tastefully decorated with foliage and flowering plants sent by Mr. M. T. May, gardener to the Marquis of Bute, Chiswick House. The Committee, with their Chairman and Secretary, deserve much credit for the excellent results of their praiseworthy efforts.

— MR. C. ORCHARD, Bembridge Hotel, Bembridge, writes concerning the CHRYSANTHEMUMS AND THE WEATHER IN THE ISLE OF WIGHT. "The Chrysanthemums in the Isle of Wight are looking very well indeed. Mr. Wilkins, gardener, The Castle, St. Helens, has some good ones, more especially the incurved blooms. The Ryde Show is next week, and I think we shall see some good blooms and plants. Volunteer, I think, will make a good show; Japanese, with long spreading florets, white suffused with pink. Mrs. J. Wright I have seen good, especially in cut-down plants; in fact my system is gaining more in favour of cultivators than ever, and the examples I have in my front hall have quite startled some who have been prejudiced against it. The sharp frost on Sunday night (October 26th) cut up all the tender plants, and spoilt all the *Sœur Melanie* blooms out of doors, but Madame Desgranges it did not hurt so much. They do well on our reclaimed land."

— READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The second autumn meeting of this Association was held at the usual place on Monday evening, when a large number of gardeners assembled to hear a paper on "Pears" by Mr. T. Bowie, the able gardener at Sutherlands, Reading. Mr. Wm. Lees occupied the chair. Mr. Bowie dealt with the subject in a very concise and practical manner. His remarks on the root culture of Pears were warmly applauded, and in dealing with varieties he considered twenty-four necessary to obtain a supply of Pears over the longest possible period. Mr. Bowie exhibited fifty varieties of Pears, an admirable collection. There were also several other collections. Mr. J. Woolford exhibited thirty varieties, Mr. C. Durman sixteen varieties, and Mr. Pound, senr., and the Honorary Secretary showed some good examples of the leading varieties—altogether a fine display, which added greatly to the interest of the evening. A discussion as to stocks, soils, &c., was well sustained by the members, and there is no doubt that much practical good will result.

— STOVE ARALIAS.—Those gardeners who have to keep up a supply of table plants know how useful a batch of Aralias are, as these are generally favourites for the embellishment of the dinner table, especially such varieties as *A. Veitchi* and *A. Veitchi gracillima*, as the growth is so elegant and not likely to cause an obstruction. To keep up a supply the nurserymen are usually resorted to, as with their special contrivances they have not much difficulty in keeping up a stock of saleable plants. Grafting is the usual mode of procedure for the increase of plants, the stock being *A. reticulata*, but they may also be propagated

from cuttings. *A. filicifolia*, as its name implies, has very Fern-like foliage and is easily increased by cuttings. In this manner a stock of useful plants are easily kept up. *A. Chabrieri* may also be increased by the same means. This makes a very handsome specimen if kept potted on. When allowed to become root-bound the under branches do not develop properly. All the species named above luxuriate in a stove temperature, and soon grow into useful plants. Vigorous syringing through the summer months will keep the plants clean; if this is not attended to the plants may fall a prey to soft scale and mealy bug, especially on the young growing points. Tall plants when kept repotted have a capital appearance for standing in rooms.—  
A. YOUNG.

— SPECIAL PRIZES FOR BORDER CARNATIONS.—It will be remembered that Martin R. Smith, Esq., offered at the Carnation Conference, held at Chiswick in July last, special prizes for border Carnations grown wholly in the open air. Mr. Smith has now issued regulations for awarding these prizes, and the sum of £21 is offered in three classes, £7 being given in four prizes in each class as follows:—Class 1.—For the best border variety of self-coloured Carnation, not less than twelve blooms, to be shown in bunch or bouquet, with its own foliage and buds. Class 2.—For the best collection of twelve varieties of self-coloured border Carnations, not less than six blooms of each variety. Class 3.—For the best collection of eighteen varieties of flake, lizarré, or fancy Carnations or Picotees, not less than six blooms of each variety. In these two foregoing classes the flowers are also to be shown in bunches or bouquets, with their own foliage and buds. Each exhibitor will be called upon to sign the following declaration:—"I certify that all blooms shown by me for the prizes offered by Mr. Martin Smith have been cut from plants which have been wintered without protection in the open garden, and that they have been grown without bands or ties round the calyx; that they are staged without dressing, and exactly as they are cut from the plants." The stems in all cases are not to be less than 9 inches in length. The blooms to be staged in bottles, tins, or glasses, and not in the usual way in boxes. No bands or ties are permitted round the calyx, nor are paper collars or wire supports to be employed. A burst calyx will disqualify. Non-compliance with the above regulations will disqualify the exhibitor.

— NATIONAL AURICULA AND NATIONAL CARNATION SOCIETIES (SOUTHERN SECTION).—The annual meeting of the members of these Societies took place at the Hotel Windsor, Victoria Street, by the kind permission of the Horticultural Club, on the 28th ult., the Rev. H. H. D'Ombraïn presiding. The reports of the Committees of the two Societies were read by Mr. Douglas. That of the former declared there was no lack of interest in the cultivation of the Auricula, and though the early months of the year were characterised by weather of an ungenial nature, a large number of plants of Show varieties were staged, generally of good character. The Alpine varieties were never before finer and more numerous. The Fancy Polyanthuses and Primroses were also very fine and attractive. In reference to the Carnation, the report set forth that the interest in this flower materially increased during the year, as was shown by the Exhibition and Conference held at the Chiswick Gardens, both of which were well attended; and so numerous and fine were the Show varieties, that it proved the best Exhibition held by the Society. The yellow grounds, the selfs, and Fancies, were shown in the very best character. The Treasurer's balance-sheet of the Auricula Society showed an income of £83 11s. 3d., and an expenditure of £72 3s. 3d., including £61 12s. 6d. paid away in prize money, leaving a balance of £11 8s. in the hands of the Treasurer. It was also stated that ten new members had been added during the year. The balance-sheet of the National Carnation Society showed receipts £77 4s. 11d. and disbursements £67 10s. 9d., a balance of £9 14s. 2d. being carried forward for next year. The reports and financial statements were unanimously adopted. The Presidents, Vice-Presidents, and members of the Committee were re-elected, with the exception of Mr. J. James, deceased. The name of Mr. Martin R. Smith was added to the Vice-Presidents. The schedules of prizes were then revised. In the case of that of the Auricula Exhibition, the amounts of the prizes for six, three, and one specimen gold-laced Polyanthuses were reduced, and a first prize of 20s. apportioned to each of the classes for Fancy Polyanthuses and Primroses. The schedule of the Carnation Society was passed unaltered. Mr. Douglas reported that the Council of the Royal Horticultural Society would contribute the same sum as last year towards the prize list of the two Societies. The dates of the two Shows will, as usual, be on meeting days of the Royal Horticultural Society; the Auricula Show at the Drill Hall on April 21st, and the

Carnation and Picotee Show on July 21st, also at the Drill Hall. The meeting closed with the usual vote of thanks to the Chairman.

### CHRYSANTHEMUM SOCIETIES AND SHOWS.

THE following list has been prepared at the request of numerous correspondents, who have supplied us with the particulars here given, and it will, no doubt, be found useful by many who are concerned with exhibitions during November. The name of the society, date of show, with the Secretary's name and address are given in that order.

- Ascot, Sunninghill, Sunningdale, and District, Nov. 6th and 7th; F. T. Patton, The Links, Ascot  
Banbury, 19th Nov.; H. F. Bennett, 46, High Street, Banbury  
Bath, November 12th and 13th; B. Pearson, 14, Neilson Street  
Batley and District, Nov. 22nd; John T. Booth, Batley  
Bedford, Nov. 19th and 20th; J. Sanders Clarke, 49, Linden Road  
Bedford and Bedfordshire Chrysanthemum Society, Nov. 19th and 20th; Oliver C. Coombs, 28, Mill Street, Bedford  
Birmingham and Midland Counties, Nov. 12th and 13th; J. Hughes, Northwood Villas, Metchley Lane, Harborne, Birmingham  
Borough of Croydon, Nov. 11th and 12th; Wm. B. Beckett, 272, Portland Road, South Norwood, S.E.  
Bournemouth, Nov. 12th and 13th; Charles Brown Carnarvon, Cavendish Road  
Bradford and District, Nov. 7th and 8th; George Taylor, 102, Godwin Street, Bradford  
Brighton, Nov. 11th and 12th; Mark Longhurst, 18, Church Road, Hove  
Bristol, Nov. 13th and 14th; F. Wilford Jones, Hill Avenue, Totterdown, Bristol  
Cardiff and District, Nov. 18th and 19th; C. R. Waldron, 96, St. Mary Street, Cardiff  
Chelmsford, Nov. 12th and 13th; P. Edwards, 100 High Street  
Cheshunt, Nov. 14th and 15th; R. Archer, Hatton Road  
Chorley, Nov. 21st and 22nd; James Sargeant, 64, Market Street, Chorley  
Cornwall Royal Polytechnic, Nov. 12th, 13th and 14th; John P. Cregoe, 7, Tehidy Terrace, Falmouth  
Cranbrook and Weald of Kent, Nov. 13th and 14th; Albert Baker, The Hill, Cranbrook, Kent  
Credon, Nov. 13th; G. Lock, Belle Parade Cottage, Credon  
Croydon, Nov. 11th and 12th; W. Beckett, 272, Portland Road, South Norwood, S.E.  
Crystal Palace, Nov. 7th and 8th; W. G. Head  
Dawlish, Nov. 13th; H. L. Friend, 3, Priory Terrace, Dawlish  
Derby, Nov. 14th and 15th; G. Sutherland, Arborctum Square  
Devon and Exeter, November 7th; G. D. Cann, 16, Queen Street, Exeter  
Diss (Norfolk), Nov. 18th; Rev. F. Page Roberts, Scole Rectory  
Eastbourne, Nov. 11th and 12th; C. H. Simmons, Endlewick, Eastbourne  
Eccles, Patrieroff, and Pendleton, Nov. 14th and 15th; H. Huber, 183, Worsley Road, Winton, Patricroft  
Exmouth, Nov. 11th; W. J. Godfrey, Rolle Street, Exmouth  
Green Street and District, Nov. 19th and 20th; W. G. Ray, Mount Pleasant Nursery, Green Street, near Sittingbourne  
Guildford, Nov. 12th and 13th; Arthur Jupp, Greencroft, Stoke, Guildford  
Hampstead, Nov. 12th and 13th; Robert Frisby, 47, Flask Walk, Hampstead, N.W.  
Hartlepool, Nov. 18th and 19th; B. C. Laycock, 147, Studley Road, West Hartlepool  
Hayes, Nov. 7th and 8th; W. Henry Burr, Dr. Triplett's Schools, Hayes, Middlesex  
Highgate, Hornsey, and Finchley, Nov. 5th and 6th; Thomas Press, 11, Victoria Cottages, Archway Road, Highgate, N.  
Hitchin, Nov. 14th and 18th; Pearson T. Harris  
Hull and East Riding, Nov. 19th and 20th; Edward Harland and James Dixon, Manor Street, Hull and 2, County Buildings, Hull  
Isle of Sheppey, Nov. 6th and 7th; James W. Fuller, 3, Alexandra Road, Marine Town, Sheerness  
Kettering, November 14th and 15th; H. T. Favell, 8, Mill Road, Kettering  
Kingston-on-Thames, Nov. 11th and 12th; G. Woodgate, Warren House Gardens  
Leicester and Midland, Nov. 14th and 15th; H. F. Anthony and E. E. Waite, Knighton Church Road, South Knighton, and 12, Diseworth Street, Melbourne Road, Leicester  
Lewes and District, Nov. 11th and 12th; Geo. Stroud, 20, High Street, Southover, Lewes  
Lindfield, Nov. 5th and 6th; Clive Wheeler, High Street, Lindfield, Sussex  
Liverpool, Nov. 18th and 19th; E. Bridge, 3, Cedar Terrace, Tarbock Road, Huyton  
National Society.—Great Festival, Nov. 11th, 12th, 13th, and 14th; R. Dean, Frampton Park Nurseries, Hackney

Norfolk and Norwich, Nov. 20th and 21st; John E. T. Pollard, 7, Lady's Lane, Norwich  
 Northamptonshire, Nov. 12th and 13th; E. Draper, 2, Primrose Hill, Northampton  
 Pembrokeshire, Nov. 6th; R. H. Treweeks, Main street, Pembroke  
 Portsmouth, Nov. 5th, 6th, and 7th; F. Power, 36, Queen Street, Portsea  
 Putney, Wandsworth, and District, Nov. 6th and 7th; John Moore, Upper Richmond Road, Putney  
 Ramsbottom, Nov. 15th; H. H. Nutter, 14, Crow Lane, Ramsbottom, near Manchester  
 Rugby, Nov. 19th and 20th; William Bryant  
 Scarborough, Dec. 2nd and 3rd; Thomas Henry Pexton, 136, North Marine Road, Scarborough  
 Scottish Horticultural, Nov. 20th, 21st, and 22nd; R. B. Ferguson, 6, South St. Andrew Street, Edinburgh  
 Southend-on-Sea, Nov. 13th and 14th; John Brown, Reeko House, Hamlet, Southend-on-Sea, Essex  
 St. Neots (Hants), Nov. 10th; William Ratchelous  
 Street, Nov. 14th and 15th; A. D. Porter, Street, Somerset  
 Stroud, Nov. 6th and 7th; E. C. Davis, 10, Rowcroft, Stroud, Glos.  
 Swansea, Nov. 19th and 20th; Messrs. T. Kneath and W. Roberts  
 Taunton, Nov. 13th; Edgar Poynter, Castle Green, Taunton  
 Teddington, Nov. 13th and 14th; David Anderson, The Nursery  
 Tiverton, Nov. 20th; R. P. Cosway, Lime Cottage, Tiverton  
 Tooting, Nov. 5th and 6th; H. Brown, 39, Defoe Road, Tooting, S.W.  
 Truro, Nov. 11th and 12th; Alfred Blenkinsop, 11, Princes Street, Truro  
 Tunbridge Wells, Mid-Kent, and East Sussex, Nov. 12th and 13th; Ernest Charlton, 37, Ye Pantiles, Tunbridge Wells  
 Twickenham, Nov. 18th and 19th; J. J. G. Pugh, 2, Heath Road  
 Walkley, Nov. 7th; M. Taylor, 9, Spring Hill, Sheffield  
 Wellington (Somerset), Nov. 14th; Charles Tite, Shutes House, Wellington, Somerset  
 Wells (Somerset), Nov. 5th and 6th; Albion George Andrews, St. Cuthbert's Lodge, Wells, Somerset  
 Westerham, Nov. 19th and 20th; Frank George Remnant, High Street  
 Weston-super-Mare, Nov. 11th; W. H. Vanes and S. Lewis, High Street, Weston-super-Mare  
 Wimbledon and District, Nov. 13th and 14th; Dr. Geo. Walker, 12, Lingfield Road, and W. W. Thomson, The Nurseries, Hill Road, Wimbledon  
 Winchester, Nov. 13th and 14th; Chaloner Shenton, 74, High Street, Winchester  
 Yeovil, Nov. 19th; E. H. Oakley, Eason Terrace, Yeovil  
 York, Nov. 19th, 20th, and 21st; J. Lazenby, 8, Spurriergate

#### NOTES ON TEA ROSES.

IN reading the account of the Rose season of 1890 by "D., Deal," on page 331, I was pleased to see him recount the numerous successes during the season of the Rev. F. R. Burnside with his Tea Roses. His garden must indeed be a paradise when his plants are in bloom, and the thought of such a garden must make more besides myself feel a little envious, for in many parts of Lancashire we are so unfavourably situated as to scarcely attempt the cultivation of the choicer varieties of Teas, except in pots. For several years I tried with some of the better varieties in the open, but our soil is so stiff, and only a short distance from the clay, that it was a difficult matter (without having to go to a great amount of labour) to get any satisfactory return from them. Each time that I used to see such splendid boxes of Teas at the shows I always seemed to be braced up again for another trial, and having had a bundle of Tea Roses sent to me by a relative, I made another effort. I had three cartloads of road sweepings (which contained grit, leaves, and manure) and a few barrowloads of sods, mixed together. Having marked the ground out where I intended to plant, I took out a good trench and filled it up with the compost mentioned. I then planted the Roses carefully, filling over the roots with the same compost, and working it well amongst them. A slight treading completed the work. They stood the winter remarkably well, and I only lost one plant. This summer I have had some beautiful blooms of Safrano, Madame Falcot, Madame Cusin, Madame de Watteville, Homere, Souvenir d'un Ami, Niphotos, Madame Lambard, Madame Van Houtte, and several others. In addition the wood is in much better condition, and I intend to plant a few more this season, for I have been pleased with the result. I attribute in a great measure my share of success to the road sweepings, which contained the requisite properties to keep the roots in a sweet and healthy state.—R. P. R.

#### GARDEN ROSES.

I SEND you a list of Roses which I think may be useful to some of

your readers who may be planting Roses for decoration or for massing in beds:—La France, Cannes la Coquette, Mrs. Bosanquet, Souvenir de la Malmaison, the Old Pink China, common Moss, Mdlle. Blanche Durrschindt, Earl of Pembroke, Rosa Mundi, Merveille de Lyon, Hon. Edith Gifford, Madame François Pittet, Madame Cusin, Madame Chedane Guinoisseau, and Viscountess Folkestone. As a climber, Gloire de Dijon is the best for all purposes, and Cheshunt Hybrid is a good companion.—J. L. B.

#### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 28TH.

SCIENTIFIC COMMITTEE.—Present: Mr. McLachlan (in the chair), Mr. Morris, Mr. Blandford, Dr. Oliver, Dr. Scott, Dr. Müller, Dr. Masters, and Rev. G. Henslow, Hon. Sec.

*The Fog Report.*—Dr. F. Oliver reported to the Committee that through the kindness of one of its members an experimental conservatory had been placed at its disposal, and was now in process of equipment for the purposes of the inquiry into the effects of London fog upon vegetation. The pump for fog washing, mentioned at the last meeting, would be put in order and arrangements made for its use directly leave had been obtained from the Council of the Meteorological Society. Dr. Oliver further stated that he was fitting up his own conservatory attached to the botanical laboratories University College with apparatus of appropriate character, so that he could follow out both the macro- and micro-scope effects of fog, and also of some of the noxious constituents known to exist in fogs. The amended circular is now ready for distribution, and will be distributed forthwith.

*Garrya elliptica in Fruit.*—Mr. Morris exhibited sprays of the fruit of this North Californian shrub. The berries have a tomentose, ash-coloured, dry skin, and are compactly arranged in a dense spike. They were received from Mr. H. D. Pochin of Bodnant Hall, Denbighshire, who described it as fruiting well, and that numerous plants have been raised from the seeds. The male plant was introduced in 1828, and first flowered in the gardens of the Horticultural Society in 1834 (*Bot. Reg.*, tab. 1686).

*Supposed Bigener between Dahlia and Helianthus.*—Dr. Scott exhibited flowers received from Mr. E. J. Lowe of Shirenewton Hall, Chepstow, of white Dahlias, the supposed offspring of a cross between the ordinary single white Dahlia and Helianthus decapetalus. The "cross" agrees with Dahlia in general appearance, and in the involucre, shape of receptacle, paleæ, external characters of the florets, and form of stigmas, but differs as follows:—The corolla-tubes of the disk florets especially the outer ones, are more ventricose. The stamens are shorter; the pollen has blunt and obliquely truncate prickles, and not conical as in the Dahlia. The style is shorter, the stigmatic arms being less divergent, with shorter papillæ. The above differences do not appear to amount to more than may be perhaps seen on various seedlings of Dahlia. The fruits, however, show more pronounced peculiarities, besides being only one-fourth in quantity. The achenes are smaller, less compressed, much less obovate in form, and have prominent ribs, which are not evident in Dahlia. The achenes are also about half as long. It may be added that neither in the pollen or stigmatic character does the "cross" agree with Helianthus. Mr. Lowe observes that in a cross it is often difficult to detect the effects of the male parent, and mentions *Fuchsia fulgens* crossed by "Semiramide" and the reciprocal cross, the seedlings in both cases resembling the female. Other observer have experienced the same fact, or, as Mr. Lowe expresses it, the female parent "received life from the pollen without showing traces of it, the active property of the male seeming to be enough to produce seeds, but not to show the characters of the male."

*Apple Diseased (?)*.—A remarkable Apple, with a superficially translucent appearance, was received from Mr. Marshall of Bexley. Being possibly due to a fungus it was forwarded to Professor Ward for examination and report.

*Carex Species (?)*.—A plant was received from Mr. Robson of Altrincham for name; not being in flower it was referred to Chiswick for cultivation.

*Grapes Attacked by Larvæ.*—Some Grapes were received from Mr. Galpin of Putney Heath, with the supposed larvæ of *Tortrix angustiorana*. Some doubts being expressed by Mr. McLachlan as to their identity, they were referred to Mr. Blandford to rear and to report upon them later.

FUCHSIAS.—These again now play an important part in many floral arrangements, and the showery season of 1890 has suited them admirably. In some instances good sized specimen plants were kept in their pots and plunged, and in other cases they were planted out. The latter plan answered best, the plants surpassing those plunged in spite of the good attendance the latter received, but when it comes to lifting and storing those already in pots are much the least trouble. The others can be taken up and potted, using any common loamy soil and pots just large enough to hold the roots, the soil being firmly packed about these. They are given a good watering when first lifted, and subsequently no more is supplied than is needed for keeping the wood plump yet dormant. Fuchsias keep fairly well after the foliage has fallen if laid on their sides under a greenhouse stage, and also in light sheds and outhouses.—B.

## NEW CHRYSANTHEMUMS.

At the meetings of the Royal Horticultural Society's Floral Committee on October 28th, and of the similar officials of the National Chrysanthemum Society on the next day, October 29th, several very promising novelties were shown, and as nearly twelve at the two places were found worthy of certificates some idea can be formed that the general merits were above the average. Numerous as are the varieties now in cultivation it is evident that we can still expect useful and handsome additions from the Continent, from America, and from our own raisers. The best of those shown were the undermentioned.

**GLOIRE DE ROCHER.**—For this handsome Japanese variety a first-class certificate was unanimously awarded, and the general opinion seemed to be that it would take a place amongst the best novelties of the year. It was shown by Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, and concerning it there is a rather interesting history. Mr. Wormald for some years past has, on account of ill health, spent the winters with his family in Algiers, and has there indulged in what may be termed horticultural recreation under better climatic conditions than prevail at Mitcham. Chrysanthemum cuttings and plants have at various times been sent out to him and his friends there, and most of the best varieties in cultivation here have thus been despatched. A year or two since young plants of a selection of Japanese were, however, specially sent over, with the object of securing seed. One of Mr. Wormald's friends has succeeded in raising a large number of seedlings, but apparently without any special crossing, or even without preserving the names of the parent plants. Some of the more distinct were sent from Algiers to Morden Park to see what characters they would develop under Mr. Gibson's care, and up to the present "Gloire de Rocher," the name of which indicates the place where it was raised, is by far the best.

I saw this soon after the bud showed its colour, and again later on when it was much more advanced. Then it was somewhat in the style of Mrs. Falconer Jameson, but with more substance in the florets, and the colour was an improved Val d'Andorre, very rich and telling. A few days later it had completely altered in character—the florets instead of spreading flat had straightened and developed until the bloom was quite globular in form, of considerable size, the colour still very bright, and the florets showing their reverse surface of a golden bronze tint. The illustration (fig. 54) was prepared from one of the blooms shown, and it was stated after the meeting that the stock had passed into the hands of Mr. N. Davis.

It is surprising that our British nurserymen, who make a speciality of Chrysanthemums, have not made a more general system of engaging agents in suitable places to raise seedlings for them on some definite principle instead of having to depend almost exclusively upon continental and American growers. Even where seed has been sown here it is strange what a roundabout way our people have of procuring it. For instance, I know one nurseryman here who has been successful in obtaining several novelties of undoubted merit, yet who obtains all the seed from a German firm, who again has to procure it from growers in the South of France, Italy, or Algiers. Now that such good prices are secured for new Chrysanthemums possessing distinct characters an investment of this kind might be expected to find a fair return on the outlay, much more, indeed, than when the demand was limited to a comparatively few specialists.

**MADAME GAYRAT.**—Perhaps next to the variety just described the one here noted attracted most attention at the National Society's meeting, and especially because new incurved varieties are so seldom brought out. It is a medium sized bloom, very neat, clean, well built, and with florets of good substance; white, or pearly blush, tipped with pink. It is much in the style of the seldom seen variety Aimée Ferrière, from which it is said to be a seedling, and some expressed doubts as to whether it would be found distinct enough for exhibition purposes. In the general opinion, however, it was superior to the parent in all points, while a few regarded the suggestion that it was a small Jeanne d'Arc. It found sufficient favour to gain a certificate by a good majority of votes, and will no doubt be tried by many next season. Mr. Robert Owen was the exhibitor. I have seldom seen a first rate bloom of Aimée Ferrière, but a few days after the meeting I saw one that might be considered an excellent type of the small flowered incurved which so many wish to encourage.

**MRS. IRVING CLARKE.**—This is a Japanese of American origin sent out by Craig last year, and found its way here, but I do not remember seeing it shown anywhere until now. The blooms are large and of good substance, with rather narrow curled florets of a pale but clear and pleasing flesh pink colour, the glossy surface of the florets adding to its appearance. A certificate was awarded to Mr. Owen for this variety, which has been included in the N.C.S. list of select Japanese for exhibition, and merits the attention of those in search of novelties worth adding to present collections.

Certificates were also awarded for the following, which will be referred to at length another time. William Laing (Owen), Japanese

reflexed, rosy salmon; Alberic Lunden (Owen), Japanese reflexed, rich magenta, very deep colour; Duchess of Westminster (Owen), Japanese Anemone, bronze centre, blush rosy florets; Viviand Morel (Laing), Japanese, rose and white striped, large and handsome, certificated N.C.S. and R.H.S.; Mdle. Marie Hoste (Laing), a Japanese, white streaked pale purple, very distinct; William Neville (Cannell), reflexed, average size and good form, deep orange.—LEWIS CASTLE.

## THE NATIONAL CHRYSANTHEMUM SOCIETY.

THE following circular and programme respecting the Centenary Festival at the Royal Aquarium, November 11th, 12th, 13th, and 14th next, has just been issued by the Hon. Secretary (*pro tem.*):—I am desired by the Committee to remind you that the Great National Centenary Festival will take place as above, and I shall esteem it a great favour if you will make this important occasion known as widely as possible to all lovers of flowers in your neighbourhood. It is an occasion when all admirers of the Chrysanthemum should cordially unite to make the celebration worthy of the National Society. Earnest attention is called to the following particulars:—The Committee appeal to all supporters of the Society to assist in making the Exhibition the most extensive and important ever held, by contributing exhibits, and especially specimen plants, so that an imposing and thoroughly representative display may be made; also to be willing to leave their plants on view the entire four days the Exhibition is open to the public. The Superintendent is empowered to pay a certain proportion of the cartage expenses. The work of judging will commence at eleven o'clock, when the hall will be cleared, and all exhibits must be staged ready for the Judges by that hour. To facilitate staging, a number of stewards are appointed to direct exhibitors in doing so.

The opening ceremonial will take place at 1 P.M., when Lord Brooke, M.P., President of the Society, and Lady Brooke will be present. After an inspection of the Exhibition, an address will be presented to Lady Brooke, and her ladyship will declare the Exhibition open. Conferences on the Chrysanthemum will take place on Tuesday, the 11th, and Thursday, the 13th; at 6 P.M. on the 13th, a grand banquet will take place in St. Stephens' Hall, in lieu of the annual dinner, Lord Brooke, M.P., the President, in the chair. On this occasion ladies will be present. Applications for tickets, price 5s., accompanied by a remittance, must be made to the Hon. Secretary, not later than the evening of Monday, November 10th.

**Programme.**—Tuesday, November 11th. The Exhibition will be arranged ready for Judges by 11 A.M. The Floral Committee will meet at 12.30 P.M. The opening ceremonial will commence at one o'clock. The President, Lord Brooke, M.P., and Lady Brooke will be met at the entrance by the Reception Committee and the invited guests, and conducted round the Exhibition. An address will be presented to Lady Brooke, and the Exhibition formerly declared open to the public. At 6 P.M. a Conference meeting will be held in the iron room under the presidency of Sir Edwin Saunders, F.R.C.S., V.P., and papers will be read by Mr. Shirley Hibberd, F.R.H.S., "On the Origin of the Florist's Chrysanthemum;" by Mrs. Marian Throver, representative of the Northern Tasmanian Horticultural Society, "On Chrysanthemums in Tasmania;" and by Mr. G. T. Haite, F.L.S., "The Chrysanthemum in Art." Wednesday, November 12th, will be devoted to an inspection of the Show, verifying awards, &c.

On Thursday, November 13th, a conference will be held in the iron room at 2.30 P.M., Sir Guyer Hunter, M.P., Vice-President, in the chair, when papers will be read by Mr. Briscoe-Ironside "On Experiments in Chrysanthemum Culture," and by Mr. C. Gibson "On Chrysanthemums for Exhibition." At 6 P.M. prompt a grand banquet will take place in St. Stephen's Hall, Lord Brooke, M.P., President, in the chair, supported by representatives from foreign and colonial affiliated societies and others. Private entrance from Broad Sanctuary.

On Friday, November 14th, St. Stephen's Hall will be arranged as a lounge, so as to afford opportunity for conversation. At 4 P.M. an informal meeting will be held with the object of affording opportunity for suggestions as to the future operations of the Society. The Exhibition will close at 9 P.M.

## THE NATIONAL SOCIETY'S SCHEDULE.

To the National Chrysanthemum Society is due the honour of offering for competition the largest amount of prizes for one class, and a thoroughly comprehensive schedule of prizes has been prepared and issued, if I except one thing. Single Chrysanthemums have no provision made for them, although they are invited in a honorary manner. Out of the fifty-four classes contained in the schedule, one thinks there might have been found room for at least one class for this very interesting section. To some persons single Chrysanthemums have a charm which no other kind supplants. I fancy that those persons who are responsible for the compiling of the schedule have never seen these blooms in the same condition as they are always staged at Portsmouth for instance, where they are one of the features of the Show, or they would I think find room for them. If they are wishful to encourage the growth of this section, they ought to know full well that the simplest, most rapid, and effective manner of gaining this end is to offer substantial, or even a small recognition, for the trouble expended in obtaining the necessary effect. Some may think perhaps that as I have thus written at some length upon this omission of an otherwise excellent schedule, that I am doing so in a earping spirit. Such is not the case. I know full well the value of single Chrysanthemums in a decorative point of view, my object being to encourage their extended growth in

all possible ways, and in no manner can this be so well done as by the making a class specially for them. Public encouragement is needed to

all to be distinct, and for which the unprecedented sum of £75 is offered in prizes, allotted thus—£25, £20, £15, £10, and £5, in the order here

FIG. 54.—JAPANESE CHRYSANTHEMUM GLOIRE DE ROCHER.

ensure success in any phase of class making. No matter in what reasonable manner classes are made there are certain to be exhibitors.

What is termed the centenary class is one in which forty-eight blooms are stipulated for, half to be incurved and the remainder Japanese,

named. In addition all the competitors in this class will be presented with a bronze centenary medal in commemoration of the festival. Surely such prizes as these have never before been offered for Chrysanthemums, and should bring competitors in strong force. Hitherto the complaint amongst

growers of these flowers has been that the value of the prizes has been so unequally balanced between the first and the following prizes that a second prize collection, which may be only slightly inferior to the first, gets but a small compensation as compared to its relative merit with the premier collection. In the present instance the Committee have wisely prepared for any objection in this direction, as also they have in demanding that such prizes shall be won by distinct blooms, entirely ignoring the duplicate system of stipulating for twenty-four blooms in either section, but not more than eighteen varieties. There is no doubt but that the existing conditions are the correct ones in such a class as this; it provides a surer test of the skill of any grower to produce forty-eight blooms in this manner than where duplicates are allowed. Now with such a large increase of varieties in both sections, the task set is not nearly so arduous as it was a few years since. Even if no other class was provided in the schedule, the Committee of the National Chrysanthemum Society deserve a splendid exhibition in these two sections provided for cut blooms, for the spirit displayed in offering so much money to be competed for. But it would not surprise me much if competition were limited after all to a few of the leading exhibitors. Let us hope this will not be the case.

Class 2 in the schedule is set apart for the competition of Societies, known as the "Trophy" prize, the handsome sum of £10 going with the premier object in this class. In this case the blooms may be the production of one or more growers, but to be staged in the name of the Society to which each contributor belongs, of course all belonging to the one Society in whose name the entry is given. The cash to be equally apportioned to the growers of the flowers staged. This class will be likely to suffer somewhat this year in consequence of the larger one previously noted. I should not be surprised either if the class were altogether dropped in a few years, as beyond the cash prize there is no ultimate end for the Trophy. It is a novelty, such novelties generally have a short existence.

Class 3 is for forty-eight incurved blooms in not less than twenty-four varieties, neither shall there be more than three blooms of any one variety. Splendid prizes are here offered, also £10, £7 and £4 are the sums for the three prizes, with the addition of the bronze centenary medals for all competitors. Such a class as this provides a splendid opportunity for a display of the "Queen" family, and now that they are so numerous no doubt they will be used in great force in providing massive stands of blooms. For those who cannot stage such a large number of blooms as demanded in the preceding class others of less numbers are provided, classes 4 and 7 being for twenty-four and twelve blooms respectively, both stipulating for distinctness of kind. Substantial money prizes are offered in both classes. Even another class is available for those who cannot stage in these just mentioned. Class 8 being for twelve blooms distinct, those competing in previous classes not to do so in this. Such an arrangement provides opportunities for all who are wishful to compete.

Classes 5 and 14 are devoted to what I will term "novelty" classes. In both the Veitch medal and £5 is offered as first prize, with sums of £3 and £1 as second and third prizes, for twenty-four blooms of incurved and Japanese kinds distinct, "to be staged with not less than 8 inches stem above board, with foliage as grown." From the wording of the class there is nothing to prevent the blooms being "dressed" in the orthodox manner, excepting, of course, the length of stem stipulated for, although I infer such is not the wish of the framers of this class. The Veitch medal is a prize I know highly coveted by gardeners in general, and it is to be hoped that good competition may be the result of these classes, and something new in the manner of presenting blooms to the public may be witnessed in consequence.

Class 6 provides an opportunity for those who are continually "railing" at the presence of such large flowered sorts as the Queen type, at the expense of smaller and neater varieties on the exhibition table, as it provides for the latter to the exclusion of the "objectionables," as I will term them. I shall not be surprised if those who have grumbled the most do the least towards filling this class. The particulars are as follows:—Eighteen incurved blooms distinct, excluding the Queen and its synonyms; neatness and symmetry to be considered of greater importance than mere size of bloom. And as there are now so many beautifully formed blooms naturally of the Princess and Teck varieties, there ought not to be any difficulty whatever in securing the necessary number. Given an equality of flowers the person who is the greatest expert with the dressing instruments will carry off this prize, and may not inaptly be called the dressers' class. It must not, however, be assumed that good dressing only will succeed. The blooms must be available first, no matter how well a dresser may act he cannot turn a badly grown bloom into a perfect one; what he can do is to improve those already well grown. This class will no doubt prove as interesting to many as any in the schedule. The prizes are good, £5, £3, and £1 being offered.

Similar classes are made for the Japanese section as for those noted, and will no doubt cause a greater display. Competition generally is more keen than in the incurved section; varieties to choose from are much more numerous, and the forms so variable that a greater number of people prefer these to the stiff-looking incurved. Prizes are also offered for the usual six blooms of one variety in both sections, and for the same number of blooms of certain new varieties.

Classes are also provided for reflexed, Anemone, and Pompon sections, the latter always producing strong competition. In the present case there should be no falling off in this respect. The prizes in all cases are certainly adequate, and the conditions easy.

For the first time I note a class has been made for twelve Japanese incurved blooms, but without any intimation of what is considered to be an incurved bloom of this family or section. No doubt exhibitors of experience will stage only those which properly come under the designation of incurved when fully developed, which is the correct estimate of an incurved Japanese specimen. Many sorts incurve their florets when unfolding them, but as they develop an alteration is effected, the same kinds being then thoroughly reflexed. Such as these in a half-expanded state cannot be taken as examples of what is required.

Amateurs, single-handed gardeners, and metropolitan growers are well provided for. Numerous valuable prizes are set apart for them by the Society and through the kindness of enthusiastic donors. In classes 35, 36, 37, and 38 the conditions state that these classes are for those who employ one permanent gardener, and also for single-handed gardeners. I take it that what is meant is that the employer of a permanent gardener may compete in his own name, as also may the single-handed gardener with his employer's property, in the same manner as the gardener who has, say ten or more men under him. The two cases in the classes referred to here are, as far as the gardeners are concerned, identical, both coming strictly under the heading of single-handed. I consider these regulations slightly confusing in the manner indicated in the schedule. A class for an unlimited number of cut blooms, any varieties, is set apart for foreign growers, of which it is to be hoped they will avail themselves, which would provide means of comparison between home and foreign produce. This is a capital opportunity for M. Phatzer to show us what can be done in Roubaix.—E. M.

#### CHRYSANTHEMUM BLOOMS DAMPING.

IN my opinion the damping of Chrysanthemum blooms arises from various causes. Rank immature growth, caused by loose potting and the excessive use of stimulants, coupled with taking buds too early and leaving the plants out of doors too late in the season, in order to keep the flowers back, is, I feel certain, one of the causes of blooms damping. This season I left outside a few plants after they showed colour, notably Belle Paule, Stanstead White, Queen of England, and some others. Since housing they have more or less succumbed to damp.

Firm potting in good fresh fibry loam, preferably from a limestone district, with one-fifth fresh horse droppings, the same quantity of burnt refuse, and about one-twentieth dissolved bones or bone dust I find the best compost for the final potting. I commence feeding as soon as the pots are full of roots, using soot water, farmyard liquid, and the liquid from a cesspool alternately in a weak state, and occasionally (say once a week) give a little sulphate of ammonia, 1 oz. in each four gallons of the liquid until the blooms are about a quarter open, then discontinue feeding. After housing I sprinkle the lower leaves, &c., and all available surface of the house with flowers of sulphur, and am very careful with ventilating, airing the houses as carefully as a forcing house during the spring months, and in dull damp weather always keep the pipes slightly warm. I find that the blooms are more free from damping in a dry airy house than one where the atmosphere is at all stagnant.

Watering is always done in the morning, and any moisture from the pots is always dried up with a cloth after it has passed through. Where practicable I always elevate the pots on wood trellis, staging so that plenty of air can play through the plants, besides having the advantage of raising them up to the light. I know nothing as a cure for damping in blooms, but use the above precautions as a preventive. Plants should always be housed before they show any sign of colour in the blooms.—W. J. IRELAND, *Singleton Gardens, Swansea.*

#### DRESSING CHRYSANTHEMUM FLOWERS.

MUCH has been written and said for and against the practice of improving the appearance of the flowers by this practice of pulling out with tweezers malformed and superfluous florets, and arranging those left in the best manner possible, so as to present the flower as nearly perfect in form as may be. Many decry dressing in any form, and contend that all flowers should be exhibited as grown, but were the committees of Chrysanthemum societies generally to provide a class or classes in their prize schedules for such blooms, I am convinced that from several combined causes such efforts must soon end in failure. So long as judges award the prizes to the most highly finished and perfect flowers, and the public by their verdict support them in so doing, so long will exhibitors endeavour to secure such finish and perfection by all legitimate means, of which proper dressing—which allows of adding nothing whatever to, but only taking from, that which is imperfect or superabundant—is one. The aim of the dresser should not be to in any way distort the flower, or to alter it from the form Nature intended it should take, but merely to assist in perfecting it in such form.

To do this most effectually, and with the least possible injury to the blooms, it should be commenced when they are only partially developed, and be continued, doing a little in the matter of the removal of faulty florets, seed organs, &c., at intervals of a few days until the growth of the bloom is completed.

What is termed "centering" the blooms is a practice now generally adopted by exhibitors, and should be performed when the blooms are about three parts developed. This consists in taking out with a pair of somewhat broad and sharp-pointed tweezers a small portion of the centre of the bloom, generally about half an inch across in large flowers, and containing an innumerable quantity of small undeveloped petals, the taking away of which allows the surrounding ones to develop fully, and assume the required form. Many of the largest among the

Queen family, such as Queen of England, Empress of India, Emily Dale, Bronze Queen, Golden Queen, &c., when well grown form a hard centre most densely packed with small florets, which could never all properly expand, and in endeavouring to do so unassisted they would cause the upper half of the bloom to reflex instead of incurving. Blooms so grown could not after being cut be made by any skill in dressing to appear perfect in form, whereas they can be by judiciously centering them when only partly developed, and whilst the flower is still growing. Nature is thus assisted to complete her own work in her own way. Some varieties, such as Princess of Wales and its sports, Prince Alfred, Lord Wolseley, Venus, Mrs. Rundle, &c., when well grown require scarcely any dressing, save the removal perhaps of a few faulty florets, whilst the blooms are growing; whilst others, such as some members of the "Queen" family mentioned above, Refulgence, Lady Hardinge, Mrs. W. Shipman, Prince of Wales, Jeanne d'Are, and some others require much attention whilst growing, and some skill after they are cut to secure perfection.

The last named variety when grown from the crown bud is most likely to come with florets split at the end, recurving a little at the points. No amount of skill or patience in dressing will render such a smooth perfect flower. It is therefore always advisable to take terminal buds of this variety, which, although producing slightly smaller flowers than those from crowns, are much smoother, and more likely to assist in gaining a prize than the larger but rougher. Japanese varieties require less attention to dressing than the incurved, but even they may be assisted and improved, always remembering that whatever form or type Nature has intended the flower to take is the type to be aimed at, and all which is done to the flower in the matter of extracting faulty florets, removing centres or rearranging, incurving, or straightening florets left, should be with the object of rendering such type as pronounced, complete, and perfect as possible.—W. K. W.

#### CHRYSANTHEMUMS AT LEWISHAM.

MR. H. J. JONES is well known in the Chrysanthemum world, for during many years he has been more or less identified with the culture and exhibition of the plants, especially during the past three or four seasons when in business with Mr. N. Davis. He has now returned to his old district, and the Ryecroft Nursery, Hither Green, Lewisham, provides him with scope for his energy and perseverance. One large house is devoted to a display of Chrysanthemums, and not only is the house one of the largest appropriated to this purpose around London, but the show is also for effectiveness one of the best we have seen. The structure is 104 feet long, 25 feet wide and 14 feet high to the central ridge. About 2000 plants are included in 350 varieties, and there are not less than 10,000 blooms expanded at the present time. The plants are dwarf, and are arranged on one slightly sloping bank from one side to the path, so that an uninterrupted view is at once obtained upon entering the house. Most of the plants are grown without any severe disbudding, and have a free natural appearance admirably adapted for grouping. Thus there are over 100 Mdle. Lacroix in 24-size pots, flowering profusely, their pure white flowers showing to excellent advantage at the back or interspersed amongst the others. The collection comprises the best varieties in all the sections as well as many novelties that have not yet been fully proved, though they seem very promising. Special attention is being paid to the continental raised incurved, which have been generally discarded here as worthless, perhaps often without giving them an adequate trial. From one raiser in particular Mr. Jones has secured some new varieties that are worthy of note. One of these, named Camille Flammarion, is a purple tinted incurved, several shades darker than Violet Tomlin, as there grown. Sarah Bernhardt is another incurved purple and white. Madame Farrien is a medium sized variety of the same type, golden bronze, while M. R. Bahuant, if it keeps its character as a true incurved, is very extraordinary. The florets are very broad, of a deep rosy red tint totally distinct from any other variety in form and colour. It is said to be a seedling from one of the Queen type raised by M. Hoste. Madame Mante is another incurved of a fine bronze tint, the florets broad and obtuse, forming a neat bloom. Chrysanthemums are not, however, the only objects of attention. Tuberous Begonias and Tomatoes out of doors have been special features during the season, 20,000 of the former being planted out, and from the latter some tons of fruit have been obtained. Mr. Jones is evidently in earnest in his work and deserves success.—VISITOR.

#### CHRYSANTHEMUMS AT THE ABBEY PARK, LEICESTER.

THE fine Chrysanthemum house at this well-managed park is now filled with a fine lot of strong, short, sturdy plants, having excellent foliage well down to the pots, and giving abundant promise of producing a fine display of flowers, which will be at their best about the middle of November. The house is a handsome light structure with a double span-roof supported on light iron columns, which are draped with greenhouse climbers in which *Cobocca scandens variegata* plays a conspicuous part.

The size of the house is 60 feet by 40 feet. The plants are all arranged in sloping banks on the gravel floor. A very broad bank runs up the centre of the house, sloping each way from the broad gravel paths under the centre of each roof-span to the top of the columns supporting the central roof tree. The plants next the path are not more than 3 feet in height—what are known as cut-backs; whilst those against the central columns are natural grown standards 8 or 9 feet in height. These close up between the opening between the two sections

of the house, and give it the appearance of being two separate houses connected by a broad pathway between other banks of Chrysanthemums at the further end from the doors. This seems an admirable arrangement for a house intended for a public display. As the visitors, who esme in their thousands, pass in regular order up the first house between the sloping banks on each side, across the end, and down the other house likewise, the outgoing stream thus emerging some 20 feet from the ingress, and preventing confusion. About 1400 plants are housed, of which fully two-thirds are grown on the cutting down principle. Many of the earlier varieties are now carrying some very fine flowers, which would make a creditable display on the exhibition table, and, indeed, considering that the plants producing them were "cut-backs," I was astonished at their depth and solidity. Very fine indeed was F. W. Burbidge in the way of Mdle. Lacroix, but a fuller, deeper flower, of a purer white, and every way superior as here shown. Chas. Lawson, a pink reflexed Japanese was also very fine, also Miss Gorton, a full reflexed flower in the way of Bouquet Fait, but larger, and Dr. Dufresne, a new French variety, creamy yellow, reflexed Japanese. Amongst older sorts now in fine condition are Mandarin, Mons. W. Holmes, Lord Wolseley, Lady Selborne, Dr. Macary, Hiver Fleuri, Marguerite Marrouch, Maiden's Blush, Reverie, L'Isle des Plaisirs, Comte de Germiny, James Salter, Japonaise, Fernand Feral, Soleil Levant, Mrs. Dixon, Geo. Glenny, Mrs. G. Rundle, &c. The present is not the first, but will be decidedly the best public display yet held of the flower in this park, and appears likely to compare well with the excellent displays of like character in Finsbury Park and the Temple Gardens. Mr. Burns, the able Superintendent, seems determined that in all such matters the park under his charge shall be equal to any elsewhere, and in this he is ably seconded by his foreman, Mr. Burton, to whose skill as a cultivator the present fine condition of the Chrysanthemums is due. The display will be open to the public throughout the present month.—W. K. W.

#### CHRYSANTHEMUMS IN THE ISLE OF WIGHT.

I MUST confess to an agreeable surprise to find Chrysanthemums so well grown here. Much interest is taken in the flower, and it is evident that gardeners, amateurs, and I might say cottagers, have got the prevailing fever. The town of Ryde encourages two exhibitions, one the first week in November for the professional element, and the second a fortnight later for the cottagers. At the first Exhibition some good cut blooms are generally shown, the tug of war resting between Mr. G. Wilkins, gardener to W. S. Ridley, Esq., The Castle, St. Helens, I.W., and Mr. J. Earle, gardener to Henley Grosse Smith, Esq., The Priory, St. Helens, both of whom are very good growers and exhibitors. J. O. Brooke, Esq., Swanmore, near Ryde, is an enthusiastic amateur, and grows and shows well, and is generally to the front. The baskets, epergnes, designs, and stands of triplets that are encouraged at this Exhibition form an agreeable relief to the visitor from the monotonous rows of cut blooms. There are no stiffly trained plants exhibited here, but, trained on the bush system with from thirty to fifty flowers of good average quality, they make a good display. Mr. G. Wilkins is generally to the front with these, and this season he bids fair to hold his own. Newport, too, in the centre of the island, holds an Exhibition during the second week of November, which is well patronised, market growers, amateurs, and cottagers coming out well. The climate here is favourable for plant growing and ripening the wood; the greatest art is in "timing the buds," many of the Queen family and other early incurved coming too early if the bud was taken to suit exhibitions near London. Mr. G. Wilkins this year seems to have hit the happy medium. His plants are very strong and heavily timbered, and the incurved blooms, especially the Queen section, look very promising. A salmon buff sport of two blooms from a Golden Empress resembles Emily Dale or John Doughty—another instance of the confusion likely to arise with these sports this year. This is not recognised as anything new.

I find here there is the old grievance of getting varieties not true to name. Moonlight has been bought, grown, and shown for Pelican, White Venus for Mrs. Heale, and Mr. Wilkins has just got a plant this year that he purchased for Golden John Salter which turns out to be Mr. Brunlees. To the cultivator that has gained experience the disappointment would be bad enough, but to the uninitiated it means confusion and possibly disqualification on the exhibition table. I have seen good blooms of Violet Tomlin, but some have come very pale, and likely to cause a little confusion with its parent the Princess of Wales. Volunteer (Jap.), an American introduction, is likely to make a good show flower. It has long spreading flowers, bluish white. Mr. Wilkins has got two good flowers, also Mrs. J. Wright on a cut down plant, very good. Mr. G. Burt, gardener to — Darnley, Esq., Brading, has got a good show of bloom, very select but good varieties, distinct decorative varieties finding most favour. Volunteer is here very good, being tried with other new ones for the first time. Avalanche, Sunflower, Wm. Robinson, Wm. Cobbett, Salmon, Mr. Matthews, Terra-cotta, Wm. Holmes, Mrs. Orchard (reflexed Jap.), Old Gold, and Mrs. J. Wright being amongst the best that find favour in a very interesting collection. There are many others, but time will not admit of more being said at present.—C. ORCHARD.

#### CHRYSANTHEMUMS AROUND LIVERPOOL.

##### CLEVELEY ALLERTON.

MR. CROMWELL grows 600 plants, mostly on the tall system, and all looking very promising. Most notable in the Japanese are Belle Paule, Comte de Germiny, Madame C. Audiguier, Volunteer, Etoile de Lyon, and Stanstead White, extra strong; Sunflower, Charlie Sharman, Sarah

Owen, and Mrs. J. Laing. Of incurved varieties the Queen family all look very well, and some excellent flowers are showing of Mr. Bunn, John Salter, Violet Tomlin, Empress Eugénie, Miss M. A. Haggis, &c. Amongst new varieties W. W. Coles and Mr. A. H. Neve are very good. Of Ada Spaulding it was too early to speak, but the plants were strong. The flowers are being developed in the Azalea house, and will be taken from there to the corridor, the roof of which is glazed with Hartley's rolled glass, the flowers keeping a long time under the subdued light.

#### AYMESTRY COURT, WOOLTON.

Mr. C. Osborne, Captain Robinson's head gardener, has a collection of some 250 plants, exclusive of Pompons, &c., which are grown on the pinched and the three-bloom system, and right well they are grown. The Japanese section is very good, the following being the most conspicuous:—Japanese.—Mons. Bernard, Etoile de Lyon, and Sunflower are the best I have seen so far; Avalanche, Boule d'Or, Mrs. F. Jameson, Stanstead White, Comte de Germiny, M. J. Pigny, J. Delaux, Fimbriatum, Condor, E. Molyneux, Stanstead Surprise, Meg Merrilies, T. Stephenson, and R. Brocklebank. Incurved.—Jeanne d'Arc, Princess of Wales, Violet Tomlin, Lord Wolseley, Prince Alfred, and the Queen family are very good; also Princess Beatrice. Newer varieties are Puritan, fine; We Wa Mr. Osborne considers identical with Mrs. Wheeler, and does not intend to grow it again; George Maclure, and Sunset, not expanded, but very promising; Mrs. A. Carnegie, a beautiful colour, with large buds; Volunteer is not considered nearly so good as Belle Paule; W. W. Coles, excellent; Madame Louise Leroy is one of the finest introductions; and, last, Mrs. Alpheus Hardy, which is all the raiser claims for it, and a great beauty. Mr. Osborne has exhibited for several seasons with much success, and is likely to be seen again this year.

#### OTTERSPOOL, AIGBURTH.

Although Mr. Lindsay, through the death of Sir T. Edwards-Moss is not likely to exhibit this year, Chrysanthemums at Otterspool are still largely and well grown. They are not so tall as usual, but are sturdy well matured plants, with thick leathery foliage down to the pots, and would no doubt have done him credit on any exhibition table. The following are developing grand blooms:—Etoile de Lyon, Stanstead White, Stanstead Surprise, Avalanche, Marsa, Mrs. Falconer Jameson, and Bouquet de Dami, a beautiful full silvery white flower, which ought to be better known. Amongst the incurved Miss M. A. Haggis, Violet Tomlin, Mrs. Heale, and Princess of Wales stand out prominent. The Queen family is represented in Mr. Lindsay's excellent style. The secret in the timing of these lies in early pinching. At Otterspool few are grown on the orthodox system, but from six to nine flowers are aimed at. If more collections were so treated less would be heard of being too early or too late. By so treating them Mr. Lindsay believes a late or intermediate crown bud is secured, which is the one that develops into the most perfect and well timed show flower. Avalanche so done, and carrying twelve flowers, was quite a show. I have in my mind's eye a plant of Pelican which I saw two years ago. It was in a 9-inch pot, and carried six magnificent flowers, which I have never seen equalled, I trust Mr. Lindsay may soon be seen as an exhibitor again, for his stands were always of the highest order.

#### HIGHFIELD, WOOLTON.

Here there is a collection of 500 plants, and although Mr. Haigh, Mr. W. H. Tate's excellent gardener, does not exhibit, his collection is a rich one and well grown, and if he exhibited he would be a formidable opponent. Particularly striking in the Japanese were Album Fimbriatum, Etoile de Lyon, Stanstead Surprise, Stanstead White, Condor, Mons. Bernard, Boule d'Or, T. Stephenson, Holborn Beauty, Meg Merrilies, R. Brocklebank, C. Wagstaffe, and William Holmes, a charming pair for decorative work. Violet Tomlin superseded all others of the variety I have seen this year. The blooms were over 4 inches deep, and all other parts in proportion. Princess of Wales, Empress of India, Prince Alfred, Lord Wolseley, Refulgence, and others were of the highest quality. Of the newer varieties I may draw your readers' attention to L'Automne, a splendid salmon buff incurved variety, a large flower, excellent in petal, and one which ought to be in every collection. Volunteer is not cared for, and I saw Ada Spaulding for the second time. I must see it much better before I would grow it. It is more like an incurved Japanese of a very poor variety. Leon Fraiche is really a grand variety, and Mr. Haigh does not intend to grow We Wa again. John Doughty is spoken highly about.

#### ELM HALL, WAVERTEE, LIVERPOOL.

On my visit to Mr. Cox I found him looking over his Chrysanthemums, of which he has this year 500 plants, arranged here, there, and everywhere. They are all grown on the non-pinched principle, and many of them are much shorter than usual. The Japanese are excellent, and here I saw some of the finest flowers of E. Molyneux I have ever seen. Others worth noting: Avalanche, Album Fimbriatum, T. Stephenson, Belle Paule, Madame C. Audiguier, Jeanne Delaux (magnificent), B. le Prailly, Sunflower, Carew Underwood, Mons. Bernard, Stanstead White, and Stanstead Surprise. The incurved were very solid and broad in the petal. The Queen type were represented by very fine flowers; the same may be said of Princess of Wales family, and again of the Tecks. The newer varieties in the Japanese were Annie Clibran, syn. Pink Lacroix, very good; and Oriental, a beautiful, narrow-petalled variety, of a venetian red colour, flaked with gold. It is one Mr. Cox thinks

will come much larger another season, and if so it is destined to become a great favourite. Of the incurved John Doughty is a splendid addition, and a century in front of Bronze Queen. Mrs. Coleman is a grand variety, and for size Emily Dale Improved is far away ahead of Emily Dale. Of Anemones, Gladys Spaulding is one which ought to be in every collection. There is here a striped sport from Queen of England. It is of a lighter shade, but with a violet stripe down each petal; a very pretty variety. Although so many of the large flowering ones are grown, Mr. Cox has wisely made ample provision by growing a houseful of Pompons, Anemones, and reflexed varieties for cutting purposes. Mr. Cox is well known, having taken many first-class prizes, cups, &c., and his blooms are just right for the shows.

#### CAMP HILL, WOOLTON.

Mr. Jellicoe has this year a large number of very promising flowers. They are rather later than many collections I have seen, but will be none the worse on that account. At the earlier part of the season Mr. Jellicoe suffered very much from the damp, but at the present time they are quite free from it. His best blooms of Japanese are E. Molyneux, Mrs. F. Jameson, Condor, Stanstead White, Surprise, Criterion, and others, and of the incurved varieties Mr. Bunn, White Beverley, Lord Wolseley, Jeanne d'Arc, Refulgens, all the Queen family, Hero of Stoke Newington, Princess Teck, &c. Mr. Jellicoe is a thorough grower of the Chrysanthemum, having taken the silver cup twice at Liverpool, and other valuable prizes in all parts of the country.

#### LINGDALE LODGE, OXTON, CHESHIRE.

The residence of G. Cockburn, Esq., is about two miles from Birkenhead, and in Mr. Geo. Burden Mr. Cockburn has a gardener who can grow the Chrysanthemum to perfection. The Japanese varieties are all excellent, the se worthy of mention being Avalanche, Criterion, Stanstead White, Mrs. Wright, Belle Paule, T. Stephenson, J. Delaux, Mons. Bernard (extra fine), Etoile de Lyon, Fimbriatum, Duchess of Albany, Stanstead Surprise, Mrs. F. Jameson (grand), Mr. H. Whellam, &c. The incurved varieties are of the highest order, and never have I seen such a houseful staged, not a bad flower amongst them, and for size of bloom and petal they cannot be surpassed. The Queen family are perfection, and Beauty, Violet Tomlin, Princess Teck, Miss M. A. Haggis, Prince Alfred, Lord Wolseley, Mrs. Shipman, Princess Beatrice, &c. are good. From the last named Mr. Burden has a very pretty sport; it has the same build as the parent but the colour is a bronzy rose shading to yellow, and a beautiful bloom it is; it is quite distinct from Mrs. Shipman, and Mr. Burden will do well to take care of it. Mr. Burden is not so well known yet, having only exhibited three years, but with much success at Birkenhead, Liverpool, and last year at the great Centenary Show at Edinburgh, and is destined to soon take a foremost position; he is an enthusiast, and is well supported by his excellent employer, Mr. Cockburn. There are 450 plants grown, both on the pinched and the orthodox principle. The new varieties worth growing are Mr. E. W. Clarke, Maggie Mitchell, Marsa, Puritan, W. W. Coles. John Doughty is grand and Emily Dale Imp. is an improvement in size. Ada Spaulding is a Japanese incurved from an early bud, but may be better later.

#### DOVE PARK, WOOLTON.

Mr. Carling grows 300 plants, but unfortunately he had many of the most promising shoots broken by the severe gale we had just before they were housed, and the crippled shoots testify to the effects of the wind. Nevertheless, they are very fine, Edwin Molyneux, Mrs. F. Jameson, Florence Percy, Stanstead White, Stanstead Surprise, Condor (grand), Avalanche, F. A. Davis, Fimbriatum, Geo. Daniels, and Sunflower particularly so. The incurved and specially strong are Princess Beatrice, Violet Tomlin, Nil Desperandum, Refulgens, Miss Haggis, Geo. Atkinson, Puritan (splendid), and Madame Louise Leroy, perhaps one of the best blooms in the collection, are worth growing in the Japanese. In the Anemones Nelson and Sabine, and the incurved Mrs. Coleman and John Doughty, were noteworthy. Mr. Carling has exhibited in various parts with much success, and will be seen again this year.

In conclusion I wish to state that what new varieties I have mentioned are thought worthy of being grown, not by myself alone, but by the growers whose collections they are in. The colour of the flower I have not described, as they are to be found in all good catalogues, and I would most respectfully ask those who by their courtesy and kindness have made the compiling of these notes a lighter task than they would otherwise have been to accept my warmest thanks.

#### CALDERSTONES.

In visiting Calderstones, Allerton, the residence of Mrs. MacIver, a few days ago, I was heartily welcomed by Mr. W. Tunnington, the popular gardener, who has presided over the gardens at Calderstones for a great number of years. As might be imagined at this season of the year, the first thing we conversed about was the Chrysanthemum. As we walked through the houses, where the Chrysanthemums were arranged, it was a treat to hear Mr. Tunnington relate some of his experiences; and, although not having been an exhibitor for some few years, there was the same master hand exhibited in their cultivation. Amongst the Japanese, which were very good, were the following:—Madame Louise Leroy, Etoile de Lyon, Avalanche, Mons. Bernard, Mons. H. Elliott, Marsa, Martha Harding, Mrs. W. Stevens, Stanstead Surprise, E. Molyneux, Sunflower, &c. Incurved: All the Princess of Wales type were very good, and Lord Wolseley, Refulgens, Mr. Bunn, and the Queen

family. In every department excellent order is maintained, and to see the Eucharis as grown by Mr. Tunnington, which comprise considerably over 100 large pots, is a sight which cannot be adequately described. Orchids, stove plants, Pines, and other fruit are exceedingly well done. In fact, the place is perfect, and cannot be fully entered upon in this article. It is with the Chrysanthemum Mr. Tunnington's name is most prominently associated, and he is certainly one of our leading authorities. He was, I believe, the first northern grower to ever contest at the London shows, and succeeded in 1880 in winning the Kingston cup and a valuable timepiece, his blooms at that time causing quite a furore. Besides that he has won the cup at Liverpool in addition to many more valuable prizes, and last year his paper at the Sheffield Conference was characterised as one of the best ever written. His manner is honest and straightforward, and his sound facts always command attention. I shall ever remember my visit to him, and trust that he may be long spared to attend as a judge of the flower he loves so well. He is engaged in that capacity this year at some of our principal exhibitions.—R. P. R.

## CHRYSANTHEMUM SHOWS.

HAVANT.—OCTOBER 31ST AND NOVEMBER 1ST.

THE season's campaign opened in the pleasant Hampshire town above mentioned on the dates named. It was the seventh Show of the Society, and was held in the Town Hall. Although the exhibits were not quite so numerous as during the last two years, the quality left nothing to be desired, and the blooms throughout were remarkable for freshness and colour. Cut blooms formed by far the most important part of the Exhibition. The principal class was for twenty-four distinct varieties, half Japanese, the remainder incurved. A silver cup and substantial money prizes were offered in this class. Mr. Payne, gardener to Mrs. Ernald Smith, The Oaks, Havant, succeeded in carrying off first honours with a capital lot of incurved and Japanese, well staged. The varieties were:—Incurved: Golden Queen of England, Queen of England, Empress of India, Lord Wolseley, Prince Alfred, Miss M. A. Haggas, very fine; Refulgens, Jeanne d'Arc, excellent; Novelty, Princess Beatrice, Jardin des Plantes and Empress Eugénie. The Japanese were Madame C. Audiguier, Mr. R. Brocklebank, Avalanche, Edwin Molyneux, Stanstead White, Carew Underwood, Puritan, Gull, Mrs. J. Wright, Madame Baco, Mdle. Lacroix, Mons. Bernard, and Sunflower. Mr. R. Woodfine, gardener to C. P. Boyd, Esq., Emsworth House, Havant, was a good second, the Japanese being slightly superior to the incurved. Etoile de Lyon, Criterion, and R. Brocklebank were some of the best blooms. Mr. J. Agate, nurseryman, Havant, was third.

The next important class was that for eighteen blooms, distinct, nine incurved and the rest Japanese. There was only one exhibitor, Mr. Steptoe, gardener to R. Gale, Esq., Horndean, but he was deservedly awarded first honours for medium-sized even blooms. Five competed in the class for twelve distinct Japanese blooms. Mr. Payne followed up his previous success by securing the leading position with large, fresh, highly coloured specimens of Madame C. Audiguier, Avalanche, Edwin Molyneux, R. Brocklebank, Soleil Levant, Marguerite Marrouch, Stanstead White, Baronne de Prailly, J. Délaux, Madame B. Pigny, M. Bernard, and Mrs. J. Wright. Mr. Agate was a very close second, staging well. Especially good was Mrs. F. Jameson and M. Bernard. Mr. J. Parrott, gardener to Mrs. V. Smith, Woodlands, Havant, was third. For the same number of incurved Mr. Payne again received premier honours with medium-sized neat examples of Jeanne d'Arc, Empress of India, Queen of England, Lord Alcester, Alfred Lyne, Miss M. A. Haggas, Refulgens, Novelty, Mrs. Heale, Nil Desperandum, Jardin des Plantes, and Prince Alfred. Second, Mr. Woodfine. Third, Mr. Agate.

Anemones of the large section in twelve blooms, not less than six varieties, were well shown by Mr. Steptoe, Mr. Agate second, in whose stand two fine blooms of the new Gladys Spaulding were noticeable. This variety has a remarkably large bright yellow centre, with bronze lilac guard florets. In the Japanese Anemone class for twelve blooms in not less than four sorts Mr. Payne won another first prize, Jeanne Marty being especially good; Messrs. Agate and Steptoe followed, both staging well. Fresh blooms were forthcoming from the three exhibitors in the class for twelve reflexed, Mr. Woodfine leading the way with a handsome stand, Mr. Steptoe second, and Mr. Agate third.

Pompons, although not shown largely, were very good in quality. For twelve sprays of three blooms Mr. Agate was easily first, Mdle. Elise Dordan, Golden Madame Marthe, Prince of Orange, and the brilliantly coloured Eynsford Gem being the best. Mr. Agate had a magnificent stand of single varieties, undoubtedly the finest yet seen. Effie; Bessie Conway, a seedling, white ground, striped purple lilac, large, and most effective; Florence, deep blush, of charming form; Elegant, bronze yellow, thin petals, very effective; and Charming, yellow, cup shaped, were the most striking varieties.

Much the best bouquet of Chrysanthemums and Fern was shown by Mrs. Conway, a charming arrangement; Mr. Agate second. Single-handed gardeners and amateurs staged most creditable examples in their respective classes. For a group of Chrysanthemums in pots, arranged in a space of 40 square feet, Mr. Agate was easily first with well grown plants, carrying large blooms, mainly of Japanese varieties. Mr. Roberts, gardener to E. R. Longcroft, Esq., Hall Place, Havant, was second. Mr. Agate had the best table plants and Primulas.

Hardy fruit made a good display. Especially fine were the six dishes of Pears from Mr. Marriner, gardener to Colonel Thistlethwayte,

Drayton; as also were the six dishes of Apples from the same exhibitor, Cox's Pomona and Margil being extra fine. Mr. Gait, gardener to General Napier, Oaklands, had the best two bunches of black Grapes, Lady Downe's, good in all respects. Mr. Woodfine was second with Alicante. Mr. N. Fuller, gardener to the Right Hon. H. Matthews, Idsworth House, Horndean, staged a superior collection of nine sorts of vegetables, Cauliflowers, Tomatoes, Puritan Potatoes, and Beet being most noteworthy. Messrs. Ewing, Sea View Nurseries, Havant, arranged a fine lot of cut shrubs, "not for competition," which were much admired. Mr. Penford, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant, staged two dozen good blooms of Chrysanthemums, for exhibition only. Mr. A. Chignell, the Hon. Secretary, deserves commendation for the admirable manner in which he managed this excellent Show.

KENT COUNTY.—NOV. 4TH AND 5TH.

THOUGH this is only the third season of the above Society it has established one of the leading Exhibitions of this popular autumn favourite in England. The keen competition in all the classes, of which there are fifty, and the quality of the exhibits are proofs of good management. Energy and spirit are thrown into the preparation of the schedule of prizes, which are of a substantial nature, and as a further stimulation the Society wisely recognise extraordinary merit by awarding an elegant framed artistic designed diploma where such merit is seen. Six were awarded this year, and the following were the fortunate recipients:—Mr. G. Newman for a magnificent hand bouquet; Mr. Blackburne for six Japanese blooms, Avalanche; and another to the same exhibitor for six Etoile de Lyon, the high colour of which has never been surpassed. Henry Finchin, Esq., Hartley House, Cranbrook, Kent, also was awarded one for his collection of incurved and Japanese in the silver cup class; and Mr. Blick was awarded the sixth for the finest bloom of Mrs. Alpheus Hardy ever seen in this country, fully 7 inches across. The thanks of all are due to Mr. Needs and his able coadjutors (Messrs. Davis, Stevens, Jones, and others), who have laboured so assiduously to arrange and carry out such an admirable display as was to be found at the Rink, Blackheath, on Tuesday and Wednesday last.

Class 1, forty-eight blooms, twenty-four Japanese and twenty-four incurved, distinct.—First prize Centenary silver cup, value £10, and a money prize of £8. Second prize, £6. Third, £4. Fourth, £2. This inducement brought out five grand collections, remarkable for both size and finish, the premier position being awarded to Mr. J. Blackburne, gardener to John Scott, Esq., Elmstead Grange, Chislehurst, with incurved. Back row: Lord Wolseley, Queen of England, Violet Tomlin, Golden Queen, Golden Empress, Empress of India, Lord Alcester, Princess of Wales. Middle row: Jeanne d'Arc, Miss Haggas, Mr. Jay, Mr. Heales, Prince Alfred, Bronze Jardin des Plantes, Empress Eugénie, Jardin des Plantes. Front row: G. Glenny, Princess Beatrice, Princess of Wales, Lady Hardinge, Princess Teck, Mrs. W. Shipman, Nil Desperandum, and Mrs. Rundle. All the blooms in this collection were grand, Mr. Jay being, perhaps, the least desirable bloom, somewhat pointed, but fine for that old variety. Japanese: Stanstead White, Mons. Bernard, Fair Maid of Guernsey, Sunflower, Meg Merrilies, Etoile de Lyon, Ralph Brocklebank, E. Molyneux. Second row: Madame C. Audiguier, Boule d'Or, Baronne de Prailly, Avalanche, magnificent; Val d'Andorre, Mrs. J. Wright, Stanstead Surprise, Gloriosum. Front row: Thos. Stephenson, J. Délaux, Maiden's Blush, Sarah Owen, Mdle. Lacroix, Madam John Laing, Mons. H. Elliott, and Madame Baco. Many of the blooms in this collection were of such breadth that a great portion of their florets overlapped each other. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, closely followed for second honours, his incurved were remarkably neat, and the Judges had to well consider them before the awards were made. So close were they, that by only one point Mr. Sullivan lost the premier award. His collection was composed of—Back row: Golden Empress, Prince Alfred, Empress of India, Emily Dale, Alfred Salter, Queen of England, John Doughty, Lord Alcester. Second row: John Salter, Miss A. Haggas, Lord Wolseley, Jeanne d'Arc, Prince of Wales, Violet Tomlin, Novelty, Mr. Brunlees. Front row: Mrs. N. Davis, Lady Harding, Mr. Heales, Refulgence, Hero of Stoke Newington, Jardin des Plantes, Nil Desperandum, and Princess Beatrice. Japanese—Back row: Etoile de Lyon, Boule d'Or, E. Molyneux, Stanstead White, Madame J. Laing, Val d'Andorre, Avalanche, Marguerite Marrouch. Middle row: Fair Maid of Guernsey, Mrs. F. Jameson, Madame Baco, Sarah Owen, Sunflower, Belle Paule, Mons. Bernard, Condor. Front row: Gloriosa, Dormillion, Eynsford White, Alpha, Mons. J. Laing, Mons. Garnar, Madame Lacroix, and Mr. H. Cannell. Mr. Edmund Whittle, gardener to C. H. Goschen, Esq., The Ballards, Croydon, was a really good third, and we believe he is almost a new grower, his Golden Empress being the premier bloom in the whole Exhibition. His Japanese were also highly creditable indeed. Mr. Coombes, gardener to W. Furze, Esq., Roselands, Teddington, fourth.

There were seven collections of twenty-four Japanese, distinct. Mr. Blick, gardener to Martin R. Smith, Esq., The Warren, Hayes, gained the first place with Stanstead White, Ralph Brocklebank, Baronne de Prailly, Mons. J. Pigny, Madame C. Audiguier, Edwin Molyneux, Sunflower, Etoile de Lyon. Middle row: Mrs. Falconer Jameson, Stanstead Surprise, Mrs. J. Wright, Mons. Bernard, Carew Underwood, Gloriosum, Avalanche, and Comte de Germiny. Front row: Mrs. Alpheus Hardy, the finest bloom ever seen in England; Golden Dragon, Madame John Laing, Mr. H. Cannell, Mrs. Beale, grand; Sarah Owen, Jeanne Délaux, and Florence Percy. Mr. Blackburne was second, and

Mr. John Doughty, gardener to Mrs. M. Tomlin, Angley Park, Cranbrook, Kent, third. For twelve Japanese, distinct, there were eleven competitors, each collection running very close. Mr. Blackburne was again to the front with Mons. Bernard, Sunflower, Edwin Molyneux, Etoile de Lyon, Meg Merrilies, Val d'Andorre, Avalanche, Ralph Brocklebank, Madame Baco, Mrs. J. Wright, Baronne de Prailly, and Gloriosum. Mr. Doughty was second, and C. E. Shea, Esq., Fooks Cray, Kent, third.

For twelve incurved, Messrs. Whittle, Briscoe, Ironsides, and M. A. Munnock, gardener to A. J. Scutton, Esq., Eagle House, Eltham, were placed first, second, and third in the order of their names. Mr. Whittle's collection were superior to the others, and consisted of Empress of India, Golden Empress, Queen of England, Lord Alcester, Alfred Salter, John Doughty, John Lambert, Lord Wolseley, Mrs. Shipman, Miss M. Haggas, Violet Tomlin, and Jeanne d'Arc. In the class for twelve reflexed, Mr. Joseph Mitchell, gardener to A. W. Arbuthnot, Esq., Bridgen Place, Bexley, Kent, stood ahead of the other fine boards with Golden Christine, King of Crimson, Mdle. Madeline Tezier, Garibaldi, Amy Furze, Pink Christine, Golden Christine, Peach Christine, Cullingfordi, Felicity, Cloth of Gold, White Christine. Mr. F. Moore, gardener to W. C. Pickergill, Esq., Blendon Hall, Bexley, and Mr. C. Holbrow, gardener to Major Budden, Banner Cross, Grove Park, Lee, shared second and third honours.

Anemones were well represented, and in the class for twelve Mr. Sullivan was awarded first position with Jean Marty, Mons. Pankouche, Sœur Dorothee Souille, Souvenir de Madame Blandineries, Nelson, Mr. Judge Benedict, Laing's Anemone, Gluck, Mons. Charles Lebocq, Marguerite Solleville, Lady Spaulding, and George Sand. Messrs. Mitchell and Moore were second and third respectively. For six blooms Queen family Mr. Chas. Cox, gardener to John Trotter, Esq., Brickenden Grange, Hertford; Mr. Whittle and Mr. Moore were placed in the order of their names.

In the class for twelve incurved, excluding the Queen family, there were five competitors. Messrs. W. Ray & Co., Sittingbourne, were placed first with a fine stand of the following:—Prince Alfred, Jeanne d'Arc, Lord Wolseley, Violet Tomlin, Miss A. Haggas, Alfred Lyne, Princess of Wales, Empress Eugénie, Lady Hardinge, Mrs. Heale, Refulgens, Mrs. W. Shipman. A very fine stand indeed. Mr. Doughty was placed second, and Mr. Shoesmith, gardener to M. Hodgson, Esq., Shirley, Croydon, third.

For six Japanese, white, Mr. Mitchell was placed first with Avalanche; Mr. Adlam, gardener to W. S. Milnes, Esq., Woodstock, Lee, second with Elaine; and Mr. Hazell, gardener to R. J. Mitchell, Esq., Bickley Park, third with Avalanche. For six Japanese, yellow, the first award fell to C. E. Shea, Esq., for magnificent blooms of Sunflower; and the second and third prizes were awarded to the same variety, Messrs. Mitchell and Payne being the prizetakers in the order of their names. In the class for six Japanese, any variety, no less than thirteen varieties were staged. Etoile de Lyon, from Mr. Mitchell, was a good first; and Edwin Molyneux, from Messrs. Doughty and Shea, was second and third respectively. Six incurved, one variety, Mr. White staged six as even blooms of Golden Empress that was ever staged, to which a first prize was deservedly awarded. Messrs. Hazell and Papworth received second and third honours, but a long way behind the first prize stand. Ten exhibitors staged Avalanche. In class 44 Messrs. Blackburne and Doughty were first and second respectively, both running each other very close for first place. For eighteen Japanese, distinct, Mr. Blackburne again takes the leading place with Mons. Bernard, Sunflower, Edwin Molyneux, Avalanche, Ralph Brocklebank, Etoile de Lyon, Stanstead White, Stanstead Surprise, Gloriosum, Val d'Andorre, Sarah Owen, Mrs. J. Wright, Thos. Stevenson, Fair Maid of Guernsey, Baronne de Prailly, Meg Merrilies, Madame Bacco, Madame John Laing. Mr. Blick received the second prize with an attractive collection, and Mr. Leadbetter third, all exhibiting well. In the corresponding class for twelve Messrs. Hazell, Barnes, and Skinner were placed in the order of their names, the varieties being similar to the foregoing classes.

For twelve incurved, distinct, Mr. Whittle was well ahead with Queen of England, Golden Empress, John Lambert, Lord Alcester, Lord Wolseley, Alfred Salter, Empress of India, John Doughty, Miss M. Haggas, Violet Tomlin, Jeanne d'Arc, John Salter. Mr. Barnes, gardener to A. Bovell, Esq., Grove Park, Lee, was placed second; and Mr. Leadbetter, gardener to A. G. Hubbuck, Esq., Chislehurst, third.

Amateurs, twenty-four blooms, twelve Japanese, twelve incurved, distinct, silver cup, value £5 5s., presented by Mr. Norman Davis, Camberwell, brought out a good competition, and Henry Fincham, Esq., Hartley House, Cranbrook, was deservedly awarded the first prize with incurved Prince Alfred, Jeanne d'Arc, Violet Tomlin, Princess of Wales, Mrs. Heale, Princess Beatrice, Miss Haggas, Refulgence, Nil Desperandum, White Venus, Lord Derby, Mrs. Haliburton. Japanese: Mons. Bernard, Comte de Germiny, Carew Underwood, Etoile de Lyon, Mrs. F. Jameson, Edwin Molyneux, Avalanche, Madame John Laing, Val d'Andorre, Mons. Bacco, Baronne de Prailly, and Sunflower. W. G. P. Clark, Esq., 10, Fishpond Road, Hitchin, was placed second; and Dr. George Walker, Wimbledon, third. This was a highly attractive class, and in no way inferior to the open classes.

There were several collections staged for the class of eight incurved, eight Japanese, and eight reflexed, Messrs. Blackburne, Mitchell, and Moore being placed in order of their names for collections that could be scarcely surpassed. A large competition of hand bouquets, épergnes or vases, and baskets of flowers.—Mrs. Newman, first; Mr. R. Chard,

second; and Mr. Nunn, gardener to J. Soames, Esq., Greenwich, third for épergnes or vases. For bouquets, Mr. G. Newman, first; Mrs. Jones, second; and Messrs. Perkins, Coventry, third. Mr. C. Davis, jun., a lad only eleven, also secured two prizes in the amateur classes for six varieties. Groups were well done, and several collections staged. Mr. J. Payne, gardener to T. Williams, Esq., Lewisham Park, first. The flowers were of massive substance, and contain a plentiful sprinkling of the Queen family, and other well known exhibition varieties with good foliage. Mr. James Hudd, gardener to J. W. Prior, Esq., was placed second with slightly dwarfier plants, Etoile de Lyon being very conspicuous in his collection. Mr. T. Dobson, gardener to F. P. Preston, Esq., South Bank, Blackheath, third with fine flowers.

Miscellaneous groups were set up by Mr. Mullins (gardener to W. Strong, Esq., Blackheath), Mr. Hudd, and Mr. Jeffrey (gardener to Mrs. Crundall, The Moat, Eltham), who were placed in the order of their names for light and graceful arrangements. Mr. Jones, Hither Green Lane, exhibited a pleasing group not for competition, and Messrs. Laing & Sons a highly attractive collection of fruit. Altogether a magnificent display was provided, of which Kent may be well proud, and which was admired by a fashionable company.

#### SURREY.—NOVEMBER 3RD AND 4TH.

ALTHOUGH the above named Society has adopted a county name, only a moderately attractive display was made in the Peckham Public Hall on Monday and Tuesday last, which, however, brought a good company of visitors, so that we hope that the Society will be benefited and obtain new subscribers, as the total income last year from all sources was only £43. This is small for the thickly populated district in which the Show is held. A little more energy and spirit is required all round so to bring exhibitors from a greater radius, but praise is due to those who did compete, especially in the group class, for several very tastefully arranged groups furnished the sides of the spacious hall. Mr. Witty, Superintendent of Nunhead Cemetery, took the premier position with a group occupying a space of 100 square feet. Mr. Elson, gardener to M. Peate, Esq., Loughborough, received second honours, and Mr. Dominy, Nunhead, third. Smaller sized groups were staged by Messrs. Bolton and Snoad, who were first and second respectively.

Mr. Elson secured the first prize for twenty-four cut blooms, and the National Chrysanthemum Society's silver medal. His twelve Japanese were creditable, but the stand of incurved was not far enough advanced. He was the only exhibitor in this class. Messrs. Lindsay, Falkner, Vaughan, Worley, and Strudwick shared the honours in the other cut bloom classes, which contained nothing special.

Table plants were very graceful, Mr. Elson securing two first prizes for very pretty collections. Mr. Bennett received two first prizes for bouquets. Mr. Major, a local nurseryman, exhibited some very fine Gros Colman Grapes, grown in the neighbourhood. Messrs. Laing of Forest Hill, and French of Camberwell, staged groups not for competition.

#### IPSWICH.—NOVEMBER 4TH.

WITHIN the past few years the Ipswich and East of England Horticultural Society has developed into one of the best horticultural organisations in the eastern counties. This has been accomplished mainly by the influence of the Honorary Secretary, the Rev. H. Berners of Harkstead Rectory, who is widely and well known as an enthusiastic and skilful amateur horticulturist. Both the summer and autumn shows are now very creditable displays, but the progress made with the Chrysanthemum Show is especially notable, and on the occasion of that held on Tuesday last the advance was most marked, for, as some have expected, the early exhibitions are securing many fine blooms that would have been too late for the second week dates. The Public Hall at Ipswich is a spacious lofty building, light and well adapted for a show of this character, the large hall being devoted to Chrysanthemum groups, plants, and cut blooms, with a few miscellaneous groups, while a large room adjoining contained the fruit, of which Grapes, Apples, and Pears were exceedingly well represented. In the hall the arrangements were good. Upon a stage at one end the specimen plants and miscellaneous groups were placed, and in front of these the groups of Chrysanthemums had a very bold effect, others being round the sides of the building, and the cut blooms were placed upon two long tables extending the whole length of the building. We can only refer briefly to the principal exhibits this week, as the demands upon our space are so great.

CUT BLOOMS.—These constituted an important portion of the Exhibition. The competition was very keen, and the Judges (Messrs. G. Gordon and Lewis Castle) had a considerable task in several classes to determine the relative positions of the exhibitors. In the open classes Mr. H. Lister, gardener to Lord Brooke, Easton Lodge, Dunmow, Essex, was the most successful competitor, staging handsome blooms, both of incurved and Japanese, which secured the premier awards in the two leading classes of the Show, repeating the success that he has for several years gained at Ipswich. With twenty-four cut blooms, twelve incurved and twelve Japanese, distinct, there were eight competitors, and Mr. Lister was first with substantial, well-finished examples of the following:—Incurved, back row: Lord Alcester, Queen of England, Golden Empress, Empress of India. Middle row: Jeanne d'Arc, Emily Dale, Alfred Salter, Lord Wolseley. Front row: Prince Alfred, Mrs. Heale, Refulgens, Empress Eugénie. Japanese, back row: Avalanche, Sunflower, Condor, Mrs. Wheeler. Middle row: Ralph Brocklebank, Meg Merrilies, E. Molyneux, Madame C. Audiguier. Front row: Pelican, Mrs. F. Jameson, Blanche Pigny, Criterion. The second place

was secured by Mr. W. Dance, gardener to Mrs. Lowe, Gosfield Hall, with very handsome Japanese and even clean incurved. Third, R. C. Notcutt, Esq., Anglesea Road, with good Japanese and even, but small, incurved. Mr. Notcutt was, however, very successful in other classes, and evidently pays much attention to his Chrysanthemums with good results.

Mr. Lister was again first for twelve incurved, showing good blooms of Golden Empress, Empress of India, Lord Alcester, Prince Alfred, Emily Dale, Jeanne d'Arc, Lord Wolseley, Empress Eugénie, Mrs. Heale, Princess of Wales, and Miss Haggas. Messrs. Dance and Messrs. Saltmarsh & Son, Chelmsford, followed in the order named.

Amongst seven competitors with twelve Japanese, Mr. M. Chenery, gardener to J. Limmer, Esq., Woodside, was first with beautiful examples of Maiden's Blush, E. Molyneux, Avalanche, Etoile de Lyon, Comtesse de Beauregarde, Sunflower, Val d'Andorre, Lady T. Lawrence, Oracle, Madame C. Audiguier, Boule d'Or, M. Baco. Mr. Notcutt followed closely, only losing first place by a point or two in an imperfect Etoile de Lyon. Sunflower and Soleil Levant were very fine. Mr. Lister was third.

Five competitors entered in the amateurs' class for twenty-four cut blooms, twelve incurved and twelve Japanese. W. H. Lees, gardener to the Duchess of Montrose, Sefton Lodge, Newmarket, took the lead with deep handsome blooms of incurved. Back row: A fine example of Alfred Salter (silver medal as the best bloom in the amateurs' classes), Emily Dale, Prince Alfred, Queen of England. Middle row: Jeanne d'Arc, Lord Alcester, Empress of India, Lord Wolseley. Front row: Nil Desperandum, Princess of Wales, Refulgens, and Miss M. A. Haggas. The Japanese were not so good, the varieties being Etoile de Lyon, Ralph Brocklebank, E. Molyneux, Fair Maid of Guernsey, Thunberg, Madame C. Audiguier, Comte de Germiny, Avalanche, Soleil Levant, Madame Laing, Madame B. Rendatler, and Blanche Pigny. The second prize went to A. D. Helford, Esq., Great Bergholt, who had even, well balanced blooms of both incurved and Japanese, and he lost the first place by very few points. The Rev. H. Berners was third with another meritorious stand, the blooms even, clean and bright throughout.

In other cut bloom classes the Rev. H. Berners was first for six crimson reflexed, staging beautiful examples of Cullingfordi. For reflexed and Anemones Mr. Notcutt won the chief place with excellent blooms, Messrs. Lees and Dance also showing well. The best plants were in the groups, and those with which the Rev. H. Berners secured first honours were admirable, bearing large richly coloured blooms, E. Molyneux, Val d'Andorre, and Meg Merrilies being very notable for their size and colour. The Hon. W. Lowther, M.P., followed, and Dr. R. Casley was third. The two leading miscellaneous groups were from Messrs. Caldecott and Gilbert, who were first and second respectively, both tasteful and effective. The most successful exhibitors of fruit were Mr. Sheppard, gardener to Captain Berners, Woolverstone Park, Ipswich, and Mr. Rogers, gardener to Lord Rendlesham, Rendlesham Hall, who had excellent samples of Grapes. Baskets of flowers, bouquets, and stands of flowers were also well shown. The Committee and supporters of the Society have every reason to be satisfied with their work, and the public of Ipswich signified their appreciation by attending in large numbers.

#### BRIXTON AND STREATHAM.—NOVEMBER 4TH AND 5TH.

FOR a number of years the Brixton Chrysanthemum Society has been famed for its annual shows in the school room behind the church near the top of the hill, but this year larger and more imposing quarters were engaged for what proved to be one of the most satisfactory exhibitions this Society has ever held. The Public Hall near Streatham station was devoted to the exhibits, and for general quality and effect we have never seen a show of similar size to equal this. Specimen Chrysanthemum plants, Ferns, and foliage plants, Orchids, and Primulas, besides a delightful display of cut blooms in all the sections, with fruit and vegetables as usual, constituted an exhibition with which the district, the Society, the Committee, and the courteous Secretary, Mr. John Salter, had just cause to be amply satisfied. The fittings of the hall, the general elegance, the tables covered with red baize, and the tasteful arrangement, left nothing to be desired, and it is to be hoped that an abundant attendance of visitors completed the satisfaction of all concerned.

Turning to the cut flowers first it may be noted that the general quality was very satisfactory, and it is surprising how close some of the competitors' collections are in merit. With twenty-four Japanese Mr. T. Mursell, gardener to Mrs. Burton, Tower House, Leigham Court Road, was first with handsome blooms of the following:—Back row: Etoile de Lyon, Sunflower, Fair Maid of Guernsey, E. Molyneux, M. J. M. Pigny, Gloriosum, Mrs. Clark, Stanstead White. Middle row: Ralph Brocklebank, Maggie Mitchell, Charles Sharman, Belle Paule, Val d'Andorre, Mrs. Thomson, Golden Dragon, Stanstead Surprise. Front row: Avalanche, L'Adorable, La Triomphante, Mrs. F. Jameson, Elaine, Comte de Germiny, Mrs. Alpheus Hardy, and Boule d'Or.

Mr. Mursell was also awarded the Centenary bronze medal of the National Society for this collection, and he was followed by Mr. W. Howe, gardener to H. Tate, Esq., Park House, Streatham; and Mr. S. Ashby, gardener to B. H. Holman, Esq., Leigham Court Road. For twenty-four incurved Mr. Howe took the first place, showing excellent blooms of Golden Empress, Empress of India, Violet Tomlin, Emily Dale, Alfred Salter, Lord Alcester, Princess of Wales, John Salter,

Jeanne d'Arc, Lord Wolseley, Princess Teck, Jardin des Plantes, Beauty, Miss Haggas, Barbara, and Prince of Wales.

In the specimen plant classes Messrs. Clarke, Cherry, and Weston were the chief exhibitors, while in fruit Messrs. Howe, Wiggins, Pearce, Guyett, and Bonnewell secured the leading prizes.

#### FRUIT FORCING.

VINES.—*Earliest*.—For affording ripe Grapes in April the Vines, whether in pots or planted out, must now be started. Bottom heat in neither case is indispensable, though in all forcing operations it hastens growth considerably, therefore in forcing Vines in pots place fermenting materials in the pit in which the pots are stood on pedestals of loose brickwork, being careful not to allow the heat about the pots to exceed 70° to 75°. Suspend the Vines in a horizontal position over the fermenting material to insure a regular break. Syringe three times a day, keeping every part of the house moist by sprinklings in bright weather. Vines started at this season require a higher temperature to excite the buds than those started later. A temperature of 50° to 55° at night and 60° to 65° by day will not be too much to start with. Where no fermenting material is used sprinkle the floors and other available surfaces, but not the Vines, with guano water, 1 lb. to twenty gallons of water, or the drainings of stables diluted with six times the quantity of water at closing time two or three times a week.

Early forced planted out Vines should have the border, or preferably the pathway or floor of the house if convenient, covered with 2 feet depth of leaves and stable litter in a state of fermentation, occasionally turning the material, as the ammonia given out is very beneficial to the Vines, and a moist genial atmosphere maintained with regularity. The inside border should be soaked with water or liquid manure at 90°. Outside borders must be attended to; if fermenting materials are not obtainable cover with a good thickness of leaves, with tarpaulin, shutters, or lights to throw off rain or snow.

*Houses for Starting in December*.—The pruning must not be further delayed, as it induces rest, and the Vines are not so liable to bleed. Dress the cuts with styptic or knotting as a safeguard. In pruning two eyes are ample for affording useful bunches, but Vines that do not afford bunches as large or so freely as desired should be allowed more buds, four to six, according to their vigour, yet with the wood stout and short-jointed the close pruning will mostly afford the most satisfactory results, as what is gained in size of bunch is lost in size of berry, compactness of bunch, and good finish. A good useful bunch of well-coloured thoroughly ripened Grapes is always appreciated, therefore aim at that, as size, whether of bunch or crop, is quite secondary. Dress the Vines, cleanse the house, having all in readiness through cleanliness and good order for a start at the proper time.

*FIGS.—Early Forced Trees in Pots*.—Where these have been placed outdoors they should be taken under cover to protect them from the cold autumn rains. It is presumed that the trees have been top-dressed, repotted, or had the drainage rectified, as advised in a former calendar. The trees should be placed in a rather dry, well ventilated house. Any thinning or shortening of crowded or attenuated growths should be attended to, and the trees dressed with an insecticide; but they must first be washed with tepid softsoap solution, 8 ozs. to the gallon of water, using a somewhat stiff brush, especially if scale has been or is present, following with the same, to which sulphur has been added to bring it to the consistency of cream, being careful not to damage the points of the shoots and the embryo fruit.

Ripe Figs early in the season are a necessity in most establishments, and are not difficult to obtain; but a light well ventilated house is necessary, with the command of plenty of heat, having pits containing fermenting materials to afford bottom heat to stimulate the roots and assist in their feeding. The Fig requires good support, trees in pots needing abundance of liquid manure when growing, the trees being most prolific under limited root space. One of the great advantages of Fig culture in pots is the supply of occasional dishes from a few trees, a number of varieties being readily grown in a house of moderate dimensions, and which if forced come in at a time when the dessert is not too varied. Brown Turkey is the best of all Figs for any purpose and the best white is White Marseilles. Angelique, Col de Signora Bianca (flesh red), Pingo de Mel, and St. John's have yellowish or white flesh; and Black Ischia, Black Marseilles, Brown Ischia, Dwarf Prolific, Early Violet, Bondance Précoce, Col de Signora Nera, Brown Ischia, Violette de Bordeaux, and Negro Largo are good dark Figs for pot culture, affording a long succession.

*Early Forced Planted out Trees*.—Untie these from the trellis and pruncheon them. Those with the roots restricted to small borders will require the shoots thinned where too crowded, but those not having the roots restricted will need a hard pruning at the upper part of the

trellis, cutting back those shoots that have reached the upper part of the trellis or limit, to where the succeeding shoots start. Remove any elongated spurs, reserving such as are short-jointed and fruitful. The house should be thoroughly cleansed, washing the woodwork with hot water; washing the walls afterwards with quicklime and sulphur. Wash the trees with soapy water, and afterwards dress with an insecticide. Then secure the trees to the trellis, allowing room for the growth of the branches, forking the surface of the border slightly, remove the loose material, and apply a top dressing of short partially decayed manure about 2 inches thick, and if dry afford a good watering. Ventilate freely at all times, except when frost prevails, which is best excluded, employing no more artificial heat than is necessary.

*Succession Houses.*—Prune and cleanse the trees without delay, especially where insects have obtained a footing. Complete any lifting, root-pruning, &c., remembering that Figs with the roots restricted or limited to a somewhat small area are more manageable and fruitful than those with an unlimited root area. Any unfruitful trees should be rather severely root-pruned, and the roots restricted to moderate sized borders, depending more on active feeders near the surface, encouraged by mulching, than a large extension of roots.

*PINES.*—Afford liberal ventilation to houses or pits containing young plants whenever the weather is favourable, as keeping the houses constantly closed and saturated with moisture is more injurious than beneficial. Water will not be required frequently, yet the plants must be examined every ten days, watering such as require it, as too great dryness is more injurious than is credited. In the fruiting department lose no opportunity of closing the house at 85°, keeping the night temperature at 70°, or a few degrees less in cold weather. Remove all the superfluous suckers, retaining one only, the best on each plant. Suckers on successional plants that appear before the fruit is visible should be removed, unless an increase of stock is urgent. At this time of year it is usual to make new beds of fermenting materials for the young plants. Tan is unquestionably the best material, a good substitute being found in Oak or Beech leaves, which should be collected as dry as possible. In forming beds of leaves they should be firmly pressed; tan, on the other hand, should be placed lightly together.

*CUCUMBERS.*—Secure to the plants a regular temperature of 70° at night, 5° less on cold nights, 70° to 75° by day, advancing to 80° or 85° with sun heat. Admit a little air at the top of the house whenever the weather is favourable; but it must always be done without lowering the temperature, it being better to shut off the top heat for an hour or two when the sun is powerful than to admit air when the winds are sharp and cold. Judicious and moderate ventilation is, however, beneficial in carrying off steam or accumulated moisture, and in imparting flavour to the fruit. The syringe may be laid aside except for damping the walls, paths, &c., in the morning and afternoon in warm, bright weather, keeping the evaporation troughs filled with liquid manure. The water or liquid manure given to the roots must be of the same temperature as the house, as also must the soil that is added to the beds.

Encourage the autumn fruiters now in full bearing with copious supplies of liquid manure, not too strong or too often, taking care to avoid overcropping by removing the fruit as soon as it is full-sized for table, and all deformed fruit when seen. Go over the plants at least once a week for the removal of bad leaves, stopping one joint beyond the show of fruit, cutting away superfluous growths.

Winter fruiters should not be allowed to fruit now, or their energies will be so impaired that they will not show and swell fruit at the new year onwards; therefore let them advance well up the trellis before stopping, training the side growths evenly and not too thickly, as it is important that the foliage have good exposure to light and air. To impart vigour to the main branches stop at a few joints of growth. If fruit must be had stop at one or two joints beyond the show of fruit, allow few male blossoms and no tendrils, removing them as fast as they appear, and add fresh warmed soil as often as the roots have fairly covered the surface of the bed. If mildew appear dust with flowers of sulphur, and subdue aphides by frequent but moderate fumigations with tobacco. Red spider will not give trouble if an ammonia-charged atmosphere is maintained; but it must not be too strong, and thrips are evidence of too dry an atmosphere.

#### PLANT HOUSES.

*Crotons.*—Where a sufficient stock of young plants has not been prepared, well coloured side shoots may still be rooted singly in small pots. The shoots must be cut off where the wood is soft, and then they will root quickly in brisk heat. If the wood is hard they will be a long time before roots are formed at this season of the year. Plants that are well coloured and large enough for the purpose for which they are required should be kept where the temperature is 55° to 60°. This will prevent their making fresh growth, which would spoil their appearance, for the majority of varieties will not colour foliage made after this date. Plants that it is intended to grow into larger specimens next year should not be confined at their roots. These will produce abundance of fresh roots, and be in the best possible condition for making free growth early in the year. Plants from which heads and side shoots have been removed may be cut back a few joints, and thoroughly washed with petroleum and water, one ounce to the gallon. This will free them from scale if any exists upon them. The small scale to which these plants are subject can be readily destroyed by one or two applications when they have no young tender foliage upon

them. If the stock plants are clean, Crotons should be grown to the size they are required without recourse to sponging, which, however carefully done, is sure to injure the foliage to a certain extent. Stock plants that are slightly pruned back will soon burst fresh growth buds, when they may be potted if confined at their roots. With plenty of active roots and a moderate amount of root room the cuttings will be free and vigorous in comparison with those from plants that have been pot-bound for some months. Plants that have growths upon them and are intended for the same purpose may also be potted, and what are only small shoots now will be well developed shoots in spring. Keep the temperature for the general stock of these plants from 60° to 65° at night according to the weather.

*Dieffenbachias.*—Potting is often discontinued when autumn arrives, but it is a great mistake when the object is to advance the plants. Plants that need larger pots at the present time will be seriously checked if left until the turn of the year. Repot those plants that need more root room, and although growth will be slow they will make roots freely, and be ready for potting again towards the end of January. Plants that have become tall may have their tops taken off, and will root freely in brisk heat. Cuttings with bold foliage at the top will make large plants quickly in spring. If the old stems are required for stock stand them amongst other plants in a heated structure until after the new year, when they may be cut into lengths and placed into pans or boxes.

*Dracenas.*—Those that it is necessary to grow into larger plants whether warm or cool varieties, should not be confined at their roots. Those raised from the stem during May and June may be placed into 5 and 6-inch pots; while those raised later may be placed into 4-inch pots. If they are to be used for decoration in these sizes when ready surface some with Selaginellas, others with a few seedling Ferns, and others with a mixture of both and *Panicum variegatum*, small rooted pieces of the latter should be used. This adds materially to their beauty when used singly in vases. Plants of large growing kinds that are well rooted in 6-inch pots may be placed into 8-inch. To do these plants well they should never be confined at their roots until they have been given their final shift.

*Gardenias.*—Those that are well rooted in thumbs may have their points removed, and be placed into 4-inch pots. If kept in brisk heat they will be bushy little plants by spring. Plants that are swelling and forming their flower buds should be kept in a temperature of 60° to 65° at night. Do not allow them to become dry at their roots, but water them carefully, and avoid giving them cold water, strong stimulants, or syringing them with strong insecticides, or else the flower buds will be deformed and fail to give satisfaction. A check from any cause should be avoided, and the roots kept active if large bold flowers are required.

*Poinsettias.*—Plants that have commenced to develop their bracts should be grown in a temperature of 65° until they are thoroughly developed, when they can be carefully hardened and used in any position. Give these plants weak stimulants every time water is needed, or better still, apply a little artificial manure to the surface of the soil about once a week. Do not keep later plants in a higher temperature than 58° at night. Nothing is gained by hurrying these and Euphorbias, for they will be invaluable during December and until the end of the year.

*Allamandas.*—Keep plants that are growing in a temperature of 60° to 65°, and encourage them by giving weak stimulants frequently. Top-dress the plants with manure if confined at their roots; they will soon take possession of it, and flowers will be produced freely for some time to come. Keep perfectly dry plants that are to be starting into growth towards the end of next month. They should not be in a lower temperature than 50°.

*Pandanus Veitchi.*—Strong suckers may be taken off and inserted in small pots. Place a little sand at the base of each, and stand them in any warm house; it is not necessary to place them in the propagating pit, for they root equally as well outside. Those that are growing too large for 5, 6, and 7-inch pots may be placed into 10-inch. Plant the surface of the soil with *Nephrodium molle*, or small pieces of *Microlepia hirta cristata*. Either look well, and add wonderfully to the appearance of these plants when used in large vases singly. The variegation of the plant is shown to perfection with a groundwork of green beneath. However carefully Mosses and Ferns may be arranged about the base of the plant, they never look so well as when they have grown naturally in that position. This plant bears room decoration well, and may be kept in for three or four weeks at a time without injury. The Ferns may suffer slightly, but both are free growers, and a few weeks in a warm house are sufficient to restore them again to health.

*Acalyphas.*—Root singly in small pots a number of cuttings ready for growing in spring, or to form good heads for re-rooting. These are useful plants for table, room, or conservatory decoration. They grow readily, and colour beautifully if exposed to the sun. They are probably best grown on a single stem for most purposes, but handsome bushes can be formed for large vases by inserting four or five cuttings in a pot and growing them together without pinching until they are 18 inches high. When the plants begin growing keep them separate by placing a stake to each, so that the leaves will form naturally round the stem. If good tops are used for cuttings the lower leaves will arch gracefully downwards and half hide the pots. Where small cuttings are used the plants can be potted down without injury, for they root freely from the stem.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### THE WEATHER.

ALTHOUGH October was somewhat frosty, and the temperature was down to 20° on the 28th, the bees have carried more pollen and on more days than I ever experienced during the same month. Previous to the rain on the 27th, and as is usually the case, the birds have made havoc with the Currant and Gooseberry buds, being about ten days earlier with the devastation than the average of years.

### PREPARED FOR WINTER.

Owing to the protracted season I was a little later in getting my hives prepared for the winter's campaign. But they are now completed, and stand either in outside cases with dry hay between and over the hive, or with several folds of sacking on the sides and hay on the top, with an oilcloth projecting well down the sides, and covering part of the stand. The semi-circular roof of galvanised iron throws the drip well off the sides, and protects both front and back from rain. This porch gives most freedom and protection, with least obstruction to the bees. If I had a new term of a bee-keeping life to begin, this would be the only form I would adopt. It is not only the handiest but is the cheapest to begin with, and costs less at first than any other system ever devised, and the hive proper will last far longer than double cased ones, or outside cases.

### DYSENTERY.

As dysentery is brought on by damp hives, and the honey absorbing an undue quantity, owing to the form of hive and mode of management, our bees have an entire immunity from that disease. Costiveness is a common occurrence amongst bees that have nothing but Heather honey and abundance of pollen. This costiveness has been termed dysentery by some writers, whereas it is simply the opposite, and occurs amongst the most healthy bees. To prevent it I allow a few pounds of beet sugar dissolved in its own weight of water. That has now been supplied to nearly all of them, and I have no dread of an Arctic winter injuring the bees in the slightest.

Dead bees on the floor are a frequent annoyance to some; that, as well as detachments of bees dying, are unknown in my apiary.

### MICE IN HIVES.

The present month is the one when mice are seeking for winter shelter and take readily to hives. They kill the bees by eating their heads and thorax, and their offensive odour is abominable and injurious to bees; they ought to be well guarded against. With very narrow entrances they are kept outside, but sometimes they nestle in the wrappings and eat into the hives. To prevent this traps or poison should be used, as hives seldom rally from the injury of mice. The slide of perforated zinc, as used by Wm. Hogg, Castle Douglas, is an effectual plan of keeping them from entering the hive by the doorway, but it has the same evil effect as it has in the other ways it is applied in bee management, by hindering the bee's exit and return at a time when it is most desirable they should have free egress and ingress to and from their hives.

### EKES DURING WINTER.

These ekes, or "raises" as they were termed, belong to the Stewarton method, but they have the fault of drawing damp, which cools the bees before leaving the hive, and being so much below the comb many bees get chilled on their return before they reach it. The ventilating floor fully obviates these inconveniences, and preserves the bees, as the moment they leave the non-conducting comb they are outside, and having little or no toilet to perform evacuate while on the wing, and return in a vigorous state to the hive without any delay or much loss of heat. In cases where (from want of better resources) it is necessary to use ekes, always

place a bit of fresh comb a little beyond the entrance, so that the bees can avoid the damp and conducting sides of the eke, and reach the combs and cluster in safety when the sun is low and the air chilly.

### PREPARING FOR SUMMER.

Bees should now require no more attention, that is, provided they are wind and water tight with sufficient stores, till the months of April or May, beyond an occasional look to see all remains as they were prepared. Everything required for next summer should be overhauled and put in readiness when required. As our swarms were not numerous this year, the frames we deprived the bees of filled with Heather honey, will be the only ones requiring foundation, those prepared last year being still in readiness and in order. I will not touch nor overhaul them until May, but will then go over every one, and remove all traces of the spiders' webs; between them and the earwigs they keep the moths down, so I rather encourage the former, and have no trouble with moths in my hives.

I have disposed of all my prize hives, and may, if the year be good, require a few of the cheap sort to take their place, being in reality the best hive for all purposes, although it has not been the greatest prizewinner. As these additions will be for swarms, only two divisions and stand, if supers are excepted, will complete the hive; no outlay whatever will be made but what is necessary. The floors being for summer work only will be made on the cheap, and without feet. When so made they do not oscillate so much when in transit on a vehicle as with feet, however short they may be, and can, if required, be piled two tier, thereby getting more hives to their site at the Heather in a shorter time and at a cheaper rate than when fewer have to be taken. The stand will, with the exception of one of the sides being in two pieces, which I will hereafter explain, and minus the feet, be the same or similar to the complete floor and stand.

It consists of a rim of five-eighths wood from 4½ to 6 inches broad, having a sheet of perforated zinc the full size of the stand upon the top edge. One of the sides will be in two pieces, which combined, will measure about an inch less than the full breadth, leaving an opening nearer the bottom than the top of about an inch wide. The under rail being a little narrower than the upper a fillet of wood will be required all round on the inner side of the stand, so that the shutter or false floor comes flush with the under edge of the upper rail, when another fillet at each side of the shutter is nailed to the stand at an angle, so that when the shutter is down it admits air, and can be caught hold of to raise it to its place when to be shut or when to be drawn out. It will be observed the two under fillets keep the false floor at its place at the back, and a button keeps it up when closed. This arrangement of the floor makes it handy for those who keep their bees in houses, and is much easier kept free from débris than when feet are added, as there is no obstruction to prevent its easy removal or replacing, while its cheapness and the simplicity of its make recommend it.

### AMERICAN IDEAS.

Ever since a correspondent advised me to read the American journals I have endeavoured to do so, and get any benefit likely to be derived from those go-ahead people. Owing to my absence so long at the Heather, I am still a long way behind with correspondence and reading, and have only received the August number of "Gleanings," which contains the only bit of information worth knowing. A considerable time was spent and paper wasted both in this country and America discussing the theory that compression was necessary to produce workers from the egg that is naturally a drone egg, or rather what would without fertilisation produce a drone. Then others maintained that it was the bees that had the power of changing the sex. The Editor of "Gleanings" appears to have the weakness of leaning to that side, but let his own words speak for him. He says, "For instance, if you take a frame of worker comb containing eggs in worker-cells and nothing else, and put it in a queenless hive, more or less drones will be found

emerging from worker-cells, whereas had the frame been left in the hive where the eggs were laid there would have been no drones at all." I must take in the whole sentence as my text, but must lay considerable stress upon the last clause, "there would have been no drones at all." Your bee-keeping readers, as well as naturalists, will observe that there is something extraordinary, if not prophetic, in the statement, the text tells us so, and the context confirms it. Bees sometimes make what we consider a mistake in rearing a royal cell round a drone larva, but I have never witnessed the same lavish expenditure of wax upon the drone-royal cell as when it contained a queen. I have often found workers in queen cells, but they were never matured, too long perhaps in being selected for transformation, and I have repeatedly had perfect queens from ordinary looking worker cells, and I am informed that the Punic bees raise queens sometimes in the same apparent manner as are drones, and as many as 500 at one time.

But how does the editor of "Gleanings" know that if the frame of comb had been allowed to remain in its original hive "there would have been no drones at all." It will, perhaps, be as well to leave the editor of "Gleanings" alone in his profound knowledge of the past, present, and future, and tell your readers how the drones came there. For aught any of us know the eggs of what matured into drones might have been in these combs from the first, as queens can, and do sometimes when fertile, lay drone eggs in worker cells, and sometimes fertile workers are present and at work at the same time as the queen regnant. Moreover, it sometimes happens that queenless hives are entirely destitute of an egg-laying bee, and sometimes they have them, so there is no mystery whatever in finding drones coming forward in a queenless hive, nor is it a miracle to find sometimes an effete queen in a hive supposed to be queenless, but still able to lay a few eggs of both worker and drone, and which may account for the so-called removing eggs from one cell to another, or even from one hive to another, and it is not the first time I have observed a defective queen take refuge in another hive. I trust if the editor of "Gleanings" does not profit from the above, and cease plunging into the mysterious, he will see it advisable to alter his opinion as to how drones are produced, and give to the public reliable information, so that all may profit thereby.—A LANARKSHIRE BEE-KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Stocks for Fruit Trees (Plum).**—We cannot answer your questions without name and address, which are not, however, wanted for publication. If you send what is requisite please repeat your questions.

**Celery Fungus (R. L.).**—You would see a reply on this subject to a correspondent on page 393 last week, after sending your letter. To that reply we have nothing to add, except that the fungus appears to be unusually prevalent this year.

**Pruning Plum Trees (W. E.).**—If your sketch fairly represents the trees, and especially in the wide space between the main branches, we should not shorten the side shoots at all, except the tips of any that

are soft and unripe through pushing late growth after the summer pruning, and to prevent overcrowding. The more closely you prune the more freely will the growth be made, and the less the number of blossom buds unless the roots are pruned in the same proportion. If the trees were ours we should check the root action now, and limit the pruning to thinning and the removal of soft growths as suggested.

**Roses for Arches (G. B.).**—The free-growing Ayrshire Roses, such as Alice Grey, Bennett's Seedling, and Splendens, are suitable for covering arches and arbours, as also are the Boursault Roses Amadis, elegans, and inermis. You may add also the evergreen Rose Félicité perpétué. These are all free, indeed more or less rampant growers, and are very effective when covered with their great clusters of flowers. If you desire Roses less floriferous, but to produce better blooms over a longer period, plant such varieties as Gloire de Dijon, Belle Lyonnaise, Reine Marie Henriette, Cheshunt Hybrid, with the climbing forms of Victor Verdier, Jules Margottin, Bessie Johnson, and Charles Lefebvre, also the vigorous-growing Madame Clemence Joigneaux. You do not say how many you require, but probably we have named sufficient.

**Straightening Fruit Trees Grown Aslant (W. G. P.).**—You do not state the cause of the evil, but it usually arises from three causes—viz., sinking of the ground after planting with neglect to ensure secure staking, through force of wind from a particular point, or from neighbouring objects shading them, whereby the trees seek the light. The only remedy in any case is to lift the trees, or at least remove some of the earth from over the roots, so as to facilitate the stems being brought to the perpendicular and properly secured against winds. If the leaning be due to wind or shade it would be best to lift the trees entirely, and turn their heads the other way round; this, however, would only afford temporary relief, as the trees would assuredly take to their former course until the cause of it was removed. If it arise from improper planting it will only be necessary to straighten the trees as advised, and thin their heads on the heavy side, cutting back any straggling growths, so as to form an evenly balanced head.

**Myrtle Unhealthy (W. B. O.).**—If you closely examine the under sides of the leaves you will find near to the midrib a number of scale insects. They are not very conspicuous, but are plainly visible to the trained eye of a gardener. These insects must be destroyed, and the upper surfaces of the leaves must be cleansed of the dirty incrustation that adheres to them. You allude to the Myrtle as a tree. If the "tree" is only 2 or 3 feet high it will not be tedious process to sponge every leaf with warm soapy water, dislodging the scale as the work proceeds with a pointed stick if necessary. This will undoubtedly prove the best remedy; but if your tree is many feet high the work would certainly be tedious. The sprays, however, do not suggest that they have grown on a large tree planted out, but on a tree in a pot, that not only needs thoroughly washing, but also additional support either from fresh soil or more copious supplies of water. It is certainly in a very weak and unsatisfactory state. After sponging the leaves as directed the plant should be well syringed with clear water.

**Gsier Peelings as Manure (Oxford).**—The bark of the Willow is rich in potash and soda, and reduced to vegetable mould is a good manure. The peelings should be thrown into a heap, and to every cartload of them add a bushel of salt and a similar quantity of quicklime. By keeping them damp but not wet, and turning at intervals, outside to inside, the decay of the material would be accelerated. If the peelings get dry damp them with urine, which will increase the manurial value of the heap. If burned, there would at once be available mineral substances of great value to fruit trees, and your soil being low and damp, or containing vegetable matter or humus, it would be a better dressing for fruit trees than vegetable soil. The organic matter, however, is lost in the burning, which it is desirable to retain, particularly when the applications of the *débris* is to be made on light soils or those deficient in humus.

**Gardenia Unhealthy (F. P.).**—If you have sent us a fair sample of the plants they are certainly far from being satisfactory. We should first of all repot them, removing any loose soil from the roots, and place them in clean well-drained pots smaller than those they are now in, using a compost of light turfy loam, fibrous peat, and leaf soil in equal parts, with a free admixture of charcoal broken small and silver sand. We should then plunge the plants if possible in a bottom heat of 85° to 90°, and apply water with great care, giving sufficient to keep the soil healthily moist without saturating it. This, with judicious syringings governed by the state of the weather, and a temperature of 70° as a minimum, would induce fresh root action. This accomplished, we should prune the plants rather severely, removing at least all such growths as you have enclosed, and should then expect healthy shoots and dark green foliage to follow. This effected, the plants could be kept clean and healthy by copious supplies of water, frequent syringings, and a very moist warm atmosphere.

**Protecting Standard Roses (M. T.).**—It would have been far better if the buds had not moved at all. If the winter proves very severe you will have great difficulty in preserving those "just in leaf, and others showing incipient growth." If you have dry fern in readiness and envelope the stems as well as the tops when sharp frosts occur you may save a number of the Roses, but we should do what you propose with those you are "particularly anxious" to keep—namely, pot them at once. Be very careful that the roots are not dried during removal, and pot firmly in a compost of two-thirds loam and the re-

mainder wood ashes or leaf soil. Give a good watering, and afterwards maintain the soil in a healthy moist condition. The Roses after being potted will be better outside than in so long as the weather is mild; and a few degrees of frost will do no harm, especially if fern is packed round the pots. There is danger in over-protection—that is, placing the Roses in too warm a temperature, and keeping them there for three or four months. As you do not say what your conveniences are for wintering them we cannot give you more precise information; but if you have not a suitable place for storing them in pots it would be preferable to dig them up, laying them close together with their roots carefully packed in soil, and then cover the plants with fern or straw in thickness proportionate to the severity of the weather. We have preserved many Roses by this practice, but the work needs to be done well, and judgment exercised in applying and removing the covering.

**Mina lobata (E. B.).**—The particulars you require were given some time ago, and were as follows:—"Occasionally instances are brought under notice of old plants that have been lost sight of in gardens for years again coming into favour, and one of the most recent examples of such a recovery is afforded by *Mina lobata*. This plant was introduced from Mexico in 1841, when seeds were sent to the Earl of Burlington at Holker by G. Frederick Dickson, Esq. From Holker plants were sent to the London Horticultural Society, but being exposed in severe weather they were lost, and only two seeds saved. It does not appear to have extended beyond the gardens of a few who were interested in curious or rare plants, and it either gradually died out or became so extremely scarce as to be practically unknown to the majority of cultivators. A short time since Messrs. Haag & Schmidt re-introduced it to Europe, and now it is in the hands of most of the British seedsmen and nurserymen. The genus *Mina* was named in honour of a Mexican celebrity, Don Francisco Xavier Mina, and this species is said to have been generally grown in Mexico for a number of years for ornamental purposes. It is nearly related to the *Ipomæas*, which it particularly resembles in the foliage, but the flowers are totally dissimilar both in form and arrangement. They are in one-sided racemes, which attain the length of 16 inches, the flowers gradually expanding from the base to the tip, which continues to elongate throughout the season. The corollas are ovoid in the bud, when they are of a bright red colour, the expanded flower being tubular and varying from red through yellow shades to white. The older flowers at the base of the raceme are of the lighter tints, and there is thus gradation in each from white or yellow to the deep red terminal buds, giving a strangely varied appearance to the plants. *Mina lobata* is a rapidly growing plant and covers a high wall in a month or two. It grows well at Raby Castle, Darlington, and has a most remarkable effect. Writing in reference to the system of culture adopted, Mr. R. Westcott observes as follows:—"The seed is sown in February in a stove temperature, and the plants kept in the same house until established in 3-inch pots, using light fibry soil, gradually reducing them to greenhouse and cold pit temperature. By that time they should be in 6-inch pots, which will be sufficiently large until they are planted out about the second week in June, which should be on a well-raised border against a south wall. The soil should wholly consist of light fibry loam mixed with a liberal portion of half-decomposed cow manure. The plant, which is of coiling habit, should be trained on strong cords, and the shoots will soon reach the top of any ordinary garden wall. The plants here reached the top of a 13 feet wall this season, and then ran horizontally, flowering at every joint and maturing a quantity of seed. The flowers have a novel and most pleasing effect in bouquets."

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. A.*).—1, Fearn's Pippin; 2, Warner's King; 3, Cox's Orange Pippin; 4, Cellini; 5, Court Pendu Plat. (*W. S.*).—1, Marie Louise d'Uccle; 2, Brown Beurré; 3, Sweet Laden is no doubt correct; it is an old Sussex local cider fruit. It is not the same as Lady Apple. (*I. C. M.*).—1, Not known; 2, Winter Calville; 3, Five-crowned Pippin; 4, Emperor Alexander; 5, too much decayed; 6, Beurré Amande. (*A. M. M.*).—Spanish Bon Chrétien, a stewing Pear. (*W. Allingham*).—1, Pine Apple Russet; 2, Aromatic Russet; 3, Braddock's Nonpareil. (*George Knight*).—1, Beurré Clairgeau; 2, Comte de Lamy; 3, Susette de Bavay; 4, Easter Beurré; 5, Seckle; 6, not known. (*G. S. Stott*).—We regret we cannot name the Apple sent. Probably a local northern variety. (*Jahn Turner*).—Royal Russet. (*J. H. W.*).—1, Knight's Monarch; 2, Hacon's Incomparable; 3, Belle après Noël; 4, Comte de Lamy; 5, Nouveau Poiteau; 7, Easter Beurré. (*F. Jellico*).—Both are Cox's Orange Pippin. (*T. Arnold*).—1, Mère de Ménage; 3, Golden Harvey. Pear No. 1, Nouveau Poiteau; 2, Maréchal de Cour. Sorry we cannot name the others.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*M. C. B.*).—The Oak is *Quercus Cerris*, the Thorn *Crategus tanacetifolia*. (*E. B.*).—1, *Datura suaveolens*. 2, *Abutilon vexillarium*.

3, *Franciscea calycina*. 4, *Davallia dissecta elegans*. 5, *Mina lobata* (see reply above). 6, *Ceanothus dentatus*.

MANURES.

At no better season of the year could special attention be drawn to this subject, as it must enter fully into plans for another year's cropping if we would have a full measure of success in our work. The paper on "The Right Use and Valuation of Artificial Manures," which Mr. Thomas Brown, chemist to the West Norfolk Farmers' Manure Company, read before the Norfolk Chamber of Agriculture on the 11th October, was therefore especially well timed, and we desire to give readers of the Journal the benefit of its teaching.

The chief point of Mr. Brown's paper was the importance of legislative intervention for the prevention of fraud. His estimation that the annual direct loss to agriculture through the sale of inferior and worthless manures amounts to an annual sum repre-

sented by seven figures, or in other words, fully £1,000,000 yearly, is evidently based upon careful calculations, and he is quite right in thinking that a far larger sum is lost indirectly in the resulting deficient crops. Well says he that our legislature has interested itself with the general question of adulteration with the result that last year, out of 70,000 tests made of articles of food by the public analyst, 5000 cases of fraud were detected, and he suggests that agriculture should also be defended by similar machinery. He also points out that "It is generally admitted that it is for the public good that the soil of England should produce a maximum of food. It is also admitted that this end cannot be attained without a large consumption of so-called artificial manures, imitations of which are more easily produced and less easily detected than are those of food. Therefore it must be a public necessity that a stop be put to the sale of useless imitations or fraudulent adulterations of those admittedly necessary substances." This valuable paper absolutely bristles with facts and figures in support of his arguments, and the only possible conclusion is that he is right, and that we should no longer lag behind other countries, for in Germany, France, the United States of America, Canada, &c., the Governments have established public stations where farmers can have samples of manures tested free of cost, and adulteration, if present, detected and punished.

The importance to the farmer of such protection is obvious, but it is emphasised by the statements that in our crops there is annually removed from our soils 170,000 tons of lime phosphat, and 100,000 tons in animals, milk, cheese, &c., sold. The total is equal to the phosphate existing in about 1,000,000 tons of ordinary superphosphate of lime. The amount of nitrogen is still greater, that of potash more than half as much. This drain of fertilisers is met by us by using 1,000,000 tons annually of artificial manures, and by the use of 700,000 tons of food cakes and grain imported from foreign countries; there is thus returned 25,000 tons of bone phosphate, 30,000 tons of nitrogen, and 10,000 tons of potash.

Under the distinctive heading, "What to Use, When to Use, How Much to Use," much sound practical advice is given. In common with other practical chemists, Mr. Brown says that neither magnesia or iron salts are necessary, and that the only fertilisers the farmer requires are nitrogen and bone phosphate generally, and occasionally potash, lime, and soda. He answers the question, In what form shall these bodies be applied? "From the cheapest sources if in an available form," and the articles yielding a more or less available supply are thus tabulated:—

ONE TON OF	CONTAINS POTASH	COSTING
Muriate potash ...	1128 lbs. ...	2d. per lb.
Sulphate potash ...	1050 lbs. ...	2½d. per lb.
Kainit potash ...	300 lbs. ...	2d. per lb.
Nitrate potash ...	1040 lbs. ...	£16 10s. per ton.

ONE TON OF	CONTAINS NITROGEN	COSTING
Nitrate soda ...	350 lbs. ...	5¾d. per lb.
Nitrate potash ...	300 lbs. ...	13d. per lb.
Sulphate ammonia ...	470 lbs. ...	5¾d. per lb.
Dried blood... ..	270 lbs. ...	7d. per lb.
Peruvian guano ...	170 lbs. ...	10d. per lb.
Fish guano ... ..	180 lbs. ...	6¾d. per lb.
Greaves ... ..	180 lbs. ...	6¾d. per lb.
Rape cake ... ..	100 lbs. ...	10d. per lb.
Dissolved bone ...	65 lbs. ...	6¾d. per lb.
Wool waste ... ..	110 lbs. ...	5d. per lb.

ONE TON OF	CONTAINS AVAILABLE PHOSPHATE	COST PER 100 LBS.
Superphosphate ...	600 lbs. ...	11s.
Dissolved bone ...	800 lbs. ...	10s.
Peruvian guano ...	675 lbs. ...	11s.
Rape cake ... ..	80 lbs. ...	11s.

ONE TON OF	CONTAINS INSOLUBLE PHOSPHATE	COST PER 100 LBS.
Fish guano ... ..	450 lbs. ...	7s.
Thomas's slag ...	800 lbs. ...	6s.
Bone flour ... ..	1300 lbs. ...	9s. 9d.

We give this table in full as being most valuable for comparison, and as a safe basis for the selection of chemical manures for home mixing. But we must caution our readers against the assumption that they can obtain small quantities of any of the manures at the prices quoted, as they are only given as showing the relative value of the different available fertilisers and the best form in which to obtain them. For example, in nitrate of potash we have a most powerful fertiliser, but its high price is practically prohibitive, and we naturally turn to muriate of potash as the cheapest and best source of potash for farmers. So also in nitrogen, we see at a glance that nitrate of soda and sulphate of ammonia are best, and we may add that for general use the nitrate is generally preferable.

WORK ON THE HOME FARM.

Cleaning and stirring of arable land has gone on right through October, and we may well record the fact of having had nine consecutive weeks of fine weather for autumn cultivation this year. Plough, harrow, and cultivator have done the work to good purpose indeed, leaving the land cleaner than it has been for many years. Steam tackle has been in full work, most sets being engaged by eager farmers, in some instances for weeks before they could be had. All land not under a crop now has been thrown up into high ridges with the double plough, to be so left till spring, when it will harrow down as fine as a bed of ashes, and if well handled may be sown long before land left on the flat can be dry enough for working.

Water furrows made by the plough have been finished with spades at the lower end, so as to ensure the free escape of surface water running down into the ditches. The "eyes" or outfalls of all land drains have been examined and all obstructions removed, and any necessary ditch scouring is now being done. These are small matters of detail worthy of careful attention, for the stoppage of a drain often spoils a large patch of corn. The draining of wet land is now being done, the landlord supplying the pipes, and the tenants doing the work. Depth of drains and distance apart must depend entirely upon the nature of the soil. We have drained at all depths from 2 to 4 feet, and can only give general advice in a matter, where actual inspection is so necessary before a safe decision can be arrived at. For bog land pipe drains are useless, the only safe plan being to make trenches wide enough to admit an ordinary fagot, and if possible to use fagots of alder wood. Our advice in this matter of bog draining was asked recently by a gentleman in Ireland, who had already made his arrangements for pipe draining a bog. Evidence of the presence of oxide of iron was afforded by a yellow ochreous deposit upon the margin of the stream running through the bog, and our assurance that a similar deposit would soon choke the pipes if they were used, induced him to abandon them for fagot drains, and so render success a certainty. Whatever may be the manner of making the drains, nothing short of good sound true work will answer, and very careful supervision is indispensable.

GREAT MALTING BARLEY COMPETITION.—At the Brewers' Exhibition, London, no less than fifty-six English and twenty-two foreign competitors exhibited samples of malting Barley. The first prize and champion cup open to the world were awarded to Webbs' Kinver Chevalier, shown by Mr. J. Akers of Goring, Berks. This is the fourth annual competition that has been held, and on each occasion Messrs. Webbs' Barley has won similar honours.

REMARKS.

26th.—A good deal of bright sunshine, with overcast intervals and showers of sleety rain at 11 A.M., 2.30. P.M. and 5.30 P.M.; cold throughout.  
27th.—Cloudless and cold.  
28th.—Sharp frost early; slight fog till 10 A.M., then bright sunshine, and slightly foggy again in the evening.  
29th.—Showers at 4 A.M.; mild and overcast till 10.30 A.M.; then fine with occasional sun, and slight showers in evening.  
30th.—Mild and dull in morning; bright sunshine in afternoon; misty evening.  
31st.—Dull and rainy morning; overcast afternoon; fine evening; very mild throughout.  
1st.—Cloudless early; bright and fine throughout.  
A week of variable temperature, specially noticeable for the very sharp frost on the 2th of October.—G. J. SIMONS.

SINCE the Chrysanthemum Centenary Festival, which was opened at Westminster on Tuesday last, must be regarded as the crowning event in the history of the National Society, the time is an appropriate one for a consideration of the origin, progress, and work of the organisation which for so many years has been devoted to the encouragement of Chrysanthemums and their cultivators. No special society has attained such a powerful and important position in the horticultural world as this, and there must be some substantial reason for so remarkable an advance. Its origin was lowly, and for many years its work was confined to a very limited area, yet within less than ten years it has sprung into the first rank of horticultural societies both as regards the number of members, the scope of its influence, and in general usefulness. First it is evident in endeavouring to explain this phenomenal progress, it must be assumed that a central authoritative Society was urgently required. Secondly, the system of management adopted must have been exactly what the circumstances demanded, and the workers selected for assistance in the various projects must have combined earnestly in the performance of their honorary duties to have effected such results.

The contrast of the present condition of the Society with that of its earlier years is indeed astonishing, and one old cultivator has given an excellent review of matters in the following words:—"What a host of pleasant reminiscences is started by a glance at the names of some of our Chrysanthemum fathers! Perhaps the very first that are entitled to recognition are the founders of the original Stoke Newington Chrysanthemum Society, Messrs. Holmes, Tant, and James. How little they ever dreamt that their mutual resolve, while returning from the Vauxhall Dahlia Show of 1845, on the top of a 'bus, to hold a friendly competition at the old Rochester Castle in the following November (the loser to pay for a steak supper), would have resulted in such an organisation as the National Society of to-day. Truly, it was the 'day of small things,' but was none the less the foundation of one of the most successful and useful florists' societies that we have yet seen. It was not long ere the 'mum' fever spread like wildfire throughout the north of London; and amongst those who had the opportunity of visiting these early shows, who will forget the truly gigantic plants staged by Holmes; the smaller, but none the less creditable, 'Poms' of James, or the blooms of Tant? They were indeed the marvels of the hour. Very soon other competitors appeared on the scene, and made their mark. Amongst them, none will forget 'Old George Taylor,' who wrote, it is said, the first treatise on the culture of the Chrysanthemum; Tom Merry, too, with his box of cut blooms, was for many years a prominent competitor; E. Hutton, of the Bank of England, represented the amateurs of the day; Arthur Wortley, later on Secretary of the Society, was often well to the fore with his flowers, mostly cut from plants grown in the open border, and trained against the wall, with no other protection than a weather board above them; Scruby and Dan Monk each scored their victories—aye, and well-earned they were; while our old esteemed Edward Sanderson was then often the recipient of the highest honours, as witness the store of cups and trophies he cherishes at Willesden. Proud he may well be of his share in developing the love of the 'Autumn Queen.' Charles Wilkinson and Williams, the then beadle of West Hackney Church, each had

their day of fame, and were recognised amongst the growers of the time. A few years later, and who will not remember the specimen Pompons of David Hutt's culture? Have they ever been equalled? Certainly never surpassed."

To briefly review the history of the Society it may be stated that the year following the conversation above recorded was practically the commencement, the first public show being held in 1847 at the inn named, and from then until 1864, shows were held annually either at the Rochester Castle or the Manor Rooms. During this time the show improved considerably both in the number and quality of the exhibits, and meetings for discussion were also held. At one of these, on March 28th, 1850, Mr. W. Holmes (father of the late Hon. Secretary), read the first essay on the culture of the Chrysanthemum, and in the following year, on February 27th, Mr. George Taylor contributed an essay on the same subject, which was afterwards amplified and published as a book that was for years the recognised authority on all points relating to specimen plants. In the same year—namely, 1851, Mr. John Edwards became President, and Mr. E. Sanderson was appointed Secretary. In 1873, after holding several shows with varying fortunes in the Defoe Road, Stoke Newington, and elsewhere, the Society was converted into the Borough of Hackney Chrysanthemum Society, and the exhibitions were continued in the Defoe Road until 1877, when they were transferred to the Royal Aquarium, Westminster, and an important era in the life of the Society was commenced. This proceeding did not, however, meet with the approval of all the members, and some retired, forming a new Society at Stoke Newington, which has not had a very successful career. The late Mr. William Holmes became the Hon. Secretary in the year of migration to Westminster, and a rapid improvement was soon seen, for the number of members increased from fifty-two in 1877 to 200 in 1883. A rapid advance under a vigorous and progressive policy justified the adoption of the title "National Chrysanthemum Society" in the year 1884.

Progress still continued in a remarkable manner, and after two or three years it became evident the Society must still further extend its sphere of operations. One of the projects taken into consideration early in 1888 was arranging for holding a show at some provincial town in connection with the local Society. Letters were received from the secretaries of several affiliated societies, and ultimately it was resolved to hold a Show at Sheffield in November, 1888. Another important matter was also taken in hand in that year—namely, the preparation of an authoritative catalogue of Chrysanthemums that would be likely to prove of real service to cultivators. A Committee, comprising thirty of the leading experts in Great Britain, was appointed, with a Revision Committee of three. The work was issued early in the autumn, and was well received. A permanent Revision Committee, comprising Messrs. Lewis Castle, G. Gordon, and Payne, was then appointed, and each member was presented with a silver medal for the services rendered in the preparation of the work. A supplement was issued in 1889, and a revised edition in the present year, including the varieties brought into notice since the autumn of 1888.

At the close of the eventful year named Mr. Edward Sanderson, who had been connected with the Society for forty years, during thirty of which he held the office of President, resigned his post greatly to the regret of all members. A sub-committee, comprising Messrs. Jukes, Wynne and Castle, was appointed to revise the rules of the Society and suggest names for President and Vice-Presidents, with the result that some important alterations were effected. The rules were rendered more uniform and systematic, and Mr. Castle having obtained the consent of Lord Brooke to act as President, he was unanimously elected at the annual meeting in January, 1889, to that office, with the Earl of Lytton, Lord Ebury, Sir Guyer Hunter, Sir Edwin Saunders, Dr. Robert Hogg, J. Wormald and E. Sanderson as Vice-Presidents,

Mr. R. Ballantine as Chairman, and Mr. E. C. Jukes as Vice-Chairman of committees.

The programme for 1889 included three metropolitan Shows and a provincial Show at Hull in conjunction with the Hull and East Riding Society. This proved a great success; one of the finest Exhibitions of Chrysanthemums ever seen in the north was provided, and there was a large attendance of visitors, resulting in a satisfactory financial balance. In the present year the Committee decided to concentrate their efforts upon the Centenary Festival, the result of which is recorded in another page. The programme for Tuesday was as follows:—The opening ceremonial commenced at one o'clock, Lady Brooke and several friends being met at the entrance by the Reception Committee and the invited guests, and conducted round the Exhibition. An address was presented to Lady Brooke, and the Exhibition formally declared open to the public. At 6 P.M. a Conference meeting was held in the iron room under the presidency of Sir Edwin Saunders, F.R.C.S., and papers were read by Mr. Shirley Hibberd, F.R.H.S., "On the Origin of the Florist's Chrysanthemum;" by Mrs. Marian Thrower, representative of the Northern Tasmanian Horticultural Society, "On Chrysanthemums in Tasmania;" and by Mr. G. T. Haité, F.L.S., "The Chrysanthemum in Art."

Fortunately we can find space for Mrs. Thrower's paper this week, the others are reluctantly reserved for the present.

To-day, Thursday, November 13th, a Conference will be held in the iron room at 2.30 P.M., Sir Guyer Hunter, M.P., Vice-President, in the chair, when papers will be read by Mr. Briscoe-Ironside "On Experiments in Chrysanthemum Culture," and by Mr. C. Gibson "On Chrysanthemums for Exhibition." At 6 P.M. prompt a grand banquet will take place in St. Stephen's Hall, Lord Brooke, M.P., President, in the chair, supported by representatives from foreign and colonial affiliated societies and others. Private entrance from Broad Sanctuary. On Friday, November 14th, St. Stephen's Hall will be arranged as a lounge, so as to afford opportunity for conversation. At 4 P.M. an informal meeting will be held with the object of affording opportunity for suggestions as to the future operations of the Society.

Elsewhere in the present issue we give seven portraits of the ladies and gentlemen who have been specially concerned with the Centenary proceedings—namely, Lady Brooke, Lord Brooke, President; Sir W. Guyer Hunter, M.P., K.C.M.G., and Sir Edwin Saunders, F.R.C.S., Vice-Presidents; with Mr. R. Ballantine, Chairman; and Mr. E. C. Jukes, Vice-Chairman, as representing the officers of the Society. Besides these we are enabled to give a portrait of Mrs. Marian Thrower, who attended the Show and Conference as a representative of the Tasmanian Society, which is affiliated to the National Society.

## GROWING AND SELLING FRUIT.

(Concluded from page 351.)

### GATHERING, MARKETING, AND STORING WALL FRUITS.

APRICOTS should be gathered as soon as they are well coloured and before they get soft, and are best disposed of near home if possible, as the French fruit, although not nearly so good, makes prices low in the markets. There is generally a good demand at the houses of the neighbouring gentry for this fruit in country places, at from 2s. to 4s. per dozen, according to size and scarcity of the crop. In some seasons cottagers have been known to make enough money to pay the rent from one Apricot tree on their house. If this fruit is sent to market, it must be carefully packed in small shallow boxes, just deep enough to hold one layer of fruit, with plenty of pink or blue tissue paper placed between them, so as to leave the upper part of the fruit bare when the box is unpacked without disturbing the fruit. Some more paper should be placed over the top and the lid lightly tacked on. Apricots will not keep after the fruit is soft more than four or five days.

PEACHES.—These must be gathered carefully as soon as they begin to feel soft at the base, and then sent to market as quickly as possible. They require very great care in handling, or they show every finger mark in a short time, and only realise very low prices; but if carefully gathered and packed, good Peaches will bring from 4s. to 10s., or even 12s. per dozen if extra fine and the crop is scarce.

Moderate crops only should be grown, one fruit to each square foot being plenty; that is, each fruit when ripe should be almost a foot away from any others, as near as can be judged. At this rate a tree 20 feet wide and 12 feet high would give twenty dozen, worth from £4 to £8. To have large fruits that will realise these prices they should be thinned when as large as peas to 6 inches apart, and again when as large as small walnuts to 13 inches apart. For marketing the fruit the salesmen generally supply boxes about 3 inches deep that will hold about two dozen in one layer. Each fruit should have a strip of white tissue paper wrapped round the sides, so as to cover the lower half of the fruit. A twist at the bottom after wrapping it round will help to keep it on. Strips of cotton wool about 1 $\frac{3}{4}$  inch wide are then cut across the piece and opened out from each end, so as to form a thin strip of wadding about 2 $\frac{1}{2}$  feet long and 1 $\frac{3}{4}$  inch wide. This is carefully rolled round the fruit as many times as it will go over the tissue paper. The boxes should be lined with cotton wool inside, and the Peaches placed in them close together as they are wrapped. When the box will hold no more, small pieces of wadding may be gently pushed in the corners of the boxes and wherever there is room, so as to make all secure and prevent any movement of the fruit. If they are packed in the way I have described, they should now be firmly in the boxes with nothing around the upper half of the fruit, so that everyone can see their size and colour when offered for sale. A sheet of tissue paper must next be laid over them, and then one or two pieces of wadding, the same size as the box, so as to fill all up and prevent any movement when travelling. Packing Peaches requires great care, but pays for all the attention bestowed upon it. I have for several years past packed from 4000 to 6000 annually in the above manner, and have no complaints from anyone about damage, although some of it travels 400 to 500 miles. There is no system equal to it, although moss, dried grass, and other things are sometimes recommended. The table on which the packing is done should always have a strip of wool on it to lay the fruit on. Peaches will keep several days if laid on some dry and soft material in a cool and dry room.

MORELLO CHERRIES.—These must be gathered when perfectly dry, and when they have assumed a dark red colour; they are best packed in 1 lb. punnets, as recommended for Strawberries, and are worth from 6s. to 12s. per dozen lbs., according to size and crop. They should be cut off the trees with scissors to avoid stripping the bark off the tree.

PEARS.—The largest fruits must be packed closely together in boxes or shallow baskets as soon as they commence changing their colour. They should not be put more than two layers deep. The smaller fruit can be packed in half sieves as recommended for Apples. They must always be got to the market before they get soft, or will not fetch good prices. Those packed in boxes should have some paper shavings put at bottom and top and all round them to prevent bruising of the skin.

PLUMS.—Directions for packing these have been given previously.

### ENEMIES OF WALL FRUITS.

PEACHES AND PLUMS.—Green fly or aphis, which comes underneath the young leaves and at the points of the shoots, and sucks out the juices of the plant, is the worst pest, and must have early attention. London tobacco juice, to be obtained at any chemists, is the best remedy. Half a pint should be mixed in 3 gallons of water, and the trees syringed with the mixture after the sun is off them. If this is done before the flowers open, and again soon after the fruit becomes visible, there will not be much fly afterwards. Red spider is troublesome sometimes in hot dry seasons, and as a preventive it is well on the evening of the first warm day to syringe the trees with water containing 1 oz. of Gishurst compound to each gallon, and to repeat this syringing before the fruit gets the size of walnuts. The insect is not a spider, and is very seldom red, but is very destructive when it is once established. It is smaller than the cheese mite, of a similar colour, and increases very fast if dry and warm, eventually causing all the leaves to drop off if left undisturbed. Earwigs will eat small holes in Peaches and Apricots when nearly ripe, and the fruit soon decays after. They should be trapped by placing pieces of dry Broad Bean or Onion stalks about 1 foot long in the trees. They will get in these during the night, and should be blown out into a can of water in the morning. A tablespoonful of petroleum allowed to swim on the top of the water will kill them as soon as they get in it. Woodlice are often troublesome by eating the fruit, and should be caught by turning some small flower pots upside down near their haunts, with a little dry hay or moss inside, and examining them every morning as for earwigs. Blister sometimes attacks the leaves of Peaches, causing them to grow extra thick, and of a pale colour. This is caused by cold winds rupturing the sap vessels when the leaves are young and tender. The worst

leaves should be picked off, as they encourage insects to take up their residence on them.

**CHERRIES.**—Black fly will sometimes attack Cherry trees very badly. The best remedy is to syringe with the tobacco water solution as recommended for green fly as soon as the first flies are seen.

**PEARS.**—Birds will often eat small holes near the stalk of Pears, causing them to decay quickly; tits are the worst. The best plan is to net the fruit on walls if they are attacked.

#### PROTECTION OF THE FLOWERS IN SPRING.

As both the Peach and Apricot come from a much warmer country than ours they flower very early in the spring, and are very liable to be damaged by the late frosts. It is best to hang old fish netting of a double thickness loosely over the trees, and let it remain until the leaves are a fair size, and all danger of frost is over. Branches of Spruce, Fir, and Yew stuck in the trees at intervals are the best substitute if net cannot be obtained. These protecting materials should not be put on until the first flowers open in spring, and must not be left on too long, or the young shoots will grow through them and they will be very difficult to remove.

#### CONCLUSION.

Fruit growing has been recommended to farmers as a cure for the agricultural depression. The speakers and writers probably thought that anybody could grow fruit, and they were right to a certain extent; but when it comes to a question of profit, those will have the most who pay the most attention to it and have the best knowledge of the business—in other words, success in this matter depends on close attention to all details, and strict and sound business principles, carried out with energy and perseverance. Fruit growing is not an Eldorado, where anyone can pick up gold; it has to be diligently sought for. I have mentioned this because a person unacquainted with the subject might read what prices it is possible to get, and think they were to be had every year. It is not so; a full crop of fruit is very seldom brought to maturity, probably not more than once in ten years. The greatest skill and attention will not compensate for dull wet seasons, which cause badly ripened wood and a short crop the following year; or for late spring frosts, which kill the tender blossoms when they open. But for all this money can be made from fruit growing, and it will probably develop much more in the future, as the population increases and greater facilities are given for obtaining land.—**W. H. DIVERS.**

### SMALL FERNS FOR DINNER TABLE DECORATION.

**FASHION** in dinner table decoration, like most other things, is continually changing. When I began my gardening career Ferns and bright foliated plants were liberally used, while cut flowers were only employed in small quantities, and were generally reserved for filling epergnes of massive design which invariably occupied the centre of a table, and in too many instances greatly obstructed the view from one side to the other at that particular point. A few years later cut flowers were almost entirely used, with the exception of a few small Palms or plants with graceful foliage which were dotted about at irregular intervals—and to my mind these designs when well carried out resulted in some of the most perfect examples of dinner table embellishment that construction and artistic skill could devise. There was, however, one great drawback to these beautiful but fleeting displays—viz., the numbers of choice flowers which were required for the purpose during the autumn and winter months, and the supply to be drawn from the occupants of glass structures was so great that even in large establishments the resources were taxed to their utmost. The vases in the boudoir and the drawing room, where choice flowers might be shown off to advantage for days, had to be filled with more commonplace flowers in order to keep the dinner table in floral splendour for a few hours. In many gardens where the extent of glass is ridiculously small when compared with the quantities of cut flowers required, able and energetic cultivators know only too well how their efforts to grow both plants and fruits to a high state of perfection are crippled by the constant demand for cut flowers, and which often necessitates the growing of a great variety of plants in one house, a practice which is seldom productive of good results. Happily for those placed in such unfavourable circumstances there has been a growing tendency during the last few years to employ Ferns and other graceful foliated plants more extensively for dinner table embellishment than heretofore, consequently less quantities of cut flowers are needed for that purpose, and are therefore available for the adornment of other rooms, where their scent and beauty are appreciated for a longer period.

Although to a great extent we have returned to plants used for dinner table ten or twenty years ago, the manner of arranging them, and the receptacles for holding them, are both a contrast and an advance upon the somewhat massive style which was prevalent then. The plants used now are, as a rule, smaller than formerly, and the receptacles provided for holding them have a great range of variety both in size and design. China, glass, silver, and gold are fashioned into stands and vases, or ornaments exceedingly pretty, and of almost every conceivable shape, but in the majority of cases the aperture intended for the reception of plants is small, in many instances only large enough to hold Ferns or plants that have been grown in thumb pots, while in other cases there is room for the reception of pots varying in size up to 6-inch. For filling ornaments of the above description Ferns of various kinds are especially adapted, and in order to provide a continual supply for that purpose, a regular system of raising young plants must be followed. When once the right method is adopted, it is surprising how easy it becomes, although it certainly requires a good deal of attention. We are constantly on the look out for young seedling Ferns which spring up plentifully upon the walls of plant houses and among pot plants, and when removing old fronds containing spores we shake them over the frame which covers the central bed in the stove, to distribute the spores, and doubtless this accounts for the young seedlings that are constantly appearing. These we secure as soon as they are large enough to handle, and dibble them into pans filled with light soil, with a liberal addition of sand and fine charcoal. The pans are then placed under hand-lights kept in a greenhouse during the summer, and in Cucurber houses or stoves in the winter and spring. With proper attention to watering and damping the foliage with the syringe these seedlings soon grow into useful little Ferns. When well rooted the strongest of them are transferred to 3-inch pots and the weaker to thumb pots. Numbers of well grown Ferns in these sized pots we find extremely useful for dinner-table ornaments of various descriptions, but they should be carpeted with Selaginellas, which look much better than using moss for covering the soil. Small pieces of Selaginella Kraussiana and aurea should be dabbled into the soil as soon as the plants are placed in the pots in which they are wanted for use. Then by the time the Ferns have grown into a condition suitable for use, the Selaginella will have formed into a carpet at the base. When the latter is inserted in the soil the pots ought to be placed under a handlight again, and kept there till well established, when they may be given more light and air to harden the fronds. In some cases tins are made to fit into low gold and silver stands. There ought to be two sets of these tins, so that Ferns in one set may be growing while the others are doing duty on the dinner table.

Any Ferns prove useful, and by constantly pricking off seedlings a great variety is obtained, and when they become too shabby for the table the old fronds should be removed, the plants repotted and grown for supplying cut fronds, or for ordinary decorative purposes. By these simple means a full stock of Ferns in great variety is easily kept up.—**H. DUNKIN.**

### PANCRATIUMS.
