*Handy Book of Fruit Culture Under Glass.* By DAVID THOMSON. Second Edition. William Blackwood & Sons, Edinburgh and London.

MR. D. THOMSON'S excellent manual on fruit culture is so well known and so generally appreciated by practical gardeners, that lengthy reference to it is quite unnecessary. The fact that a second edition has been called for is a sufficient indication of its popularity. The various chapters upon the Pine Apple, Vine, Peach, Nectarine, Fig, Melon, Strawberry, and Cucumber have been revised and some minor additions have been made, but in general there have been few alterations, for few were needed. In addition to the carefully written and useful calendar of monthly operations requisite in fruit houses, the chapter upon heating by hot water which appeared in the first edition is repeated. This is of such a thoroughly useful character, and we have had so many inquiries on the subject lately, that we give the greater portion of it in the author's words.

#### OBSERVATIONS ON HEATING BY HOT WATER.

"Notwithstanding all the elaborate essays that have from time to time appeared in the horticultural press on heating hothouses with hot water, I have the best reasons for believing that many whom the matter intimately concerns have still but very vague and erroneous ideas regarding the principles upon which the proper adjustment of hot-water boilers and pipes depend.

"It is my belief that, if those who have to do with fixing pipes and boilers were to make themselves acquainted with the effects of heat and the power of gravitation on water, it would be next to impossible to commit the blunders, and resort to the unnecessary and expensive precautionary measures, one so often meets with and has to deal with. It is no part of my intention to pretend to deal with that imponderable and powerful agent called by men of science caloric, but which I shall call heat—hypothetically regarded as a subtle fluid, the particles of which are to each other repellent, but attractive to all substances, though in various degrees. But the effect of heat upon water, an element composed of minute and distinct particles that are supposed not to have the quality or power of transmitting heat the one to the other, as in the case of solid bodies, is one of the matters concerning which some knowledge is indispensable in the case of all who have anything to do with heating by means of heated water circulating in pipes.

"The particles of which water consists, it need scarcely be said, have a capacity for heat from different sources, but most manifestly so to us in this case from combustion in the fireplace. Now the expansion of bodies is one of the most universal effects of increasing their heat. This expansion takes place to a greater degree in some bodies than in others. Liquids expand much more by the same increase of heat than solid bodies, and air more than either. With the expansion of the individual particles of water their specific gravity becomes less;

in other words, they become lighter in proportion to their size. Here lies the whole secret of hot-water circulation in pipes and boilers, and the well-known law which should regulate their relative positions. The heated particles of water bound upwards, and, as 'Nature abhors a vacuum,' their place is taken up by a rush of colder and heavier particles. It is of very little practical use to cavil about the question as to whether heat or the greater specific gravity of the cold water which jostles up the warmer and lighter plays the greater part in sending up and away the stream of hot water. Both have a hand in it no doubt. This influence of heat upon water can be very manifestly shown by filling a tumbler with cold water, and mixing with it some coloured particles of matter, and then immersing the tumbler in a vessel filled with hot water. It will at once be seen, by the motion of the particles of coloured matter, that at the sides of the tumbler there is an upward current of heated and in the centre a downward current of colder water. This goes on until the whole is of the same temperature. A glass of warm water immersed in cold has the current reversed in its course—upwards in the centre, and downwards at the sides, where the water is being cooled. Here is the whole secret of the motion and course of heated water in the boiler and pipes of a properly adjusted heating apparatus. And one would suppose that the simple understanding of this would prevent any from making mistakes. Yet, strange to say, some who undertake hothouse-heating are entirely ignorant of these simple and well-established facts.

"Wherever the heat generated by combustion in the furnace acts most directly and powerfully, from that surface bound upwards the particles of water, and to that spot, simultaneously, drop the colder particles of water, to be in their turn sent bounding on their errand of warmth. Anything that attempts to contravene this law of gravitation will be rebelled against by the elements concerned with unmistakable violence and persistency. Clearly, then, the outlet for the water, thus lightened and charged with its freight of heat, should be at the highest part of the boiler; and that by which the cold water is to run in and down, to take its place, should be at the lowest point. Boiler inventors and manufacturers recognise this important part of the matter, and always place the flow pipe at the highest, and the return pipe at the lowest point of boilers.

"Great importance has been attached by many to the necessity, or at least the great desirability, of having the boiler fixed at a very much lower level than the pipes, and also to the necessity of laying all the flow pipes on the incline the whole length of the house to be heated. The importance, too, of having the return pipes on a considerable decline has, in my opinion, been very much over-estimated. It is entirely unnecessary to form deep damp stokeholes in order to sink the boiler to a level much below the main body of the pipes, as is so very frequently met with. And as to having the pipes running at an incline after starting from so high a level, I consider it entirely unnecessary. Indeed, one of the most efficient heating apparatus I ever superintended started from about a foot above the level of the boiler, and ran down a gradual decline into the boiler. Immediately the water enters a hothouse it begins to part with the heat absorbed from the fire, gets colder, increases in specific gravity as it speeds in its way back to the boiler again, and a downhill career is most natural to it as soon as it leaves the highest point of action, where its heat is the greatest. Practically I have never found much difference when the pipes went the whole length of the house on an incline or on a dead level all the way round till it came near to, and dropped into, the return-opening of the boiler. Indeed there is little fear of a good circulation provided the pipes do not at any point descend and rise suddenly, and most especially that at any point they do not dip below the level of the return-opening into the boiler. I have had the working of apparatus where pipes, descending perpendicularly, crossed under a walk and rose again perpendicularly to heat another range of 80 feet of glass; but at none of the points were the pipes lower than 2 feet above the level of the return-opening into the boiler. This undesirable arrangement worked pretty well until hard firing became necessary, then the water was thrown out in plunges at the supply cistern. Such an arrangement should always be avoided.

"There is another error frequently committed in arranging the route of the water. Suppose, for instance, a boiler fixed at one end of a house of, say, 80 or 100 feet long, as part of the work allotted to it. As in the case of span-roofed houses, it may be desirable to have three or four rows of pipes all round the house. Now it is not uncommon to find two rows called the flow-pipes taken all round the house to near the boiler, and there to start back with other two on the same route into the return-opening of the boiler. This is giving the water a long journey, and the return-pipes will be found comparatively cold by the time the water gets to the boiler. Now, if instead of this the whole four pipes be connected with the flow-pipe, and go round the front and end of the house nearly on a level, and start along the back down a decline to the boiler, and there plunge down the drop-pipe into the return-opening of the boiler, it will be found that while any portion of the pipes may not be quite so hot as the beginning of the two flow-pipes in the former case, there will not be any portion of them nearly so cold as the last portion of the return. I do not say that this is the best way to conduct the water; but I have proved from experience that the arrangement indicated is the better of the two named, when the pipes are, from any necessary conditions, laid all round the house in this way.

"The supply of waste water to the boiler and pipes is often placed anywhere that looks most convenient; but the proper place is to attach the supply-cistern to the return-pipe somewhere near the boiler. Fixed to the flow, the water will be frequently plunged out by the upward tendency of the hottest water. It is also very undesirable to leave the supply-cistern to be kept full either by pouring in water from a pot or by turning a tap, which is often neglected. There should always be a cistern supplied by the action of a ball-cock, and then the anxiety connected with the neglect of supply does not exist."

#### KITCHEN GARDEN.

A FIRST sowing of Peas can be made on a south border, and to prevent the ravages of mice damp the seed and coat it with red lead before sowing, or a sprinkling of paraffin is even more effectual. The seeds should be sown more thickly at this season than in the spring, covering them lightly with soil and afterwards with sifted ashes an inch thick. William I. and First and Best are suitable varieties. Broad Beans may also be sown on a sheltered border and treated similarly to the Peas. Early Mazagan is the hardier, but in most winters Early Longpod survives, and the pods are much larger. Globe Artichokes, if cleaned and exposed as before advised, will be somewhat hardened, and should be protected before severe frost occurs. The soil around the crowns must be removed to the depth of 4 inches, giving a good dusting of quicklime, and surrounding the crowns with ashes in lieu of the soil removed. The spaces between the plants and rows may be covered with litter 6 inches deep. Cut and remove decayed Asparagus stems, and apply a dressing of manure to the beds, avoiding, however, raising them too high. Clear away the decayed leaves from Rhubarb, remove the loose soil from around the crowns, replacing with some well-decomposed manure, covering the crowns and manure with soil from between the rows, and in the spaces between the plants give a good dressing of manure.

Seakale to be forced on the ground should have the decayed leaves removed, be given a light sprinkling of salt or quicklime as a deterrent of slugs, and some ashes placed around and over the crowns. Continue in favourable weather to earth-up Celery, protecting in severe weather that fit for use. Broccoli which has become leggy should be heeled or laid in, so that the stems of the plants will be well covered with soil. Plants grown on poor or firm soil have made short stems and sturdy growth, and will not need this treatment. Look out for slugs in recent plantations of Cabbage and Lettuce, dusting them with lime or soot. Applying manure and digging or trenching vacant ground should be proceeded with when the weather is favourable, as the beneficial results accruing from fully exposing the soil to the operation of the weather cannot be over-estimated, especially where the soil is of a stiff adhesive nature. Throw up such soils in the roughest manner possible and in ridges in order that pulverisation may be thorough; and in light soils where this will not be necessary the exposure of the soil will be beneficial. Remove all decayed leaves from Brussels Sprouts and winter vegetables generally, as such only harbour vermin.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—Where it is intended to have fruit of these ripe early in May with certainty, the house containing the trees for that purpose should now be closed, but no fire heat except to exclude frost need be employed until next month, and the house should be freely ventilated at and above 50°. A thorough soaking of water at a temperature of 70° to 75° must be given the inside border, and the trees damped in the early part of fine days and early on fine afternoons; but when the weather is dull there will be sufficient moisture without resorting to syringing, and it is important that the buds and wood become dry before night. The outside border should be covered with a good layer of leaves, litter, or dry fern, but not so thick as to cause fermentation, and if there be shutters or

tarpaulin to throw off heavy rains or snow it will be an advantage. Oak or Beech leaves with a third or fourth of stable litter being at command may be placed in a heap and turned over once or twice, for making up a bed inside the house the beginning of next month.

As the trees in the succession houses become divested of their leaves the lights may be removed, as no harm will result when the wood is thoroughly ripened. Where the lights are not removable the cleansing of the house and trees may be proceeded with, unloosening the branches from the trellis, and securing them to it again after the house has been cleansed and the trees pruned and dressed with an insecticide. The pruning must be confined to removing such shoots as escaped notice at the pruning or thinning after the fruit was gathered. A space of 12 to 15 inches or more should be allowed between the young wood. Remove any loose surface soil, and supply strong turfy loam with a little bonemeal and wood ashes intermixed, making it firm, and giving a good watering. Have the house as cool as possible. Late trees of which the wood does not ripen well should have the roots wholly or partially lifted, commencing to remove the soil at the point most distant from the trees, and preserving the roots as intact as possible, especially the fibres near the stems, and after rectifying the drainage place the roots in fresh compost. If only partial lifting is resorted to, the roots should be raised, bringing them near the surface and not covering them deeper than from 4 to 6 inches. Give a good watering, keeping the house rather close for a few days, and, ventilation being then ample, the foliage will ripen freely.

*Figs.*—The first batch of Figs for early forcing in pots should now be dressed with an insecticide to destroy the pests which infest the trees in a more advanced stage. In employing the insecticide care must be taken not to rub off the young fruit. Very little pruning will be necessary if the plants have been regularly pinched-in during growth, but if the shoots are too crowded they may be thinned, and any elongated shoots cut back. A bed of leaves is a great aid to successful early forcing, and to secure them in a fit state for the purpose they should now be thrown into a heap with a fourth of stable litter, turning them over when warm and damping if necessary. Equally important for the trees is a free exposure to light. The pots may be placed on pillars of open brickwork to prevent their settling with the fermenting materials, and to keep the growths near the glass. The house can now be prepared, and the pots placed in position by the end of the month, the fermenting materials being then placed round the pots, but not to raise the temperature above 70°. Pruning planted-out trees should be proceeded with, but in the case of trees which have the roots restricted to small borders very little pruning will be needed, providing attention was given during the season of growth to thinning and stopping the shoots. Trees not having the roots so restricted, and the object being to secure a supply of young growths over the whole surface of a large trellis, will require pruning somewhat hard at the upper part. Shoots which have attained the limit of the trellis should be shortened back to the part at which the succeeding shoots start. All elongated spurs must be removed, reserving some of those which are short-jointed and fruitful.

*Cucumbers.*—The temperature outside and the diminution of the duration of light will necessitate a slight decrease of temperature, which may be kept at 65° at night, falling to 60° on cold mornings, but 2° or 3° warmer when the weather is mild, 70° being the minimum by day. Ventilate when the air is mild. Avoid sudden fluctuations of temperature, paying close and careful attention to stopping, thinning, and regulating the growths. Be careful to apply water to the roots of about the same temperature as the house. The plants for winter-fruiting should be allowed to extend up the trellis before stopping, afterwards training the shoots to the right and left of the main stem. Continue to add a little fresh soil as fast as the roots cover the surface of the bed, removing all tendrils and male blossoms as they appear. Fumigate moderately upon the first appearance of aphides, and promptly apply flowers of sulphur for destroying mildew, quicklime being the best antidote for canker.

#### PLANT HOUSES.

*Stove.*—Plants in a state of rest should not be subjected to a low temperature, for though many plants will bear it without showing

immediate bad results, yet it causes the loss of the roots, especially if the soil be moist; in fact stove-flowering plants of such kinds as *Ixoras*, *Dipladenias*, and *Allamandas* are often injured by resting in too low a temperature. Rest is best effected by keeping the roots moderately dry, and the atmosphere correspondingly so, reducing the temperature to 60° to 65° at night, with an advance by day in bright weather to 75°. Tropical plants do not need cold to induce rest, but dryness to harden the growth. Some of the strongest plants of *Poinsettia* should be placed in the stove to bring them into flower; also *Euphorbia jacquiniæflora*, keeping the latter near the glass, as the colour is then not only brighter but the sprays last much longer in a cut state.

*Orchids*.—*Acrides*, *Phalænopses*, *Saccolabiums*, *Vandas*, and similar kinds will, owing to the gradual lowering of the temperature, be in a partial state of rest, and will only need sufficient water at the roots to keep the moss damp; if allowed to become too dry the lower leaves are apt to shrivel and fall. Prevent premature growth by keeping the house comparatively cool and dry; moisture, however, must not be neglected, a little water being poured over the pathways when the temperature is rising in the morning, completing all watering and syringing by noon, so as to have the house dry before the temperature lowers. Air should be admitted by the bottom ventilators, only a little being necessary to keep the temperature from rising too high. Imported plants not having completed their growth must be kept in a moist atmosphere and watered, and plants growing on blocks must be examined and watered as they require it. Plants of *Dendrobium nobile* that have completed their growth and have the buds swelling may be placed in the East India house, and they will be in flower by the new year. *Cattleyas* require a long rest, the pseudo-bulbs not being allowed to shrivel, but very little water will keep them plump. *C. Warscewiczii* now starting will make a fine display during the winter. *Lælia purpurata* which has not completed its growth should have a good position at the warmest end of the house. *Calanthe vestita* coming into flower must have very little water, and to prevent the buds falling keep the plants fully exposed in the driest part of the house. *Cypripediums* require water liberally at all seasons. Many *Odontoglossums* and *Masdevallias* are still growing, and must be kept moist at the roots.

## THE BEE-KEEPER.

### BEST TIME OF COMMENCING BEE-KEEPING.

IN districts where bees are extensively kept bee-keeping may be commenced at any time of the year, for in such districts there is no difficulty in finding people ready to sell part of their stock. In the month of September, generally speaking, bee-farmers take their honey and finish their harvest. In doing this their hives are lessened in number about one-half. Hives at this season may be readily obtained at low rates, say a trifle more than the value of their honey. At the time of harvest clever bee-farmers mark the hives most suitable for maintaining the number usually kept, and take the honey from the rest, carefully preserving the bees and young queens of the honey hives to strengthen and perfect those kept for stock. If any of the bees require feeding, syrup is given them in September. This is simply the routine work of well-managed apiaries. Hives so prepared are valuable and can be confidently trusted, and, therefore, are worth more than their honey value; indeed, their value increases as their honey is eaten. As autumn and winter pass away and spring appears stocks of bees rise in value, and continue rising till the time of swarming. Buyers then want swarms. In our opinion the best time to commence bee-keeping is during the dull months of autumn and winter—say any time between September and March inclusive. During November, December, and January hives may be safely removed from one garden to another without much risk of losing bees by the change. In February bees begin to fly farther from home, and therefore there is some risk in changing hives in February, March, and September.

From March the September bees know the pasturage and country well for a mile and a half in all directions around their hives. Swarms only on being hived can be safely removed a short distance at this busy season. As we generally advise those who consult us as to how bee-keeping should be commenced to pur-

chase hives near home if they can find them, we would like all to remember that the best time to buy hives near home is in the dull months of winter. In purchasing hives at a distance from home and having them sent there is no risk of loss of bees, but the expense of carriage may be a consideration. In the autumn and winter months there is little if any risk at all in losing bees by suffocation in being removed from distant places. At this time of the year hives can be removed from one end of the land to the other without loss of bees or breakage of combs. To those who have resolved to have bees in their gardens next year, let me advise them to look around them for hives at their earliest convenience. Those who do not know the difference between a good and a bad one, a strong and a weak one, should apply to a respectable bee-keeper for a stock or two, or instruct a trustworthy agent to do the work of buying for them. Many ladies and gentlemen have failed at the commencement of bee-keeping by having worthless hives, and some have failed by some mishap with a good hive. When failure happens in the first year of commencement it is a great misfortune and disappointment. To prevent the possibility of misfortune to beginners we have advised those able to buy two hives to begin with them; and we believe that those who followed the advice given have not regretted doing so. If any unexpected misfortune fall on one hive, the other hive may produce results so satisfactory as to make the owner fear no failure in the future. After one season of success bee-keepers seldom dream of failures in the future.

As to the price of hives we cannot speak with confidence, for in different localities the prices vary so much. In bad seasons hives are lower in price than in good seasons; and this is easily understood, for bees in bad seasons are dear at any price, and in good seasons good hives are cheap at any price less than £3 each. In Ireland and in some counties in England where bee-keeping is not well understood, hives are small and low-priced—from 10s. to 20s. each. Stock hives range from 30s. to 40s. each. Swarms in May and June range in price between 10s. to 30s. each according to locality and size. We have always thought it the better way to make a commencement with a stock hive, so that there is a chance of having a return from it the first year or a multiplication of stock.—A. PETTIGREW, *Bowdon*.

### LIGURIANISING.

I HAVE been experimenting of late with Ligurian bees. Having lost an English queen through old age, and as I intended to replace her with an imported Ligurian queen, I wanted to make sure she was not in the hive, so I gave them some Ligurian eggs, and the queenless bees at once built queen cells and sealed up three queen cells in a short time. This having removed my doubts, I cut out two of the queen cells and placed them in a small bar-frame hive (one that a queen came in from Italy) with over one hundred bees. One of the cells did not come to maturity, and the other queen was born without a wing, so that if she had been needed or born in another hive she would have been no use, as she could not have been mated, not being able to fly. I destroyed her, and gave the same bees a piece of comb containing Ligurian eggs on the 12th ult., and on the 17th they had one queen cell built and sealed, and on this morning, October 25th, the queen is hatched. This is only about twelve clear days from the bees received the eggs. But it is only fair to state that it was all done in a warm glass house.

I want to know if I can make my queen a drone-breeder in spring by supplying her with as much brood as will keep up the numbers? I have already three Ligurian queens, and by raising a number of young queens early in the season this plan would produce early drones to fertilise them. Perhaps some of your readers have tried it successfully. If it is practicable, any number of queens could be raised in these little boxes in spring and given to black colonies, and then be fertilised by the drone-breeder's progeny, and so ligurianise an apiary without loss of time to the bees.—COMBER.

### BEE SHOWS AND BEES IN IRELAND.

I QUITE agree with Mr. Edwards that Mr. Pettigrew's remarks on the bee tent ought not to pass unnoticed, and am glad to see the article from "COMBER" on the subject, as, far from the manipulations in the tent frightening spectators, I know of instances where persons previously afraid to touch bees have, from the instruction received at the recent show near Dublin, driven many hives successfully unaided and without gloves. I think this is sufficient proof that the shows tend to the advancement of bee-keeping.

I fear the wintering of stocks this year will be bad, as they

have dwindled remarkably since 15th August, when breeding ceased here. The season here has been very bad, many cottagers getting no profit at all this year, except in favoured places, where skeps sometimes reached 50 lbs. gross. My bees were working at the Ivy during the fine mild weather last week as if it were May. I fear this will make them dwindle still more.—SUBSCRIBER.

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (Anxious).**—The best work on the planting and management of forest trees with which we are acquainted is Brown's "Forester," published by Messrs. Blackwood & Sons Edinburgh and London. (*A Learner*).—You will find the "Orchid Growers' Manual" a very reliable work. It is published by Mr. B. S. Williams, the Victoria and Paradise Nurseries, Upper Holloway, price 7s. 6d.; post free, 8s.

**Fruits for North Wall (F.).**—You neither name the district in which you reside nor the height of the wall. Besides Gooseberries and Currants Morello Cherries thrive well on a north aspect. In many places Plums also succeed well, Victoria being very fruitful, and in some localities early Pears produce good crops in such positions as those to which you allude, but we have no means of judging whether they would be likely to succeed in your garden.

**Vines in Pots (Item).**—The Vines of which you send us a sample are of no use for fruiting in pots. You had better cut them down as you propose, and also raise others from eyes. No one can say which would be the better, as so much depends on the treatment they receive. Vines for fruiting in pots cannot be successfully grown in a shaded position.

**"The Herefordshire Pomona" (J. L. C.).**—Many excellent coloured plates of Apples appear in this fine work, which is published by David Bogue, 3, St. Martin's Place, Trafalgar Square.

**Abutilons (F. W.).**—If you have convenience for wintering the seedlings we should not cut them down, and in all probability they will flower early in the spring, and afford you an opportunity of testing their merits. If you cut them down you will have to wait much longer before you can determine the value of the varieties.

**Washing Minton's Tiles (Flora).**—We cannot suggest anything better for drying the moisture from the floor of your conservatory than a good woollen mop; the work would be done much more economically than with a sponge, and we think quite as effectively.

**Hyacinths in Water (Two Inquirers).**—You will find reliable instructions on this method of growing Hyacinths on page 248 of No. 64, the issue of September 15th of the present volume. If the number has been mislaid others can be had from the publisher post free for 3½d. each.

**Roses in Pots (K. A.).**—You had better let the plants have all the air possible, but it would be advisable to shelter them from heavy rains to prevent the soil being saturated, as this would prove very injurious to newly potted plants. We should also place on the lights on the occurrence of frost. You may prune them any time after the leaves have fallen. When you cover them in wet mild weather prop up the lights as fully as possible.

**Vines not Bearing (A Constant Reader).**—There are no signs of the phylloxera on the roots you have sent, but they are very fragmentary. In all probability unsuitable soil is the cause of the injury. You had better remove the whole, or the greater part of it, providing good drainage, raising such roots as need it, and placing them in fresh compost. All the unhealthy portions should be cut off, and if you place a good proportion of wood ashes in the soil in contact with the roots the production of fresh fibres will be accelerated. Had you sent a portion of wood as well as roots we should have been better able to judge of the condition of the Vines and the probability of their restoration. The roots should be covered 4 or 5 inches deep with soil, and the border further mulched with manure. The work should be done at once.

**Rain Gauge and Rainfall (A. T. Liverpool I.).**—There are many different rain gauges, and we have not had experience with one of the kind you mention, nor are we able to furnish you with the rainfall of your district during the time you name. If you send a stamped directed envelope to G. J. Symons, Esq., F.R.S., Camden Square, London, he would probably oblige you with the information you need.

**Exhibiting Grapes (J. A.).**—If the schedule expresses that "distinct species" must be staged, and there is no qualifying clause in favour of black and white Grapes being allowed, then no one can stage more than one dish of Grapes in the collection without being disqualified. If the conditions express distinct dishes or distinct varieties, then black and white Grapes would be admissible, as they usually are in collections of fruit. You had better ascertain the intentions of the committee; framers of schedules often employ terms of which they do not appreciate their true significance.

**Destroying Mildew on Chrysanthemums (S. H.).**—A simple remedy that has frequently been recommended in these columns is to dust the

affected parts with sulphur immediately the mildew appears. Some cultivators syringe the plants with a solution of softsoap or Gishurst compound at a strength of 2 ozs. to a gallon of water, and apply the sulphur to the foliage when it is wet; it may remain on for a day or two, or until the mildew is destroyed. Remedies of all kinds are often, however, rendered ineffective through their application having been too long deferred.

**Grapes Decayed (J. Turner).**—It is impossible for anyone to tell why the Grapes have decayed without being acquainted with the condition of the Vines and border, the weight of the crop, and the treatment that has been given. We can only reply to you as we replied to a correspondent last week. If you will state how the border was made and drained, with the nature of the compost, and also send fair examples of wood and foliage, we will give the subject our best attention.

**Repotting Dendrobium nobile (A Subscriber).**—The best time for repotting these Orchids is after flowering, as growth then commences. Those that you wish to hasten into flower may be now placed in a warmer house, retaining the others in their cool quarters until they are wanted. One cause of the growth starting prematurely is keeping the compost too wet, and this should be carefully avoided. *D. chrysanthum* may be grown either in a pot or basket, but the latter is preferred by many growers.

**Various (J. P.).**—We do not know any work that would precisely answer your requirements. Perhaps the following hints will be of service to you. The *Brunsvigia* and *Hæmanthus* may be grown in a greenhouse or similarly cool structure, and require a compost of light turfy loam and sand, the pots being well drained. The *Sauromatum* succeeds best in a warmer structure than the above, and needs a compost of loam and sand. The Orchids and *Ophrys* may be either grown in a cool house or frame, and must be provided with well-drained pots and a compost of light loam and peat in equal parts, with a good proportion of sand.

**Importing Wild Plants (W. E. B.).**—Considerable difficulty is experienced in importing wild plants in a live state, and few, except bulbs or those with creeping roots, thrive satisfactorily for any length of time. This especially applies to alpinists. They should, when the experiment is tried, be carefully lifted, injuring the roots as little as possible, surround these with damp moss, and pack closely in tin boxes. Where seeds can be obtained it is generally the best mode of introducing such plants. The lists to which you refer are frequently published in the leading daily papers; but we do not consider such lists very reliable, as the prices are always fluctuating according to the daily supply of produce.

**Peeling Vines (Gloucestershire Subscriber).**—We do not approve of peeling and scraping Vine rods, and can only conceive the practice defensible if the Vines were infested with insects, and even then we should try and destroy them before having recourse to a practice which as sometimes carried out is injurious. If you dissolve about 2 ozs. of Gishurst compound or softsoap in a gallon of water, and thoroughly wash the rods with the solution when it is as hot as the hand can be borne in it for a moment or two, not many insects will escape if the work is well done with aid of an old spoke brush. It is as necessary to cleanse the house as to wash the Vines where insects abound.

**Trees not Fruitful (Item).**—The roots of the Elm trees no doubt penetrate the Peach border, and more or less impoverish it, and cropping a Peach border close to the trees is not good practice; still, with care early crops may be grown on such a border, as may be seen in hundreds of gardens, but the work needs to be carried out with judgment and care. If fruit trees grow luxuriantly root-pruning is advantageous, not otherwise. Drainage is only necessary where the subsoil is wet. The condition of your Pears either indicates that the varieties are not good or the trees need more support, such as removing a little of the surface soil from the roots, and giving a dressing of manure. By the term "east wall" we presume you mean the east aspect of a wall. Plums and Pears would grow there and bear fruit, but with greater certainty if the blossoms were protected from frost in spring. We cannot usefully name any varieties, as you do not state how many trees you require, nor mention the length of the wall.

**Sowing Fern Spores (J. C.).**—The spores of some species of Ferns retain their vitality for a considerable period, and instances have been recorded of spores germinating that have been taken from dried specimens preserved for years in an herbarium. As a rule, however, those which germinate quickly, such as the *Gymnogrammas*, also retain their vitality for a comparatively short period, so that it is safer to sow the spores as soon as they are ready than to wait to a more favourable season. Prepare shallow pots or pans, three parts filling them with clean rough potsherds, over these place some finer portions, and fill up with light soil and sand. The soil should be baked or exposed to the action of fire sufficiently to destroy the spores of any coarse-growing Ferns, the germs of fungi, or any other of the lower order of vegetation, the rapid increase of which if allowed to remain would speedily destroy any of the more delicate Ferns in a young state. Thoroughly moisten the soil, and stand the pot or pan in a saucer that should be kept filled with water, which, rising by capillary attraction, will obviate the necessity of frequently applying water to the soil after the spores are sown. When it is observed that the clusters of spore cases on the fronds are approaching maturity the fronds may be removed carefully and laid upon a sheet of paper in a dry position, where the spore cases will burst and liberate the extremely minute spores, which can then be scattered on the surface of the prepared soil. Some prefer placing the fertile portions of the fronds upon the soil at once; but in either case care must be exercised to cut the fronds before the spore cases are fully mature, or you may lose the spores, and after carefully sowing the empty cases and waiting for a month or two find that all your labour has been in vain. Cover the pots or pans with a piece of glass to prevent evaporation, and place them in a shaded close house or pit where an intermediate temperature is maintained, and if not allowed to fall below 50° there are few of the free-growing Ferns from either tropical or temperate regions that will not germinate satisfactorily.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*Worcestershire Vicar*).—We are sorry we cannot aid you in determining the name of the Pear; it had not been packed firmly, and by shaking to and fro arrived here a shapeless mass. (S).—Your Pear is Dunmore. (*J. Digby*).—1, Dumelow's Seedling; 2 Golden Reinette; 3, Cox's Orange Pippin; 4, Court Pendu Plat. (*A. W.*).—1, Beurré de Capiaumont;

2, Beurré Diel; 3, Zephirin Gregoire; 4, Ne Plus Meuris. (J. D. S.).—2, Margil; 3, New Northern Greening; 5, Alfriston. We have received other parcels of fruit that will be referred to in a future issue.

**Names of Plants (J. H.).**—1, Lastrea glabella; 2, Lastrea quadrangularis; 3, Polystichum species; 4, Doodia blechnoides; 5, Asplenium obtusilobum; 6, Adiantum tetraphyllum.

COVENT GARDEN MARKET.—NOVEMBER 9.

BUSINESS remains the same with an improved demand for Grapes. Home-grown Apples still reach us in good supply to the almost total exclusion of foreign goods. Kent Cobs easier.

POULTRY AND PIGEON CHRONICLE.

STABLE ACCOMMODATION FOR HORSES.

ALTHOUGH this subject is not strictly connected with the home farm, yet, as on many gentlemen's estates the food and litter required for the nag horses is often derived from the farm, it is our intention to relate some experience in connection with the erection of stables and their internal accommodation necessary for horses, such as hunters, hacks, racers, and also for harness work; in fact, what we have to state will apply equally to all the horses kept upon any gentlemen's or noblemen's estate.

Health and longevity are matters of the greatest consequence, and they cannot be secured without judicious stable accommodation and management of the horses. We will consider first the construction and position of stables best calculated to contribute to those desirable objects. We prefer a high and dry soil upon which to erect the buildings, with a frontage and aspect to the westward, that being a point of the compass from which we seldom get extreme heat or cold in the English climate. On the other hand we think it conducive to the health of the horses that in exposed situations the protection afforded by plantations of timber trees, such as Larch and Scotch Firs, are desirable; still we must not overlook in selecting a position for the stable the situation of the mansion, having due regard to appearance, convenience, and economy, a gravel or sandy soil probably being the best whereon to erect our building. With regard to materials for the erection we prefer stone walls as well as roofing, such as we often see in certain districts and in Scotland; when compared with brick and slate or iron roof, a stone building is warmer in winter and cooler in summer, and also more enduring. The

cost will be regulated by the materials, which can be most easily obtained in the district where required for use. As it is not convenient to give any plans of architecture or construction we will describe as nearly as we can such designs and principles of construction by explaining in detail the objects we have in view. It is not our intention to describe, except in one or two cases, such stables as were formerly in use, and have since during the past twenty-five years been given up and repudiated by judicious owners of valuable horses, and those who can afford to make an outlay in arranging their stable accommodation upon a style and extent commensurate with their requirements; we shall therefore endeavour to describe only that which we consider best in stable accommodation in such a way that a single stall or a single loose box may by multiplication only, be carried out to any extent which may be required. It is not necessary either to discuss estimates of cost of the building and construction of such stables as we recommend. We prefer to allude more particularly to the advantage or otherwise of certain plans of construction as compared with others which have been advocated.

The first, as we consider, real attempt to make any decided improvement in the accommodation for horses in their stables by Government authority which we have noticed occurred through a Commission appointed to consider the improvement of barracks, who published a report in 1864 on the ventilation of cavalry stables. This contains some suggestions that have since borne fruit by inducing the builders of nag stables, especially those for gentlemen's horses, to consider the actual requirements of horses to keep them in health, and to apply in their construction various scientific modes of ventilation and other practical advantages. The old rule for the construction of cavalry barracks seems to have been that the men should be housed over the horses, and this system has prevailed even up to the present time in various stables in some gentlemen's establishments. The rooms above, however, hindered ventilation through the roof, and air shafts, if adopted at all, offered but an imperfect remedy. The horses generally stood in a double row, heel to heel, with a single path up the centre.

The report states, "The defects of this arrangement are clearly indicated by the following recommendations of the Commission:—That the old transverse arrangement of stables be discontinued. That in future all troop stables be built with open roofs and ridge ventilation from end to end. That the roofs be partially and sufficiently glazed to afford plenty of light. That in so far as concerns facility of ventilation and supervision the open-roofed stable, having a central passage 14 feet in width between the stalls, is preferable to the open-roofed stable with a central division wall, and two passages each of half that width. That besides ridge-ventilation and light each stall should be provided with a swing window over the horse, and a row of perforated bricks should be carried round the stable under the caves. That each stall should have a supply of fresh air introduced in the space between the stalls about 6 inches from the ground through perforated bricks. That improved impervious paving be introduced. That all drainage within the stable be carried away in shallow impervious open drains by a rapid slope to the outside of the stable; covered drains and cess-pits within the stables or near the stable walls being discontinued."

We now offer some suggestions and remarks, chiefly taken from the body of the report, which will further explain this subject; and as these were made by Mr. H. P. Frere in an essay published in the "Journal of the Royal Agricultural Society of England" in 1864, we quote them in order to exhibit certain matters which, without plans and sections, may not be so easily understood by the reader. "As to the open roof. Since no suggestion is made as to the covering of the roof with slate or otherwise, the question of partially liming or ceiling between the rafters is not touched upon. The report is in this respect somewhat defective. It is suggested that the light be admitted on the northern side of the ridge. The question of paving involves the following:—Paving should wear well, not become slippery, be watertight, be easily cleansed. The objection to cess-pits extends to all sewers or covered drains within stables, which are merely cess-pits of another form. The drains, like the stable floors, should be impervious to moisture, and made of smooth materials, carefully laid, having as rapid an incline as is possible to obtain. These gutters should discharge into an underground drain (which should be a drain pipe) at a distance of at least 12 feet from the stable wall. As the surface drains always receive a considerable quantity of dung, besides urine and water, it would be advantageous to provide a trap at the openings of the underground drain to prevent any effluvia from returning and to avoid stoppages. Mr. Frere further observes when it is in contemplation to provide stable accommodation for horses in stalls amounting to 100 square

feet superficial, and 1600 cubic feet for each horse, the question arises, Whether a single step further would not serviceably provide each horse with a box? With judicious management and a moderate supply of straw the utmost comfort of the horse may thus be combined with the best economy of manure."

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Upon some of the sand and gravel soils where the practice is to sow late the horses will be still engaged in working the land and drilling Wheat. Upon these dry soils we prefer to sow an early white Wheat, especially if it is in a southern or south-eastern county, such as the Champion White from Berks; Morton's Red-strawed White from Gloucestershire and Hampshire, the long-eared Rough Chaff from Essex, and the Fenton White from the northern districts and Scotland. These are well adapted for very dry thin soils which are not likely to throw up an abundance of straw, for these, as well as the Chidham white sort from Sussex, are long-strawed varieties. Where the land is really in full condition and of a strong loamy nature we prefer the Club-headed Rough Chaff. This grows very short in the straw, and is hardly ever known to fall down or become laid, and is certainly the most productive and best qualified Wheat we know of; for on good land last year we saw fourteen sacks per acre grown, and this year twelve sacks per acre, with a very moderate bulk of straw, and grown upon a dry gravelly soil in a southern district. The land has been very dry, in many cases working as light as Barley soil should do. Some parties have hesitated to sow or drill while the land is so dry; but we never hesitate to sow when the period has arrived, for we never can tell what weather may occur further on in the season. This has been one of the finest seasons for Wheat-sowing we can ever recollect, especially for the strong, cold, flat-lying soils. Ground of this nature has been worked very fine on the surface, and the only thing to be feared in consequence is an abundance of weeds in the spring, such as Gold-weed, Marigold, and Black Bent Grass. Should this be the case, and the Wheat sown or drilled close so that it cannot be horse-hoed, the weeds cannot be destroyed, and may therefore seriously injure the produce; hence the necessity of drilling at 10 or 12 inches between the rows. Upon land given to weeds the crop is never safe unless the horse-hoe can be worked freely between the lines. Carting and storing Mangolds will still be going on, but ought now to be finished, and the pitting of Carrots and Swedes continued.

The odd horse in some cases has been lately employed in carting Clover and Ryegrass off the lea ground intended for Wheat, and a valuable produce has been available for the cart horses and other stock, including dairy cows. Cutting Clover and grass in the same manner will be continued for some time yet. Although at harvest there seemed to be hardly any prospect of grass this autumn, yet we are now cutting a very valuable produce, and shall continue for two or three weeks yet unless severe frost occurs to destroy the crop. Some farmers object to cutting young Clover and grass seeds at this period; but we have done this at times for many years, and prefer it to feeding, especially with sheep or horses, as these bite so closely on the crowns of the Clover plants as to cause them to die off during the winter, and it is often through injudicious treatment the Clover plant is lost, and the land in consequence is called Clover-sick.

*Hand Labour.*—The men and women having now finished picking and gathering the Potato crop and pulling the Mangolds for storing and pitting, will now for some little time be engaged in pitting in heaps in the field other roots, such as Carrots and Swedes. When this work is done by the acre, as it always should be, whole families may be employed with advantage to themselves and their employer. The fern and also rough grasses should now be cut in the plantations and rough grounds and used for various purposes, such as covering the heaps of stored roots and littering yards for young cattle, thus saving straw, which is dear everywhere—in some districts nearly or quite as dear as hay—and should therefore be economised.

*Live Stock.*—Young cattle and dairy cows have lately been consuming the Mangold leaves where the land is clearing for Wheat-sowing. In case, however, the land is held over for Barley and drege in the spring the leaves may well be ploughed in, for they always prove a useful manure for the next cereal crop. The bullocks in the boxes intended for sale at Christmas should now be allowed the full and utmost quantity of superior food, say 4 lbs. of cake per day and 2 lbs. of mixed meal composed of bean and maize meal, good sweet Oat straw, and a diminished quantity of roots (not more than 56 lbs. of Mangolds, 60 lbs. of Cabbage, or 56 lbs. of Carrots per day), without hay, good-conditioned straw being the best and safest food for really fat animals if fed for profit. Even if intended for competition in the cattle show we must beware of hay, for it is, when the cattle are well fed in other respects, the most dangerous as well as damaging food they can receive. We say this with confidence after a long experience.

The management and attention to the bull on the home farm is an extremely important matter in various ways, for it is not only proper that the animal should be well treated and fed but that the apartment where it is kept should be convenient and also very strong. We saw recently a statement which related that a bull broke his tether by accident, and whilst at liberty in the farmyard attacked and seriously disabled his keeper and assistant. Our rule is that the

apartments called the bull pens should be separated by a sliding door which can be drawn or withdrawn, so that the man in charge may never at any time be in the actual presence of the bull either for littering the pens or for any purpose.

#### FAMOUS POULTRY YARDS.

KNIGHTON VICARAGE (THE REV. M. H. & MRS. RICKETTS).

We have described poultry yards and poultry yards, each in some way differing from the others, and from some peculiarity of its own interesting to the fancier; but still there has been this common to all of them—in all we have before seen some few breeds, in some cases only one or two, in others possibly ten or a dozen, bred up to exhibition standards. We have now to describe a yard far different from all the others, and unique, we believe, among English poultry yards. Imagine an establishment of ninety runs, where eighty varieties of fowls are to be seen! Our readers may well pause here, incredulous with wonderment. We turn to the schedule of the great Crystal Palace Show, where representatives of every kind are generally supposed to be collected, and find that provision is made for but forty-five distinct sub-varieties. Here is a private establishment where, granting fifteen sorts to the "any other variety" classes of the Palace, half as many varieties again are to be seen as at the great National Exhibition, for eighty is in truth as nearly as possible the number which are to be counted in excellence at Knighton Vicarage.

Before we come to the birds we must give some account of their surroundings. It has been our fortune to see many yards in lovely places; it would seem as if poultry fanciers had a peculiar eye for the picturesque; probably the truth is that when Nature has made country beautiful with undulation there are to be found spots specially inviting for the indulgence of such a pursuit.

On the Welsh side of a deep valley through which the Tees flows, dividing Shropshire from Radnorshire, rises the little town of Knighton; almost in it, and yet quite out of it, is the vicarage, perched high above the valley. We enter by a short carriage drive. On the right the church is close at hand, the vicarage in front, and beyond it across the valley a precipitous Beech-clad mountain. The woods are glowing golden with the evening sun upon their autumn tints. Past the walled churchyard to the right a lawn, with here and there a stately tree, slopes gently down to a paddock, where we at once spy many poultry runs. To the left is a kitchen garden, divided by shrubs from the lawn and walled all round save on the side towards us. Here, too, are signs of many more poultry runs, and the shrill voices of many Bantam chanticleers catch our ear. As we approach the house, on each side in the distance are peeps of lovely Welsh border scenery; but the poultry are our business, and we must hasten to them.

We should first tell our readers that the object which Mr. and Mrs. Ricketts set before them in making their collection is not to keep any one sort of surpassing excellence, or to breed so many prizewinners, but to have a good specimen pen of every known kind of poultry, and indeed many which can scarcely be called known. This is the great peculiarity of the Knighton collection. Breeds which we have heard of as possibly to be seen here or there, abroad or in some obscure place, are here to be found together and seen at a glance, side by side, as easily as the Pheasants at the Regent's Park gardens.

The establishment is divided into two complete departments. The one which we have seen on the left of the entrance, and which occupies a large part of what once was kitchen garden, is the special care of Mrs. Ricketts, and is devoted almost entirely to the smaller varieties of poultry—Bantams, Silkies, Polish, and Sultans—and admirably adapted it is to its purpose. A substantial stone wall is the boundary of the garden; it curves gently, so that the aspect of the part given up to poultry varies from south to east. Against it are many houses, and from them run their neatly gravelled yards to a walk whence all can be seen; we counted about forty, all the very picture of tidiness. Without disparaging the many beautiful yards we have visited, we may confidently say that none have ever interested us more than this range of houses. The gravelled walk curves round parallel to the wall; on the right are the runs, on the left a thick Privet hedge, lately planted for shelter, and trained against wire, and beyond it a large closely mown lawn, the playground of many tiny Bantams and other privileged chickens.

But we must tell our story in order. First come a block of six houses; all are double, with inner and outer apartment, specially

constructed for Polish. The fronts of the outer parts are partially glazed like garden lights, and the doors of sparrow-proof wire. In these the birds are fed and entirely confined in wet or bad weather; the good result is very apparent in their bright glossy condition and fully expanded crests. These and all the houses are made ratproof. Strong small-meshed wire netting is nailed to the wall and sunk 6 inches into the ground, and then a layer of cement is laid over all the floor, topped of course with dry earth. The yards are entirely covered with coarse clean gravel from the neighbouring river, and their inmates supplied twice daily with fresh green food. First are a mixed collection of various promising Polish chickens, then a pen of adult White-crested Blacks; then Golden, one hen with a magnificent crest; then Padue Chamois, a beautiful lot; we have never seen their like since the great Paris Exhibition; the cock rich in his tints of sienna and Indian yellow, and well nigh through the moult, and one hen in particular with great clearness of the white spangling on her canary plumage. As we proceed, here and there a walk crosses the main walk at right angles, running up to the wall with ranges of minor runs on each. In the first of these lesser alleys is one somewhat larger house, the habitation of a multitude of small stock, which run out on the grass lawn. Double gates across the chief path prevent their trespassing upon it as they cross to their runs. These and all the gates about the place have small hooks on both sides to prevent all chance of accident from their being blown open.

Bantams of endless variety in form and colour are tenants of the next places; all have little perches upon which the cocks delight to elevate themselves and crow. There are White Rose-combed and Black Rose-combed—a cock of the latter kind we specially admired; Cuckoo—like miniature Scotch Greys—White Japanese with black tails; Dark Japanese, black with brown hackles, the offspring of Lady Brassey's famous stock brought home in the *Sunbeam*, but hardly so short on the leg as their parents; Tailless of various colours, one cock light-coloured in body with glowing parti-coloured saddle hackle such as we have seen imported from India; Nankins of various merit, rose-combed and single-combed, by far the best of them being a tiny single-combed cock, which confirmed our long-formed opinion that the smallest specimens of the breed are single-combed; Black and White-booted, one pair of the former very short and compact; Silver-laced and Gold-laced, three pullets of the latter much took our fancy for their bright ground colour and even lacing; Game Bantams of every sub-variety, many of high style and well fitted for the exhibition pen; there are Black Reds which we saw in a first-prize pen at Wolverhampton, and wheaten hens, and a cock of splendid colour evidently bred from one which we greatly admired for his splendid hues, now too often sacrificed to form; beautiful Brown Reds, among them one pullet splendid in golden neck; Duckwings and Birchen Duckwing, and Piles as handsome for their rich markings as their tiny size; one pair would grace any show room. The contrivance of their many little runs and houses of all shapes and sizes is most clever, and seems a very labyrinth.

At one place we came upon a novel and comfortable home for a troop of infant Bantams, for, like all enthusiastic fanciers of these pygmies, Mrs. Ricketts rears some late-hatched broods; but what a shock to the gardener's feelings! Cuttings have been ousted and chickens reign in a garden frame; the little things twittering happily under the glass, and utterly unconscious of withering east wind outside. More and more blocks of larger and equally well-kept yards! We can scarcely remember all their inmates; white Silkies and coloured Silkies, rich quaint-coloured Brownies clad in æsthetic shades of gold and bronze, whose origin was in a famous Shropshire yard; La Flèche, and pure White Houdans, not mongrels, but veritable Houdans in comb and claw; then a beautiful bird, a Pile Houdan cock, his red and yellow markings deep and good, a sprightly vigorous fellow; then come Polish again, Silvers, and next our favourite the old-fashioned pure White, some of them mediocre, but one hen a really grand bird. Then last of the Polish, some chickens whose race is not yet distinctively founded, blue with white crests, promising to be lovely. Last, but not least, in the range were Sultans, a fine pen and getting fast through the moult, as were nearly all the birds in these warm and nice quarters. We shall hope to see them exhibited, for the cock and at least two hens are well worthy of it, and with their two-roomed house, like the other tufted birds they are well screened from sun and rain. A grass run is being cut off from the larger chickens' lawn for their special benefit. Here we turn round to the left and come back by the said lawn; on it are several coop-like houses with little runs in front, and over it run little Bantams of all kinds mixed with Sultans, Andalusians, and White Leg horns.

Through all this multitude we scarcely saw a drooping or sickly bird. The secret of this is that every house and yard is kept scrupulously clean, purified every morning, and constantly disinfected. All are carefully watched by the eye of their mistress, and any that ail are at once removed to a hospital and doctored. Even beyond the special playground of the chickens are still younger chickens in the remaining portion of the kitchen garden. Their mothers are cooped, and they run merrily among the vegetables in quest of insect food. But we are outrunning our space; our tale is scarcely half told, and is, we are sure, too interesting to a true fancier to be curtailed, so we must resume it in another number.—C.

### THE POULTRY CLUB.

Will you kindly allow me to remind your readers that the Annual General Meeting of the Poultry Club will be held at the Crystal Palace on Tuesday next, at 3.30 P.M.?

The Report will be then submitted, and several questions connected with the preparation of the Standard of Excellence and other matters will be discussed.

The Meeting is open to all who may desire to attend.

I may perhaps mention that the subscriptions of Members elected at the Palace Meeting run from the 1st January next.

47, Chancery Lane, W.C.

ALEX. COMYNS,

Nov. 8th, 1881.

Hon. Sec., Poultry Club.

### OUR LETTER BOX.

**Stocking a Rabbit Warren** (*Old Subscriber*).—Wild rabbits are better than tame for a warren, and the best time for stocking is early spring. One male to thirty females will soon stock an acre. The number that can be grown depends entirely on the pasturage and the food that is otherwise supplied. If they eat the trunks of established trees it is evidence that the warren is overstocked, and the animals must either be reduced in numbers or the food supply increased. Rabbits will bark young Larches and destroy them—that is, trees that have been newly planted, but they will not attack established trees unless driven by famine to do so. Galvanised wire netting 3 feet above ground will suffice if it is properly fixed below ground also. It is little use sinking it straight down, as the animals are very persevering, and will burrow under it sooner or later. The best mode of fixing is to bend the bottom of the wire inwards, or facing the warren, covering a foot of it 3 or 4 inches deep. They invariably commence scratching within a foot of the fence, and of course, if they come in contact with a layer of wire, their further progress is obstructed; but if there is no such obstacle they will descend for 3 or 4 feet if the soil is light.

**Roup** (*F. R.*).—We can only suggest the application of the usual roup remedies. Begin with a dose of castor oil, afterwards wash the face and nostrils frequently with Labarraque's solution of chlorinated soda diluted with twice its quantity of water. Give also Walton's roup pills as directed on the box. The house where the birds have been should be thoroughly disinfected. If there are any other symptoms than those you have described write again, and we will advise you as to further treatment. We cannot understand the blindness of the recovered birds. Do you mean that one eye remains closed, or that the sight of one eye is destroyed?

**Distinguishing the Sexes of Canaries** (*C. L. R.*).—Cock birds are more bold and fierce in general appearance than hens, and have a more bloomy plumage. Their heads are somewhat larger and longer than the hens', and they stand a little higher upon their legs. They are also more sprightly in their action. When in full vigour of song, especially approaching the breeding season, the cock birds can generally be told by (what is understood by the fancy), "blowing" them. Many fanciers can easily pick out the cock birds from the hens when in their nests.

### REMARKS.

30th.—Fine, bright, and cold.

31st.—Hazy; calm, fair, cold.

1st.—Hazy, cold, with showers of snow and sleet.

2nd.—Fair, sunshine at intervals.

3rd.—Rain and fog, but milder; clear in evening.

4th.—Very damp and warm, house walls streaming with wet.

5th.—Fine, warm, spring-like day.

The mean temperature of the week is considerably below the average, although the last two days were exceptionally warm; no better proof could be given of the low temperature prevailing in the early part of the week.—G. J. SYMONS.

17th	TH	Kingston, Westminster Aquarium, Tunbridge Wells, and
18th	F	[Brixton Chrysanthemum Shows.
19th	S	
20th	SUN	23RD SUNDAY AFTER TRINITY.
21th	M	[Shows.
22nd	TU	Southampton, Manchester, and Northampton Chrysanthemum
23rd	W	Birmingham and Wimbledon Chrysanthemum Shows.

### IMPORTED ORCHIDS.

**T**HIS subject is one which is not thoroughly understood by all gardeners, though it is of the greatest importance to everyone interested in Orchid culture, and it is, moreover, a subject upon which very little has been written. Probably a few remarks may therefore be useful to some readers of the Journal.

It has often been asked, What becomes of all the Orchids that are annually imported to this country?

Many thousands of plants from various parts of the world find their way into the English market from the numerous collectors employed by the leading nurserymen, such as Messrs. Veitch, Bull, Williams, Hugh Low & Co., Sander, and the New Plant and Bulb Company, besides private gentlemen and others. Then it is again asked, What becomes of all these? The question has been answered by many, and by all in the same way—namely, that more Orchids are killed than are grown. Before Orchids were so well understood as they are at present thousands of valuable plants were killed owing to the collectors not furnishing the growers with sufficient information with regard to the temperature, climate, and altitude where the plants were found growing in their native habitats. If they came from the tropics it was thought they all required the same treatment, but experience has proved this to be a fallacy.

The trade that is known as Orchid-importing is rather a critical one, subject to great fluctuations and disappointments. It is very disheartening to both employer and collector, when a very valuable importation of Orchids has been received, to find on opening the cases that there is scarcely one living plant. The condition in which Orchids are received depends in a great measure on the time in which they are collected. This may be considered the most important point, for if the plants have abundant young growths the chances are against their arriving in this country safely. The best time for sending the majority of Orchids to England is when the season's growth is completed, and they have been subject to a certain amount of drying or ripening; but no rigid rule can be laid down for the guidance of collectors; much depends upon their own skill and judgment. Packing is another very important matter, for if Orchids are not well and securely packed they present a miserable appearance when taken from the cases. Each collector has his particular style of packing plants, as certain genera require to be packed quite differently from others. I need not go into details with regard to packing, for there is so much to be said in connection with it that a whole chapter may be written on it.

When Orchids are newly imported they present at the best

of times a rather sickly appearance; but with a little kind treatment they soon revive provided there is sufficient life and vigour in them to make fresh growth. Many are under the impression that when Orchids are newly imported all that they require is to be potted, placed in a high temperature, and given plenty of water to "freshen" them up; but it may be here remarked that nothing proves more fatal than such treatment. When the plants are received they should be thoroughly examined, taking care to remove any loose or decayed matter they may have about them. Of course different genera require different treatment, and I will take some of the principal that are of most importance to horticulturists and give a few particulars respecting each.

**AERIDES.**—These are all epiphytes, and may be grown in either pots or baskets, baskets being preferable for many species. The present genus includes several very showy species, of which the following will be fair samples:—*A. crispum*, *A. Fieldingi*, *A. japonicum*, *A. odoratum*, and *A. quinquevulnerum*. They are always imported in dry boxes or cases. If the plants arrive in the best possible condition they have a slightly shrivelled appearance. Much depends on the time they have been coming. They should immediately be spread out thinly in a cool stove for a short time, placing them so as the foliage will not come in contact with any wet material. They should remain in this position for a few days until the foliage is becoming a little plump. Little or no water will be required on their roots or leaves, as the plants will take up sufficient from the atmosphere. Shade is essential to all newly imported plants. After the plants have plumped a little they may then be potted, using only broken potsherds and sphagnum. After they have commenced growing a top-dressing of sphagnum will be beneficial, watering them rather sparingly till they commence rooting.

**ANGRÆCUM.**—*Angræcums* of the *A. eburneum* type are rather difficult to import, for they generally lose a large number of their lower leaves. I find it a good plan to hang them up for a time to enable the leaves that remain to become firmer in texture, after which the plants may be placed in potsherds and sphagnum, watering rather sparingly till they begin to form fresh roots. *A. eburneum* and *A. sesquipedale* are the two most showy species, but there are several others that are extremely pretty and well worth growing.

**ANSELLIA.**—Provided *Ansellias* are collected at the proper season and are packed safely there will be no difficulty in establishing them. They may be potted as soon as convenient after they have arrived, in crocks, peat, and sphagnum. They will require to be watered rather cautiously till they begin to make fresh roots, after which time they may be watered more liberally and removed to the warmest end of the stove.

**CALANTHE.**—*Calanthes* of the *vestita* type are so well known that nothing need be said here with regard to imported pseudo-bulbs, for they are propagated so readily in this country that they are not frequently imported now-a-days. This section of *Calanthes* is the most useful of any Orchids, *Dendrobiums* excepted; they are easily grown, and what makes them more valuable is that they flower at a time when choice flowers are scarce. Many gardeners imagine that they are difficult to cultivate and require some special treatment, but they grow well in any ordinary stove temperature provided they are favoured with a good light position during the season of growth.

**CATTLEYA.**—These are often received in poor, and in some

cases almost worthless condition. It sometimes happens that the collectors cannot always find them at the proper time, and are sometimes delayed in transit; the consequence is that the young growths are too far advanced. When this is the case they seldom do much good the first year; owing to the growths being made in total darkness they are very weak. After a short time it will soon be visible if they intend to grow or damp off. When the growths are in such a stage they may be greatly assisted by placing them in a very shady place for a few days, gradually introducing them to more light. The young growths will then gain strength provided there is not too much heat and moisture in the house, after which time they may be potted in a very light compost, using crocks or chareoal freely. Very little water will be required till they have fresh roots. When Cattleyas are received in good condition they are by no means difficult to establish.

**CÆLOGYNE.**—There are many species in this genus that are of no real value to the horticulturist. *C. cristata* may be regarded as the most handsome and useful; indeed, it is a plant that ought to be more extensively grown. This is not difficult to import, owing to the fact that it has large pseudo-bulbs. Even if they lose their leading growth they invariably break back from the second pseudo-bulb, making rather small growths the first year. They may be potted as soon as convenient, keeping them rather cool and dry for a time.

**CYRIPEDIUM.**—This is another useful genus and general favourite with all. The common species, such as *C. insigne*, *C. barbatum*, and *C. venustum*, are very easily managed; the choicer kinds require a little more attention. I find that some of the species, such as *C. caudatum*, *C. Stonei*, and *C. villosum*, do well potted in crocks and a little moss till they commence growing, when that may be succeeded with moss and peat, watering more liberally as root action advances.

**DENDROBIUM.**—The value of Dendrobiums is well known, and they may be classed amongst the most useful Orchids. The species vary greatly, some producing pseudo-bulbs only an inch or two long, whilst others attain the length of 6 or 7 feet. It is difficult to lay down any strict rule for Dendrobies, there being several sections, some of which grow better on blocks, others in baskets, and some in pots or pans. The same rule applies to Epidendrums as to Dendrobies. *E. cretatum* grows to a height of 8 or 9 feet, and slender, and some only attain the height of so many inches.

**LÆLIA.**—Some species of Lælia are very showy and extremely fragrant. With regard to imported Lælias they may be placed on blocks, in baskets, or potted at once; the condition in which they have arrived will be the best guide. If the growths are advanced they will require every encouragement; if, on the other hand, they are dormant it will be most advisable to keep them quiet till they start.

**LYCASTE.**—The genus Lyeaste includes two or three species that are well worth cultivating, *L. Skinneri* being the most generally useful. They will, nevertheless, require much about the same treatment, and may be potted as soon as received in a light compost, all succeeding best in pots or pans and placed in a cool stove, requiring little water till growth has commenced.

**MASDEVALLIA.**—Nearly all the species of Masdevallia are great favourites with Orchid-fanciers. Some of the most showy kinds, such as *M. amabilis*, *M. Harryana*, *M. ignea*, *M. Lindenii*, *M. tovarensis*, and *M. Veitchiana*, are extremely useful. They are rather difficult to import owing to the fact that they are found at high elevations, where it is naturally cool and moist; the great difficulty is in bringing them through the hot plains, the great variation in temperature proving fatal to thousands of plants. If they reach this country alive they generally lose a quantity of their leaves. No time should be lost in having them potted and placing them in a cool house. Masdevallias should never be allowed to become dry at the roots at any time.

**ODONTOGLOSSUM.**—Everyone that knows what an Orchid is will be familiar with at least one species—viz., *O. Alexandræ*. This species is cultivated and imported more extensively than any other, and anyone who has been a frequent visitor to the London auction rooms could not fail to observe in what unpromising condition the importations are received. Often have

paper bags of *O. Alexandræ* been sold for 10s. Probably one-half of the plants that were in the bag were nearly dead when they were bought; but the purchaser is well pleased with his bargain, for he knows that if he can only induce three or four pieces to grow he will have a cheap ten shillings' worth at the expiration of a couple of years. *O. Alexandræ* and all the other species belonging to that section may be potted as soon as convenient in a mixture of peat and sphagnum, with a little broken chareoal, and placed in a cool close house for a time till they commence growing, when more air can be admitted, for they delight in a moist cool atmosphere.

**ONCIDIUM.**—This is an extensive genus, some species of which are very showy, yellow being the predominating colour in the flowers of many species. Oncidiums are extremely variable, some species having pseudo-bulbs longer than one's fist, whilst others are quite destitute of pseudo-bulbs; *O. Lanceanum* and *O. luridum* represent the latter section. It will be safe to say that all the species possessing pseudo-bulbs may be treated as advised for Odontoglossums, the majority of them coming from cool districts; while, on the other hand, the *luridum* section requires the temperature of the East Indian house.

**PHALÆNOPSIS.**—Phalænopses have been imported rather extensively of late by two or three of the leading London nurserymen, and small plants were at one time offered at 5s. each. So many plants have been lost in transit to this country that it has been found advisable to establish the plants on sticks or pieces of wood before sending them home. If they are much shrivelled when received they will be greatly benefited by spreading them out on a board or something similar for a short time till their leaves have become a little more firm, after which they may be placed in baskets or shallow pans, and suspended from the roof in the warmest stove.

**PLEIONE.**—These will in all probability be imported in large masses, and should therefore be divided. There will be two or three-sized pseudo-bulbs. Each size should be potted separately and suspended near the glass in the stove or Orchid house. A mixture of fibry peat, loam, and sphagnum will suit them admirably. If the young growths are far advanced when imported great care should be taken not to injure the young roots, as they are produced with the growths.

**SACCOLABIUM.**—What has been advised in this paper for *Aerides* will apply with equal force to *Saccolabiums*, as they are very closely related to each other in general appearance. To grow *Saccolabiums* successfully they require a very high temperature.

**VANDA.**—These form noble plants to the Orchid house when not in flower, and when *V. tricolor* and *V. suavis* are well in flower they are very handsome. Imported plants may be treated as *Aerides*, and when established should be potted in sphagnum and chareoal.

I have only named a few of the most useful genera. It would be impossible to lay down any rigid rule for the guidance of amateurs, as so much depends on the condition in which Orchids arrived, also whether they are from cool or tropical regions.—W. K.

## STRAWBERRY FARMING.

(Continued from page 252, last volume.)

**Manuring.**—I am reminded by the near completion of the present volume that I promised to conclude my articles with a few hints on the subjects of manures and Strawberry enemies. In regard to the former subject I do not assume to lay down directions suited to all soils and localities, but confine my remarks to the course which experience has proved to be best suited for such soils as we have here. As I have a strong conviction that similar thin soils, such as cover many unreclaimed moorlands, will by-and-by be in demand for Strawberry farms, and that such soils will be found the most profitable for the purpose, my remarks may be of some benefit to intending growers.

A cardinal rule in all cultivation is to return to the soil a full equivalent to what we may remove. In the case of the Strawberry the necessity of this is even more apparent than in ordinary farming, for here there is properly no annual rotation of crops. The same crop is raised year by year so long as we can induce the plants to bear, and the Potato rotation every five or six years is looked on more as a cleaning than a recruiting crop. The same

ingredients are therefore being drawn from the soil year after year. First of all we lift the annual crop of from 1 to 3 tons of fruit per acre; next we annually lift, say, double that weight of runners and weeds with adhering soil; then lastly, at the end of the rotation, we remove all the old plants, say 10 tons per acre. This constant drain upon a thin stratum of soil must in a few years render it incapable of further production, unless we can contrive to restore a full equivalent. It is evident that we simplify the problem by first of all restoring the weeds and plants in the form of a decayed compost, leaving only the equivalent for the fruit to be considered. Some growers in their ignorance burn all weeds, reducing the equivalent of a ton of soil to 1 or 2 cwts. of sand with a slight admixture of potash and other minerals; and, as if even this were of no value, neglect to return it to the land, or only scatter it about the spot where it was burned. In this way the body of the soil is reduced, and the valuable volatile products of the plants dissipated in the air.

In the early days of sugar cultivation in the West Indies it was usual to employ as fuel the magass, or refuse cane from which the juice had been extracted, the ashes being carefully returned to the land. Gradually but surely the fertility of the soil diminished. Experts recommended various animal and mineral fertilising agents, but the full powers of the soil were not recovered until the megass was replaced by coal and returned as a top-dressing to the land. The humus was being surely exhausted, and no mineral matter could take its place in enabling the soil to retain sufficient moisture to render soluble the food ingredients contained in it. The case is very similar to what is now before us. The ripe fruit of the Strawberry, like the expressed fruit of the sugarcane, contains little else than water, and its removal from the land only slightly impairs its powers. The more solid parts of the plants and weeds rob the soil to a far greater extent, and the first concern of the grower should be to return these in the form best fitted to repair the loss. This brings us to that most valuable adjunct of the Strawberry farm, the compost heap. Thither all refuse from the land should be carted and stacked in neat heaps 4 or 5 feet deep. Some at once mix the rubbish with quicklime to hasten decomposition, but it is better to allow the heap to ferment, which it will speedily do if stacked when somewhat dry. We believe in using as little lime as possible, and find that 1 cwt. to the ton of rubbish is quite enough if the heap be first allowed to heat for a month or two.

After turning and mixing with the lime and any road-scrappings or ditch-cleanings that may be available the heap is again allowed to ferment for a month or more, when, as fast as good barnyard manure can be obtained, it is turned over by degrees and well mixed with the manure. The latter is used as fresh as possible, and in quantity sufficient to heat thoroughly when mixed. This heating effectually destroys the vitality of any weeds or seeds that might afterwards become troublesome. From time to time the contents of the wash-tank may be thrown over the heap, and by the time the season for top-dressing comes round the whole should appear a mass of fibrous soil. We recommend its use mainly as a top-dressing for all plantations that have yielded a crop. Young plantations well laid down ought to do without dressing till they have yielded a full crop. The compost is spread along the rows of plants on the approach of winter, and besides affording nourishment in the most suitable form helps to protect the crowns from frost. The rows are then slightly earthed up with the plough. The portions of plantations nearest the buildings may have the contents of the wash-tank given them instead of top-dressing during the winter. Such is all the assistance in the way of manure that the most successful growers in this quarter give their plants, and nothing else seems requisite. We thus return all we take from the soil, the added manure being considered a full equivalent for the fruit sold off.

Artificial manures have been tried, though in a haphazard way, but I have not been able to trace any distinct benefit from their use; notably, some of the farms mainly employing them give every sign of exhaustion, especially where combined with the plan of burning the rubbish. I therefore avoid giving any directions as to such manures. To be applied at all with certainty of advantage we should require a careful analysis of soil, plant, and fruit, and this I cannot afford. Were such an analysis taken, say, of soil producing the highest quantity of fruit (and there are instances of 4 tons to the acre in this locality), one might have data on which to decide with certainty the kinds and quantities of artificial manures necessary to maintain the fertility of our soil, or to render other localities suitable for this valuable crop. Meanwhile I find that the course I advocate is eminently successful.—  
WILLIAM RAITT, *Blairgowrie*.

NOTE.—The annual growth of spongiolous roots on or near the surface renders surface-dressing almost a necessity; and if, as I

venture to think, these roots are the main feeders of the fruit, while the older and deeper roots are the feeders of the plant itself, there is a ready explanation of the excellent effects of such dressings when applied so that they can be readily assimilated.—  
W. R.

#### CHÆNOSTOMA HISPIDUM.

THE genus *Chænostoma*, though including more than twenty species, is not largely represented in English gardens, for few species besides *C. hispidum* and *C. polyanthum* are in cultivation, and these are rarely seen except in a few large and choice collections, such as those of the leading botanic gardens. They might, however, well receive more attention, as dwarf compact plants that possess any pretensions to beauty are always useful for deco-

Fig. 72.—*Chænostoma hispidum*.

rative purposes, especially in greenhouses or conservatories, where the want of sufficient diversity in the plants suitable for the front row on shelves and stages is frequently experienced. *C. hispidum* (fig. 72) is particularly useful for this purpose, as neat compact little bushes 6 to 9 inches in height may be obtained in 60 or 48-size pots; and though the pinkish white flowers are small, they are produced in great numbers and continuously over a good portion of the summer, sometimes quite concealing the foliage, the plants resembling compact masses of flowers. A compost of light loam, peat, and sand suits both *C. hispidum* and *C. polyanthum*, the latter differing from the former chiefly in its more straggling habit, and in its flowers being mauve or lilac-tinted. Propagation may be effected either by seeds or cuttings in spring, though cuttings may also be inserted in early autumn.—L. C.

#### GARDEN POTATOES.

WILL you let me point out that "SINGLE-HANDED'S" first proposition on page 371, that "Potatoes on rich old garden soil produce much greater crops of haulm than of tubers," is hardly correct or to the point? The expression is vague, misleading, and unscientific, especially coming from such a writer. Had he said that "haulm was produced at the expense of tubers in soils over-rich in soda and lime, and deficient in potash," he would have conveyed a distinct and plain meaning; and had he added that the continual application of farmyard manures tended to produce this state of things, it would have expressed all he wished. Rich old garden soil is produced in most cases by the application of stable-yard manure which the gardener is usually allowed, and this, together with the returned vegetable refuse—if in a green state all the better—will keep a garden fertile for

a very long time, if not for ever. Our garden here is about one hundred years old, and has, as long as anyone remembers, been tilled exclusively with these manures, and it continues to produce good crops of all kinds of vegetables, Potatoes especially. We have had tubers lying in the fruit-room for a month, some of which weigh 2 lbs. each. These manures will provide a considerable quantity of potash, straw and manure included in the stable-yard manure, but not nearly enough, according to "SINGLE-HANDED," and our Potatoes ought by this time to be elongating their tops and producing fewer and fewer tubers of constantly decreasing size, but such has not happened yet. Indeed the haulms have never been over-luxuriant—not more than I like to see them. Onions are equally as good as Potatoes. The subject taken up by your correspondent is an important one; and I might, perhaps, suggest that the interests of the practical gardener would be best consulted by taking up one garden vegetable at a time, stating what substances it requires most of to grow it successfully, and where the gardener can most readily find them. There are plenty of works on plant-chemistry, some, I think, published at your office; but in practical garden articles I think the subject might be brought home in a more concise manner than is being done, and more to the advantage of those for whom the information is intended.—PRACTICAL.

### CHRYSANTHEMUM SHOWS.

So far the exhibitions have proved better than was expected by many growers, but there has been more irregularity in the exhibits than usual, some being of excellent quality, and others of very inferior merit. Both incurved and Japanese blooms have been well shown in the leading collections, but really good specimen plants have not been so numerous as during previous years.

#### RICHMOND.

THOUGH this was the first Show of the season, and fixed at a somewhat early date—the 10th inst.—even for the south in the present year, and though many had predicted a failure, yet it is satisfactory to record that in number of exhibits and general good quality all the success was attained that could have been desired by the most hopeful of the Society's supporters. As on the last occasion, the spacious and handsome rooms of the Castle Hotel were secured for the Exhibition, one being devoted to the groups of Chrysanthemums, the majority of the specimen plants, the fruit, and a few miscellaneous exhibits, while the other which overlooks the Thames contained the cut blooms and table plants, the small intermediate apartment being appropriated to the vegetables.

*Groups.*—One class was provided for a group of Chrysanthemums arranged for effect, to occupy a space not exceeding 50 square feet, the prizes being £2 10s., £2, and £1 10s. The competition was extremely spirited, nine groups being entered, forming the chief feature in the first large room. The plants, too, were mostly in good condition, the flowers large, and the arrangement tasteful. But in those that failed to secure a position among the prizewinners the principal defect was the bareness of the front rows, due to the plants employed being too tall. Two feet height of bare stems in the front allowed all the pots to be seen, and imparted a harsh unfinished appearance to some that were otherwise satisfactory. The chief honour was adjudged to Mr. C. Bond, The Gardens, Orford House, Ham, who staged a bright and compact but not crowded group, the blooms being of notable size, and the different colours well disposed. Mr. W. Brown, St. Mary's Grove Nursery, Richmond, was a very close second with a handsome group, the only defect of which was a rather too noticeable approach to crowding; but for this it would have well merited a higher position. Mr. J. Sallows, gardener to J. J. Flack, Esq., Heddingham House, Twickenham, was third, his plants being very strong and the foliage surprisingly vigorous, but the flowers were scarcely sufficiently numerous, and the arrangement was rather loose.

*Specimen Plants.*—These formed the weakest portion of the display, not in numbers but in quality. The leading collections were generally satisfactory, but there was considerable disparity in the equality of the second and third-prize plants in most of the classes. In the class for six large-flowering varieties Mr. Sallows was placed first with dwarf flat-trained even specimens, Mrs. Dixon, Mrs. G. Rundle, Julia Lagravère, George Glenny, and St. Patrick being the most noteworthy. All were flowering well. Mr. G. Stevens, St. John's Nursery, Putney, followed with larger specimens, not so formally trained, but bearing abundance of flowers, especially an example of Julia Lagravère, which was very handsome. Mr. J. Coombes, Sheen House, Richmond, was third with small plants. For three standard large-flowering varieties Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, was the chief prizetaker with neatly trained examples of Mrs. G. Rundle, Mrs. Dixon, and George Glenny. Mr. Sallows followed closely with good plants, but too recently tied. The best single specimen in the large-flowered section was Mrs. Haliburton from Mr. E. Beckett, who was followed by Mr. Stevens with Mr. Brunlees, and Mr. G. Trussler, gardener to A. Cooper, Esq., Thistleworth, Twickenham.

Specimen Pompons were shown in four classes, but the best were those in the class for six specimens trained with single stems. Mr. G. Stevens was first with dwarf neat plants of Lilliputian, Rosinante, Golden and Lilac Cedo Nulli, Mr. Hutt, and Bijou. Mr. W. Brown followed with taller plants, President being very fine. Mr. J. Wainstaff, gardener to J. H. Elam, Esq., Firsleigh, Isleworth, staged the finest single specimen—a handsome example of Rosinante, flowering profusely. Mr. J. Coombes followed with Mdle. Marthé, and Mr. W. Brown with President, both good. The above-named exhibitors also secured the chief prizes in several other smaller classes.

*Cut Blooms.*—The competition in nearly all the cut bloom classes was very keen, two long tables being occupied with the boxes. Three classes were devoted to incurved varieties—namely, for eighteen, twelve, and six. The best stand of eighteen was contributed by Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, the flowers being of excellent form, but those in the front row were slightly flat, and the others were not large but very neat. The varieties were Miss Mary Morgan, Snowball, Prince Alfred, Princess of Wales, Baron Beust, Mr. Heale, Inner Temple, General Bainbrigge, Princess Teck, Lady Hardinge, George Glenny, Princess Beatrice, Barbarossa, and Eve. The bloom of Inner Temple was one of the best we have seen. Mr. E. Berry, gardener to the Countess of Leven, Roehampton, was second with good blooms, but not quite so even as the first. Nil Desperandum, Rev. J. Dix, and John Salter were admirably represented. Mr. J. Bennett, gardener to F. Rodewell, Esq., Feldheim, Wimbledon, was third with neat blooms. There were five exhibitors. Ten collections were staged in the class for a dozen blooms, and nearly all were satisfactory. Mr. W. R. Strong, gardener to Mrs. Reid, Kenwolde Court, Virginia Water, was an excellent first with very handsome blooms, particularly the examples of Golden Queen, Empress of India, Golden Empress, and Queen of England in the back row of the stand; these were not only large but of great substance and good form. The other blooms were of similar merit. Mr. Elcombs, gardener to F. H. Brown, Esq., Lawn Bank, Teddington; and Mr. C. Slade, gardener to Lady Bowater, Richmond, were second and third respectively with very creditable blooms. Collections of six were well shown by Messrs. W. R. Strong, E. Coombs, and J. Strong, gardener to H. Sweet, Esq., Dornley House, Weybridge, who were the prizetakers among nine exhibitors.

Japanese varieties were represented by several beautiful collections. The best twenty-four blooms were staged by Mr. E. Molyneux, and were greatly admired, being large, of good substance, and bright in colours. The chief varieties were Baronne de Prailly, Peter the Great, Alba Plena, Cry Kang, Mdle. Moulise, Duca!, Peter the Great, James Salter, Criterion, M. Ardene, Hiver Fleur, Bouquet Fait, Elaine, Madame Berthe Rendatler, L'Incomparable, Nympe, Triomphe du Nord, and Red Dragon. Mr. Sallows was a close second with fine flowers but rather looser than the first. Bronze and Red Dragons, Chang, and Nympe were noteworthy. Mr. W. R. Strong was third, his best blooms being Père Delaux and Triomphe du Nord, the former very rich in colour. Five collections were staged. The class for twelve was well filled, eight competitors entering. Mr. G. King, gardener to R. Few, Esq., Esher, was accorded chief honours for excellent blooms of Soleil de Levant, Criterion, Oracle, Cry Kang, and M. Ardene amongst others; Messrs. J. Strong and J. Hill, gardener to A. Savory, Esq., Potter's Park, followed closely. Mr. J. Hill gained the first prize for twelve reflexed blooms, the varieties being Cloth of Gold, Christine, Golden Christine, Mrs. Forsyth, Dr. Sharpe, Phidias, and Chevalier Domage, all of fair quality. Mr. Sallows was a good second, his best blooms being Mrs. Forsyth, William Shipman, Annie Salter, and Mazeppa. Anemone-flowered varieties were not largely shown, nor were they of first-rate quality. Mr. J. Bennett had the best, including Lady Margaret, George Sands, Empress, Prince of Anemones, Fleur de Marie, Gluck, and Mr. Pethers.

*Fruit.*—Though not so largely shown as last year, fruit of good quality was staged, particularly the Apples and Pears. For a collection of six dishes of fruit Mr. J. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, was first with well-coloured Alwick Seedling and Muscat of Alexandria Grapes, neat King of the Pippins and Hollandbury Apples, and Beurré Superfin Pears. Mr. J. Munro, gardener to Lady Chichester, Cambridge House, Twickenham, followed. The best four dishes of Apples among the thirteen collections staged were from Mr. E. Beckett, the varieties being Cox's Orange Pippin, King of Pippins, Emperor Alexander, and Blenheim Pippin, all of even size. Mr. Kinghorn, Sheen Nursery, Richmond, was a very close second with fine examples of Ribston and Blenheim Pippins. Mr. W. Fanning, The Convent, Roehampton, was third. Eight collections of Pears (four dishes each), Mr. G. King winning the premier prize with Marie Louise d'Uccle, Beurré Diel, General Todtleben, and Catillac. Messrs. W. Fanning and Hudson followed in that order.

*Vegetables.*—In the class provided by the Society for a collection of vegetables, six varieties, the competition was remarkably keen, though the prizes were small. Fifteen collections were staged. Mr. J. Hill was first with creditable examples of Autumn Giant Cauliflowers, Snowflake Turnips, Aigburth Sprouts, Model Cucumbers, Hathaway's Excelsior Tomatoes, and Schoolmaster Potatoes. Messrs. J. Edie, gardener to P. Adie, Esq., Worton Hall, Isham, and B. Murrell carried off the other prizes with clean healthy vegetables.

In addition to the above, table plants were numerous and well

represented, bouquets and stands of flowers also. Several special prizes were offered, the chief being those presented by the Duke of Teck, Baroness de Rothschild, John Hales, Esq., G. G. Meason, Esq., and Messrs. Daniels Bros., for all of which the competition was good. Among the miscellaneous exhibits not for competition were fine groups of Primula and Pelargonium blooms from Messrs. H. Cannell and Son, Swanley; Cyclamens from Mr. R. Clarke, Twickenham, and Messrs. C. Lee & Son, Hammersmith; and wreaths from Messrs. Smith and Larke, Kensington. The general arrangements of the Show were well conducted by Mr. G. Eyles, who is now Secretary to the Society.

## CROYDON.—NOVEMBER 14TH.

A pretty show was provided in the small Public Hall by the Croydon Horticultural Society, most of the thirty-five classes enumerated in the schedule being represented by several exhibits. Cut blooms were well shown in all the sections, the Japanese and incurved being particularly good in size, substance, and colour. There was a falling-off in the number of plants and Grapes, but the fruit and vegetables were finer than usual, and altogether the Exhibition was quite satisfactory and creditable to the management of the energetic Secretary, Mr. A. C. Roffey.

*Cut Blooms.*—The chief class in this section was that open to all England for twenty-four cut blooms, comprising twelve Japanese and twelve incurved. The premier prize was secured by Mr. E. Gibson, gardener to J. Wormald, Esq., Morden Park, who had some very even substantial flowers. His Japanese included Fair Maid of Guernsey, M. Ardene, Criterion, Baronne de Prailly, Peter the Great, Ethel, Hiver Fleur, Cry Kang, Red Dragon, Lutea striata, Garnet, and Fulgore. The best incurved were Golden Queen, White Venus, Venus, Golden Empress, Refulgence, Barbara, Prince of Wales, Beethoven, Mrs. Dixon, Mrs. Rundle, Golden Eagle, and George Glenny. Mr. J. Fewell, gardener to J. C. Lanyon, Esq., Birdhurst, was a very good second, his incurved blooms being particularly neat in form. The chief class in the section confined to gardeners and amateurs within a radius of four miles from the Town Hall was that for twenty-four incurved blooms, in which Mr. Fewell was the most successful exhibitor, carrying off the first prize with small very well-formed blooms. Mr. T. Elsey, gardener to D. Cornish, Esq., Dagnal Park, and Mr. J. Johnson, gardener to W. C. Straker, Esq., Hazelsland, followed closely. Messrs. Fewell and Johnson also staged the best collection of twelve incurved varieties. Mr. Fewell won the premier prize for twelve Japanese blooms with good examples of Daimio, Madame B. Rendatler, and Sarnia; Messrs. Elsey and Johnson securing the remaining prizes with smaller blooms. Good collections of twelve large Anemone-flowered varieties were contributed by Messrs. Fewell and Elsey and Johnson. The class for twelve large-flowered varieties shown with foliage as grown was interesting. Mr. Fewell was again the leading exhibitor, having Garnet, Roseum Pictum, and Dr. Masters in good form. Mr. S. Brice, gardener to Mrs. Frith, Addiscombe Road, was a close second, the Anemones Fleur de Marie and Acquisition being the chief flowers. Mr. Edwards, gardener to W. M. Robinson, Esq., was third. For six blooms of any large-flowering variety Mr. Fewell was first with Sarnia. Mr. Waghorn, gardener to Dr. Stokoe, Beddington Park, second with Golden Beverley; and Mr. Edwards third with Alma. In the amateurs' classes some of the chief prizetakers were Messrs. F. Minchener, D. Waghorn, L. Elsey, and Brice.

Only two groups of plants were staged, the first by Mr. J. Woods, and the second by Mr. F. Minchener, both small but well arranged. In the class for three large-flowered plants Mr. F. Green, gardener to A. Burton, Esq., Park Hill Rise, secured the chief award with Queen of England, Cherub, and Christine, both fairly well flowered. The same exhibitor was first with a single specimen of Christine. Mr. G. H. Cooper, nurseryman, Sydenham Road, showed a stand of good blooms including Japanese, Anemones, and incurved. Mr. W. Curd, florist, Addiscombe Road, exhibited a fine bank of Chrysanthemums and a group of miscellaneous plants. Mr. C. Chaff, Park Hill Nursery, Croydon, staged a pretty group of Chrysanthemums and other plants. Mr. W. Carr, gardener to Stephenson Clarke, Esq., Croydon Lodge, contributed a number of neat standard flowers very well, and arranged up the centre of the room. Several table plants and Orchids were also shown from the same garden. Mr. Fewell staged neat specimen Ferns in the class for four, *Asplenium marinum* and *A. myriophyllum* being particularly healthy, especially the latter. Primulas were well shown by Mr. C. Welstead, gardener to Mrs. Lodge, and Mr. Fewell.

*Fruit.*—Apples and Pears were much more largely represented than usual, the quality being good and the entries numerous in each class. For three dishes of Pears Mr. J. Woods, gardener to J. Nickinson, Esq., Sankeston House, Thornton Heath, was first with good samples of Duchesse d'Angoulême, Beurré Colmar, and Beurré Diel. Mr. W. Jones, gardener to J. R. Brougham, Esq., The Bridge, Wallington, and Mr. J. Rodbourne, gardener to Baron Heath, Coombe House, followed closely in that order. For three dishes of dessert Apples Mr. W. Jones was the winner with Blenheim Pippin, Cox's Orange Pippin, and Ribston Pippin, all of fair size; Messrs. J. Woods and Rodbourne being second and third respectively with neat samples. Mr. Jones was also first with kitchen Apples, followed by Messrs. Fewell and Rodbourne. Mr. J. Fewell was accorded chief honours for three admirably coloured bunches of Black Alicante Grapes; Mr.

C. Crouch, gardener to J. Cooper, Esq., Duppas Hill, taking second with large bunches of the same variety, but rather too much rubbed. Mr. Fewell had the only collection of white Grapes—three finely finished bunches of Muscat of Alexandria. Mr. J. Penfold, gardener to the Rev. Canon Bridges, Beddington, contributed a collection of eighteen dishes of fine Apples not for competition. Mr. J. Woods also had a collection of Apples and Pears; Mr. Evans, gardener to Lady Ashburton, Addiscombe Park, staged an interesting collection of Quinces, Oranges, Pears, and Apples, and Mr. C. Chaff sent several examples of Apples.

*Vegetables.*—Several very satisfactory collections of vegetables were staged. Mr. J. Cooper, gardener to J. C. Macdonald, Esq., Waddon, was accorded the premier prize for well-grown Cauliflowers, Savoys, Parsnips, Brussels Sprouts, and Onions among others. Mr. Fewell was an extremely close second; his Cauliflowers and Savoys being excellent. Mr. Rodbourne was third with smaller examples. There were five entries. Mr. W. Curd also contributed a collection not for competition. Potatoes were shown by Mr. F. Minchener, South Norwood, and J. Johnson. Mr. Gold McKay, West Croydon, contributed a pleasing group of plants, fruit and vegetables.

All the chief exhibits not in competition mentioned above were highly commended by the Judges.

## STOKE NEWINGTON.—NOVEMBER 14TH AND 15TH.

A very satisfactory Exhibition was arranged in the Assembly Rooms, the cut blooms and specimen plants being equal to the general style characterising the exhibits at Stoke Newington. Mr. W. Goldsmith, the Secretary, deserves much credit for his energetic efforts to maintain the credit of this old-established Society.

*Specimen Plants.*—In the class for ten specimen Chrysanthemums Mr. H. Langford, gardener to J. Barnet, Esq., Coleraine House, Stamford Hill, carried off the premier prize with very handsome specimens well grown and bearing some fine blooms. The varieties were George Glenny, Julie Lagravère, Barbara, Madame Marthe, Christine, Mons. Charles Hubert, Lord Derby, Roseum Pictum, Fair Maid of Guernsey, President, all very good. Mr. W. Monk, gardener to W. Fowler, Esq., Forest House, Leytonstone, was placed second with a less even collection, but including several very fine specimens, especially the standards at the back—namely, Fanny, Venus, and The Cossack. Other specimens were also highly creditable to the grower. For the best half-dozen plants of large-flowered varieties Mr. Langford was again the leading exhibitor with very compact vigorous specimens in admirable condition, especially Princess of Wales, Hero of Stoke Newington, and Mr. Corbay.

Standard specimens were a remarkable feature, and were represented by some very handsome plants. Mr. S. Gilbey, gardener to B. Booth, Esq., The Cazenoves, Upper Clapton, won principal honours with four admirably grown and neatly trained specimens of the varieties George Glenny, Prince of Wales, Mrs. G. Rundle, and Mrs. Dixon. Mr. F. Wells, gardener to W. H. Smee, Esq., The Limes, Woodbury Down, was a very good and close second, his plants being trained a little flatter than the other. In the class for four Pompon standards the last-named exhibitor gained the first prize with excellent examples of Antonelli, Bob, Madame Marthe, and Lilac Cedo Nulli, all very well flowered and evenly trained. Mr. Gilbey followed, his two best plants being the dark-coloured varieties Prince Victor and Fanny.

Dwarf-trained Pommions were similarly well shown by several exhibitors. For five plants in pots not exceeding 9 inches in diameter Mr. F. Wells carried off the principal award with highly creditable examples of Sœur Melainie, Prince Victor, Golden Cedo Nulli, and Mrs. Hutt. Messrs. H. Langford and S. Gilbey followed with less evenly trained plants. Only one collection of six Pommions was staged—namely, by Mr. F. Wells, who was deservedly awarded the chief prize. The plants were flowering most profusely, Fanny, Madame Marthe, Cedo Nulli, and President being the varieties. The best single specimen was exhibited by Mr. Langford—a large example of Peter the Great, 5 to 6 feet in diameter.

*Cut Blooms.*—The principal class in the incurved section was for twenty-four blooms, in which flowers of very high quality were shown. Mr. S. Gilbey gained the first prize with very even, substantial, handsome blooms of the following varieties—Empress of India, Golden Queen of England, Princess of Wales, Nil Desperandum, Lady Hardinge, White Beverley, Barbara, Hero of Stoke Newington, Antonelli, Golden Beverley, Princess Teck, Mr. Brunlees, Golden Empress, Mrs. Heale, John Salter, Queen of England, Princess Beatrice, White Globe, Refulgence, Jardin des Plantes, Eve, Cherub, and George Glenny. Mr. Martin, gardener to F. Appleford, Esq., The Cedars, Woodbury Down, was second with smaller blooms, but very neat and bright in colour. Mr. R. Payne, gardener to J. R. Crook, Esq., Warwick House, Stamford Hill, was third, the last two collections being very nearly equal in quality. The competition in the class for twelve blooms was keen, and the quality of the blooms good. Mr. E. Young, gardener to G. Thompson, Esq., Stamford Hill, and Mr. G. Langdon, gardener to Drs. Monroe and Morris, Brook House, Clapton, were awarded equal first prizes, the blooms in both stands being of moderate size but excellent in form and substance. Mr. Payne was placed third. Mr. F. Wells' collection was highly commended. Messrs. E. Young, F. Wells, and G. Langdon had the best stands of six incurved blooms among half a dozen competitors. In the Boroughs of Hackney and Finsbury district class Mr. W. Gold-

smith, Grove Road, Stamford Hill, was deservedly placed first with very creditable samples. Mr. J. Broughton, 86, Winstone Road, Stoke Newington, had a good second-prize collection. Mr. D. Mouk, gardener to H. P. Leschelles, Esq., The Highams, Bagshot, Surrey, was the winner of chief honours in the open class for twenty-four blooms, staging very neat examples. Equal second prizes were accorded to Mr. W. Monk and Mr. R. Strong, gardener to Mrs. David Reid, Kenwolde Court, Virginia Water, who both exhibited well. Japanese varieties were not largely represented. Mr. W. R. Strong carried off chief honours for twelve with fine blooms, being followed by Mr. W. Monk, who showed his blooms with stem and foliage attached. The prize offered by Mr. G. Peachey, Stamford Hill, for the best bloom of the new *Chrysanthemum Angelina* was awarded to Mr. W. Martin for a beautifully formed flower of that variety.

A very handsome collection of blooms not for competition was contributed by Mr. Thomas Cochrane, Superintendent of Finsbury Park. They were greatly admired, some blooms being unusually fine, especially Princess Beatrice, Barbara, Dupont de l'Eure, and Mrs. Heale.

#### BOROUGH OF LAMBETH.—NOVEMBER 14TH, 15TH, AND 16TH.

The bad effects of the present season, so generally regretted, were but slightly apparent at this amateur urban Society's exhibition. The plants were not quite so numerous as usual, perhaps, and in some of the smaller classes for cut blooms the quality was not quite up to the usual standard. In other respects there were few notable defects, and the members and exhibitors deserve much credit for the satisfactory results obtained in such a crowded district of the metropolis. The past season has been an unfortunate one for the Society, as it has lost two of its leading officers—namely, Mr. James Wilsher and Mr. Thos. Summers, who held the posts of Treasurer and Honorary Secretary respectively, and who by their efforts had contributed greatly to the establishment and prosperity of the Society. Messrs. W. Halstead and J. R. Crisp now hold the positions of Treasurer and Secretary.

*Specimen Plants.*—The chief feature of the display were the groups of twelve *Chrysanthemums*, and in the class devoted to these Mr. W. Clarke gained the leading prize with good examples of Pompons and Anemones, the former being very well flowered and healthy. Mr. Ball followed with taller plants, and Mr. Tracy with others rather irregular. Six very well grown standards were shown by Mr. Tracy, the heads being neatly trained, and the flowers though small of good form. The same exhibitor had the best three standards, very similar in condition to the others. Mr. Fill secured the leading prize in the class for six pyramid Pompons, chiefly Anemones, healthy, but not with very large flowers.

*Cut Blooms.*—The principal collections of incurved varieties were those in the class for twelve dissimilar blooms. Mr. Ball won the premier award with very neatly formed blooms of Prince of Wales, Golden Beverley, Mrs. Haliburton, and Hero of Stoke Newington among others. Messrs. Little and Tracy secured the second and third prizes in the class in that order. The blooms shown in the class for six incurved were rather small, but the competition was keen, nine stands being shown. Messrs. Ball, Halstead, and Little were the prizewinners in that order. Japanese are always well represented at this Show, and the present occasion was no exception to the rule. Mr. Tracy won chief honours with a neat and creditable collection of twelve, of which Fulgore, Royal Soleil, Arlequin, and Orphée were the best. Mr. Ball was a close second, his blooms being very richly coloured. Mr. Crisp was third with neat samples. Five collections were staged. In the class for six Japanese varieties six stands were contributed, Messrs. Ball, Howett, and Tracy winning the prizes. Anemone Pompons were represented by four stands, the blooms being good. Messrs. Ball, Clark, and Fill were the only exhibitors. Three blooms of *Chrysanthemum* Mr. Bunn were shown by Mr. Ball. This variety is a root sport from Beverley, raised by a member of the Society in 1874.

A fine bank of flowering plants, Palms, and *Dracenas* was contributed by Messrs. J. Laing & Co, adding much to the interest of the Show.

#### WALTON AND WEYBRIDGE.—NOVEMBER 15TH.

Though, perhaps, this Show was not quite equal to some that the Society have held, yet it was very creditable to the exhibitors, and some of the collections both of plants and cut blooms were excellent. As usual Mr. Masters had arranged the exhibits to the best advantage in the three rooms devoted to them at the School, producing a very pretty effect. Taking the classes for large-flowering varieties first, the chief class was

*Specimen Plants.*—For six plants, dwarf-trained, the leading exhibitor was Mr. Cornhill, gardener to E. Pettitt, Esq., Oatlands, who staged beautifully trained, even, healthy specimens bearing good substantial blooms. The varieties were Venus, excellent; Mrs. Dixon, handsome; Mrs. Haliburton, very good; Prince of Wales, superbly flowered; G. Glenny and Baron Beust, both compact and neat. Mr. Lavay, gardener to Mrs. Wilson, Walton, was second with looser and taller specimens but well flowered, James Salter being especially fine. The best four was staged by Mr. Polley, gardener to Mrs. Rogers, Oatlands—very vigorous and neatly trained specimens. Faust was one of his best plants. Mr. Millican, gardener to Mrs. Cobbett, Walton, was a very good second, but the varieties were not so distinct as in the first. Standards were well shown by several ex-

hibitors, Mr. Millican carrying off the chief prize for four rather loosely trained examples, but bearing large and well-formed flowers. Mr. Polley followed closely with Gloire de Toulouse, the best plant being very well flowered, but a bad example of Venus spoiled the collection. Mr. Cornhill had the best single specimen—Mrs. G. Rundle, admirably grown; Mr. Lavay followed with the same variety.

Pompon varieties constituted a pleasing feature, the plants being compact and the blooms abundant. Mr. Cornhill was accorded chief honours for six specimens, trained flat, 3 to 4 feet in diameter, and as well flowered as could be wished. Astrea, Aurore Boreale, Marie Stuart, and Judy were the best varieties and the finest plants. Mr. Millican was placed second with taller and less compact specimens, the stakes being also rather too prominent; otherwise the plants were creditable examples, especially President. Messrs. Lavay, Polley, and Reed, gardener to C. H. Ledward, Esq., Weybridge, were the prizewinners in the class for four dwarf Pompons, but their productions were not first-rate. Mr. Polley contributed four very good standards, easily gaining the chief prize with Madame Montels, Marguerite de Cox (fine), Antonius, and Marie Stuart. Mr. Millican followed. For two standards Mr. Lavay was the premier exhibitor, having neat specimens of Marguerite de Cox and Stella well flowered. Mr. Polley was awarded the prize for the best single specimen Pompon, an example of Antonius.

*Cut Blooms.*—These were good generally, and in some instances specially fine. For twenty-four incurved Mr. Burrs, gardener to H. H. Rigg, Esq., Hersham, was the principal winner with even blooms of fairly good substance, including particularly fine examples of Empress Eugénie, Mr. Corbay, Faust, Rev. J. Dix, Lady Slade, Barbara, and Nil Desperandum. Mr. Cornhill secured the second position with blooms of a little less substance generally, though Baron Beust, Barbara, and Lady Talfourd were well represented. In the open class for the same number of blooms Mr. Strong, gardener to Mrs. Reid, Virginia Water, occupied the leading position with handsome specimens of Empress of India, very fine; Barbara, good; Mr. Brunlees, Golden Empress, Princess of Wales, and John Salter among several others of good quality. Mr. Burns secured the second place with blooms very little inferior to the first. Mr. Hill, gardener to H. Savory, Esq., Chertsey, was a good third with neat examples. Good collections of twelve incurved blooms were shown by Mr. Strong, gardener to H. Sweet, Esq., Weybridge; Mr. Boxall, gardener to T. A. Hickley, Esq., Walton; and Mr. Millican, the competition being keen in that class. Reflexed flowers were shown by Mr. Cornhill in satisfactory condition, the twelve for which he gained the first prize including Chevalier Domage, Dr. Sharpe, Julia Lagravère, Ariadue, and Christine, all fine. Mr. Millican had a neat second-prize stand, and Mr. Lavay took the third honours.

Japanese were strongly and well represented. The leading collection of twenty-four was staged by Mr. Brown, who had excellent examples of Soliel Levant, The Daimio, Garnet, Criterion, Baronne de Prailly, Père Delaux, Cry Kang, Chang, Ethel, and Apollo. Mr. Cornhill followed with smaller blooms, but very fresh and bright. Messrs. Strong, Millican, and Boxall staged very clean collections of twelve blooms, securing the prizes in that order.

For twelve bunches of Pompons, not less than nine varieties, Mr. Polley was successful in obtaining the chief award. The blooms were even and of good substance, the leading varieties being President, Model of Perfection, Golden Cedo Nulli, and Madlle. Marthe. Messrs. Lavay and Cornhill were second and third respectively with creditable collections. Mr. Cornhill was the premier exhibitor of twelve Pompon Anemones, his stand including Antonius, Firefly, Mr. Astie and Aster in fine form. Messrs. Lavay and Polly were the other prizetakers. Large Anemone blooms were not so well shown as usual, Messrs. Cornhill and Millican being the prizetakers with only moderately good flowers.

The special prizes offered by the Committee for the best twelve incurved blooms of two varieties were adjudged to Mr. Strong for Golden Empress and Lady Hardinge, very handsome and large, and to Mr. Cornhill for Baron Beust and G. Glenny. The prize for two *Chrysanthemums* grafted with not less than two varieties was obtained by Mr. Millican, each of his specimens being three or four distinct varieties. Dr. McDonald also presented a special prize for two hanging baskets of *Chrysanthemums*, several tasteful arrangements being contributed. Special prizes were offered by Messrs. Wilson of Walton for two standard Japanese *Chrysanthemum* plants, Mr. Lavay taking the first position with Elaine and Red Gauntlet, very finely flowered. Mr. Millican took the second position with much looser plants, but fairly good in flowers. Stands of flowers and bouquets were well shown by Mrs. Cornhill, Mrs. Cobbett, and Mrs. Wardel, also by Messrs. Plowman, Burns, Millican, and Cornhill.

#### PUTNEY.—NOVEMBER 16TH.

Four years have now elapsed since this Society was formed, and each year the shows have been so good that it must now be regarded as firmly established. The present Exhibition, as heretofore, was held in the Assembly Rooms, and never before has the large hall been so attractively and meritoriously furnished. *Chrysanthemum* plants, cut blooms, table plants, stove and greenhouse plants, fruit, and vegetables were all represented in a manner creditable alike to the cultivators and the district. The groups of *Chrysanthemums* have perhaps never been surpassed, especially those arranged by Messrs. Mahood & Son and Mr. Stevens, and the contest between

them for the cup was extremely keen. The former exhibitor was, however, successful; but Mr. Stevens' group was, perhaps, the best we have seen occupying a secondary position. The plants in both showed high cultivation, being strong in growth, with excellent foliage and grand hlooms. It is not necessary to enumerate the varieties, but highly noticeable in the first-prize group was the surpassingly rich Japanese L'Incomparable, fine tasselled rosy-salmon-coloured hlooms of Triomphe de Challet, and some seedlings. It may be stated here that Messrs. Mahood secured the prize in the class for seedlings with an unnamed variety bearing some resemblance to Meg Merrilees, but with more thread-like florets, the bloom being very large. Mr. Bennett, gardener to H. Rodewald, Esq., Wimhledon, had the third prize in the chief class for groups. The specimens on the whole were not equal to the untrained plants, still some good examples of culture were staged. Mr. Stevens was the premier exhibitor, followed by Mr. Hoskins, gardener to J. Williams, Esq., Putney. The chief prize for a large-flowered specimen plant was won by Mr. Bentley, gardener to Sir Thomas Gabriel, Bart., Wimhledon Park, with a fresh and good Mrs. Dixon; Mr. Stevens following closely with Christine. Mr. Hoskins was an easy first in the class for single specimen standard plants with Mrs. Haliburton with grand hlooms, also for six and three Pompons respectively, staging among others Golden Madame Marthe, Marabout, and President excellently. The first variety named is no doubt worth the attention of all cultivators. Mr. Tite, gardener to Mrs. Reid, Putney Hill, and Mr. Bentley had the remaining prizes for standards; and Mr. Ansell, gardener to G. Reid, Esq., Putney, for six and three Pompons respectively with healthy, informal, creditable examples. Messrs. Hoskins, Ansell, and Stevens had the prizes in the order named for single specimen Pompons, the best plant being St. Michael, a semi-glohe  $4\frac{1}{2}$  feet in diameter.

Cut hlooms were not so remarkable for size as for freshness and evenness throughout the classes, and there were but few points between the respective prizewinners. In the class for twenty-four blooms Mr. Holmes, gardener to A. B. Hill, Esq., The Hawthorns, Clapham Park, secured the first position. This stand contained the premier hloom in the Show—Golden Empress of India; very fine also were Mrs. Haliburton, Empress of India, Princess of Wales, and Prince Alfred. Mr. Berry, gardener to the Countess of Leven and Melville, Roehampton House, was an excellent second; and Mr. Handley, gardener to Miss Pearson, Wimhledon, third. In consequence of the crowd round the boxes we did not obtain the names of the winners in the class for twelve hlooms. For six blooms Messrs. Bentley, Lyne, and Berry were the successful competitors. For six blooms of Anemones the prizes went to Messrs. Berry, Bennett, and A. Holmes, all of whom exhibited well.

In the class for twelve Japanese hlooms there was excellent competition, Messrs. Stevens, Berry, and Bentley being awarded the prizes with stands of nearly equal merit. Mr. Stevens's stand contained a huge Criterion, a brilliant Mons. Lemoine, and a fine Meg Merrilees; Mr. Berry having La Nympe, superb, and Mons. Ardene, remarkably fine. For six hlooms Mr. Bentley was first, Mons. De-laux being rich, and Mons. Ardene and Fulgore very good. Mr. Lyne, Wimhledon, was a very close second, Peter the Great and Berthe Rendatler being his most noteworthy hlooms. Mr. Stevens was an excellent first for twelve Pompons, followed by Messrs. Bennett and Haines with stands of nearly equal merit.

Prizes were offered for stove and greenhouse plants, which were won by Messrs. Stevens first, Hoskins and Woodhams equal second, and Mr. Bentley third. The finest plant in these collections was a splendid example of *Dendrohium nobile* from Mr. Hoskins. Table plants were numerous and excellent, but were difficult to judge by being crowded, and it was still more difficult to ascertain the names of the prizewinners. Mr. Bennett was, however, first with superior examples. For Zonal Pelargoniums Mr. Brierley, gardener to Miss Joppin, was first with very dwarf floriferous plants, five out of six consisting of Vesuvius and its varieties; and for Primulas, which were fresh and good, Messrs. Woodhams and Newell were the most successful exhibitors. Ferns were of superior merit, especially those from Messrs. Martin, Stevens, and Bridal, who obtained the prizes. Mr. Bridal also obtained the first of Mr. Pitt's prizes for mixed groups of plants, followed by Messrs. Hoskins and Mahood.

Fruit was better than on any previous occasion at Putney. Mr. R. Holmes had the chief prize for black Grapes with Alicante superbly finished, Mr. Bennett second with Mrs. Pince well coloured, and Mr. Alderman, Elm Court, Mitcham, third with Alicante; the last-named exhibitor had the first prize for excellent Muscats, followed closely by Mr. Bentley, who had also the first prize for dessert Apples—King of the Pippins, Blenheim Pippin, and Boston Russet, Messrs. Haines and Heading taking the remaining prizes. This was a very good class, as was the corresponding one for kitchen Apples, in which Messrs. Haines, Bridal, and Woodward secured the prizes as named.

Collections of vegetables were very fine, especially those of the prizewinners Messrs. Coombes, Sheen House, Bridal and Woodward, who staged produce that is seldom excelled at any exhibition.

The Show was admirably managed by Mr. Stevens, the competent Secretary, Mr. Moore and Mr. Pitts, and was worthy of the patronage of the visitors who crowded the Hall during the afternoon and evening.

ADVICE TO YOUNG GARDENERS.—I have read with pleasure Mr. Elliott's excellent communication on page 433. I am afraid it is too

true that many young men only study their present fancies and do not think sufficiently of the later years of their life. I left a small place for a larger one, where I could acquire more experience, but received less wages. I am glad to say that I am within reach of a night school which I attend three nights a week, and the other nights I study at home. I am learning geometry and Latin, besides the usual school routine. I read and study Thompson's "Gardeners' Assistant" and Forsyth's book on "Fruit Culture," which, though old, I think good. I read this Journal every week, and I find it very instructive: but I think contributors might give their experience with less "personalities" sometimes. I have never previously contributed to a paper, and I do so now to thank Mr. Elliott and Mr. Pettigrew for the good advice they have given, so I hope older and wiser men will not look down on me for writing this.—A YOUNG GARDENER.

#### TEMPERATURES FOR GRAPES.

I HAVE no wish, and do not need to adduce other people's practice to substantiate my own; but I desire to state that Mr. Barker (page 422) is wrong in stating that Mr. Taylor's temperatures are much above mine. Practically there are no differences between them, except that while Mr. Taylor's fall  $18^{\circ}$  below the maximum temperature and  $13^{\circ}$  below the minimum recommended for Muscats by high-temperature practitioners at the flowering period, I allow  $7^{\circ}$  lower still, minimum, by fire heat. After flowering our figures are the same, only I go a little above Mr. Taylor in day heat at starting and after flowering. It must be remembered also that the Longleat vinery is described as span-roofed. With regard to the time of our Grapes ripening, that has nothing to do with the matter. I ripen all our late Grapes at the end of September in preference to a month earlier, and any of your readers who care to refer to back volumes of your contemporary the "Gardener," will find that I have on more than one or two occasions stated as much and recommended the practice.

It must also be borne in mind by those who say fire heat is needed in September to make up for low night temperatures in the corresponding month in spring—April, that the night temperature of September is very considerably higher than April, necessitating less fire heat. Further, low night temperatures are practised by me for several months at the earlier stages in February, March, and April at least. Is all the coal saved by proportionally low temperatures during all that time used in September, may I ask? and if not, when? I am perfectly sure we save coal and much of it. I am sure also that I could ripen our Muscats as soon as other people by a higher day heat alone, and may do it for experiment's sake. There is another thing to be considered. It has been stated by good authorities, Mr. David Thomson for example ("Gardener," 1877, page 148), that "Black Hamburgs as a rule colour best in a low night temperature," and I am of opinion that Muscats do also; indeed I cannot see why the rule in one case should not hold good in the other, proportionally, so long as the sun heat is made the most of.

Some of your correspondents, of which Mr. Barker of Hindlip is an example, call on their opponents to "come to the exhibition table," and show what they can do. Will those gentlemen produce their own record of victories in fruit exhibition? If they will do this I shall be pleased to produce mine, and then we shall see who has most reason to rely on that test. I am acquainted with the names of the prizewinners at our noteworthy horticultural shows for twenty years back at least, and I cannot remember that the names of some of those who have identified themselves with this discussion, and against me in this paper and elsewhere, have been so much as recorded once, and under these circumstances it hardly becomes them to trade upon other people's successes. Moreover, I have no doubt Sheffield gardeners will be glad to meet them at Handsworth. The prizes are better than are offered at Edinburgh, and as good as the best provincial shows, except Manchester, and the exhibition is patronised by such places as Thoresby, Welbeck, Osberton, Ossington, Worksop Manor, Grimstone Park, Bagot Park, and many others in England, besides your humble servant, who when he was in the habit of competing there regularly (he may be excused mentioning), carried off the £8 cup twice, and an equivalent prize in money the third time for fruit, out of a possible five times, the main feature of his exhibit on each occasion being Grapes and Pines, both grown on the cool system. I will say nothing of other shows at present. Will your correspondents who have written lately pick up the gauntlet and do battle?—J. SIMPSON, *Wortley*.

THIS subject has been much discussed in your columns of late, and I have no doubt that good will result from it. I do not wish to enter into the controversy in a condemnatory spirit regarding

either the high or low temperatures, any further than to say that I do not agree with such low temperatures for Grapes during their flowering period as some writers advocate. I consider they go too far when they recommend a night temperature of 50° for Muscats in flower, unless the temperature be proportionally high by day. What I should recommend is that the night and day temperature be recorded when writing on this subject, as they are both equally valuable to the Grape-grower. I think the saving in coals is a very small matter to consider, and will neither greatly benefit the private grower nor the grower for market. I will confine myself to a few remarks on my own experience during the past season.

All Grape-growers are aware that early-started Vines require to be brought forward more gradually than those started later in the season. High temperatures with early Vines mean small wood, poor foliage, and on the whole badly finished Grapes. At least I have found it to be the case during my experience amongst Vines. If the Vines are in healthy condition at starting they may, with judicious management, bear the strain of hard forcing for a few years. I only use a thermometer in the early house, as a rule. This season I placed one in each of the late houses during the flowering period. One of the late houses contains four varieties of Grapes—Muscat of Alexandria, West's St. Peter's, Black Alicante, and Lady Downe's. This house I tried with a low temperature, with the result that I am determined never to try the same again. Black Alicante set very well; the other varieties are unsatisfactory, especially the Muscats. The temperature of this house was sometimes as low as 50° in the morning, and never higher than 65° by day, unless with sun heat, when it was allowed to rise as high as 80° or 85°. The other house contains two varieties—Lady Downe's and Black Alicante. This was treated in the usual way. At the time the Vines were flowering the night temperature was never lower than 60°, rising by day according to the weather, and a better house of Grapes I never desire to have. The bunches are good in shape and size, large in berry, well finished, and as black as Sloes.

When I took charge here a little over four years ago, those Vines were condemned to be taken out. As they were comparatively young Vines I advised my employer to retain them; we did so, and the result is far beyond my expectation. Both houses were started at the same time, the 1st of February. In that where the low temperature was maintained the Grapes are not all fully ripe yet, and judging by appearances the Muscats never will be. In the other house they were all ripe by the middle of August, and I am sure will keep longer in good condition than those ripened later. I have found that Grapes well ripened by the end of August will keep for a longer period in good condition in the Grape room than those ripened during September and October. I cut all our Grapes on the 21st of December last year, and I sent them in regularly in good condition every day until the 26th of May in the present year. I kept two bunches of Lady Downe's in fair condition till the first week of July. They were sent in with those cut first from the early house, the old a little shrivelled, but in flavour they were pronounced to be excellent.—J. MCKELVIE, *Leadenham*.

#### DAHLIAS IN POTS.

HOWEVER beautiful Dahlias are when grown in the borders, they bear no comparison with those flowers produced by plants in pots under glass. Unfortunately the Dahlia season outside is often cut short by early frosts. But when plants are in pots their period of blooming can be greatly extended. They are invaluable just before Chrysanthemums or Camellias are plentiful. Even if blooms of the plants mentioned exist in quantity, Dahlias are still worthy of a place, as they are distinct and very showy, and some of the single scarlets possess a brilliancy not to be found in Chrysanthemums. I think some varieties of Dahlias will soon rank amongst our best flowers for conservatory decoration at this season of the year. The singles are most suitable for cutting, and when arranged with other flowers are light and elegant. Those that have not grown them should give a few plants a trial another year, and I feel confident they will not be disappointed with the results. From my experience of them in pots they are more easily grown than Chrysanthemums, and not half so liable to lose their foliage.

When the necessary stock for outdoors has been rooted, a batch of cuttings can be taken for growing in pots. They may be established in 60's and hardened off by the time it is safe to plant outside. The plants to be grown in pots can be transferred from the small size to those 10 or 12 inches in diameter, and secured to a strong stake. They can be grown outside, and need but little attention beyond abundance of water, and liquid manure when the pots are full of roots. The shoots will need pinching from

time to time to remove the flowers, discontinuing the practice according to the time the plants are wanted to bloom. The pots mentioned will be large enough for good specimens. They can remain outside until the approach of frost, when they must be housed at once.

I have now some plants in full flower and others later of a variety called White Aster. This is a gem for pots, the flowers being pure white and very freely produced. The blooms, which are beautifully fimbriated, are a purer white when opened under glass than when produced outside. For church decoration the blooms of this variety are unsurpassed. *D. Juarezii* is a curiosity amongst Dahlias with its double Cactus-shaped flowers, which are of a rich crimson colour and quite distinct from any other double variety. This is a strong and bushy grower and well suited for pots. This variety is largely grown in Mrs. Macrae's garden by my friend Mr. Woodfield, and is truly grand indoors. The single variety Paragon is very fine indoors; the beautiful colours of the flower come out so bright, which are rich dark velvety maroon with a shade of purple round the edge of the petal, the centre being yellow. *D. Cervantesii*, orange scarlet; *D. lutea*, yellow with dark centre; *D. coccinea*, rich scarlet, a showy variety and very striking; *D. glabrata*, much smaller in the flower than the above, and not so showy, and yet worth a place for the lilac colour of its flowers; *D. alba*, as its name implies, has white flowers, and is most useful for cutting. The varieties mentioned are all good for growing in pots for indoor decoration.

There can be no doubt that the single forms are by far the most beautiful and useful for cutting, White Aster perhaps excepted for some purposes. The single forms can be readily raised from seed, and I have seen, amongst a number of seedlings grown in the garden above referred to, some beautiful varieties. One was especially good and distinct, being striped like a Carnation.—W. B.

#### FRUIT TREES IN COTTAGE GARDENS.

JUDGING from the majority of cottage gardens throughout the country, I think it may safely be asserted that fruit-tree culture is neglected as a rule. In many a large old Apple or Pear tree may be seen, but a healthy plantation of young trees can hardly be found. One or two new trees may be bought-in to take the place of an old one that may be dying, but planting or cultivating with a view to profit is seldom thought about. According to what I have been told and have seen, nothing is more profitable in any cottage garden than a number of useful fruit trees; and if every cottager planted a few good varieties of Apples, Pears, and Plums, but especially Apples, in their gardens, beauty, interest, and profit would be added to their homes.

The best of fruit trees can now be bought very cheaply, and when once bought and planted little further outlay is necessary; and with some kinds, such as Lord Suffield, King of the Pippins, Keswick Codlin, and Hawthornden Apples, and the Victoria Plum, crops can almost be depended on annually. In my neighbourhood fruit trees in cottage gardens are not plentiful, but those who have them often pay their house rent or more with what is derived from the fruit they sell. This must be regarded as a clear gain, as no annual outlay is needed, and the trees can generally be grown along the sides of paths and in corners without interfering in any way with the ordinary crops of vegetables. We feel sure if a number of suitable fruit trees were planted in every cottage garden throughout the country they would prove most valuable to the owner.

From the excellent fruit notes which have lately been published in these pages information respecting fruit trees of the most trustworthy description may be learned from all parts of the country; and I would advise all cottagers and amateurs thinking of planting fruit trees to draw their information respecting varieties from this source according to their locality.

Local nurserymen, too, can always give good advice on this subject, as it is seldom they grow any varieties but those which they have proved to be most suitable to the district. In all cases we recommend that only good healthy young trees be planted. Excellent specimens of the kind we mean may be had from 2s. to 3s. each. Now is the time to plant, and cottagers should take the hint.

In selecting positions for fruit trees care should be exercised that they are not placed too close together, or too near the paths, or very much in the shade; nor do they require the very best part of the garden, as very often a few barrowloads of good loam placed in barren places will prove an excellent site for a fruit tree. Nothing surpasses fresh loam for fruit-tree culture, and the great majority of cottagers can easily secure this. In planting young trees it is important that they be made quite firm, and to insure this it is always well to stake every one securely as

it is planted. The thoughts of after culture and future difficulties need not deter the most inexperienced from planting, as if good varieties and trees are secured they will succeed in a surprising way for years without any pruning. The most fruitful trees we possess are those which have never been pruned since they were had from the nursery thirty or more years ago; and they require no more attention than the Oaks in the forest, and yet they hardly ever fail to bear a crop of fine fruit. Facts like this make us still more anxious that cottagers should enjoy the great advantages of having a few fruit trees, and we hope that abler pens will help in this good cause.—A KITCHEN GARDENER.

#### HAWARDEN CASTLE.

SEVEN miles from Chester and two and a half miles from Broughton Hall station, on the Mold and Denbigh line, Hawarden Castle is situated. The drive from the station is a pleasant one, and the greater portion on each side belongs to the owner of the Castle, the Right Hon. W. E. Gladstone, M.P. The forest

trees all along the route appear to be in luxuriant health, and many of them are of large size. The views over the landscape must be grand when the trees are clothed with foliage. The Castle is a noble building, and stands some 700 to 800 feet above the level of Chester, and was, I believe, built during the eighteenth century. On the south side is a magnificent specimen of *Magnolia grandiflora*, which covers a large space, and has reached a height of 50 to 60 feet up the Castle walls. This growth has been made since the winter of 1860-61, when the tree was cut down by the severity of the weather to within 2 feet of the ground. The injury done to it last winter was comparatively little. A short distance from this fine *Magnolia* stands a large old *Camellia*, the health of which shows the hardiness of these shrubs. From this front of the Castle a grand view of the park can be obtained, which is well wooded, undulated, and picturesque; indeed it is a question if a more magnificent park can be found in any portion of the country. The trees mostly stand singly, and must either have been judiciously planted or Mr. Gladstone has applied his axe in time. The individuality of the trees is a great feature

Fig. 73.—GLASS RANGE AT HAWARDEN.

both in the woods, park, and pleasure grounds. Many of them are of large size, and their branches sweep the ground. The late storm has not done so much damage as in many places, yet several monsters have succumbed under its force. In the pleasure grounds stand two very large Limes, their stems being about 3 feet apart, and yet joined together about 5 feet from the ground. Whether they have become united naturally or artificially I am unable to say; however, they are curious and interesting.

Some little distance from the Castle now occupied stand the ruins of the old castle. The ground appears to have been raised artificially; if so, the work was one of great magnitude. These ruins present such a natural and beautiful appearance that I cannot attempt to describe them. From the top the country for miles round can be seen—Chester, as well as the Duke of Westminster's fine seat, and all other prominent features of the neighbourhood. The hillside is covered with trees, which hide from view the ruins from the park. Below is a small running stream, which ripples and winds through the park and woods, and adds to the beauty of the scene. One side of the ruins is covered with Ivy, and the tree variety has established itself on and amongst the walls, and in many instances has attained a large size. No

attempt is made to keep the grounds in the vicinity of the ruins neat and trim; in fact, the greater portion of the grounds are of such a nature that they would be spoiled by dressing and keeping. Some large specimen Hollies 30 to 40 feet high have been allowed to develop naturally, and now look gorgeous laden with their red coral berries. Large clumps of Rhododendrons and other flowering shrubs abound in various positions, and must look gay when in flower as seen from the Castle.

The flower garden is in close proximity to the Castle on the south side, and is laid out with Box. The beds are a fair size and numerous. The design is neat, and the effect must look gorgeous during the summer season.

The glass is situated in the kitchen garden but is not extensive. The principal range (fig. 73) is being rebuilt by Messrs. Boulton and Paul of Norwich. The new range is 170 feet in length. The centre house forms a conservatory for large Camellias and Palms; this house is 50 feet by 28 feet, and faces the centre walk leading to the west point of the Castle. The lean-to houses, four in number, are each 35 feet by 16 feet, and form one early vinery, one vinery for Muscat of Alexandria, and a third for late crop; the other house is for Peaches. The houses on the left of the con-

servatory were erected last autumn. The conservatory and other houses are now nearly completed. The whole are heated by a check-end saddle boiler. In the rear are new offices, night and day rooms for the men, potting houses, fruit rooms, &c., extending the entire length of the range. The houses are arranged from plans prepared by Mr. Forsyth, and they are light, airy, and well constructed, in fact all that can be desired for the purposes for which they are intended. The young Peach trees have made luxuriant growth and have ripened their wood well. The old Vines are retained in one of the houses, and young canes from them are being trained between to take the place of the old ones in a few seasons. These Vines have made good growth in spite of their exposure outside to the severity of last winter when the house was being built. Mr. Forsyth informed me these old Vines had improved wonderfully since a quantity of fresh soil had been placed to their roots.

The fruit trees in the kitchen garden and on the walls are very old, but young trees are being planted, and others have attained a fruit-bearing condition. With these brief notes I must leave the gardens and grounds I had so long wished to see, and thank Mr. Forsyth for showing me through them.—VISITOR.

THE "HORTICULTURAL DIRECTORY," now in the twenty-third year of its publication, will be ready on the 23rd inst. Price 1s.

— IN addition to the four CHRYSANTHEMUM SHOWS that are held to-day (Thursday)—namely, Kingston, Westminster Aquarium, Tunbridge Wells, and Brixton, and which have been mentioned in a previous note—we have received information respecting the following fixtures, which will conclude the exhibiting season. Manchester, Southampton, and Northampton, 22nd and 23rd inst.; Maidstone, Birmingham, and Wimbledon, 23rd inst.; Wellingborough, 25th and 26th inst.; and Liverpool, 30th inst. As the southern exhibitions have so far proved better than was expected, we may reasonably hope that the northern shows will fully maintain their credit.

— A SCOTTISH correspondent desires to ask Mr. Jefferson if he tasted the ALNWICK SEEDLING GRAPES to which he awarded the first prize at the Handsworth Show, and if so, if he would be kind enough to state their quality. Our correspondent further asks if "SINGLE-HANDED" will be good enough to say where the Grapes were grown under the cool system that he has intimated were of excellent quality as staged at the late show at Edinburgh.

— A CORRESPONDENT recommends the following ZONAL PELARGONIUMS FOR WINTER, that he says contribute greatly to the effect of the conservatory at Norris Green, which is now gorgeous. The varieties that are extra fine are Vesuvius, Wonderful, Madame Thibaut, White Vesuvius, Apple Blossom, Sophie Birkin, and Fanny Catlin.

— THE finest Japanese Chrysanthemums in the Richmond Exhibition was PÈRE DELAUX, a variety introduced about three years ago. Mr. Strong, from Virginia Water, exhibited four beautiful blooms in different stands, which were much admired. The colour is a bright velvety red, a few florets having a slight turn-over. This fine Japanese variety is recommended to the notice of Chrysanthemum fanciers.

— ONE of the most beautiful trees in the autumn is LIQUIDAMBAR STYRACIFLUA, which might be much more frequently planted with advantage to the possessors of gardens, for at all times there is a pleasing lightness and gracefulness in the habit of the tree that admirably suits it for a position

on lawns. [During September and October last the specimens of this tree in the neighbourhood of London have been very bright, the neat and deeply cut leaves assuming rich tints of rose, crimson, and yellow, which, combined with the bright green of the unchanged portion, had a beautiful effect. In the sunlight the trees appear to be illumined by a soft rosy light that is especially noticeable towards evening when the sun is getting low.

— "INQUIRER" writes—"I have read your report of the MEETING OF THE FRUIT COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY HELD AT CHISWICK, and I observed that second-class certificates were awarded to some new Potatoes which had been grown in the garden. Can you inform me what is the value of a second-class Potato when so many first-class varieties are to be obtained? The number of Potatoes that are now being forced upon the market is so great that we can surely dispense with any that are only worthy of second-class certificates."

— "A GROWER" writes that, "the Pompon CHRYSANTHEMUM ROSINANTE is one of the really useful varieties for decorative purposes. It is free in habit yet compact, and bears its white rose-tinted flowers in dense clusters. I grow a number of small plants in 32-size pots, and find them most valuable for the conservatory during the present month. The neat clusters of flowers are well suited for cutting, as they are not too large, and the delicate tint is most pleasing when they are arranged with brighter-coloured varieties."

— THE example of SALVIA PITCHERI, shown at the last meeting of the Royal Horticultural Society from the Chiswick Garden, was deservedly admired by many visitors, and it would be difficult to display the beauty of the plant to better advantage. Single plants are rather slender in their growth, though not less attractive on that account when the flowers are freely produced; but to insure the most imposing effect several plants should be grown together, as in the case of the Chiswick specimen referred to above. About half a dozen plants were placed at equal distance from each other in a large pan, but they were sufficiently developed to fill the space without appearing crowded, and the tall spikes of bright blue flowers were secured on light stakes. In this way some dozen of spikes were brought into view in the most advantageous manner.

— THE Council of the Society of Arts, on the recommendation of the Judges in the late COMPETITION OF PLANT LABELS, are prepared to renew the offer of a Society's silver medal, together with a prize of £5, which has been placed at their disposal for the purpose by G. F. Wilson, Esq., F.R.S., for the best label for plants. The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in the open border. These considerations will principally govern the award. Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary of the Society not later than May 1st, 1882.—(Nature.)

— ONE exhibit in the class for BERRY-PRODUCING PLANTS FOR DECORATION at Richmond last week was especially noteworthy—namely, that from Mr. G. King, gardener to R. Few, Esq., Wolsey Grange, Esher, who was accorded the first prize. His plants comprised equal numbers of the compact-growing small red-fruited Capsicum Tom Thumb, and the large yellow-fruited Capsicum Princess of Wales, the latter trained as standards with a clean stem about 18 inches high, the branches being trained on a flat circular trellis, from the under surface of which the fruits were pendulous. The plants were all well grown and in small pots.

— THE meetings of the LINNEAN SOCIETY to be held during the present season, are fixed for the following dates—November 17th, December 1st and 15th. 1882, January 19th, February 2nd and 16th, March 2nd and 16th, April 6th and 20th, May 4th and 24th, June 1st and 15th. The chair will be taken at 8 P.M. at each meeting, except the anniversary on May 24th, when it will be taken at 3 P.M.

— VERY handsome at the present time is a specimen of *CESTRUM AURANTIACUM* in the greenhouse at Kew. The plant is trained up one of the pillars, and is completely covered with dense clusters of orange-yellow flowers, which in form closely resemble the well-known *Habrothamnus fascicularis*. The value of this plant cannot be over-estimated, and it is surprising that nursery-men do not bring it prominently before the public, as it is by no means common in gardens. The fact of flowering so profusely at this time of year is quite sufficient to recommend it to notice, and the specimen above referred to also flowered earlier in the season, thus giving two lengthened supplies of its peculiar tinted blooms.

— THE Lessees of the ALEXANDRA PALACE announce that in 1882 a series of special HORTICULTURAL EXHIBITIONS will be held through the whole of the year under the superintendence of the Horticultural Director, Mr. Forsyth Johnson, from whom particulars can be obtained. A permanent exhibition of horticultural appliances is contemplated, in addition to the monthly displays of fruit and flowers, some of which this year have proved very attractive.

— THE new and distinct *BEGONIA SOCOTRANA*, for which Messrs. J. Veitch & Sons, Chelsea, obtained a certificate at the last meeting of the Royal Horticultural Society, is not only a handsome and valuable addition to the genus, but it may be expected to prove the parent of a distinct race of Begonias, intermediate in general characters between the tuberous and the ordinary types. The bold peltate leaves impart quite a unique appearance to the plant. The bright rosy flowers also are neatly rounded in form, the petals differing comparatively little in size—an additional recommendation in a florist's point of view. As we understand that the plant is easily and quickly increased it will, no doubt, soon become popular.

— A CONTINENTAL periodical states that "the once famous CEDAR FOREST OF LEBANON, formerly so extensive, has dwindled down to the dimensions of a mere thicket, numbering about four hundred trees. To save it from complete destruction and preserve it at least in its present extent, the Governor General of the Lebanon has issued a special ordinance containing a series of stringent regulations calculated to check if not quite put a stop to the vandalism and carelessness of most travellers. It is expressly forbidden to put up tents or other kinds of shelter within the district of the trees, or to light fires, or to cook any provisions in their vicinity. No one is allowed to break off a bough or even a twig from the trees. It is forbidden to bring any beasts of burden, be they horses, mules, asses, or any other kind of animal, within the district. Should oxen, sheep, goats, or other pasturage cattle be found within the prescribed limits they will be confiscated."

— AMONG the TROPICAL FRUITS IN COVENT GARDEN MARKET during the last week or two some fine specimens of Custard Apples have been noticeable. These, no doubt many of our readers know, are the produce of species of *Anona*, the one in question bearing the popular name of the Sweet Sop (*Anona squamosa*), to distinguish it from the Sour Sop (*Anona muricata*). The specific name of the former refers to the appearance of the fruits, which are broadly ovoid in shape, the surface seeming to be covered with flat scales. Large specimens of the Avocado

Pear (*Persea gratissima*) have also been observable, and this fruit is not nearly so frequently seen in the market as those first mentioned. They closely resemble a Pear in shape, being about 6 inches or more in length, broad at the apex, and tapering to the base. They are reddish-brown in colour when mature, and are greatly esteemed in the West Indies. *Persea* is a Lauraceous genus allied to the Cinnamon. Though a native of our own country and other temperate regions, the fruit of the *Arbutus Unedo* is not frequently seen in the market. A week or two ago, however, several large boxes of the brightly coloured, tempting, Strawberry-like fruit were noticeable in the central avenue. The fruits were larger and more richly coloured than they are usually seen, and would make a handsome dish for the table, but would be of no other use, as, notwithstanding its attractive exterior, the fruit possesses no qualities to recommend it for eating.

— OUR correspondent "W. J. M." sends us the following note on FRUIT AT THE CLONMEL SHOW—"The display was an excellent one from local growers. Upwards of thirty varieties of Apples, nearly as many Pears, well-grown Grapes, Medlars, Nuts, and many other fruits common to this season were staged; and in addition fine specimens of green and scarlet-fleshed Melons (Eastnor Castle and Munro's Little Heath), Telegraph Cucumbers, and Garibaldi Strawberries. These came from Mrs. Bianconi, Cashel (gardener, Mr. Palmer); Shanbally Castle, the residence of Lord Lismore (gardener, Mr. Wilsher); and from Knocklofty, the residence of Lord Donoughmore (gardener, Mr. Ryan), respectively. The Apples and Pears sent by Mrs. Crean, Glenview, contained some remarkably fine specimens. The competition was very close, and the following varieties had first prizes in their several sections. Dessert Apples—Cox's Orange Pippin and King of the Pippins, also a new seedling Apple which was raised by Mr. Clibborn, Anner Mills House, larger than Cox's Orange Pippin and of the flavour of the Ribston Pippin, but larger than either, remarkably handsome in colour. Alfriston, Emperor Alexander, and Beauty of Kent were the leading varieties in the baking or kitchen section, and deservedly. Some splendid Pears were also shown. Several connoisseurs thought they had never seen finer examples of Beurré Clairgeau and Duchesse d'Angoulême; while Beurré Amanlis and Glou Morceau, as well as the immensely large Catillac and Vicar of Wakefield, were prizetakers. Equal first prizes in the class for collections of eighteen distinct varieties of fruit went to Lord Lismore and Mrs. Bianconi, and second to Lord Donoughmore. There were three splendid collections of vegetables, each containing at least thirty distinct varieties. The first prize went to Captain Moore of Barne (gardener, Mr. Saville)."

#### THEORIES IN GRAPE CULTURE.

I AM glad Mr. Bardney has criticised my remarks under this heading on page 383, and in a right spirit too. Personalities engender personalities, and should be avoided in public controversy as much as possible. A person may be altogether wrong in his ideas and practices, but if he ventures to publish these, and thereby provokes an instructive discussion, he is deserving of credit for his share in the good work; at all events there is no necessity to point out his lack of ordinary intelligence as an argument against him.

It seems I have advanced too much or not enough to satisfy Mr. Bardney; but it is difficult to be brief yet explicit. My argument is against extremes, and it is simply this—it is a mistake to rob Vine borders of much of their fertility to meet the supposed requirements of the young Vines, and that the results would be nearly or quite as satisfactory in the first instance, and decidedly more lasting, if the practice of regulating the top growth were more in accordance with that I endeavoured to describe. According to my experience, the disadvantageous result of so much unrestricted growth is the creation of many more roots than are really needed, and a

houseful of growth that will be cut away and burnt. The latter however, Mr. Bardney says, is not a loss, as the ashes "can be returned to the border for food again for the Vines." I cannot but admire that observation. Wood ashes are undoubtedly of great service to the Vines, as supplying the requisite potash; but the ashes thus obtained, even if applied, would not go far towards restoring the fertility needlessly expended.

The advantage claimed by Mr. Bardney as the result of unrestricted growth is the certainty of securing heavier and well-finished crops without the risk of early exhaustion. Now this is just the result I ask for proof of; but it must be further substantiated to convince me. For instance, what number of bunches did Mr. Bardney allow on each Vine the second year after planting, and again the third year, and their aggregate weights?

Mr. Bardney's case alone, however, whatever the results may be, is not sufficient to demonstrate the correctness of his or the incorrectness of my assertions, simply because his borders are made piecemeal, whereas the majority of cultivators, either of necessity or from choice, complete their borders at once. These, therefore, have not the opportunity of pinching back the leading roots in order to more thoroughly fill a limited width of the border. On the contrary, the roots rapidly run through the whole, and as rapidly exhaust that whole of its fertility. What is the consequence? The first few years excellent crops and prizes are taken, but presently comes a reaction, and unless an expensive remedy in the shape of a renewal of the border is resorted to, failure from exhaustion takes place. Of such growers it is said "they have had their day," "their borders are exhausted," "their Vines are getting old," and similar, by no means complimentary, expressions. It is true that borders can be enriched from the surface, but after all that is not equal to what the roots find in the body of a well-constituted unexhausted border. If this is not so, why does Mr. Bardney shift his Vines from the pots in which they were grown into still larger pots? or Mr. Coleman and other noted growers frequently renew the fronts of their borders? All borders eventually become exhausted, and it is necessary to renew them occasionally; not, however, to furnish food for storing, but rather to provide a feeding ground for the next season's new roots. At the risk of being again voted ignorant, I assert there is a possibility of storing up much sap needlessly. Did anyone observe any great harm accrue to Vines that bled excessively when started? I never did; and I am not in the habit of going about with, metaphorically speaking, my eyes shut.

Growers of Vines in pots will not be much impressed with Mr. Bardney's crop. A weight of about 6 lbs. of Grapes per Vine is far from being an extra heavy crop. In the large pots Mr. Bardney fruits them in they ought to perfect such a crop, and not be exhausted, without resorting to extended top growth.

I have two important reasons for finding fault with Mr. Bardney's otherwise excellent practice with the planted-out Vines. The first fault is encouraging the leading shoots to extend as fast as they can till they "resemble a thicket at the top of the house, the laterals only being pinched up to the place where the leader was stopped the second time." By so doing he strengthens the top of the rod at the expense of the base; the only advantage really gained being an "abundance of sources in which to exhaust the supply of sap." This again is a doubtful advantage. Anybody can grow good bunches at the top of the house, but it is not everybody who can secure equally as good at the front. Make a good start by well furnishing the base with vigorous laterals, and by ordinarily fair treatment these will continue strong. It is at the base where growth should be encouraged in case of defective root-action, and not at the top; at all events, to so great an extent as your correspondent advocates. There is no doubt unrestricted growth enlarges the stems, but nurserymen do not depend upon the head of a young standard Apple tree to strengthen the stems; on the contrary, the laterals are retained and gradually shortened till this is accomplished, when they are cut away. The finest Vine stems I have yet seen were treated similarly, with this difference, the laterals down to the ground are still retained. I do not believe in rapid commencements, but prefer rather to keep the stems constantly swelling; and instead of a short-lived reputation as a good Grape-grower I should be infinitely more proud to be able to remark of a house of Grapes, say at the end of nine or ten years, "that is the best crop of Grapes I have yet secured from those Vines since planting them." At that age the border could not well be too full of roots; it is in the earlier stages that I object to having the borders needlessly exhausted.

The other objection to a houseful of top growth in the earlier stages is this. I attach much importance to the crop of Grapes or Tomatoes that can be grown on the back wall or in the body of

the house, preferring to have supernumeraries in these positions rather than crowded in among the permanent Vines.

When I submitted my views on this subject I did not expect to meet all the arguments that might be adduced in antagonism to my opinions, and certainly did not think of airing my limited scientific knowledge, knowing as well as "SINGLE-HANDED" that science must be thoroughly understood or let alone in a public discussion. At the same time I fail to see where I gave such lamentable proof of my ignorance of the rudiments of the structure and functions of plants, including the Vine. He must have a poor opinion of my intelligence if he supposes I am under the impression the borders are filled with roots for no presumably good purpose. What they are so filled for I leave to the advocates of the practice to explain, and merely argue against it, being under the impression a much less number of roots would suffice. Vines trained as I described would also have "ample working power of foliage, ample room to work in, ample feeding, ample supplies of heat and light," and it is unnecessary for me to dip still deeper into science to assert such foliage thus obtained would be in a better state to elaborate sap than those that are included in a "thicket of growth." A few large leathery leaves are preferable to a greater number of thin papery foliage, and young sappy growth surely does not do much towards filling the "reservoirs with organised material in the autumn." That it is necessary to have material stored at hand to support the young growth of Vines is obvious, but it is superabundance to which I object, as this results in the formation of too sappy growth. It is not necessary to retain the whole of the roots of well-established Vines, the canes of which are severely pruned; and if a number of the roots are severed in the autumn before the loss of foliage, they will heal and produce more roots, which in good soil will afford a plentiful supply of sap when this is really required.

In support of my arguments, and in conclusion, I quote the following from a contemporary relating to fruit-growing at Sawbridgeworth—"The most surprising evidence of the accommodating nature of the Vine was that of two plants, Black Hamburg and Royal Muscadine. The pots in which they grew were 12 inches in diameter, but perforated, and standing on a small bed of compost, into which the roots were allowed to spread. The bed was scarcely a yard square and not more than a foot in depth. Of course the roots were fed with liberal doses and dressing of manure. After the crop had been taken and the canes thoroughly ripened the soil in the bed beyond a margin of 4 or 5 inches from the pot is entirely cut away and replaced with fresh compost. The two Vines in question were bearing each—and had borne for two years, I was told, previously—from twelve to fourteen splendid bunches. The Vines consisted, of course, of single canes, and stood on each side of a doorway in a house 9 feet wide, in which young Vines were grown"—not much room for unrestricted growth there, and the majority of the "underground stems generally called roots" were not much valued, at all events as "reservoirs."—W. IGGULDEN.

Two able correspondents have questioned the soundness of Mr. Iggulden's views on the management of Vines, and I am not disposed to dispute the general accuracy of their statements, but still I do not regard them as conclusive. The subject of rampant growth in the early stages of a Vine's career, as advanced by Mr. Iggulden, is highly worthy of discussion. Great enthusiasm exists amongst growers of Grapes, and enthusiastic people often carry their notions to extremes. Mr. Iggulden is, perhaps, apt to restrict his Vines unduly, and Mr. Bardney and "SINGLE-HANDED" to attach too much importance to a free extension of growth; but whether they do so or not depends on their mode of pruning afterwards. Mr. Bardney states that he pinches the laterals up to a height of 3 or 4 feet, and beyond that the Vines are allowed to grow as much and as fast as they can. If he cuts them down in winter to the point below where free growth was encouraged, he will simply cut off the best buds that would, if left, produce the best bunches and finest Grapes. The eyes on the lower or restricted portion will be weak in comparison with those above them, and weak eyes produce weak growths, and these cannot afford the best Grapes.

If Mr. Bardney can remove nine-tenths of the growths from the Vines and preserve all the root-fibres alive, as he appears to think he can, I do not hesitate to say that he stands alone. Anyone who examines Vines grown in pots, no matter how well they may be grown, will find that many fibres decay even when the canes are not materially shortened, and they will certainly do so in a border where the Vines are severely pruned. The main roots, however, will not decay, and these undoubtedly are storehouses of food for the Vines. But the question arises, Of what avail is food if it is in greater quantity than can be appropriated, as it

cannot be by Vines luxuriantly grown, and then nearly all the stems, which are also food stores, cut away? The method advocated—assuming that it is followed by close pruning—is more generous than economical, and often results in the undue exhaustion of the border. It is true “nothing is lost” in nature, but it is equally true that all that is extracted from the Vine border is not returned to it, as Mr. Bardney suggests it might be, and there is a wide and most important difference between what is done and what might be done in Grape-growing as in other matters.

No doubt there are many readers of these pages who have seen Vines that have been grown luxuriantly and unrestrictedly, and then pruned severely, disappoint by the small size of their bunches and fruit. I have seen many such. In a few years the Vines have improved, but this only showed that the wild growth

in summer and hard pruning in winter was not perfect treatment. It is, I believe, a fact that Vines have been so managed, with the object of storing them with food, and others in the same house planted as supernumeraries, and confined to single stems that have not been much shortened, with the result that the “supernumeraries,” to speak paradoxically, are now the permanent Vines, and the (another paradox) “permanent” Vines have vanished. How does “SINGLE-HANDED” explain this scientifically?

I have seen some of the finest Vines and best crops of Grapes that have come under my notice produced much in the manner that Mr. Iggulden has described, but not quite so closely pinched; and I suspect Mr. Bardney’s pot Vines were prepared much in the same way—and it is of preparing young Vines that Mr. Iggulden wrote. His after management of established Vines

Fig. 74.—*DRACÆNA LINDENI.*

would not, I presume, differ materially from that followed by Mr. Bardney, “SINGLE-HANDED,” and other good cultivators.—  
AN OLD GRAPE-GROWER.

#### *DRACÆNA LINDENI.*

AMONG the numerous beautiful plants, for the introduction of which both continental and English horticulturists are indebted to M. Linden of Ghent, *Dracæna Lindenii* (fig. 74) deserves a high position. Red and green-leaved *Dracænas* are abundant, and any departure from the prevailing types is especially welcome now there is such a general demand for novelties. *D. Goldieana* is, perhaps, one of the most remarkable forms of the genus; but next to this must be ranked *D. Lindenii* and *D. fragrans variegata*, the two latter closely resembling each other in habit and form of leaves, but are quite distinct in the variegation. *D. Lindenii* has a dark green stripe down the centre of the leaf, with yellowish white margins. The other form has the light colour in the centre of the leaf, the margins being green. Near the edge of the leaf

in the former is frequently a narrow band of green, and sometimes irregular streaks of green and pale rose break through the light marginal bands. The leaves are 8 to 15 inches long, about 3 inches broad at the widest portion, and tapering gradually to each end. The footstalks clasp the stem, and the blade is slightly recurved, so that while possessing a bold appearance it is also graceful.

Remarkable evidence of the value and general appreciation of this plant is afforded by the fact that no less than four English firms have obtained certificates for it this year—namely, Messrs. J. Veitch & Sons at Regent’s Park, B. S. Williams and R. P. Ker at Manchester, and W. Bull at Kensington.

#### THE LONGLEAT VINERY.

I BEG to enclose you a good photograph of the vinery at Longleat, from which you will see the crop of Muscats is all it has been described to be. It should be noted also that, although the vinery is 30 feet wide, it contains only eight rows of 4-inch pipes,

which, if my recollection serves me right, is just about half or a little more than half the quantity of piping which I saw in a high-temperature cultivator's vinery in the Lothians once that was either only 20 or 24 feet wide, and contained twelve rows or more pipes. This means a considerable difference in the expense to begin with. True, the difference in the mean temperatures of the spring months is some 2° in favour of Longleat over the Lothians, but cold nights are nearly equal according to the occasional accounts in your pages of both places, while the west coast rejoices in a preponderance of dull skies and rain, which must equalise matters to some extent.—CORRESPONDENT.

[The photograph affords a fair idea of the interior of the Longleat vinery, but by no means does justice to the appearance of the crop. A house of Grapes so large cannot be successfully photographed.—ED.]

#### GETTING ON.

SOME time since I read an article by your much-esteemed correspondent, Mr. Pettigrew, on "Lessons of Life for Young Gardeners" that interested me much and amused me also. I believe your correspondent was prompted by the best of motives, and believed all he himself stated; but he will excuse me, I hope, in saying that his opinions are not shared by a great many gardeners of experience. Shortly, Mr. Pettigrew's theory, as regards success in life among gardeners, is simply that the best men are all but sure to come to the front. I am not going to deny that the good men sometimes reap the reward of their industry and good behaviour, but I do not for a moment believe that the rule holds good in gardening. If it does, then my experience is different from other people's. By good places I simply mean the most respectable and the best paid, and I suppose this is what Mr. Pettigrew means too. Now I know a very large number of gardeners in both large and small situations, well paid and ill paid, and I can conscientiously say that I would grievously wrong the last—the men who have not got on—if I was to say they were in any respect, or on the average, inferior to the first. Many of the best men I know are men in small places, not a few of them single-handed, and they have been trying energetically all their lives to get further up the ladder, but without success, and chiefly because they lack influence. It can hardly be expected to be otherwise: there is no competitive examination among gardeners for situations, and success is largely a question of luck or influence. It is a great mistake to suppose that all the best places are filled by the best men, but such ought to be the case if, as Mr. Pettigrew says, the best men are sure to come to the front. Is even a fair proportion of them there? If it was so, would there be so many changes, so many dismissals for incompetency? Would there be so many ill-managed gardens where everything is found to render management successful but skill and energy? I think not. I should think, sir, that your experience as a horticultural editor has made you aware of this long ago—made you aware not only that the best men do not always get the promotion they deserve, but that they often also fail to meet with that appreciative encouragement they should expect. When I recall to my mind the circumstances under which many men have obtained excellent situations I am driven to one conclusion only—that success is largely a matter of chance, both in public and private gardens. The fact is indeed notorious.

I am not speaking as a disappointed man, for few have less reason to complain than I have, I am glad to say; but I simply give you my opinion, gained from experience and acquaintance with a large number of gardeners in high places and low ones as well, and not a little acquaintance with employers. I cannot here specify cases, but I could do, and they would startle your readers a little. This, however, I may be permitted to state, that out of a large number of first-rate situations I have known filled during the past thirty years, I could point to very few of them in which the success of the chosen man was due to his own special qualifications as a man or a gardener. Some of them have turned out bad and some well, and several of whom the best things were expected have turned out best, and are now well-known men and gardeners. In numbers of instances the thing was managed by "a friend in court," and but for whom the applicant would have had no chance whatever. Let not your young readers be discouraged, however, by these remarks. It is their chances of the first step—securing a good situation—that I regard as most precarious and most doubtful, but it is the most important step of all. Once in a place, however, it requires ability and a knowledge of one's business, as well as all the good qualities pointed out by Mr. Pettigrew, to keep it, and for this reason alone young men ought to strive to fit themselves for their duties in the best manner possible.

Another thing. If head gardeners would do their duty themselves by promoting their men according to merit, that would in itself greatly facilitate the progress and success of the most deserving, because the weeding-out process would begin at the beginning, and fewer inferior men would be left. But gardeners, as is well known, do not follow this wholesome rule.

In conclusion, I may say that I am aware it is the custom of most writers to expatiate on brighter prospects of the most deserving and clever men; and in business capacities, where men are their own masters and control their own affairs, this view is no doubt the right one; but it is different in the fight for situations in gardening. I believe there is little or no foundation for much that is written in the *couleur de Rose* vein. When a good man obtains a good place the chances are that he will shine; but the stars are few, and who will venture to assert that the brightest orbs in the horticultural firmament are the men who fill the best places?—DUNEDIN.

#### EUPHORBIA JACQUINIÆFLORA.

HAVING profited by many useful hints in the Journal, I have thought that perhaps my experience as to the propagation of the above plant may be useful to some of the readers of its pages. We had a large specimen planted out against the back wall of a stove, but through some cause in the spring of this year its leaves commenced turning yellow and falling, which convinced me at once that all was not well with it, and as it was a particular favourite with my employers I wished to find, if possible, the cause of its unhealthy condition. On removing a little soil from the collar I found that the bark was quite decayed. Probably the cause of this was being planted too deeply, the ball of the plant being fully 4 inches below the level of the soil. As there was not the least chance of its recovering I determined to try an experiment with the branches. The plant was lifted and divided, not using the knife, into a number of pieces, each piece with a heel. Some of the growths thus secured were over 5 feet in length and as thick as a man's finger. I then made a small trench the whole length of the wall, which was filled with leaf soil and sand; the branches were placed in about 6 inches apart, giving a watering to settle the soil, then secured to the wire against the wall. This operation was done in March. In due time they commenced growing, only three out of about thirty dying. The wall, which is 8 feet in height, is now well covered with luxuriant growths, some of which have attained the length of 5 feet and are showing their flower buds.

The above way of propagating this old and most useful winter-flowering plant may not be new to all who read the Journal, but it may be to some, and in the hope that it may prove useful I submit it.—J. RICHARDSON, *Calverton Hall, Notts.*

#### THE CUCUMBER-ROOT DISEASE—ANTS.

"W. J." writes, on page 379, inquiring about this disease. I have been troubled just in the same way as your correspondent, but did not know the real cause of the plants failing until I saw the illustration and examined the roots of my plants. I imagined that they had used up all the plant food in the soil and were starving, consequently I gave the beds a coating of cow dung an inch thick, watering heavily for two or three days. The effect has been very satisfactory. Of course, all the young fruits which were injured were cut away, as they would never have been marketable. Whether this cure would suit the Melons I do not know, as I have no faith in growing them in a Cucumber house.

I have been pestered with ants and tried all sorts of cures—arsenic and treacle, guano, paraffin, but all to no purpose. I lately, however, noticed that they were very fond of Apple. I have since fed them liberally on it. I lay the pieces on top of the wall alongside the pathway. Every half hour I go along the house with a can of boiling water, and, dropping the pieces in, kill from twelve to twenty ants on each piece, setting the baits again for further execution. I have not seen this method recommended before, and can say that it is both cleaner and less dangerous than others which I have tried.—HORTUS.

SEEDLING VERBENAS.—It may possibly be of service to some readers if I state my success with seedling Verbenas last summer, and how the plants were raised. The seed was sown in moderate heat the last week in February, and the plants when ready were pricked off in small pots in a mixture of loam, decayed cow dung and leaf soil, with a fair amount of silver sand, and were gradually hardened in cold pits. Some were potted for conservatory decoration; they proved most useful, and several produced first-class flowers. Plants of the best varieties are now in a cold frame; they

will be eventually cut down and placed in heat, and the young growths will be inserted as cuttings in February. I find these beautiful flowers not only add a charm to the flower garden but are exceedingly useful in pots and hanging baskets for conservatory and table decoration.—H. C. OGLE, *Chilworth Manor, Hants.*

#### SCRAPS ABOUT FRUITS.

**SIBERIAN CRABS FOR PRESERVING.**—For three years I have particularly noticed the productiveness of the scarlet Siberian Crab, and this year the jam made therefrom has been pronounced by all to be the most desirable of all the various kinds. This Crab also has the advantage of hanging long, is most beautiful, and uncooked is not cared for by children. I cannot too strongly recommend it, for it has only to be known to be much sought after for making into jam, and fine weather for the gathering can be waited for. We strain it to take out the scales, but some prefer it whole, though we do not consider this the best way.—JOSEPH WITHERSPOON, *Chester-le-Street.*

**APRICOTS.**—Taken as a whole the crop of Apricots proved the most valuable of any grown. We had a fair sprinkling of fruit on trees trained to walls with south-east and west aspects, but the greatest quantity of the best quality were taken from those on a south wall, these receiving the benefit of protection by Parham's glass coping and blinds. Early Moorpark was the first to ripen, and yielded heavily. Hemskerk formed an admirable succession to this, and produced large-sized fruit in abundance. The trees of Moorpark that were planted at the same time as the two preceding varieties have been dead some years, and those since planted are fast dying, a quarter of a tree going at a time. This is much to be regretted, not only because of the blanks it causes, but also on account of the superior quality of the fruit. It will not be planted again, the preference being given to Hemskerk. Kaisha was fairly prolific, but was rather dry, and Shipley's was much smaller than anticipated. Musch-Musch is not worthy of the space devoted to it, and will have to make way for better varieties, and neither the Roman nor Turkey are much admired.—W. IGGULDEN.

**SERVICEABLE GOOSEBERRIES.**—The large Early White, White-smith, Early Sulphur, Sulphur, Crown Bob, and Red Warrington are generally profitable. The latter especially is recommended as being free-bearing and a good keeper, while Sulphur is excellent for dessert purposes, and also hangs fairly well.—ESSEX.

**STRAWBERRIES v. FROST.**—Have any readers of the Journal noticed that old plants are usually more injured by frost than young plants are? This is my experience, and affords proof of the necessity of frequently forming fresh beds. Sir C. Napier was the most injured, and British Queen also suffered considerably. Vicomtesse Hericart de Thury proved the heaviest cropper and the worst in quality. Keens' Seedling, Sir J. Paxton, La Grosse Sucrée, and Dr. Hogg were fairly remunerative, and young plants stood the severity of last winter well.—M. H. F.

**USEFUL PLUMS.**—Orleans must be considered one of the most profitable culinary Plums. Victoria usually bears abundantly, as also does Pond's Seedling, or Fonthill as it is called hereabouts. Mitchelson's bears prodigiously. I would prefer having standards of those mentioned, devoting the wall space to choicer dessert varieties, of which Transparent Gage is one of the best, and the excellent Coe's Golden Drop seldom fails.—SOMERSET.

**MARGIL APPLE.**—To lovers of miniature fruit trees that crop heavily and early I cordially commend Margil upon the Paradise stock. It is a first-rate dessert fruit, small in size but delicious in flavour, just coming into use now, and generally continuing good till after Christmas. Its synonym of Never Fail is justly descriptive of its remarkable propensity to bear fruit abundantly every year after it has once begun doing so, and it forms fruit buds so early that it is no uncommon sight to see dwarf trees not much larger than a Gooseberry bush heavily laden with fruit.—A KENTISH GROWER.

**HOW WE BEAT THE BLACKBIRDS.**—After two or three seasons' use netting, especially old fish-netting, is easily torn. Of this the blackbirds would seem to be aware, for often have I seen them dash at old netting and force their way through; but this was invariably at the sides of covered bushes, and never through the top. Acting upon this fact last summer, when our splendid crop

of Warrington Gooseberry began to ripen, a frame of poles was erected around them, netting placed over the top, and Russian mats on the sides, care being taken to peg them securely to the ground. The plan was a great success. Not a blackbird could get in; nor did they appear to try, but, like wise birds, at once owned themselves beaten, and turned their attention to less closely guarded quarters.—E. L. O.

#### MANAGEMENT OF HEAVY SOILS.

THAT there is no ground so heavy that it cannot be made to produce enormous crops I quite believe, and that there are different ways of bringing it to that desired end is equally certain. Being one of those who are located on heavy soil, and having been successful in securing a greater depth of workable soil, and at the same time growing heavy crops of vegetables, it may be acceptable if I describe the practice, although it may not be new. We double-dig or trench every second or third year as practicable; and whether the ground be single or double-dug we always throw it in ridges, doing it as early as possible in the autumn, at the same time adding manure or whatever dressing we may have for it. If double-dug we do not turn all the dressing to the bottom, but give another layer after the first spit is turned over, always working in a good sprinkling of fine ashes, and when it is not the desired depth we bring a small portion of the subsoil to the surface. During frosty weather we give a good sprinkling of sifted coal ashes. The whole is well forked over on frosty mornings during the spring, and again before the crops are put in. If the soil is very shallow we do not bring the second spit to the surface, but give it a dressing of lime and ashes and turn it over in the bottom of the trench; a year or two afterwards it is treated as above. The secret of success afterwards is to well loosen the soil between all growing crops, and at all times to be sparing with farmyard manure. Heavy soil so treated has exceeded our expectation. Although differing somewhat from Mr. Taylor's mode of procedure, we are aiming at the same end—namely, to grow crops of vegetables of the first order, and to obtain a greater depth of workable soil.—G. SUMMERS, *Sandbeck Park.*

#### NOTES ON POTATOES.

I AM aware I am treading on dangerous ground when I criticise such an opinion as Mr. Thomas Laxton's. Like "W. J. M." (see page 425), I have always found Champions one of the best of Potatoes. This season I have grown it largely and am well satisfied with the results. It is with me like balls of flour, and the flavour equal to that of any Potato of my knowledge. Among the varieties I have grown this year is Paterson's Victoria, and I am quite astonished that Mr. Pearse (see page 426) finds it worthless. Here it is excellent, the crop good and nearly free from disease. Beauty of Hebron is a good early variety, but the flavour is not in comparison with Scotch Champions. Magnum Bonum is with me this season coarse, although the quality is good. Suttons' Reading Hero is a remarkably fine Potato and sure to come to the front; in fact, I characterise it Scotch Champion's own brother with shallow eyes. It is a capital cropper, free from disease. I may mention Vicar of Laleham, Adirondack, and Vermont Champion, which I have grown this season, which are all worthy of the honour conferred upon them of being certificated by the Royal Horticultural Society. I send you a Potato which I call Uxbridge Kidney, which for cropping and using I should say has but few rivals.—R. GILBERT, *Burghley.*

AT page 425 of last week's issue your correspondent, "W. J. M.," takes exception to my comparison of Reading Hero with the Champion Potato as being less waxy, and alleges that the latter variety does not fulfil this character in Ireland; but here, as compared with the Schoolmaster, Regent, or Fluke, which are *par excellence* light, floury, and digestive Potatoes, the Champion is undoubtedly more or less waxy and internally very solid-fleshed, although the outside is floury. In the centre the Champion is generally of a yellowish colour and approaching somewhat to the condition of a well-ripened Myatt's Prolific or a Lapstone. To me personally this quality is not objectionable. The Champion has also the advantage of being very satisfying and highly nutritive, and probably more so than the light-fleshed sorts; nevertheless the latter are preferred by the public and in the market, especially during the winter. In using the term I did not intend to convey that the Champion approached the condition of the Early Shaw, a typical waxy Potato, and which I have found to deserve this character in Ireland as well as in England. Grown on strong land the Champion is more waxy than on light

soil, but under all circumstances it differs very materially in this respect from Schoolmaster and Reading Hero, although both are dry; but perhaps the English language is not sufficiently replete to express the exact eating qualities of a Potato, especially where tastes and opinions as well as soil and locality must be taken into account. Growers for market in this locality give the Champion the character of being somewhat waxy, and I have seen somewhere in the daily press a similar character accorded to it in the west of Ireland, but doubtless climate as well as soil has something to do with its condition.—T. LAXTON, *Bedford*.

#### SILKWORMS AND SILKWORM-REARING.—1.

IN the oldest book now extant—or rather, one should say, in the collection of the oldest books, since it embraces the writings of many authors, that is in the Old Testament—we perceive that silk is mentioned more than once. But it may be open to debate whether the Hebrew word is rightly translated, and I incline to the view that a fine linen material is probably meant, and that the Jews did not get a knowledge of silk until near to the beginning of the Christian era. The New Testament names it but once, and there, doubtless, *sericon* does stand for some silken fabric; taking its name, as is supposed, from an old word signifying “to shine,” and applied, Parkhurst thinks, to a people in China or India, the first weavers of silk, because of the splendour or opulence of their land. Might it not rather be from the lustrous appearance of the article in question? Yet it is uncertain, and we also do not know, and never shall know, who was the person to whom the sight of the silkworm’s cocoon proved suggestive, leading him or her to wind and utilise the threads. We say “him or her,” because, with all respect for a great living poet, we cannot accept an assertion he seems to make, that women rarely discover or invent. Indeed, it so happens here that the Chinese have a tale which ascribes the origin of silken fabrics to the Empress Si-ling-chi. This is but a myth, yet, all things considered, it is quite likely the desire for a new article of dress may have led some oriental dame to try experiments with the silkworm’s thread. And several circumstances point to China as the region where the most important of all the caterpillars yielding silk, *Bombyx Mori*, was first reared for profit; though silk has long been produced in India from the “Tussar” species.

Chinese records of undeniable antiquity contain details of regulations respecting silk culture, which show the existence of an early trade in this article. The Mulberry trees were protected by special laws, and their planting was encouraged, and those who reared silkworms were not allowed to send the insect out of China in any of its stages, or to furnish information concerning the production of silk. It would probably be by way of Persia that silk reached Asia Minor from China chiefly; some of the coarser sort manufactured in India seems also to have reached those cities where the people, many centuries ago, became famous for their rich carpets, in which gold and silken threads were mingled with other materials. The price of silk was enormous, for when the first samples came into Greece they were worth more than their weight in gold. It was only known there from the reign of Alexander the Great, who may have obtained it direct from India. And it is worthy of remark that another great military hero, Julius Cæsar, is stated to have brought silk to Italy, where, under the luxurious years of the Roman Empire, silken robes became in general demand.

Still, for centuries after the Christian era, no silkworms came into Europe, so jealously did the Chinese guard them; and the story has been frequently repeated that two missionary monks who had been in China to make inquiries, having reported to the Emperor Justinian, succeeded on a second visit in obtaining eggs, which they concealed within hollow walking-sticks. These were brought, so it is said, to Constantinople about A.D. 550, and colonies of the insects were soon established in several parts of Turkey and Greece. The species was undeniably our *Bombyx Mori*; and from the extensive planting of trees in a district of South Greece to supply leaves for their food, this is thought to have been named the “Morea,” from *Morus*, the Mulberry. For six centuries more silkworm culture did not extend itself from Greece to other European countries.

At last, however, a war broke up the monopoly thus held by Greece; and after Roger, King of Sicily, had overrun that country, he removed to Italy many of the persons who had been employed in rearing silkworms and in weaving silk. These he lodged in houses near his palace at Palermo during 1168, so that he might watch their proceedings. Slowly from this beginning the art of silkworm-rearing became known in other parts of Italy, until silk manufactures assumed great importance in the towns of Florence and Venice. Some time in the fourteenth century French-

men returning to their native land from a sojourn in Italy made their countrymen acquainted with the silkworm and its favourite tree. Without Mulberries it was not possible to breed silkworms, and several attempts to encourage the planting of these were considerably checked by the unsettled state of the nation. The Lyons manufacturers during a long period employed silk which they obtained from Italy, but the home-rearing of silkworms made a great advance under Henry IV.

Leaving the Continent for the present, we notice the fact that in the days of the Tudors silken articles were rare in England, as appears from Queen Elizabeth having received with much pleasure the offering of a pair of silk stockings. Towards the close of her long reign she had no doubt secured a variety of articles of silk, which would be found, could we get a sight of it, upon the long list of nearly four thousand dresses and other garments that were contained in her wardrobes at her decease. Her successor, James I., took a special interest in the culture of silk, as is proved by an experiment he entered upon with the idea of developing a new English industry. Having studied the history of the silkworm, he thought the insect might be profitably reared in England. St. James’s Palace had become the occasional residence of our kings, and at a short distance from it to the west James chose a piece of land of about five acres, and had it planted with Mulberries. This was in 1609, the ground being that which subsequently became the site of Buckingham House. Whether it was by accident or intention I cannot say, but the position was rather a suitable one, sheltered from the winds, and in a part of Pimlico that is milder than some of the London suburbs. James expended the sum of £935 (to be exact) upon the planting of this Mulberry ground, this by no means representing his whole outlay upon the business, for he obtained many thousands of slips from the Continent. Some of these he distributed in various districts. It was at this time, no doubt, that one William Shakespeare planted his Mulberry tree at Stratford-on-Avon, which was to attain to great celebrity.

It has been suggested that the English spring and summer were more equable in temperature 250 years ago or so than they have been observed to be since the changes of weather have been exactly recorded. If this was the case, silkworm-rearing in the open air, or with slight protection, might have had a better chance then; yet it appears King James’s scheme was a failure. Silkworms were, however, fed in the Mulberry Garden during his reign and a part of the next, for there is an old deed by which Charles I. assigned to Lord Aston’s keeping this garden, its buildings, trees, and silkworms, for a term. Afterwards the Mulberry Garden was converted into a pleasure resort for the fashionables. “A silly place, but with a pretty wilderness,” Pepys remarks.

Another experiment in silk-culture was tried about a century later. The spot chosen for this was Chelsea Park, at that time called Wharton Park, and originally a sandy tract of land near Brompton Heath, over which deer wandered when Chelsea was only a little village. A patent was granted to the Raw Silk Company in 1721, and a great portion of the park set with Mulberries. Silkworms were reared there. Some articles were also manufactured, for Thoresby mentions in his Diary that he had seen one of these designed for a present to the Princess of Wales. For a while this was one of the sights of London, and many foreigners came to see Chelsea silkworms and their silk, but a few years brought the enterprise to a finish through want of sufficient capital to persevere, so Faulkner states.—J. R. S. C.

#### ON THE ADVANTAGES OF VISITING GARDENS.

WE are from time to time, through the writings of those who have visited various large gardens, able to form an idea of the manner in which plants are grown in different establishments, and to many gardeners this is the only means whereby they are able to learn what is passing in the large gardens in the country.

If employers could only be brought to see the immense advantages to be derived from the adoption of the practice of sending their gardeners to visit notable places we should not hear of so many failures, and a better feeling would be created between master and man. Take, for instance, a gardener living some hundreds of miles from London. What advantages he derives from an occasional visit there! The various parks, gardens, and nurseries are full of interest and instruction. He meets noted growers, who are always willing to give him the benefit of their experience. He sees many plants he has only heard of before, different styles of bedding, and hints on the treatment most suitable. He will probably see some fruit or vegetable brought to a higher state of excellence than his own: he soon learns where his treatment is wrong, and on his return home with his note

book full of hints and suggestions, immediately commences the work of reformation.

There is always something to be learnt in gardening; and the gardener who is able to visit different establishments is continually improving his knowledge, and from seeing something done better by others with less advantages than he has himself, he is induced to try more earnestly than ever to master difficulties.

The facilities for travelling are very great, but gardeners cannot always afford to pay their travelling expenses, but if employers would do this occasionally I am sure they would be gainers in the end; and if those who doubted the wisdom of doing this were to ask those who had tried the experiment, I think the answer in many cases would be, Go and do likewise.—CANTAB.

#### PELARGONIUM GUILLON MANGILLI.

YOUR correspondent in describing his "Run to the West," gives a description of this variety which may mislead some who purchase it. In flowers as in other things there is a variety of taste and judgment. Allow me to give mine. Early this spring I obtained three cuttings of the above Pelargonium, all of which struck and did well. They are now fine robust plants bearing from eight to ten trusses of bloom, but they have disappointed me. In the first place the flower is neither single nor double, but a confused mixture of petals, none of the flowers being of good form; and secondly, the colour is neither one thing nor the other, but again a confused mixture, which in my opinion and that of the family, who are pretty good judges, is not pleasing. I have a span-roof house 25 feet long, which from this time forward for many weeks will be a blaze of beauty, and fragrant with sweetest odours. The plants consist of Pelargoniums, Bouvardias, Begonias, Gesneras, Heliotropes, Poinsettias, &c., all grown during the summer with a view to blooming when the frost has destroyed the outdoor plants. It is very interesting to compare the habit and the flowers of the different Pelargoniums. In point of habit Guillon Mangilli is perfect, but in the comparison of flowers he is in our judgment nowhere in the race. My principle in the cultivation of flowers has always been "Little and good." I have for years selected the best and thrown the others away. How barbarous I shall appear to Mr. Taylor, if I say that I am almost doubtful whether his pet will appear among my favourites next year. "Eureka," or as some call it, "I've Got It," seems a first-rate single white, but I have not proved it long enough to be certain.—A LOVER OF HORTICULTURE.

#### A ROCKERY FOR ALPINE PLANTS.

(Continued from page 418.)

WE are now to speak of the Sedums, and without wishing to be dogmatical I repeat the opinion already expressed, that many of them had better be avoided as rockery plants. Those of the *S. acre* and *S. rupestre* class spread too rapidly; others, however desirable in gardens, are too large for rockeries, and do very well in well-drained raised borders. Amongst these are that fine plant *S. spectabile*, also *S. Maximowiczii*, *S. Telephium*, and such plants; but many neat and pretty kinds remain, which you will easily find out for yourself if you observe their habit when planted out on a rockery, and are not misled by their innocent appearance when confined in a small pot at the nurseryman's. I think I must give the first place to *S. Sieboldii*, of which a large plant has for a month been the prettiest object of my rockery. Though generally cultivated as a greenhouse plant—I suppose because it flowers so late—it is quite hardy, and is generally in flower even here early in September, and goes on through October regardless of many degrees of frost. *S. pulchellum* is another favourite, flowering earlier—about July. It grows luxuriantly and flowers freely; but the usual Nemesis of free-flowering awaits it, for it dies off almost entirely after flowering, and if not constantly increased by inserting slips, which strike readily anywhere, it is liable to be lost. *S. Ewersii* is also beautiful, bearing bright rose-coloured flowers in the hottest suns of summer. This list can be added to with cautious discretion.

The genus *Dianthus* supplies some of our prettiest Alpines, of which the cultivation requires care. The loam of the rockery should be abundantly mixed with coarse grit, to which a little peat may be added; and the plants should rest on ledges of bare rock, in the full sun, and on no account be overgrown by coarser growth. Raising these plants from cuttings requires practice, and they are more easily grown from seed, but beware of trying to divide a plant of *Dianthus*. It is said that *D. alpinus*, one of the prettiest, will not thrive on a slope, but must have a level shelf. The gem of the family is *D. glacialis*, and one of the easiest to grow. *D. neglectus* should wonder why it was so called, for it

deserves to receive great attention. The natives, *D. deltoides* and *D. cæsius*, are well worth their room, though the former is apt to spread untidily unless frequently propagated—a thing necessary to be observed with regard to the whole class. Some of the true alpine species, as *D. carthusianorum* and *D. arenarius*, have provokingly long flowerstalks. Some of the *Drabas* are so pretty in leaf that they are worth growing for that alone; but being early spring flowers, their flowers, though not showy, are acceptable. Amongst those which I grow *D. aizoides*, *D. bæotica*, and *D. glacialis* are the best. They grow slowly, and do best when left alone. They like to have a surface of fine gravel spread under them, and indeed there are few alpine plants which are not better for this. It keeps the surface of the soil open and moist, and prevents delicate leaves from being drabbed with wet.

The *Campanulas* are an indispensable genus of plants, but beware of some of them. *C. rapunculoides*, often found on old walls, is perhaps about the worst weed which can be had on a rockery; and *C. pumila*, from its habit of underground running, becomes very troublesome, though it is pretty. But there is one running kind which is so rare and so pretty that it has free leave to grow where it likes here, and other plants are arranged accordingly: this kind is *C. Allioni*. Other good sorts are *C. garganica*, *C. muralis*, and *C. isophylla*, names under which you will get a great variety of plants. They like living amongst the stones on the top. Do not neglect the native *Harebell* and its white variety, which is never obtrusive. *C. pulla* likes the foot of the rockery in moist soil; and in still moister spots, in peat soil mixed with sand, by all means grow together the two sweet little natives *C. hederacea* and *Anagallis tenella*, which I have often found wild in the same sod.

Catalogues of Alpines often contain a long list of *Arenaria*, many of which I have never seen, but I grow several sorts. The most remarkable is *A. balearica*, which runs over several square feet of sandstone—I cannot get it to grow on limestone—clinging quite close to it, and thriving alike on the horizontal and the perpendicular surface. *Arenaria verna*, with its stars of the purest white, wants a great depth of sand for its tap root, and then when established does well. *A. triflora* resembles it much, and is more easy to establish. *A. purpurascens* is also good.

We must not omit the *Veronicas*, the best of which, *V. rupestris*, shows a decided preference for limestone over sandstone. It wants a large surface, say at least a square yard, to show it off to advantage, and in June, when this mass is smothered with sky-blue flowers, your friends will come miles to see it; but it is a continuous bloomer, and still at the end of October the plants are gay with flowers. Do not confuse this plant with a native mountain species, *V. saxatilis*, of more compact and upright shrubby habit, and very neat. It has a red-flowered variety known as *V. Grievi*. *V. pectinata*, which also has red flowers and blue flowers, is worth growing for its elegant crimped foliage, but the flowers are early and abundant. *V. glacialis* is neat and compact. If you like plants with variegated leaves I hardly know a better than the variegated form of *V. Chamædrys*, which trails well over stones. Other variegations suitable for rockeries are the variegated forms of *Arabis lucida*, *Aubrietia*, and *Saxifraga umbrosa*. All these require to be watched, and any tendency to revert to the natural colour checked by nipping off the shoot, or it will carry with it all the growth and the variegation will disappear. I recommend also the tiny native *V. spicata*, quite different from the garden form of that name, and seldom growing more than 4 inches high. A clustering variety of it, *V. spicata eorymbosa*, is one of the most profuse autumn flowerers I know. If *V. hybrida* could be grown as it grows on the rocks at Llandudno and Gloddaeth in Carnarvonshire it would be one of the best of rockery plants, but it loses colour in cultivation, though on the barren parts of the rocks it is worth its room. The side of our rockery facing south-east will of course have far more sun than that facing north-west, and I have perhaps not sufficiently distinguished between them. Many plants do equally well in both aspects. The Alpine and Himalayan Primroses, however, especially like to have their roots and leaves out of the hot sun, and should be planted accordingly. *P. denticulata*, *P. rosea*, *P. capitata*, *P. involucrata*, *P. viscosa*, and others too numerous to mention, should have many snug corners assigned to them. Leaf soil mixed deep into the loam helps them to do well.—C. WOLLEY DOD, *Edge Hall*.

(To be continued.)

#### EUCHARIS AMAZONICA.

AMONGST choice plants there are few that can excel the *Eucharis* in beauty and fragrance. The flowers are always welcome. It is easily propagated by division, and those in possession of a

few bulbs can easily obtain fine plants in one or two years. One advantage is, that plants can be brought into flower at any time of the year after they have made good growth and been rested. The compost I find most suitable is rich fibry loam, charcoal, fine bones, and plenty of silver sand to keep the soil open. The size of the pots employed should be regulated by the purpose for which the plants are required. One strong bulb in a 4-inch pot can be used for table decoration, and is very pretty surrounded with moss.—J. T. B.

#### HARDY FRUIT GARDEN.

THE recent frosts have caused many leaves to fall, therefore a commencement can be made in pruning, nailing, or tying the growths of fruit trees against walls. Beyond thinning the growths where too crowded, and shortening back any closely situated or elongated spurs, the knife should be used as little as possible at this season, as much reduction of the head will result in a corresponding increase of growth. In the case of the Morello Cherry the shoots should be well thinned, removing those that have borne fruit and have become bare of fruitful wood. Similar remarks apply to Apricots. Cherries other than Morellos will need only the removal or shortening-back of the old spurs as may be necessary from their extending too far from the wall. Apples, Pears, and Plums require similar treatment, seeking to maintain an equal distribution of spurs throughout the trees, and as close to the wall as circumstances admit. Old trees that have become a mass of crowded elongated spurs, and do not bear so freely as desirable, may have a portion of the old branches removed, and a young shoot taken up from near the base in the place of that removed. In this way old unfruitful trees may be well furnished with fruitful wood in three years. The shoots of young trees, or those in course of extension, should be laid in their full length, provided space admits and the shoots are sufficiently numerous, otherwise they may be cut back so as to give growths where needed. Pear trees infested with scale should be unloosed and dressed efficiently with train or other oil, which to be efficacious must be applied with a brush when the trees are quite dry. Cherry trees that have been infested with aphides should have all shreds or ties removed, and the wall as well as the trees washed with diluted tobacco juice and a solution of soft soap, 1 lb. to a gallon of water, to be further diluted with three gallons of water and one gallon of tobacco juice. Plum trees that have been infested with blue aphides may be treated similarly to the Cherry trees.

Any trees, whether against trees or in the open as pyramid, bush, or espalier Apple, Pear, or Plum trees that require lifting or root-pruning to check over-luxuriance and induce a fruitful habit, may now be taken in hand without fear of the wood shrivelling, as would be the case when the trees are very vigorous, and before the leaves had fallen. The distance from the stem at which the trench should be made will depend on the size of the trees and their vigour, for when very vigorous they will have stronger and fewer ramifications with fewer fibres near the base of the trees. Ordinarily 2 to 3 feet will be a safe distance for bush, pyramid, or espalier fruit trees, making a trench about 2 feet deep, and from this work under toward the stem so as to cut through any roots having a downward tendency. The loose soil must be removed with a fork over the roots, and a little at the outside of the ball, but no attempt should be made to remove the soil from the roots near the stem, and after paring smooth any jagged roots fill up the trench with fresh loam, laying in the roots carefully as the work proceeds, and ram the soil as firmly as possible. If the trees are found to be too deeply planted lift them carefully, apply some fresh soil well rammed down so that their roots at the stem will be about 6 inches above the surrounding level. This will bring the roots near the surface. The advantage of having the trees somewhat raised above the surrounding ground is considerable in heavy or

damp ground, but in shallow and dry soils level but not deep planting is advisable. The surface roots should not be covered more than 3 inches, and a good mulching of partially decayed manure given from the stem outward fully a foot further than the roots extend. Peach and Nectarine trees against walls not usually ripening the wood well, do much better if lifted as soon as the wood has become firm and the leaves give indications of maturity. Lift them entirely, removing the soil from the roots carefully, replanting them in fresh compost near the surface, and making the whole firm. This induces shorter-jointed wood, which seldom fails to mature and bear fruit satisfactorily.

Leaves should be removed from borders, and the surface soil may be pointed over lightly with a fork. The loose soil so formed, as well as the remains of former mulchings, can be scraped off, and a surface dressing of fresh loam and well-decayed manure in equal proportions applied, adding about a fortieth part of bone meal and a similar proportion of wood ashes or charred refuse, which, from supplying potash, is a good dressing for fruit borders. A little soil from the open spaces may be spread over the top-dressing, the other part of the border being pointed over. Trench ground for fresh plantations of fruit trees, and prepare stations for planting in orchards or elsewhere, pushing forward operations of this character whilst the weather remains favourable.

#### FRUIT HOUSES.

*Vines.*—Vines in pots started as advised in former calendars are now growing, and should have the temperature increased to 60° at night and 10° to 15° rise by day, and before the shoots become too long the rods should be secured in position. Disbud when the best breaks can be distinguished, and as the moisture from the fermenting materials will be considerable the necessity for syringing will be lessened. Keep the fermenting material replenished, bringing it up about the pots so as to secure to the roots a temperature of 70° to 75°. Water as required with tepid liquid manure, and for the present ventilate moderately, and when necessary afford it at the top of the house only. Frequently turn over the litter in the early house, replenishing as the heat declines with fresh litter direct from the stables. Hamburgs required to be kept as long as possible must have the atmosphere dry and the house ventilated very carefully in dull weather. In fine weather both front and top ventilation may be given, providing fire heat in the early part of the day, turning it off at noon, and closing when the pipes become cool, a temperature of 40° to 45° at night being sufficient. Muscats should have a temperature of 50° at night, admitting air freely when the weather is favourable, the atmosphere for these and late Grapes being kept dry. As the leaves fall Hamburgs and other thin-skinned Grapes can be pruned, thoroughly cleansing the house and washing and dressing the Vine rods, and surface-dressing the borders as advised in former calendars.

*Pines.*—Strict attention must be given ventilating pits or small houses containing young stock, for unless this is properly done the plants will soon become weakly. A night temperature of 60° to 65° by day from fire heat will be sufficient to keep the plants slowly growing through the winter, commencing to ventilate at 65°, and a free circulation of air should be permitted through the house or pit when external influences raise the temperature to 75°. Keep the plants near the glass and do not crowd them, the bottom heat being 80°. Suckers may be kept on the stools until starting time in March, in a moist pit with a bed having a slight bottom heat, and a night temperature of 55°, keeping them moderately dry at the roots. This plan is preferable to potting at this season.

*Cucumbers.*—During the ensuing three months ventilation will require careful attention; and whilst a little air should be given at every favourable opportunity, it should be excluded as far as possible when the external air is cold. When the sun is bright and likely to raise the temperature above 80° the top heat can be turned off, so as to lessen the necessity of giving air in quantity to keep the temperature down. Moisture in moderate quantity will be needed in the atmosphere in bright sharp weather, but in dull foggy weather be very sparing of moisture, ceasing to charge the evaporation troughs.

## PLANT HOUSES.

*Stove.*—Gardenias to flower through the winter months, having completed the growth and set their buds, will need a brisk heat of 70°, the plants being placed as near the light as possible. With a sufficient stock of plants the fine fragrant flowers of these plants can be had all the year, but at no season are they more prized than in the winter. *G. intermedia* is the most useful and free-flowering. *G. Fortunei* also has large flowers, indeed the largest, but they are not so abundant as in *G. intermedia* and *G. florida*. Plants of *Eucharis amazonica* which have been rested for about six weeks, after completing growth, must be placed in brisk heat and well supplied with water to enable the plants to throw up the flower scapes at once, to ensure flowers for Christmas and the new year. Bouvardias to flower freely through the winter months require a brisk heat and plenty of light. Plants that are partially deciduous, such as Allamandas, Clerodendron Balfourianum, Aristolochias, Combretums, and Bougainvilleas, should be dried off, but it is not advisable to allow the wood to shrivel. Stephanotis will also need to be kept dormant by dry treatment, not suffering even if the leaves become a little soft, but they must not be allowed to shrivel, or they will fall off and impair the health of the plants; similar remarks applying to Medinillas and Hoyas. Plants of Aphelandras, Francisceas, Luculias, Ixoras, Ipomœa Horsfalliæ, Tabernæmontanas, and others of an evergreen character, or flowering during the winter months, must not be kept so dry, but have a sufficient supply of water to keep the foliage in good condition.

*Ferns.*—The temperature should be such as to induce rest in the plants, and the moisture proportionately reduced. Varieties of Adiantum, Pteris, &c., most in demand for decoration and cutting, usually appear in the fernery in numbers, and these when large enough should be potted in thumb pots, employing loam with a fourth of small crocks, which prevents the soil becoming sour and induces firm growth. Where the plants are not sufficiently numerous spores must be sown.

## THE BEE-KEEPER.

## BEE FARMING.

"CAN you tell me how to get information on bee-keeping on a large scale to make an income of, say, £300 a year on the average? Where is it carried on in Great Britain and America? What are the profits? And all other information useful to an inexperienced person who contemplates it as a livelihood?—W. M. B."

Extraordinary as the above inquiries may seem to many, they are no doubt the lawful issue of much of the gushing matter published in various books and journals by enthusiastic or interested writers. Occasional profits of hundreds per cent. are taken as fair proofs that bee-keeping must be an eminently profitable and safe pursuit; but taking our uncertain climate into account, it is doubtful if on an average of years bee-keeping in this country can be relied on as affording more than a fair ordinary return for the labour and capital invested. Under other conditions, such as obtain in more favoured climes, experienced persons have made handsome profits; but with the memory of certain notable failures still fresh, we can do no better than warn "W. M. B." against indulging in such airy visions as his queries involve. To be plain with him, we would say that his project is an impossible one under his conditions. No "inexperienced person" need attempt things on such a scale with any hope of success.

At the same time there is no reason why, under other conditions, even an "inexperienced person," provided he be possessed of capital, brains, and perseverance, may not succeed even better than "W. M. B." hopes to do. I am at present engaged in advising in a case that will illustrate. A shrewd commercial gentleman of means, casually called on to market honey from a certain favoured island, after two years and certain inquiries concludes that it will pay him to start a large apiary in the same locality. He sensibly takes the best advice he can obtain in his neighbourhood, and resolves to put the whole concern into the hands of the most successful practical bee-keeper whose services he can procure. Such a one I have just engaged in the person of my neighbour Mr. W. Mann, whose name is favourably known to the readers of this Journal—a bee-keeper who has both brains and hands, understands

all about bees, queens, and honey, can make all his own gear, keep his head in every emergency, and has been a most successful honey-taker for many years. Unless "W. M. B." is prepared to undertake a few years' training in the practice of bee-keeping, so as to get the needful experience, he must be prepared to entrust the management of an apiary to some such expert as I have mentioned. That is a first condition towards the £300 a year.

In the next place a suitable locality must be selected. I much fear the British Isles must be reckoned at best only a second-rate one. No doubt in certain seasons an apiary of a hundred stocks will yield the desired income in almost any county in England, Scotland, or Ireland; but such seasons are the exception. So far, then, as this kingdom is concerned, we would say, "Go slowly." If he must, "W. M. B." should select the best known honey locality—such as County Waterford, in Ireland. I visited it in 1879 on a tour of observation, and, after seeing the length and breadth of the three kingdoms, I concluded County Waterford, specially the neighbourhood of Clonmel, the best honey locality I had ever seen. Messrs. White & Son, Grocers, Waterford, told me they had sold 40 tons of drained native honey in 1878, and I believe they sold 30 tons this year. Taking into account the miserable system of bee-keeping that produced such results in the case of only one house, I have no hesitation in recommending the neighbourhood as the best in these islands. The enterprise I have already referred to is, I consider, safe as far as this point is concerned; the locality selected is all that could be desired.

"W. M. B." may rest assured that American bee-keepers have their difficulties as well as we. Although Harbison of California has more than once harvested over 100 tons of honey in a season, even there there are poor seasons, of which the past has been one, so poor that many stocks died of starvation. The eastern States suffer dreadfully from winter death, and the southern have not been fully proved.

In the next place bee-farming must be conducted according to the system most suitable for the locality. A style of hive must be chosen, the dimensions of which, form of frame, and general adaptability, are according to certain laws known only to the experienced, and varying with the locality and the object aimed at—viz., comb or extracted honey. To save labour and multiplication of appliances only extracted honey or only comb honey should be worked for, according to prices, risks of transit, &c. As meeting the case of a warm climate where swarming is difficult to control, the apiary I have referred to is to be run wholly for extracted honey, the price of which, even on the spot, is so good as to make it greatly preferable to a necessarily smaller quantity of comb honey with all its risks in transit.

Such are a few of the points on which "W. M. B." or others like-minded should post themselves. The fullest information on bee-keeping on a large scale can only be obtained by perusing such works as "Cook's Manual" or "Root's A B C of Bee-keeping," American books sold by George Neighbour & Sons, 149, Regent Street, and other hive-dealers.

Should "W. M. B." propose to manage his intended apiary himself, dispensing with the services of an expert, he cannot do better than commence with three or four stocks in his own neighbourhood, and by practice and reading he will in the course of a year or two be in a position to judge for himself regarding the practicability of his larger proposal.—WILLIAM RAIT, *Blairgowrie*.

## CLARIFYING HONEY.

In taking honey it is desirable to save it from the taint and stain of farina. It is rather difficult to do this without loss of honey, as both honey and pollen are found together in the central combs of a hive, often in the same cells. If the honey be taken from the combs by pressure, and then run through a bag of muslin or cheesecloth, the danger of having the honey made impure by farina is great, and if the combs are broken by using a knife, and placed in a bag or strainer without pressure, the danger of having impure honey is greater in our opinion. Pure honey has not the taint of farina. If the cells of farina be broken by pressure or by cutting in taking honey there will be some contamination—the colour and taste of the honey will be both injured. We desire quality rather than quantity. Many combs with farina in them are placed aside for feeding purposes. Some weeks ago a gentleman in Lincolnshire offered to sell me a hundredweight of honey in bottles at a reasonable price. Knowing the gentleman had an extractor for taking the honey, and believing that his was good and pure, I ordered twenty-eight bottles of 4 lbs. each of honey. The honey arrived, and I found it to be a mixture of clover and ketlock honey injured by farina. If the honey had been purely taken it would have been very good. Doubtless the bees gathered both sorts simultaneously, and thus mixed them. Let me here say that

ketlock honey is rather strong-tasted, and not equal in any way to clover honey.

We now come to the point of clarifying impure honey. I have heard that honeycombs can be whitened and improved in appearance by the fumes of sulphur, and that some Irishmen who carry combs about the streets of English towns for sale resort to the sulphur-cleansing process. About clarifying run honey I have something to say. A few months ago I took a leaf out of the book of an American gentleman on a visit here. He described very minutely the process adopted in America for extracting maple syrup and preparing it for table use. In boiling it the white or gluten of eggs was largely used in clarifying it. It struck me that the white of eggs may be useful in clarifying honey. I have tried it and found it to answer fairly well. It clears and improves the honey much by uniting with the impurities in, and carrying them to the top of, the honey in a thick scum; and if this scum be allowed to cool it will become rather tough, and may be taken off like a piece of leather or strong paper. By this it will be seen that the honey is warmed and stirred with the gluten. Honey should never be allowed to boil. How many eggs should be used to a stone of honey? I am a novice in this work and cannot yet tell. I have so far used the white of one egg to a stone of honey. Probably more gluten may be used with advantage if the honey is strongly tainted with pollen.—A. PETTIGREW.

#### TRADE CATALOGUES RECEIVED.

Osborn & Sons, Fulham, London.—*Catalogue of Shrubs and Trees.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Trees and Shrubs.*

Francis and Arthur Dickson, The Upton Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Roses, Trees, and Shrubs.*

S. Mahood & Son, Lower Richmond Road.—*List of Chrysanthemums.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Salvia nemorosa** (S. M. & A.).—This is no doubt the plant to which you refer. It is a native of Southern Europe and the East. The species was named by Linnæus, and appears to be synonymous with *S. sylvestris*, also of Linnæus.

**Vines Unsatisfactory** (J. T.).—So far as we can judge from your letter and the wood you have sent, we think the state of your Vines arises from either drought at the roots or overcropping, or both combined; and further, we think the house has not been judiciously ventilated.

**Dracænas for Greenhouse** (Vindex).—The following will succeed in an ordinary greenhouse:—*D. congesta*, *D. rubra*, *D. atrosanguinea*, *D. Draco*, *D. lineata*, *D. australis*, *D. nutans*, *D. (Cordylina) indivisa*, and *D. Veitchii*.

**Treatment of Orchids** (Constant Inquirer).—The Sophronites can be grown either in a small basket or on a block, and requires a moderate supply of heat and moisture at all seasons. If your plant is quite healthy we cannot understand why, with the treatment you have given, it does not flower. Suspend the basket near the glass. The non-flowering of the *Dendrobium* is probably due to the growths not being fully ripened. Place it in a light position.

**The Orchid Album** (J. E. B.).—This work is published by Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, in monthly parts, price 5s. each. The coloured plates of the first part, which is the only one we have seen, were very well executed.

**Damaged Cucumbers** (C. E.).—The box forwarded did not contain any insect, but some specimens of a small land shell. If this mollusc is really the cause of the injury complained of it can only be dealt with as other molluscs (snails, slugs, &c.), are, by applying what remedy you think best under the circumstances, and this your experience will enable you to determine.

**White Grapes** (A. Roberts).—So far as we can judge from the much-shaken and injured specimens, of which not one sound berry reached us, the variety is the Golden Champion; it is, we feel certain, not Buckland Sweetwater.

**Schinus Molle** (Edith).—This shrub is not deciduous, and your specimen is doubtless unhealthy. You do not say whether it is in a pot or planted out. If planted in good soil in a light conservatory it ought to grow large enough to produce flowers and fruit. We are unable to answer your second question

relative to the date of the last edition of the work you name, but you can obtain the information by writing to the publishers, Messrs. Bradbury & Evans, Bouverie Street, London.

**Potting Lilioms** (J. J. M.).—A compost of two-thirds of turfy loam and one third of turfy peat with sufficient sand and crushed charcoal to keep the soil porous will be suitable. The bulbs may be potted now, surrounding them with sand, and covering them an inch or more deep. If you place them at once in the pots in which they are intended to flower the pots should not be quite filled with soil, but space should be allowed for top-dressings. If the pots can be buried in moist cocoa-nut fibre refuse or ashes there will be less danger of the bulbs being injured by mistakes in watering. A cold frame or the floor of a greenhouse will be suitable for accommodating the pots until the plants commence growing, when they must have a light position and abundance of air. They thrive well plunged in ashes in the open air in summer—better indeed than in a greenhouse, unless the structure is very light.

**Fuchsias in Winter** (F. M. S.).—"Summer-struck Fuchsias" is a term having such a wide application that we hardly know how to answer your question. We have summer-struck plants that have flowered freely and are now ripening their wood. These we shall allow to rest during the winter, but they will not be dried excessively. We have other plants in 4-inch pots that have not flowered. These are now a foot high and growing freely. Their growth will be continued in a light house in which the temperature will seldom fall below 50°, and they will make fine specimens next year.

**Tuberous Begonias** (Idem).—As soon as the plants have ceased flowering, or are waning in freshness and beauty, gradually diminish the supply of water, giving less and less as the foliage changes and falls. If they are placed on a moist base in the winter the soil will probably absorb sufficient moisture to keep the tubers fresh; if on a dry stage, they may need watering occasionally to prevent the soil becoming dust-dry. Very small tubers are more likely to shrivel than larger ones are, and there is the greater necessity for exercising care in preserving them. They may be wintered in an ordinary greenhouse.

**Bush Fruit Trees** (A. Yorkshire Rector).—Most of the Apples and Pears named on page 367 will succeed as bushes, but Elenheim Pippin grows too strong for that method of culture. Better Pears can be named than those submitted for orchard trees. It will probably be to your advantage to state the number of trees you require of Apples, Pears, and Plums respectively, and varieties adapted for your purpose and district will be selected.

**Wire Trellis for Vinery** (F. J.).—The wires for forming the trellis should be the best drawn and annealed No. 6, and fixed lengthwise of the house, and at from 16 to 18 inches distance from the glass. No cross or upright wires are needed, but you will need 1½-inch angle iron at each end, pierced with holes at 9 inches apart to admit the wires, and bolt holes for securing the angle iron to the woodwork at the ends of the house. In addition to these you will require guide iron bars three-quarters of an inch by a quarter of an inch, pierced similarly to the end or straining iron angle bars to allow of the wire being passed through at the proper distance apart and from the glass, three stays being sufficient for each. The bars may be fixed 4 feet apart, or as near thereto as the rafters admit. The wires are threaded at each end and tightened with thumb-screws. We should plant the Vines at one end, it being immaterial which, and train the rod along the front and take growths from it at 4 feet apart for furnishing the trellis, and half that distance from each end. The Vines may be lifted carefully now and planted, or it may be deferred until late March or early April.

**Red Spider on Vines** (W. B. C.).—We doubt if any remedy is so good as the one we named when the foliage is seriously infested with the insects; but there is no reason why the pest should be allowed to increase to the extent that your letter appeared to imply, since pure water applied regularly with the syringe, a genial atmosphere, and proper ventilation, will keep it in check. If the Vines are properly syringed daily, or even twice or thrice a week, except when they are in flower, until the Grapes commence colouring, red spider will do little or no injury. The vapouriser was advertised by Mr. Wells, Earlswood Nurseries, Redhill, Surrey, and its price is 15s. So far as we can understand the cause of the young growths dying, it arises from the sun extracting the moisture from them faster than it is supplied by the roots. Is the border sufficiently moist at the time of the injury? If it is you must apply shade to prevent evaporation; you probably did not apply it soon enough before.

**Primulas Unhealthy** (W. M.).—The small worms are doubtless the cause of the injury, and have been introduced with the leaf soil. The only remedies we can suggest is to first try perfectly clear lime water, made by pouring a gallon of water on a lump of fresh lime weighing from half a pound to a pound, and removing the scum after standing for a day or two; or, if this fails to destroy the worms, mix a fluid ounce of paraffin with two gallons of water, minding that the mixing is effectual by violent agitation, and with this water the plants. You had better, however, try its effects on a few at the first and note the results.

**Stoves for Heating Vinery** (T. G., Co. Dublin).—We cannot advise the use of such stoves as you name for the purpose in question, nor do we think there are any stoves made that would answer your expectations. You say "hot-water pipes cannot be used without starting the other houses." Perhaps if we had a correct plan of the houses and their appurtenances we might see a way of overcoming the difficulty. We have seen so many instances of things that "cannot" be done, and which were afterwards accomplished, that induces us to think we have not seen the last; still, for all that, you may be correct in your judgment. Stoves heated with oil would certainly not be safe.

**Wall Trees** (J. H. B.).—Your first question is unanswerable, as everything depends on the age and size of the trees as to whether they can be transplanted or not. Trees of the form you have sketched are admirably adapted for furnishing vacant spaces on walls, and are largely and successfully grown for that purpose. Cordon trees have only one stem, studded with fruit spurs from base to summit. If you cut a long straight branch from one of your trained Pear trees it is the exact representation of a cordon tree minus the roots. These trees are well adapted for filling vacancies on walls, or for covering walls entirely, and may be trained either vertically or obliquely, the latter method being generally preferable.

**Scale on Ferns** (M. L. W.).—The fronds you have sent are much infested with scale, which you will find extremely difficult to extirpate. The quickest and perhaps the best plan would be to remove the fronds and burn them, removing also the surface soil from the pots and adding fresh. New fronds would soon spring up, and the plants would be better and cleaner than they are now. Possibly, however, only some of the fronds are infested, and in that case it may not be necessary to remove all. We once destroyed scale on plants similar to yours by dipping the small plants in a solution of softsoap as hot as the hand

could be borne in it for a moment, and the large plants were laid on mats and syringed; every stem was then reached, and the solution did not drain into the soil. About 2 ozs. of the soap was dissolved in a gallon of water, but Gisburst compound or nicotine soap would do as well, perhaps better.

**Myrtle Unhealthy (H. B.).**—If you closely examine the under sides of the leaves you will find close to the midrib a number of scale insects. They are not very conspicuous, but are plainly visible to the trained eye of a gardener. These insects must be destroyed, and the upper surfaces of the leaves must be cleansed of the dirty incrustation that adheres to them. You allude to the Myrtle as a tree. If the "tree" is only 2 or 3 feet high it will not be tedious process to sponge every leaf with warm soapy water, dislodging the scale as the work proceeds with a pointed stick if necessary. This will undoubtedly prove the best remedy; but if your tree is many feet high the work would certainly be tedious. The sprays, however, do not suggest that they have grown on a large tree planted out, but on a tree in a pot, that not only needs thoroughly washing, but also additional support either from fresh soil or more copious supplies of water. It is certainly in a very weak and unsatisfactory state. After sponging the leaves as directed the plant should be well syringed with clear water.

**Asparagus in Heavy Soil (H. W.).**—Undoubtedly drainage is essential in your case, but we should not excavate deeply; and if the site is very wet and the rainfall considerable, drains with good outlets should be provided for carrying off the water, otherwise excavations, even with brickbats in them, become mere watertraps. You must also obtain lighter soil, such as decayed leaves and garden refuse of any kind, and if you can burn the soil where the beds are required it will improve it greatly. For fuller and practical information on growing Asparagus we refer you to page 543, No. 25, vol. i., third series, the issue of December 16th, 1880. If you do not possess this number it can be had from the publisher in return for 3½d. in postage stamps. It contains information that will be of much service to you in endeavouring to grow Asparagus in heavy soil.

**Paraffin Stoves for Heating (A Reader).**—We are not aware of anything better than good paraffin for burning in the stove you name. There is no doubt of the desirability of having a pipe to carry off the fumes produced by combustion, as these are injurious to plants. We, however, do not think a house 23 feet long can be efficiently heated with a paraffin stove, especially if the winter proves long and severe. Some plants can doubtless be kept alive, but their healthy growth is another matter. A small boiler and two rows of 3-inch pipes would be far more effectual, and a house of the dimensions of yours is well worth such an apparatus. If, however, you decide to try stoves you must have at least two, and we much doubt if they will give you the satisfaction you expect.

**Protecting Standard Roses (J. W. A.).**—It would have been far better if the buds had not moved at all. If the winter proves very severe you will have great difficulty in preserving those "just in leaf, and others showing incipient growth." If you have dry fern in readiness and envelope the stems as well as the tops when sharp frosts occur you may save a number of the Roses, but we should do what you propose with those you are "particularly anxious" to keep—namely, pot them at once. Be very careful that the roots are not dried during removal, and pot firmly in a compost of two-thirds loam and the remainder wood ashes or leaf soil. Give a good watering, and afterwards maintain the soil in a healthy moist condition. The Roses after being potted will be better outside than in, so long as the weather is mild; and a few degrees of frost will do no harm, especially if fern is packed round the pots. There is danger in over-protection—that is, placing the Roses in too warm a temperature, and keeping them there for three or four months. As you do not say what your conveniences are for wintering them we cannot give you more precise information; but if you have not a suitable place for storing them in pots it would be preferable to dig them up, laying them close together with their roots carefully packed in soil, and then cover the plants with fern or straw in thickness proportionate to the severity of the weather. We have preserved many Roses by this practice, but the work needs to be done well, and judgment exercised in applying and removing the covering.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (R. S.).—1, Red Doyenné; 2, Easter Beurré; 3, 4, not known—worthless; graft them with better sorts; 5, Nouveau Poiteau; 6, Thompson's. (G. S., Sandbeck Park).—3 and 8, Baxter's Pearmain; 5, Rhode Island Greening; 6, Minchall Crab; 7, Hunthouse; 9, Small's Admirable; 12, Emperor Alexander. (A. B.).—We are sorry we cannot recognise your Apple. (A. S.).—1, Old Pomey; 2, not known; 3, Monkton. (C. G.).—1, Boston Russet; 3, Keswick Codlin; 4, Barton's Free Bearer; 5, Gogar Pippin. (Edward Leigh).—1, Fearn's Pippin; 2, Franklin's Golden Pippin; 4, Bishop's Thumb, The others we do not know. (Reader).—1, Napoleon; 2, Ne Plus Menris; 3, Pigeon. (Dr. Francis).—1, not known; 2, Swan's Egg; 3, Catillac; 4, Golden Pearmain; 5, Cornish Aromatic. (J. T.).—1, Wormsley Pippin; 3, Margil; 4, Mère de Menage; 6, Ecklinville; 7 and 11, Dumelow's Seedling; 9, Gloria Mundi. (Leon).—We have taken great pains to name the fruit sent, and are unable to recognise any of the specimens with certainty. (N. T. M.).—Red Ingestrie. (N. J.).—1, not known; 2, Reinettes de Canada; 3, Fearn's Pippin; 4, Norfolk Beefing; 5, not known; 6, Selwood's Reinettes. (S. T.).—Pears.—1, Beurré Diel; 2, Winter Nelis; 3, Aston Town; 4, Brown Beurré; 5, Doyenné Boussoch; 6, not known. We have attended to all the fruit we have received, except two boxes, and we have no means of knowing by whom they were sent.

**Names of Plants (J. B.).**—Pinus Hartwegi. (W. E. B.).—1, Selaginella Walllichii; 2, Selaginella cuspidata (typical form); 3, Selaginella hamatodes; 4, Davallia canariensis, var.; 5, Polypodium plesiosorum, var. appendiculatum. (Great Marlton).—Streptocarpus Rexii. (A. S.).—Cureuligo recurvata. (W. G.).—1, Asplenium marinum; 2, Adiantum euneatum; 3, Pteris serrulata; 4, P. argyrea. (X. Z.).—1, Cestrum aurantiacum; 2, Lonicera sempervirens; 3, Crowea saligna; 4, Acacia platyptera; 5, Cocciloba platyclada. (W. R.).—1, Bertolonia Van Houttei; 2, Pittonia Verschaffeltii; 3, Cypripedium insigne.

COVENT GARDEN MARKET.—NOVEMBER 16.

THE supply of home-grown Apples has fallen off this week, but with some small consignments from Canada prices remain the same, except for the best produce, which is in better demand. Kent Cobs firmer.

POULTRY AND PIGEON CHRONICLE.

STABLE ACCOMMODATION FOR HORSES.

(Continued from page 439.)

WE have one more quotation to make from Mr. P. H. Frere's essay on the improved construction of stables, published in the "Royal Agricultural Society's Journal" in 1864, because it has reference to a plan of box stabling which we had practised previously for seven years or more. He states, "When I last visited Mr. Lawes's farm at Rothampsted, the cart-horse stabling struck me as almost perfect, though obtained by the conversion of a wide, old, boarded cart-lodge into horse boxes in a homely style and at a very moderate expense. These boxes, ten in number, form a double row, with a raised walk 4 feet 6 inches wide down the centre. A shed at one end acts as a store for hay and straw, and likewise holds the chief part of the harness. Stout iron rods are used for the sides of the boxes; the wooden pillars, which form two corners of each box and range along the central path on either hand, afford a great stay and support to the old defective roof; each horse has his own rough door opening to the outside, so that he never disturbs his neighbours. The building is detached from the yards, so that one objection connected with stables opening inwards on farm premises does not here arise—viz., the horses when they go in and out for work or water do not disturb any other stock in the yard. There is louver boarding over each door, the litter on the top was clean, the air sweet, without a trace of ammoniacal gases; yet, when Mr. Lawes called for a fork and stirred the bedding from beneath, a moist mass appeared reeking with the strongest vapours. I have seen of late spacious costly halls for stabling cart nags, where neither the ventilation, the standing, nor the appliances for making and removing manure were half as satisfactory as those of Mr. Lawes."

WE have thought it well to notice this matter, as it gives a hint of utility for home farmers, under certain circumstances, for the management of farm horses, and likewise to some extent leads up to practices which we have utilised in the stables for horses employed in fast work. Before relating this, however, we shall

refer to those plans of internal accommodation for horses as recommended by some firms, and which are now much in fashion, and generally approved by noblemen and gentlemen who possess horses of the greatest value; we shall, therefore, notice the stable fittings, including horse boxes and stalls, &c., as sold by two important houses in the trade—viz., Messrs. Collam & Co., and the St. Pancras Ironwork Company. Although there are other firms and companies who can supply all the requisites for stabling, yet we have selected these merely as illustrations of what the trade can supply.

The different style of loose boxes and stalls of various patterns and combinations of plans offer not only the most approved of the day, but of the most fashionable appearance as well as utility in practice; for at present the plan is to provide the most impervious floors to either stalls or boxes with a drainage, by covered gutters from the apartments, into a trapped main which will clear away the liquid manure and fine sweepings into tanks and conveniences of various forms situated outside the buildings. There are also various devices illustrated for the conversion of stalls into loose boxes, and *vice versa*, by ingenious and simple methods. The division of the stalls or boxes are for the most part composed of wooden panels surmounted by iron grating of various patterns; but boarding is best fixed with seasoned wood, which is fixed in iron frame and sill by the patent wedge plan, in order that when repairs are required it is easy to remove the wedge and replace new boards. There is, however, a patent sill made with groove to receive boarding for the division of stalls or boxes, and also for ventilation, by means of the opening in the sill. However perfect the ventilation of a stable may otherwise be, if the ammonia and gases generated on the floor underneath the litter cannot escape there will always be some foul air retained, which it is the object by the improved sill to remove. We must now refer to the floors of both stalls and boxes which are now recommended, and in general use in some of the most important establishments where valuable horses for fast work are kept.

This subject is alluded to in a very practical manner by the St. Pancras Company. Speaking of paving and drainage they say, "There are four important points to be considered in relation to paving—1st, strength and durability; 2nd, cleanliness; 3rd, safety; 4th, good appearance." Colonel Fitzwygram in his book, "Horses and Stables," says, "The material required for really good paving must be non-absorbent, watertight, easily cleaned, durable, and not slippery. It is not, however, easy to find a material which combines all these requirements." The St. Pancras Company believe that their last invention completes a system of paving which supplies Colonel Fitzwygram's desideratum in the fullest manner. The bricks sold and recommended by them are perfectly non-absorbent, and when properly laid on concrete and carefully grouted at the joints with Portland cement form a perfectly non-absorbent floor and watertight surface, through which no moisture can penetrate. They are made of the hardest materials that can be obtained. The clays are specially selected, and burnt at the highest temperature, the bricks are therefore hard and most durable; they are also gritty as well as hard, so that they will not polish in wear and become slippery. These patent bricks have been used in Her Majesty's stables for many years past, as they are found to be the most durable of any yet tried. Two faults are common to all ordinary forms of bricks, except the perfectly plain ones—namely, that the drainage passes along channels formed at the joints, and is therefore very liable to soak into the foundations, and that the chequers or cross-grooves retain dirt and wet in spite of sweeping. Both these faults are avoided in the new patent form of brick. When this is used the drainage runs along the solid impervious brick, only occasionally crossing a thin joint; and as there are no cross grooves one sweep of the besom sends all the dirt down immediately, and the semicircular form of the groove itself prevents dirt sticking at the bottom of it, as it always does more or less in angular grooves. The grooves in these patent bricks present the most perfect foothold for the horse in rising. Another advantage is that they carry away the wet so readily of themselves that they can be laid with much less fall than common paving requires. There are three principal colours used—viz., blue black (Staffordshire), brown (Welsh), and orange or yellow (clinker). The last-named give a very cheerful appearance to a stable, passage, or yard, and the colour improves in use.

We note that as regards the drainage either of stalls or boxes that the patent surface drain can be made either open or covered with wrought iron, the advantage of which in respect of strength, straightness, fewness of joints, and safety is fully apparent; and that this patent gutter used with syphon drain pot, and with the patent bricks, makes probably the most perfect surface drainage for stables ever devised. In some plans we note that the surface

gutter is carried up to the point where water can be received direct from the drinking trough, and the waste water running down the gutter carries with it the urine, and tends thus to purify the atmosphere of the stable. We also note that Butterworth's registered dip trap, being designed as a sanitary drain pot, is made with a syphon trap cast in one piece with the pot, so that it cannot get out of order, and is always self-acting—a matter of great importance. Notwithstanding the various devices for ventilating stables it is, we think, advisable to have inlets for fresh air—such as perforated bricks or air tubes—under the racks or mangers, in order that a current of atmospheric air may carry the foul air up to the roof of the stable, where the outlet may be of various plans. The latest device we have noticed is Kite's patent roof-ventilator, as applied to the roof of any stable or cow house. We have given these lengthy details because, before concluding this important subject, we shall have to relate the details of plans for stables of a totally different character from those above described.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—The chief work is still in connection with ploughing and seeding the land with Wheat where root crops may have been fed off by sheep, such as common Turnips, Rape, and also where Carrots or Mangolds may have been removed. If the land be light we recommend ploughing and pressing and sowing broadcast in preference to ploughing and drilling, because the seed will be buried deeper than when drilled, and in consequence will maintain a better hold on the subsoil. On the stronger lands it may be well to drill the seed at a wide distance, say 10 or 12 inches between the rows, for such soils are often infested with weeds in the spring, in which case the only way to obtain a full crop is by using the horse-hoe to destroy the weeds and to move the surface of the soil. This is often more important than an application of manure, simply because the weeds are destroyed and the surface soil effectually moved by one operation. Sow Wheat on land that has been cleared of a crop of Potatoes, but in case this should be delayed by adverse weather we would wait until spring and sow White Canadian or other early best white Oats. In case the Potatoes were grown with artificial manure the land should receive a moderate coat of box-made dung. This will answer better than reversing the manure, because the season is delayed too much by carting and spreading dung before planting Potatoes. The same plan may with advantage be adopted with Mangolds, unless the yard or box manure can be laid out and ploughed in during the winter; for in this way there is no hindrance at seed time—a matter of great consequence to the Mangold crops. In all the land intended for roots next year, especially Potatoes and Mangolds, which has been autumn-fallowed, a few bunches of couch are frequently left. These, before the winter ploughing takes place, should be forked out by the women, as 2s. 6d. expended in this way often saves the outlay of 20s. worth of horse labour, besides saving valuable time at the sowing or planting season.

*Hand Labour.*—This will now consist of filling and spreading dung, making out water furrows on the Wheat land recently sown. Men should also go spade in hand after a heavy rain and examine the water furrows which may have been partially blocked by the silt collected in them, which will require to be removed with the spade. All the root crops, as fast as the leaves fall, should be examined, and any bunches of couch grass forked out before the sheep are folded on the land; for after the sheep have trodden these lumps of couch into the land the opportunity for forking it out may be lost entirely by other work intervening. Draining work and trenching the meadows may now be done with advantage. In the irrigated meadows the drowner should be employed making out the leading and drawing trenches, for the water should now be laid on so that the first floods which occur may be thrown over the meadow, and thus the deposit of silt, always left by the first floods of the season in the largest and most valuable proportion.

*Live Stock.*—As we are making these notes in the first week in November we still recommend that wherever the Clover seeds and Italian Ryegrass are of sufficient bulk for cutting they should be used for horses or any other cattle. We are now doing this on the home farm with great benefit to the animals, and with much more advantage to the grass plant than feeding off by sheep, as they cannot be trusted to feed fairly, but actually eat out the crowns of the Clover plants. No sheep should be fed on Clover after the 1st of November. We are using the Mangold leaves and Carrot tops for different animals, including breeding sows in the yards, which do well upon such food with a few peas or beans in their troughs twice a day. We may now expect lameness more or less amongst the sheep after the heavy rains peculiar to the period, and should be prepared with the remedy as fast as they break down. The latest remedy advised for washing the feet is with carbolic or salicylic acid dissolved in water; and if the infested animals' feet are dressed on the second day after it is noticed, and they are placed on dry grass land by themselves, they will soon recover without the disease spreading amongst the flock. This is now an interesting period for the owners of the best Somerset horned ewes,\* for in many flocks more than half the sheep have lambed. There is probably no stock which will pay better

for good shepherding than these beautiful animals and their lambs, for some of the latter will be ready for the butcher at Christmas where they have been well fed and cared for. Wether sheep and tegs have been doing well since harvest whilst feeding on Turnips, Rape, or Thousand-headed Cabbage. The weather having been favourable they have not required so large a quantity of cake as usual. The in-lamb ewes, both Hampshire and Dorset downs, should now be kept fairly well; but at no time should they be allowed as much as they could eat of Turnips. Rape is not good for them, but Thousand-headed Kale is the best for them with a run upon old lea during part of the day.

**BIRMINGHAM CATTLE AND POULTRY SHOW.**—We publish below the number of entries for the ensuing Show on November 26th, 28th, 29th, 30th, and December 1st—namely, Cattle, 161; Sheep, 88; Pigs, 58; Corn, 55; Roots, 124; Potatoes, 104; Poultry, 2409; Pigeons, 902.—Total 3901. The gross total is the largest ever received since the Society was established, and the resources of the hall will be hardly taxed to find room for the whole. The increase is pretty general in every section, roots and pigs excepted, and these are fully up to the average.

**CLONMEL ROOT AND FRUIT SHOW.**—Probably many readers of the Journal who may have heard of the state of tension betwixt classes in many parts of Ireland, will be surprised to find that our Show here this year has been the best ever held, both in the number of the exhibits and the extent of the collections as well as their superior merits. The roots, too, were admittedly the finest ever shown, and it is worthy of observation that the unusually large specimens and those that showed unmistakable signs of having been forced unduly, were, when examined by the judges, found to be rotten at the core, or unfit for keeping purposes. This applies generally to Turnips, Mangolds, Carrots, Parsnips, and Cabbages. I noticed, too, that when we came to the large number of exhibits grown for the prizes offered by the Messrs. Sutton, Reading, England, that, though the Turnips and Mangolds were of unusual size, they were invariably sound.—W. J. M., *Clonmel*.

**THE HULL AND EAST RIDING CATTLE AND POULTRY SHOW.**—The sixth annual Exhibition will be held in the Rifle Barracks and Grounds, Londesborough Street, Hull, on December 13th, 14th, 15th, and 16th. The prizes include a piece of plate, value £25, or that amount in money, for the best beast in classes for tenant farmers; a piece of plate, value £50, or that amount in money, for the best Shorthorn in the open classes; a piece of plate, value £50, or that amount in money, for the best Scotch or crossbred beast in the open classes; the challenge plate, value £100, for the best beast in the Show; also a large number of pieces of plate or silver cups in other classes. All entries close on Monday, November 21st. Entries for poultry, Pigeons, and Rabbits will be received up to Wednesday, November 30th, on payment of 1s. extra for each entry.

## POULTRY AND PIGEONS

### SPRING CHICKENS.

WE wrote a week or two since of January chickens for exhibition, we now add a few words as to early chickens for table. In the spring and first part of the summer chickens fetch exceptionally high prices in the market, and those who have a suitable place for rearing a few clutches in the winter months will find their extra trouble amply repaid by the larger return obtained.

Those who intend to rear any number of early chickens for table will find it pay them to procure some pure-bred birds to cross for this purpose. A few Brahma or Langshan pullets mated with a short-legged Houdan or Dorking cockerel will produce chickens that will grow rapidly, feather easily, and put on flesh sooner than almost any other cross or any pure breed. A cross between a Game cockerel and Dorking pullets will also be found to produce a plump hardy chicken of very delicate flavour. The produce of this cross do not grow so rapidly as the Dorking-Brahmas or Dorking-Houdans.

It would not pay the poultry keeper who only means to rear a few chickens to incur the expense of an entire breeding yard. His best plan will be to purchase a cockerel of some pure breed and cross him with the best laying hens or pullets selected from his own stock. If the hens are of good size a Brahma cock may be used; if they are not large a medium-sized Dorking, Houdan, Crève Cœur, or Scotch Grey will be more suitable.

As for chickens intended for table there is no necessity to have them hatched after the commencement of the new year, the setting may now be commenced as soon as eggs can be had. If an incubator is used it will be well in placing it to guard specially against draughts. When the egg-drawer is taken out

to cool the eggs it must only be left out about ten minutes, and the eggs must not be exposed to excessive cold. A thin piece of flannel thrown over them will obviate the risk of a chill from exposure. If the eggs are set under hens the nests should be placed in some warm corner, and be formed of dry ashes or earth covered with an ample supply of fine straw. Nine, or at most ten, eggs should be the number allowed to an average-sized hen. The hens should not be permitted to remain long off their nests, and on cold days a piece of flannel may be thrown over the eggs whilst the hen is off the nest.

Any dry sheltered place will do for the chickens, provided they have a fair share of liberty and are not put upon a wooden or stone floor. A clay floor lightly covered with ashes or sand is best; but if the floor be of wood or stone it may be made perfectly safe by covering it with an inch or two of dry earth, sand, or ashes. Special attention must be given to cleanliness, and any tendency to clog upon the chickens' feet is an indication that the earth requires to be turned over or renewed. While the chickens should be carefully saved from exposure to extreme cold any coddling must be avoided. We once had a servant who allowed the chickens to bask before the kitchen fire in cold weather, and we lost more from that cause than any other. A few days of such luxury rendered them unfit to meet the least exposure, and they speedily succumbed to colds and similar complaints.

The feeding must be generous, and a meal or two by candle-light at night or in the early morning is almost a necessity. A little meat must be supplied, and green food should not be forgotten.

For laying stock, it will be time enough to commence setting towards the end of January. Pullets hatched too early begin to lay in August, and moult along with the old stock.

### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Crystal Palace Hotel on Monday, 14th November, at 4.30 P.M. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Hon. and Rev. A. Baillie-Hamilton, and Messrs. T. W. Anns, R. A. Boissier, T. C. Burnell, A. Comyns, O. E. Cresswell, H. R. Dugmore, R. E. Horsfall, S. Lucas, L. C. C. R. Norris, and G. Vigers.

**ELECTION OF MEMBERS.**—The following new members were elected—Samuel J. Adams, Doveridge, Derby; F. G. Milner, Hon. Sec. Leek Show; G. C. Livett, Cambridge; William Samuel Owers, Nightingale Villa, Mildenhall, Suffolk; Mrs. F. A. Puget, The Grove, Totteridge, Herts; and J. G. Pearson, Westbury House, Market Drayton, Salop. The following new Associate was elected—R. B. Astley, Tott's Nest, Ashstead, Epsom.

**RAMSGATE SHOW.**—The Secretary reported that, in accordance with the recommendation of the Committee, Mr. Boissier had applied to the Secretaries of the Ramsgate Show to refund to him the amount of return carriage paid by him to the South-Eastern Railway Company, and that he had thereupon obtained payment of his claim.

**STANDARD OF EXCELLENCE.**—The Standard Sub-Committee submitted the following report—

#### REPORT OF SUB-COMMITTEE.

Since our last report we have, as directed by you, issued blank forms of Standard to a number of leading fanciers of each variety. Considerable delay has been caused by the great number of forms necessary, and the impracticability of having them printed owing to differences in the forms applicable to the several varieties. Further delay has arisen from the difficulty in getting the forms returned filled up.

We have commenced the task of framing a draft Standard upon the basis of the replies received, and herewith present the result of our labours with respect to both varieties of Brahmas. We have also partly framed the draft Standard of Cochins.

We have had four lengthy meetings within the past fortnight, and, judging from the progress which we have already made and the labour involved, we do not consider that we should be justified in continuing the task as we are at present constituted.

Owing to the difficulty experienced in holding such frequent meetings as would be necessary to the speedy completion of the draft Standard, we think it will be necessary that some greater distribution of labour should be effected.

We therefore propose that a great increase in the number of the Sub-Committee be made, and that the work of comparing the forms filled in by the various fanciers be distributed amongst the members of the Sub-Committee enlarged as suggested; and that subsequently meetings of such Sub-Committee be held for the purpose of revising and approving the work of its individual members.

By the adoption of this method we hope that the preparation of the draft Standard may be greatly facilitated, and that the complete work may be in the hands of fanciers within the ensuing year.

As stated in our former report, we recommend that the general annual meeting be called upon to decide by whom the Standard shall be finally settled before publication.

The report was adopted, and it was resolved "That the entire Committee do form a Sub-Committee for the purpose of framing the draft Standard."

**CLUB SHOW.**—The final arrangements as to the schedule, &c., of the Club Show at Cambridge, and the nomination of the Judges, were under the consideration and were agreed upon.

**ANNUAL REPORT.**—The annual report was revised and approved by the Committee, and directions for its publication given.

SHOWS UNDER CLUB RULES.—The Secretary reported that Dove Valley (late Mayfield) and Southport Shows are to be held under Club rules, and subscriptions were granted to each of these Shows.—ALEX. COMYNS, *Hon. Sec. Poultry Club, 47, Chancery Lane.—Nov. 15th.*

#### THE ANNUAL REPORT OF THE POULTRY CLUB.

LADIES AND GENTLEMEN,—We have, as your Committee, thought it desirable that the annual report of the proceedings of the Club be presented to you at the General Annual Meeting. We, therefore, now lay before you a brief account of what has been done since our previous report, issued in October, 1880.

It will be in your recollection that at the last General Meeting a number of resolutions intended for the guidance of your Committee were passed.

We have endeavoured to carry those resolutions into effect, and we refer to several of them at length in a later part of this report.

The increase in the number of your Committee has to some extent obviated the difficulty formerly experienced in getting together a sufficiently large number of Committeemen to form a fairly representative meeting.

Your Committee has met ten times since the last Annual Meeting of the Club, and numerous meetings of sub-committees appointed to consider various matters have also been held.

Some twenty new members and as many associates have been added to the Club during the year, and it now numbers 110 members and 80 associates.

Twelve shows have been held, or are announced as intended to be held, this season under Club rules. Amongst these are Wolverhampton, Cambridge, Belfast, and Southport.

In order to mark their appreciation of the benefits to exhibitors arising from holding shows under Club rules, your Committee have granted subscriptions in aid of such shows where application has been made.

In compliance with your directions your Committee have issued a circular to all fanciers whose names appeared in the "Fanciers' Directory" for 1880. This circular directed attention to the objects of the Club, and cannot have failed to increase the influence of the Club by extending the knowledge of its rules and aims.

As further directed by you a circular was sent to the Secretaries of the various leading railway companies in the United Kingdom, calling their attention to the treatment of exhibition birds on transit to and from shows. We are happy to have to inform you that, in compliance with a suggestion contained in the circular, many of the principal companies have issued to their employés a notice directing that special care be taken in the handling of exhibition poultry, and that no delay be allowed in the forwarding of them.

Your Committee will feel obliged by your communicating to the Secretary particulars of any cases of rough handling which may come under your notice.

The circular sent out by your direction to secretaries of shows has led to several alterations in the dates of exhibitions being made, and some clashing of shows being thus avoided.

The preparation of a Standard of Excellence has been commenced, and a Sub-Committee appointed. The Sub-Committee have presented two reports to your Committee, which they have adopted, and have referred the matter back to the Sub-Committee. The first report has been published, and need not here be set out in detail. The Sub-Committee have, in accordance with the plan suggested in their first report, issued blank forms of Standard to a number of leading fanciers of each variety. Some delay has been caused by the great number of forms necessary, and the impracticability of having them printed owing to differences in the forms applicable to the several varieties. Further delay has arisen from the difficulty experienced in getting the forms returned filled up. The Standard Sub-Committee have, however, now commenced the somewhat arduous task of compiling a draft Standard upon the basis of the replies received. Their second report relates to the preparation of a draft Standard. Some proposals as to this matter will probably be submitted to you, and it will be for you to decide how the Standard shall be finally settled.

As some misapprehension has arisen as to the object of framing a Standard, your Committee think it desirable to state that they do not recommend or suggest the application of the Standard in an arbitrary way to the actual work of judging, but merely propose that it should be used as a check upon inconsistencies in judging. To be of value it should represent the views of the majority of fanciers of each breed, and your Committee have therefore endeavoured to obtain the aid of leading fanciers as well outside the Club as within it. The number of those to whom the forms have been issued has necessarily been limited; but as it is intended that the Standard before being finally settled shall be submitted to public criticism, it is hoped that all who are interested will assist by giving their views upon the draft Standard.

Several disputes between members and others have been adjusted upon the intervention of the Club.

Several claims by members against shows and individuals have also been settled upon the intervention of the Club.

In some cases of defaulting shows your Committee have guaranteed the expenses of legal proceedings to recover the amount claimed. In regard to such matters the Club has no power to initiate proceedings itself, and can only act by giving publicity to the cases of default, and thus preventing a repetition of them.

Your Committee regret to have to inform you, that in one case brought before them they have thought it necessary to disqualify a well-known exhibitor from competing at shows held under Club rules.

The legal opinions taken by your Committee as to owners bidding for or buying in their exhibits in open and selling classes have been so recently made public, that a lengthy reference to them appears unnecessary. It has been suggested that a test case should be tried at the cost of the Club, with the view of getting a legal decision as to the question incidentally raised as to the right of exhibitors to withdraw their exhibits from sale. Your Committee do not think this point of such importance as to warrant a heavy expenditure of the Club funds, and do not recommend the adoption of the course suggested.

An opportunity having presented itself of purchasing a small private collection of books treating of poultry, your Committee have so far carried out your recommendation as to the formation of a Club library as to acquire this collection for the Club. They have not yet framed any rules as to the management of the library, which is, indeed, hardly of sufficient dimensions to be of much practical importance.

Acting on your recommendation your Committee have decided to hold a Club Show. A favourable opportunity presented itself through the courtesy of the Committee of the Cambridge Ornithological Society, and arrangements have been made with that body that the Club Show of poultry be held at Cambridge in conjunction with the Show of Pigeons and Rabbits of the local Society on the 4th and 5th of January next. The preliminary arrangements have been entrusted to a Sub-Committee acting under the direction of your Committee. The schedule is in the printer's hands, and will shortly be issued. To avoid any misapprehension it may be as well to state that the entire administrative management of the Show will be in the hands of the local Society, whose Secretary will act as Secretary of the Show.

The annual balance sheet for 1880 has already been published. Your Committee need not therefore now further refer to the financial position of the Club.—F. G. DUTTON, *President*; ALEX. COMYNS, *Hon. Sec.—Nov. 14th, 1881.*

#### THE CRYSTAL PALACE SHOW.

THIS Show, the great event in the year for poultry and Pigeon fanciers, commenced on Monday and closes to-night. It reached larger dimensions than ever, the exhibits numbering no less than 5021, of which 2851 were poultry and 2170 Pigeons. These figures are a conclusive answer to those who allege that general interest in such matters is declining. The arrangements were as usual admirable; but the difficulty of having so large a show competently judged is more clearly exemplified than ever. Still, we think that something more might have been done by the Committee to avoid incurring the dissatisfaction of exhibitors. It is well known that one or two of the Judges who officiated as to the leading varieties have been on previous occasions found wanting. The Dorkings were for the first time judged by Mr. Raines, and loud were the complaints amongst exhibitors as to the system, or rather want of system, on which the awards were made. Dark Brahmas were once more taken by Mr. Teebay; and once more, especially as to the pullet class, were the awards severely criticised on all hands. As an instance of the high prices which still prevail for Dark Brahmas, it may be mentioned that the winning Dark cock (Sir H. Thompson's) was a short time since purchased by his present owner for sixty guineas. The Light Brahma classes were judged by Mr. Lucas, who here made his *début*, and, as we anticipated, gave almost general satisfaction. In Partridge Cochin hens and pullets Mr. Dixon's awards were even more severely criticised than those in the other classes to which we have referred. Here indeed there is great need of some fixed standard being arrived at. Mr. Smith's decisions in the Game classes were, as usual, well received; and Mr. Burnell, who had the somewhat arduous task of adjudicating upon the French, Leghorn, Plymouth Rock, Andalusian, Minorca, Langshan, Sultan, and table-fowl classes, was, we thought, generally happy in his selections.

We may say that we had on the Saturday evening an opportunity of seeing the arrangements for receiving and penning the exhibits, and that the care and method with which the vast mass of birds were dealt with was most praiseworthy.

#### OUR LETTER BOX.

**Cutting Fowls' Wings (T).**—You can prevent your birds from flying by cutting what are known as the flight feathers of one wing. The flight feathers are those which when the wing is closed are completely covered by the secondary wing feathers, which alone are visible. If you leave the outside flight feather untouched the appearance of the bird will be entirely unimpaired. If, however, you want the birds for exhibition, this cutting of the wing might be regarded as a disqualification in some breeds. There is, we believe, a wing-lock sold by Miss May Arnold intended for preventing exhibition birds from flying. You might, perhaps, try this.

**Rape Cake v. Wireworms (F. H. H.).**—It is only rape cake, not oil cake, which is said to destroy wireworms, and it is further said that they fill themselves to repletion by feeding thereon and are thus killed. If it does destroy them the rape cake should be drilled with roots or corn at the rate of 5 cwt. per acre, broken into pieces about the size of horse beans or peas. We, however, do not place much reliance on the destruction of wireworm by their feeding on any kind of cake. Our experience in extirpating them is not by their destruction. We managed a farm for thirteen years on the four-course system of cropping—viz., Wheat, roots, Lent corn, and Clover. During this period the wireworms increased greatly, and made it very difficult to obtain a plant of roots or corn in consequence of their depredations. We then commenced Potato culture, and after one course of these we seldom saw a wireworm on the farm, for we found that they ate their way into holes in the Potato tubers, and secreted themselves, and were sent away with the tubers at digging time.

#### METEOROLOGICAL OBSERVATIONS.

30th	W	Liverpool Chrysanthemum Show.

### THE CHRYSANTHEMUM.

It is only during the present century that the Chrysanthemum has commanded marked attention, and so popular has it become that numerous societies have been established for the improvement of the flower that imparts cheerfulness to the departing autumn. In 1808 only ten varieties were known, in the next nineteen years they had increased by thirty, making a total of forty sorts in cultivation, while thirty years after it has been stated that one collection alone contained 750 varieties. It may be roughly estimated that the Chinese forms of the Chrysanthemum have been grown generally in gardens in England about fifty years, while the Japanese section has just attained its majority from the date of the first introductions by Mr. Fortune in 1860. Although many of the very old sorts have almost or quite gone out of cultivation, or at least are widely dispersed, still a large number of the incurved kinds now to be found on exhibition tables are many years old, for we are almost at a standstill in raising new varieties of these from seed. Sports we frequently have, some kinds producing them freely, notably the "Queens," which have furnished us with several beautiful variations; the grand trio of "the Rundles," Jardin des Plantes, Venus, and others; but in raising new and improved incurved varieties from seed we are doing nothing.

From the French we have received numerous forms of the Japanese type, many of them valuable additions. Ten years ago the Japanese section was known only to a comparatively small circle of cultivators; but now the long lines of boxes, containing hundreds of large flowers of peculiar, quaint, and grotesque forms, and of great diversity in colour, ranging from pure white to the most brilliant hues, are a striking feature at all the leading shows. Indeed, so rapidly have the Japanese forms increased of late, that it is easier now to stage a collection of twenty-four distinct varieties of this section than it is to arrange the same number of good incurved varieties.

It is not surprising in such a number of varieties so strikingly dissimilar, and some of them showing clearly marked characters, that some sort of classification became necessary. This want, indeed, was recognised years ago. In 1833 A. H. Haworth, Esq., F.L.S., formed an arrangement of the then existing forty-eight sorts, dividing them into sections. This classification was published in Loudon's "Gardener's Magazine" and the "Floricultural Cabinet" for that year, as follows:—Section I., Ranunculus-flowered, in which there are thirteen varieties named—viz., Yellow Indian, White Indian, Warratah Yellow, Spanish Brown, Blush Ranunculus-flowered, Small Deep Yellow,

Small Pale Yellow, Small Flat Yellow, Buff or Copper, Rose or Pink, Pale Pink, Expanded Light Purple, and Quilled Light Purple. Section II., Incurving Ranunculus-flowered.—Under this heading there are six described as Incurving Lilae, Curled Blush, Quilled Pink, Large Quilled Orange, Gold-bordered Red, and the Superb White. Section III., China Aster-flowered, "often showing a dise, and then much resembling China Asters."—We have here six more described as Sulphur Yellow, Two-coloured red, Early Crimson, Clustered Pink, Early Blush, and Paper White. Section IV., Marigold-flowered, with well-formed double flowers, resembling double Cape Marigolds in shape and size, and known by the names of Golden Bronze-back, Superb Clustered Yellow, Golden Lotus-flowered, Changeable Pale Buff, Starry Changeable Purple, Late Purple, and Brown Purple. "Section V., Tassel-flowered, being very tall plants with very large double and more or less conspicuously drooping flowers, whose petals are usually elongated and quilled, and often greatly resemble the form of a tassel." This appears to have been a very important section in those days, and under it are described eleven varieties. As the name "tasselled" has been applied by some writers during the past two or three years to different forms of Japanese, it may be well to cite from the author of that distinctive term:—"The Tassel-flamed Yellow.—The magnificent flowers of this tall plant appear rather late, and often measure above 5 inches in expansion, and make, perhaps, if not a more neat, at least a more showy appearance than any other of the group, being double and composed of innumerable chiefly quilled incurving petals, hanging more or less downwards, and when at their best resembling a flame-coloured tassel." Others are Tasselled Salmon and Yellow, Quilled Yellow, Late Quilled Yellow, Large Lilae, Tasselled Lilae, Tasselled Purple, Changeable Tasselled White, Narrow Quilled White, and Great Tasselled White. The remaining five are described under Section VI. as Half-double Tassel-flowered, with only half-double flowers and narrow elongated quilled petals, often drooping, and somewhat resembling a tassel. The five are Half-double Quilled White, Pink, Buff, Orange, and Pale Orange. Thus Mr. Haworth in dealing with forty-eight varieties divided them into six different sections, and it is a question if his arrangement was not more satisfactory than that of the present day with the legion of varieties now in cultivation. In forming Sections V. and VI. we might fancy the author was dealing with Japanese varieties, and it will be noticed that he divides the tasselled flowers into two sections. Not a few cultivators think that the time has arrived when the tasselled flowers of our day—the Japanese, should also be grouped in two sections; and as the classification of Chrysanthemums is still a matter of controversy, I will attempt an arrangement which, even if it does not form the basis of a settlement, may possibly lead to a recognised mode of grouping if those readers who are interested in the subject will co-operate to the end in view.

SECTION I.—Flowers in which the florets naturally incurve, in many instances to form a perfect sphere, the type being represented by such flowers as Mrs. George Rundle and Empress of India, which are merely cited as examples; others of this section will be subsequently named.

SECTION II.—Flowers the florets of which naturally reflex or turn backwards. This is a very important section, and the flowers are scarcely met with at exhibitions except where classes are specially provided for them; they are, nevertheless,

very pretty and very desirable to grow for home decoration. Dr. Sharp, King of Crimson, Cloth of Gold, Chevalier Domage, Felicity, and Mrs. Forsyth are well-known examples. But there are other flowers which it is very difficult to decide upon, such, for instance, as Julia Lagravère, President, Trevenna, &c. They are almost too small to be included, yet are too large to be admitted amongst the Pompons. As there is a danger in making too many sub-divisions, I feel that all those which are frequently termed hybrids (of which the varieties just named are good examples) must for the present be included in Section II.; in fact, I have frequently seen Julia Lagravère exhibited in a stand of twelve reflexed, and when disbudding has been practised and a large bloom is produced and placed in the front row it is generally one of the most telling in the stand on account of its richness of colour.

SECTION III.—Japanese, or, as expressed by some, Tasselled varieties. This is now a most important section, and one that may be well sub-divided, as from the rapid increase in the varieties and the introduction of partially incurved and reflexed forms it is almost impossible to meet with a collection of the pure old-fashioned Japanese form as introduced by Mr. Fortune and afterwards increased by the late Mr. Salter. Size and substance of flower in many cases have taken precedence of form. We have all shades of colour and all shapes. For instance, the exquisite pure white Elaine is a very bad type of a Japanese; its petals, or more correctly speaking florets, quite reflex, and yet who could dispense with it from their collection? Then there is Peter the Great, a most pleasing yellow with long narrow flat florets, which naturally incurve and form quite a ball. Others have florets that curl and twist in divers shapes, as in the Dragon class—Chang, James Salter, Hero of Magdala, and M. Crousse; while with M. Ardene, Jane Salter, Sarnia, Alba plena, and several others, their florets are straight and almost rigid like the bristles of a broom. In Bouquet Fait, Fulgore, Meg Merrilees, Baronne de Prailly, &c., the florets droop and fall beneath the calyx of the flower in long hair-like curls. I cannot think that the varieties described as tasselled by Mr. Haworth will apply correctly to our present forms of Japanese, with the exception of perhaps one, and that is Soleil Levant. Considering the well-defined characters that exist in the Japanese flowers now in such great variety, the question arises whether the true tasselled varieties should not be separated from those with flat florets. There are sufficient of both to form good classes, and the subject might be considered by committees of Chrysanthemum societies. Having made the suggestion I pass on to the other types of the flower under notice.

SECTION IV.—Large Anemone-flowered varieties. These are very striking, and so distinct to the foregoing to almost indicate another species. The majority of them are composed of an outer fringe of flat florets, while the centre is formed of short quills, which in a well-formed flower rise up in the form of a hemispherical disc. Gluck, Prince of Anemones, and Lady Margaret may be taken as fair examples of this section. The varieties are by no means so numerous as the other two sections, still there is no difficulty in being able to exhibit twelve distinct kinds.

SECTION V.—Small Anemone-flowered or Anemone Pompons. These, while possessing the same small foliage and dwarf habit of the Pompon or Liliputian reflex flowers, have an outer ring of flat florets, with a raised central disc exactly after the manner of the larger-flowering Anemones in the foregoing section, but barely reaching a fourth of the size of these. The neatness and perfect form of each flower are very striking, and when set up on the exhibition table, three stems of each variety with their foliage raised from 4 to 6 inches from the boards, they are always admired; but they are seen to a great disadvantage when set up with single stems only, therefore framers of schedule of prizes would do well to stipulate for three stems cut to form a bunch.

SECTION VI.—Pompons. These are miniature flowers very double, each being a perfect half globe of reflexed florets. The varieties are very numerous. Middle Marthe, although one of the largest of the section, is a beautiful pure white and a model of the type; Bob and the varieties of Cedo Nulli are other good examples.

Mr. Douglas, in his useful work on florist flowers, forms a separate section of the early-flowering or summer-blooming varieties; but is this necessary? I think not. They are mostly good examples of the Pompon, and for an outdoor display are most valuable; but we are obtaining early-flowering varieties from the other sections, especially the Japanese, and before long we may have forms of Elaine and James Salter blooming early out of doors. Already Mr. Cannell describes Madame Desgrange under the head of Early-flowering as a white Japanese. Further details on varieties and their treatment must be postponed.—J. W. MOORMAN.

#### FRUIT TREES IN COTTAGE GARDENS.

IN an article on this subject, at page 448 of the *Journal of Horticulture*, "A KITCHEN GARDENER" gives advice to the tenants of such gardens to plant fruit trees liberally, with a view to the profitable sale of such produce. Such advice is, no doubt, sound so far as the experience of the writer in question extends, but the advice is not equally good for all localities. It seems to me a duty to state something within my own knowledge of what may be said on the other side of the question, so that the *pros* and the *cons* may be fairly before those who would plant.

Can the fruit be sold after it is grown? In the neighbourhood from which I write so great has been the crop this season of Apples, Pears, and Plums, that they have been practically unsaleable. One poor man with a productive orchard of Apples and Pears adjoining his house, after trying hard to sell on better terms, was considered fortunate in disposing of the whole of his produce for 1s. 6d. a bushel all round. The Apples were not what are termed "cyder Apples," but comprised several good keeping sorts, Orange Pippins and White Nonpareils. Others have sold their Apples for 1s., and even 9d. a bushel. Such prices would barely cover the cost of gathering. A great quantity of cyder has been made from all sorts of Apples, not because it was wanted, but it seemed better to do this than to let the fruit decay. Some very fine ripe Victoria Plums sent for sale to a village shop realised about three farthings a pound.

I made several inquiries, partly with a view of assisting my poorer neighbours to dispose of their produce. Writing to the nearest market town (ten miles off), no reply was vouchsafed by a dealer to the question whether or not he would purchase fruit. Presumably he had already more than he could sell. On calculating the cost of hampers or casks for packing, with the carriage to the nearest station and the railway charges, it was clear that the expenses of transport would exceed the market value of the fruit.

Those cottagers who live so near to a good market town that they can themselves carry their fruit thither, may well plant fruit trees; but the results of so doing, in the case of the far larger number who live in villages more or less remote or scattered over the country, will certainly be doubtful. I can quite understand why the tenants of my own few cottages have more than once declined my offers to stock their gardens with young trees of good sorts. The objections were twofold—the trees would overshadow their Potato and Cabbage ground, and they probably could not sell their surplus fruit.

I would further suggest, whether it might not be possible to organise some plan by which dealers should send round carts or waggons in the fruit-gathering season from village to village, to purchase on the spot the carriageable kinds of fruit. The practicability of such a scheme could be determined by those who possess the necessary technical knowledge.

A word of caution to those who are about to plant. I have in previous years planted several hundreds of fruit trees. The selection of sorts has been made by myself. The great majority has come from Messrs. Rivers of Sawbridgeworth and Smith of Worcester, and in every instance the trees are true to name. The minority has been obtained from local and less famous fruit nurseries, and very many of these trees are not true to name. Thus Joséphine de Malines turns out to be Williams' Bon Chrétien, Red and White Ginetting both bear the unmistakable fruit of the Devonshire Quarrenden, and so of many others.

The result in such instances is much the same as it would be if you had ordered a case of port wine, and not opening it for a year or two after receiving it, had then found by some unaccountable muddle, your bottles contained porter and not port wine. The disappointment would not, perhaps, be so great in the latter case, because the matter could be more easily remedied, but your expressions of gratitude to both classes of purveyor would, no doubt, be emphatic.

I might have troubled the readers of the *Journal* with an account of the varieties of Apples, Pears, and Plums that have

been found most productive among the many that I have planted, had not the subject been treated recently in its pages by so many able pens.—A SURREY PHYSICIAN.

#### A CLUMP OF TREES.

FEW matters in forestry or landscape gardening require greater care, judgment, and forethought than planting and arranging an ornamental clump of trees. If well done, nothing affords greater satisfaction. Growing yearly in importance and beauty it is always a pleasant sight as a whole; and the gradual development of each tree, the manner in which each individual of the group tells upon the others in contrast or harmony of form, foliage, or colour, are all sources of interest, pleasure, and instruction. Badly done it is, on the other hand, a deplorable and vexatious sight. Crowded, sickly, or stunted growth; heavy masses of evergreen foliage unrelieved by deciduous growth, or a badly chosen confused mass of deciduous trees without a single Conifer or tree which retains its foliage in winter—these are some of the most conspicuous faults; but a still more common one is that of neglected clumps, planted with all due care and with well-assorted trees, but too thickly, as is so frequently the case. Their growth has become intermingled, drawn, and attenuated past all remedy, for, the mischief once done, no subsequent thinning and admission of light and air can possibly restore the wasted vigour.

In this, as in much else, we live to learn and to unlearn, the latter process being by no means easy. There are two distinct kinds of clumps that I have in mind—mixed clumps of various trees, and clumps of one kind only. Of the latter I can recall many admirable examples, not simply from the large size or symmetrical growth of the trees, but rather from the fine effect produced by each in its well-chosen position. Take for example a clump of *Cedrus Deodara* in a corner of a park—a formal right-angular corner—very conspicuous, having one of its lines defined by a row of fine old Beech trees, and the other by a belt of underwood and Oaks. The Cedars stand out singly upon the turf about 60 feet apart, and well away from the other trees, all of them deciduous; and although they have only been planted nine years a striking effect is already produced. One day, in another generation or two, when they become large trees, the clump will be quite worthy to rank with the beautiful Cedar lawn at Mount Edgcumbe.

Of other clumps of one kind of tree I may mention a grove of magnificent old Beeches near a stream of water, some of them not more than 80 feet apart, others twice that distance; no other trees are near them, nor are any wanted at any season of the year, for the grand old trees are sufficient in themselves to rivet the attention. A bold clump of Silver Firs high up near the crest of a steep hillside, with a wood of Oak, Beech, wild Cherry, and various other deciduous trees below it, is singularly well situated as a background to a charming woodland scene, visible from the windows of a house standing upon an eminence on the other side of a valley. I have a particular regard for this clump, because I saved it from the hands of a destroyer some years ago—one of those dangerous improvers who only value a fine tree for the quantity of scantling to be cut from it.

Mixed clumps are justly much more cared for, but it is not so easy to plant them successfully. The nature of the soil must be our guide to selection, for it never answers to plant deeply rooting trees in a shallow soil. For a deep rich soil we may take varieties of Oak, Ash, Elm, Magnolia, and Plane, with the Tulip Tree, Poplar, Lime, Douglas Fir, Spruce, and many of the loftiest Conifers; while for shallow soil, Beech, Birch, Maple, Chestnut, *Cratægus*, Cherry, *Pyrus*, Robinia, Willow, and many Conifers answer best. Particular care should be given to planting the permanent occupants of a clump far enough apart to allow a full and symmetrical growth. It is not easy to lay down rules for distances, but it may be stated that trees with spreading heads should be from 40 to 100 feet apart, according to their known dimensions and the nature of the soil.

Bear in mind the effect of summer foliage, and also the beauty of autumnal tints. The Cherry, Birch, Beech, Maples, Liquid-amber, Tulip Tree, Scarlet Oak, Purple Beech, Whitebeam, and some of the Willows, are all so picturesque in autumn as to materially contribute to the beauty of a clump then. One of the most beautiful trees for the margin of a clump is *Acer polymorphum atropurpureum*, but it does not seem likely to attain to any considerable altitude in this country, the growth being slender and somewhat spreading. Mountain Ash, too, is good for the margin, both for its sweet-scented flowers and scarlet berries. It was very beautiful this year.

Larch may be planted among the trees as nurses and gradually cut away, or other trees may be planted with a view to subsequent removal, thus converting the clump into a nursery for the first

few years of its existence. Whatever method of treatment be resolved upon, frequent attention must be given to the trees for several years, and they will well repay all our care. Let me impress this strongly upon the reader. Too often trees are left to take their chance after the planting, with the common result of debility, disease, or death.—EDWARD LUCKHURST.

#### CROWEA SALIGNA MAJOR.

WHEREVER New Holland plants are grown in numbers for the greenhouse the Croweas almost invariably receive some attention, for amongst such as flower late in summer and early in autumn these are very attractive. Moreover, they are as easily grown as

Fig. 75.—*Crowea saligna major*.

any other plants from the same district, and much more easily than many. One of the finest varieties is *C. saligna major*, of which a spray is represented in fig. 75. It is a form of the species *C. saligna*, which is a very useful, free-flowering, and strong-growing plant, but the individual flowers are not so large as in this variety, which is appropriately termed *major*. Another form, also with large flowers, is named *striata*; but the colour is very much lighter, being a pale delicate pink, while in *C. saligna major* it is a rich deep rose.

The spray from which the engraving was prepared was taken

from an extremely well-grown specimen in one of the houses at The Firs, Lawrie Park, Sydenham.

#### POTATOES OLD AND NEW.

I REMEMBER many years ago, when visiting the Warden's garden at Winchester College with old Mr. Weaver—as good a man as he was a gardener—that I asked him what he considered the best Potatoes. His reply was, "With the exception of a few Ashleafs for very early use I grow only one kind, and that is the Dalmahoy; it comes in as a second early, and it lasts throughout the season." Twenty years have elapsed since then; a Potato mania has set in; Potatoes of all kinds and from all quarters have been introduced. America, its native home, has sent us a number of coarse and worthless varieties; seedlings have been raised; selected stools have been brought forward; and yet in 1881 I am coming to the opinion Mr. Weaver expressed in 1861, and am inclined to believe that for all purposes after the very early sorts no Potato can surpass the Dalmahoy. What, then, it may be asked, is the use of the Grand International Potato Show? I say, None whatever to the general public. Hundreds of worthless varieties are brought forward. They are, perhaps, good-looking, well washed, and daintily set up, and some are even certificated; yet, notwithstanding, nothing has been done to give us reliable information as to good Potatoes, how to keep them from disease, &c.

Of course there is the question, What is a good Potato? I have a neighbour who cannot endure a floury Potato; a close waxy one is his idea of goodness. I have a young friend who delights in "pig's Potatoes"—*i.e.*, small close little things which we think only fit for the pigs, but in the ordinary mortals the idea of a good Potato is a medium-sized floury Potato with a good flavour; besides this, for a garden it ought to be of moderate-sized haulm and a fair cropper. Now, if this is a correct view there are many that will fail to fulfil the conditions. One of the American Potatoes has found much favour with cottagers—Early Rose, but I have not yet tasted one that was eatable. It is a good cropper, and, ripening early, can be lifted before the disease attacks it; and as cottagers, as a rule, do not much care about quality in Potatoes, it is likely to be popular; but when taken to market its inferiority is soon seen. It will not fetch within a third as much as Regents or Victorias. Take, again, another American—Snowflake, a pretty-looking Potato, a fine cropper and floury; but it lacks flavour. It is like flour in the mouth, and has as little flavour as it has, and therefore, although at one time I was inclined to grow it, I have given it up. Then there is *Magnum Bonum*, undoubtedly a wonderful cropper and of fair quality, but its haulm is far too coarse for a garden; but where Potatoes are grown for market it, and probably still more Reading Abbey, will be a very useful variety, but neither the one or the other are garden varieties. Scotch Champion is a very valuable sort to some people if the stories we hear of the quantity sent to Ireland be correct; and for Paddy, who has no objection to a "taty" with a stone in the heart of it, it seems to have answered well. I have been unfortunate, for I have never tasted one that was worth anything, coarse and unpleasant to the taste. Lapstone is, I believe, the very best of all Potatoes, and if imitation is the most flattering, it has been flattered enough. Heaps of tubers have been and are shown as Lapstones which have no relation whatever to it; but when true its flavour is unsurpassed, indeed I think unequalled, by any Potato in existence; but it is too delicate, and is gradually dying out. The only kidney variety that I know that at all approaches it is one called Lady Paget, and much grown in the neighbourhood of Sherborne, and of which Mr. Pragnell, the able gardener at Sherborne Castle, might be able to tell something. The Regent class is, perhaps, after all the most valuable of the various classes of Potatoes. The old Scotch Regent, the Kent Regent, the Dunbar Regent, Schoolmaster, and Dalmahoy are all excellent Potatoes. The Regent is, however, very much subject to be attacked by disease; but the Dalmahoy, which is somewhat earlier, and can therefore be lifted in good time, is not with me so subject to it, and gives a fair crop of good-sized Potatoes.

I believe nothing is to be gained by having extra large Potatoes. A medium-sized one is, as a rule, far better eating. And is not the same true of all vegetables? Does not great size produce coarseness? Is not a medium-sized head of Celery better than those enormous heads which some delight to produce? Is a Broccoli that fills a soup plate as good as one about the size of a cricket ball? or a Cucumber  $2\frac{1}{2}$  feet long equal to one of 12 inches? And so I am always content with medium-sized Potatoes.

There is another point on which I have altered my opinion. I used to think that it was a barbarous custom to cook Potatoes

without their skins; but I find that much depends on the cook. They should be always steamed, not boiled; and when carefully done they are better, I do believe, when peeled first. One gets rid of that earthy taste which often spoils a Potato; and, moreover, the cook is able to detect any disease and reject the tuber, whereas when boiled in their skins enough may be left to injure the Potato, although it may not be visible to an inexperienced eye.

I have, I am perfectly aware, advanced some opinions in this short paper which are heretical and may be displeasing to many; but at any rate they are honest, not formed upon any insufficient grounds. I have grown during the last twenty years nearly every Potato that has been brought out. I had no prejudice against any one sort, or special favouritism for any other. I may be quite wrong in my estimate of what a Potato ought to be, but there are matters incident to every subject on which one may write, and if it induces anyone to show that I am wrong no one will be more ready to admit it than—AN OLD "TATER."

#### GREEN DRACÆNAS.

As market plants these are often seen, but in large and in small establishments they seem to have been neglected since the coloured kinds have become so plentiful. We do not wish to say one word against the latter, but to point out that as table plants, surrounded by pure white cloth, flashing crystal, coloured decanters and glasses, to say nothing of fruits and flowers, they are very much less effective than the green varieties. Coloured or variegated plants, which are attractive enough among other plants, are seldom so good for such work as those with green foliage. We know here our coloured Dracænas find small sale compared with the green kinds. Doubtless this is one reason for the popularity of Palms.

There is one fact more to recommend green Dracænas—namely, that they are even easier to propagate and grow than coloured kinds, and that, while the coloured kinds need stove heat, the green kinds thrive in greenhouse temperature, a fact that those who possess only a greenhouse should note. They also endure indoor ill-usage better because they are hardier. *D. congesta* and *D. rubra* are two of the hardiest, and perhaps the best. The former is more elegant than the latter, the latter more substantial than the former; but both are handsome plants not easily surpassed for table decoration. Neither are new, as both are cheap.—A DECORATOR.

#### PEARS FOR WALLS.

"JOHN BULL" does not need to make any excuse for the paper in question, whether he be a gardener or not. It is only by stating our experiences and our convictions, and having them discussed, that we are ever likely to improve. What I wrote was to cause others to pause before committing themselves to a method of fruit-tree culture so winningly advocated by "JOHN BULL."

As for the boldness displayed by me in writing after Mr. Taylor and Mr. Warner, my paper was in the hands of the Editor before their papers appeared. Moreover, I did not and never have advocated the employment of Quince stocks in preference to Pear stocks. I know many places where Quince stocks have failed altogether, and others where they succeeded admirably. The question is not so much one of stocks but of tops, and I still think—indeed, I am convinced—that in the majority of instances large trees are much less profitable than are smaller ones. I have lifted the roots of large hopelessly barren trees out of the subsoil, and have thus restored such trees to something like fertility, and I have helped to train the branches and roots of smaller trees that were kept small because of the lifting, and even pruning, that was necessary to keep the roots among the healthy soil, and I cast my vote in favour of such trees. I do not advocate pigmies—that is one extreme, successful enough under certain circumstances; and the giants referred to are the other extreme, also successful under certain circumstances, but in a majority of instances not successful at all.

"JOHN BULL" says he has "never been so foolish as to imply that bad weather does not affect Pears on walls." Well, I have only his words for it, and the words he used were, that although climatical reasons made Peach houses necessary, the objection had no force as applied to Pears. He asks if I never heard of bad weather spoiling the Wheat and Potato crop, and, if so, if we would discontinue the culture of these crops. I do not see the analogy of the cases. We did not advocate discontinuing Pear-growing. Assuming that there are good, better, and best ways of growing them, my idea is that we should choose the best. But I will not assume, as "J. B.'s" words entitle me to do, that he is

so remote from civilisation as never to have heard of farmers abandoning the cultivation of Wheat and Potatoes, and substituting something else that promised better returns, just as we would have "J. B." not to be so particular about the exact length of his trees' branches, but to "go in" for abundant and early fruitfulness.

My advice "to secure early and abundant fruitfulness and not to bother with the affairs of our grandchildren," affords your correspondent a chance of saying that I hold the "jerry builder's creed." Again, I fail to see the analogy. The jerry builder's work not only does not promise shelter for future generations but threatens to destroy, and is a constant source of annoyance to the present. Pear trees trained on the "short-cut to fruit"-principle cannot be called dangerous, while to the planter it is "J. B.'s" trees that are likely to annoy. To liken either system to the jerry builder's work is exceedingly far-fetched; but if it is allowed at all, surely it applies not to the training we advocate, but to that advocated by "JOHN BULL."

I did not say that Pear trees would not grow without having borders made for them. But I said, and say still, that first-rate results need not be looked for from trees trained as advocated without good borders. That they will grow we are all aware, but we want something more than growth—we want fruit; and not only fruit but good fruit, and we have yet to learn that good Pears can be produced all over these islands from trees the roots of which are allowed to run into cold clay or cankered gravel. Here and there, especially in favoured spots, this may do, but few are so favoured.

"JOHN BULL" says that the question is not "walls *versus* orchard houses." That is quite true, but he asked the possessors of *new* walls to "seriously consider" how to fill them. We asked such to "seriously consider" whether it would be wise to build at all, but rather to "consider" whether orchard houses would not be more profitable. Whether the erection of orchard houses would "cause the removal" of existing walls is beside the question, as it is not a question of removal but erection when new walls are concerned, and to new walls alone we referred.

I put what I thought a pertinent question when I asked why the gentlemen and gardeners whose memories were long enough to remember the "splendid and splendidly" trained trees were grubbed up. I am asked now, "Who said they were grubbed up?" I inferred that what was merely a memory must be gone; and that if only gardeners and gentlemen of a certain age only could remember them, that they must have been grubbed out.

I am sorry that some things your correspondent asks me do is not just now in my power. I am far from my home where the copies containing "JOHN BULL'S" article and my own are, and so cannot refer to them. There are many other things I would have liked to reply to, but illness makes me stop here. The doctor enjoins change and rest; these I can only have for a very short period, and I feel neither willing nor able to grapple the subject. My purpose will be served if attention shall be aroused on an interesting subject.

One thing more and then I close. I am asked to furnish proofs that such training as I advocate is superior to his. If he wishes to have samples submitted of trees and their produce, I can only say that most of my experience has been gained under others. Under masters I have worked both (or rather a variety of) systems, and to say that here this failed, and there that succeeded, would be invidious. Still the results—it matters not who secures them—must be the test whereby to judge of systems, and my experience is as I have tried to indicate; and I feel that for my part, had I a new plantation of Pear trees to plant against walls to-morrow, I could best secure satisfactory results by planting trees in good loam on Pear stocks and keeping the roots fibry near at home—near the surface, mulched when need be, fed when need be; and this means restricted top growth, because of restricted root growth; fine fruit because, the roots being near the surface, the sap would never be cold, and because of this feeding applied just where and just when required. This is just the threshold of the subject, but here necessity compels me to stop.—A. H. H.

**BRACHYCOME IBERIDIFOLIA.**—This pretty annual is generally known as the Swan River Daisy. About the last week in June I sowed a few seeds of it in the open ground. In August, noticing that some of the plants which had plenty of room were dwarf and sturdy, I at once potted half a dozen of them, and they have not only pleased me for the last few weeks, but they have received favourable notice from several visitors. How long they will continue growing and flowering I cannot say. At present they show no indications of giving way; and although they are not so full of bloom as the plant represented in the figure on page 413, they are not to be despised at this season, the small blue Cineraria-like flowers and Asparagus-like

foliage both contributing to the attractiveness of the greenhouse.—W. W.

## ROSES.

WITH every passing year there is to my mind a confirmation of the position that Roses succeed better on their own roots than on any stock. This is admitted of many Roses. I believe it to be true of all varieties. It is now commonly recommended that scions on the Manetti should be planted so deep that the bud will form roots. This, so far as concerns that stock, concedes the whole point. But it is true of the Briar and every other stock. The most delicate Roses are, with rare exceptions, more hardy than the Briar tribe. In nine-tenths of the deaths of standards the fatality is found in the stock and not in the scion. Plants budded on John Hopper, Edward Morren, and other robust-growing Roses do better than on the Briar, and even where a scion succumbs the stock will itself produce blooms. But for the difficulty of producing large quantities on their roots I think the budding mania would soon end.

Cuttings of all Roses strike readily. Most of them can thus be propagated in the open air. A few delicate varieties may need some protection; but that raises the question whether plants that cannot be propagated and do not thrive in the garden are worth cultivation. I think they are not. But rosarians have, like other people, wild fancies. To some Rose-growers there is pleasure in producing Roses under needless difficulties. These enthusiasts forget that the Rose is queen of the garden. A plant which will not thrive except under glass, or when wrapped in swaddling clothes, should be discarded in common with scentless varieties and those shy bloomers that reward a year's labour with a single flower. I am by degrees discarding all plants except those grown on their own roots. This is, it is true, the whim of an amateur. But I have been so vexed with stocks throwing up suckers, thus depriving the Rose plant of its nurture, and with the death of the stock while the Rose itself was healthy and vigorous, that I have resolved to do without Roses budded on any stock which is not itself a good Rose.

I have a great many of our best sorts growing with more vigour on their own roots than on any stock, and, so far as I have had the means of judging, Roses are more floriferous on their own roots than on Briar or Manetti stocks, and the blooms come of better form. My advice to everyone who grows a small number of Roses would be to have none except on their own roots. If they desire a standard, let it be on a good Rose tree. It is no deformity to have several varieties growing upon the same stem. Indeed in this way variety may be a great advantage. The stock may thus carry its crown of flowers from June to November by budding early and late varieties upon it. This is the only mode in which standards should be grown.

I daresay that some lovers of the Rose may be disposed to impeach me for treason. But I hope to live until it will be treason to disfigure our gardens with mop-sticks and mop-heads.—W. SIMONS, *Gwainarren, Merthyr Tydfil.*

## VAPOURISERS.

I SHOULD like very much to see the question of vapourisers or spray-distributors discussed in your paper. Nothing would be more useful to a horticulturist than a really efficient instrument for such a purpose, but as yet I have found none. I have used for several years Maw's spray-distributor, which is sold for the diffusion of scent, and most useful I have found it for Roses in pots, Pelargoniums, &c., but for a vinery this is too small. I applied recently to the maker of the vapouriser which you described and figured in your paper, and he sent me one on trial. I found it, however (whether from my own fault or that of the instrument I cannot say), a total failure. It did not work well horizontally, and the moment the nozzle was raised so as to bear upon the leaves of a vinery its action ceased altogether.

Many years ago I saw in a horticultural paper the figure of an American instrument, which I thought might be very useful, but I do not know whether it could be obtained in this country. The vapouriser was hung with a swinging joint on the nozzle of a pair of bellows, so that whichever way the instrument was held the vessel containing the liquid retained its perpendicular position. By working the bellows the spray was distributed.

A really efficient vapouriser would, I should imagine, be most welcome, not only to English horticulturists but to Indian Tea-planters. The great enemy which they have to contend with is the red spider. Their method of cultivation is the following:—Supposing a shoot of the Tea plant to contain five leaves, they take two and the final bud and leave three, from the base of which

fresh shoots are developed. It is upon these old leaves that the red spider fixes, and a vapouriser that would dislodge or kill the red spider before fresh growth has begun would, without exaggeration, be worth thousands a year to the planters. Can none of our clever men invent such an instrument, cheap and simple in action? or is there one already in existence?—A LOVER OF HORTICULTURE.

#### SENECIO PULCHER.

SENECIO PULCHER, the Beautiful Groundsel, deserves its name, being beautiful either as a conservatory plant or in the open border if well grown. It is, however, rather difficult to manage. In better climates than mine it may be what it is called a hardy herbaceous perennial; but though the roots are not killed by frost, no plant has yet flowered with me which has been left in the open ground all winter. I find it best, therefore, to give it biennial treatment, the particulars of which I will describe. It produces fertile seed very sparingly in this country. A large quantity of seed which I saved last year gave me only two or three plants, and Mr. W. Thompson of Ipswich tells me that he has tried in vain to obtain good seed. In default of seed, plants must be raised from root-cuttings. In autumn after the plant has flowered it must be lifted and the soil shaken from the roots, a number of which will be found about the thickness of Wheat straw. The larger of these may be cut into lengths of  $1\frac{1}{2}$  inch, and inserted upright in a pan of sandy loam, so that their tops are even with the surface of the soil. If these are kept through the winter in a greenhouse or frame having an average temperature of about  $50^{\circ}$ , a large proportion of them will be found to be growing. When the leaves are as large as a sixpence the plants may be potted singly, giving them large pots to encourage the development of roots, which in this plant are large and many in proportion to the leaves. If by liberal treatment any of them have made leaves 6 inches long by the end of May they may be planted out or potted on for the conservatory, and induced to flower the first autumn, but in most instances the growth is provokingly slow.

I keep them in the open air in pots through summer, and, after a second winter in a cold frame, plant them out in May. The soil should be rich, moist, well-drained loam, and the situation sheltered from hot sun. Some of the best of these two-year-old plants have this year made leaves 15 inches long, and five or six flowerstalks, each producing a dozen flowers. If left out in the winter in cold damp soil, the cold or the wet, or both together, cause the crown to rot, and the roots are found detached from it. These will form shoots late in spring, but will not be nearly such strong plants as when treated as I have advised. After the larger roots have been cut from the plants which have flowered the crown may be potted, either whole or divided; but as far as my experience goes it seldom makes a flowering plant again for two years.—C. WOLLEY DOD.

#### THE CHAMPION POTATO.

THIS excellent variety has been largely cultivated during the last few years. Nearly all new vegetables and flowers have the best of situations, the best of soil, and the very best of care bestowed upon them at the first time of sowing or planting, yet when they prove good less care is taken with them, and they are planted in inferior soils and positions. Last year in this district the Champion Potato was grown extensively, the season was very dry, and the yield was enormous and of very good quality. Last season they were planted as widely as the year before, but in many instances in worse soil, the result being a complete failure. The variety does not like wet land. For instance, in this district some were planted in wet mossy land, while others from the same seed bags were planted in drier sandy soil. Those planted in the wet mossy land were scarcely worth forking up, while those in the sandy land were a very good and sound crop. Magnum Bonum thrives fairly in wet land, and is a better keeper than the Champion. There is an old variety called the Skerry Blue very largely grown in some of the midland counties. It is not a very handsome Potato nor yet large, but it is quite as good in quality as the Champion if well cultivated. All intending planters of the Champion would do well to exercise a little forethought as to the nature of the soils, if they desire in return a good crop and good quality.—A NORTHERNER.

CURIOUS PEAR.—By accident at the picking of the dozen or eighteen Pears that followed some late blooms, this fruit in question was hidden and unnoticed till the foliage began falling. High up on the tree it had a somewhat quaint appearance, but on close

inspection it seemed to me an effort to make a Pear out of another Pear, like the Rose occasionally blooms from the growth in the centre of another bloom. There was a division in the Pear, as if a string had been tied round it. The larger portion of the Pear was farthest from the stem. At this constriction four or five small leaves, one of them an inch long, were found, the stems of these leaves appearing to be lost in the pulp of the fruit. On section there was no trace of a seed vessel in the smaller portion, and very slight in the larger.—Y. B. A. Z.

#### SILKWORMS AND SILKWORM-REARING.—2.

ALL the caterpillars that yield silk belong to the family of the Bombycina—moths easily distinguishable by their broad fore wings, under which the hind wings are hidden when the insect is at rest: also by their stout bodies, and the absence of a tongue for taking food. Though the antennæ are variable they are usually short, frequently comb-like or beautifully feathered in the males. Many other caterpillars placed in different groups of the order, which includes the butterflies and moths, are producers of a silk which forms a part or the whole of the cocoons they make, by some attached to substances above ground, by others placed beneath the earth, yet these are not available for manufacture. Even amongst the Bombycina the valuable silk-spinners are but few, and these do not occur naturally in a temperate climate such as ours. Bombyx Mori, pre-eminently the silkworm, may be considered to have its home in China, and the majority of those species that have been experimented with in these recent years have their habitats either in Asia or America, and in a variety of situations, but seldom in very warm regions.

At an early period in history there evidently was some silk manufactured by a carding process. The ancients, as we call them, were, however, awake to the special excellence of the cocoon spun by B. Mori, because it was formed by a continuous

Fig. 76.—Bombyx neustria.

thread; hence it could be reeled or wound off, and a few species beside this one present the same peculiarity. We have in Britain a goodly number of Bombycina that spin cocoons, but none whose habit is to work the body of their cocoons with one thread. In the attempts that have been made, therefore, to get some sort of silk from our native insects it was found necessary to card the substance.

There does not appear to be much probability that the cocoons of any of the British moths will be turned to account in this way, and, were it possible, the rearing and management of the caterpillars present nearly as many difficulties as does the nurture of exotic species, supposing it were conducted on a large scale. Many of the Bombycina—the tiger moths, ermines, and eggers, for example—mix their hairs in the cocoons, which is sufficient to render them useless for their silk. The lackey moth (fig. 76), which we have represented with the silkworm moth for comparison, is produced from a yellow cocoon which has a superficial resemblance to the cocoon of the latter. This moth, Bombyx neustria, is darker in colour and generally less than B. Mori (fig. 77), but, like that species, it is inclined to be sluggish. The caterpillar is very different from the silkworm, slightly hairy, and of various colours. The cocoon is not very dense in its silk, and with that the caterpillar mingles a sulphur-coloured powder, the use of which is not known. Our handsome moth called the Emperor (Saturnia carpini) spins a curious double-mouthed cocoon of tough brown silk. A near relative of this species has attained to a place on the list of silkworm moths—the S. pavonia major, an insect larger and still handsomer. The cocoon, however, is not likely to become

of commercial importance, I should say; nor do appearances indicate that any of the recent candidates for the patronage of the rearers of silkworms will obtain the position so long occupied by the Mulberry species, though some persons are strong in their assertions that *Bombyx Mori* is getting "worn out."

Caterpillars, as may be here observed, are not the only sources of silk. Long ago an ingenious person conceived the idea of getting some good out of an insect commonly disliked, by collecting the webs, or rather the egg-cocoons, we believe, of various spiders. Some of these were, with difficulty, made into a coarse fabric, but the supply was insufficient for practical purposes. At a recent meeting of entomologists held in the Westminster Aquarium several cocoons of a new kind was exhibited, presumed to be the work of a *Bombyx*, and received from Queensland. The cocoon resembled that of the silkworm, *Attacus Cynthia*, only rather larger; on examination it was discovered to be the nest of a colony of young spiders. On the exterior this cocoon was tough and papery, within there was a mass of loose silk, amongst which the eggs of the spider had been deposited.

Again, seeing that in the case of *B. Mori* the connection is manifest between the leaf upon which the caterpillar prefers to feed, so silky in its texture, and the substance produced by the insect, some folks once imagined they might get silk direct from the Mulberry leaves, but the experiment did not answer. The stalks were chiefly used in the attempt, which dates back to the seventeenth century, at an early date in which Olivier de Serres also suggested that the liber of the Mulberry would afford a valuable fibre, which by plans he particularised could be made into cloth equal to that yielded by hemp or flax. Nothing much was done for many years in this direction; the project was revived some thirty years since by two Frenchmen, with no results of any importance, however.

Fig. 77.—*Bombyx Mori*.

To this same Olivier de Serres belongs the repute of having powerfully stimulated the culture of silk during the reign of Henry IV., who was anxious to stop the transmission of money from France for the purchase of raw silk. He was also famous for a book of his, the "Théâtre de l'Agriculture," the perusal of which led this monarch to say that Serres was his master in agricultural knowledge. Having published full instructions concerning the culture of the Mulberry and the rearing of silkworms, he had the pleasure to witness the effects, in the planting of many thousands of these trees, while eggs of the silkworm were distributed throughout France, with a view to ascertain what districts were best suited to its habits. For some time the production of silk and its manufacture went on favourably, but a severe check was given by the revocation of the Edict of Nantes, which drove the Protestants of the Cévennes and other places into foreign lands. Many silk-weavers came to Britain, and our silk trade grew rapidly, being perhaps at its best under the early Georges. In 1719 Mr. Lambe constructed an elaborate silk-spinning machine, which required a building nearly a quarter of a mile long. He obtained £14,000 from Parliament in reward. As lately as 1821 silk to the value of eight millions was worked up in this island, but from a variety of causes our silk factories have declined, and France yet remains the principal European country where silkworms are reared and silk goods produced.

The title of the "Father of Modern Silk Culture" has been applied by Figuier and other authors to the Abbé Boissier de Sauvages. He was himself an experienced feeder of silkworms, and had investigated the history of this insect, so far as it was then known, though hardly, we think, deserving of this pre-eminence for his works on the subject. Count Dandolo, a man of Venice, did his part, rivalling or surpassing the Abbé, by what he published upon the art of silk culture about the beginning of this century. Amongst the matters he specially insisted upon was the avoidance of overcrowding the worms, the necessity of fresh air, a careful regulation of the temperature, and regularity in the supply of food. Several Frenchmen have distinguished themselves in the present day by their diligent endeavours to encourage silk culture; and though it is difficult to mention modern names without appearing to make an invidious selection, we may single out MM. Beauvais, Robinet, and Guerin-Melville.

The last-named gentleman devoted a life to the economy of silkworms of various kinds, and he was the first to rear French specimens of *Attacus Cynthia*. Dr. Wallace has published some interesting reports of his experiments with that species, also with *B. Pernyi* and *Yama-Mai*; and Mr. Wailly of Clapham has reared successfully a number of silk-yielding species, some previously unknown in Britain.—J. R. S. C.

#### RESPONSIBILITY OF GARDENERS.

AT the time I wrote the article referred to by "ANOTHER MANY-HANDED GARDENER," I had been visiting some very large and famous gardens, where I found the plants in pots very much below par. Some of them were large enough and bad enough. At the same time, or rather shortly before, I had visited some smaller gardens, and was charmed with the beauty and health of the plants in pots. I tried to account for it, and although I have "riled" some of the "many hands," for which I am sorry, I still think I am right both in the facts and the explanation. "ANOTHER MANY-HANDED" knows much more about Eskbank than I do, for I never heard of the show mentioned. I was thinking of Edinburgh, and some even "owre the Border." As to mentioning reasons why some at least of the large places in Edinburgh and Glasgow carry off the prizes, I should be obliged to say what had better not be said—facts that would be at once recognised, and statements which would raise much ill feeling; and as I do not intend doing this, "ANOTHER MANY-HANDED" must excuse me following in the lines laid down, although I may safely say a large purse has had best skill before now. I may say, however, that when "ANOTHER MANY-HANDED" has to employ such logic as this—Here A B (a many-handed), has beat C D (a single-handed), with plants so large that C D's house could not accommodate them, for they, like most houses about small places, were not meant for elephantine productions; therefore, C D is not such a good gardener as A B—he must be greatly confused, and this is just the logic which refers us to the prize list at large flower shows.—SINGLE-HANDED.

#### NOTES ON APPLES AT GIRTFORD IN 1880 AND 1881.

APPLES have been but a small and inferior crop at Girtford during the past season, the fruit also being generally small. The blossom was largely injured by the May frosts, but I consider a good deal of the defective crop arose from the floral organs being only imperfectly developed during the untoward season of 1880, the wood not being thoroughly ripened. From similar causes I had only a partial crop in 1880. The soil in which my Apples are grown is light, hot, and sandy. The summer temperature averages high, but the springs are cold and unsuitable to the setting of fruit. Perhaps, therefore, the following notes as coming from an unfavourable Apple district may be of some value, as I am convinced that only the hardiest varieties will do at Girtford.

The best early Apples were Mr. Gladstone, Early Julian, and Quarrenden. The two former bore freely in 1880 and 1881. Mr. Gladstone is a very handsome and useful early sort, a finer edition of Early Margaret, and appears also more fertile than Margaret, as the latter did not fruit last year. Quarrenden was also fertile this season, but not so much so in 1880. Lord Suffield also bore fairly this year, but not last. Golden Noble, a first-rate autumn cooking Apple, known chiefly in the midland counties as Orange Pippin, appears more entitled to the name than the true variety, as having more resemblance to the Orange, had a good crop both years. Cellini has been fertile and good both seasons. Early Strawberry bore this year, and is a good and pretty Apple. Keswick Codlin did not fruit either season. Cox's Orange Pippin has a few fruits each year. Sleeping Beauty bore well in 1880, but no fruit this season. Schoolmaster, the new and handsome Apple of which I have but one small fruiting bush, bore well both seasons, and promises well to become one of our standard fruits. Stamford Pippin, my first pomological production, has been very fruitful both on the Paradise stock and as a standard each season. The good qualities and rich vinous flavour of this Apple are hardly yet sufficiently known. It has, however, one defect, as it will not bear frost, and must be gathered before the early frosts appear. Peasgood's Nonsuch and Lord Burghley, two of my protégés, have both fruited on young trees this season. Sturmer Pippin, slightly fertile in 1880, has borne a good crop this year. Franklin's Golden Pippin, a fine dessert fruit, bore well this year, but not in 1880. Cockle Pippin had a heavy crop last year, but none this. Court Pendu Plat cropped heavily both seasons. The old and Winter Hawthorn dends have each had a full crop this season, but scarcely any in 1880. Normanton Wonder, a few small fruit only each year. Norfolk Beefin bore fairly in both seasons, and this

year the fruit is very fine, indeed the largest Apple in the garden. Reinette Superfin and Warner's King had each a few fruits on young trees. Missouri Pippin, a very handsome and useful American variety, has borne freely on quite young trees and seems an acquisition. French Crab has had a few fruit in both years.

The following good Apples have not fruited as yet at Girtford—viz., Ribston Pippin, Annie Elizabeth, Nelson Codlin, and Blenheim Pippin; and although I have grown the latter Apple in various forms and in many situations during twenty years, I have never seen but two or three fruits on it. All the Apple trees seem well set with plump buds, and augur well for a crop next year if only the spring be propitious. Several seedlings have borne a few fruits this year, and in more than one instance this is apparently owing to the ringing or tying of branches tightly round with wire, the consequent stoppage of the flow of sap tending to early fertility. I am trying also the French Paradise as a stock for this purpose.—T. LAXTON, *Bedford*.

#### THE PHYLLOXERA CONVENTION.

WE have received from Mr. Aug. Van Geert, President of the "Chambre Syndicale" of Belgian nurserymen, the terms of the Convention which was signed at Berne on the 2nd inst. relative to the exportation of plants from one country to another. The Convention of the 17th September, 1878, is annulled, and the following are the terms of that of the 2nd November:—Plants, shrubs, and all vegetables except the Vine sent out from nurseries, gardens, and hothouses are admitted to international transit, but cannot be introduced to a State except through the custom house. The said objects shall be packed securely, but in such a manner as to permit the necessary authentication, and ought to be accompanied by a declaration of the sender and an attestation of the competent authority of the country whence sent out—*a*, That they come from a soil separated entirely from the Vine by a space of 20 metres or less, or by some obstacle to the roots judged sufficient by the competent authority; *b*, That the soil does not itself contain a plant of the Vine; *c*, That it is not there made any depôt of that plant; *d*, That if it had there had Vines attacked with the phylloxera, total eradication, poisonous operations repeated during three years' investigations, have been made, which assure the complete destruction of the insect and the roots.

The declaration of the sender accompanying plants of Vines ought—1, To certify that the contents of the packet are entirely sent out from his establishment; 2, To indicate when they have been received, and the address of the consignee; 3, To declare that no Vines are in the package; 4, To state if the package contains plants with clods of earth; 5, To bear the signature of the sender. The attestation of the competent authority ought always to be based on the declaration of an official expert. The convention of September 17th, 1878, is referred to on page 2, vol. i., new series, the issue of July 1st, 1880.

#### LATE-STRUCK CHRYSANTHEMUMS.

IT was not till the present season that I discovered the value of late-struck Chrysanthemums. I do not claim originality for the method, for I believe it has been practised for years by some gardeners, but at the same time it is not generally known and practised. Chrysanthemums may be said to be chiefly grown in gardens for two purposes, one for the embellishment of the conservatory, the other to supply blooms for cutting. The old method of growing Chrysanthemums answers admirably for the latter purpose, but in some conservatories tall plants cannot be accommodated. At one establishment where I was employed the show house was rather a peculiar one: it was a span-roofed structure with a passage down the centre, all the plants had to be arranged on the two shelves; the consequence was that no tall plants could be employed. In such establishments the use of late-struck or dwarf Chrysanthemums is apparent. Last year we grew a few late-struck plants, but owing to some mismanagement they did not prove equal to my expectation. This season I have grown a good batch and paid a little more attention to them; the result is we have some first-rate plants, and I find them extremely useful.

My plan of growing them is a very simple one. In spring after the cuttings are taken from the old plants the stools are then planted out. They require no more attention through the spring and summer. It is from these that I take the cuttings for my late plants about the first week in August, selecting, of course, the strongest shoots. The cuttings are inserted in large 60-pots, placing three cuttings in each, and using a rather light compost of loam, leaf soil, and sand in equal parts. The pots are then plunged in a dung frame made up expressly for the purpose, and kept close till the cuttings are rooted, shading of course

being employed in bright weather. The young shoots are rather hard at this time of year, and they take a little longer to form roots than they do in spring. When the cuttings are rooted more air must be admitted in order to prevent the plants being drawn. After the pots are filled with roots the young plants should be potted into 48-sized pots, using a good rich soil, one-fourth of which should be well-decayed manure. After the plants are established in the new compost the lights may be removed altogether for a time, and weak liquid manure may be given advantageously twice or three times a week till the plants are in bloom. It is, perhaps, necessary to state here that no pinching is required, for they invariably break with three side shoots. I have some plants that have as many as twelve shoots from the three cuttings, and many of the flowers are 3 inches across; others, again, do not break out but continue to grow on. These produce the finest flowers, some of which are 5 inches or more in diameter according to the variety. They are very useful in many ways. They are admirably adapted for small vases where single plants are required, as they carry their foliage to the rim of the pots, looking as fresh and healthy as the day the cuttings were taken from the parent plants. I have a good batch of these late-struck plants in bloom now, and others coming into flower, whilst the late plants are only just showing flower. Thus a good long season of flowering is obtained.—W. K.

WE have received a copy of the third edition of M. Ed. Pynaert's work, "LES SERRIS VERGERS," which is a complete treatise on the forcing of fruit trees under glass. The subject is treated most skilfully and exhaustively, and the text is copiously illustrated by well-executed woodcuts. In this edition M. Pynaert has made many additions and improvements on the former; all the latest systems and appliances are referred to, even including Dr. Siemens' experiments with the electric light as applied to plant-growth.

— RELATIVE to the MILDNESS OF THE AUTUMN a Lincolnshire correspondent informs us that Wallflowers are blooming in his garden, and *Myosotis dissitiflora* is a sheet of blue. A writer from Hertfordshire says that Primroses, Polyanthuses, and Auriculas are flowering very freely; and a gardener writes from Kent that "the Black Currant bushes are swelling their buds rapidly as if it were spring."

— "W.X." writes, "CHRYSANTHEMUM MADAME DESGRANGE should be grown by everyone having a supply of cut flowers to maintain. It is past now, but was in full beauty a month ago. The flowers are pure white."

— WE note with much regret the sudden death of the HON. A. LESLIE MELVILLE of Branston Hall, because he was such an ardent garden admirer, and had such a great respect for gardeners as a body, many of whom he esteemed as his friends. By his great practical knowledge of horticulture and the high social position which he occupied he was frequently applied to for gardeners, and many good men obtained excellent appointments on his recommendation. Mr. Melville had long found the advantage of sending his gardener to see the works of others, and he was, in fact, visiting the Chrysanthemum shows near London when his esteemed employer died. He was one of the oldest contributors to the *Cottage Gardener*, and occasional notes from his pen appeared in our columns up to a recent date. He died on Saturday last in the 82nd year of his age.

— THE testimonial fund that was a short time ago instituted for MR. BRUCE FINDLAY has resulted in the noble sum of £1078 17s. The presentation, we presume, was made last evening (Wednesday), a circular before us announcing that as the

date of the ceremony in the Town Hall, Manchester, under the presidency of the Mayor. We trust the recipient of this remarkable token of esteem will long enjoy the position he has won as a skilled and trusted horticulturist, and able administrator of a Society that has prospered under his management and attained to much more than local fame.

— REFERRING to the note of our correspondent on *GRAPE* IN SCOTLAND (page 450), another Scottish correspondent states that our readers must not consider that all cultivators adhere to the old 75° night temperature for setting Muscats, as some of the foremost cultivators have modified their views and practice on that point. Much lower night temperatures, he states, are practised than formerly, and the Vines and crops have not deteriorated, while fuel has been economised.

— "IT is well known," observes a correspondent, "that *CALANTHES* are some of our most useful winter-flowering plants when well grown. I think the best way to grow them is singly in small pots or shallow pans. My plants have succeeded well this year. Each pseudo-bulb, old and new, was potted singly in small 48's, three parts filled with potsherds. The compost employed was fibry loam two parts, one part peat, and one of decayed cow manure. When the pots were filled with roots liquid manure was given freely. The temperature of the house was about 65° by night. The pseudo-bulbs when potted were only about 3 inches long. Growths of *C. Veitchii* are now about 9 inches long."

— WE have received the first two parts of the *ICONOGRAPHY OF INDIAN AZALEAS*, by M. August Van Geert, published at Ghent, a work devoted to coloured figures, with descriptions, of the best varieties of these popular plants. The work is issued in monthly parts, each containing three chromolithograph plates, those now before us being well executed. The descriptive notes are written by M. V. Cavelier, and in the English edition are translated by Mr. Thomas Moore, jun., Chelsea. The varieties represented in these two parts are *alba speciosa plena*, *Madame Paul de Schryver*, *Antigone*, *Elise Lieber*, *Madame Louis Van Houtte*, and *James Veitch*.

— THE forty-second annual report of the Council of the *ROYAL BOTANIC SOCIETY* states that the proceedings of the Society during the past year have been very satisfactory in every sense, the receipts showing a large increase over those of previous years, and the public displaying a growing interest in the objects sought by it. The total receipts during the year were £7232, exclusive of £400 raised in debentures, and the expenditure was £4860. The Council express satisfaction at the value which is attached to the Gardens as a means of furthering the study of botany, but particularly in its relations to the other sciences, arts, and manufactures. They report an increasing number of applications from artists, medical students, and others for admission to the Gardens and for specimens; while Professor Bentley's botanical lectures are yearly more fully attended. At the same time the Gardens are rendered a source of pleasure and a valuable and agreeable retreat in the heart of the metropolis.

— ON the evening of the 16th inst. Mr. F. A. Fawkes delivered his first of three *LECTURES ON HORTICULTURAL BUILDINGS* at the Crystal Palace. The lecture was illustrated by diagrams, and the subject was treated in an exhaustive manner. The sites for houses, forms of structures, with details of building, were in turn referred to. Alluding to the pitch of roofs the lecturer remarked—"In order to receive the sun's rays within 10° of a right angle at noon, for sixteen weeks before and sixteen weeks after the longest day, the roof must, in London, be inclined at an angle of 37° from the horizontal, adding 1° for each degree north, and subtracting 1° for each degree south. In most cases, however, for growing purposes, a lower pitch economises space and artificial

heat, and is really more advantageous, a pitch of from 26° to 30° being very suitable. This angle of 26° is equal to a rise of about 6 inches to the foot, one of 30° to 7 inches, of 33½° to 8 inches, of 36½° to 9 inches, of 40° to 10 inches, of 43° to 11 inches, and 45° to 12 inches rise vertical per horizontal foot. For fruit-growing along the rafters from 36° to 40° would be a suitable pitch, for plant-growing in low houses from 26° to 30°, and for wall-fruit cultivation, where a narrow high pitch is advisable, from 65° to 70° may be suitable. With the same width and the same pitch, a span and a lean-to roof contain the same area." On the question of wood *versus* iron roofs for houses, the following remarks are pertinent—"For ordinary cultivating purposes the 'sash' construction is rapidly going out of fashion in favour of the 'sash-bar,' as the latter is simpler, cheaper, affords less obstruction to light, and less woodwork to rot or harbour insects. This suggests the question, Is iron better than wood, or not? As it is desirable to employ a minimum mass of materials consistent with strength and durability, iron is far preferable in this respect to wood. It is also more durable if well painted; if painting be neglected it will rust, damage the plants, and wear out. On the other hand, iron houses are more costly than wood; heat is conveyed away from the interior rather more rapidly; and unless the glass is carefully put in it is apt to crack. [For these reasons, for growing houses, wood is preferred to iron. Copper has been used for sash-bars: it is much better than iron, but proportionately more expensive. If wood be used, it is extremely necessary that it be thoroughly seasoned, on account of the varying temperature within and without, and the exposure. If the wood is not well seasoned crevices will soon appear, in which moisture and insects will be harboured, and the house will soon become useless.]"

#### DOUBLE ZONAL PELARGONIUMS.

I AM sure many of your readers will, like myself, be much obliged to one who signs himself "A LOVER OF HORTICULTURE" for his remarks with regard to *Pelargonium Guillon Mangilli*. It has always been a mystery to me why this double *Pelargonium* in particular should have received so much commendation. I began to think it must be my want of taste in not admiring it. I confess I cannot really like any of the double *Pelargoniums* I have seen as yet. No doubt they are useful for cut flowers, as they last longer and the petals do not fall so soon, but there is a roughness and coarseness about most of them, and generally speaking they run to leaf instead of flower. I have discarded one after another, and have yet to find one which I think worth the trouble of careful cultivation. When at different times acting as judge at some of the larger shows, as Leeds, York, and elsewhere, I have always noticed when the plants of double Zonals have been staged next to, or in the same line as the single, how very inferior the effect is. There is, I consider, much more variety in colour and habit among the singles. Nor can I see the wisdom of growing too many plants in pots of the same kind of any of the Zonals. *Vesuvius*, for instance, is no doubt very free-flowering, but there are too many good varieties now which with proper management may be made to bloom nearly all the year round, that it seems a pity to rely on a few only.—C. P. P.

#### NOTES ON VEGETABLES.

WOULD it not be a valuable innovation to devote a column to short notes on vegetables? We have all obtained aid from the fruit notes, and doubtless much knowledge would thus be disseminated. What would, perhaps, be of most interest at this time would be notes as to the usefulness of the different varieties of standard vegetables. We are all generally agreed as to the best Apples and other hardy fruits; but with vegetables, which are constantly being added to with new varieties which are to supersede all the older kinds, there might not be the same unanimity amongst growers. The *Journal* is always filled with valuable matter, and it is astonishing how week after week such valuable numbers are produced; but I do not think your readers would like the *Journal* less for the new feature I now propose.

May I set the stone rolling by saying a few words as to the best Potatoes? I am not old-fashioned, but really after trying new kinds year after year, aye, even some that have had certificates

granted only the other day, I returned to old varieties for garden croppers. Next year Myatt's Prolific Kidney will be grown in the greatest quantity. Next in quantity will be the Fortyfold and Dons. There are no Potatoes, either new or old, to surpass these in flavour. The two last-named are not extra large croppers. The kidney when well grown has very large crops. The seed Potatoes ought to lie in single layers on shelves, and one single sprout alone allowed to grow. A soil rich in Potato food is another requisite. These conditions will insure a very large yield of fine kidneys.—E. S.

#### CHRYSANTHEMUM GOLD BUTTON.

LAST spring I placed two plants of this variety in a border along with some others; by the end of September, when they commenced blooming, they were 2 feet in diameter and densely covered with flower buds. About the middle of October they were taken up, potted, and placed in a cool house, and until the present time we have been cutting from them every day. For those who have little accommodation for growing flowers this is one of the easiest managed and useful plants we have for providing a supply of cut flowers during October and November.

We have several other good varieties of small-flowering Chrysanthemums here, but none that produce the same quantity of flowers; and then the bright lively colour—clear bright yellow, shows to good advantage when associated with green Fern fronds.—JNO. SHORT, *Darlington*.

#### WHAT PLANTS USE.

(Continued from page 372.)

##### THE SOURCES OF PLANT FOOD—PHOSPHORIC ACID.

A REFERENCE to the analytical table of farmyard manure will show that phosphoric acid is generally present in fair quantity. In stableyard manure, owing to the hard feeding of the horses, it is generally more abundant still. Animal excreta in almost all cases have, in addition to organic and other mineral matter, a large per-centage of phosphoric acid. The ash of horse droppings contains 10 per cent. The same analysis shows 62 of silica, so the 10 per cent. must be considered high. The great amount of silica is present in the hay, but is of small account to garden crops. It, therefore, serves merely to dilute the other matters, and of itself counts for little as a garden manure. Guanos are generally very rich in phosphoric acid and ammonia salts, but they vary much. Still, after the ammonia guanos owe very much of their value to the phosphoric acid they contain. A good guano should possess 20 to 25 per cent. of bone earth (phosphate of lime) and about the same of ammonia. It is not often that they are so rich, and often they are very deficient in both. Mineral phosphate of lime is found in many different districts in the form of apatite and coprolites—the last supposed to be the remains of animal excreta. These are to be had in the markets in a manufactured state, such as superphosphate of lime. Very often they are mixed with other ingredients, such as dissolved bones, kainit, nitrate of soda, and guano, and sold as "special manures." Some of these special manures are very good for the purposes for which they are offered, others worth very little. It is safe to buy only those manures sold by respectable firms, who have a reputation to lose and who issue guaranteed analyses.

These manures are generally used and their value understood, therefore we will not take up space by any further reference to them. But we wish to draw the attention of gardeners to the value of night soil as a means of furnishing phosphoric acid to soils deficient in that necessary compound, or to crops which demand it largely. Were it possible to utilise all the sewage which is at present worse than wasted, there would be no need for the importation of phosphoric acid in any form. We continually import food of all descriptions and export little. In that food we import potash and phosphoric acid, and all the other mineral elements which plants use, and these, in conjunction with what are derived from our own vegetable productions, would, if applied without waste to the soil, make that soil richer year by year, instead of allowing it, as in too many districts, to grow poor and less productive. How to profitably apply it is still an unsolved problem, but there can be no doubt that in many a country place the sewage from mansions, as well as drainage from farm and stable yards, are allowed to be wasted because of the ignorance which prevails regarding its value. There is no more powerful or more generally useful manure sold or bought than the sewage water with which we pollute our streams and rivers. Its value is not entirely owing to its phosphoric acid, but to the fact that it contains all the mineral matters required by plants in abundance.

Moreover, it is rich in nitrogenous matters, which in the soil readily become ammonia salts, nitrates, &c. We append a table showing the per-centage of each compound in night soil:—Phosphoric acid, 37.17; sulphuric acid, 2.10; potash, 10.40; soda, 2.83; lime, 14.98; magnesia, 13.48; salt (common), 1.59; oxide of iron, 4.66; insoluble matter, 12.79.—Total 100.

The reader on examining this table may be inclined, considering what we said on potash and comparing it with the list of cultivated plants and the per-centage of potash found in their ashes, to think that potash is deficient; and so it is when only the solid matters are taken, but when to these is added the urine, he will see that it supplies what the former wants. Ash of Urine (Human).—Phosphoric acid, 4.80; sulphuric acid, 1.68; potash, 6.65; salt, 55.87; lime, 15.60; magnesia, 14.80; iron oxide, 0.24; insoluble matter, 0.36.—Total 100. Common salt is largely present, but leaving that—we shall say something on that further on—it will be seen that the potash is present in greater quantity than any other compound.

As sewage comes from mansions it is very largely diluted with water. When gardens lie below the level of the house this can be economically applied by means of pipes and hose, or even by the water-barrow and can. In dry hot weather no better liquid manure can be had for ordinary garden crops, and even plants in pots, than water tainted with sewage. For Vines it is equal, we think surpasses, the best guano water. For all kinds of Cabbage crops it is first-class. Indeed there is nothing to which it may not be applied with benefit. Melons supplied with no other manure will thrive well, set, and swell off large crops year after year for an indefinite period, if freely supplied with mixed sewage largely diluted with water. Trees and shrubs thrive on it, as we can prove. Some years ago plantations were made round this place, which up till two or three seasons ago made no progress. Sewage in large quantities being available, we covered the ground among the trees with it, and left it there for the grass to cover. The result is a magnificent growth, when only starvation was apparent before.—SINGLE-HANDED.

#### DEATH OF DR. DENNY.

IT is with unfeigned regret that we announce the death of Dr. Denny, whose name has been a household word in the horticultural world for some years past. A few months ago Dr. Denny had an attack of paralysis, which laid him aside and incapacitated him for the performance of his professional duties, but his friends hoped that a change of air to the bracing climate of the east coast would have the effect of restoring him to a degree of convalescence which would enable him to recover sufficiently from the attack as to permit him to resume his former pursuits. He returned very much better in health; but the recovery was only temporary, for he succumbed on the 15th inst., at the age of sixty-two.

Dr. John Denny was the only son of Mr. John Denny, surgeon, of Ipswich, and at the time of his death was resident physician of Stoke Newington Dispensary, an appointment he held for upwards of thirty years. But it was chiefly as a horticulturist that Dr. Denny made his mark. The speciality he took up was the race of Zonal Pelargoniums, which he set himself to improve, and which he did improve with marked success. The mantle of Donald Beaton appeared to have fallen upon him, for he carried out the cross-breeding principle of that remarkable man with great success, and thereby gave to the world some of the finest forms of the Zonal Pelargonium that have ever been produced.

Dr. Denny was for many years, first a member and afterwards Chairman, of the Floral Committee of the Royal Horticultural Society, and for six years before his death he was a member of the Council, while at the time of his death he was a Vice-President of the Society. None but those who were intimately acquainted with Dr. Denny knew the extent of his devotion to the interests of the Society, and the assiduity with which he threw himself into the minutest details of its working. He was most jealous of its honour, and he strove hard to make it the faithful representative of horticulture in its highest and best sense. In the death of Dr. Denny horticulture has lost a brilliant ornament, and horticulturists a warm friend.

#### TREE-LIFTING.

AN invitation to Dunse Castle, near Dunse in Berwickshire, to see a novelty in tree-lifting, was duly taken advantage of, and when I arrived there I found several trees set up, while all around were others lying prostrate, and which were to be raised in due course. These trees had been overturned by the disastrous gale of October 14th, some of them forming a portion of a Lime tree

avenue leading to the Castle, and said to be from 150 to 200 years of age. Owing, most probably, to the poor character of the soil the trees were not so large as might have been expected; still, they are of a size sufficient to make many prophesies that the possibility of setting them up again was extremely problematical. However, Mr. Hay, the proprietor, desired them raised, and Mr. Shearer was appointed to do it. All had large balls of roots. Many of the branches were smashed, and the whole of these were cut back to the main trunk. Three strong wires were then fastened near the top of the tree, also guy ropes and a thick wire rope to pull them up with. Two screw-jacks were employed to raise the trees to an angle of 45°, then a winch 80 yards distance was set to work to draw up the tree by means of block and tackle to a perpendicular position. The soil was then filled round the roots, and the work completed by tying the ends of the three wire ropes to stakes driven into the ground at equal distances round the tree. The trees were being lifted at the rate of one a day.—B.

#### THE METEOROLOGICAL SOCIETY.

THE opening meeting of this Society for the present session was held on Wednesday the 16th inst., at the Institution of Civil Engineers. Mr. G. J. Symons, F.R.S., President, in the chair. Twenty-seven gentlemen were ballotted for and duly elected Fellows of the Society.

The evening was devoted to an account of "the Gale which passed across the British Isles, October 13th and 14th, 1881," which had been prepared by Mr. G. J. Symons, F.R.S., with the assistance and co-operation of Mr. C. Harding and other gentlemen. There is evidence of the storm being formed in the Atlantic about 150 miles south of Nova Scotia on October 10th, and that at noon on the 13th there was a considerable disturbance about 600 miles west of Galway. At that time there were scarcely any instrumental indications in the British Isles of the coming storm; the barometer was falling at Valentia, but not rapidly; and at some of the western English stations it was rising. The curves of barometric fluctuation show very plainly the advance of the depression from west to east, for while at Valentia the minimum occurred at 2 A.M. on the 14th, on the east coast of Norfolk it is recorded that it did not occur till 4 P.M. This fact, coupled with others, seems to indicate an easterly progression of the barometric minimum at nearly forty miles per hour. As far as the sea is concerned, the chief force of the gale was felt in the afternoon of the 14th in the German Ocean, and there the great loss of life and destruction to shipping seems mainly due to the exceptionally violent squalls which were peculiar to this gale, as well as to the extremely sudden manner in which the wind increased to hurricane force. The afternoon became quite darkened by the salt water blown into the air, so that it was impossible to see a ship's length ahead. The barometric chart for 9 A.M. on the 14th showed that the pressure in the north of England was an inch lower than in the south, and nearly 2 inches lower than in the south of France. The area over which injury was produced was very large, and, although not without precedent, it was happily rare. The record of 56 lbs. per square foot at the Royal Observatory, Greenwich, was the highest ever registered in that locality, and close by thirty-five trees were blown down in the park, and 15 feet blown off the top of a spire which had been erected about forty years, the stone of which shows no sign of decay, and which had retained its position almost, if not wholly, by the gravitation of its mass. The general opinion seems to be that the structural damage over the greater part of the country was by no means unprecedented, and in the greater part of Ireland and the south-west of England was not even of an unusual character, but along the east coast and in the east midlands the damage was excessive, and on the north-east coast unprecedented. In Scotland the destruction of trees was enormous.

Mr. J. Wallace Peggs, F.M.S., also read a paper on the "Structural Damage Caused by the Gale as Indicative of Wind Force," and remarked that since the Tay Bridge disaster attention had once more been directed to the subject of wind-pressure. He suggested that a conference of delegates from societies specially interested in the subject should be held, who should make experiments and carefully consider the whole question.

#### POTATO CULTURE.

As I have to supply sixty people for nine out of twelve months, I must look well to the Potato supply. I have tried many different varieties for the last five years, both kidneys and rounds, my aim having been to obtain those which my employer likes, that would bear rough treatment, and yet would be of good quality. It is very well to talk about 16 tons to the acre when the land and Potatoes are worked with fork and spade and the land in a high state of cultivation, but all cannot obtain good land, and what Potatoes are there that will bear rough cultivation? I have Potatoes that I give superior cultivation, and I secure good crops, but they will not bear rough cultivation. For instance, the Woodstock Kidney will not with me, but Suttons' Magnum

Bonum will, and so will the Scotch Champion. The produce is different, Suttons' Magnum Bonum takes the lead. I have tried both sorts side by side, and I have too many small tubers on the Champion. The flavour is good, but that of Magnum Bonum is better.

The following is what I term rough cultivation. A piece of land is ploughed up late in the autumn after root crops, such as Mangold, Swedes, Kohl Rabi, or Vetches, or a piece of lay land is ploughed up 4 inches deep, the latter ploughed again early in February. The land is very poor, and is left rough until the second week in March. The land is harrowed with one horse, and it is thrown up in ridges 2 feet apart with the plough waiting the first fine day. Farmyard manure is thrown between the ridges, which are 4 feet apart, 16 to 20 tons an acre being employed. The Potatoes are planted on the manure; at the same time I distribute 2½ cwts. of dissolved bone to an acre, and draw the earth over the Potatoes with a mattock. There is still left a ridge between every row. When the Potatoes commence growing this ridge is split with the plough forward and backward, and so left until the land is fit to work, when the Potato stems will be 6 inches high. I then distribute sixteen bushels of soot to an acre as carefully as if I were sowing Carrot seed in the rows; then a man with a fork goes through each row once to bring the earth around the Potatoes. The earthing-up is commenced with the plough, and is done in three times, and so finished it remains until the harvest. The produce is, Magnum Bonum 12 tons an acre, and Scotch Champion 10 tons an acre.

I have only tried two additional varieties this year—Beauty of Hebron and Suttons' Reading Hero, the former old with some, but quite new to me; superior in every way to Early Rose. The Reading Hero is a first-rate round Potato, the flavour very good especially when steamed. I did not try it under rough cultivation. I planted 7 lbs., which made a row 28½ yards long with other sorts, and I made a great mistake in planting them about 3 feet apart when they ought to have been 4 feet, as they grow very high and strong. The land was moderately rich, and I applied a little dissolved bone at the time of planting. The produce was 300 lbs., and 2 lbs. diseased.—R. R. S. H.

#### NOTES ON BEDDING AND BEDDING PLANTS.

ON the whole we have not much to complain of; we want more variety. It is common to hear such remarks as the following made in reference to the flower garden—"It is very nice, but the same as last year, or was it the year before?" Change, then, is of the greatest importance. I confess I find it difficult often to give that change, and to impart, if possible, a new aspect to the beds year after year. It is not a little remarkable we do not hear the same observation on other plants used for the embellishment of the garden. Thus, a bed of Rhododendrons or Azaleas calls forth no such remark.

It must be observed that the style of bedding required here is that of beds full of flowers from the end of July until frost destroys them. A few years since we found no difficulty in filling them with plants to insure the desired result, and also to give a change year after year. Calceolarias have failed; Verbenas have followed, for they disappoint us; one other trial I will give them—viz., to raise seedlings every year. I have tried Phlox Drummondii and found them quite out of place when arranged with other bedding plants, as they grow far too high and straggling to correspond with others; an isolated bed would doubtless be the best. I found the variety *P. coccinea* only wanting in compactness to make it very valuable; the colour is very rich. Seedling Petunias, like the Phlox, in some seasons makes a bold isolated bed; in the flower garden proper it is out of place and not to be thought of. One only of the selected varieties we find can be depended upon—namely, Spitfire; this makes a fine bed. Let us turn to the brighter side of the subject and note one or two plants that I find of especial value. Many have been the contrivances to keep and increase that good bedding plant *Polemonium variegatum*, but generally with unsatisfactory results. Two years since we determined to deviate from the practice of taking up and potting the plants, and allowed them to remain in the ground. Plants that have been considered hardy succumbed to the last trying winters, but not the so-called half-hardy *Polemonium*; never have I seen it half as good as this summer. It is, moreover, really increasing, and we cannot have too much of it. To see its full beauty it must be grown well in a rich soil. It is suitable as an edging for beds of many plants. One of our prettiest beds this summer contained a very dark Heliotrope edged with the feathery creamy foliage of the *Polemonium*.

Another bedding plant that proved serviceable last summer is the *Tropæolum*, and where *Calceolarias* fail we have no equal to

the Tom Thumb varieties. One thing must be insisted upon—viz., purity of stock, otherwise disappointment will ensue. The safest plan is no doubt to save the seed. This is best done by striking cuttings, wintering them on a shelf near the glass, and planting them out; the seed saved from these is likely to give every satisfaction. I find them the most effective when employed in ribbon borders or as panels in large beds—viz., between dark blue or scarlet. A softer combination will be found between white and pink. I am speaking of the soft yellow *Tropæolum*; the scarlets are equally good.

The last plant to be noticed is a very dwarf, slender-stemmed, scarlet Dahlia. I do not know its name; I had it from a neighbour some years ago. I find it excellent for a back row in ribbon borders or the centre of large beds. It has one fault—it does not flower so early in the season as *Pelargoniums* and other plants, but later on and till frost commences nothing gives more satisfaction. I have long been in want of a good yellow and a white to match this red. Though I have tried some half-dozen varieties this last summer—White Bedder, Snowball, Alba, Drap d'Or, and Golden Bedder, they all seem wanting in the qualifications so conspicuous in the red variety above mentioned. They are without exception far too stiff and brittle, though they flowered profusely, but late. My red variety is neither stiff nor brittle, having a fine wiry stem. Its graceful procumbent habit makes it as tractable as *Verbena*. This with the great number of blooms produced renders it invaluable.—JOHN TAYLOR, *Hardwicke Grange*.

#### RHODODENDRON PRINCESS ALEXANDRA.

THE greenhouse hybrid *Rhododendrons* of the *R. javanicum* and *R. jasminiflorum* type are deservedly general favourites for their delicately richly coloured flowers, which in all the best forms are freely produced. One that especially deserves a high position is *Rhododendron Princess Alexandra*, of which a spray is shown on the next page. It is by no means a novelty, having been raised some years ago by Mr. Taylor; indeed it was one of the earliest he obtained. Now it is one of the cheapest, and being of good habit, easily grown, and profuse in flowering, it certainly has sufficient good qualities to recommend it strongly to the attention of all who endeavour to render their greenhouses as attractive as possible. The flowers are not quite so large as those of some of the type—such, for instance, as *R. Taylori*. They are rather more slender but neat in form, and are produced in remarkably large and compact trusses. Individually the flowers are almost pure white, with a faint delicate tinge of pink that imparts a very pleasing appearance to the heads. A beautiful specimen in Messrs. J. Veitch & Sons' nursery at Chelsea was, a week since, in fine condition, and has been greatly admired by many visitors. We understand that this form was the result of a cross between the well-known *R. Princess Royal* and *R. Brookei*.

#### CHRYSANTHEMUM SHOWS.

KINGSTON.—NOVEMBER 17TH AND 18TH.

CHRYSANTHEMUM growers and exhibitors throughout the kingdom have this year felt more or less interest in the Kingston Show, for there was a possibility of the champion challenge vase contest being finally settled in favour either of the north or south. A third competitor, however, having entered the lists with success the result is deferred until next year, when the interest will be redoubled, as the class will be confined to the three winners. The magnificent blooms in these stands will be long remembered, and that they constituted the great feature of the Show there is no doubt. In the other classes also the blooms were good—the best we have seen this year; and though some of the classes did not appear to be so well filled as usual, yet the competition was keen in the majority. Two very fine collections of specimen plants and several handsome groups were staged, but most of the others were below the average, as has been the case at most exhibitions this year, especially as regards Pompons, very few really good examples of which have been shown. In the miscellaneous classes plants for table decoration were numerous and of excellent quality, being very usefully employed as central lines on the tables between the rows of stands of blooms. *Primulas* and berry-producing plants were also abundant, and with the fruit, including fine Apples and Pears, constituted one of the best shows held by this Society. The Drill Hall was well filled without being crowded, and a brighter or more tasteful arrangement of the exhibits could not have been desired. Mr. T. Jackson, the Secretary, and other assisting members of the Committee, certainly deserve to be highly complimented upon the admirable result of their efforts to provide an attractive exhibition.

*Cut Blooms*.—The "cup" class formed the great feature in this section, and in the six collections entered by far the best blooms in the Show were staged. Both incurved and Japanese varieties were grandly represented, but the greatest weight was in those from

Liverpool, and it soon became evident that the southern exhibitors had no chance of obtaining the cup this year. This surprised many, for the Liverpool Show is fixed for the 30th inst., and it was, therefore, surmised that *Chrysanthemums* in that district were even later than usual, but it is evidently not the case as regards at least two exhibitors, or they could not have staged such finely developed blooms. Mr. F. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, Liverpool; Mr. W. Tunnington, gardener to Chas. MacIver, Esq., Calderstone, Liverpool; Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park; Mr. G. Harding, gardener to J. Galpin, Esq., Putney Heath; and Mr. Hinnell, gardener to F. A. Davis, Esq., Anglesea Road, Surbiton, were the competitors, Messrs. Harding and Tunnington having previously won the cup in 1879 and 1880 respectively. The two Liverpool collections were magnificent, and so extremely close in quality that it was very doubtful which would take precedence. The flowers were most carefully compared individually and collectively, and after more than an hour's deliberation the Judges concluded their difficult task by placing Mr. Faulkner first and Mr. Tunnington second. The decision met with general approval, for though the difference was very slight, there were a few points in favour of Mr. Faulkner's stand taken as a whole. His incurved blooms were extremely even, of large size, remarkable substance, and good form, including the following varieties—Prince of Wales, grand; Mr. Brown, White Venus, Prince Alfred, of fine substance; Blonde Beauty, Princess Beatrice, Queen of England, Hero of Stoke Newington, Mrs. Dixon, neat; Mrs. Heale, fine; Barbara, Princess of Wales, Mr. Howe, Jardin des Plantes, Lady Hardinge, Golden Empress, magnificent; Inner Temple, excellent; Prince of Teek, Beauty, good; White Beverley, Cherub, fine; Empress of India, Sir Stafford Carey, and Venus. The Japanese in the collection were also handsome, bright, and large, representing the under-mentioned varieties—Cossaek, rich colour; Soleil de Levant, large; Mdle. Moulise, Cry Kang, fine; La Nympe, good; Comtesse de Beauregarde, Hiver Fleur, large; Mons. Lemoine, rich, neat; Peter the Great, Oracle, good; Arlequin, Baronne de Prailly, large; James Salter, Gloire de Toulouse, Fair Maid of Guernsey, Bismarck, good; Striatum, handsome; Red Dragon; Nuit d'Automne, Elaine, Tendresse, Père Delaux, very rich in colour; Bouquet Fait, and Khedive.

Mr. Tunnington's collection was especially strong in Japanese, the blooms being of admirable size and substance. Incurved blooms were also good, and some were unusually large, though compact. The varieties were Queen of England, Alfred Salter, Golden Empress, Empress of India, Princess of Wales, Emily Dale, Prince Alfred, Mrs. Heale, Sir Stafford Carey, White Venus, Refulgence, Venus, Inner Temple, White Beverley, John Salter, Beauty, Mrs. J. Rundle, Mrs. Bunn, Barbara, Princess Beatrice, Jardin des Plantes, Lady Hardinge, St. Patrick, and Prince Teek. The Japanese were Sultaine, Japonnais, Père Delaux, very rich in colour; Soleil de Levant, Magnum Bonum, Diamond, Hiver Fleur, Apollo, Fair Maid of Guernsey, Tendresse, Nuit d'Automne, Madame d'Audiguier, Peter the Great, Cry Kang, Meg Merrilees, Exposition de Toulouse, Bismarck, Sarnia, Ethel, Baronne de Prailly, Criterion, Red Dragon, Mons. Lemoine, and Elaine. The third prize was awarded to Mr. C. Gibson, whose incurved blooms were much smaller than in the preceding collections, but his Japanese were considered by many the best in the class. They were especially remarkable for the richness and clearness of the colours. Mr. Harding was adjudged an extra prize for neat examples, not, however, up to his usual standard, but it is to be hoped the credit of the southern growers will be well maintained by him next year at the final settlement of the competition.

Though less interest attached to the other classes for blooms, yet in several the competition was keen, and the exhibits of fine quality. The handsome timepiece offered for the best twenty-four incurved varieties was secured by Mr. Faulkner, who certainly has no cause to regret his journey south. The blooms were similar in varieties and quality to those in the cup collection, and therefore need not be enumerated. Mr. Tunnington was again a very close second with handsome examples. Mr. W. R. Strong, gardener to Mrs. David Reid, Kenwood Court, Virginia Water; and Mr. Burns, gardener to H. A. Rigg, Esq., Wykham Lodge, Hersham, followed in the order named, both showing well. Ten collections of twelve incurved varieties were staged, the premier stand from Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, including some particularly handsome blooms of the leading exhibition varieties. Mr. J. Strong, gardener to H. Sweet, Esq., Dornay House, Weybridge, was second; Mr. J. McPherson, gardener to S. Page, Esq., St. Leonard's Lodge, Surbiton, third; and Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, fourth. So nearly equal in merit were several other stands that extra prizes were awarded to Mr. J. Hill, gardener to H. Savory, Esq., Potters Park, Chertsey; and Mr. G. King, gardener to R. Few, Esq., Wolsey Grange, Esher. Japanese were well represented in the classes for twenty-four and twelve blooms respectively. In the first-named Mr. E. Beckett was the most successful exhibitor, the blooms being of good size, very bright, and fresh. Criterion, Daimio, Triomphe du Nord, Alba Plena, Bronze Dragon, Lutea Striata, Père Delaux, and Hiver Fleur were the best. Mr. Molyneux followed very closely, and Mr. G. King was third. The leading stand of twelve was from Mr. J. Strong, very satisfactory examples. Messrs. Burn, McPherson, Gibson, and Hill followed in that order. Mr. J. Hill had the best stand of twelve reflexed blooms, representing Cloth

of Gold, Christine, Golden Christine, Mrs. Forsyth, Garibaldi, Dr. Sharpe, Chevalier Domage, and Phidias; Messrs. Sallows and Watson taking the second and third prizes.

Four neat collections of Pompons were staged in the class for a dozen bunches, distinct varieties. Mr. J. W. Moorman, gardener to Miss Christy, Coombe Bank, Kingston, secured chief honours with an excellent stand, including good examples of St. Michael's, James Forsyth, Mustapha, Bijou d'Horticulture, Hellene, Bouton d'Argent, Nelly, Anna de Belocca, La France, Madame Marthe, and Rosinante. Mr. J. Lyne, Wimbledon, was a good second, and Mr. W. Clark, gardener to H. Nagle, Esq., Kingston, was third. Anemone varieties

were not very largely nor well shown, the most noteworthy collection being the stand of twelve Anemone Pompons with which Mr. Lync secured the first prize in the class. These were very bright and clean; Firefly, Mr. Astie, Dick Turpin, Calliope, Antonius, and Marie Stuart being the varieties. Large-flowered Anemones were contributed by Messrs. Hill, Gibson, and Bennett, who secured the prizes in that order.

*Groups and Specimen Plants.*—In the class for a group of Chrysanthemums arranged for effect in a space not exceeding 50 square feet there were four competitors, their contributions adding greatly to the brightness and beauty of the Exhibition. Mr. C. Bond, The Gardens,

Fig. 78.—RHODODENDRON PRINCESS ALEXANDRA. (See page 476.)

Orford House, Ham, was adjudged premier honours for a tasteful arrangement of healthy well-grown plants bearing blooms of good substance. Mr. J. Bass, gardener to A. Price, Esq., Park Side, Ewell, was second, the blooms and foliage of the plants indicating careful culture; the colours too were well disposed. Mr. C. Orchard, gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston Hill, and Mr. T. Jacobs, gardener to J. Shand, Esq., Fulbrook, Old Malden, followed. Specimen plants were not of first-rate quality except in a few instances; the two finest collections being those in the class for six trained large-flowered specimens, which were so nearly equal in merit that after much deliberation the Judges awarded equal first prizes to the exhibitors, Messrs. G. King and E. Beckett. Many growers and exhibitors, however, considered Mr. King's plants entitled to prece-

dence, for they were not quite so tightly and formally tied as the others; the foliage was remarkably vigorous, the blooms abundant and of good size. They were trained flat, 5 to 6 feet in diameter, very even and healthy. The specimen of John Salter, 6 feet in diameter, with considerably over a hundred fine blooms, attracted much attention. Prince of Wales, Mrs. G. Rundle, Mrs. Dixon very large, Lady Hardinge, and St. Patrick were the other varieties. Mr. Beckett's collection included Mrs. G. Rundle, Prince of Wales, Mr. G. Glenny, Hiver Fleur, Prince Alfred, and Mrs. Dixon also large, slightly flatter than the first named, and well flowered, though the blooms were in some cases rather small. The plants in both collections were admirable examples of cultural skill. Mr. Sallows had the best three specimens, neatly trained examples of Mrs. G. Rundle, Mr. G. Glenny, and Mrs.

Dixon. The same exhibitor led with three standards—those which gained honours at Richmond—neat and even; Messrs. Beckett and Jacobs securing the other prizes. Mr. Lyne had a good collection of six Pompons—Rosinante, Mr. Astie, Antonius, White and Lilac Cedo Nulli, and Mustapha being the varieties. Mr. G. King gained the chief prize for the best single specimen with Mrs. Dixon, 5 feet in diameter, evenly trained, healthy, and well flowered; Mr. Sallows following with St. Patrick, and Mr. Jacobs with Fair Maid of Guernsey.

*Miscellaneous Plants.*—The principal exhibits in the classes for miscellaneous plants were the groups, for which four substantial prizes were offered, Mr. C. Attrill, gardener to C. J. Freake, Esq., Bank Grove, Kingston, was placed first with a bright and informal group, comprising Crotons, Dracenas, Primulas, Azaleas, Lobelias, Fuchsias, and a handsome specimen of *Aloe variegata* in the centre. Mr. J. Brand, gardener to W. Clay, Esq., Elm Villa, Kingston, followed with a neat arrangement of fine-foliage plants chiefly, with a few Chrysanthemums. Mr. J. Croxford, gardener to Mr. Dunnage, Albany House, Surbiton, was third, a fine *Epiphyllum* in the centre of the group being especially noteworthy. Table plants were excellently shown by many exhibitors, Aralias, Dracenas, and Crotons being largely represented. Messrs. G. King, J. Burns, and J. Hinnell were the chief prizetakers. Mr. King also led in the class for berry-bearing plants, showing the same neat specimens of Capsicum Tom Thumb and Princess of Wales which he had at Richmond in the previous week. Primulas and Cyclamens were numerous, and mostly in satisfactory condition.

*Fruit.*—For a collection of six dishes of fruit Mr. E. Beckett carried off the chief prize with well-coloured black Grapes and fair Apples and Pears, Mr. Croxford following with smaller Grapes but similar in other respects. Apples were numerous and of good quality. Eight collections of four dishes were staged; Mr. J. Hill being first with Cox's Orange Pippin, King of Pippins, Blenheim Pippin, and Dredger's Fame, all even and of fair size. Mr. J. W. Moorman was a very close second, having superb examples of Hoary Morning and neat King of the Pippins. Mr. E. Beckett took the third place. Pears were not quite so noteworthy. Messrs. J. Benson, gardener to W. H. Roots, Esq., Canbury House, G. King, and C. Attrill, securing the prizes in that order.

Prominent among the exhibits not in competition were two handsome groups of Chrysanthemums contributed by T. H. Bryant, Esq., Glencairn, Surbiton Hill. These were valuable additions to the Show and were greatly admired. Mr. G. Smith, Kingston, sent examples of ornamental stoves. Messrs. J. Jackson & Son exhibited six bunches of Kempsey Alicante Grapes of good size and beautifully coloured; they also had several small groups of plants, and an example of an apparatus suitable for heating a small greenhouse.

#### WESTMINSTER AQUARIUM.—NOVEMBER 17TH AND 18TH.

The thirty-fifth annual Exhibition of the Borough of Hackney Chrysanthemum Society was held, as has been the custom for the past few years, in the Royal Aquarium, Westminster; and though the plants and cut blooms were neither so numerous nor of such good quality as in some previous years, yet collections of no ordinary merit were staged in several of the principal classes. However, the great feature of the Exhibition were the Apples, Pears, and vegetables, in all of which classes the competitors were very numerous and the general quality remarkably good.

*Groups and Specimen Plants.*—The majority of the plants were arranged in a large semicircular bank at one end of the building, forming an imposing group viewed as a whole. To this effect the collections in the open class for the best group of Chrysanthemums in a space not exceeding 100 square feet contributed largely, for some well-grown healthy plants were included in them. Four groups were entered, the principal prize—a five-guinea silver cup presented by the Aquarium Company—being secured by Messrs. S. Mahood & Son, Windsor Nurseries, Lower Richmond Road, Putney, who had a well-arranged sloping bank of plants bearing handsome blooms, the colours of which were extremely clear and bright. Mr. G. Stevens, Putney, took the second place with a similarly satisfactory group; indeed the difference in merit was very slight between these two exhibits. Mr. Butcher, gardener to R. A. Glover, Esq., The Priory, Hadley, Barnet, was third with a slightly formal arrangement, but the plants were healthy and the blooms of good substance. The collections of ten plants in the borough class were also notable. Mr. H. Langford, The Gardens, Coleraine House, Stamford Hill, led with well-flowered specimens of President, Julie Lagravère, Barbara, and Prince of Wales among others of nearly equal merit. Mr. S. Gilbey, gardener to B. Booth, Esq., The Cazenoves, Upper Clapton, followed, his most noteworthy plant being a neat dwarf specimen of Rose Trevenna, very pretty. For six plants of large-flowering varieties in 12-inch pots Mr. Langford was again the leading exhibitor, having compact freely flowered specimens of Lady Talfourd, John Salter, Mr. Corbay, Hero of Stoke Newington, and others. Mr. G. Stevens also staged some good specimens in this class. Pompons were not largely represented, but the chief prizewinner, Mr. F. Wells, gardener to W. A. Smea, Esq., The Limes, Woodberry Down, had neatly trained and well-flowered specimens. His premier collection of six comprised Mrs. Hutt, Cedo Nulli, Sœur Melanie, Prince Victor, Cendrillon, and Golden Cedo Nulli, dwarf-trained, even, and fresh. In this class Mr. Butcher was a close second, and Mr. G. Drain, South-

gate Nursery, De Beauvoir Town, N., a good third. Mr. Wells staged the two winning collections of four standards in the open (large-flowering varieties) and the borough classes (Pompons), the specimens of Bob, Antonius, and Prince of Wales being the most creditable.

*Cut Blooms.*—These, as stated above, were not so numerous as usual, the incurred varieties generally being rather small but neat. The Japanese were, however, of good quality in all the leading stands. The principal open class was that for twenty-four incurred blooms, in which the competition was very keen, eight collections being staged. Mr. E. Berry, The Gardens, Roehampton House, Roehampton, was adjudged chief honours for blooms of excellent form but not large. The best were John Salter, Antonelli, Barbara, Mr. Brunlees, Nil Desperandum, and Cherub. Mr. C. Sanderson, Harlesden House, Willesden, followed very closely, his stand including several blooms of fine substance. Prince Alfred, John Salter, Mrs. G. Rundle, and Mr. Brunlees were the most notable. Mr. G. Stevens took the third position, and Messrs. G. Garraway & Co., Clifton, Bristol, followed. The best twelve incurred blooms in the open section were staged by Mr. C. Gibson, The Gardens, Morden Park, near Mitcham, who easily secured the premier award with neat blooms. Baron Beust, Prince Alfred, Barbara, Cherub, Golden Empress, and Hero of Stoke Newington were among the best. In the open class for twenty-four Japanese blooms handsome examples were staged by several exhibitors. Mr. C. Gibson secured the premier award with even, fresh, bright blooms, similar to those in his stand at Kingston on the same day. Baronne de Prailly, Mons. Lemoine, Alba Striata, M. Ardene, Elaine, Red Dragon, Criterion, and M. Delaux were especially good. Mr. Herrin, gardener to J. N. Hibbert, Esq., Chalfont Park, Gerrard's Cross, was a close second, having some remarkably large blooms. Examples of The Daimio were 7 or 8 inches in diameter, and proportionately deep; Chang and Baronne de Prailly were also notable. Mr. H. Smith, gardener to Mrs. Anderson, Waverley Abbey, Farnham, was third, also with very creditable blooms, among them being fine specimens of Thunberg, Cry Kang, Red Gauntlet, Nuit d'Automne, Triomphe du Nord, and Madame Berthe Rendatler. Mr. G. Neal, gardener to B. Southby, Esq., Brampton, Oxfordshire, followed with fresh brightly coloured blooms, but a little wanting in substance. Anemone varieties were chiefly shown by Messrs. Berry and G. Neal, who carried off the principal prizes with blooms of moderate quality.

*Fruit.*—The classes most largely represented in this section were those for Apples and Pears, but black Grapes were also well shown, especially by J. Cooke, Esq. (manager, Mr. Stephen Castle), The Vineyard, West Lynn, King's Lynn, Norfolk; J. Ridout, gardener to T. B. Hayward, Esq., Reigate; and Mr. J. Bolton, who were first, second, and third respectively with well-coloured bunches of moderate size. The Norfolk examples of Gros Colman were particularly good, each of the others staging Black Alicante in fine condition. For six dishes of dessert Apples there were eleven competitors, Mr. R. Dean, Ealing, carrying off the first prize with even and fine fruits of Court Pendu Plat, Cox's Orange Pippin, Rymer's, King of Pippins, and Cornish Aromatic. Mr. Sidney Ford, gardener to W. G. Hubbard, Esq., Leonard's Lodge, Horsham, was second; and Mr. G. Goldsmith, Hollenden, Tonbridge, third, both staging good fruits. For six dishes of culinary Apples there were ten entries, Mr. H. Fowte, gardener to Sir H. Mildmay, Bart., Dogmersfield Park, Herts, winning first honours with Alfriston, Requette de Canada, Blenheim Pippin, Bess Pool, and Hollandbury, very fine. Messrs. R. Dean and C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, followed very closely. Pears were not so largely shown. Mr. Fowte, Mr. Goldsmith, and Mr. J. Stewart, gardener to H. J. Bennett, Esq., Langford Park, Essex, were the chief exhibitors and prizetakers.

*Vegetables.*—These were extremely well represented, the dozen entries in the class for the best collection of vegetables including some highly satisfactory and creditable specimens. Premier honours were deservedly accorded to Mr. R. Phillips, gardener to Captain Jackson, The Deodars, Meopham, Kent, who had remarkably well-grown examples of Carentan Lecks, Myatt's Ashleaf and Schoolmaster Potatoes, Snowball Turnips, Trophy Tomatoes, Drumhead Savoys, Veitch's Autumn Giant Cauliflower, and many others. Mr. J. Millen, The Gardens, Hamstead Park, Newbury, was second also with a satisfactory collection, but a little weak in a few points. Mr. J. Bolton, gardener to W. Spottiswoode, Esq., Coombe Bank, Sevenoaks, was third with clean and fresh but generally smaller specimens.

Potatoes were abundant, seven collections of twelve dishes and twelve of six dishes being staged. The best twelve was from Mr. R. Dean, and included Mr. Bresee, Bedford Prolific, Vicar of Laleham, Grampian, Wiltshire Snowflake, Bresee's Prolific, Matchless, Early Rose, Advancer, Red Emperor, Pride of America, and American Purple, all fine and even. Messrs. Millen and Ross followed in that order. Mr. Millen was the most successful with six dishes, taking first for neat samples of Suttons' Magnum Bonum, Beauty of Hebron, Schoolmaster, Vicar of Laleham, Late Rose, and Suttons' Fillbasket. Mr. C. W. Howard, Bridge, Canterbury, and Mr. R. Dean secured the remaining prizes.

Among the exhibits not in competition was a beautiful stand from Messrs. H. Cannell & Son, Swanley, which was as much admired by the general visitors as anything in the Exhibition. It comprised Primulas, very fine, particularly Swanley Red, exceedingly rich in colour; Salvias, S. Pitcheri being very fine; single and double Zonal Pelargoniums, and Chrysanthemums. Messrs. Sutton & Sons, Read-

ing, had large collections of Potatoes and Kales artistically arranged and representing a great number of varieties. Mr. Skinner Beresford, Brighton, exhibited about eighty dishes of handsome Apples, and Mr. J. Cooke had a basket of fine Gros Colman Grapes. All the above-mentioned exhibits were highly commended.

**BRIXTON, STREATHAM, AND CLAPHAM.—NOVEMBER 17TH AND 18TH.**

Among what may be termed the local metropolitan exhibitions of Chrysanthemums this has obtained a position of some importance, for specimen plants and blooms are usually of excellent quality, though not so numerous as at the shows of societies which include a more extensive area in their district. This year, however, the display was not quite so good as usual: not from want of general effectiveness nor from a less number of exhibits, but chiefly because the specimen Chrysanthemums were rather weak as compared with former shows of the Society. The well-grown specimens which Mr. W. Hall has hitherto shown with so large a share of success were particularly missed, and could ill be spared, though the productions of other growers gave promise of good results in the future.

**Cut Blooms.**—In the classes for incurved blooms the twenty-fours were represented by four very neat collections. Mr. A. Holmes, gardener to A. B. Hill, Esq., Clapham Park, was accorded the first position for clean, even, and compact blooms, Golden Empress of India, Mr. Brunlees, John Salter, Princess of Wales, Prince Alfred, and Lady Slade being the most noteworthy in the stand. Mr. J. Holmes, gardener to G. M. Storey, Esq., Nightingale Lane, followed with a less even collection, but including several especially large blooms, John Salter, Mrs. Heale, Baron Beust, and Prince Alfred being the finest. Mr. C. Livermore, gardener to Fred Webb, Esq., Christ Church Road, was third with smaller examples but of fair quality. The competition was remarkably brisk in the class for twelve incurved blooms, Mr. Holmes leading among the eight exhibitors with neat and fresh blooms, Prince Alfred, Sir Stafford Carey, Mr. Corbay, and White Beverley being noteworthy for their substance and form. Mr. T. Sadler, gardener to C. Lamber, Esq., Leigham Court Road, followed closely; and Mr. C. Livermore was third, also with a good collection. Several stands of six blooms were contributed, but mostly of rather inferior quality. Japanese varieties were fresh and bright, but not remarkable for their size and substance, except in a few instances. The best twenty-four was staged by Mr. J. Young, gardener to T. Hicks, Esq., Streatham Hill, who had good examples of Criterion, La Nympe, Striatum, Sarnia, Bronze Dragon, Chang, and L'Incomparable among many others of more or less merit. Mr. W. Clarke, gardener to J. Rains, Esq., Nightingale Lane, followed very closely, having Cossack, Baronne de Prailly, Curiosity, and Daimio in excellent form. Mr. A. Holmes was first with twelve Japanese, fresh and neat, Fanny Bouchardat and Madame C. Andiguier being the finest. Mr. J. Swain, gardener to Mrs. Wilson, Lower Tulse Hill, was second with smaller but very bright blooms. Good collections of Anemone varieties, both large and Pompons, were contributed by Messrs. Young, Livermore, J. Holmes, and Clarke, who were the chief prizetakers in the respective classes. For six blooms of any variety Mr. H. Holmes gained the premier award with extremely good bloom of Barbara, neat, substantial, even, and compact. Mr. W. Halliday, gardener to T. Olney, Esq., Balbam Hill, followed with fair examples of Peter the Great; Mr. C. Salter, gardener to J. Southgate, Esq., Leigham Court Road, being third with John Salter, neat and of good colour. In the "maiden" class for twelve large incurved varieties the prizes were secured by Mr. Sadler and Mr. W. Powle, gardener to W. Swinseo, Esq., Leigham Court Road, both showing fairly well.

**Specimen Plants.**—The principal class was that for six plants, large-flowered varieties, in which Mr. J. Weston, gardener to J. Martineau, Esq., Clapham Park, was awarded premier honours for specimens of moderate size but even and fairly well flowered. Cherub, Mrs. G. Rundle, and Prince of Wales were especially good. Mr. E. Cherry, gardener to Mrs. Gabriel, Streatham, secured the second place with healthy but less even plants; Mr. J. Howes, gardener to Mrs. Bennett, Upper Tulse Hill, being third. Messrs. Weston, Howes, and Cherry were also the prizetakers with three large-flowered plants, the first collection including good examples of Mrs. Dixon, Mrs. G. Rundle, and Lady Hardinge. Pyramid Pompons were rather poor, but fairly good collections of three standards were shown by Messrs. Howes, Livermore, and J. Davy, the first having neat examples of Bob and Calliope, the second of La Sultaine and Lilae Cedo Nulli, and the third of White Cedo Nulli, all well flowered. In the "maiden" class for three plants, large-flowered varieties, Mr. J. Holmes and Mr. E. Yates, gardener to S. Lutwyche, Esq., Lower Tulse Hill, were first and second respectively with neat healthy specimens.

**Miscellaneous Plants.**—The exhibits in the classes for fine-foliage plants, Ferns, and Orchids added greatly to the attractiveness of the Exhibition. For six Ferns in 6-inch pots Mr. Young secured the first position with admirably grown little specimens of Adiantum farleyense, A. cuneatum, Gymnogramma chrysophylla, and G. Wettenthaliana. Mr. Fulbrook, gardener to Mrs. Hyatt, 5, Palace Road, was a close second, a pretty example of the distinct Asplenium Belangeri being noteworthy. Mr. H. Wright, gardener to H. Voss, Esq., Streatham, followed with fair plants. Another class was provided for larger Ferns—namely, four specimens in 11-inch pots. In this Mr. J. Young was again to the fore with excellent plants of Adiantum farleyense, Gymnogramma chrysophylla, Asplenium diversifolium, and Adiantum euneatum. Mr. R. Austin, gardener to

K. Kesterton, Esq., Nightingale Lane, followed, showing Microlepia hirta cristata, Adiantum gracillimum, and A. farleyense very fine. Four fine-foliage plants were well shown by Mr. Fulbrook, who was placed first with healthy specimens, Dracaena Baptisti, D. Youngii, and Coeos Weddelliana being the best. Mr. H. Wright had smaller but well-coloured examples of Croton undulatum, Aloeasia Lowii, and others. Stove and greenhouse plants were small, and not specially noteworthy; but Primulas were represented by several good collections, particularly those from Messrs. Young, Fulbrook, and W. Staplehurst, gardener to Mrs. Walmisley, Clapham Park, who were the chief prizetakers.

Orchids were highly creditable to the exhibitors, and an important feature in the display. The best six were from Mr. C. Salter, which included healthy well-flowered specimens of Cypripedium Harrisianum, C. venustum, Vanda carulea, Lœlia præstans, and Masdevallia tovarensis. Mr. H. Wright had a good Oncidium Rogersi, and Mr. Weston staged a fine example of Houletia fragrantissima, which had a handsome spike bearing fifteen of its curious reddish-brown spotted flowers that possess a powerful spice-like fragrance. Collections of four were contributed by Messrs. Salter, Young, and H. Wright in that order, the first including neat plants of Cypripedium Harrisianum, Odontoglossum grande, Oncidium crispum, and Dendrobium heterocarpum. The best of all was, however, the beautiful and tastefully arranged group from Mr. C. Salter, which included a number of handsome Orchids and Ferns. The Judges very deservedly awarded Mr. Salter a cultural commendation for the excellent condition marking his plants.

**Fruit.**—Grapes, though not largely shown, were good. Mr. W. Howe, gardener to Henry Tait, Esq., Streatham, had the best black Grapes, three well-finished bunches of Black Alicante; Mr. R. Holmes, gardener to T. Wallace, Esq., Clapham Common, was second with handsome bunches of the same variety, but not of such good flavour. Mr. J. Walls, gardener to F. Franks, Esq., Palace Road, was third with Black Hamburgh of fair size but slightly rubbed. White Grapes were not first-rate. There were seven entries in the class for three dishes of dessert Pears, Mr. W. Hall, gardener to W. Stevens, Esq., Lower Tulse Hill, carrying off the premier prize with good fruits, Forelle being noteworthy; Mr. W. Sandy, gardener to G. Coles, Esq., Leigham Court Road, and Mr. W. Collins were the other prizetakers. Apples were for the district remarkably good both in size and general appearance. Eight collections of culinary varieties and seven of dessert varieties were staged, the winners in the former being Messrs. G. Plumridge, gardener to Dr. Markham, Nightingale Lane; J. Holmes, and T. Foote. In the other class Messrs. H. Sandy, T. Foote, and G. T. Cocks, gardener to G. S. Cundell, Esq., Clapham Park, were the successful exhibitors.

The general arrangement of the Exhibition was as usual very satisfactory and creditable to the Secretary, Mr. W. Hall.

**BRISTOL.—NOVEMBER 16TH AND 17TH.**

Although this, the eighteenth annual Exhibition, in some respects was inferior to those of recent years, it was still a great success, and reflected much credit upon all concerned. The Victoria Rooms, Clifton, in which the Show was held, are well adapted for the purpose, and nothing but favourable weather was wanting to insure a substantial addition to the funds of this noted Society. The Committee and Mr. Webley, the courteous and energetic Honorary Secretary, ably managed affairs so as to have the judging completed and the hall open to the public at the appointed time.

**Specimen Plants.**—The premier prize, a handsome silver eup value £5 5s., was offered for six large-flowered specimen Chrysanthemums, but with the exception of the winning group staged by Mr. J. Brander, nurseryman, &c., failed to attract anything above mediocrity. Mr. Brander's specimens were flat and formal, about 3 feet 9 inches across, and carrying on an average about ninety fine blooms. The varieties were Mrs. Forsyth, Mrs. Dixon, Prince of Wales, Mr. Corbay, Mrs. G. Rundle, and Alma. The second-prize group staged by Mr. H. Smith, gardener to A. Sibley, Esq., were less formerly trained, and the specimens of Venus, Prince of Wales, and Mrs. Dixon were very creditable. Mr. Brander was first with three varieties, staging in this instance good specimens of Guernsey Nugget, White Globe, and Bronze Jardin des Plantes. Mr. H. Smith was a good second. The four best Pompons were staged by Mr. Brander, and consisted of Antonius, Bob, Marie Stuart, and Golden Circle. Mr. E. T. Hill, gardener to T. Pease, Esq., followed with untrained specimens, which, however, presented the appearance of having been starved at some period of growth, but they were welcomed as a step in the right direction. Two well-flowered flat-trained specimens of The Cossack and Fair Maid of Guernsey, staged by Mr. E. S. Cole, gardener to W. Pettrick, Esq., gained the first prize in the class for Japanese varieties; Mr. W. Terry, gardener to H. C. Miles, Esq., following with two standards. Mr. E. S. Cole staged the best pyramid variety, Mrs. Rundle; Mr. Monkley following with Venus. There were also other classes for Pompons and Anemone-flowered. The closest competition, however, was for special prizes offered for three standard Chrysanthemums. Mr. H. Smith was placed first for admirably grown specimens of Venus, Mrs. Rundle, and Guernsey Nugget; Mr. Brander and Mr. E. T. Hill following closely in the order named.

**Cut Blooms.**—Of these several excellent stands in each class were staged, some of the blooms being remarkably fine. This may be said of all the first prize twenty-four large-flowered varieties staged by

Mr. J. Baylis, Winterbourne, and consisting of Princess of Wales, Cherub, Mrs. Heale, Prince Alfred, Gloria Mundi, White Globe, Barbara, Golden Queen of England, Plutus, Prince of Wales, Jardin des Plantes, Beverley, Rev. C. Boyce, Bronze Jardin des Plantes, Golden Beverley, Mrs. Brunlees, Lady Hardinge, Abbé Passaglia, Princess of Teck, Mr. W. Shipman, George Glenny, Princess Beatrice, Mrs. Rundle, and Guernsey Nugget. The most noteworthy blooms in Mr. T. Hobbs' second-prize collections were those of White Beverley, Hero of Stoke Newington, Princess of Teck, Isabella Bott, Princess of Wales, and G. Glenny. Messrs. Garraway were awarded the third prize for generally good blooms. Mr. H. Morgan was placed first in the amateurs' class for twelve blooms, staging among others good examples of Princess of Wales, Cherub, Beverley, Golden Beverley, Prince Alfred, Golden Empress of India, and Princess Beatrice. Mr. J. Waite was a good second, his most noteworthy blooms being of Barbara, Eve, and Princess of Wales. The best six large-flowered varieties were staged by Mr. J. Baylis, Mr. J. Waite following, both staging well-known old varieties. Mr. Baylis was again first with twelve Anemone-flowered in not less than six varieties, staging beautiful examples of Lady Margaret, Empress, Georges Sand, Gluck, Louis Bonamy, and Acquisition. Messrs. Garraway's second-prize collection included good blooms of Fleur de Marie, Prince of Anemones, and Acquisition. Mr. T. Hobbs was awarded the third prize. Special prizes were offered for twelve incurved blooms in two colours. Mr. Baylis easily obtained premier position with immense solid blooms of Princess of Wales and Barbara. The Japanese varieties staged in competition for special prizes were much admired, notably those staged by Messrs. Garraway and Mr. Baylis. The former's stand comprised many newer varieties, and consisted of Baronne de Prailly, Sarnia, Ethel, Fulgore, Madame C. Audiguier, Peter the Great, Red Gauntlet, Hiver Fleur, Nuit d'Hiver, Bronze Dragon, and Fair Maid of Guernsey.

*Miscellaneous Plants.*—The first prize for a limited group was awarded to Mr. W. Perry, gardener to H. C. Miles, Esq., the second to Messrs. Manic & Sons, both arranged tastefully, the former winning perhaps on account of great number of Orchids included in his group. Mr. W. Rye, gardener to J. Derham, Esq., Mr. W. Perry, and Mr. Bush in the order named were the winners in the classes for fine-foliaged plants; and the best Ferns were staged by Mr. W. Bannister, gardener to H. St. V. Ames, Esq., and Mr. Perry, the collections in each instance comprising several highly creditable specimens. A well-flowered specimen of *Oncidium macranthum*, staged by Mr. Perry, won the first prize in the class for a single specimen stove or greenhouse plant in flower; the second prize going to Mr. O'Brien, gardener to Mrs. R. King, for a large beautifully flowered *Clerodendron Balfourianum*. Eight exhibitors competed for the prizes offered for six Chinese Primulas, all staging creditably; Mr. Bannister's first-prize group being exceptionally good. Mr. E. S. Cole and Mr. W. Fox secured the remaining prizes. Mr. H. Ward, gardener to W. H. Budgett, Esq., staged the best six berried plants, these consisting of creditable examples of *Solanum Capsicastrum*, *Aucuba*, and *Capsicums* in two colours. Mr. H. Spry, gardener to G. F. Prideaux, Esq., and Mr. Rye also exhibited well in this class, and received the remaining prizes. The first-prize group of *Celosia pyramidalis* were exceptionally good both as regards culture and the quality of strain. These were staged by Mr. J. H. Vallance, gardener to J. C. Wall, Esq., Mr. W. Bannister following with creditable plants. Poinsettias were not very good. The best were staged by Mr. E. T. Hill; Mr. G. Skelton, gardener to W. K. Wait, Esq., following closely. Zonal Pelargoniums were remarkably well shown by Mr. C. Taggett in the two classes devoted to them, and Messrs. Vallance and Rye were the successful exhibitors of *Bouvardias*.

*Fruit.*—This constituted a great feature in the Exhibition, the various classes being well filled, and the quality generally being remarkably good. The best collection of six varieties of dessert fruit was staged by Mr. J. H. Vallance, and consisted of good Lady Downe's and Black Alicante, a poor fruit of Victory of Bath Melon, good King of the Pippins Apple, Alexandre Lambre Pears, and Medlars. Mr. Bannister took the second prize, and was closely followed by Mr. G. Hawkes, gardener to Col. Tuberville. The latter exhibitor spoilt his otherwise good collection by staging over-ripe Pears. Mr. G. Farmer, gardener to S. Derham, Esq., had the best Black Hamburg Grapes, and Mr. W. Bannister the best Muscat of Alexandria. The competition was very close with four bunches of Grapes in two varieties. Mr. G. Avery, gardener to J. B. Low, Esq., staged good examples of Gros Colman and Black Alicante, and these were rightly preferred by the Judges to well-coloured examples of Lady Downe's and Muscat of Alexandria staged by Mr. W. Bannister, owing to the Muscats having a few shanked berries. Mr. J. Gibson was awarded the third prize for large but imperfectly coloured bunches of Gros Colman and Mrs. Pince. Three good bunches of Lady Downe's won Mr. J. H. Vallance the first prize for any black Grapes, Mr. G. Shelton following with creditable examples of Black Alicante. There were nine collections of six varieties of Pears staged. Mr. G. Farmer was first with excellent dishes of Durandean, Beurré Bachelier, Duchesse d'Angoulême, General Todleben, Josephine de Malines, and Beurré Clairgean. Mr. Rye was a good second, and Mr. W. Bannister followed. Mr. G. Farmer was again first for four varieties. Mr. E. T. Hill was second, eleven collections being staged. The same number exhibited six varieties of dessert Apples, and the prizes were awarded to Mr. J. H. Virgo, Mr. J. Aplin, and Mr. Ban-

nister in the order named. Mr. Virgo's collection consisted of fair-sized highly coloured examples of Blenheim Orange, Ribston Pippin, Kentish Pippin, Court Pendu Plat, Colston Pippin, and King of Pippins. There were twelve collections of four varieties of dessert Apples staged, Messrs. Vallance, J. Aplin, and W. Bannister receiving the awards in the order named, Mr. Aplin also winning with one dish with remarkably fine fruit of Blenheim Orange; Mr. J. Helper, gardener to G. Pope, Esq., following with equally creditable examples of Nelson's Glory, better known as Warner's King, and Mr. H. Ward was third with fine Blenheim Orange.

*Vegetables.*—Collections of nine varieties arranged in baskets were well shown by several exhibitors. The Judges eventually awarded the first prize to Mr. E. T. Hill, Messrs. G. Avery and W. Bannister following very closely. The last-named spoilt an otherwise excellent collection by a mixed arrangement. Beet, Potatoes, and Turnips were shown much too coarse throughout. A valuable telescope offered as a special prize for a collection of winter salad was won by Mr. J. H. Vallance, an extra prize being awarded to Mr. A. Morse, both exhibitors staging particularly good produce.

Bouquets, with the exception of that staged by Mr. E. C. Cole, and awarded the first prize, were much too flat and crowded. Messrs. Ward and J. Loosemore were the other successful exhibitors. Buttonhole bouquets were of average merit, but the baskets and vases filled with autumn foliage and berries were extremely beautiful both by daylight and gaslight, and added much to the general effect. Mr. J. Aplin, Miss L. Wethered, and Mr. Monkley were the prizewinners for best-arranged baskets, and Mr. J. H. Virgo and Mr. J. Brander with vases.

The gold medal for a collection of fruit won at the great Manchester Show by the Bristol Chrysanthemum Society, and of which they have good reason to be proud, was exhibited, and attracted much attention. Messrs. Parker & Sons, Garraway & Sons, and T. Busb, nurseryman, Bristol, contributed groups of well-grown plants, which added considerably to the general effect. The Royal Horticultural Society's Silver Knightian Medal for the best collection of six dishes of dessert fruits was won by Mr. Vallance, and the Bronze Knightian Medal was secured by Mr. H. Smith for the best specimen Chrysanthemum in any class.

#### CANTERBURY.

The fourth Exhibition of Chrysanthemums, fruit, and vegetables was held by the Gardeners' Mutual Improvement Society at the Foresters' Hall, Canterbury, on the 16th and 17th of November. The Show this year quite surpassed all previous exhibitions of the Society both in the quality and number of the exhibits. The room was rather too small, but the arrangements were excellent, and reflect great credit on the managers.

*Specimen Plants.*—Near the entrance to the room were groups of plants arranged for effect, the first prize being taken by Mr. Woodcock, gardener to F. Flint, Esq. Mr. Martin, gardener to T. G. Peckham, Esq., was second; and Mr. Edwards was third. The too frequent fault of overcrowding was observable, but the effect was generally very good, and a great improvement upon that of last year. On each side of the room and at the end were fruit and vegetables, while in the centre were staged pyramid and standard Chrysanthemums, flanked on either side by trained and untrained plants of smaller size. For trained plants Mr. Martin was easily first, his pyramids being one mass of bloom; Peter the Great, George Glenny, and Middle Martbe being especially well flowered. Mr. Hawkins, gardener to W. P. Sims, Esq., showed good plants, but not equal in size or bloom to the former. The other successful exhibitors in the pot classes were Mr. Woodcock, Mr. Elvey, gardener to Major W. Plummer, and Mr. Maple, gardener to Mrs. Halbed.

*Cut Blooms.*—In the classes for cut blooms Mr. Woodcock was the most successful exhibitor. The open class for twenty-four varieties (incurved and reflexed) caused a keen competition, Mr. Woodcock being first with fresh and well-finished blooms; Princess of Wales, John Salter, Prince of Wales, Mrs. Dixon, Mrs. G. Rundle, George Glenny, and Eve being especially good. The second prize was taken by Mr. Martin, whose flowers were large but rather over-bloomed; Empress of India, Jardin des Plantes, Guernsey Nugget, George Glenny, and Barbara being amongst the best. Mr. Maxted, gardener to the Marquis of Ely, was third, his most noticeable flowers being George Glenny, Ensign, and Nil Desperandum. In the Society's class for twenty-four Mr. Woodcock was again first with good blooms of Princess of Wales, Lady Talfourd, Triomphe de Nord, and Mrs. George Rundle. Mr. Martin was a close second, showing Barbara, Beethoven, and George Glenny in fine condition. Mr. Sudds, gardener to S. Wildash, Esq., was third. For twelve varieties the same order of names was preserved. Perhaps the most beautiful flowers in the Show were the Japanese varieties, in which class Mr. Martin was first with grand blooms of Red Dragon, Peter the Great, Bronze Dragon, Hiver Fleur, James Salter, and Red Dragon; Mr. Woodcock was second. For six varieties of Japanese, for Pompons and Anemones, Mr. Woodcock was again first, the other prizetakers being Mr. Martin, Mr. Elvey, Mr. Maple, and Mr. Sudds.

The hard fruit, as might be expected from the neighbourhood, was of good quality, and indeed throughout the whole Show there was scarcely a single exhibit of an inferior kind. Grapes, however, with the exception of a beautifully coloured bunch of Lady Downe's Seedling, exhibited by Mr. Woodcock, were not good. The chief prizetakers for fruit were Mr. Russell, gardener to the Dean of Canter-

bury; Mr. Murphy, gardener to Col. Laurie; Mr. Woodcock, Mr. Martin, and Mr. Sudds. The vegetables were generally very good; Potatoes, contrary to expectation, being shown in fine condition.

In the amateurs' classes for flowers the chief prize was taken by Mr. Noble, who had in his twelve one of the best specimens (Eve) of *Chrysanthemums* in the whole Exhibition. Mr. Featherston, Mr. George, Mr. Phillpot, Mr. Kennett, and Mr. Nash also showed successfully and well.

Cottagers' classes are always interesting, showing as they do to what excellence a true lover of horticulture of slender resources may arrive. All the classes were well contested, but Mr. Coachworth was easily before other competitors, and his exhibits were most creditable. Messrs. W. Gill, R. Hopkins, and S. Bishop were the other chief prize-takers.

In the ladies' class there was room for improvement, as in none of the epergnes was there very great taste displayed. Mrs. Noble took the first prize, Miss Payne Smith being second, and Miss Hammond third. In the special prizes Mr. Murphy was first with a magnificent collection of vegetables. Mr. Woodcock was second, also showing well, closely followed by Mr. Kennett, who was third.

In the class for a dish of boiled Potatoes the growers seemed to be more scientific than the cooks, but English cooks are not generally successful in Potato-boiling. Mr. Martin showed an interesting plant with ninety-eight grafts of thirty-four varieties, while one of the features of the Show was a huge Vegetable Marrow shown by Mr. S. Leggett, which weighed 43 lbs.

Altogether the Exhibition was a great success, and it is to be hoped that it will be followed by others of increasing excellence.

#### TUNBRIDGE WELLS.—NOVEMBER 17TH AND 18TH.

This Show was held in the Skating Rink, a capacious lofty hall admirably adapted for the purpose. Bright, warm, sunny weather attracted a crowded attendance to a pretty Exhibition; for although the competition was not keen, yet all the classes were fairly well filled with exhibits that were generally meritorious, and in some instances of considerable excellence. Enough *Chrysanthemum* plants were brought together to form a bank round the sides of the hall, additional height being happily imparted to the end farthest from the entrance by a back row of pyramids; cut flowers, table plants, and fruit filling two parallel long tables down the centre. The effect of this arrangement as a whole was excellent, forming a bright well-balanced picture, and affording six distinct sides for inspection, so that the constantly increasing stream of visitors was sufficiently broken to prevent overcrowding at any point.

*Specimen Plants.*—The finest group of plants was that of eight specimen *Chrysanthemums*, with which Mr. J. Adams, gardener to T. Grant, Esq., won the tradesmen's silver cup. It consisted of a very fine dwarf Mons. C. Hubert, and almost equally large plants of Mr. G. Glenny, Dr. Sharpe, Golden George Glenny, Mrs. G. Rundle, and Antonius, with a well-matched pair of pyramids of Fanny and Calliope. Mr. F. Earley, gardener to G. A. Brittain, Esq., Ferndale House, was second with good plants somewhat overtrained, and Mr. J. Overden, third. For the ladies' silver cup, a prize of equal value and importance, Mr. R. Beilby, gardener to W. H. Tindall, Esq., was first with a good group, the best plants being Peter the Great, a handsome compact plant of the bright-hued Dr. Sharpe with very fine flowers; a capital Mrs. G. Rundle, and Golden George Glenny. In the second-prize group by Mr. W. Berwick, the most prominent place was worthily filled by a fine specimen of the lovely white-flowered Elaine; and Mr. J. Williams' equally fine example in the third-prize group of Mrs. Forsyth with large handsome white flowers was equally worthy of notice. Some of the single specimens were very good, notably Mr. Beilby's first-prize plant of Mrs. G. Rundle with exceptionally fine flowers. Mr. J. Adams was a very close second with a Golden George Glenny, so good that the Judges must have had some difficulty in coming to a decision. In another class Mr. J. Allan, gardener to G. Hanbury Field, Esq., Ashurst Park, had a particularly fine example of Mrs. Dixon, with almost every one of its bright yellow flowers perfect in size and form. Excellent plants, either winners of prizes singly or in groups, were also shown of Mrs. Haliburton with fine full flowers, by Mr. Beilby; Venus, a charming light-tinted lilac-coloured Pompon in a first-prize group of pyramids, by Mr. Earley; a Cedo Nulli with hundreds of its lovely little white flowers suffused with pink—a magnificent plant, probably the largest and best plant in the Show. Of the dark-flowered Pompon Fanny by Mr. J. Adams, to which a first prize was well awarded, three groups of standards were shown, all of them having the objectionable characteristics of stiff gaunt formality. The pretty miniature yellow flowers of Mignonette were noteworthy—so pretty that it deserves more general culture, and in the more pleasing guise of dwarf, bush, or pyramid.

*Cut Flowers.*—Forty-four stands were shown, many of them containing excellent blooms. The most conspicuous were Mr. J. Allan's first-prize stand of six Japanese with magnificent examples of Oracle, Baronne de Prailly, Apollo, Yellow Dragon, Elaine, and Soleil Levant, a very fine yellow. The same exhibitor was also first with six large-flowered incurved varieties all so good as to merit enumeration: they were Princess of Wales, Golden Empress of India, Mr. G. Glenny, R. J. Dix, Isabella Bott, and Barbara, an attractive orange brown. Mr. J. Roberts was also first in the amateurs' division with grand blooms of the Japanese Peter the Great, delicate yellow; Creole, deep

lilac; Elaine, white; Plantagenet, rich yellow; James Salter, delicate lilac; and Meg Merrilees, yellowish white.

*Miscellaneous Plants.*—Primulas made a fine display, all the plants being well grown and profusely flowered, especially those of Mr. G. Tiekner, gardener to H. Hewetson, Esq., the first prize in each of the three classes. Of plants for table decoration Mr. J. Wilkins, although placed third, had by far the most useful group, consisting of clean, healthy, medium-sized plants of *Pandanus Veitchii*, a pair of *Cocos Weddelliana*, *Dracæna terminalis*, and *D. Guilfoylei*. *Epiphyllums* were very good, especially the first-prize group from Mr. T. Maynard, gardener to Mrs. Hindley, Broadwater, Down. There were several groups of the showy *Poinsettia*, all of them much drawn up except the useful dwarf plant of Mr. J. Charlton, to which the first prize was awarded. Many useful well-flowered examples of *Celosias*, also fine *Poinsettias*, were shown, and constituted, in the opinion of many, one of the best features of the Show.

*Fruit.*—The classes for Pears and Apples were so well filled that an excellent display of well-grown fruit was brought together. Names were attached to the different varieties, but we noticed faulty nomenclature in several instances. Of the three collections of fruit shown Mr. A. Bashford was first with a handsome Queen Pine, a Berwick Perfection Melon; good Black Alicante and Lady Downe's Grapes; Blenheim Pippin, Gloria Mundi, Golden Knob, and Cox's Orange Pippin Apples; Beurré Hardy, Beurré Superfin, and Uvedale's St. Germain Pears. The same exhibitor was also first with three excellent bunches of Muscat of Alexandria Grapes and equally fine Black Alicante.

#### DARTFORD.—NOVEMBER 16TH AND 17TH.

This ably managed and successful Society held its eleventh annual display in the large Assembly Rooms, Dartford, on Wednesday and Thursday last week. The plants exhibited perhaps did not evince that high-class culture and superiority of bloom that may be met with nearer the metropolis, or as we have seen here on former occasions; still they were for the most part most profusely flowered, while the cut flowers were fully up to the average, and creditable to the cultivators in the district. Several of the Japanese forms were exhibited as untrained specimens, and well adapted they are for the purpose. Especially fine were James Salter, M. Crousse, Bouquet Fait, Gloire de Toulouse, M. Delaux, and Rosa Bonheur, exhibited by Mr. Dancer, gardener to S. Mart, Esq., Sutton House. This successful exhibitor obtained the majority of first prizes in all the plant classes. Mr. E. Ryder, gardener to E. F. Satterthwaite, Esq., Kingsfield, and Mr. H. Preddy, gardener to J. Hyland, Esq., Bank House, Dartford, also showed well, and in some cases ran Mr. Dancer rather close. The greatest interest in the Show was probably centred in the open class for twenty-four incurved blooms, distinct, for which there was an elegant silver cup offered, with a second prize of £3, third of £2, and fourth £1. The winner of the first prize, Mr. Martin, gardener to C. N. Kidd, Esq., West Hill House, Dartford, staged a most excellent collection, and was far ahead of the other competitors. His collection consisted of Princess of Wales, grand; John Salter, Mrs. Heale, St. Patrick, White Globe, Mr. Bunn, Lady Hardinge, Isabella Bott, Queen of England, Antonelli, Prince of Wales, Cherub, Eve, Baron Beust, General Bainbrigge, Lady Talfourd, Refulgence, Mrs. Dixon, Mr. G. Glenny, Mr. Gladstone, Mahel Ward (this is a golden amber sport of Eve), Hero of Stoke Newington, Mrs. G. Rundle, and Anglina. The second, third, and fourth collections were much closer in quality, some of the blooms in each stand having passed their best, but the awards eventually fell to Mr. G. Pendred, gardener to S. C. Umfreville, Esq., Ingress Abbey; Mr. T. Dancer, and Mr. A. Harber in the order of their names. Mr. Martin also secured first prizes in the classes for twelve and six cut blooms, distinct, with blooms scarcely inferior to the prize-cup lot, and in each stand set up a bloom of Mabel Ward, which we venture to predict will be a splendid addition to our incurved varieties.

There was a very great improvement in the size and character of the Japanese flowers exhibited. Some really grand blooms were staged by Messrs. Etherington, Dancer, Pendred, and Martin, who secured most of the prizes. Rosa Bonheur and Revière were especially good.

Fruit, miscellaneous plants, as well as table plants, all added to the interest of the Exhibition, and great credit is due to the energy of Mr. W. Shelton the Secretary, Mr. Cliffe the Treasurer, and Mr. Evtit the Chairman of the Society, on whom the arrangements of the Exhibition principally devolved.

#### SOUTHAMPTON.—NOVEMBER 22ND.

Autumn shows are so numerous consequent on the necessarily short period of the *Chrysanthemum* season, that the exhibitions can only have brief notice, especially those that occur on the eve of our going to press. The Royal Horticultural Society's Show under notice was, on the whole, an excellent one, and, the day being fine, it was attended by crowds of visitors, which included all the leading families of the town and neighbourhood. The plants were less formally trained than is customary in some districts, and those that secured the premier awards were good. The winning stands of cut blooms contained many excellent flowers, but, on the other hand, many were small and had lost their freshness, the best blooms having faded. Fruit was of superior quality, and vegetables were of the highest merit.

Glancing at the classes, the first prize for a group of Chrysanthemums was well won by Mr. Allen, gardener to J. Bailey, Esq., Elmfield Hill, with an imposing arrangement, the majority of the plants bearing fine exhibition blooms. Mr. Osborne, gardener to H. J. Buchan, Esq., followed with an arrangement made bright with a number of Japanese varieties. For twelve plants Mr. Allen was again in the premier position with specimens  $2\frac{1}{2}$  by  $2\frac{1}{2}$  feet, not formally trained and flattened. Very effective were the Japanese varieties—Fulton, The Cossack, Mr. Barnes, and La Nymphé. Mr. Wills, gardener to Mrs. Pearce, The Firs, Basnett, was second with rather smaller examples, King of Crimsons being especially striking. For six plants the prizes went to Mr. Thomas, gardener to R. R. Scott, Esq., Shirley, and Mr. Osborne. Mr. Allen was first for four Japanese, also for a specimen plant, with an excellent example of Arlequin; Mr. Wills following with Fulgore. In the corresponding class for incurved or reflexed varieties the competition was close between Messrs. Osborne and Allen, the former winning with a symmetrical example of Golden Christine; Mr. Allen staging a vigorous and striking plant of King of Crimsons. Mr. Wills and Mr. Axford, gardener to C. Shipley, Esq., Twyford Moors, Winchester, also secured prizes in the above classes. In the amateurs' class for six plants Captain Gibbs was placed first with fresh creditable examples, followed by Mr. Betteridge, Old Bassett.

In the cut-flower classes the prizes for twenty-four hlooms, distinct, were won by Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham; Mr. Wills; Mr. Shirley, gardener to Lord Mount Temple, Broadlands, Romsey; and Mr. McMillan, gardener to Hans Sloane Stanley, Esq., Paultons, Romsey. For the same number of hlooms, in not less than eighteen varieties, the prizes went to Messrs. Allen, Molyneux, and Wills. The two last-named exhibitors are evidently first-class cultivators, as was indicated by many fine hlooms, which, however, we cannot enumerate. For twelve blooms Mr. Molyneux was clearly ahead of the other successful competitors—Messrs. Wills; Pope, gardener to G. Atherley, Esq., Bishop's Waltham; and Mr. Chapman, gardener to W. Tasker, Esq., Manor House, Clatford, all of whom exhibited well. For twelve Japanese, distinct, the prizes went respectively to Messrs. Allen, Molyneux, and Pope, the competition being very close indeed; and for twelve in nine varieties, to Messrs. Pope, Chapman, and Axford. In the amateurs' class for twelve hlooms Mr. Betteridge and Captain Gibbs obtained the honours.

Groups of stove and greenhouse plants were too formal, Messrs. McMillan and Wills securing the chief prizes. In the nurserymen's class we can only say of Messrs. Ransom's winning group that it contained good plants spoiled by close packing. Table plants were remarkably good, especially from the prizewinners—Messrs. Wills, Budd, and Philp. Messrs. Wills and McMillan had the best Poinsettias, good; Mr. Thomas the best Solanums, good also; Mr. Allen the best single, and Mr. Blackmore, Winchester, the best double Primulas. Good Palms were staged, but we could not see the names of the exhibitors; but by far the most beautiful and valuable group of plants in the classes were Dr. Buchan's Orchids. For healthy growth, fine flowers, and choice varieties these were of conspicuous merit, and the owner is to be congratulated on possessing such a collection, and his gardener, Mr. Osborne, complimented for growing the plants so well. Nor must we forget Mr. Cannell's splendid collection of Primulas—Swanley Red eclipsing all others—and Zonal Pelargoniums. A certificate of merit was awarded for this truly admirable display.

*Fruit.*—Seventeen collections were staged in the class for three varieties of Grapes, Mr. Hall, gardener to Captain Davison, South Stoneham House, being placed first with Gros Guillaume, splendid berries, Alicante, and Muscat of Alexandria, both very good. Mr. Austen, gardener to Sir Greville Smythe, Bart., Ashton Court, Bristol, was second, Mrs. Pince being fine and excellently coloured. Mr. Budd, gardener to J. C. Dalgetty, Esq., Lockerby Hall, Romsey, third, Gros Colman being good; and Mr. Wildsmith, Heckfield, fourth with smaller bunches but fine berries. For three bunches of black Grapes Mr. Hall was first with superb Alicantes; Mr. Austen second with the same variety; and Mr. Smith, gardener to J. H. Foord, Esq., Botley, third with Gros Guillaume, both staging well. For single bunches the prizes went to Messrs. Budd, Osborne, and Sharp, gardener to Rev. W. G. Medlicott, Swanmore Vicarage, Bishop's Waltham, the two former staging Alicante, the latter Black Hamburgh, all good. The winners with Muscats were Messrs. Smith, Wildsmith, and Sanders, gardener to J. East, Esq., Longstock House, Stockbridge, all exhibiting well. Three very good Pines were staged: First, Mr. Browning, gardener to F. Holloway, Esq., Marchwood Park, with a Queen; second, Mr. Wildsmith with Charlotte Rothschild; third, Mr. Austen with Smooth Cayenne.

Of Apples and Pears the display was splendid. In the class of four dishes of each there were seventeen competitors, Mr. Wildsmith winning first honours. We cannot name the varieties, but must say Spring Beurré Pear was grand; Mr. Mair, gardener to General Calthorpe, Woodlands Vale, Ryde, was second; and Mr. Wills third. For three dishes of dessert Apples Messrs. Girford, Rowhams; Pragnell, Arduave, Bassett; and Wildsmith were the successful exhibitors, seventy-five dishes being staged. For three dishes of kitchen Apples Messrs. Hall, Wildsmith, and Chapman. Mr. Wildsmith was first with three dishes of Pears. Numbers of exhibitors who failed to obtain prizes exhibited admirably in the above excellent classes.

Vegetables were as good as the fruit. Mr. Austen was first for eight varieties with a superb collection, ten lots staged; and Mr. Sanders for salads, an excellent assortment; while Mr. Guillaume and Capt. Gibbs were successful in the amateurs' classes. Mr. Wildsmith won the handsome framed certificate for the greatest number of prizes in the fruit classes, and Mr. Allen the corresponding honour in the Chrysanthemum classes. The prizes offered by Mr. B. S. Williams for the greatest number of points obtained in the Show was not determined when we left the Exhibition. Major-General Lacey, Captain Gibbs, and other members of the Committee, with Mr. Fudge the Secretary, rendered most efficient services in making the Show what it undoubtedly was, a success, and we never saw the business of an exhibition conducted in a more workmanlike, smooth, and satisfactory manner.

#### MANCHESTER.—NOVEMBER 22ND.

The Royal Botanical and Horticultural Society's Show held in the Town Hall proved, as far as the exhibits were concerned, a great success; indeed, it was pronounced the best autumn Show the Society has had, but the plants and cut blooms of Chrysanthemums were much behind those grown in some other localities, the superiority of Mr. Young's hlooms being at once noticeable. The Primulas and Cyclamens were extra fine, and not seen in better condition at any exhibition in the kingdom. In the class for eight Chrysanthemums, large-flowered, in pots, distinct varieties, the plants were not trained but staked upright, and were carrying eight or nine blooms each. The hlooms individually were good. Mr. W. Cush, gardener to C. Agnew, Esq., Prestwick, took the lead; Mr. W. Taylor, gardener to E. C. Potter, Esq., Rusholme House, second; and Mr. F. Glover, gardener to T. Woodhead, Esq., Old Trafford, a good third. In the class for four varieties, large-flowered, Mr. W. Taylor obtained the premier award with good plants, Mr. W. Cush being second, and Mr. Glover third. The Pompon varieties were not numerous, and the plants were staked in the same manner as the large-flowered varieties. The first prize in the class for six kinds was awarded to Mr. Crinestone, gardener to T. Diggles, Esq., Brookfield. Mr. Cush was first in the class for one large-flowered variety, showing Elaine; the same exhibitor being first in the class for one Pompon, and Mr. Crinestone second. Primulas throughout the Exhibition were in grand condition; in fact, much finer than generally met with. In the class for six plants Mr. George Kerten, gardener to John Allen, Esq., Oldfield House, took the lead with well-flowered plants; the second being obtained by T. G. S. Garnett, Esq., Bolton, with smaller but well flowered examples, the flowers being large and the strain good; the third going to Mr. H. Ellis, gardener to W. Agnew, Esq., Pendleton. An equal first prize was awarded Mr. H. W. Gibson, gardener to S. Hazzopulo, Esq., for double white Primulas, the best we have ever seen staged.

*Cut Flowers.*—In the class for twenty-four cut hlooms of large-flowered Chrysanthemums, distinct, Mr. Charles Young, gardener to Joseph Evans, Esq., Hurst House, Liverpool, took the lead with hlooms far ahead of any others staged; the second prize being taken by Mr. G. Kerten, who staged both incurved Japanese and Anemone flowers in his box. W. Warrington, gardener to W. Blades, Esq., Lymm, was third. In the corresponding class for twelve hlooms Mr. Young was again a long way first, his hlooms being bright, fresh, and good. In the class for twenty-four hlooms, including Anemone, Japanese, and Pompon varieties, Mr. Young again took the lead, showing well. Mr. C. Pritchard, gardener to J. Ryder Esq., Didshury, was second. In the class for the best arranged vase suitable for a dinner table Mr. W. Plant obtained the premier award with a massive vase of choice flowers, and suitable for a very large table. Mr. H. Ellis was a good second with a light, elegant, and tastefully arranged vase.

*Miscellaneous Exhibits.*—Messrs. Dixon, Brown, & Tait, Manchester, exhibited a fine group of Solanums and Cyclamen. The former were remarkably well berried; the latter being in 8-inch pots, and the plants remarkable both for size and bloom. A first-class certificate was awarded. Mr. John Hooley, Edgelly Road, Stockport, also staged a fine assortment of small-flowering and foliage plants, the former largely predominating, a first-class commendation being awarded. Messrs. W. Clibran & Sons, Altrincham, staged a very large collection of similar plants, amongst them being quantities of Chrysanthemums, principally Pompon varieties, both trained and untrained, the large bushy plants of Mignonette being a feature, and were remarkably fine; the double Primulas in this collection were also good. This collection was also awarded a first-class commendation. Mr. John Gibson also exhibited a beautiful group of Primulas intermixed with Poinsettias and a few Roman Hyacinths, for which the Society's silver medal was awarded. Messrs. H. Cannell & Sons, Swanley, Kent, staged a fine box of cut blooms of single Pelargoniums and one of double varieties. The box of Salvias were really magnificent, S. Pitcheri and S. rutilans being intermixed. The Primulas were very fine indeed, and a first-class certificate was awarded for them. A first-class cultural certificate was awarded to Mr. G. Masters, gardener to Colonel Leigh, for a tray of Tomatoes. A similar acknowledgement was awarded to G. F. Smith, Esq., for four bunches of Black Alicante Grapes. Messrs. G. & W. Yates, Manchester, staged a choice assortment of miscellaneous plants in remarkably good condition. Mr. Swan, Fallowfield, staged a small plant of *Odontoglossum nevadense* in

flower. Mr. James Hill, gardener to George Hardy, Esq., Timperley, staged a fine *Odontoglossum* unnamed, but supposed to be *O. Chesteronianum*. The spike had fifteen flowers upon it, pure white, of good size, and blotched with large purple spots, the side petals being pure white. The markings are extraordinary and beautiful. Messrs. Cole and Son, Withington, showed *Ixora Duffi* in grand condition; the trusses were large and most brilliant in colour. It will be remembered that Messrs. Veitch & Sons sent it out about two years ago. The foliage was fully 9 inches long and 4 inches in width, and the flowers extremely bright.

Mr. Bruce Findlay is to be congratulated for the success of the Show.

#### KITCHEN GARDEN.

*Forcing Department.*—For Asparagus, pits are necessary capable of holding sufficient fermenting materials to maintain for a considerable time a bottom heat of 70° to 80°, with hot-water pipes sufficient to secure a top heat of 55° to 65°. The lights should be movable, so that at suitable times an abundant supply of fresh air can be afforded, as without this the heads will be poor in flavour. In order to obtain a supply of heads at Christmas a bed should now be formed of three parts leaves to one of stable litter, well incorporating them, and treading the bed down firmly so as to induce a steady prolonged heat. Level the surface, and place on some light rich soil 2 or 3 inches in depth, and, the heat not exceeding 80°, introduce the roots. Supply tepid water at 75° to 80°, and then cover the crowns with 2 or 3 inches of finely sifted soil or spent tan. The pit may be kept close until the heads are clear of the soil, when air should be given in favourable weather. Seakale may be forced in a similar manner, but a more moderate temperature is desirable, and means must be employed to exclude light. For Seakale and Rhubarb we prefer the Mushroom house, in which they force readily, providing the roots are placed up to the crowns in light rich moist soil, not affording water until growth appears, when tepid water may be given to keep the soil moist. Mushroom houses are usually dark, hence means are not necessary to be adopted to secure the blanching of the Seakale; but if the forcing be done in a light structure means must be employed to exclude it from the plants, and Rhubarb is also much improved thereby.

The mild weather has been very favourable for late Cauliflowers and autumn Broccoli, and of this advantage should be taken to lift those with close heads and that will admit of some further development. Lay them in a pit where they will be safe from frost; protection being given in severe weather, a supply of heads will be secured until a late period, others being lifted and placed in similar quarters at a later period. Veitch's Autumn Broccoli from coming in late is very valuable, having fine compact heads which are much hardier than Cauliflower. In fine weather earth up late Celery, and hoe between the rows of growing crops, such as Cabbage and winter Spinach. Push forward outdoor operations whilst the weather is favourable.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—The leaves have nearly all fallen in the latest houses, and the trees should at once be unloosed from the trellis, thoroughly cleansing the woodwork with soap and water and the glass with clear water, limewashing the walls. If the trees have been infested with scale they may be well syringed with water at 160°, and the trees afterwards dressed with an insecticide, if necessary repeating it before the trees are secured to the trellis. Pruning may be attended to, but if summer-pruning has been duly performed little if any will be required now. The loose inert surface soil should be removed, and good strong loam supplied, adding a little bone meal and wood ashes, but the latter must not be used more than to the extent of a twentieth part. Ventilation must be given to the fullest extent, closing the house only in case of frost. Trees that have not yet lost their leaves should be wholly or partially lifted, and the roots laid in fresh compost nearer the surface. Complete prun-

ing, cleaning, and dressing in succession houses, keeping them as cool as practicable, or if the roof lights have been removed they may remain off so long as the weather continues mild. The lights must be placed on the houses which contain trees intended to afford ripe fruit in June, still admitting air fully, and the outside border should be protected with leaves and litter. See that the roots in the inside border do not lack moisture. Continue the preparation of fermenting material for making a bed in the house, to which fire heat will be applied at the beginning of next month. Early in December the heat should be turned on in the morning if necessary to raise the temperature to 50°; at and above that temperature ventilate freely, employing fire heat at night to prevent the temperature falling below 40° or 36° in the early morning. When the buds are swelling the night temperature may be increased 5°. Until the buds show colour the trees may on fine days be syringed in the morning and early afternoon, avoiding as far as possible a close atmosphere. If there be any deficiency of moisture at the roots supply tepid water, or if the trees are weakly give liquid manure at a temperature of 70° to 75°.

*Cherry House.*—Replace the lights at once, but the house must be fully ventilated except when severe frosts prevail. Full-grown trees attended to in stopping during growth will only require those shoots shortened back to about an inch from the base, natural spurs being left, also extension growths or those required for filling vacant space. Trees in course of formation will need the central shoot or shoots cut back to originate a supply for filling the space with regularity. The fan mode of training is unquestionably the best that can be adopted, as it affords the means of filling any vacancies that occur through the trees gumming. Terminal shoots, unless for the purpose above indicated, should not be shortened. Remove all decayed spurs, afterwards thoroughly cleanse the house, and wash the trees with an insecticide, and this should be repeated before the buds commence swelling if the trees have been infested—as they usually are under the best of treatment during growth—with aphides and red spider.

#### FLOWER GARDEN.

Roses should be planted with as little delay as possible, the ground having been prepared by trenching and liberal dressing with manure. If the soil be light it will be permanently improved by mixing with it a good quantity of clay during the trenching, obtaining the clay in a dry state, and breaking it into small lumps before mixing with the natural soil. Roses are particularly fond of strong soil, especially those on the Briar, and where the soil is naturally heavy Roses on this stock succeed better than any other, having the seedling Briar for dwarfs. On light warm soils Roses succeed well on their own roots when liberally treated; and on the Manetti they thrive where the soil is porous. Roses should be planted so deep that the junction of stock and scion will be buried 3 or 4 inches beneath the soil. Cuttings of Manetti may at once be inserted to afford stocks for working next season. The wood of most Roses being now thoroughly ripe, they may be made into cuttings similar to Manetti, only the buds must not be removed. Briars for stocks for standards should be planted at once, selecting those with clean grey stems and not very spiny, as these usually grow freely and develop fine heads. Give plenty of space between the rows to allow free access at budding time, and mulch with partially decayed manure.

#### PLANT HOUSES.

*Forcing House.*—Where quantities of flowers and plants for decoration are required a house with pits in which can be formed beds of fermenting materials is a great aid at the dull season of the year. The house cannot be too light, and the means of ventilation should be ample; and if it be so arranged as to accommodate plants of various heights it will be the more useful, having shelves for such as require to be near the glass to secure dwarf growth. To insure well-developed flowers it is desirable that the forcing process be gradual, commencing with a moderate temperature, say 50° at night, and increasing to 55° in a fortnight, with 60° to 65° by day, and an advance from sun heat and liberal ventilation to 70° or 75°. Lilacs can be forced if placed at once in a high temperature; and if large bushes of these be now lifted, placed in pots or tubs and introduced to heat, and duly supplying with water, they will flower finely by Christmas. It is, of course,

necessary that all plants for forcing be well furnished with bloom buds. Charles X. is one of the finest Lilacs, but the common white is very useful, and does not require to be grown in darkness, as is necessary with the purple-flowered kinds, to obtain white flowers.

Perhaps no flowers are more esteemed at the dull season than Lily of the Valley, and to secure them in quantity a bed of fermenting dung and leaves may be made in a pit, so as to raise and maintain for a few weeks a temperature of 75° to 90°, and having hot-water pipes to afford an artificial top heat of 60° to 65°. Plants plunged in a bed of this kind at once will afford a supply of these lovely sweet flowers at Christmas and the new year. The roots must be placed on the bed when the heat is not over 90°, placing 2 or 3 inches of fine soil on the bed, then the roots, working some fine soil amongst them, and cover the crowns about an inch in depth with fine soil, after supplying tepid water. Single crowns may be employed, placing them about an inch apart, or the roots may be lifted from the beds outdoors in the mass, having first ascertained that they are well furnished with flowering crowns.

Where Hyacinths are required early a few should be placed in heat, also Narcissus and Tulips, assigning them positions near the glass, and the temperature not exceeding 55° at night. If they are taken direct from the ashes in which they have been plunged to the forcing house they must be covered with inverted empty flower pots to prevent the leaves being damaged, and after a few days tilt the pots a little, increasing this until the advancing leaves have become green, when the pots may be removed. The general stock of bulbs should not be permitted to remain plunged in ashes until the growth is advanced. They must be removed to a light well-ventilated house before more than an inch of top growth is made, and will need to be gradually inured to the light as above indicated.

Christmas Roses are not always to be depended upon at the time of year their name indicates, but any that are showing the flower stems and buds, if lifted carefully, potted, and placed in a genial temperature of 50°, will expand the flowers with certainty. *Helicoborus niger* and *H. maximus* are the best forms.

## THE BEE-KEEPER.

### BEE BATTLES.

THIEVING scouts and skirmishing parties are common in all apiaries, and hard-fought battles are occasionally seen there, and plunder is the object. Robbing bees are watchful and crafty in attempting to enter hives not their own, and experienced bee-masters know them by their conduct. In watching for an opportunity to enter hives unobserved they fly differently from bees engaged at honest work, and may be seen "standing on wing" in front of and close to the doors of hives they wish to enter, and if their attempts to enter be not resisted and thwarted they speedily accomplish their aims and carry home the honey. As soon as they gain access to it they convey to their own community the idea that a hive has been entered and honey may be had. The way in which the intelligence is conveyed is beyond our knowledge: all we here notice is the fact. The thieves of London know what "a cracked shell" means (a house broken into), and bees know what is meant by a hive undefended; and with marvellous rapidity the unresisting bees lose all their treasures.

Fortunately robbers are generally prevented from entering hives on their first attempt to do so. It may safely be asserted that in every hundred attempts to enter hives for plunder, ninety-nine are failures. When hives are weak their doors are often not well guarded and robbers enter, and sometimes the robbers kill the whole of the small force of defenders. Strong hives during a glut of honey are sometimes off their guard and let their hives be invaded, and if the robber bees are permitted to go in and out without hindrance for a short time they, generally speaking, take all the honey. Successful robberies of strong hives are not common. The robbers are generally discovered before they have done much harm—before they have lost the smell of strangers and foreigners, and when the discovery is made the bees of the invaded hive muster in strength to resist the invasion and make a determined stand against it. As some of the robbers have tasted the honey and carried off some booty, they are determined to

have more, and are difficult to beat back. In their efforts to enter, the attacking force seems to increase in numbers and energy, and while hundreds of them are hurled back and off the flight-boards, hundreds more take their places, and courageously and persistently continue the attempt to take the place by storm. A well-fought bee battle is most interesting. If the door of the hive be rather small, and the robbers successfully resisted for a while (none allowed to enter), they give up the contest and retreat.

When a hive is attacked by robbers all the bee-master can do is to contract the door, and thus make it more easy for the bees to defend it. If he sees the robbers are resisted and repelled he may know that they are so far unsuccessful, and if he find that robbers have gained access to a hive and are engaged in carrying off its honey without resistance, he should know that it can be saved by removal only to a distance of a mile or two for a time. If the robbing bees belong to the same apiary as those that are being robbed, the suggested manœuvre of Quinby may be tried. His plan is simply to exchange the positions of the hives by putting the robbers on the stand of the hive they steal from, and *vice versa*, and thus confound the robbers. My opinion is, that bees are too clever to be outwitted by this. Our plan is to remove one of the hives to a distance of one or two miles.—A. PETTIGREW, *Bordon*.

### BRITISH BEE-KEEPERS' ASSOCIATION.

THE monthly meeting of the Committee, held at 105, Jermyn Street, on Wednesday, November 16th; present T. W. Cowan (in the chair), Rev. E. Bartrum, Rev. G. Raynor, and Messrs. J. M. Hooker, H. Jonas, and the Rev. H. R. Peel, Honorary Secretary. The Chairman reported that he had been in communication with Mr. F. V. Hadlow respecting the exhibition of honey and bee-keeping appliances at the forthcoming Domestic and Scientific Exhibition to be held at Brighton on December 12th and following days. It was announced that the Executive Council of the Brighton Exhibition would grant space, free of charge, to the British Bee-keepers' Association for the display of honey and bee furniture. It was resolved that the Secretary be requested to write to the several manufacturers, asking for their assistance by sending honey, hives, and other goods for exhibition.

The Secretary submitted a proof copy of the prize list of bees, hives, and honey proposed to be offered for competition at the Royal Agricultural Show to be held at Reading next year. It was resolved to submit a similar schedule for the consideration of the Council of the Bath and West of England Agricultural Society, to be offered for competition at their annual Show to be held at Cardiff in 1882. Reports were read from Mr. Henderson the Librarian, and from Mr. Jonas, who has charge of the collection at the South Kensington Museum. With respect to the library, it was resolved that the Librarian be empowered to draw up rules and make arrangements for the loan of the books to the members through the book post. The meeting was adjourned to the 23d inst. for the consideration of the prize schedule for the Association's annual show to be held at the Royal Horticultural Gardens, South Kensington, on August 3rd, 4th, 5th, 7th, and 8th, 1882.

## TO CORRESPONDENTS.

\*\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Fungus on Lawns** (*Sol*).—Your lawn probably requires draining, but if you give it a dressing of lime at the rate of a peck and a half to a rod now, and a similar dressing early in the spring, it will probably be beneficial.

**Vine Growths Dying** (*W. C. B.*).—Your letter confirms us in the opinion we expressed last week, and we have nothing to add to our reply—namely, that you did not apply the shade soon enough; it was applied just after the injury was done instead of just before. Slight shade and a gentle syringing should be given the moment the growths show signs of flagging, and a high night temperature and close atmosphere must be avoided.

**Stocks for *Daphne indica*** (*G. M.*).—The varieties of *Daphne indica* are whip, or splice, or cleft-grafted upon *Daphne Mezereum* or *D. lauricola* as stocks, seedlings of the former, rooted cuttings or layers of the latter, being

suitable. The grafting may be done in March, the plants being then placed in a warm propagating frame until the scion has united with the stock.

**Wintering Hollyhocks (E. G. H.).**—The safest mode of wintering the plants is to pot them and plunge the pots in ashes or other suitable medium in a cold frame. If the plants are small or of moderate size they can be conveniently potted, but if very large they are less manageable in that respect, and also less likely to winter well. We have left old plants out for years, but always removed a portion of the soil from around them, and added a good thickness of coal ashes, as the water passes through these more freely than it does through soil. Your plants have been probably attacked by the Hollyhock disease, which you will find figured on page 91, the issue of July 29th, 1880. It is difficult if not impossible to extirpate this great scourge of a fine old flower.

**Burning Clay (An Old Subscriber).**—Burnt clay or ballast is excellent for forming the base of walks. When wood is plentiful a strong fire is made with it, and afterwards small coal is sprinkled with the clay in sufficient quantity for ensuring the combustion of the mass. Where wood is not plentiful coal alone is used; but when once a good body of fire is provided but little coal is needed, as the clay will burn freely if the heap is well attended to. An intelligent labourer will soon learn how to manage the piles when the clay is once set burning.

**Exporting Strawberry Plants (Amateur).**—Rooted runners could be sent in far greater numbers and at less cost than established plants could. The present will be a good time for sending them provided they can be properly treated on arriving at their destination. We should tie them in bundles and secure damp moss round the roots, then pack them in boxes when the foliage was dry, and should expect them to travel safely. If the foliage were wet they might heat in transit, and if the roots were dry they might shrivel.

**Daphne Unhealthy (L. J. K.).**—Possibly there may be scale on some of the leaders of your plant, but there is none on the one before us, the discoloration being the result of a shrinkage of the tissues. Although it is common for Daphnes to lose some of their leaves at this season, yet your plant is not in good health. Its root-action is either defective or the soil is not suitable. Probably if you were to remove the surface soil down to the roots and apply fresh turfy loam the plant would improve. If it is infested with scale the leaves should be carefully sponged with soapy water. The roots of the plant have probably been too dry in the summer. If the pot is very full of roots an occasional application of soot water would be beneficial.

**"White Wallflower" (C. C. J.).**—Our reply, we fear, will disappoint you, for your imagined treasure is not a Wallflower at all but a common form of the Ten-Week Stock. This smooth-leaved variety is distinct and attractive, and seed of it can be had from any nurseryman at the usual price. We have grown it for many years, and have had hundreds of plants. It is known as the Wall-leaved Stock, and a stray plant occasionally appears from a packet of mixed seed; but seed of this variety is also saved and sold separately by the principal seedsmen and florists.

**Winter Cucumbers (G. R.).**—Although the practice you describe is sound it is not communicated in a manner to entitle you to rank among the many competent writers of gardening literature. With care and practice, however, you might attain your object. We could write an article on the same subject more easily than revise what you have apparently written in a very hurried manner, and this fact will be a sufficient answer to your question.

**Vines Unhealthy (J. T.).**—As a rule Vines are more easily managed by amateurs when the roots have access to an outside border, as when wholly inside there is such a fear of overwatering, and the habit of merely sprinkling the surface of the soil is so prevalent, that the lower portions of the borders are much too dry. The consequence of this is, that the roots are either driven into the subsoil, or, if prevented by concrete, they shrivel. Our "Vine Manual," price 3s. 3½d., post free, will be of service to you.

**Fumigating Vinery (A Subscriber).**—Fumigation will do no harm whatever to the Vines, neither will it do good to them or to any plants unless there are insects on them. There are none on the Rose leaves you have sent, which appear to be infested with fungus. We should remove the worst of the leaves at once, and syringe the others with a solution of softsoap, nicotine soap, or Gishurst compound, at a strength of 2 or 3 ozs. to a gallon of water, and then dust the affected leaves with sulphur while they were wet. For extirpating worms from flower pots apply clear lime water, which is made by immersing a few lumps of fresh lime in a pail of water, say 1 lb. to a gallon, and letting it stand to get clear, the scum being removed from the surface as it forms there.

**Auriculas (E. L.).**—The soil reached us in a dry powdery state and contained no maggots; indeed we do not think they could live in such a dry medium. We should certainly not pot Auriculas in soil containing maggots, and, so far as we can understand your case, should report the plants in proper compost, as they cannot be safe under the conditions you name. You might, however, first try the effects of clear lime water, which would not injure the plants, and might either destroy the maggots or cause them to come to the surface, but if the soil is as dry as this before us one watering will not be sufficient. The Primrose is worth preserving, but we have several better and richer in colour.

**Potatoes Unprofitable (W. Elvey).**—You ask, "How can Potato culture pay when the price for the produce is only 4d. per stone?" Our reply is that the question depends entirely on the weight of the crop. In the "Chester-le-Street Times" that reached us by the same post as your letter, it is stated that a farmer in Durham sold his Potatoes for 3d. per stone, yet realised upwards of £22 per acre for his crop. Further, we know of a yield under field cultivation of 104 tons per acre, which if sold at the price you name would be remunerative.

**Animal Charcoal (Birkenhead).**—When bones are charred or distilled at a red heat in close vessels they leave behind a coaly residuum, to which the name of animal charcoal is usually given. By this calcination the animal matter is almost entirely decomposed. The charcoal still retains, however, a little nitrogen, and though it is seldom employed as a manure, yet it is not wholly without effect in promoting the growth of our cultivated crops. Thus in 1842, when applied to Swedish Turnips, Mr. Fleming obtained from the unmanured soil 12 tons 5 cwts. per acre; with 20 tons of farmyard manure, 18½ tons; but when manured with 10 cwts. of animal charcoal, 21 tons 2 cwts. of clean bulbs. We have not tried this form of charcoal, which is economically called bone black, to either plants or garden crops. As it would not do harm and might do good we advise you to try some experiments, of which we shall be glad to hear the results.

**Preparing Tennis Ground (A. H.).**—You say you have placed drains 7 feet apart, but do not mention their depth. If they are more than 18 inches from the surface they will not be effective in such soil as yours unless the pipes are covered with stones or rubble of any kind to within 6 inches of the surface.

We should break up the clay a few inches deep and dress it with lime freely, adding garden refuse of any kind; and if the surface can be stirred frequently when it is crisp with frost—not otherwise—it is an advantage. In the spring add the soil as you propose, making the surface perfectly level and firm, then sow the seed, sprinkling over it a little fine soil, over which draw a light roller. If you state the character of the soil and the extent of surface to be sown to a good seedsman, the right quantity of the proper mixture of lawn seeds will be sent to you for sowing, telling him at the same time you require a lawn as quickly as possible.

**Transplanting Fruit Trees (J. H. B.).**—The instructions you quote are quite right as they apply to Peach trees, but lifting old Pears is entirely another matter. As you have the trees it would not have been difficult to take the circumference of their stems a foot above the soil, and estimate the surface of wall which the branches cover. We have transplanted Pear trees with stems 18 inches in circumference, but should not have done so if the varieties had not been of proved excellence. Trees having stems a foot in circumference may be lifted with a fair chance of success provided the work is carefully done. Some workmen will transplant a tree of the larger size named more successfully than others will the smaller. As you do not appear to have had experience on lifting trees you would do well to consult a good practical gardener in your district, who would be able on examining the trees to inform you which of them would be likely to remove safely, and would also give you instructions on the spot how to proceed with the work. If you cannot do this, and will inform us of the sizes of the trees you think of removing, we will endeavour to aid you in the matter.

**Neglected Vines (T. J. B.).**—If the laterals of the Vines are fairly strong you might hope to obtain a moderate crop next year. To do this we should only retain one lateral at each spur, these being 18 inches apart; and instead of cutting close to the main stem we should prune at the boldest eye, where the wood was firm and mature, tying these pruned laterals to the main rods if needed. Next year we should encourage the growth of new canes from the base of the Vines, and afford them all the light possible, shortening the canes in the autumn according to their strength, and removing the spurs from the old rods entirely up to the height at which the young canes were pruned. By following this practice for about three years you will be able to remove the old rods entirely, and have a house of young fruitful canes without losing a crop. You must also endeavour to produce healthy roots by renovating the border, and this we should do at once. You appear to be aware of the importance of this, and we presume you understand how to proceed in the work, seeing that you do not ask for information thereon.

**Chrysanthemums (J. C.).**—Mrs. G. Rumble Mrs. Dixon, Mr. G. Glenny, Barbara, Empress of India, Golden Empress of India, Prince Alfred, Prince of Wales, Alfred Salter, Mr. Bunn, Princess Teck, Hero of Stoke Newington, White Beverley, Golden Beverley, Queen of England, Princess of Wales, Lady Hardinge, John Salter, Cherub, Novelty, Inner Temple, Aurea Multiflora, Nil Desperandum, White Venus, Venus, Mr. Corbay, Duchess of Wellington, Lord Derby, Beethoven, Isabella Bott, Beauty, Jardin des Plantes, Bronze Jardin des Plantes, Mr. Brunlees, Mrs. Heale, Lady Slade, Eve, Sir Stafford Carey, Golden Queen of England, White Globe, Mr. Gladstone, Mrs. Haliburton, Lady Talfourd, Miss Mary Merzan, Golden Dr. Brock, R. J. Dix, and Golden Eagle, are good incurved varieties.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (G. H.).—We do not recognise the small Apple you sent.

**Names of Plants (M. B. D.).**—*Tecoma capensis*, a climbing plant which succeeds in a greenhouse or conservatory. (A. B.).—1, *Oncidium barbatum* var. *limbatum*; 2, *Oncidium flavescens*. (G. W. B.).—*Coelogyne speciosa*. (J. L.).—*Woodwardia radicans*. (J. R.).—1, Not recognisable; 2, *Linum trigynum*; 3, *Justicia speciosa*; 4, *Cyanophyllum magnificum*; 5, *Monochaetum sericeum*; 6, *Goldfussia isophylla*. (William Rayner).—*Ectonymus caropeus*, the Spindle Tree.

COVENT GARDEN MARKET.—NOVEMBER 23.

BUSINESS quiet, large arrivals of St. Michael Pines this week, causing a serious decline in English fruit. No alteration in Kent Cobs.

## POULTRY AND PIGEON CHRONICLE.

## STABLE ACCOMMODATION FOR HORSES.

*(Continued from page 462.)*

It now becomes important to inquire whether the system advised yields all the advantages which we require, and which was devised for the purpose of maintaining our horses of every description required for fast work in full health and condition, and capable of the work and exertions expected of them. Many of these animals are extremely valuable, and are the pride and pleasure of their owners in the hunting field, on the racecourse, and for carriages. To fulfil any of these objects the horses must be in perfect health, and we can quite understand that many of their owners are prepared to incur great expense for the purpose of insuring this, and to obtain stable accommodation, which will be not only perfect but pleasing to the eye.

This brings us to certain important questions. Are the stall or box floors laid in the best manner and composed of the best material for the horse to stand and lie upon? Is the foot, which is certainly one of the most important parts of the animal, well provided for under the system of clinker brick floors, of whatever pattern or design? is this most calculated to maintain it in the best possible condition? We think not, for as the fashion of shoeing is now carried out the foot is not only apt to contract and become too narrow, but also it becomes too dry and unelastic, and suffers from cracks in the hoof, which with the habit of stamping in some horses soon throws off the shoe and breaks away the hoof. This is for the most part attributable to the method of shoeing now practised, which is well treated of in an essay on the subject—"The Horse's Foot, and How to Keep It Healthy," by George Fleming, F.R.C.V.S., Second Life Guards. Mr. Fleming observes, "The evils of ordinary shoeing are due to erroneous notions and a desire to make fine work. By the majority of farriers the foot of the horse is looked upon as little if anything more than an insensible block of horn, which they may carve and mutilate with impunity and as suits their fancy. Not content with rasping or chiselling away the most important and essential part of the wall or crust of the foot, the farrier must needs, to 'finish' his work in an artistlike manner, rasp the remaining portion up to the hair, thus removing the smooth dense surface, which stands very much in the same relation to the hoof that the bark does to a tree. A strange notion also prevails among grooms and farriers, that the frog should not touch the ground, and if it does it will cause the horse to go lame; hence they take every care that it shall not do so by paring it away as much as possible, or by thickening the heels of the shoe. At the same time there is no doubt that the majority of cases of 'navicular disease' and 'thrush' are more or less directly due to paring and preventing the frog reaching the ground."

We do not propose to quote more of the excellent and practical remarks of Mr. Fleming as to his plan of shoeing, but will refer the reader to our article on the shoeing of farm horses, as given in this Journal on the 5th of June, 1879, where the whole of Mr. Fleming's system is stated in detail. We have only quoted a few observations from him as showing how liable the horse's foot must be under the ordinary system of shoeing, not only to contraction of the hoof but to its liability to breakage when resting upon a hard and impervious floor; and as the old saying is, "No foot no horse," it becomes a matter of the first consideration how

to keep it healthy and equal to daily use. We do not for a moment suggest that we can obtain a better impervious floor for all purposes including drainage, but we most decidedly object to impervious floors, because they do not afford comfortable lying for horses, being too cold and hard; and contend that the absorbent floors of earth are better, the practice of which was started thirty years ago, and the attention of the public was called to it by an essay upon the subject, which received a premium at a local Agricultural Society's meeting in a southern county at that time. As, however, this system has now been in use for so long a period, we can recommend it from our practice as being the best for all the requirements of stable management. We give our experience, which includes three different arrangements: each, however, is based upon the earth-floor system more or less. First, the plan of single stalls with earth floor; second, the plan of loose box with earth floor; and third, the plan of loose box with earth at the bottom, with straw as an accumulation above, upon somewhat the same method as usual in accommodating fattening bullocks.

Before entering on the details of our plan of earth flooring, as so many persons unacquainted with the power of earth for absorbing the urine of animals are doubtful of the capacity of earth in such cases, we will first, before stating the result of our own experience in this matter, give the scientific opinions of Dr. Voelcker, in an essay from which we quote, given in the Journal of the Royal Agricultural Society of England in 1859, on the changes which liquid manure undergoes in contact with different soils of known composition. He states—"In a paper, 'Farmyard Manure and the Drainings of Dungheaps,' published in vol. xviii. of this Journal, I communicated the results of two experiments, which showed that drainings from dungheaps, in passing through soils of known composition, undergo a series of remarkable and important changes. Since the publication of this paper I have been actively engaged in following up this interesting inquiry, and at the request of the Council of the Royal Agricultural Society have now the pleasure of laying before the readers of the Journal the results of my recent researches on the subject." A series of very important details follows, relating to the power of soils to absorb the urine of animals, which we commend to the attention of the reader. It is, however, too lengthened a statement to appear here. We shall only refer to certain observations made by Dr. Voelcker in his papers upon this subject, in order to show that science fully recognises the value of earth as the proper medium for the reception of all excrementitious matters both solid and liquid, and that nothing effects so complete and rapid deodorisation and disinfection of putrid animal matter of every kind as a well-aerated soil. As soils vary in degree as to this power, it is a fact that strong and tenacious clays, as well as calcareous clays and strong loams, are more adapted than sandy or other light soils for absorbing and fixing the ammonia and other manuring agents, such as potash and phosphoric acid, by not only preventing injury to health of the animals, but retaining in the most available state all the manuring elements.

In proceeding with our subject, taking first stalls for horses with earth floors. The earth should be stored away until perfectly dry, and made fine so that it will pass through a half-inch sieve or screen, and thus enable all extraneous matters, such as sticks and stones, to be removed simultaneously. On the home farm we make use of an outhouse, shed, or barn now for the storing of earth to be manipulated by the workpeople at odd times and in wet weather, and thus fully utilise their labour at all times. In the adaptation of an ordinary stalled stable we take up the floor and excavate the earth to the depth of 18 inches. If in a dry soil it needs no concrete at the bottom if the sides are properly pinned with brick or concrete, the latter being best. In some instances we have merely excavated about 15 inches at the end of the stall nearest the manger in depth, because a tethered horse will drop its urine so much in one spot that the earth sooner becomes saturated in one part, and requires to be removed oftener than when a loose box is used. The filling-in of the earth, when perfectly fine and dry, should be done carefully by constantly using an iron-headed rammer, in order that it may be made perfectly solid for the animal to stand upon; the liquid manure will then sink into the earth without making any hollow on the surface, but the solid excrement should be removed as in the ordinary way and the floor swept as usual. One of the points in the daily attention of the groom is that much less straw is required for littering the stall than in the case of a brick or stone, concrete, or other impervious floor—a matter of no small importance where straw is scarce and dear. The floor will then secure good standing and lying for the horse; for although the earth may be rammed down firm and solid, yet it is found much better for the horses' feet, not being so liable to throw a shoe as when stamping on a

hard floor like elinker bricks; and when the animal lies down he finds a much more comfortable bed also, and as the urine is immediately absorbed the air is never tainted if the ordinary means of ventilation is adopted.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Wheat-sowing still proceeds, but is now nearly finished in all the latest districts—at least, it is sown up to the hurdles where sheep are eating off Turnips, Rape, and Cabbage. The season being so fine we advise the home farmer to sow as much Wheat as he can find suitable land for, as it is now and ever has been the rent-paying crop, except in some districts where the soil is more especially kind for Barley, and producing in ordinary seasons a malting sample of grain. The teams should now be fully employed in fallow-ploughing the land intended for Potatoes, Mangolds, and Swedes; and if the land has been autumn-tilled and cleaned of couch on the surface it may be ploughed the full depth, so that no raw subsoil may be brought up; for rather than plough too deep we would sooner use the subsoiling implement, following in every furrow behind the plough. We still note upon various farms in many districts that the land intended for Barley after Wheat or for roots in the spring is extremely foul, and in many cases no attempt has been made to clean it by autumn culture. When this is the case we do not recommend deep fallow ploughing, but we would prefer to rafter or half-plough, otherwise double-rafter or back-stetch, as either of these plans leaves the land open to frost, and sufficiently open also to allow superfluous rainfall to pass easily into the subsoil, at the same time keeping the couch near enough to the surface for working out on the first favourable weather in the spring. We note that some farmers have been following the land by deep ploughing, although heavily laden with couch grass. The result of our experience compels us to denounce this practice, for when so treated it is very rare that we can bring, even by continuous and costly labour, the couch upon the surface entirely; but we have often seen that in attempting this the roots have been divided into small pieces, rendering it almost impossible to be destroyed, especially when the spring season is showery. Trifolium, Vetches, Rye, and all catch crops look more promising than in any of the past three years. The winter Beans, winter Oats, and winter Barley are also very promising; in fact, look which way we will on the home farm we are gratified by the appearance of all our autumn seeding, nor can we recollect a finer season within our long experience for all farm work usually carried out in the autumn. Some threshing of Wheat and Barley may now be done with advantage, for it is useless to defer this work until the busy period of spring or summer, for it is a question of labour more than of policy both for men and horses; and it is also a question of providing straw for litter, fodder, and for sale, to be delivered in the period of leisure for horses. All straw should be stacked and thatched as fast as thrashed, especially now straw is selling at a high price—in fact, it is as dear as hay in some of our northern and midland counties. Still, much of it has been so injured in colour and quality by the heavy rains in the harvest that very little is fit for foddering cattle, unless it is cut into chaff and spiced and mixed with pulped roots, cake, meal, &c.

*Live Stock.*—Cattle have done well during the autumn, but foot-and-mouth disease is still prevalent in certain districts in the kingdom, and we know some farms, where the tenants were on the point of quitting, that this disease has amounted to a great disaster in consequence of non-removal of the animals and reduced condition. Sheep have been more free from foot-rot and epidemic lameness than we have known them for the past four or five years. Fattening sheep have made good progress—in fact, where the cake and corn has been liberally supplied to them more mutton has been made than in the generality of autumn seasons. Horned ewes of some of the best flocks which we have lately visited have nearly finished lambing. Some flocks have quite done, and the ewes and their lambs are now together folding on common Turnips and looking beautifully; some of the earliest lambs now weigh 8 lbs. per quarter, and will be very fat and handsome for killing at Christmas. It is very entertaining to walk through these noble flocks as we have lately done, such as we know from experience are of the finest tribes, and we are pleased to find that as the weather has been fair and fine a larger number of lambs have fallen and been saved than for some years past. It is greatly in their favour that the best sorts of Dutch and Hop Clover hay has never been known in finer condition for the feeding of early ewes and lambs; in fact, we have examined some flocks which have as yet only received hay and red round Turnips, and are as fine in condition as they well can be. It is not only the horned ewes which are so forward this year, but the west-country down ewes are also forward, and various flocks we know of are due to lamb well together during the month of December, and we notice also that they are in splendid condition. All the bullocks for fattening should now be in the stalls or boxes. We prefer the latter, especially for those which are nearly ready for the shambles, and as the Christmas demand for beef is now very near liberal feeding must be continued until they are sold.

*BATH AND WEST OF ENGLAND SOCIETY.*—At the last Council Meeting of the Society held at Bristol, it was resolved, on the

motion of the Hon. and Rev. J. T. Boscawen, seconded by Colonel Luttrell, that the Cardiff Meeting next year shall commence on the Monday in the week between the Epsom and Ascot races. The fixture of this date was justified on various grounds, among others the desirability of adhering to the old usage of the Society anterior to the existence of either of the great Metropolitan Horse Shows; the importance of the usual date to manufacturers, more especially of mowers and haymakers, who, in anticipation of the hay harvest, find a very large sale of such labour-saving machinery; and further, a desire to abstain as far as possible from interfering with the Royal Agricultural Society either as to the date or district of its meeting. As at Cardiff there are peculiar facilities, it is proposed to have a large exhibition of field implements within the show-yard as long as the Show continues; for this purpose grass crops will be provided free of charge, under such arrangements and limitations as shall be determined by the Field Stewards, for the working exhibition, within and immediately outside the yard, of grass-cutting, haymaking, rick-making, and any new appliance for saving the grass crops. With reference to the meeting, a deputation of the Glamorganshire Society, consisting of Colonel Turbervill, Mr. Garsed, and Mr. Huntley (Secretary), attended to express their desire to amalgamate with the Bath and West of England and Southern Counties Society, and, instead of holding a meeting of their own during the year, to offer prizes of upwards of £200 for competition in the Cardiff show-yard. After some discussion as to the terms on which the amalgamation should take place, it was cordially ratified on both sides by the Council and the Deputation.

## POULTRY AND PIGEONS

### POULTRY NOTES.

WE referred last week to the admirable manner in which the arrangements for receiving and penning the legion of poultry and Pigeons at the Crystal Palace Show were planned and carried out inside the building. Everything was as orderly and methodical as if only five hundred instead of five thousand birds were being dealt with. The management earned success, and we are pleased to be able to record that the Committee have had substantial proofs that their efforts are appreciated. Never before have they had such an entry, and never before has the number of visitors to the Show approached the record of this year. The sales, also, have been large; and though we have not heard of any such sensational purchases as have been made in some former years, yet many good birds in the poultry section have changed owners at prices varying from £10 to £25. Lady Gwydyr's cup and second Dark Brahma cockerels reached the latter figure, the former going to join the cup old cock and the latter to a Yorkshire yard. Amongst the Pigeons, also, sales were brisk, one bird—an English Owl—finding a purchaser at £50, and others at £30, £25, and £20.

APART from the question of judging, which is a very difficult one, and to which we referred in our note last week, there are one or two points as to which we would venture to offer a suggestion. There was a class for table poultry, pure or cross-bred, to be judged by weight only, and another for cross-bred table fowl to be judged for fineness of quality, &c., "sex and breed of parents to be stated." These are useful practical classes, and the provision which we have quoted from the schedule applied to both, and enforced, would make them of great value to the poultry farmer. As a matter of fact the rule only applies to the last-named class, and was far more honoured in the breach than in the observance. The cup for weight went to Mr. Boissier with a massive pair of Silver-Grey Dorkings which weighed 19 lbs. Second and third were fine-looking birds, probably of Brahma-Dorking origin, but the catalogue was silent as to this. In the other class the Rev. G. Gilbert took the cup with a pair of close-feathered meaty-looking pullets, but, in defiance of the printed rules, their parentage was not disclosed. We guess them to be a cross between Pile Game and Silver-Grey Dorkings; but why should we be obliged to guess? Second here went to Mr. Tegetmeier with a fine pair of cockerels. The catalogue gives the parentage here as "Dorking cock and Game hen," but adds the puzzling words "second-cross cockerels." What does this mean? Did Mr. Tegetmeier cross back to the Dorking or to the Game? and if so, how does the statement as to parentage come in? Third were evidently also of a Game-Dorking cross, but were again without pedigree. These classes ought to be the means of disseminating useful information as to cross-breeds, and it is for the Committee to apply the rule as to stating parentage to both classes, and to insist upon its being strictly adhered to.

THE other matter as to which we have a suggestion to offer is

one which may be of vital importance to some of the exhibitors. The floors of many of the pens were newly painted or coloured with some green fluid. They were partially covered with shell grit, but this did not prevent the green from coming off on the feet and breasts of the birds and being thence transferred to their heads and necks. This was bad enough, and would entail on the exhibitors much extra trouble in washing, but the risk of the birds swallowing some of the green matter with their food, and being thus perhaps seriously affected in health, is a more serious matter. We observed one very valuable hen much soiled with this green paint, and she has since her return home been suffering from diarrhoea. We suggested the paint as the cause of the mischief. We may be wrong as to this; but in any case a word of friendly caution may put the committees of other shows on their guard, and render a repetition of the painting process improbable.

THE arrangements outside the Show for the delivery of the birds were this year much improved. The railway companies formerly loaded the hampers on large vans for the purpose of sending them a few yards across the road to the Palace. This entailed a good deal of unnecessary piling-up of hampers. This year the birds were delivered by hand by the railway companies at their respective passenger entrances to the Palace. We watched the process for some time at the high-level station, and it suggested two thoughts to us. One, that the railway company might well have provided a few extra luggage trucks of the three-wheeled pattern to facilitate the work. The porters were fairly careful, and one ingenious man had constructed a good four-wheeled truck by tying together two of the ordinary luggage trucks; but in the majority of cases the baskets had to be wheeled on the ordinary trucks, and consequently tilted to a considerable extent. Our second thought was as to the general want of some means of taking hold of the hampers near the centre of the top, and thus carrying evenly two hampers, one in either hand. It is hardly to be expected that a railway porter having an enormous number of hampers to deal with should make a separate journey with each hamper; and if there be no handle at the top of the hamper he is obliged to catch hold of the hamper on one side and thus tilt it over, to the manifest detriment of the birds inside. Exhibitors should see to this.

#### THE CRYSTAL PALACE SHOW.

WE have of late years seemed to see some decline in the interest taken in the Palace Show. The entries for a year or two were somewhat below what they had been, the sales were apparently less numerous, and undoubtedly the attendance of the general public, as distinct from fanciers, was smaller. This year, however, all has again changed for the better. The Show was the largest ever held, and the Show was day after day crowded. The greatest interest, too, was shown in the multitudinous appliances exhibited—poultry houses of every kind and size, both ambulant and stationary; aviaries and runs; incubators and mothers, both "hot" and "cold;" drinking fountains and hoppers. Many of these contrivances were excellent, and offered at really moderate prices, and in consequence we saw "sold" tickets on a large proportion of them. Some of the incubators were of large size, and destined to hatch Ostriches in South Africa. Poultry-breeding is certainly not on the wane, and a healthy sign of its progress is that, as far as we could see, many of the purchasers of incubators and other appliances were not breeders of exhibition but only of table poultry.

The adult Dark Dorkings struck us as particularly handsome and in good condition, the hens especially so, and as being nearly all birds from which we should ourselves be glad to breed. This is a distinct gain, for we have often seen in the prize list decrepit old creatures, solely placed there because they were "the celebrated winners" of some celebrated breeder. We regret to see dark feet on the increase just as we have got rid of long legs. We have never been captious grumblers at judging—only those who have tried the work know its difficulty; at the same time we must say that only from great carelessness or great ignorance could any judge give a prize to such a bird as is one of the Silver-Grey cockerels. Such awards do the utmost harm. Beginners spend much money, time, and pains in producing creditable specimens, pay 8s. a pen for entering them, and then find a prize given to such a bird as ought to be the first to be given to the cook.

It is a great pity that the White and Black Cochins were mixed, the latter breed thereby being practically excluded from competition. The first White pullet, though pretty, struck us as being very small and generally inferior to the second.

It is unfortunate that Hamburgs have got so entirely into the hands of one class who understand their "improvement." Those who scruple to practise it are being by degrees ousted from the Hamburg fancy. We hear a rumour that the Rev. W. Serjeantson is on this account giving up Black Hamburgs, and is likely to take up some breed of Dorkings. Some of the Silver-pencil cockerels at the

Palace were very pretty. They would be a nice breed for some amateur to start, if only the trimming of combs could be stopped.

In the class for "Any other variety" Polish, were several good Padue Chamois, which, however, contend at great disadvantage with White-crested Blacks. Why one beautiful cock (Mrs. Ricketts') was unnoticed, while an indifferent hen or two had cards, we did not understand. We hear that an admirer, though not hitherto an exhibitor of Polish, has guaranteed the prizes for a fourth class of Polish at the forthcoming great show of the Poultry Club. This will be a good chance for fanciers of Padue Chamois, or any of less known kinds.

The little cup Pile Game Bantam cockerel, shown by Mr. E. Watson, was the winner of a very handsome sum—viz., the ten-guinea special cup for the best Game Bantam, as well as the four-guinea cup for the best Duckwing or Pile cockerel.

We were pleased to see that Mr. T. P. Lyon has added Game Bantams to his stock, and is at once as successful with them as with large Game. He won cup for his Black Red cock, and first for hen of the same breed.

It is a long time since we have seen such small good clean-legged white Bantams as were the three winning pens. Japanese Bantams by no means showed so well as last year. The cup was most strangely awarded to a pair in nice condition, but wanting all the distinctive characteristics of the breed. Their legs are comparatively long, and the cock has round sickles flowing back like a Hamburg. Surely good Japanese should have almost straight tail feathers carried very high and in squirrel fashion close to the head. There were such birds in the class, and beauties too. How could the Judge leave unnoticed such a pair as Lady Dartmouth's? They are dark frizzled Japanese. We understood that his reason was that they ought to have been entered in the Any other variety class, but they have every characteristic of true Japanese in form, head, legs, and carriage. We preferred Mr. Tearle's h.c. pair of Silver Sebrights to all the winners; their size is small, and their general contour more like the older Sebrights.

The class of Aylesbury Ducks was, as usual, small. The monopoly of prizes which a few breeders of this variety have long had prevents many who have really good specimens from showing them. Pekins had four classes, and numbered sixty birds. The cup drake was a simply gigantic bird. We could not help remarking that a Duck far beyond the rest in size, belonging to Mr. W. J. Nichols, was only h.c. Her colour, we understood, was not sufficiently yellow to satisfy the Judge's fancy. As this lemon tinge seems to vary much with the time of year and character of the water, it is not a very satisfactory test of race and quality of the bird. Fancy Ducks made a very sorry appearance. The two winning pairs of Mandarins were excellent, and Miss Arnold's Duclairs are portly, and no doubt profitable. We hope at Birmingham to see a far different display, where the beautiful varieties of fancy Ducks have proper classification.

Turkeys formerly had three or four classes; they are now cut down to one for cock and hen of any age. This is hard upon intending purchasers who want a single fresh bird. The number of Turkeys sold at Birmingham, where four classes are provided for them, is prodigious, and we should have thought that a like classification at the Palace would have been a paying concern. The winning pairs were very handsome.

The public seems attracted to the Palace Selling classes by some strange spell. Capital birds at very moderate prices in the open classes are passed, but the most antique and rubbishy specimens find ready purchasers in the Selling classes, simply because they are selling classes. As we walked down some of the long rows there seemed hardly a pen not labelled "sold."—C.

#### REMARKS.

13th.—Fine and mild; very cloudy sky with beautiful rose tints.

14th.—Misty early, overcast throughout.

15th.—Fine bright day; starlight night.

16th.—Fine morning; afternoon and evening wild and stormy with rain.

17th.—High wind in morning; fine bright day; calm evening.

18th.—Fog in morning; afternoon fine; evening damp.

19th.—Fine and mild; bright sunshine.

Temperature rather lower than in the previous week, but still much above the average.—G. J. SYMONS.

### APPLES AND PEARS OF THE LATE SEASON.

**T**is now time to speak of the year 1881 as it has proved to be. The promise of spring is over, the fulfilment of autumn is also over. My knowledge and observations must be understood to be confined to the four counties—Wilts, Somerset, Hampshire, and Sussex; further afield I have not been. What, then, of the past season? We have had lately pleasant “scraps” concerning fruit, but happily the fruits have not themselves been “scraps” or small samples, but, as far as I have seen, an abundant harvest.

Let me first speak of Pears. The Pear which has this year pleased me above all others is Beurré Hardy, a Pear particularly recommended to me a few years since by the late excellent senior Editor of this Journal. “Whatever Pears you plant, mind and plant a Beurré Hardy, that grand large Pear,” said Mr. Johnson, and my experience of it fully confirms his opinion. It is large, handsome in outline and colour, looks well on the tree and on the dessert dish, and, more than all, has ripened well; is perfect, to my mind, in its Pine-Apple-like flavour, and so juicy we seem to be eating and drinking at once. It forms also a very handsome tree both as to growth and leaf, and is fit for a lawn. Next and worst is Beurré Diel; so bad that I have uprooted the tree. Mr. Smee says of it, “Very unequal, sometimes very good.” It may be the latter, but it has proved only bad with me, though I have tried it year after year. Another very inferior Pear is Seekle, which I do not think worth growing. It is very small and of a vulgar sweet taste, fit only for a huckster’s shop and for school children to spend their pennies on.

Concerning Beurré d’Amanlis I must speak a favourable word. It has proved with me an enormous cropper of clean-grown large fruit, handsome in form. One I have (a pyramid) resembled a fountain as each branch bent with its load, and it well deserved being photographed. It is not certainly the high-class Pear that Beurré Hardy is, but it comes in well after Jargonelle. Mr. Smee speaks of it thus disparagingly: “Beurré d’Amanlis is a handsome large Pear, utterly devoid of flavour.” Now, good judge of fruit as was the late Mr. Smee, I must differ from him here. This Pear is utterly devoid of flavour until it is perfectly ripe—regularly dead ripe, then it is good, but before then it is a mere Turnip. The best early Pear I still hold to be with Rivers the Summer Doyenné, and Bergamotte Esperen is one of the best winter and spring Pears. Other Pears do not call for much comment. One remark I would make—that I gather winter Pears as late as possible, each year later than before, for I am sure it is the best plan,

and that until the leaves turn colour the fruit should be on the tree; this I take to be the right rule.

I now turn to Apples. Let no one shudder, but with further experience I should never again think of planting Joanetting, Margaret, Keswick Codlin, and—start not, lover of old days—not Golden Pippin either. Joanetting and Margaret are quite surpassed by Irish Peach in healthiness of tree, beauty and flavour of fruit, and length of keeping. So also Keswick Codlin is equally surpassed by Lord Suffield. For winter dessert Cox’s Orange Pippin eclipses the old Golden and also Ribston Pippin, because it does not eanker, and the Ribston does. I am satisfied with Duchess of Oldenburg; more and more pleased with Ecklinville Seedling, an Apple among the best twenty grown. I am also equally satisfied with Winter Hawthornden, better so called than New Hawthornden, as the term “winter” keeps it distinct from the other and older, which is a summer fruit, and very excellent it is, but the tree is given to canker, whereas the Winter Hawthornden is remarkably healthy. Beauty of Kent also eankers terribly when grown on the Paradise stock, which I regret, as it is a magnificent Apple. Lodington I think well of, but my experience of it is short, so also of Betty Geeson. As of Ecklinville Seedling, so I desire to have a special word of commendation for Gravenstein and Stirling Castle. The former is of good size, singular shape, and true to the origin of its name, “Engraved Stone.” I do not know a better Apple for the two purposes, table and cooking, and its size recommends it, together with its keeping well. Stirling Castle is another admirable Apple, of good size and beautiful shape; but the tree is apt to bear so much as to make little growth. The fruit will keep well over Christmas, and the flavour is excellent. There is a misprint in the “Fruit Manual” in regard to this Apple, where it is put down as “in use early in August,” while it is not ready until October. Did it grow as strongly it would compete for the premiership with Dumelow’s Seedling as a winter cooking Apple; but taken altogether the old seedling is unequalled. Peasgood’s Nonsuch does not bear with me, also in a certain degree Summer Golden Pippin and Striped Beefin.

Next a word about cankering. I think, first of all, there is in some varieties a strong tendency to canker, while others are perfectly healthy. I have moved into exactly the same place a Dumelow’s Seedling where another tree has died of canker; but it remains perfectly healthy, so that soil does not affect canker much, but frost increases it, particularly with new wood; also a damp situation—ground that needs draining—increases the disease in those trees given to cankering, as also “gumming” in Plum trees; but still I hold that the tendency to canker badly is innate in some varieties, such as Old Hawthornden, better called Summer Hawthornden, Beauty of Kent on the Paradise stock, Ribston Pippin, and some others.

I should gladly see many varieties of Apples and Pears disappear from nurserymen’s fruit lists, and then they would gradually go out of cultivation. I doubt whether there are more than forty first-class Apples—first-class in flavour, size, bearing, and healthiness, putting aside the eider varieties. I also should be satisfied with forty Pears for walls, forty for pyramids, and forty for standards, but I doubt if such forties fully satisfying all requirements are to be found. If we are to become a fruit-growing nation for profit we must have for the market Apples equal to those sent from America, and Pears really good, not deceivers lying on fruit dishes for show only

People, too, are apt from association and recollection to plant trees the fruit of which they liked in youth, not remembering that the untrained fruit appetite of a schoolboy and that of a man are different. Boys readily and eagerly eat the small and the sour.

I am trying several other varieties of Apples and Pears which have been figured in those numbers of the "Herefordshire Pomona" which have as yet appeared, but I cannot venture to give an opinion of their merits until another year or two. This has been a grand year for Crabs of every variety, and very much have they added to the beauty of our gardens, for Crab blossom and Crab fruit are both extremely delicate, telling, and beautiful.

An authority from Worcestershire thus writes to me in regard to the past season:—"I have seen," says he, "some remarkably good and well-ripened fruit about here this season. As regards newish Apples, I think the Ecklinville Seedling will in all probability surpass Lord Suffield. Red Hawthornden and Yorkshire Beauty are capital kinds, and the Worcester Pearmain is a very good dessert Apple, and for profit should hold its own, as it is attractive, good, and early."

And now, Englishman-like, I must end with a grumble. I was much taken with the Hampshire late-keeping Apple, Hambledon Deux Ans. I judged of the fruit, but had not seen a tree. Being determined to have a tree from Hampshire—supposing, at any rate, "good coals must come from Newcastle," so at some expense I bought an espalier from a Hampshire nurseryman. I waited two years for a specimen of its fruit, and it was not a Hambledon Deux Ans at all, but a Red Astrachan, which I did not want or wish to have in my garden. Of course I was vexed; indeed I am compelled to own that many smaller men and some larger men in the trade are very careless in this matter. When I have in walking through a nursery noticed that wrong names were on the trees, the answer I have got is, "The boys have mixed the labels." Can anyone wonder that buyers are driven to send to the great men of the trade, from whom they are sure to get what is wanted? Nurserymen injure themselves by such carelessness and drive trade away from them, but they have no one to blame but themselves.—WILTSHIRE RECTOR.

#### A ROCKERY FOR ALPINE PLANTS.

(Continued from page 457.)

HAVING lately seen the term "alpine" limited to plants which grow on the Alps, it may be as well to say that in these notes I have used the word in a wider sense. The mountain flora of the Alps is, perhaps, the richest in the world; but any flowering plants whose home is on the slopes of mountains anywhere, if quite hardy in the climate of the Alps, may by analogy be called alpine plants. However, it is not easy to define an alpine plant, nor is it necessary.

I think I proposed to name about fifty alpines, and though I have kept no account I seem to be approaching this limit; but on looking into my rockeries pretty claimants for the vacancies which remain come in sight at every turn, and some seem to reproach me with not having selected them for honourable mention, as if I had forgotten them because they flowered in spring, and had preferred others which were gay more recently in memory; but I must try to be as fair as I can.

No one can expect to grow *Androsaces* without trouble, but they are worth it. They do not mind cold, but many devices are recommended to save them from wet in winter, which they abhor. Potting and putting them into a cold frame is, perhaps, a cowardly way of solving the difficulty, though I adopt this plan with many alpines, of which my stock is small. Some expert gardeners advise laying a flat piece of glass in such a way as to keep rain but not frost from them in winter. The west winds here are too strong for that. I prefer to plant them in recesses under projecting ledges of limestone, where there is a space of 3 or 4 inches between the soil and the upper rock. In this way *A. Laggeri*, *A. sarmen-tosa*, *A. lanuginosa* in peaty soil, packed round with broken limestone, are tolerably happy through the winter, and I am gradually extending my experiments with others. A biennial of no great attractions, *A. coronopifolia*, sows itself on the barer crevices of the stones, and gives no trouble. The same may be said of *Erinus alpinus*, most useful for varying the surfaces of the limestone and growing in the smallest cracks. *Linaria alpina* is another of these self-sowing plants, and should be encouraged in bare spots where hardly any other plant will grow. *Linaria pallida* and *L. hepa-*

*ticæfolia*, good as they are in their way, must not be allowed to spread too much, as they grow rapidly. *Dryas octopetala* is a model alpine, of which you will not easily obtain too much; as well as its near relation, *D. Drummondii*; it prefers limestone, the surface of which it clothes most neatly. If *Thalictrum minus* would grow as it does in the bare crevices of its native rocks few alpines would be more attractive; but it has a tendency to become coarse in cultivation, and must be confined to the driest and poorest spots. *Lychnis Lagasæ* is a neat plant, which may be raised in plenty from seed, and, though a perennial, often damps off in winter. I will say more of this and similar shrubby plants in a future number. *L. alpina* is a neat and desirable plant for a bare upper ledge, liking a surrounding of fine gravel.

The limestone rockery is the best place for that interesting and nearly extinct native, *Cypripedium Calceolus*. Planted in a pocket in the limestone in a mixture of good loam and peat, with broken limestone about its roots and an annual top-dressing of leaf soil, it will do well, but will take some years to become a fine plant. Of the *Gentians* *G. verna* will do best in damp pockets near the base facing the sun, but must be constantly watered in summer. *G. acaulis*, too, likes full sun, and loose stones a few inches beneath the surface; it is capricious about soils, and I can give no golden rule to ensure success. *G. septemfida* likes peaty soil and shelter from hot sun. Many others are worth growing, but some are very difficult subjects. By all means give several spaces near the summit of the rockery to Wild Thyme (*Thymus Serpyllum*), not forgetting the pure white variety. It is one of the very best of rockery plants if well grown, and to be well grown it must be kept quite off the soil; but when planted with its root close to the upper edge of a slab of limestone, so that the whole growth rests upon the rough stone, it grows and flowers with a luxuriance quite unknown to it in other situations, and hangs over the perpendicular edges with elegant shoots crowded with myriads of leaves. No other Thyme, and there are many, has equal merits. I suppose I shall be expected to say something about that overrated plant the Edelweiss, which is not much better than a common Cudweed dredged with flour; but the associations which it recalls, and the sentimental veneration with which it is regarded by the people in its native country, have tended to make it popular. Its cultivation is easy if planted on the under side of a projecting ledge of limestone, and its roots packed below with broken limestone and pressed against the upper surface. So treated it flowers freely, and ripens seed, by which it may be easily increased. There is a delightful alpine plant, a native of the Himalayan range, named *Cyananthus lobatus*, which thrives well when established. It is said to do better when not exposed to full sun, but I have it on both sides of the rockery and can see no difference between them. It dies off in autumn with flower buds and shoots still immature, and you would despair of seeing it again were you not told that this is its habit, and that you will see it again shooting up with increased strength late in spring. It likes a little nest of fine sandy peat, and must not be transplanted or divided, but young shoots of it strike readily at any time. *Houstonia cærulea* is a favourite with all who can grow it, flowering from spring to autumn; this, too, likes moist peaty spots sheltered amongst the rocks.

The best rockery *Hypericum* is *H. reptans*, which has flowers as large as a florin, and in other respects resembles our native *H. humifusum*, which is also a pretty rock plant. In growth it is like a trailing shrub, and you cannot divide its root, but must take small cuttings and have patience with them. The fine showy *H. olympicum* must be treated in the same way. A tiny upright shrub named *H. egyptiacum* I always house in winter and plant out in spring. Few persons would think of planting the common Scurvy Grass (*Cochlearia*?) on their rockery. It is a plant of so many forms and names that I dare not specify the variety, but it grows abundantly to the summit of the highest sea cliffs at Llandudno, and, besides having bright smooth leaves, produces an abundance of pure white flowers just at the time when spring begins to fight with winter. I cannot omit *Erigeron mæronatum* (also called *Vittadenia triloba*), which bears for six months in the year slender branches full of pink and white flowers neater than those of any lawn Daisy. It is increased readily by slips, of which you must strike plenty, not only for yourself, but for your friends, who are all sure to ask for it.

I can do no more than name *Achillea tomentosa*, the Golden-flowered Yarrow, which flowers from May to September; *Origanum pulchellum* and *O. Dictamnus*, producing branches full of flowers like pink Hops; *Tunica saxifraga*, feathering out with grassy foliage and myriads of light rose-coloured flowers. *Onosma taurica* requires a little more notice, being a plant of great merit, and being very easy to lose. Cuttings taken early strike easily, and you should strike as many as you can, for both young and

old plants are very apt to damp off. I have kept it out through the coldest and wettest winters by packing it well round with broken limestone, old mortar, or anything which can keep the crowns of the shoots from the soil and ward off stagnant wet. I propose next to mention a few annuals or tender shrubs with which the rockery may be filled up till a sufficient number of permanent occupants can be found.—C. WOLLEY DOD.

#### PROPAGATING BUSH FRUITS.

GOOSEBERRIES, Currants, and Raspberries are favourite fruits in all gardens, and in many they are the only fruits grown. Young, healthy, strong-growing trees always fruit more freely than old worn-out bushes, and it is a good plan always to keep up the stocks by propagating. Few amateurs can raise their Apple, Pear, Plum, Peach, and other trees, but all may raise their Gooseberry, Currant bushes and Raspberry plants. They are as easily propagated as any of our softwooded bedding plants, and many may find it profitable to insert a few cuttings every winter. As in most other plants, there are some very good varieties and many very inferior. Only good kinds should be grown for stock, and those not in possession of them should buy them and increase them afterwards.

As pruning will shortly be general, it is then the cuttings must be saved. Only the strongest and best ripened of the Currant and Gooseberry wood should be selected. Clean growths about 12 inches long are the most suitable. Each kind should be tied up in a bundle separately, and the cut ends must be placed in the soil to keep them fresh. Here they may be left until a wet day or any convenient time in the winter or spring, when they may be prepared for insertion. This is done by removing all the eyes or buds from the base upwards for about 9 inches, leaving three or four good buds at the top. The leading bud should also be removed to give the others a better chance of starting. In Gooseberries the spines may be left on the wood, as they help to keep the cuttings firm in the ground. They should be placed in rows 1 foot apart and 4 to 6 inches between the cuttings. About 3 inches of the wood beneath the ground is sufficient, and the soil around them must be made very firm. They must be inserted before growth commences, and by the time the parent bushes are in leaf it will be found that the cuttings are also green and nearly all producing roots. By autumn most of them will have formed several small shoots. If space can be afforded they may be transplanted the following spring, and by the end of the second year pretty little bushes will have been secured, and they may be transferred to permanent positions.

Raspberries are still more easily increased from rooted suckers, which may be secured without disturbing either the permanent roots or the canes which will bear next season's crop. They should be lifted with a spade, and they may at once be placed in their fruiting quarters. One or two canes to every root is sufficient, and where the young canes are growing in clump together they may be divided. Of all modes of growing the Raspberry we prefer to have them in rows, and to form these the young plants may be put in about a foot apart.—J. MUIR, *Margam*.

#### LIQUID MANURE FOR ORCHIDS.

UNDER this heading your correspondent "A. H." (page 423) has referred to a subject of great importance to gardeners, and Orchid-growers especially. It is a subject that has been neglected by many, and I am glad to see "A. H." drawing attention to it. It is very true that Orchids are nourished with the excreta of both birds and mammals. They are also nourished with decayed vegetation. I well remember when receiving an importation of Orchids, in which I had a number of *Cymbidium giganteum*, noticing a quantity of decayed leaves amongst the clumps, and on a little closer inspection I discovered that the old decaying pseudo-bulbs were doing service the second time. It is well known that after the old pseudo-bulbs have produced young growths they gradually lose their leaves and shrivel. In course of time these decay and form material for the roots. I found several of these old decayed portions pierced with living roots. I should not give liquid manure to weak-growing kinds; but, on the other hand, it could and is used with great advantage for many strong-growing species. Not only are terrestrial Orchids benefited by liquid manure, but many of the epiphytes also gain advantage by it. *Dendrobiums* for instance, that have filled their baskets with roots, are greatly benefited by being watered or dipped occasionally in weak liquid manure during the growing season, and I find it a good plan through the summer to syringe weak liquid manure amongst the pots that *Dendrobiums* are growing in. There are many other plants that would gain by

occasional supplies of liquid manure. *Calanthes* for instance, after they have filled their pots with roots may have it every time they are watered. *Pleiones* are encouraged by liquid manure after they are well advanced in growth; so, also, are *Cœlogynes* and *Cypripediums*, and I have given a slight sprinkling of Clay's fertiliser occasionally over the roots of *C. insigne* with good results. At one time *Cymbidium*s, for instance, were grown in sphagnum, peat, and charcoal only, but now most of the leading Orchid-growers pot them in strong loam, and the plants thrive much better in it.—W. K.

#### PRUNING, TRAINING, AND NAILING FRUIT TREES.

MUCH pruning, training, and nailing is often done in the summer time, but it is only temporarily performed then, and now it must be done carefully. Some gardeners prune and nail as soon as the leaves have fallen. Others do the work at intervals throughout the winter, while many leave it until spring; but this we do not approve of, as that season brings its own work, and when tree-pruning and nailing have to be done then the work is likely to be done hurriedly and carelessly. As a rule we have our pruning and nailing completed by the new year, much being done in November. This year we are not quite so early, having been engaged in other work that could not be performed in frosty weather. According to the winters we now have, open weather must be taken advantage of for ground work, and there is generally plenty of time for pruning and nailing. At one time we were led to believe that pruning in severe weather was injurious to the trees, but we have never found it so in practice. If the wood is well ripened it is surprising what frost it will bear, but unless this is the case it may be injured whether it is pruned during that time or not.

Pruning is generally considered a particular operation, to be entrusted only to experienced hands. Trees of little value might be pruned by anyone, but there are others which we trust to no one. There is a right way and a wrong way of doing every thing, and in garden practice this applies more to pruning than to anything else, as all hopes of next year's crop may be quickly destroyed by carelessness, and the symmetry of the tree may be quite destroyed. There must be two objects principally in view in pruning—one to retain or improve the vigour and shape of the tree, the other to secure fruit. Plums, Apples, Pears, and many other fruits bear best on good spurs. These are generally secured by cutting-in the young side shoots to two or three buds from the base. When once spurs begin to be formed on young trees long straight shoots grow from them every summer, and if these are cut-in about the month of August the buds left often become fruit or bloom buds; but when these young shoots are not removed in some of the previous months they must be removed now. As trees become old these spurs frequently assume large proportions, and in the end they have generally to be much thinned. This thinning may be done now; and if care is taken in pruning, many fruit buds may be left near the main stems, although several of the principal spurs be taken away.

Attention must also be kept to the manner in which it is desired to train the tree. Training does not affect pruning much, but pruning affects training, especially with standard trees, as their form all depends on the way they are pruned. Overcrowding the wood must be avoided. If great attention is given to this the trees will always look well.

Neglected trees which have not been properly pruned have generally much wood growing up from the centre, and to cut it out wholesale may end in ruin, but if it is removed by degrees much benefit may be the result. It is only now and throughout the winter that such trees can be taken in hand, and we would advise in all cases that their complete renovation extend over two or three winters. The great inclination of all trees is to grow tall, and this habit requires to be severely checked or proportions will be lost. In some few cases it may be desirable to allow trees to grow quickly, but as a rule I would never allow the leading branches of young strong-growing trees to remain longer than from 9 inches to 1 foot annually. This will be the means of producing robust well-spurred branches.

All trees and small fruit bushes are pruned on similar principles, cutting out shoots which are dead and dying, those with no spurs, and all the young wood not wanted to increase the tree. Strong young branches may be left to take the place of the old ones, but after the first year they should not both be allowed to grow together. It is only in very old trees, however, or young trees, where many young shoots or branches have to be left, as when once a tree is completely furnished with bearing wood it may be kept in good health and in a fruitful state for many years without continually changing the wood. This applies to both standard

and wall trees. Fruit trees in vegetable gardens should never be allowed to become very tall; about as high as a man can reach is a suitable height. When taller than this they injure many of the vegetable crops by the shade they cast. When it is intended to keep the trees as dwarf as stated they should be encouraged outwards, so as to become bushy and round. Shortening-back and thinning-out is the way to lay the foundation for this shape. Trees which are stopped at the same place year after year sometimes form a large cluster of short spurs, and when this becomes so large as only to be a great mass of leaves and no fruit the best way is to cut the greater part of the spurs away, and by disbudding—not stopping—in summer they may be prevented becoming so close again for some years.

When much wood is laid-in in summer care should be taken that the same thing is not done at nailing time in winter, as wall trees are as much benefited by plenty of sun and air about the fruit, leaves, and wood as standards are. Our Morello Cherry trees are the only trees we allow to retain young wood thickly. Plums, Pears, Peaches, and Apricots are treated on a different system, plenty of space being given them. Peach trees are the last to be pruned, as they are sometimes more liable to lose some of their young wood in winter than hardier fruits, and late pruning allows provision to be made for this. Other wall trees are nailed from now onwards as they are pruned. There is no great art in nailing, but there is a little taste wanted to distribute the branches properly. The inexperienced at nailing, as in pruning, are always inclined to fix a number of branches very close to each other and leave much space between others. Keeping the branches in the right direction from base to top, being careful with the fruit buds, not putting in two or more nails where one would do, and keeping the branches all at equal distances from each other, are a few of the main objects to bear in mind.—A KITCHEN GARDENER.

#### NOTES ON POTATOES.

PERHAPS I am dull, therefore cannot see the good results of Potato exhibits at local, general, or international shows. Admitting a good display of good "taters" to be a great attraction, are they any the less mystifying to the uninitiated? To the initiated they are, to say the least, unedifying, as the kinds securing premier awards are known to fail in the most important consideration—viz., use. Exhibition Potatoes must be shapely, but that they are good for food is not apparent. I confess to being unable to comprehend the object of Potato shows, unless it be that Potatoes have attained to such a degree of excellence as to have no practical value. In what, then, consists their value? Happily show Potatoes have not received any mark of appreciation from the general public, whose requirements the grower finds is best met after the earlies are over by staple varieties. Taking Ashleaf in one of its many forms as representing early varieties in kidney, and Early Shaw or Early Oxford in round sorts; Matchless Kidney (Huntingdon), and Fortyfold of second early; Don, Rock, and Regent of late varieties, the new sorts have little value. The Ashleaf, Fortyfold, and Don date back more than fifty years, and though Champion be new it can only be classed as a form of Rock, which with Regent and Skerry Blue have been with us many years, and are still popular. The new sorts make little headway against the old favourites. Why? Certainly, not because "no variety of Potato will retain a robust constitution with good quality more than ten years," as stated by Mr. Pearse at page 426, and I must confess to not being able to see in what we are indebted to the raisers of new varieties. Some are good, but many fail in the most important particulars—viz., productiveness in combination with quality, whilst others are handsome but are indifferent croppers, or so poor in quality as to be only worth growing for exhibition.

Perhaps the half dozen varieties I shall name as being all that are necessary to a full supply of Potatoes of unquestionable excellence, may cause some to conclude that my experience is extremely meagre, in which case it will be instructive to secure for the readers of the Journal the benefit of their experience. My soil is light loam, and if there be any quality in a Potato it becomes apparent. Veitch's Ashleaf, which is not the same as Royal Ashleaf, often substituted for this variety; Yorkshire Hero, a form of Lapstone, with a better constitution; Dalmahoy, Walker's Regent, York Regent or Dunbar Regent, and Skerry Blue (the latter will probably be supplanted by Brinkworth's Challenge). The Regents and Skerry Blue are only suitable for field culture. Those that do not care for even half a dozen sorts will find Veitch's Ashleaf, Walker's Regent, and Dunbar Regent meet every want. I have omitted Champion, which, though a wonderful cropper, is, I consider, too coarse and strong-flavoured, and I never could see what difference there is between Scotch Champion and Champion Rock.

I set out with the intention of making some remarks on the sorts that I have grown, and this I will now endeavour to do briefly. For an early Potato Myatt's Prolific Ashleaf is as good as ever, cropping well, and of good table quality; but there are more small tubers in the crop than in Veitch's Ashleaf, hence the preference for that variety. Early Bird is very fine and prolific, with dwarf haulm, but it becomes diseased with me to such an extent as to preclude its growth. Gloucestershire Kidney and Huntingdon are second early sorts and capital croppers, but are much given to disease, for which reason with Bryanston Kidney, also a wonderful cropper, they have been discarded. Prince Arthur crops well, and, though good by September, keeps well also; but it is very much diseased this season, and generally is when the disease prevails. Its tubers are large and even in size, and the quality excellent. Early Rose, Extra Early Vermont, and Beauty of Hebron appear to be of one type, and though heavy croppers are of poor waxy quality, and not worth growing where quality is expected as well as quantity. Snowflake bears abundantly, the tubers being large and even; yet, though excellent in flavour, they lack flouriness, and from their whiteness when cooked are tempting. It is much subject to disease. St. Patrick, a great cropper, of sturdy growth, and for its size, which is of the first, is good in quality. It is a second early or main crop variety. Wormleighton's Seedling may be described as an improvement in quality on Magnum Bonum, being a magnificent cropper, and will be grown where bulk is the chief object. It and Magnum Bonum were very free from disease. Magnum Bonum is remarkable for everything but quality. Woodstock Kidney is handsome, a good cropper, and of good quality and early, being well worth growing. International, though perhaps the finest exhibition kidney, and an immense cropper, is of very poor quality. McKinlay's Pride, an early handsome kidney, not large, but very even in size, with a dwarf compact top, but the quality is only moderate; these were very little diseased. Late Rose, Fluke, Hundredfold Fluke, and Belgian Fluke are all great croppers and good in quality for late use. Burns' Seedling, which I admire very much, is a flattish round, or somewhat kidney-shaped, the tubers very even in form and of good size, there being a difficulty to obtain whole tubers for seed; growth dwarf and sturdy, quality excellent. This is a second early, a good cropper, not liable to disease, and keeps a long time. Early White Kidney is not so good nor so early as the other forms of early kidneys. Mona's Pride is a capital variety, and not so much grown as it merits. Bountiful, a red kidney, is very pretty, and though it crops well the tubers are too small; the fine nutty flavour is its chief merit, unless its fine form and colour make it unique for exhibition. Lapstone, in my opinion, is the finest quality Potato, and in light soil is first-rate in every respect as a second early, continuing good for a long time. There is no Potato I relish so much as this, and I have little trouble with disease, as the crop is lifted as soon as the disease spots appear in the foliage. The quality is not deteriorated even if the tubers be lifted when far from ripe, as the good properties are developed early.

Among round varieties Rector of Woodstock is very handsome and the quality excellent, but though there are plenty of tubers they are too small, not half the crop being large enough for table. Early Market has short haulm, but the tubers, though of superior flavour, are not large nor abundant. Porter's Excelsior is very handsome and proportionately useless. Red Emperor, very handsome, a moderate cropper, with quite as many small as there are tubers of a useful size, quality fair, its chief merit being in appearance. Victoria is all haulm in a wet season, but in a good season crops heavily and is excellent, but liable to disease. Schoolmaster is very disappointing, for, although it crops heavily, the tubers are much warted or carbuncled, and the crop is spoiled. Grampian crops heavily, the quality is good, but very much diseased. Radstock Beauty is a real beauty, a good cropper, and the quality fair. Vicar of Laleham is of sturdy growth, the tubers have plenty of substance, and are produced freely. Although the tubers are purple the flesh is beautifully white and first-rate for table; it is well worth growing as a second early or main crop variety, and will, I think, be in demand for market purposes. Beauty of Kent, a second early, has dwarf sturdy haulm; the tubers are very handsome, with a rough skin of a rosy pink colour; it appears a good keeper, crops moderately well, and is very free from disease. Bliss's Triumph is a second early, crops moderately well, and is handsome, with a quality fairly good. Bedford Prolific, another second early, cropping well; tubers good shape, and fine smooth skin, cooking capitally. Red-skinned Flourball never were anything but huge waxy lumps with me, but Vermont Beauty baked splendidly, and may be grown for that purpose, but is too large for steaming.—G. ABBEY.

YOUR correspondent "OLD TATER" has been rather unfortu-

nate in his experience of Potatoes. He finds very few of them good. He must be rather particular, or the soil in his district is not very suitable for the crop. To begin with, he says that he never tasted an Early Rose Potato that was eatable. I have several sacks of this kind grown on a piece of garden land near me, which are excellent in quality and entirely free from disease. Then, again, he speaks badly of Snowflake, whilst I have found it one of the best there is, but shall not grow it any more because it is so very subject to disease. Reading Abbey I have grown for two or three seasons, but it will not be grown any more. Magnum Bonum is the popular favourite here, and more of that kind will be grown in gardens next year than of all the rest of the Potatoes together. I had ten sacks, and only saw two or three bad tubers. The quality this year is very good, I would not desire better.

Some seasons it is not very good in the autumn, but improves in quality towards spring, and continues good to the very last. I can quite understand that on some heavy soils it may not always turn out well, and small gardens which are much shaded by trees are not favourable for producing tubers of good quality, but an occasional change of seed will help, with good cultivation, to improve the quality.—AMATEUR, Cirencester.

#### WINTER NELIS PEAR.

FOR upwards of sixty years this valuable dessert Pear has been grown in the gardens of this country, having been introduced from Belgium in 1818. The present popularity of Winter Nelis is sufficient proof of its excellence, and it holds its own as firmly as

Fig. 79.—PEAR WINTER NELIS.

ever among the many varieties that rank as high-class Pears. This Pear is not only of superior quality, but the tree is hardy and bears freely, and there is no garden in which late Pears ripen that should not contain a tree or trees, according to the form in which they are grown and the demand for fruit. From cordons on the Quince stock we have gathered fruit of the first order of merit, and about equally good produce from large trees on the Pear. In favourable localities valuable fruit is produced by pyramids, but in most districts the trees should have the shelter of walls. The fruit with good management may be had in use over a long period. We have from one tree had a daily supply for two months, obtained by placing a few at a time in a high temperature, and the quality during the whole period has given great satisfaction. The following is the description of this fine old variety:—Fruit below medium size, roundish-obovate, narrowing abruptly towards the stalk. Skin dull green at first, changing to yellowish green, covered with numerous russety dots and patches of brown russet, particularly on the side next the sun. Eye open, with

erect rigid segments, set in a shallow depression. Stalk from 1 to 1½ inch long, curved, and set in a narrow cavity. Flesh yellowish, fine-grained, buttery, and melting, with a rich, sugary, and vinous flavour, and a fine aroma.

#### PREPARING BORDERS FOR ROSES—SELECTION OF VARIETIES.

WHERE it is intended to make new beds or borders of Roses the work should be commenced in earnest, having the ground attended to in draining if this be necessary, and in trenching as deeply as the good soil will allow. In shallow soils, instead of bringing the bad soil to the surface it should be well loosened with a pick, and some partially decayed manure mixed with the upper and better soil. Light soils will be much improved by an application of clay in small pieces, and those long broken up are greatly benefited by working in some fresh turfy loam. It is hardly possible to have the soil too rich and deep for Roses, the resulting

flowers being proportionate to the provision in the soil for the growth of the plants. Light and shallow soils should have material added that will increase their power of retention; cow dung may be mentioned as cool and moisture-holding, and such soils will suit Roses on their own roots where those on the Briar can hardly exist.

Varieties that succeed on their own roots and make effective growth are the following. Hybrid Perpetuals, red or crimson—Charles Lefebvre, Mme. Moreau, Duc de Rohan, Annie Wood, Comtesse d'Oxford, Duke of Edinburgh, Dupuy Jamain, Général Jacqueminot, François Michelin, Etienne Levet, Maréchal Vaillant, Pierre Notting, Prince Camille de Rohan, and Sénateur Vaisse. Shades of rose—Captain Christy, Antoine Mouton, La Souveraine, Madame George Schwartz, John Hopper, Hippolyte Jamain, La France, Emile Hausburg, Pauline Talabot, Thomas Mills, Reine du Midi, Marquise de Castellane, Marquise de Chambon, Mr. Veitch, and May Turner. Pink—Lyonnaise, Duchess of Edinburgh, Comtesse de Jaucourt, Abel Grand, Baroness Rothschild, and Princess Beatrice. White or blush—Madame Roland, Madame Lacharme, Baronne de Maynard, Bessie Johnson, Coquette des Blanchés, and Olga Marix. China Roses make fine beds, and should be on their own roots; the common or Monthly, blush, is fine for effect. Mrs. Bosanquet, flesh; Fabvier, carmine; Cramoisie Supérieure, crimson purple; and Louis Philippe, reddish crimson. Baronne Gonella (Bourbon) also does well on its own roots; also Gloire de Dijon and Cheshunt Hybrid. With a good mulching over the roots Roses on their own roots are safe no matter how severe the winter, and equally so are those on the Manetti, as when cut down to the mulching they start freely in spring from the base; indeed, our losses in standards have been so great that we shall have no more of them, and in good soil advise our friends to have dwarfs on the seedling Briar or Manetti, and plant so that the junction of bud and stock is 3 inches beneath the surface.

For general purposes it is preferable to grow the free-blooming varieties in quantity, of which the following may be mentioned. Hybrid Perpetuals—Alfred Colomb, Annie Laxton, Baroness Rothschild, Boule de Neige, Charles Baltet, Charles Darwin, Charles Lefebvre, Comte Raimbaud, Dean of Windsor, Duke of Connaught, Dupuy Jamain, François Courtin, François Michelin, Général Jacqueminot, Harrison Weir, Jean Soupert, John Hopper, La France, Madame Devert, Madame Victor Verdier, Magna Charta, Marie Louise Pernet, Maréchal Vaillant, Marquis of Salisbury, Marquise de Castellane, Marquise de Ligneris, Miss Poole, Mrs. Veitch, Pauline Talabot, Prince Arthur, Princess Mary of Cambridge, Richard Laxton, Sénateur Vaisse, Sir Garnet Wolseley, and Thomas Mills. Although most of the above are fragrant, the following are highly so—Bessie Johnson, François Courtin, Harrison Weir, Madame Thevenot, Marchioness of Exeter, Miss Hassard, Miss Poole, William Jesse, Duchess of Edinburgh, Rev. J. B. M. Camm, Madame Oswald de Kerchove, and Mrs. Jowitt. The Moss Roses are indispensable, especially in bud. Mrs. W. Paul and Perpetual White are good in the Perpetual class. Some of the summer Roses, though now at a discount, are really beautiful, and especially valuable in cold localities. Of Provence none are more fragrant than the common or Cabbage. De Meaux valuable for its earliness. Crested Moss very beautiful, and Unique or White. Of Moss Roses Lanei, Angélique Quétier, and Marie de Blois are exquisite in bud; common Celina and White Bath are also beautiful.—G. A. G.

#### RESPONSIBILITY OF GARDENERS.

"SINGLE-HANDED'S" apologetic reply on page 471 is not quite satisfactory. He is unable to state, apparently, that he has had the opportunities of judging of the matter in dispute that I spoke of. If he had he would never have insinuated that many-handed men won prizes because they produced the largest plants. It is not so; and, besides, the schedules are usually so arranged that all exhibitors have equal chances of obtaining prizes. As for small places not having houses big enough to grow specimens in, the excuse will not do, for such places are not so much distinguished by the size of the houses as by their fewer number only. In one of the most noted places for specimens in England, a few years ago, the houses were so small that the stages were taken out and the plants grown on the floor to give them head-room, and very well they looked so arranged. May I also point out that the Eskbank people do not reckon the Edinburgh Show a local one? And if "SINGLE-HANDED" calls "owre the Border" local, he must attach a much wider meaning to the word than other people, seeing it is nearly one hundred miles off. The only local show is the one referred to by me, and his friend at Eskbank does exhibit there, and seldom, or never, anywhere else, and he is

not more successful than his neighbours. This is said without reflecting on his admitted abilities. It is not I, but "SINGLE-HANDED," who has introduced names and places with the object of praising one and disparaging the other, the last just as plainly indicated as if they had been named, and without either reason or provocation on the writer's part; and I simply want to show that your correspondent's statements and conclusions are not correct.—ANOTHER MANY-HANDED MAN.

#### SCRAPS ABOUT FRUIT.

PITMASTON DUCHESS PEAR.—Again has this Pear failed to develop any of that richness of flavour which it is said to possess, and I have reluctantly come to the conclusion that it will never do so at Oldlands. Why? There are seven cordons of it planted in a deep rich border of our light soil, specially prepared for the culture of Pears and Roses. They are remarkably vigorous, have reached the top of the wall before many others, and the fruit was large and handsome—quite as large as the size mentioned in the "Fruit Manual" by Dr. Hogg. I may add that due care was taken to gather it at the proper time, and it was carefully watched and tested during the process of ripening in the fruit-room. Is it a question of soil? If so, I should be glad to learn the nature of the soil in which it is found to succeed. Or perhaps the stock upon which it is grafted has some influence on the quality of its fruit; all the cordons of it here are upon the Quince. I have not tried the effect of ripening it in a warm room, which is undoubtedly beneficial to some Pears, notably to the fruit of Besi Vaet.—EDWARD LUCKHURST.

THE BEST TWELVE PEARS.—Jargonelle, Williams' Bon Chrétien, Marie Louise, Fondante d'Automne, Comte de Lamy, Seckle, Doyenné du Comice, Winter Nelis, Jewess, Knight's Monarch, Glou Morceau, Madame Millet. These are chosen partly from an extensive collection growing here, and also from observations in many parts of the country, as probably the best, or, at any rate, an excellent dozen to recommend for general culture. To make such a selection is by no means an easy task, so many sorts of the highest excellence having to be left out. One has in selection to remember the known effects of soil, stocks, and climate; growing experience and more intimate knowledge of the peculiarities of different sorts serving to render us more cautious in pronouncing this to be good, that to be bad. Twenty years ago I was much more confident as to the merits of such Pears as were known to me than I am now; but, then, rash youth has its day with all of us.—SUSSEX.

RIVERS' EARLY PROLIFIC PLUM.—In Mr. George Bunyard's work on "Fruit-Farming for Profit," it is stated of this Plum that "it is a very weakly grower, and never makes a big tree." Now, the result of my nine years' culture of it is certainly totally at variance with this statement, for several pyramids planted side by side with numerous other kinds of Plum have all grown with a vigour so uniform and uncommon as to render them as conspicuous for size as they are also for symmetry. They are kept closely pruned, and so the height was restricted to feet; but to judge from the vigorous shoots which they subsequently made they would have been twice that height by this time had they been left unpruned. It is a singular fact that the soil in which these trees have grown so well and borne heavy crops of fruit is poor and thin, but well drained, for which reason I have for some years regarded this Plum as one of the most profitable to plant for market purposes in any soil. The fertility of the soil in the neighbourhood of Maidstone is notorious, and I am anxious to learn something of the experience of other fruit-growers in that district about a matter that is of undoubted general importance.—A KENTISH GROWER.

PEARS NOT KEEPING.—Pears are keeping very badly with us this year. Marie Louise became spotted and soon were decayed, and many others have gone in the same manner, and Beurré Bachelier with others that are not ripe until December are now (November 18th) quite ripe, indeed over-ripe. Hacon's Incomparable has borne a full crop this year, doing admirably on the Pear stock near a west wall, and is one of the very best in its season—viz., November and December. General Todtleben has been better than usual, the fruit being of better form and less gritty than I have found it hitherto, and not liable to decay at the core. Beurré Diel is also first-rate, not at all gritty, but melting and good. Bergamotte Esperen is already ripening, so that the Pear season appears likely to be much shorter than usual as regards the keeping sorts, which is the more to be regretted as the crop was light.—G. A.

**APPLES FOR DWARF CULTURE.**—It is essential that trees for this purpose be free and early bearers. Some that I have found to answer this description are Stirling Castle, Keswick Codlin, Jolly Beggar, Betty Geeson, Cellini, Ecklinville Seedling, Small's Admirable, Norfolk Bearer, Nonesuch, Large Hunthouse, Winter Hawthornden, and Winter Majetin: those are kitchen. For dessert—White Juneating, Irish Peach, Devonshire Quarrenden, Kerry Pippin, King of the Pippins, Cobham, Cox's Orange Pippin, Court of Wick, Margil, Braddick's Nonpareil, Dutch Mignonne, and Sturmer Pippin. The soil here is light loam, the situation elevated 540 feet above sea level, in North Yorkshire.—YORKSHIRE CULTIVATOR.

#### AREAS OF GLASS STRUCTURES.

IN your notes (page 473) of Mr. Fawkes' first lecture at the Crystal Palace it is said that "with the same width and the same pitch, a span and a lean-to roof contain the same area." Though this is correct it will convey a wrong impression to many, who will suppose that by the words "contain the same area" cubical contents are meant. There is the same superficial area of roof in A C as in A B D, and the same ground space is covered, but the contents of the span are only half that of the lean-to. I find that many gentlemen and gardeners have a great difficulty in understanding this, as they mostly say that a 16-foot sash lean-to covering 13 feet wide, being the same width as an 8-foot sash span roof, must have the same contents, or "area" as they frequently call it. The matter may seem trifling, but it is a common error and may be worth explanation.—B. W. WARHURST.

#### WHAT PLANTS USE.

(Continued from page 474.)

**SULPHURIC ACID.**—One of the peculiarities of cow urine is the quantity of sulphuric acid it contains. Like potash, this is present in much larger proportion in the liquid than in the solid excrements of animals. It is met with in sulphate of ammonia, which is a very stimulating manure, and owes its rapid action chiefly to its ammonia, but there can be no doubt that the sulphur it contains is also of benefit to many crops. It is also met with in sulphate of lime or gypsum, and is much used on the Continent for cereals and in America for Potatoes. Its use in this country is nothing to speak of; why, we know not, for if accounts are to be believed, the Germans and the Americans find it of great service. In some accounts before us we read of the addition of ten bushels per acre of "plaster" doubling the crop. Unless this be "tall" talk, we must suppose that the undressed soil must have been singularly deficient in sulphur, or lime, or both—a by no means uncommon occurrence in many of the now impoverished lands in the United States.

In dissolved bones, or superphosphate of lime, it is also largely present, and possibly the use of these has helped to limit the use of "plaster," gypsum, or sulphate of lime, by which names the substance is known.

**LIME.**—This is such a well-known substance, and its use so generally understood, that little need be said in this place about it. It may be well, however, to recapitulate briefly the effects of lime on soil. (1) Applied to heavy clay land lime tends to lighten it, make it more easily worked, drier, and therefore warmer and the crops earlier, adds plant-food to the soil, and by its chemical action prepares many other unavailable plant-foods present in the soil, and so conduces to an earlier, more vigorous growth. (2) Applied to old garden land rich in organic remains, it hastens their decay, and so liberates the mineral salts they contain, thus preparing them for being utilised by the growing plants. In practice it is often found that an application of lime to land long manured will produce greater crops for one or two seasons than will an application of ordinary manure. (3) Applied to sour land it does much to cure the sourness by combining with the acids and forming salts which are either available as plant-food, or, such as are soluble, easily washed from the soil by the rains which pass through into the

drains. Cultivators will require to imitate this cleansing action of rain in the case of fruit-tree borders under glass by drenchings of water which will pass through the soil and into the drains, carrying the hurtful matter along with it. Readers of the Journal will recall instances of Vines and other indoor fruits being permanently improved by an application of lime. In the case of borders where there is reason to believe that sourness exists, an application of lime is a cheap and easily applied remedy. (4) Applied to lawns (and grass land generally), it does much to destroy moss, which, by reason of the "survival of the fittest," may be spoiling the grasses, and it does much to nourish many of the smaller-growing kinds which cannot thrive on land where lime is absent, or nearly so—a state of matters everywhere existing where for long years lawns have been continually robbed by having the known grass, with all the mineral matter contained in it, continually removed, and robbed by having its lime and other matters continually washed beyond the reach of the roots by the rains. Lime applied at intervals maintains the turf in good condition. In our case, we find phosphoric acid, potash, and nitrogen in some form necessary in addition. These we supply in the form of bone-meal and lime sprinkled on in spring, and a dressing of urine in wet weather during winter. This application we have found to have an almost marvellous effect on worn-out lawns.

Where slugs abound lime may be made to kill "twa dogs wi' ac bane." When newly slaked and sprinkled over ground where these abound it will destroy them, and afterwards prove beneficial to the soil. In applying lime to inside borders it is best to use newly slaked lime mixed with water to the consistency of milk. When newly slaked it is soluble in water, and, applied as we have recommended to the surface of borders loosened to secure its admission, there is no trouble causing it to reach every part of the border. Sprinkled on the border it quickly assumes the insoluble form, and is less readily diffused through the soil. It, however, even in that state never fails to descend and prove beneficial, although the effects are less rapid. When newly burned wood ashes are to be had in quantities, and regularly applied to the soil, liming is not necessary, because wood ashes contain a plentiful supply, not of lime only, but of all the other mineral elements of plant food.

**SODA.**—This is present in all natural manures. It is available in the form of common salt and nitrate of soda, or in the form of soda crystals. Possibly the most economical method of applying it to soda-loving plants or ground deficient in soda is in the form of salt to land rich in decaying organic matter, and in the form of nitrate of soda to new land which has little organic remains. Water from laundries contains much soda, and water containing soda is a valuable manure. Applied to Spinach and Strawberries, both "soda plants," it produces an astonishing result on exhausted land.

Here we have a quantity of Grove End Scarlet Strawberries, which bear wonderfully on a piece of very thin very poor ground, and manured with soapsuds only. For three years we have given a portion of the plot cow urine for manure, a portion we have given soapsuds to, and to a third we have given nothing. We find that the part dressed with urine produces a ranker growth of leaves than either the undressed portion or the portion dressed with the suds; and that the last, while producing a more robust growth than the undressed portion, and less than that dressed with urine, produce double the amount of fruit foot for foot than either. The urine, we find, scarcely increases the yield of fruit; its strength is expended on leaves. This we attribute to the nitrogen. Common salt in our district applied to Strawberries always tells favourably on the crop, but more especially on well-manured land; but even on poor ground its effects are great. On poor land we find nitrate of soda preferable, but not on rich; in that case the leaves grow too much.

We ought to say that our situation is inland. In districts influenced by the nearness of the sea soda in any form is a useless addition, for it is deposited by the rain, and it is, therefore, unnecessary to apply it artificially. On light inland soils it seldom fails to produce favourable effects.

Common salt is used by all plants, and is always present in common manure; but, being very soluble, it is being continually washed from the soil, and its addition, either by the rain or otherwise, becomes necessary to the best results. In America it has been found that salt and soot alone produced better crops of Potatoes than any other manure. As Potatoes require very little salt, we can only suppose that where salt produces effects like that referred to it must have been singularly deficient in the soil and manure alike, and that all the other matters necessary were present in moderate abundance. Like lime, salt is easily carried away, and, like lime, it is comparatively inexpensive, and always repays with high interest its application to land in inland situations.

**SILICA.**—Silica is always present in greater quantity in ordinary manure than garden plants require, and most soils contain an unlimited amount of it. We need not, therefore, say anything under this head.

**IRON.**—This, needed in such small quantities, is always present in stable manure, and is being continually added to soil worked by iron tools by their wearing that it is never found necessary to add iron to soil. Indeed the trouble is too often to dispose of it, for in many soils it is present to an injurious extent.

**MAGNESIA.**—The only form in which magnesia is to be had in the markets is as Epsom salt. Epsom salt is composed of sulphuric acid and magnesia. This compound has been applied with advantage to farm crops, but I do not know of any experiments with it on garden crops. Where magnesia is deficient its application would doubtless do good. In an impure form this salt is to be had very cheaply.

As we said before, there are other mineral matters which enter into the composition of plants, but those we have named are those which are generally considered of importance and to be had in the market. All the matters required by plants are to be found in ordinary manure and in all fertile soils. In a concluding paper we shall say something on soils and some of their peculiarities.  
—SINGLE-HANDED.

(To be continued.)

IN reference to our remarks upon RHODODENDRON PRINCESS ALEXANDRA on page 476, Mr. Taylor informs us that the parents were R. Princess Royal and R. jasminiflorum, not R. Brookei as we stated.

— RELATIVE TO BUSH FRUIT TREES FOR YORKSHIRE GARDENS, a Yorkshire clergyman, who has had considerable experience in fruit-growing, informs us that he will readily aid a "YORKSHIRE RECTOR," who recently sought information on this subject, if he will communicate with him through this office.

— IN a note referring to VAPOURISERS, Mr. Warhurst asks "If Bentley's water-spray would answer the purpose described by 'A LOVER OF HORTICULTURE' (page 449) for vapourising?" Another correspondent, "J. R." directs attention to Keel's blight-destroyer, which is applied through a vapouriser, and asks if any of our readers have proved its merits.

— A NORTHERNER finds "SALVIA SPLENDENS very useful at this season of the year. Many gardeners plant it out, but the best way is to strike cuttings early and grow them on in pots, keeping them well stopped. It is not of much use for cutting, as it does not last long in that state; but it is for conservatory decoration that I find it so useful, the colour is so telling."

— "ANOTHER plant worth growing at this season of the year is SCHIZOSTYLIS COCCINEA. It is more often seen planted out during the summer, but I find it thrives best when potted, which should be done in April, placing the strongest plants together so as to have them all in bloom at once to make a show. Stand the pots in a shady place for the summer, keeping them well supplied with water."

— A PAPER advocating the use of river water for domestic purposes, and explaining a very simple and "self-acting" method of rendering it absolutely pure, was published a year ago by Mr. Shirley Hibberd under the title, "WATER FOR NOTHING." A considerable impression having been exhausted, Mr. Hibberd withdrew the pamphlet, and it was reported "out of print." The demand for it continuing, he has now yielded to the persuasions of his publisher, and a re-issue of the paper may be obtained from Mr. Effingham Wilson, 11, Royal Exchange.

— A CORRESPONDENT writes that in the Cambridge Botanic

Garden several annuals were conspicuously valuable in pots for greenhouse decoration during the autumn. They were CALLIOPSIS DRUMMONDI, SCABIOSA ATRO-PURPUREA, LOASA VULCANICA, and CUPHEA ZIMAPANI. The two last are still in flower, and the Cuphea being of fine purple colour is much admired. The Calliopsis has taken particular attention, perhaps from some novelty in its use as a pot plant, because out of doors it has not been the subject of remark. It is at least a bright flower, always useful for cutting wherever grown.

— MR. J. C. BARNHAM of Norwich writes [as follows respecting DAPHNE INDICA—"I have often seen it stated that Daphne indica requires to be grafted on stocks of D. Mezereum; but so far from this being absolutely necessary, I find that cuttings strike very readily, and the young plants so obtained flower the same year. Possibly this hint may be of service to some of your readers who grow this fragrant and useful plant."

— PARTS 13, 14, and 15 of Messrs. Cassell's re-issue of "PAXTON'S FLOWER GARDEN" contain several handsome coloured plates, with descriptive and cultural notes, and a continuation of the gleanings and original memoranda. The coloured figures represent Odontoglossum Cervantesii, Oncidium hæmatochilum, Bejaria coarctata, Hoya ovalifolia and H. pallida, Phalænopsis intermedia var. Portei, and Chionodoxa Luciliae. The last-named is especially well executed as regards the form and colour of the flowers and the general habit of the plant, but the leaves have a rather unhealthy yellowish appearance.

— MR. G. ABBEY writes—"The Rose has been so much improved in recent years that we hardly dare venture to write complimentary of an old favourite; but some notice is deserved by the still popular common CHINA or MONTHLY ROSE (Rosa indica odoratissima), for it has a profusion of blooms in succession from June to November. The blush-tinted or delicate pink buds are very beautiful, making a grand display with its many companions. Indeed this Rose makes a charming bed worthy of the most favoured position: in fact it is good in summer when Roses are plentiful, and is supreme in autumn when others are uncertain, more blooms being produced on a plant in November than is present on dozens of Hybrid Perpetuals. It is hardy; but if the weather is so severe as to kill the head, shoots are produced from the base."

— THE ROYAL HORTICULTURAL SOCIETY OF IRELAND held their Winter Exhibition of Chrysanthemums and fruit on Thursday last in the new Concert Hall, Exhibition Palace. Chrysanthemums were well shown in the chief classes, the principal prizewinners being Francis Low, Esq., Avonmore, Stillorgan; Richard Pim, Esq., Stradbroke Hall, Blackrock; Alexander Comyns, Esq., Ardcaune, Glenageary; and the Rev. F. Tymons, who contributed particularly fine blooms. Fruit was chiefly shown by C. S. King, Esq.; Captain Shuldham, Gortmore; Viscount Powerscourt; Charles Cobbe, Esq.; and Lord Annaly, Woodlands, Clonsilla.

— A CORRESPONDENT writes as follows relative to THE SEASON IN DURHAM—"The weather has been far finer lately than it was in what ought to have been the harvest months. In August and September we scarcely ever had twelve hours of fair weather; in October we had a continuous succession of disastrous gales and cold weather. Since November came, however, with its "brief summer of St. Martin's," we have had fine bright bracing weather, with the thermometer often as high as 66° during the day, and, as if to make this November more remarkable, we have not had a single fog. The benefit to all people engaged in the cultivation of the land is incalculable. Fruit prospects are being benefited very materially by the bright sunshine; while farmers are enabled to bring up arrears of work and get large breadths

of corn sown on land in good condition, which was not the case a month ago. Early spring flowers are coming into bloom in all directions, while many wild flowers seem to be deceived by the fineness of the weather."

— THE annual display of CHRYSANTHEMUMS AT GARBRAND HALL, EWELL, the residence of Mrs. Torr, is this year quite as attractive as usual in general effect, although, like many other growers, Mr. Child has experienced a difficulty this season in obtaining blooms of first-rate size and substance. After inspecting the necessarily formal arrangements of Chrysanthemums at the numerous exhibitions, a tasteful and unique mode of displaying the beauties of those useful plants, such as that under notice, is especially welcome. The method adopted by Mr. Child has been frequently described, but as some readers may be unacquainted with it a brief reference may be useful. A span-roofed Peach house 100 feet long has a path down the centre, and on each side of this is a trellis about 6 feet high, with arches at intervals of a yard or two. Over the trellises and arches the plants are trained, and as the majority are flowering very freely the effect is very beautiful. Some fine clusters of snowy white Mrs. G. Rundle are particularly noticeable, numerous other varieties being represented.

— "AN INHABITANT OF FARLEIGH" writes—"A few days ago we lost a horticulturist to whom we are indebted for one of the most popular fruits sent to market in its season. Mr. JOHN CRITTENDEN of East Farleigh died at the great age of ninety-four, who, as the introducer of the Farleigh Prolific Damson, conferred a great boon on the community at large. The deceased was a man much respected by all who knew him, and his name has long been associated with the Damson in question, of which thousands of bushels are yearly sent to market, and its popularity is still increasing, thousands of trees being sold each year; but some particulars regarding it having appeared in this Journal a few years ago need not be repeated here. Suffice it to say that Crittenden's Damson is one of the standard fruits of the day and neighbourhood, and those having trees of older varieties are having them cut down and grafted with that kind, and even many Plums are so treated. So that Mr. Crittenden lived to see his protégé firmly established in public estimation and widely spread. A near neighbour of the writer put in upwards of ten thousand young plants of it last winter, and many others have quite as many, so that its popularity is not expected to diminish. The records of some of the stories of its prolificness would almost appear to border on the marvellous, yet it is only a matter of plain fact; and in the parish where it originated it is both the rich man's tree and the poor man's also, and the traveller can hardly move 20 yards without seeing one."

— A PRESENTATION of £1000 together with a gold watch to Mr. BRUCE FINDLAY, and another for Mrs. BRUCE FINDLAY, was made on the 24th ult. in the Town Hall, Manchester. The Mayor (Mr. Alderman Baker) presided. The Mayor, in his introductory address, spoke of the progress which had been made in connection with the Botanical Society since Mr. Findlay's appointment as Curator in 1858, and congratulated the members upon the altered and improved condition of things at the present time, as compared with the old régime, at which time he (the Mayor) became a member of the Council of the Society. The state of the gardens and the subscription list had undergone a considerable change for the better, which was owing in a very large measure to the labours of Mr. Findlay, aided by the members of the Council, and more than all, perhaps, by Mr. Joseph Broome. Mr. Broome cordially thanked the Mayor. Mr. Findlay had been before the people of Manchester for three and twenty years, and a more assiduous man in any position he (Mr. Broome) had never known. Subscriptions to the testimonial were sent in so bounteously that the Committee began to find the list was

assuming greater proportions than they had ever anticipated. The result was that 270 subscriptions were received, amounting altogether to £1106 19s. 6d. Mr. Broome then read and presented the address, which had been engrossed and illuminated on vellum and encased in morocco, and likewise handed over to Mr. Findlay a purse containing a cheque for £1000, and the two gold watches and chains. The following is the text of the address—

To Mr. Bruce Findlay, Curator and Secretary of the Royal Manchester Botanical and Horticultural Society.

DEAR SIR—Your career as Curator of the Manchester Botanical Society commenced in the year 1858, twenty-three years ago.

The zeal and energy which you have exhibited for the prosperity of the Society, as well as for the general extension of the science of botany, floriculture, and horticulture, have been watched with interest by your numerous friends.

Your suggestions to the Council of the Botanical Society have been characterised by rare judgment. The annual Whitsuntide exhibitions converted a small local exhibition into one of an extensive national character, with the result of giving pleasure and instruction to forty or fifty thousand visitors, and also causing a considerable improvement in the financial position of the Society. The autumn international display held by the Society in 1873 was only second to the grand international Exhibition which took place in August of this year in celebration of its jubilee. This latter Exhibition your friends recognise as your crowning achievement.

In the position of Curator and Secretary of the Manchester Botanical Society you have at all times laboured devotedly, and your friends feel that the present year is an appropriate time to mark the esteem in which you are held by them, not only by reason of those works to which allusion has been made, but for the invincible resolution, quiet perseverance, and business-like qualities you have displayed during your long and arduous career. Your health suffered somewhat from the labour and anxiety for the success of the recent great Exhibition. We hope, however, that the beneficial influence of this Show, and the appreciation we now acknowledge with pleasure of your work, will be some solace to your mind, and will aid you in your restoration to health.

As a token of the esteem of a large circle of friends, we desire your acceptance of a purse containing £1000, and the accompanying gold watch and chain, which we hope may continue to record for you the flight of time during many years of health, happiness, and prosperity. We also desire you to present our best wishes to your wife, together with the gold watch and chain provided for her.—We are, yours faithfully,

(Signed)

THOMAS BAKER, Mayor of Manchester.  
JOS. BROOME, Chairman.  
SAMUEL BARLOW, Treasurer.  
ROBERT TAITT, Hon. Secretary.

Town Hall, Manchester, November 23rd, 1881.

Mr. Bruce Findlay cordially thanked the many most generous friends who sent him so munificent a testimony of their respect and esteem, but stated, however, his future action must show such thanks as he could not speak. The substantial and beautiful gifts were valued by him and his wife, but they prized still more highly the friendship and confidence with which the gifts are stamped.

#### THEORIES IN GRAPE CULTURE.

THE question raised by your able correspondent Mr. Iggulden under the above heading has more than a passing interest for me, inasmuch as some eight or ten years ago a short note of mine, kindly inserted in your pages, failed to bring forward any correspondence on either side. In that note I tried to point out what I considered the folly of encouraging Vines to grow as advocated by Mr. Bardney and then cutting it all away in the autumn. The storing of sap goes on most at the tips of the young rods, as anyone can tell by the thickening of the wood and the prominence of the eyes, and therefore when cut away the Vine is robbed of nearly the whole season's work. I generally leave theories for abler hands to discuss; but when we read such advice as that given by Mr. Bardney and "SINGLE-HANDED," I think practical experience should have something to say as well as science. Mr. Bardney grows his Vines on economic principles; he makes them self-supporting by burning the prunings and manuring the border with the ashes. The little handful of ashes his pruning will produce may be very good so far as it goes, but it is but a "drop in the bucket" of what they require, and will in no wise compensate for the stored-up sap he has consigned to the flames. "SINGLE-HANDED" contends that the sap is stored in the "underground stems" (roots is too common a term for some folks), but if half the roots die in consequence of cutting off the

top, or from being in a cold wet border, what good does it do the Vine?

My practice for the past dozen years has been to restrict the young rods of Vines to an annual growth of about 8 feet, cutting away only about 2 feet at pruning time. The laterals are allowed to meet, but not to become crowded, and are shortened to two or three joints as soon as growth ceases, so that the storing process may be concentrated in the rod itself as much as possible. Under such treatment it is reasonable to suppose that the Vines will make less gross roots, which will be most likely to winter well, and there is the least possible amount of stored-up sap removed by the knife. All things considered, I think this is quite as economical as Mr. Bardney's plan. If, when I burn the prunings, I have a little less ashes to return to the border, he must admit that I have taken a good deal less out of it. A restricted growth and moderate pruning is more in harmony with Nature than this natural growth and hard pruning.—R. INGLIS.

No doubt Mr. Iggulden has endeavoured to fortify his position by strong arguments, and that good Grapes have been produced under the system he advocates I do not deny. Nor do I wish to assume that all are radically wrong in their ideas of growing Vines that do not follow the dictates of those who grow them on less restricted principles. I am always open to conviction, and no one is more willing to reject any system entertained—from whatever source it may be advanced—for one likely to prove of greater advantage and produce more satisfactory results. In the present discussion I fail to see the disadvantages resulting from a good quantity of roots. It is unnecessary for me to say that a Vine makes roots in proportion to its leaves, and that the canes are in proportion to the extent and vigour of their roots, and, therefore, better able to produce and bring to perfection a satisfactory crop than a Vine is capable of doing when restricted.

I could mention names of growers who practise a restricted system and have largely advocated and recommended it from time to time, whose young Vines when they bore one or two fair crops of fruit were exhausted and declined in vigour yearly and had to be removed. Other instances I can point to where Vines in the hands of good Grape-growers and exhibitors have been very unsatisfactory after a few years, the Vines not proving their lasting properties when subject to restriction; and the same has been said of them—as expressed by Mr. Iggulden in relation to those grown on unrestricted principles, "they have had their day."

The principles of unrestricted are largely practised by many in this neighbourhood, and in the majority of instances the Grapes are superior to those grown under restriction. I should like Mr. Iggulden to see a house of Muscats, when the fruit is hanging, not many minutes' walk from here. The Vines are about fourteen years old, and have been grown on the system your correspondent condemns. This house is described thus, on page 159 of the Journal for September 4th, 1879:—"The crop is a grand one. The bunches commence close to the ground; indeed some of the finest of them nearly touch it, and they hang with great regularity all over the house, but as a rule those on the south roof are the finer. They are nearly all of handsome tapering shape, and range from 3 lbs. to 4 lbs. in weight." "A fact worthy of notice is the free growth of foliage that is permitted and its disposition. The roof is not unduly crowded with foliage." "But this is the case until the Grapes commence colouring, when the growths are drawn out, and often can be seen hanging from the roof, and then gradually removed except the top and bottom. But growth is encouraged from the base and termination of the rods, this growth trailing on the inside border, which is covered as thickly as an Ivy bank with foliage. The first thought that arises is, Does not this extraordinary growth deprive the bearing laterals and bunches of some support? The crop gives a very emphatic answer in the negative. From the base of one or two Vines growths of great vigour were rambling for 20 or 30 feet on the surface of the border, and yet the wood and fruit of those Vines were as fine if not finer than those of other Vines which had not produced such luxuriant basal growth. This growth is encouraged for the purpose of stimulating active root-action, from which the crop benefits. On lifting up the mass of foliage resting on the border the manure-surfacing is seen to be completely permeated with white roots, which go far to explain the fine condition of the Vines and crop. This almost wild extension of laterals, in positions where they do not crowd the Vines, I observed at other places 'about Liverpool,' where Grape culture is well carried out, and the fact is worthy of mention and of the attention of cultivators in other districts where a different and closer system of stopping the laterals prevails." The two crops on these Vines, since the above notes were written, have been even superior, and worth a long

journey to see. I can mention other Vines grown where unrestricted principles have been resorted to, not only being more lasting, but they have borne heavier crops of fruit than any restricted Vines I have seen. Vines thus grown are not so liable—when free growth is continued both at the base and top—after a few years to become exhausted or produce smaller bunches as those restricted, stopped, pinched, and confined to a single stem.

Last year I saw a fine house of young Vines grown on Mr. Iggulden's principle, the supernumeraries being left 8 or 10 feet long, and it would have been impossible for them to have looked more promising to produce a good crop of Grapes. What was the result? The bunches were small, not averaging half a pound in weight each, and they much disappointed me. Mr. Iggulden seems anxious to know what fruit I took from my Vines the second season, and in return perhaps he will say what he can take from permanent restricted Vines. I took the second year 6 lbs. of Grapes, and the third 12 to 13 lbs. from each Vine, some of the bunches of Black Hamburgs weighing  $3\frac{1}{2}$  lbs. each. They finished well, and have made good strong wood—as strong as could be wished without being pithy—and showed no debilitating effect upon them; in fact, I believe they would have carried half as many more without injury in the least. I have stated under the mark, as I did in the case of the pot Vines, some of their bunches weighing over 2 lbs. Having no wish to exaggerate I would always prefer to be under than over the mark, and as I only weighed the whole produce of one pot Vine, which was certainly the best, and was carrying 10 lbs. of Grapes all but a few ounces.

During the first season when planting from eyes it is an impossibility to encourage much growth of laterals at the bottom if wished. The eyes only can be plumped and the bottom thickened by stopping them as before described. My remarks apply to permanent Vines. I will challenge either Mr. Iggulden or any other grower to prove that a Vine unrestricted at the top thickens more than one that is restricted, at the "expense of the base;" but, on the contrary, when restricted, and the sap is confined, then the top swells to a greater size and produces more prominent eyes near the extremities, and thus leaves the lower portion of the rod considerably thinner. This is readily observable in ninety-nine pot Vines out of every hundred, and it would be even as marked in Mr. Iggulden's supernumeraries if only stopped and confined to 8 feet. If Vines in pots are stopped when about 9 inches or 1 foot in length, and again when 3 feet, the cane is then more of a similar size throughout. If the Vines have been stopped as described it is a matter of but little moment how long they are pruned the second season; they do equally as well if left 4 or 5 feet as if pruned back near the base—in fact, I am no advocate, if the Vines have made good growth the first season, to cut them down within 1 or 2 feet of the border. No advantage is gained. If left longer plenty of shoots will start, which, if allowed liberty to extend at the base, the stem will continue to swell, and at the end of the season will be considerably thicker at the bottom than the top.

The second season's treatment of my Vines after pruning is this: If they break well, which they have always done, the laterals are stopped about two leaves beyond the bunch; or, if I want no fruit, about the same distance. The uppermost laterals, if they are taking the lead of the basal ones, are kept closely pinched, and perhaps the leader, if extending too fast, when 3 feet long or at the latest when a foot or two longer. I have no further standard for regulating the stopping of the leader than the progress and strength of the lower shoots. The end lateral growth is removed in every instance when pinching the leader, so as to compel the main end bud to break instead of a lateral growth taking the lead. All the lower laterals are kept pinched (except the two or three at the base, which are allowed to extend) until this bud has again started into growth. The leader is again stopped when it has made about another 8 feet of growth. The laterals up to the first stopping are kept pinched, as is usual, while up to the second they are allowed to cover the trellis without crowding. Care is taken to obtain growths as near the base as possible, which are allowed to extend as well as the leader until the top is reached, when they are allowed to go down the back wall. The bottom growth which covers the front of the border is regarded by growers of Vines on unrestricted principles of vital importance to the thickening of the stem and equal distribution of the sap, thus giving to cultivators the advantage of producing as large bunches at the bottom and middle of the house as at the top. Again I assert, as large bunches cannot be produced at the bottom as the top when the Vines are restricted. This is proved by the fact that in the majority of gardens where restrictive ideas of growing Grapes are entertained the bunches are always the smallest at the bottom, and Mr. Iggulden cannot deny it, for I am sure he has seen the same fact again and again himself.

Your correspondent concludes my practice is to allow unlimited growth only at the top, or is not sufficiently acquainted with unrestricted after the first season's growth. Mr. Iggulden's statement goes so far to prove that unlimited growth is of some advantage "in case of defective root-action." If restricted Vines are liable in any stage to show signs of exhaustion, and this resulting from a defective root-action, the soundness of an unrestricted growth is evident. Moderate crops for a series of years on restricted Vines become in the end much too heavy, and

exhaustion is the result. How are such Vines to be recruited? Either the crop for a season must be sacrificed or restriction discontinued. This being the case, advocates of restriction would have to follow the system they condemn to restore to the Vines their former vigour. Many able Grape-growers have found the advantage of giving Vines previously restricted greater freedom of leaf-growth after they have commenced to go back. I am convinced that unrestricted Vines not only continue longer to produce fine bunches and heavier crops, but their fruitfulness

Fig. 80.—*CYPRIPEDIUM SPICERIANUM* (see page 500).

is extended over an unlimited period of time without signs of exhaustion.

All Vine borders in time become exhausted whether the Vines are restricted or not; but much can be done in supplying them with food from the top of the border, by which means they can

be kept in good condition for a very long time. The lasting properties of a Vine border materially depend upon the condition and nature of the material employed. If loam is of a retentive nature it lasts double the time of much lighter loam.

If the system of unrestricted is so unsound in the early stages of a Vine's growth as Mr. Iggulden appears to suppose, it is a wonder Mr. Wm. Thomson had never found it out, and who has attained greater success than he has done? In the seventh edition of his book on the Vine, in describing the planting of some small Vines in 1864 (pages 32 and 33), "which were no thicker when planted than a writing quill," he says, "The Vines were just bursting their buds when planted; and instead of adopting the usual practice of stopping or rubbing off all the buds but one or two, I allowed all to grow and tied them carefully to the wires. By this means I had in some instances ten rods to one Vine, all of which during the season ran to the top of the house and partly down the back wall, a distance of 30 feet, and many of these rods were as strong as ever I had previously seen a single rod from a Vine the first year it was planted. In January, 1865, when they were cut down, the whole house was a perfect thicket of wood.

I cut back all these Vines to within a foot of the front sashes, and trained up two rods from them the following season, fruiting them in 1866." Further on he says—"If, instead of permanent vigour and productiveness, an immediate return were the object aimed at, I have no hesitation in saying that such a Vine would have yielded 50 lbs. of Grapes the following autumn." I feel confident that such an able cultivator would not have tolerated this unlimited growth if it had exhausted the borders to such an alarming extent that Mr. Iggulden supposes, or have been no permanent benefit to the Vines. Like Mr. Iggulden, I never saw any harm apparently result from Vines bleeding, but who knows what such Vines might have done had they not bled?

Now to the statement of "AN OLD GRAPE-GROWER" where he says, "If he cuts them down in winter to the point below where free growth was encouraged he will simply cut off the best buds that would, if left, produce the best bunches and finest Grapes." Would "AN OLD GRAPE-GROWER" not do the very same with Vines grown on a more restricted system, or would they be left the whole length? If cut back at all the best buds would be cut off, as they are generally near the top, especially when restricted. If "AN OLD GRAPE-GROWER" grows a pot Vine under whatever system he likes, he cannot obtain the buds as good at the bottom as the top. If he was to cut it back for planting, or rub off the buds when breaking into growth—if he wanted to shorten it, how would he retain the best portion of the cane and do it? It would be interesting to know how he prunes his Vines. If, on the spur system, how does he manage without cutting off all the best buds? for they are not either on restricted or unrestricted Vines at the base of the growth.—W. BARDNEY.

#### CYPRIPEDIUM SPICERIANUM.

AMONGST the many beautiful *Cypripediums* which are now in cultivation, the one represented in fig. 80 (p. 499.) is likely to take a prominent position as a popular favourite with Orchid-growers. It is unquestionably one of the most beautiful in the genus, and that it is already becoming appreciated is evident from the high prices realised for small specimens at auction sales in London. Not many weeks ago a plant with two growths in a 54-size pot was sold for sixty guineas—a rather long price for so small an example. An Orchid in such demand as this will no doubt receive the careful attention of propagators, and it may be soon expected to become more abundant and cheaper.

The species is a native of the East Indies, whence plants were sent to Mr. Spicer several years ago, and from him they passed into the possession of Messrs. J. Veitch & Son of Chelsea. It is an ally of the well-known *C. insigne*, having narrow bright green leaves and one-flowered scapes. The flowers are especially notable for the large pure white dorsal sepals, which are slightly green at the base, and have a central purplish line from the base upwards. The lip is neat in form, reddish brown in colour, with a narrow margin of pale green. The petals are green with red streaks and dots, and prettily crisped at the margin. The stamino-ode is broad and one of the attractive features in the flower, being bright purple, contrasting strikingly with the handsome white dorsal sepal.

The accompanying engraving was prepared from a specimen recently flowering in Messrs. Veitch's Chelsea Nursery, and faithfully represents the leading characters.

#### STRAWBERRY FARMING—THE FUNCTIONS OF ROOTS.

I HAVE read in your Journal with much interest and instruction Mr. Raitt's excellent articles on Strawberry farming. If I understand correctly the sentence at page 443, Mr. Raitt thinks that a Strawberry has two sorts of roots which perform separate functions in the economy of the plant. I do not think that such is the case in any plant, and I shall endeavour to explain how roots grow, how they take up nourishment, and how assimilation takes place in the higher plants.

From the embryo the root strikes downwards into the soil, and having at its point or root-cap a number of small cells called the spongioles. This root-cap covers the outermost cells of the growing point, and forms a shield to the root when growing in the hard soil. The primary root throws out secondary or lateral rootlets, which continue spreading as the plant grows. At the apex of every root and rootlet the cells of the spongioles are continually forming so long as the plant is growing. These cells have closed but permeable walls, hence all nourishment from the soil must be in a fluid state. The nutrient fluids are absorbed by the cells on the principle of endosmose and exosmose. This principle constitutes the property which all fluids and gases of

different densities possess—viz., diffusing and intermixing through a permeable membranous wall till they become of equal density. As the cell-sap in the cells of the spongioles has a higher specific gravity than the moisture of the soil a strong current is set up, whereby the thinner fluid of the soil presses into the cells, pushing upwards the denser cell-sap, and so on from cell to cell till the fluids become of equal density. The farther progress of the nutrient fluids into the vegetable tissue is carried forward by capillary attraction, centrifugal force, and the evaporation from the leaves. A small portion only of the cell-sap passes out into the soil. It is found by experiment that this portion of the cell-sap is always acid. This acid helps to dissolve the necessary salts out of the soil for the well-being of the plant. We often see the small roots of plants as if they were eating into hard stones. The acid of the exosmotic current dissolves the stones, thereby enabling the roots to absorb the soluble saline matters indispensable to the plant.

As long as a plant is in life and vigour it must have access to water in order to form organic substances from inorganic food materials. This water is entirely supplied by the roots; and all roots, whether near the surface or deeper down, perform, so long as they are in a growing state, the same functions. Young and vigorous roots near the surface, and revelling in abundance of food materials supplied by a liberal top-dressing, will perform their functions much more vigorously than those deeper down in soil that may be partially exhausted of the necessary ingredients.

The substance besides water which forms the bulk of plants is carbon. Carbon forms about 50 per cent. of the ingredients of plants. Cellulose, lignin, starch, gum, and sugar are all compounds of carbon and water. The great bulk of this carbon is derived from the atmosphere by the decomposition of carbonic acid (carbon dioxide). On the leaves and green part of plants, but more abundantly on the leaves, are small pores or openings called the stomata. Surrounding the stomata are crescent-shaped cells with very thin walls containing chlorophyll, the source of the green colour in plants combined with particles of protoplasm. I may remark in passing that protoplasm is the essential constituent of all cells; and as cells, either separate or combined, are the elementary organ of all plants, so protoplasm is the true life of the cell and the formation and origin of all new cells and all new development. The stomata form a connection for interchange of gases between the intercellular spaces in the body of the plant and the outside air. The chlorophyll cells act as guards for closing and opening, more or less, the stomata as required. Iron is an essential constituent of chlorophyll, and its action is very languid without access to light. Through the action of chlorophyll plants decompose carbonic acid from the atmosphere, taking up the carbon by the stomata and liberating the greater part of the oxygen. Light and heat are necessary for an energetic action of chlorophyll, which is essential for the full vigour of the plant in order that it may perfect its fruits and seeds. The want of light and heat in a cold sunless summer makes the action of the chlorophyll languid, hence unripe fruits and immature grains.

Thus it is the leaves that are principally concerned in the process of assimilation, and the roots in the absorption of fluid nutriment, and both are necessary for the formation of new organic compounds in the plant. It is beyond the scope of this article to refer to the various other movements and changes that are continually going on in a growing plant.

Different species of plants absorb different nutrient matters from the soil, and it is on this selective power of plants that the basis of true agriculture is founded—viz., the rotation of cropping. I quite agree with Mr. Raitt, however, that as in his case, where rotation of cropping cannot be practised, there is nothing better than liberal top-dressing from the compost heap. Artificial manures are only stimulants, and in large quantities soil-exhausters.—J. S., *Arbroath*.

#### CHRYSANTHEMUM SHOWS.

CLOSELY following the principal London exhibitions the three midland towns, Northampton, Birmingham, and Wellingborough, have held satisfactory shows, well maintaining the credit of horticulture in their respective districts. The rapidly extending popularity of the Chrysanthemum is evidently not confined to the neighbourhood of the metropolis, and year by year the shows are increasing in number and importance.

NORTHAMPTON.—NOVEMBER 22ND AND 23RD.

Ten years of steady progress have placed this Society in a substantial position amongst provincial horticultural societies, and, judging by the results at present attained through judicious and energetic management, the future advancement will be rapid and satisfactory. The Exhibition held upon the above dates was probably

the best yet seen in Northampton both in the number and quality of the exhibits, all the principal classes which were provided for specimen plants and blooms of Chrysanthemums, fruit, and vegetables being well represented, and in some instances the competition was extremely keen. The spacious hall of the Corn Exchange, admirably adapted for an exhibition of this kind, was well filled without being crowded, and considerable care was exercised in the arrangement to provide the most effective display possible. Most of the exhibits were placed upon tables extending the full length of the hall, while near the wall on one side were collections of Chrysanthemum plants, and on the other side chiefly vegetables, the groups occupying the end opposite to the entrance, and forming a pretty bank of flowering and fine-foliage plants.

The classes were in two sections devoted respectively to gentlemen's gardeners or market gardeners and to amateurs, the latter being defined as exhibitors who do not employ a gardener either regularly or occasionally. Among these the Society appears to have done some really valuable service, having encouraged many working men to employ their spare time in the cultivation of plants and vegetables, in some cases with highly creditable but surprising results considering the limited resources at the command of such growers. But the good and useful work of the Society has by no means been confined to that portion of its supporters, for it has encouraged an honest but keen rivalry amongst the local gardeners, imparting an impetus to horticulture in the district that is now becoming distinctly evident in the improved productions staged. Much more, however, remains to be accomplished, and under the able management of the enthusiastic Honorary Secretary, Mr. E. Draper, success in no mean degree may be confidently expected. Happily, too, Mr. Draper is well supported by a practical and energetic Committee, who thoroughly appreciate their Secretary's efforts to render the Society a credit to the county.

*The Cup Classes.*—In the four principal classes for Chrysanthemums silver cups were offered as the first prizes—namely, two value three guineas each for gardeners, and two value two guineas each for amateurs. In the gardeners' class for six specimen large-flowering Chrysanthemums, incurved varieties, Mr. J. Holland, gardener to W. Jeffrey, Esq., Billing Road, was the most successful exhibitor, gaining the cup with neat well-grown plants of moderate size, none exceeding a yard in diameter, but even and fairly well flowered—Mrs. Dixon, Mrs. George Rundle, and Prince of Wales being especially noteworthy. Mr. F. S. Ingram, gardener to W. Butlin, Esq., Dustan, was a good second, also with neat specimens; and Mr. Hilburn, gardener to C. J. R. Woolston, Esq., Wellingborough, taking the third position with even plants, but tied in rather too formally. The cup offered in the amateurs' class for a similar number of specimens was deservedly won by Mr. W. F. Henman, Great Houghton, who had half a dozen well-grown plants of moderate size, evenly trained, and creditable both in foliage and flowers. Lady Talfourd and Mrs. Dixon were in especially good condition. Mr. T. Manning, Lower Mounts, and Mr. J. Arnsby, Lower Thrift Street, secured the second and third prizes in that order, both showing very fair examples.

Cut blooms were represented by several good collections. The cup-winner in the gardeners' class for twenty-four incurved varieties was Mr. E. Berry, gardener to the Countess of Leven and Melville, Roehampton, who staged clean, even, substantial blooms of the leading varieties, among which John Salter, Lady Slade, Empress of India, Lady Talfourd, and Prince of Wales deserve notice for their size and good form. Mr. J. Green, gardener to W. Shoosmith, Esq., was a very close second with neat blooms, some of the finest being John Salter, St. Patrick, Barbara, Lady Hardinge, Jardin des Plantes, and Hero of Stoke Newington. Mr. J. Holland was third with a collection inferior to the preceding in very few points, and containing several handsome flowers, among which was a pale yellow sport from Mrs. G. Rundle named Mr. T. Boddington, a neat bloom with broad florets. The successful competitors in the corresponding amateurs' class for twelve blooms were Mr. Henman, Mr. Manning, and Mrs. Bromwich, Kilsby, all of whom had neat blooms, rather small but compact, and clear in colour.

*Specimen Plants.*—These added greatly to the brightness of the Show, for though none was especially remarkable for size, yet the blooms were abundant, in some instances of good form, and in all fresh and clean. Taking the gardeners' classes first, the chief was for six Chrysanthemums of any kind "grown naturally," that is untrained, W. Shoosmith, Esq., contributing the prizes. Mr. T. Wood, gardener to J. Phipps, Esq., Sunnyside, took the leading position with healthy specimens, mostly flowering very freely, Julia Lagravère, Ariadne, and Guernsey Nugget being particularly noteworthy in that respect. Mr. J. W. Abrahams, gardener to E. Howes, Esq., followed, having good plants of Dr. Sharpe and Mrs. Dixon; Mr. G. Rickard, gardener to W. Hill, Esq., securing the third award with well-flowered examples. The best four specimens, incurved varieties, were staged by Mr. Abrahams, carefully trained and healthy plants; Mr. J. Payne, gardener to T. Shepard, Esq., Billing Road, and Mr. Ingram being adjudged the other prizes in the order mentioned, each contributing fairly satisfactory plants of moderate size, Mr. Holland had the finest single specimen incurved variety, an example of Mrs. G. Rundle, neatly trained and profusely flowered. Mr. Abrahams followed with George Glenn, and Mr. Payne with Guernsey Nugget, both fairly good. Mr. Abrahams secured chief honours with four Pompons, even and fresh specimens of the White and Yellow

Cedo Nulli, Fairy, and Shirley Hibberd; Mr. Payne was second, his best plant being White Ceddo Nulli in very satisfactory condition; Mr. Green obtained the third place with creditable examples of Bronze Ceddo Nulli and Bob. Mr. Abrahams' well-flowered plant of White Ceddo Nulli was placed first in the class for one specimen Pompon, Mr. Green securing a similar position with Madame Marthe as a standard. In the amateurs' classes for plants Messrs. Henman, Manning, Arnsby, Penn, and Payne were the prizewinners, the first three named showing remarkably well-grown specimens. Mr. Henman exhibited particularly well, taking three first prizes. His best plant was a beautiful example of Chevalier Damage, asymmetrically trained as could be desired, the flowers very abundant, of good size, and bright colour. As a specimen indeed this was one of the best plants in the Show. Several of the plants in Messrs. Manning's and Arnsby's collection were also very creditable.

*Cut Blooms.*—These were numerous shown, the competition being generally keen; but no blooms of unusual size were staged, indeed the majority were not above medium size, though they were compact, neat in form, and fresh in colours. In the gardeners' section the chief class was for twelve incurved varieties, Mr. Berry being adjudged principal honours for good blooms; John Salter, Barbara, Cherub, and Lady Slade being prominently noticeable. Mr. J. Green followed very closely with clean neat blooms, Mr. Holland taking the third position. Nine collections of six incurved blooms of one variety were staged, Mr. Green leading with Hero of Stoke Newington, fine; Mr. Berry following with Princess Teck, neat; and Mr. Abrahams third. In the next class, for six distinct varieties, there were a dozen entries, the majority of blooms being close in quality. Mr. Berry was again to the fore, having General Bainbrigg, Golden Empress, and John Salter in capital condition. Messrs. Abrahams and Wood were second and third respectively. Messrs. Berry and Green were the prizetakers in the class for Japanese, Anemone, and reflexed varieties, four of each, both exhibitors showing good blooms. Messrs. Green and G. Oram, gardener to Mrs. Whitworth, had the best collection of twelve Pompons, the former having Dick Turpin, Antonius, and Mr. Astie very good. The blooms in the amateurs' collections were mostly small but neat, Mr. Henman being again one of the principal prizetakers; Mrs. Bromwich, and Messrs. Green, West, Tew, and Manning being the other successful competitors.

*Miscellaneous Plants.*—The great feature of this portion of the Exhibition were the Primulas, which were both numerous and well flowered. Some very fine specimens were staged, but in a few instances the pots were a little too large, and rather detracted from the appearance of really well-grown plants. In the class for twelve the leading collection was shown by Mr. Holland, the plants being first-rate in foliage and flowers, the latter large and of good form. Messrs. Green and Ingram followed very closely, both having creditable plants. The best six were from Mr. Payne, Messrs. Holland and Oram taking the second and third positions with healthy plants. In the class for a miscellaneous collection of twelve plants, not less than six in flower, three exhibitors appeared, all contributing healthy specimens. Mr. Hilburn gained the leading prize with first-rate examples of *Gleichenia semi-vestita*, *Rondeletia speciosa*, an evenly trained globular specimen 5 or 6 feet high, *Eucharis grandiflora*, and *Eucephalartos villosus* amongst several others. Mr. J. S. Ingram, gardener to W. Butlin, Esq., was second, also with fresh, healthy, well-grown plants; *Cypripedium insigne*, *Yucca aloifolia*, and a very distinct form of *Odontoglossum* being especially notable. Mr. Fairbrother, gardener to R. Jurnes, Esq., Cliftonville, was third with a fine *Platyterium alaicorne* and several other praiseworthy plants. Pretty collections of British Ferns were contributed by Messrs. Penney and Oram, who gained the prizes in the order named. Mr. Green had the only two pots of *Mignonette* in the gardeners' class, but there were admirably grown specimens of Miles' Hybrid Spiral profusely flowered. Stands of flowers and bouquets were mostly arranged tastefully, the principal prizetakers being Messrs. Fairbrother, Abrahams, Oram; Walter, gardener to R. Eykyn, Esq., Gayton House; and J. H. Allen, gardener to H. Pritchard, Esq., Abington House, in the gardeners' section; and Messrs. Manning, Payne, Penn, and Arnsby in the amateurs' classes.

*Fruit.*—Like most of the other classes those devoted to fruit were well filled with creditable produce. The leading collection of six dishes was staged by Mr. J. Day, gardener to A. Seymour, Esq., Norton Hall, who had well-ripened black and white Grapes, and fair Apples and Pears. Mr. Ingram was second with samples nearly equal to the first in quality, including a handsome Pine Apple. Black Grapes were contributed by Messrs. Holland and Payne in fine condition, the berries being of good size and well coloured in both instances. Apples were largely and well represented, ten collections of six culinary varieties and eleven of six dessert varieties being staged. In the former, Mr. J. Bowler gained the chief award with New Hawthornden, Hanwell Souring, and Gloria Mundi particularly fine. Mr. Gardiner, gardener to Sir H. Wake, was a good second, and Mr. Oram third. The winning collection of dessert varieties was from Mr. W. Chapman, gardener to H. P. Markham, Esq., Pitsford, who had excellent samples of Wyken and Ribston Pippins. Mr. Bowler followed, also having Wyken Pippin in fine condition; Mr. Gardiner being third with Court of Wick and Adams' Pearmain very neat. Mr. D. Taylor, gardener to the Duke of Grafton, secured chief honours with six dishes of dessert Pears, good fruits of Josephine de Malines, Easter Beurré, Duchesse d'Angoulême, Glou

Morceau, and Benrre Bachelier. Messrs. Day and Gardiner followed closely with good examples. In the amateurs' classes some praiseworthy fruits were shown, especially the Apples, the prizewinners being Messrs. Penn, Dunkley, Payne, Hodson, and Mrs. Bromwich.

*Vegetables.*—Some capital vegetables were shown, and some of the leading collections would not have disgraced any exhibition. For eight distinct varieties Mr. J. Eads, The Gardens, Woolton Hall, was deservedly awarded the chief prize for even clean samples admirably set up. His Turnips, Onions, Potatoes, Cauliflowers, Beet, and Brussels Sprouts were excellent, and well merited the admiration they attracted from visitors generally. Mr. J. Day obtained the second position also with very creditable samples, the Onions and Cauliflowers being the leading features. Mr. Oram was a good third. Eleven collections were entered in this class, and throughout the productions were of more than average merit, the Brussels Sprouts being especially notable. Potatoes alone formed a show of no ordinary interest, there being nine exhibitors in each of the two classes. Messrs. Allen, Day, and Chapman had the best dishes of kidney varieties, International, Pride of America, and Snowflake being those chiefly represented. In round varieties Mr. Ingram won the leading position with fine examples of Bresee's Prolific and Schoolmaster amongst others. Messrs. Oram and Seaton were the other prizetakers, both showing well. Amateurs also exhibited collections of vegetables and Potatoes in very praiseworthy condition, Messrs. W. Stephens, Henman, G. Harrison, Dunkley, Mawley, Penn, and Hickman being the prizewinners.

Several miscellaneous groups of plants and flowers were staged, one of the largest and brightest being that from Messrs. John Perkins & Son, Billing Road, Northampton, who had Pelargoniums, Ericas, Chrysanthemums, and Capsicums very tastefully arranged. Mr. J. Wesley, Blisworth, sent a stand of fine Pelargonium blooms, and Mr. J. Day a pretty basket of Calanthes, Poinsettias, and Ferns, which was highly commended. Two satisfactory facts in connection with the Exhibition deserve notice—namely, that the receipts at the doors were about £20 in excess of last year, and all the prizes were paid to the winners on the evening of the second day, a practice that might be advantageously adopted by many other societies. If the Society should find itself in the possession of a good balance some of the prizes might be profitably increased in value, and would no doubt lead to keener competition.

#### BIRMINGHAM.—NOVEMBER 23RD AND 24TH.

With this Exhibition the Birmingham Chrysanthemum Society attained its majority, and a more satisfactory celebration of that interesting period in its existence could scarcely have been held. Of the twenty previous exhibitions probably few have excelled this in the number and quality of the productions staged in competition or otherwise, certainly at the same period of year the weather could not have been more favourable; but in another very substantial and encouraging way the coming of age was rendered especially memorable. The balance of £11 odd previously to the credit of the Society will no doubt be greatly increased, for the receipts in the two days amounted to considerably over £100, compared with £84 last year, and such progress as this must indeed be sufficient to satisfy the most hopeful of the Society's supporters.

The Town Hall was, as usual, engaged for the Show, but the basement was not large enough to accommodate all the exhibits, and the galleries were, in addition, nearly filled with the smaller plants, blooms, &c. In the body of the Hall a central table bore the fruit, stands of flowers, bouquets, Primulas, and some miscellaneous collections not in competition, while at the sides of the Hall the specimen Chrysanthemums and groups of stove and greenhouse plants formed two handsome banks of flowers and foliage that were particularly striking when viewed from the gallery. A little more space between the central table and the side stages would have been an advantage, for in the evening, when the visitors were most numerous, they experienced considerable difficulty in passing round even to obtain a cursory glance of the exhibits. This could no doubt be easily remedied, and in other respects the arrangements were all that could be desired; and the leading members of the Committee—Mr. W. B. Latham, Mr. W. Spinks, Mr. G. Stacey, and Mr. C. Redfern (Secretary)—deserve great praise for the energy they display in the conduct of the Society's affairs.

*Specimen Plants.*—In the display of Chrysanthemums the specimen plants form the chief feature at this Show; and though the entries in some of the classes were not quite so numerous on this occasion as at some previous shows, yet the plants were of excellent quality, especially the two collections in the class for nine specimens, distinct varieties, in which the prizes offered were a silver cup value £5, £3, and £2. Mr. W. H. Dyer, gardener to T. W. Webley, Esq., Selly Oak, was accorded the leading position for evenly trained, healthy, well-flowered specimens 4 to 5 feet in diameter. The blooms were mostly of good substance, neat form, and fresh in appearance, the foliage also being abundant and vigorous. The varieties were Jardin des Plantes, G. Glenny, Guernsey Nugget, John Salter, Prince of Wales, Mrs. Dixon, Prince Alfred, Mrs. G. Rundle, and Bronze Jardin des Plantes. The second prize was accorded to Mr. J. Crook, gardener to W. Millward, Esq., Edgbaston, whose plants were not trained quite so low as the others, but even, well grown, and with abundant blooms, though these were rather small. Lady Slade was very finely represented. These were the only collections in the class, which, consider-

ing the value of the prizes, was rather surprising. For six specimens also the competition was confined to two exhibitors, Mr. F. Denning, gardener to J. Jaffray, Esq., Park Grove, Edgbaston, securing chief honours with compact examples, Prince Alfred and John Salter being particularly noteworthy for their neatness and floriferousness. Mr. W. Jinks, gardener to J. E. Wilson, Esq., Edgbaston, followed with fairly good plants, but bearing blooms a little too small, though Lady Slade was well shown. In the next class for three specimens the competition was keener, four collections being entered. Mr. Dyer was again the most successful exhibitor, having John Salter, Mrs. Dixon, and Golden Empress, with fine blooms and fresh healthy foliage. Mr. Jinks took the second position with neat examples of Lady Hardinge, Mrs. G. Rundle, and Mrs. Dixon, the latter having blooms of good colour. Six Pompons were well represented by plants from Mr. Dyer and Mr. Jinks, who gained the prizes in that order. The first had flat-trained specimens in fine condition, the Golden, White, and Lilac Cedo Nullis, Rose Trevenna, and St. Michael being the leading varieties. In the other group the best plants were Model, St. Michael, the Golden and White Cedo Nullis, all well flowered. The best three Pompons were the three Cedo Nullis from Mr. Dyer; Mr. G. Newell, gardener to L. Hayman, Esq., Edgbaston, following with smaller specimens. The very successful exhibitor in these classes, Mr. Dyer, who carried off nearly all the first prizes, also had the best single specimen, an example of John Salter, 5 to 6 feet in diameter, and bearing a large number of fine blooms. Mr. Denning was placed second with a fair Prince Alfred, the same exhibitors taking similar positions with a single specimen of a Japanese variety, both showing Elaine, but Mr. Dyer's specimen was uncommonly well flowered—one of the finest we have seen this year. Messrs. Dyer and Newell were the prizewinners in the special class for "a bank of natural-grown large-flowering Chrysanthemums," both contributing bright and effective groups of good plants.

*Cut Blooms.*—Though only three classes were devoted to these some fine collections were staged, especially in that for eighteen blooms, incurved varieties, in which a three-guinea silver cup was offered as the first prize. This Mr. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, Liverpool (following up his success at the Kingston Show in the previous week), succeeded in winning with handsome blooms similar to those in the cup stand at Kingston, but not quite so compact and solid as they were. A very fine bloom of Barbara in this stand was selected as the best bloom in the Exhibition, and awarded the prize offered by Mr. Outram. The second prize for the premier bloom, given by Mr. Spinks, was adjudged to Mr. C. Neal, gardener to P. Southby, Esq., Bampton, Oxfordshire. Following Mr. Faulkner in the cup class Mr. W. Shingler, gardener to T. Tonks, Esq., Harborne, gained the second prize with large and well-formed blooms, John Salter, Mr. Gladstone, and Hero of Stoke Newington being the most prominent. Mr. J. Palmer, gardener to R. C. Bradley, Esq., Handsworth, was third with smaller examples. Messrs. Faulkner, Shingler, and Neal were the prizetakers with stands of twelve incurved blooms, all of fair quality. For twelve blooms grown within three miles of Stephenson Place, Messrs. Shingler and Palmer secured the awards with neat and creditable blooms. Extra prizes were awarded to Messrs. Comfort, Beal, and Palmer for stands of fine Japanese blooms, those for the first-named being particularly fine and rich in colour.

*Miscellaneous Plants.*—Ample provision was made for these in the schedule, and with very satisfactory results, for the plants staged in competition were generally of considerable merit, and added greatly to the beauty of the Show. The principal class was for nine plants, excluding Chrysanthemums and Primulas, two handsome collections being entered and forming fine groups each side of the Hall near the orchestra. The premier position was won by Mr. Jinks, whose plants were in excellent condition, including Croton Andreanus remarkably well coloured, Plumbago rosea flowering profusely, Eupatorium odoratum large and literally a mass of flowers, Dieffenbachia Bausei, and several other Crotons, all similarly well grown. Mr. Dyer was a close second, having a very fine specimen of Pteris cretica variegata, the other most noticeable plants being Cycas revolutus, Dendrobium nobile, and Croton variegatus. For this time of year all these plants were in excellent condition and very creditable to their growers. Mr. Jones was adjudged the premier prize for six plants, his specimens of Anthurium crystallinum, Kentia Fosteriana, and Chorozeza Henchmanni being particularly fine. Mr. Denning was second, also with healthy examples; Kentia Fosteriana was very noteworthy.

Primulas are well grown in the neighbourhood, and that the Committee recognise them as a speciality is evidenced by the fact that seven classes are devoted to these plants. In nearly all these the competition was good, and in consequence there was a display of Primulas such as we have not seen equalled this year, some hundreds being staged both in the body of the Hall and in the gallery; in fact, they seemed to abound in all directions. The majority, too, were very healthy and profusely flowered. In the nurserymen's class for twelve single varieties, six red and six white, Mr. Tomkins, Spark Hill, staged beautiful plants, having remarkably large flowers of great substance and good form. The foliage was also very vigorous and of a fresh healthy green colour. The second position was obtained by Messrs. Pope & Sons, King's Norton, who had plants of great merit. Mr. Tomkins was placed first with six plants, equally as fine as those already mentioned, with handsome trusses of flowers; and Messrs. Pope & Son followed with creditable examples. In the

gardeners' classes for twelve and six specimens respectively the exhibits were good. Messrs. W. Shingler; G. Caldicott, gardener to W. Mathews, Esq., Harborne Road; Jinks, and Jones being the prizetakers, all showing well-grown plants, especially those in the larger class. Six double-flowered varieties were contributed by Messrs. Jinks and Jenkins, those from the former being the more profusely flowered, but the latter were dwarfier and more compact. For six Fern-leaved Primulas Mr. Tomkins won chief honours with fine examples of the beautiful variety *The Queen*, with extremely large flowers. Mr. Johnson, gardener to Mrs. Elliott, The Cedars, followed with neat but smaller plants. The special prizes offered by Mr. J. Tomkins, Mr. Petch, and Mr. T. B. Thomson brought out good competition, and the exhibits added largely to the already extensive display of Primulas, Messrs. Denning, Caldicott, Jinks, and the Rev. E. H. Kittoe securing the principal positions.

Poinsettias, though by no means so numerous as the Primulas, formed a feature of great interest owing to their dwarf habit and the brilliant colour of the large heads of bracts. At this time of year well-grown Poinsettias are particularly serviceable in brightening an exhibition, and there are few gardens where their usefulness is not fully appreciated for decorative purposes. In the class for three specimens Mr. Dyer gained his accustomed position—first, with very fine plants, the stems about 2 feet or a little more in height, and clothed with vigorous rich green foliage down to the rims of the pots, and each specimen had eight to ten large heads, the bracts broad and richly coloured. Mr. Crooks followed with plants of similar height but not bearing quite such fine heads, though fresh and clear in colour.

Mignonette was similarly well represented, Mr. Dyer staging the winning collection of three specimens admirably grown, neatly trained, and well flowered. They were 2 to 3 feet high, somewhat cone-shaped but compact, without being formal; indeed they well deserved the position accorded them. Mr. Doughty took the second position with freely flowering plants but rather too tall, showing too much bare stem at the base though otherwise creditable.

A special class was devoted to plants for table decoration, the prizes being offered by Mr. B. S. Williams, Upper Holloway; Mr. Redfern, and Mr. Grice, and the resulting competition produced a pretty array of neat useful plants which occupied considerable space in the gallery. Mr. Denning had the best nine specimens in 5-inch pots, all even and admirably adapted for the purpose of table decoration, *Grevillea robusta*, *Dracæna congesta*, *Areca lutescens*, *Cocos Weddelliana*, *Pandanus Veitchii*, *Aralia Veitchii*, *Croton angustifolius*, and *Casuarina ericoides* being the most notable. Mr. Crook also had a praiseworthy collection, Mr. Jinks following closely with similar light neat plants, *Aralias gracillima*, *leptophylla*, and *Veitchii* being the leading specimens.

Bouquets and stands of flowers were represented by several tasteful arrangements including choice flowers of many kinds, Orchids predominating. In the nurserymen's class for a hand bouquet Mr. Hans Niemand, Edgbaston, was adjudged the premier prize for an extremely pretty arrangement of Orchids, *Lælias* being especially prominent; *Dipladenias*, Roman Hyacinths, white Chrysanthemums, and *Adiantum* fronds. These were lightly and effectively arranged, and formed one of the most tasteful and delicate bouquets we have seen this season. The second-prize bouquet (with several other exhibits) was removed early on the second day of the Show, the exhibitor, we understand, being dissatisfied with the award. It is regrettable even if he had any cause for considering himself aggrieved, which in the opinion of the majority was not the case, that he should have thus acted in direct contradiction to the rules of the Society. In the gardeners' class the bouquets were also neat, especially that from Mr. Merriman, gardener to H. L. Hayman, Esq., Edgbaston, for which the chief prize was awarded. Orchids and *Bouvardias* were freely employed with excellent effect. Mr. G. Newell was a close second, and Mr. Denning took the third position with a creditable contribution. The same exhibitors also carried off the leading prizes for an epergne of flowers, mostly bright and elegant.

*Fruit*.—Some excellent fruit was staged in several of the leading collections, Apples being very largely shown. The chief class was that for a collection of six dishes of fruit. Mr. W. A. Bannister, gardener to H. Amer, Esq., Bristol, was awarded the premier prize for well-coloured bunches of Lady Downe's and Muscat of Alexandria Grapes, neat Blenheim Pippin Apples, and Ickworth Impératrice Plums amongst others. Mr. Jinks was a good second, his *Beurré Diel* and *Duchesse d'Angoulême* Pears being particularly fine. In the next class, for four dishes of fruits from growers residing within three miles of Stephenson Place, some creditable examples were staged, Mr. Denning taking the leading position with good Buckland Sweetwater and Black Hamburg Grapes. Mr. E. Chadwick, gardener to Mrs. C. Neilson, Kenilworth, being second; and Mr. Jinks third, both showing well. Black Grapes were abundant and mostly fairly coloured. Mr. W. Comfort, gardener to G. H. Everett, Esq., Knowle Hall, leading with Black Alicante; Mr. W. H. Clarke, gardener to Lady Edward Ashbourne, and Mr. Doughty following in that order. Messrs. Clarke, Bannister, and Jinks were the chief exhibitors of white Grapes. In the class for twelve dishes of Apples, six dessert and six culinary varieties, Mr. R. Dean, Ealing, gained the chief award with good fruits similar to those he staged at the Westminster Aquarium. Messrs. Bannister and Jinks followed closely with praiseworthy samples. The same exhibitors were also

the principal prizetakers in the other classes for Apples and Pears, the latter not being shown in remarkable condition.

The exhibits not in competition were numerous and highly attractive, the baskets of plants contributed by Mr. R. H. Vertegans, Chad Valley Nurseries, being especially handsome, and well deserved the commendation they received from the Judges. The baskets were 5 or 6 feet in diameter and about a foot in depth, the sides being covered with sprays of evergreens. One contained a number of plants of *Rivina humilis*, the lower portion filled in with white Primulas, and the contrast between them and the bright red berries of the *Rivinas* was most pleasing. Others contained *Begonia insignis* in first-rate condition, Azaleas, *Bouvardias*, and *Calanthes* associated with Poinsettias, the last-named being remarkably fine. A first-class certificate was also granted to Mr. Vertegans for plants of

*Sisymbrium millefolium*.—This was shown as a plant well adapted for table decoration. The specimens were 9 to 12 inches high, with finely divided leaves 3 to 5 inches long, 2 inches broad, and slightly curving, imparting a most graceful appearance to the plant.

Large and handsome collections of Primulas and Pelargonium blooms were staged by Messrs. H. Cannell & Sons, Swanley, the white and red Primulas being greatly admired; the rich colour of the variety *Swanley Red* was indeed remarkable. Mr. Hans Niemand had some well-grown Cyclamen; Mr. J. Tomkins sent plants of *The Queen* Primula very freely flowered; Mr. T. Hewitt, Solihull, had a stand of Pelargonium blooms; Mr. T. B. Thomson contributed some Primulas and a number of artificial flowers; and Messrs. Cranston of Hereford sent some fine Apples, representing many varieties.

#### WIMBLEDON.

Although somewhat late in the season this Exhibition was one of the best ever held in Wimbledon. All the classes were well filled, and there was a remarkable absence of old blooms. The Show took place in the Lecture Hall, which is well suited for a display of the kind, being spacious and easily accessible for competitors and visitors. The Secretary of the Society, Mr. H. A. Rolt, and the Committee must be congratulated on the excellency of the Show.

*Groups*.—Of these seven were staged in the various classes. For the chief place there was a keen competition between Mr. G. Stevens, St. John's Nursery, Putney, and Messrs. G. Mahood & Son, Windsor Nurseries, Putney. The premier prize was ultimately awarded to the first-named grower, his group being considerably fresher than that of his rival, who secured second honours. Mr. Goodyear, gardener to the Rev. A. Malan, Eagle House, Wimbledon, was third; and Mr. Elliott, gardener to the Rev. J. M. Brackenbury, Wimbledon School, who was next, was highly commended for a well-flowered group. Three amateurs' groups were staged, and were of more than average merit. Mr. H. A. Rolt, of Maud Villa, Wimbledon, took the first prize with a neat and diversified group; Mr. J. Townsend, Lingfield Road, Wimbledon, being a close second with more profusely flowered plants, variety and quality, however, being not so good. Mr. Mereday, Denmark Road, Wimbledon, took the third position.

*Cut Blooms*.—For twelve incurved varieties Mr. W. R. Strong, gardener to Mrs. D. Reid, Virginia Water, was placed first, his best examples being *Golden Empress*, *Golden Queen Empress*, *Barbara*, and *Cherub*. Mr. C. Gibson, gardener to J. Wormald, Esq., of Morden Park, Mitcham, only lost by a few points, his *Hero* of Stoke Newington being especially fine. Mr. G. Stevens was third with smaller blooms of good quality; and Mr. Woodgate, gardener to H. Hammersley, Esq., Coombe Wood, was also commended for a very fresh stand. Mr. G. Stevens was an easy first for six incurved blooms, *Golden Empress* and *Empress* being very handsome. Mr. Bennett, gardener to H. E. Rodewald, Esq., Fieldheim, Wimbledon Common, and Mr. J. Bentley, gardener to Sir Thos. Gabriel, Bart., Edgecombe Hall, followed in the order named. In the class for six Japanese Mr. Stevens was again the victor, having fine examples of *Meg Merrilees*, *Sultan*, and *Yellow Dragon*. Mr. Bentley and Mr. Bennett were second and third respectively. A prize given by a friend for twelve Japanese was awarded to Mr. W. R. Strong, *Père Delaux* being one of the best blooms in the Show; *Boule d'Or* was also good. Mr. Gibson's and Mr. G. Stevens' stands were filled with large and fresh flowers, and were both highly commended. In the amateurs' class for six blooms Messrs. H. A. Rolt, J. Mereday, and J. Townsend took the prizes.

*Miscellaneous Exhibits*.—There were several groups of flowering and foliage plants exhibited not for competition. Messrs. Mahood and Son sent a fine lot of plants, as also did Mr. Bridle, gardener to R. B. Evered, Esq., Putney. Mr. Law, gardener to R. S. Dean, Esq., The Priory, Wimbledon, had a group containing some well-grown *Bouvardias*. Amongst the latter was a sport called *Priory Beauty*, from *B. elegans*, of a light mauve colour. It has a free habit, and the colour is very pretty. A certificate was unanimously awarded the plant by the Judges. Mr. D. S. Thomson, The Nursery, Wimbledon, sent a well-arranged group and a spray of *Lapageria alba* bearing twenty-one blooms, which was very highly commended. J. F. Schwann, Esq., Copse Hill, Wimbledon, contributed a nice collection of Orchids in flower; and Mr. J. Lyne, gardener to A. Schlusser, Esq., Belvedere, had in one of his two groups some grand spikes of *Calanthe Veitchii*, besides some good specimen Pompons of excellent size and quality. Mr. Alderman, gardener to C. Czarnikow, Esq., Mitcham, showed six bunches of Muscats and Black Alicante well finished; and Messrs. Logan & Rance, nurserymen, Wimbledon, a collection of Cyclamen, double Primulas, and Coleus. Other exhibits were sent

by Messrs. J. W. Moorman, Gibson, B. Dove, Goodyear, Woods, Bradford, Bennett, Newell, and Legg. Some of these sent large collections of fruit, which attracted much attention.

WELLINGBOROUGH.—NOVEMBER 25TH AND 26TH.

The first Exhibition of Chrysanthemums held by the Wellingborough Floral and Horticultural Society was very creditable to the projectors, a pretty display being provided in the Corn Exchange. The Committee wisely fixed the date of their Show two days after that at Northampton, and in consequence thus permitted many to exhibit at both, which was a manifest advantage to the Wellingborough Exhibition. As the first effort it was very satisfactory, and no doubt will be followed by better results in the future if the financial success is sufficiently promising to encourage another attempt. The arrangements were good, and the Society's affairs appear to be well managed by the Honorary Secretaries, Messrs. J. Pendred, G. F. Bearn, and J. Dulley, aided by a good Committee.

The specimen Chrysanthemum plants were mostly neat and well-flowered, but as the majority were similar to those at Northampton it is not necessary to enumerate them. The principal prizewinners were Mr. Abrahams, gardener to A. Howe, Esq.; Mr. Hilburn, gardener to C. J. R. Woolston, Esq.; and Mr. Clayson, gardener to W. Woolston, Esq., who showed well in the first five open classes. A pyramidal specimen of Elaine from Mr. Clayson, for which an extra prize was awarded, was very well flowered, though the blooms were rather small. Several of Messrs. Hilburn's and Abrahams' plants were also fresh and clean. In the amateurs' classes Mr. Henman of Northampton was a successful exhibitor, Messrs. Clayson and Manning also contributing specimens in most of the classes.

Cut blooms were not very largely represented, but they were generally neat and of good form. Mr. Hilburn's winning stand of twenty-four incurved varieties included fine blooms of John Salter, Lady Hardinge, Mr. Jay, and Mrs. Heale, Mr. Abrahams following with slightly smaller samples. In the class for twelve the positions of these exhibitors were reversed, but their stands were nearly equal in merit. Messrs. Henman, Clayson, and Manning were the successful amateurs, all showing creditably.

Miscellaneous plants formed an important feature in the Show, some really handsome specimens being staged in the leading collections. For "ten plants of any kind" Mr. Hilburn gained the premier award with well-grown specimens of *Ixora Williamsi*, *Eucharis grandiflora*, *Rondeletia speciosa*, *Lantana borbonica*, and *Encephalartos villosus* amongst several others. Mr. Brockhurst took the second position with fine specimens of *Croton angustifolius*, *Cycas revolutus*, and *Alocasia metallica*. Both these collections were good and close in merit, but the first was clearly entitled to his position. Ferns were also admirably shown by Mr. Hilburn, who had fine specimens of *Dicksonia antarctica*, *Davallia Mooreana*, and one of the best examples of *Adiantum gracillimum* we have seen; it was nearly 4 feet in diameter and in excellent health. Mr. Brockhurst followed with smaller specimens but fresh, his *Adiantum Sanctæ-Catherinæ* being notable. In the corresponding classes for amateurs Messrs. Percival and Clayson were the chief winners, staging Ferns in particularly fine condition. Two beautiful collections of Primulas were shown by Messrs. Clayson and Brockhurst, who were awarded equal first prizes, the plants being very healthy and well flowered; those from the last-named exhibitor were all double varieties, including some of the newer forms admirably represented.

Fruit was not shown in great abundance, but the majority of the exhibitors contributed very well grown samples. Mr. D. Percival, gardener to W. Blott, Esq., had the best two bunches of Grapes—excellent specimens of Black Alicante and Gros Colman finely coloured and with large berries. Mr. Clayson followed with Trebbiano and Black Alicante, also well coloured and but little inferior to the first-named. Mr. Percival had the only collection of six dishes of fruit, and gained the first prize with remarkably fine Gros Colman Grapes, which formed his best dish. Messrs. Henman, Sanders, Dunkley, and Curtis showed good samples of Grapes and Apples and Pears in the amateurs' section.

Vegetables, both in the amateurs' and cottagers' classes, were confined to Potatoes and Celery, most of the exhibits being of good quality. A few bouquets and stands of flowers were also staged, but do not demand special mention.

KITCHEN GARDEN.

*Forcing Department.*—Chicory can be readily forced in a Mushroom house, or it may be forced in any structure with a temperature of 55° to 60°, light being excluded so as to insure thorough blanching, otherwise the leaves are too bitter to be palatable. If Potatoes are required early, sets of some approved early variety should now be

inserted in leaf soil preparatory to being planted out in pits. The sets must be placed in a temperature of 55° to 60°, and when the shoots are 2 or 3 inches long the sets will be ready for transferring to pots or beds. Where forcing operations are extensively carried on it is important to have in readiness a good supply of fermenting materials for immediate use; and as it is a mild and durable heat that is needed in forcing vegetables, two or three parts leaves to one of stable litter will be better than all litter. Now that leaves are obtainable a good supply should be stacked for use as required during the winter and spring. Keep up a supply of French Beans by an occasional sowing according to the demand and the space available, affording a night temperature of 60°, and 70° to 75° by day. Under favourable conditions ventilate frames or pits containing Radishes, Cauliflowers, and Lettuces, stirring the soil occasionally between the two latter, and remove yellow or decayed leaves.

HARDY FRUIT GARDEN.

The pruning of Gooseberry and Currant bushes should be proceeded with as opportunity offers, although where bullfinches are numerous the pruning may be deferred until spring. In pruning Gooseberries it is important that the branches be disposed so as to leave the bushes open in the centre, and that they be regularly placed around the stem. The side shoots upon the branches should be cut-in to two or three buds from the base, and the terminal shoots in a similar manner, provided the bushes are of full size, but if extending the points of the growths need only be removed to preserve the symmetry. Bushes in course of formation will only need the side growths cut-in to about half an inch from the base after a reservation has been made of shoots for furnishing the bushes. Where the bushes are very vigorous a moderate thinning the shoots is preferable to spurring them in closely.

Red and White Currants having the branches radiating from the centre equally to leave the centre of the bushes open should have the shoots of the last season's growth spurred close in, as Currants usually form natural spurs abundantly, and the removal of the spray is essential for the admission of light and air. The extremities of trees of full size must also be cut close in, but any bushes in course of formation should have the growths, unless very long, left entire. Black Currants must not be spurred in, but have the old growths well thinned out where young growth admits of its being done without endangering next season's crop. This will keep the bushes well furnished with young bearing wood, upon which depends the production of a plentiful crop of fine fruit. The current year's fruiting canes of Raspberries have already been removed. The canes should be secured to the stakes or trellis with tarred string, the points of the shoots above 4 or 5 feet in length being removed. When the pruning is completed and the trimmings cleared away a thorough dressing of manure should be applied, pointing it in lightly near the stem of the bushes or stools, and deeper in the spaces between the plants, without disturbing the roots. A loose surface is, however, desirable to allow of rain and air having free access, and to admit of hoeing for the destruction of weeds.

FRUIT HOUSES.

*Vines.*—Vines in pots started early are now in free growth, and should have a night temperature of 60° to 65°, and 70° to 75° in the daytime, ventilating a little at 70°, and moderate ventilation at 75°, allowing an advance to 80° or 85° from sun heat, closing early at 80°. Disbudding having been attended to, it will now be necessary to stop shoots which, though showing fruit, will not be allowed to carry it at the fourth, fifth or sixth joint, it being sound practice to have leaf-development somewhat in excess of that actually needed for encouraging root-growth to keep up the supply of nutriment to the fruit-bearing growth, as Vines with plenty of foliage have a reserve to fall back upon if the resources of the Vine should be unduly taxed, as often happens from excessive evaporation. The shoots intended to carry fruit must not be stopped until two or three joints are made beyond the fruit, then pinch out their points, and rub off the laterals below the fruit, but on a level with and above the fruit allow them to remain, stopping these to one leaf. Keep up moderate moisture in the house, but syringing the foliage should be discontinued after the bunches appear. Turn over the fermenting materials, keeping the heat steady around the pots at 75°.

The house advised to be closed for starting early in this month to afford fruit ripe early in May must now have fire heat to maintain a temperature of 50° to 55° at night and 60° to 65° in the daytime, not exceeding the latter without free ventilation. If the Vines are young or have usually been started at a later period, they will need at least 5° more. Place the rods in a horizontal position and syringe them several times a day, having on the floor of the house if practicable some fermenting materials. Protect the outside border from heavy rains and snow. No further delay must be allowed in preparing the house where the Vines are to be started early in the year to afford ripe Grapes early in June. Black Hamburgh and other kinds cleared of their crops and the foliage being down should be pruned to plump well-developed buds, which in well-ripened short-jointed wood will be found at the second joint at the base of the current year's growth. This modification of the spur-and-rod system of pruning is more successful than the close-spur system, and is well worth practice. Any undue extension of the rods or spurs is obviated by cutting out those long and bare of growth, and securing young wood from the main rod, or as near thereto as possible.

*Cucumbers.*—Keen winds have necessitated careful attention to ventilation, especially as the days have been bright, the object being to prevent a chill by too great an influx of cold air, and at the same time obviate the evil of the temperature rising too high, which can only be done by turning off the top heat, so as to lessen the necessity for ventilation. In dull weather avoid great fluctuations of temperature, 60° to 65° at night and 70° to 75° in the daytime being suitable, and maintain the bottom heat steady at about 80°. Moderate atmospheric moisture will only now be necessary. The evaporation troughs need only be charged when the air is light. Continue removing old foliage and exhausted growths, avoiding overcrowding and overcropping, and giving liberal encouragement to the roots by fresh compost, with an occasional supply of weak liquid manure. Remove all staminate blossoms and tendrils from the winter-fruiting plants which are well advanced and showing fruit freely. The blossoms, if the weather prove dull, will need fertilising to insure the fruit swelling.

*Pines.*—Light during the next two months will be of limited duration, and sunshine can only be expected occasionally, and for so brief a period as to have little effect upon vegetation; hence the necessity of a diminished temperature, under which the plants will make more satisfactory progress than when growth is encouraged at this season by a high temperature. The main object to be secured is the maintenance of a vigorous vitality without promoting much growth, and to this end the plants should have plenty of room and a light position. If not already done the temperatures should be reduced to the winter standard—viz., for successions under ordinary treatment 55° to 60° at night and 65° by day; and in the fruiting department 60° to 70° at night, according to external conditions, with a rise of 5° by day. For young stock 55° at night is sufficient, ventilating at the top of the house at 60°, allowing the temperature to rise to 65° with liberal ventilation. Fire heat need be used only to prevent the temperature falling below 55°, the temperature at the roots being 70° to 75°. Queens which are required to start into fruit early in the ensuing year should have the heat at the roots now gradually raised to 90°. When external conditions are favourable execute with dispatch whatever may be necessary in the way of renewing fermenting beds.

#### PLANT HOUSES.

*Greenhouse.*—Heaths and other hardwooded plants are in dull weather at this season very liable to be attacked by mildew, especially plants that have grown freely during the summer, also young stock which are in a more favourable condition for its development than older and slower-growing plants. They should be laid on their sides and freely dusted with flowers of sulphur, allowing it to remain on four or five days, when it may be syringed off, or plants but slightly affected may be dusted with the sulphur; but care must be used to keep the sulphur from the soil, as, if washed down to the roots, it will do serious injury. Sulphur water is also a good remedy for mildew, 3 or 4 ozs. mixed with a gallon of water, well stirred and allowed to remain for four days. The clear water may be poured off and used, dipping small stock and syringing large plants laid on their sides over a vessel large enough to catch the water.

*Liliums.*—In the cultivation of Lilies it is essential to disturb the roots as little as possible at any time, and especially when active; hence potting should always be carried out as soon as the growths have died, and in the case of large masses of bulbs that it has become necessary to divide, it is important that the work be done without delay. Good fibrous loam, a fifth of decayed manure or thoroughly reduced leaf soil, and a little sand, form a suitable compost. In potting leave space over the bulbs for a top-dressing of rich compost, so that none of the roots that are formed above the bulb will remain uncovered. Do not keep them in more than an ordinary greenhouse temperature during the winter, having the soil moist until the bulbs have started into growth.

Chrysanthemum cuttings may now be inserted in small pots singly, selecting sturdy cuttings of 3 inches length, and with a small portion of root stem, placing in ashes in a cold frame kept close and shaded from sun until rooted, when ventilate freely in favourable weather. Protect in severe weather with mats.

#### FLOWER GARDEN.

The beds and borders present a naked uninteresting appearance unless they have been filled with some of the many dwarf and beautiful variegated shrubs, which at this season show to great advantage. These in combination with early spring-blooming plants and bulbs will afford some interest almost continuously. Complete whatever is contemplated in this respect, and make good any defects at present distinguishable. Walks require frequent attention in sweeping and rolling. Lawns can hardly have too much rolling, as, besides consolidating the surface, it improves the texture of the grass.

## THE BEE-KEEPER.

### PLEASURES OF BEE-KEEPING.

THE pleasures of bee-keeping, like many other enjoyments in this world, are not unalloyed. Where is the apiarian who has not felt the pain of being stung, the loss of swarms, and the disappointments of unfavourable seasons? Notwithstanding, the pleasures of bee-keeping are many and great, and many of them are enjoyed by lovers of Nature in the higher classes of society, and it is evident that the interest taken in bee-keeping is now increasing amongst different classes of the community. This is not to be wondered at, for a swarm or stock of bees is a little community by themselves, presenting features of social and active life—an organisation complete in itself, possessing instincts of wonderful industry and thrift, of order and cleanliness, of courage and self-defence. Many men choose pleasures that are not toilsome, that recreate much and cost little; and those derived from bee-keeping are amongst them. I think it is Burke who says in his "Essay on the Sublime and Beautiful," that throughout nature both the beautiful and sublime may be seen, and pleasure derived from both, and that the sublime is calculated to make the most lasting impression on the mind. And dare we not to venture to say that a close observer finds in the apiary things beautiful and things sublime—something to admire and something to astonish?

It will, I think, be admitted by many that I have had a large share of experience amongst bees. I have had considerable experience, and in looking back over the past to compare the gains and losses, the pleasure and the pains, I find that the profits and pleasures far outweigh the losses and disappointments. They may be contrasted but cannot be compared, as the preponderance is all on the happy side. The simple fact of possessing a few swarms of bees has, in my history, produced happiness, and the study of their habits has been a perennial source of enjoyment. For health of body and material comfort, as well as for mental recreation, I owe much to my bees.

In entering my garden early on a summer morning what do I find? That the bees have been out before me, and are busy carrying in the water necessary for the day before the dew has gone from the grass, and before honey can be gathered from the flowers. If I press my ear close to a hive I hear a hum of contentment and activity. Who can tell me how many nameless offices have been performed by the bees in their hive while I and other folk were asleep? Who can tell me that any of the bees sleep at all? I turn up a hive in early morning to find what

progress the bees have made during the night. Hundreds of cells have been built, hundreds of eggs have been laid, and the queen busily occupied in laying more; hundreds of maggots have been attended to in their cradle cells, hundreds more have been sealed up in order that they may be quiet and unmolested while they pass into the chrysalis state. Both the home life and night work of a bee hive are wonderful.

Some old books on bees divide the working community into classes, and tell us that each has a distinct function to perform. We thus have nursing bees, wax and comb-building bees, honey-gatherers, sentinels, &c. We have always thought that this idea is too fine-spun, or too much drawn out. On examining bees returning from the fields it will be found that while many of them have been gathering honey and pollen in the fields they have also been secreting wax, and four and six plates of wax may be seen oozing out of or being excreted from the furrows of the abdomen of each bee as it enters the hive. I have often told the readers of the *Journal of Horticulture* that the secretion of wax is voluntary on the part of the bees, and this voluntary action is a marvellous fact in their history; but I think I have stated the fact that while bees are at work in the fields they can and often do secrete wax. It is considered good work to kill two birds with one stone, but here we see that bees do more, for they perform three very important functions simultaneously in manufacturing wax while collecting both honey and pollen.

In noticing the senses of bees it will be found that they have five, all keen and interesting. The phenomena of the five senses of bees contain matter enough for a large book. Few men have power to grapple with this large subject, but the simple bee-keeper derives pleasure from noticing and knowing how useful the senses are to his bees. He knows their sense of smell is so keen that they can find the best honey within two miles of his garden, that they can find honey in the smallest flowers, and that if a single drop of honey fall on a garden walk or garden lawn it will not be overlooked or forgotten by his bees. He knows, too, they will detect by smell the presence of a strange bee in their hives.

As to their powers of sight, bees can see and follow a cricket-ball or stone as fast as it can be thrown from the hand. An American gentleman, talking to me about the powers of flight of the honey bee, said that some flies in America could follow and dance round the ears of his horse going at a full gallop. We have often been struck with the quickness of the sight and flight of bees in following an object that provoked them.

The swarming of bees is one of the most interesting and pleasure-giving outcomes of an apiary. The first sight or appearance of drones every season caused such delight in Bonar that he sat down and made himself some whisky toddy on the occasion. More apiarians than Bonar are pleased to see drones appear in the spring months. Their appearance indicates that the bees are preparing for swarming.—A. PETTIGREW, *Bowdon*.

#### TRADE CATALOGUES RECEIVED.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogues of Roses, Forest and Ornamental Trees.*

W. P. Laird & Sinclair, Dundee, Scotland.—*Catalogues of Trees and Shrubs and General Nursery Stock.*

H. & F. Sharpe, Wisbech.—*List of Potatoes.*

William Paul & Son, Waltham Cross, Herts.—*Catalogue of Hardy Trees and Shrubs.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. W. H.).—The address you require is, we think, Messrs. Boulton & Paul, Norwich, and you had better submit the inquiry to them that you have sent to us.

**American Blackberries (A. H.).**—They can be obtained from any of the principal nurserymen.

**Work on Hybridising (M. B.).**—You will find much information upon this subject in "Cultivated Plants, their Propagation and Improvement," by Mr. F. W. Burbidge, and published by William Blackwood & Sons, Edinburgh and London.

**Abies Albertiana (F. G.).**—If the specimens are similar in habit they are both forms of the same species, as there is considerable variation in many Conifers that are raised from seed, but we consider No. 2 the typical example of Prince Albert's Spruce.

**Grapes Shrivelling (A. B. C.).**—We are unable to inform you why your Mrs. Pince's Grapes have not finished satisfactorily. Possibly the Vine is not in a healthy state in consequence of defective root-action, or the crop may have been too heavy. We have cut very good Grapes of Mrs. Pince grown on a Black Hamburgh stock.

**Winter-flowering Begonias (A Young Gardener).**—The following will no doubt meet your requirements, as they are free-growing and flowering—*Begonia insignis*, *B. seemperflorens*, *B. weltoniensis*, *B. Ingrami*, and *B. parviflora* or *B. Richardsiana*.

**Begonias (C. B.).**—It is not usual for those who have raised new plants to send seeds or cuttings to applicants for them. They are only sent for trial to growers selected by the raisers, and on the understanding that no portions of the plants will be distributed by those to whom they are entrusted. You will probably hear more about the plants you name eventually.

**Advice to Young Gardeners (One in Hope).**—We are glad to learn that you, with others, are endeavouring to profit by the advice to which you refer. Your letter indicates a laudable desire to do what is right, and we trust you will continue your endeavours towards that end. We would also advise you to study grammar and orthography. In your short note there are six errors in spelling, and a still greater number of grammatical inaccuracies.

**Dwarf Peas (H. W.).**—Two good dwarf Peas are Carter's Extra Early Premier Gem and Suttons' Bijou, but we do not know which would suit your soil and purpose the best. You had better try them both. We do not know what "conservatory creeper would resist mealy bug;" perhaps some of our readers can supply the information. A good book, such as you appear to require, is Brown's "Manual of Botany," published by Messrs. Blackwood & Sons, London and Edinburgh. The price is 12s. 6d.

**Marechal Niel Roses for Christmas (W. H. C.).**—So long as the present mild weather continues the plants now bearing flower buds may be kept in the greenhouse; but if by the occurrence of severe weather the temperature of the house should fall below 40° the flowers will probably fail to expand, but they would open if the plants were placed in the Cucumber house. As to when they should be placed there depends entirely on the weather and the size of the buds; flowers can only be had on a given day by the exercise of sound judgment on the part of the cultivator. If the pots are filled with roots weak liquid manure would be an advantage, not otherwise.

**Strawberries Flowering (R. E. M.).**—The plants received a check by the hot weather in early summer, and the mildness of the autumn has accelerated their flowering. Probably if some of the plants were potted—those with the fruit half grown—the fruit would ripen in a light warm greenhouse. Many cultivators have ripe Strawberries at Christmas, but the plants require careful management. You may remove the flowers as you propose, but the crop next summer can scarcely be expected to prove so good as if the plants had not flowered now.

**Lapageria alba (F. Z.).**—It will succeed in a conservatory in which the temperature does not fall below 40° in the winter, but if the minimum is 45° it will be better, and a rather shaded position in summer is advantageous. Suitable soil consists of turfy peat, a little loam, and lumps of charcoal. Good plants can be grown in 11-inch or 13-inch pots, the shoots being trained to a trellis, a flat one being most suitable. Whether grown in a border or pot, good drainage should be secured. A border 4 feet long, 2 feet wide, and 2 feet deep, clear of the drainage, will support a large plant. The drainage should be very good, for during the season of growth the watering must be plentiful, and at no time must the soil be allowed to become dry. During the growing season a plant in a large pot will require a gallon of water daily, and one in a border thrice the quantity.

**Rabbits Injuring Trees and Shrubs (Mrs. S.).**—In an article upon the above subject in this *Journal*, page 136, vol. xxxviii., the writer summarises his experience in the severe winters of 1878 and 1879 as follows:—Beech, Cupressus Lawsoniana, Thujaopsis borealis, White American Spruce, Portugal Laurels, English Yew, Retinospora pisifera, Wellingtonias, and Piceas (except *P. pectinata*) did not suffer to such an extent as to interfere with their after growth; while Rhododendrons, Kalmias, Andromedas, Irish Yews, Corsican Pine, Birch, and Alder received no injury." Fuller particulars respecting trees and shrubs which were greatly injured will be found in the article in question.

**Liliums (Somerset).**—To have the varieties of *Lilium laucifolium* in flower in August and September the plants should be wintered with the pots plunged in ashes in a cold frame or pit, affording protection over the lights in severe weather. In May the plants may be placed outdoors on ashes in a sheltered sunny position, and if duly attended to with water they will flower at the time required, being placed under glass when the flowers are expanding. *Lilium longiflorum* may be treated similarly, but will not flower so late. After the buds are formed the plants may be placed at the north side of a wall so as to retard the flowering. *L. Thunbergianum* is early-flowering, but it may be retarded as advised for *L. longiflorum*. For your purpose *L. laucifolium* vars. are far the best.

**Cucumber House (S. C. F.).**—The lights make no difference as regards their width for the growth of Cucumbers, as the trellis, or wires forming it, require to be fixed longitudinally or lengthwise of the house, 30 to 36 inches being a sufficient distance apart for the plants. We should have ventilators at the top of the house in the roof and not in the back wall. To have the roof lights at an angle of 45° the back wall will need to be the same height as the width of the house, reckoning from the top of the front lights, which are 2 feet 6 inches; the width of the house in that case will be 8 feet; the height of the back wall will be, your having 2 feet of brickwork in front in addition to the front lights, 12 feet 6 inches. An angle of 35° is more suitable, the width of the house 9 feet inside, and the back wall about 10 feet 6 inches, which is allowing for 2 feet of brickwork under the front lights. Two rows of 4-inch piping will be needed for bottom heat to the bed, and three rows for top heat, two rows at the front of the house and the other adjoining the pathway and just over the bed, this row being filled with evaporation troughs.

**Pruning and Potting Neriums** (*J. Ellerton*).—The flowers are borne from the points of last year's shoots, and the flower stems have usually flower buds that do not all expand in one season, therefore leave them until another season. Plants that become ill-shaped should be cut down in April, foregoing flowering for a season, encouraging growth by placing them in a moist and warm atmosphere, and in July remove them to a lighter position, repotting when the shoots are a few inches long, and whilst in heat. Neriums are better under rather than over-potted. Three parts fibrous loam, one part each of sandy peat and leaf soil, and one-sixth of sand, form a suitable compost. Cuttings of young shoots rather firmly inserted in sand, under a bellglass, in hotton heat of 75°, shaded, or shoots inserted in bottles of water in the sun, root freely.

**Tuberose Culture** (*A. J. D.*).—Mr. Taylor has described his method of culture as follows—The imported bulbs are received in December or January, when they are at once potted singly in 6-inch pots, and plunged where they can have the benefit of bottom heat to start them into growth. After they once start fairly they can be grown in a lower temperature and without bottom heat; and when all danger of frost is over, if they are not wanted to flower early, they can be placed in a deep cold pit and be merely protected from the worst of the weather till the flowers commence opening, when they will be improved by being taken into the greenhouse. Plants so treated will generally flower some time between July and October. After flowering most people throw them away as useless. This is quite a mistake, as I will endeavour to prove. Mine are at once shifted into 7 or 8-inch pots without disturbing the ball, using a good rich compost consisting of turfy loam with a little decayed manure, a few half-inch bones, and a little charcoal. They are again placed in a warm house and soon commence throwing up shoots, one of which only is left to grow, and it soon forms a new bulb on the top of the old one, which will not fail in its turn to send up a good strong flower stem. The American variety known as The Pearl is one of the best, and is largely grown by those engaged in supplying cut flowers for Covent Garden Market.

**Pickling Tomatoes** (*Mrs. W. E.*).—Scald and peel green Tomatoes. Lay them on dishes, and strew salt thickly over them. Let them stand twenty-four hours, occasionally pouring off the liquor that the salt extracts. Drain them and gently squeeze them, as it is this juice that weakens the vinegar and makes them spoil. Take a large jar, put in a layer of Tomatoes, then a layer of sliced onions, mustard seed, cloves, and white pepper, or whole black pepper; or two pods of red pepper may be broken up and put in the jar. When the jar is full pour very strong vinegar over, and in a few days they will be ready for use and will keep well. They should be kept in a cool place.

**Early Cinerarias** (*D. H.*).—They may be flowered in autumn and early winter, the seed being sown in March in a hotbed, and the plants grown throughout the summer in cold frames, shifting them into their blooming pots in August, and removing them in September to a light airy position where they will have a temperature of 45° to 50° from fire heat. If kept in an ordinary greenhouse they will not flower until the new year.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*H. Galton*).—It is the true Broad-eyed Pippin. Court Pendu Plat is quite different from this. The fungoid affection is no doubt caused by the humid situation. It is difficult to advise what to do under the circumstances, since draining is probably an impossibility. (*Ramatho*).—1, Wyken Pippin; 2, not known; 3, Golden Winter Pearmain; 4, Sops-in-wine; 5, Cox's Orange Pippin. (*S. H.*).—Apple Hollandbury. Small Pear Nutmeg, called also Besi de Caissoy; the larger, Duchesse d'Orleans. The plant is referred to below. (*A Reader*).—1, Not known; 2, Sturmer Pippin; 3, Franklin's Golden Pippin; 4, Golden Winter Pearmain; 5, Warner's King. (*J. Harper*).—1, Golden Nohle; 2, rotten; 3, bad specimen; 4, Formosa Pippin; 5, Court Pendu Plat.

**Names of Plants** (*A. C.*).—Eunonyms europæus fructu-alho, the White-fruited European Spindle Tree. (*S. H.*).—The specimen you sent was very diminutive, but appears to be an Erigeron, probably *E. pusillum*.

COVENT GARDEN MARKET.—NOVEMBER 30.

TRADE remains the same, business being quiet with scarcely any alteration.

POULTRY AND PIGEON CHRONICLE.

STABLE ACCOMMODATION FOR HORSES.

(Continued from page 487.)

THE earth floors of stalls for horses should be made on the surface a few inches below the pathway behind the stall in order to prevent the urine leaving the earthen surface, for it will be instantly absorbed if it does not overflow the boundary of the stall. The urine of the horse is, we consider, much stronger in ammonia than that of the horned cattle, as evidenced by the more pungent effluvia arising from it; the effect of the earth, however, in fixing and deodorising the noxious vapours is instantaneous, and ill odour is entirely absent in a well-managed earth floor. We cannot, however, refrain from noticing a novel application of vulcanised indiarubber called "The Vale of White Horse Patent Bedding," to supersede litter for stables, which was lately exhibited, and has found, it is stated, considerable favour with the owners of valuable horses. It consists of a bed sheet of vulcanised rubber, on which another sheet is corrugated in a way to make it a warm, dry, elastic mattress for a horse to lie or stand on. In point of economy, salubrity, and for the preservation of horses' feet, it has claims which seem to meet with much attention. As we have not yet seen the mattress we are not prepared to criticise it, but it must be preferable at any rate to the various materials employed in constructing impervious floors for stables; and with regard to economy, that must consist in the saving of straw, but the actual salubrity is not so easily imagined. We apprehend that the drainage is effected by the corrugated or fluted surface, and in this case it would be led by the incline of the floor to the back part of the stall and in direct communication with the open gutter, into which all liquid portions would either flow or be swept away as in the absence of the mattress. It seems to us very important that the floor on which the mattress is to rest should not be composed of any hard material like clinker brick, as the friction and wear of the mattress would be very great, and therefore we recommend that the earth floor be laid as usual, but with an incline for the mattress to rest upon; for not only would the wear and friction be reduced to a minimum, but in the event of any urine overflowing the margin of the mattress on either side it would be immediately absorbed and rendered innocuous by its contact with the earth.

We must now consider the advantages of a loose box with earth floor which we have used for our nag horses for many years. One great point is, that in the event of the earth being laid down quite fine and dry, and well rammed to make a level and firm surface, and laid 2 feet in depth, that, unlike the earth floor to a stall, it will not require any renewal or removal of earth for several years, especially if a strong clay or calcareous loam is used, and yet be free from any unpleasant exhalation during the whole period. In fact, it may in some instances last without changing the floor for four or five years. This plan of management of a loose box is unobjectionable in every respect if ordinary care is taken with the ventilation and the daily removal of solid excrement, and the floor swept with a hard broom. The feet of the horse will be of course dry at times, but not so much so as when standing on clinker bricks, nor will the stamping of the horse throw the shoe, but at the same time the lying for the animal will be first-rate, the advantages of which compared with any impervious floor cannot be fully estimated except

by practical experience. Especially it is of importance to consider that during the absence of the grooms by day or night there is no necessity for immediate cleansing the earth floor, because the urine is instantaneously absorbed, fixed, and deodorised, whereas that on an impervious floor, when it comes in contact with broken straw or dirt of any kind, which if not immediately removed the evaporation of ammoniacal gases instantly commences, and increases until the drain, gutter, and floor are flushed and swept, and which cannot be, or is not usually, done during night.

We have now to refer to our third system alluded to—namely, that of accommodation by boxes with earth at the bottom and accumulation of litter thereon. Perhaps we cannot do better than describe where this plan was thoroughly carried out with great and careful detail. The stables were designed for the accommodation of some valuable race horses about twenty-three years ago. It consisted of twelve boxes 13 feet square, divided by stout boarding and open iron railwork above. The boxes were excavated 2 feet below the pathway and concreted at the bottom and sides, and the door for entrance was a sliding one, which is much to be preferred to a door on hinges, for the latter when opening into the pathway is sometimes the cause of accidents. The centre pathway was 9 feet wide, with a tramway along the centre, upon which was worked two trucks, one for conveying food, and the other for removal of dung and supplying straw and earth to the boxes. This tramway was conveniently laid in communication at one end of the building and passing between the stores for corn, hay, and straw, the saddle and harness rooms, and leading through the centre of the coach-houses at the other end, through which any refuse may be conveyed by truck. The door of the boxes was placed on one side of the front of the box; on the other half of the front the manger was placed inside of sufficient capacity to hold both corn, hay, chaff, and one division for water, in order that the horses may be fed and watered without the groom entering the box, for a shutter was made to let down and the food supplied out of the truck on the tramway. The roof of the stable was an open-ceiled one inside, with a false roof about 18 inches below the ridge, with an opening of 9 inches and louver board, but this space was secured by perforated zinc plating. In this way good ventilation was obtained, for also over each alternate box a swing window was placed on either side of the building, not only giving ample light, but assisting in ventilation if required. Also at each end of the centre pathway, as between the corn stores at one end and the carriage offices at the other, sliding doors were placed, which may be opened for ventilation or closed to prevent draught. The entrance for the horses was in the centre of the eastern side of the building, the site of which was north and south from end to end and well sheltered by trees and shrubs. The boxes were filled at the bottom with dry prepared loamy soil, and rammed down to the depth of about 8 inches, except at the entrance for the convenience of the horse passing in and out, where it was raised nearly to the threshold. Straw bedding was used as cleanliness required, but always sparingly. No excrement was removed but spread and covered with litter-straw, which was supplied to the stores in single bond trusses, which were cut with a thatcher's knife at the bond, which rendered the straw short enough to prevent its becoming disturbed on the surface by the horses' feet. The straw may now, however, be supplied in lengths of about 15 inches as cut by the chaff-cutting machine.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This work now consists of fallow-ploughing land which has been autumn-cultivated, and if any case of hindrance has occurred by weather preventing the couch being cleared off it may now be carted away to heap after being collected in rows by the forks. Sometimes we have known farmers plough it under; but it does not answer, because, instead of dying during the winter, it is found ready to start into growth in the spring. We, however, now are alluding to that portion of couch which may have been brought to the surface only, without sufficient time and labour having been bestowed upon it to free it from the soil. In this case, when not freed from the earth, it is admirably adapted for laying out as manure on any dry turf land where it can be carted on to without injuring the pasture by treading and cart tracks. We have frequently found that it improves pastures. Some persons fear that the couch may take root and render the grass land foul, but it is not so, for the worms pull it into their holes; it then acts as manure in decaying. In fact, nothing ever can grow so as to compete with old turf, for it has possession of the surface; and even when all the rubbish, including seeds of weeds obtained when winnowing corn, is laid upon old pasture land, it will not grow, but decays and acts as manure only.

*Hand Labour.*—Hedging, ditching, banking, draining, and such

work now prevail. There is, however, the pitting of roots in the field to be done, which answers a good purpose, as it protects the roots against depredation by game and rabbits in a severe winter. In a mild one it prevents the sprouting and spring growth or delays it, and therefore maintains the full feeding value of the roots. When in pits the roots can be carted away to the homestead for feeding young stock in the yards and store pigs; at the same time the Swedes are useful upon many farms where Mangold is not grown much, or has failed, for the feeding of fattening bullocks in the boxes, and also for dairy cows in the strawyards, as it maintains them in useful condition until calving time arrives.

*Live Stock.*—The wether sheep or fattening ewes should now receive a full allowance of cake and meal of beans, peas, or maize, mixed with their cut roots in the troughs. Cotton cake made from decorticated seed is better for store or milking stock than fattening animals, and answers a good purpose when given to the early-lambing horned ewes, which have lately, together with their lambs, been put upon root-feeding. By all means we advise the home farmer to have the roots prepared clean and passed through Gardner's cutter, even for the common Turnips, which some farmers will not cut, as they are said to be soft enough to be eaten without cutting, and so they are for stock sheep; but for fattening animals they ought to have eaten their allowance of roots and the meal mixed from the troughs and lie down, instead of being engaged so long cutting their own food, which will not allow them much time for rest. The lambs, too, are not old enough to eat much, but they may run forward and eat the grains of roots with some hay and cake in their troughs. To make first-quality lambs they should only go forward through the lamb-gate into a fold which has been cleared of the growing roots, so that they may get only such food as may be considered not only the most fattening, but also the best to keep them in health. We do not like to see the lambs running forward eating the tops of Swedes or Turnips in a frosty morning: large numbers are annually lost by diarrhoea from this system of feeding. We, therefore, always feed our lambs entirely on prepared food in troughs, of the finest Dutch or hop-clover hay cut into chaff, of either White Carrots or Drumhead Savoy Cabbage passed twice through the cutter and mixed with cake meal, bean, or barleymeal, and with this food they will eat a good portion at the earliest period. At the same time in covered troughs with back to the wind we place split beans or grey peas mixed with broken cake; and as young lambs will go to the troughs for shelter they are then often induced to eat cake and pulse at the earliest period. This is a matter of great importance, not only for them, but also for the ewes, because a well-fed lamb will not depend so much upon the mother's milk, the ewe gaining flesh whilst it gives milk, and in consequence we generally sell our ewes and lambs about the same time to the butcher, as they will both be in prime condition if fed as above directed.

**LORD TREDEGAR'S CATTLE SHOW.**—At this Show, which was held on the 22nd ult., the piece of plate, value twenty guineas, offered for the best male horned breeding animal selected from any class in the yard, the gift of the Corporation of Newport, was won by Mr. T. J. Carwardine, Stockton Bury, Leominster, with "Lady Carew 4th;" and the corresponding prize for the best female animal, the gift of Samuel Homfray, Esq., Glen Usk, Newport, was won by Mr. B. St. John Ackers, Prinknash Park, Painswick, Gloucestershire, with "Lord Wilton."

WE understand that "Spratt's Patent Food," which was given successfully to the dogs at the Birmingham National Dog Show this week, will also be used for feeding the dogs at the Kennel Club Show, which commences at the Alexandra Palace on the 9th December.

#### FAMOUS POULTRY YARDS.

KNIGHTON VICARAGE—THE REV. H. M. AND MRS. RICKETTS.

(Continued from page 440.)

WE must proceed from the chicken lawn where we paused. We did not, however, walk once straight through this range of yards in order as we have described them, but returned again and again during a pleasant two-days visit to admire their admirable contrivance and pretty inmates. Hence we passed through a door in the stone wall which backs the yards to other runs, of a kind which all fanciers find useful, but which do not pretend to be ornamental. Here in a back yard were many hens of many varieties, good layers of eggs, and foster-mothers of more treasured chickens. Close by, in a wired enclosure, were a party of cocks, about twenty in number, all running together. The moult always has a somewhat subduing effect on the spirits, but still they struck us as being the most extraordinarily happy family we ever saw. Among them we specially admired a White Minorca, nearly

through his moult, sprightly, and in trim condition, and a Partridge Cochin deep and densely fluffy. Through a passage we came to another yard, and here in another wired enclosure were more cocks of many kinds, and hard by a most necessary adjunct to every large poultry establishment—the hospital. It is a dry building with lots of pens against the wall, and can be heated, when necessary, with a little gas stove. Next came the sitting-house, a room, as it should be, devoted entirely to its important purpose. We particularly liked the construction of some of the sitting nests. They are simply boxes without bottoms, perforated with holes to admit air, and one side opening on a hinge serves as a door. The hens thus sit on the ground. The advantage of such boxes is that they ensure moisture from below to the egg and absolute privacy to the hen, while they can easily be thoroughly purified.

We must now attempt, however inadequately, to describe the other great range of nearly fifty runs, the special care of Mr. Ricketts, devoted to the larger breeds. We have said that on the right of the entrance a grass field is seen sloping away eastwards from the garden lawn. About this they are ranged. Most of them open into the field, but as at the time of our visit their inmates were moulting, when fowls require less range, the field was tenanted by troops of pullets of many kinds. Among them were a number of Buff Cochins, good in shape and fluff, chiefly of Tomlinson's strain. We helped to select a promising half-dozen of these for next year's stock. On the left, as one goes down the field, are a long double row of yards, the front ones opening into the field, the back line accessible from a path behind. Being intended for large fowls, these are, of course, far larger than the gravelled range before described, and all are of grass. They were once larger still, each having consisted of two of the present runs. We should have been inclined to have them so, knowing well the great difficulty of keeping small grass runs fresh and green, but the growth of the establishment and the multitudes of the breeds kept necessitated their division into two rows. In every one is a comfortable dry house. Among their inmates were Cochins of all kinds, Dorkings of all kinds, and many others too, but our memory fails us to record the order of them all. Beyond this double row, still on the left, is a very large house; in the back part of it roost the troop of several dozen pullets which we have seen running over the paddock. In front are some half dozen small runs, most useful places for single cocks and moulting birds, each with a separate roosting place inside the house. Hence at right angles to the double line of yards runs off towards the right another range, cutting off the smaller end of the paddock. All open into the front paddock for the daily exercise of the birds when necessary, but their grass runs are hardly so large as the others, and would, we think, be better gravelled. Here were Andalusians and Leghorns, Game of various kinds, and Hamburgs, and Derbyshire Redcaps, fine strong-looking birds and peculiarly rosy for the time of year, somewhat like large Golden-spangled Hamburgs; and a pen of curious Eastern fowls brought from Constantinople, of gold colour and brown with small dark crests.

Through a gate near the large house, which we left on our left hand, is yet another row of houses and runs all on the same plan, and all opening into the other part of the paddock behind the last-named row. Here were Spanish, Langshans, and more Cochins. But we need not enumerate all the breeds; to do so would simply be to catalogue the known breeds of larger fowls. We had seen cursorily the whole of this marvellous establishment; it remained to inspect more carefully the inmates of many a pen, especially some fine Buff Cochins in the back row of the double line of runs, so we turned our steps towards the garden by a pretty path between them and a shrubbery, whence rapidly descends a precipice towards the river Teme below, called the Tees by a printer's error in the former part of our description. We had had a charming sight, one not to be enjoyed elsewhere in England, we believe. We should advise our fancier friends, who have the chance, to ask the favour of a view of the famous Knighton yards.—C.

#### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at Bingley Hall, Birmingham, on Monday, the 28th November. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Rev. W. Serjeantson, and Messrs. A. Comyns, A. Darby, L. C. C. R. Norris, and E. Pritchard.

CLUB SHOW.—The proof schedule was revised, and classes were added for Black Cochins, French (any other variety than Houdans or Crève Cœurs), and Duckwing Game. The list of Judges with the classes upon which they are to adjudicate, submitted by the Secretary, was revised and finally settled.

Messrs. A. Comyns and H. Radclyffe Dugmore were appointed

Poultry Club Stewards to be present and supervise the arrangements at the Show on behalf of the Club, and it was arranged that neither of these gentlemen should take part in the competition.

The number of cups to be offered was also discussed, and it was decided that there should be thirteen for the poultry classes, varying in value from five guineas to two guineas, and to be given in addition to the money prizes in all cases.

SHOWS TO BE HELD UNDER CLUB RULES.—Communications from the Secretaries of the Uttoxeter, Hednesford, Waverley, and Gosforth (Newcastle-on-Tyne) Shows, stating that it was intended to hold these Shows under Club rules, were read, and subscriptions were granted in aid of their respective funds.

DISQUALIFICATIONS.—Three cases of trimming were brought under the notice of the Committee. Directions were given to the Secretary to ascertain further particulars, and the consideration of these matters was postponed until the next meeting.

MEETINGS OF THE COMMITTEE.—It was decided that in order to facilitate the election of those desiring to avail themselves of the privileges of membership of the Club at the forthcoming Cambridge Show, two meetings of the Committee should be held in December, the first on Friday the 9th inst., and the second on Friday the 16th inst., the latter date being the latest at which an election would give the benefits of membership at the Club Show.—ALEX. COMYNS, Hon. Sec., 47, Chancery Lane, Dec. 1st.

#### BIRMINGHAM SHOW.

THIS great Show, which alone contests with the annual meeting at Sydenham for the premier position in importance and numbers, commenced on Saturday last. The entries both in poultry and Pigeons were more numerous than ever, the former numbering 2412 pens, and the latter 903. Birmingham, being eminently a practical place, naturally gives more prominence to the poultry than to the Pigeon department, and it is chiefly in the latter that the numbers at Birmingham fall short of those at the Palace.

At Bingley Hall even a larger number of familiar faces are to be seen year after year than at the Palace; and if some of the old ones are, alas! wanting, there are many younger ones which are gradually becoming sufficiently familiar to fill up the blank.

Never within our recollection has the quality of the birds in both sections been better than it is this year. There may be a falling-off in some classes, but the average taken over the whole Show is far above what we have been accustomed to.

Brahmas still hold the first position, as they have now done for some years, Sir Henry Thompson's champion £60 bird coming first among the cupwinners. The first prize for cockerels again goes to Stoke Park, though we can hardly say that we like the winner quite so much as his yard mates at the Palace, one of which has here gained second for his new owner. Mr. Percival won the cup with a hen which we have not seen this season, but which much reminds us of his winner of last year. Mr. Norris's winning hen at the Palace had here to take second place, although we much doubt whether she will not regain her lost position when she has fully moulted out. In the pullet class public opinion has for once had its effect. Never before do we remember Mr. Teebay to have given way to the popular voice, but he seems here to have recognised the force of the familiar adage, and has completely upset his own awards at the Palace. The first-prize pullet came from the yards of the Rev. T. C. Peake, and is nicely pencilled and of clear grey colour; but it seems to us that if Mr. Teebay desires to restore the Brahma hens to what they once were he must go more for size and shape, and not let pencilling, even though of so excellent a type as that we have here, have such undue weight. There were many excellent pullets in the class of good Brahma type, and amongst the prizewinners we especially noted the fourth of Mr. Norris as being large, shapely, good in colour, and nicely pencilled, though hardly quite out yet. She must surely have her revenge later.

Mr. Leno's awards in the Light Brahma classes were generally well received. Here Mr. G. H. Wood took premier position both in cocks and cockerels, closely pressed in the former, however, by Mr. Norris and Mr. Percival, and in the latter by Mr. Haines and Mr. F. S. Clarke. There seems to be some division of opinion as to the correct type of these birds, and in our views Mr. Leno's inclines rather to give undue prominence to birds which are very short in leg and rather of a Cochin stamp. In the hens and pullets Mr. Norris and Mr. Haines were respectively first, the former taking the cup with his well-known pullet of last year. Messrs. Birch and Mr. G. H. Wood respectively stood second in each class. Mr. Norris's hen is a lovely bird, but even her owner pronounces her as rather too much of a Cochin for his fancy. You can hardly have a Brahma hen too short in the leg, but then so much roundness and extreme fluffiness which are characteristic of a Cochin are hardly desirable. We could not entirely agree with the pullet awards, and thought several in the class better than the first.

The Dorkings were more numerous and better in quality than last year. We think they are rather hardly treated in the matter of prize money, and would suggest to the Birmingham Committee the advisability of increasing the number and amount of the prizes. A first prize of £2 and second of £1 is hardly adequate when the entry is 8s. per pen. In the Coloured birds Mr. Butler Smith, Mr. Cranston, the

Rev. H. R. Peel, and the Messrs. J. A. and M. F. Smyth, were the principal prizewinners. In Silver-Greys Mr. Cranston carried everything before him. He is a fancier who will put the Dorking breeders on their mettle. He seems to be able to get the Silver-Greys almost equal in size to the Coloured. In the variety Dorking classes Mr. J. E. Pilgrim, Col. Logan, and the Countess of Dartmouth and Mr. O. E. Cresswell were the most successful exhibitors, the prizewinners being, with the exception of those from Patshull (which were Cuckoos), Whites. There is room here for some improvement in size, but this, we believe, is a difficult point to get.

Cochins were numerous and good, especially the Buffs, where Mrs. Barton, Mr. H. C. While, Mr. G. H. Proctor, and Mr. Henry Tomlinson were the winners of cups or firsts. Mr. While's winning cockerel was, however, closely pressed by Mr. Stanton's second-prize bird, which, though hardly so even in colour, had more size and width. Mr. Tomlinson's pullet was easily ahead in a class of fifty-five. We noticed in her a peculiarity which we do not remember to have before observed—namely, that all the feathers on her back and saddle were edged or laced with a fine golden fringe. This, though a little spoiling the uniformity of colour, had a very charming effect. The Partridge birds were not so numerous as the Buffs. The contest for the cup for cock or cockerel between Mr. R. P. Percival's old bird and Mr. G. H. Wood's cockerel was somewhat close, but, as we think rightly, resulted in the coveted honour going to the latter. In hens and pullets there was again a want of decision on the Judges' part as to type. It is certainly time that Partridge Cochin breeders had some means of knowing what they are to breed for. Mr. Southern was first with a finely marked hen, and took the cup with a pullet of somewhat similar stamp, thus almost completely reversing the Palace awards. In White cocks or cockerels Mr. A. Darby deservedly had his old place with grand birds, and only yielded one point in hens and pullets respectively to Mr. Percival, whose large, shapely, and clear-coloured hen took the cup, and to Mr. Chase, whose pullet stood first in a nice class. Blacks were not very numerously represented. Mr. Darby, Lady Gwydyr, Mr. R. S. Williamson, and Mr. Lurgen dividing the honours amongst them; the lion's share, however, falling to Mr. Darby.

Langshans do not seem to make any great strides in popular favour or to show any great advance in quality. The cup here went to Mr. R. H. Bush with a cockerel.

In Malays the Rev. A. G. Brooke and Mr. G. Burnell were each awarded cups; the former for a fine cockerel, and the latter for a hen.

The French breeds were only moderately represented as to numbers, the Houdans being most numerous. Mrs. David Lane was here most successful, taking the cup and a first with fine birds. In Crève-Cœurs Dr. Lloyd, Mr. Cannan, Mr. Jackson, and Mr. J. T. Calvert all showed excellent birds, and to the former was awarded the cup.

Spanish seemed to us to show rather a falling-off in quality of face, roughness and coarseness of texture being somewhat prominent. Mr. J. Bolton and Mr. William Croke each had a cup, the former also taking first prize, and a similar honour being awarded to Lady Allsopp.

Andalusians were well represented, and seemed to be advancing in popular favour. Mr. Brooke and Mr. R. A. Boissier had here each a first.

The white carlobe seems to be a particularly difficult point in the Leghorns, and we are not sure that undue prominence has not been attached to it. They are essentially laying birds, and it seems a pity that they should be spoiled as such by undue striving for what after all is a minor point. Mr. W. Bradbury here deservedly carried off all the prizes.

Plymouth Rocks, under the auspices of the Club, seem to be making rapid strides. There were eighteen entries, and though to our eyes they do not present many signs of beauty, still their first-rate useful qualities should recommend them to general notice. Mr. Stevens here stood first, followed by Mr. Bradbury.

Minorcas were not numerously represented, although a cup was offered for them. This was awarded to Mrs. Baskerville.

Polish had a very liberal classification, but did not come out in very large numbers, the average for the twelve classes being only eight. The quality was, however, good, except that we did not like to see quite so much white in the crests of the Golden birds, and we think that there is a tendency to carry the plucking of the black feathers from the front of the crests of the White-crested Blacks to an extreme. The cup went to Mr. C. H. Huish; and Mr. Rawnsley, Mr. Unsworth, Miss B. Beldon, and Mr. G. C. Adkins were also winners of numerous prizes.

In the Sultans we seemed to recognise the hen in Miss Beldon's prize pen as being the same large-crested spurred hen that was shown by Mr. Atkinson at the Palace, and previously by Mr. Beldon elsewhere. She is of first-rate quality, and well worthy of her honours, to whomsoever they may be justly attributed.

Mr. Darby was again to the front in Silkies, and Mr. O. E. Cresswell here showed a nice pair of Japanese Silkies which were highly commended.

The Game classes were so numerous that we cannot pretend to go into them in detail. Captain Heaton's old Black Red, which he claimed from Mr. Lyon last season at £100 10s., took the prize for the best Game cock in the Exhibition, and also as a matter of course Messrs. Spratt's silver cup for the best Black-breasted Red, cock or cockerel. Mr. Lyon was a second time successful in carrying off the challenge cup, value fifty guineas, for the best bred Black Red cockerel. This is the second consecutive season in which he has

gained this distinction, and he has but to add one more to the list of his triumphs to become the permanent owner of this coveted piece of plate. The £30 challenge cup for the best Black Red pullet, which also fell to Mr. Lyon last year, was this year wrested from him by Messrs. J. A. and H. A. Staveley. The winning of these prizes under such a judge as Mr. J. H. Smith, and in such classes, is sufficient evidence of the excellence of the birds to which they were awarded, and we need not comment further upon it.

Aseels still seem to find favour amongst their supporters, Miss Mortimer easily holding her own in both classes.

Hamburgs were only moderate classes as to numbers, but were generally good in quality. The cups went here to Mr. James Long and J. W. Kelleway for Blacks, Mr. William Cowan for Golden-pencilled, Mr. Caleb May for Golden-spangled, S. Fielding for Silver-pencilled, and Mr. H. Beldon for Golden-pencilled birds of the high quality which these exhibitors' birds usually attain. It seems a pity that the prizewinning should be here in the hands of so few, but we hardly see how this can be avoided.

In the variety class Mrs. Muir deservedly took first with a fine pair of Scotch Greys; second went to Buff Polish, and third to La Flèche, both good pens. The Eymore Blacks again caught Mr. Burnell's fancy, but this time only got a high commendation.

The cup for Bantams other than Game was awarded to the Rev. W. Serjeantson with a beautiful pair of Sebrights.

A flagrant case of attempted fraud was discovered in the White Bantam class, where the birds of Mr. Sam D. Rhodes, to which a prize had been awarded, were disqualified on account of false sickle feathers having been inserted in the cock's tail. This had been so skilfully effected that there was nothing in the appearance of the bird to excite the slightest suspicion, and it was only through the fact that a Bantam breeder who had observed the same bird at the Crystal Palace with very short sickle feathers being surprised to see the length which these feathers had now attained, drew the attention of some other fanciers to the matter, that an examination was requested and the insertion of the feathers discovered. We trust that the just punishment which followed the discovery of this case will be a warning to others not to attempt such practices, which are a disgrace to the poultry fancy, and have occasioned the retirement from its ranks of many honourable men.

Game Bantams were not nearly so numerous as at the Palace, which was easily accounted for by the classification. Mr. John Filkin took the cup with a Black Red cock, and the other three first prizes were awarded to Mr. J. R. Fletcher.

In the variety Bantams the Countess of Dartmouth headed the list with a beautiful pair of Japanese.

Ducks, Geese, and Turkeys were all numerously represented. The cup for Aylesburys or Rouens went to a fine pen of the latter, shown by Mr. P. Unsworth; that for Pekins to Mr. Henry Allen with a very large pair of the true type. These birds seem rather to be driving the Aylesburys out of market, which is a pity. There is plenty of room for both, and it is an undoubted fact that the Aylesbury are much superior in table qualities to the Pekins, the great size of which is more apparent than real.

The cup for Fancy Ducks was awarded to Mr. Robertson Gladstone with a beautiful pen of Mandarins. The extended classification here did not seem to create as good a competition as one would have wished, there being only three pens in the classes for Mandarins, Carolinas, and Call Ducks respectively, while the Any other variety class had but five entries. It seems a pity that fanciers should not avail themselves of the opportunity afforded by the liberality of the Birmingham Committee in giving classes for these beautiful birds.

## REMARKS.

- 20th.—Fine dry day, with sunshine; slight rain at 9.30 P.M.  
 21st.—Stormy morning, high wind and rain, afterwards fine and bright; rain in evening.  
 22nd.—Fine, bright, and mild.  
 23rd.—Damp in early morning, afterwards bright and fine; sudden gust of wind and sharp shower at 4.30 and 6.45 P.M.: starlight night.  
 24th.—Overcast and dull; high gusty wind, rain 10.30 P.M.  
 25th.—Rain and gusty wind during night and early morning, calm later, but dull and rainy throughout.  
 26th.—Very fine, bright, sunny morning; slight rain from 2 P.M., and very heavy gale in evening.  
 A wet, warm, and windy week.—G. J. SYMONS.

## SEASONABLE NOTES ON THE KITCHEN GARDEN.

**T**HE general aspect of the vegetable garden is very different now from what it was in summer, when fine rows of Peas and Kidney Beans ornamented many of the quarters and supplied choice and valuable dishes for the kitchen; but although the season for such is past, there should still be no scarcity of good and useful vegetables. It is not so much great space as good management that secures this, and when every foot of ground is constantly kept filled with what is most wanted it is surprising what a quantity may be had from a moderate-sized garden in twelve months. To do this, however, little will be accomplished by haphazard work. Sometimes crops may happen to come in right, but as a rule they will not; and an over-abundant surplus of produce at one time and little or nothing at another will be the result. A system of cropping must be strictly followed. This is the best way to make kitchen-garden work easy and a constant supply of vegetables a certainty. The weather may bring some crops in before they were expected, or it may retard others; but there is generally something coming in, and there are many ways of overcoming such difficulties, well known to all who give the kitchen garden due attention.

So far this autumn has been most favourable for vegetables. The practice must be bad indeed where there is a scarcity now. Veitch's Autumn Giant Cauliflower is heading as well as it did in August and September, and Veitch's Protecting Broccoli promises to be useful for a long time to come. Other Broccolis are very forward, and will come better in to time than they have done for some winters past if they do not receive a check; and although there is no appearance of this now, it may come soon, and for this all should be prepared. It is the tender centre of the Broccoli which requires to be most protected, and when they are heeled over on their sides the large outside leaves cover and protect the hearts. When Broccolis are lifted and laid on their sides many of them often receive a check, and the heads often come small in consequence; but their full size is not seriously interfered with if they are heeled over where they grow. This is done by taking a small spadeful of the soil from one side of the root and pressing the plant over on this side. Some of the roots may be broken in doing this, but many of them will not, and these will enable the heads to attain their full size. All the plants should be laid in one direction, and those with heads should have the leaves tied over the top if frost is expected. Taking them up and placing them in sheds should be the last plan, as they often shrivel there, and then flavour is lost. After this time large

heads should not be desired; small heads are more easily protected, and most valued in the kitchen and dining-room.

Our earliest-sown Brussels Sprouts have succeeded remarkably; but those sown very late, which we thought might come in late in spring, seem slow in swelling, and probably they may not be very satisfactory, so that I would advise all who wish to have fine sprouts now and for the next four months to sow early. February and March are, we find, the best months. Many of the large leaves on the stems are now withering, and they should be removed, as they are liable to make the sprouts decay. To avoid this we have taken all the side leaves from our plants, and the buttons and the little Cabbage-like growth at the top are all that remain. We always find this answers well, but the very latest or half-grown plants are not touched until spring. The new varieties of the vegetable which are being introduced do certainly produce much larger sprouts than the old varieties, but their size is their only recommendation, as they are not so neat on the table as the small marble-like knobs that were solely grown at one time. In flavour, too, the larger are not so good as the others. Their colour is mostly white, not green, and the large are much more tender than the small. With us the new varieties have produced very large sprouts at the bottom, and they taper to the top, but the old Dalkeith variety has its stem covered with sprouts all of similar size, not crowded together, and we know from experience that this sort remains uninjured through all changes and extremities of weather.

Winter Spinach, always so useful and easily grown, is making more growth now than we have seen it for some years, and care must be taken that it does not become crowded. The large outside leaves should be removed before they become yellow, and an open space must always be seen between the rows.

Some of our most promising autumn-sown Cabbage were much injured by the great storm on October 14th, but after that we planted more, and the open weather has been so favourable for them that they are quite as early as we desire to have them for cutting in April. Taken all the year round I know of no more useful green vegetable than Cabbage, and they are well worth that attention required to produce a constant supply. The plants we placed out last autumn and cut from in spring are still in the ground. The small heads we have had from them have been very numerous, and there are plenty of the stems with from six to a dozen heads now. They will all be left in the ground until Potato-planting time in the spring. Another favourite Cabbage crop is that sown in July, as the plants are now hearting as fine as we ever saw them in April or May, and if the weather remains mild young Cabbage of the finest possible quality will be cut at Christmas and the new year. Coleworts are often sown to come in at this time, but we do not consider them so good in flavour as the Cabbage.

The extra rainfall we have lately had has not benefited the Parsnips. The crowns are decaying, and may continue to do so if they are not taken out of the ground. This is the best plan to adopt with part of the crop, and if they are stored in ashes or sand most of them will remain good. Savoys are, as usual, heading well, the hardiest being Green Globe, and the largest Drumhead, which is rather too coarse for the dining-room. Nearly all our winter Greens are planted between Potato rows, and at the present time there is hardly a square yard of unoccupied soil to be seen in five acres of ground. If the weather remains mild we shall have too many Greens, but

if it comes severe many may be destroyed, and still there will be enough.

At one time we were only anxious to have the ground cleared and turned up in autumn to be benefited by the frost in winter; but although this no doubt does much good to heavy soil, a kitchen garden properly worked soon becomes friable enough, and does not need to be turned up to the frost continually.

As to frost killing grubs and vermin, I think this must be a mistake, as all have been more plentiful this last year or three seasons than we ever saw them before; and this is not in gardens alone, but in fields as well, where farmers have been troubled much by wireworm, Turnip fly, &c.

As ground becomes vacant now it may be turned up roughly, but no crop should be destroyed simply to make room for digging. Lime should be dug in now and at any time throughout the winter, but not just before cropping. Gas lime is an excellent insecticide if it is dug into the ground some months before the crop is put in. Carrot ground is kept thoroughly clean by it, and Onion grubs or flies are seldom troublesome where it has been used. One small spadeful to each two square yards is sufficient. Except for Potatoes, Carrots, Parsnips, and similar roots, manure is never dug into the soil until the crop is about to be planted. To dig the manure in the soil now for Onions, which will not be sown until March, is to our mind wasting the best part of it; but if it is only forked into the surface of the soil a day or two before the seed is sown the crop will have the full benefit of it at the time they want it most. The same remark applies to many green crops.

Any seeds saved this season should be examined frequently, as some which may not be thoroughly dry or matured may cause the others to decay. Many early Potatoes are sprouting fast in the coolest place we can find for them, but they will not be allowed to grow very far and waste their energies before they are turned over and every growth rubbed off. This is the only way to keep Potatoes in good condition.—A KITCHEN GARDENER.

#### PLANTS FOR INDOOR DECORATION.

As it has become a common practice in both large and small establishments to decorate the house with exotic plants, and gardeners are often puzzled to keep up a supply which shall be creditable to themselves and appreciated by their employers, it would be advantageous if we could induce some of those who have had large practice in such work to give us the result of their experience; for it is of the greatest importance, especially where the space is limited, that we should know what is best to grow for the purpose.

As decorative plants I think the *Dracænas* surpass any others. Their forms and colours are so varied, some having broad upright leaves of stout texture while others are light and graceful, and varying in colour from the most delicate green and white to the deepest crimson and almost black. I will take them first, and enumerate, so far as my experience goes, those varieties that best endure the dry atmosphere of a heated gas-lit room. *D. terminalis* has always been a great favourite with me; for although not quite so graceful in habit as *D. Cooperi*, it is quite as bright in colour, and where the latter will stand one night the former will stand a dozen. *D. Guilfoylei*, like the former, is also fine for rooms, and having light green and white striped foliage it is a good companion for it. During last winter's frost I had a specimen in a cold passage opposite a window; it was frozen until the soil was hard. Of course I thought the plant was killed, but it is still alive and thriving, which proves it to be quite hardy. The old *D. ferrea* is also very useful and quite distinct, being almost black. Of the dark green-leaved forms *D. nigra* is most useful. *D. grandis* and *D. Baptisti* soon become spotted and lose their lower leaves, so I cannot recommend them. The same may be said of *D. Hendersonii* and *D. amabilis*. The old *D. gracilis* stands well, but *D. gracilis marginata*, although such a handsome table plant, will not endure gas. I had a plant of it which lost thirteen leaves in two nights. *Dracæna australis* and its varieties are good. *D. regina* does not stand well, and as it is reported to be the parent of so many of the new varieties it remains to be seen how they will behave. I have also found the following to be useful plants for indoor decoration:—*Curculigo recurvata* should be largely grown; it stands well, and is one of the best of table plants. *Pandanus Veitchii* is another of which we cannot have too many specimens. Young plants of *Ananassa sativa variegata* are handsome for the table. *Panicum plicatum* and *P. plicatum*

*variegatum* raised from seed and grown quickly are ornamental and useful.

Crotons are also good, but, like *Dracænas*, some are better than others. We use the old *C. angustifolius* and *C. variegatus* in quantity. The one which I have found to stand best of all is *C. irregularis*. It will remain in good condition twice as long as any other Croton that I have tried. There are other good and handsome plants, such as the choice *Aralias* and *Palms*, but as they cannot be propagated in such numbers as the foregoing, they are used more sparingly.

Let me advise those who have much indoor decoration to do, to employ *Selaginella* to cover the surface of the soil in the pots, and to hide the rim of the pot. It is a notable fact that at the late International Exhibition at Manchester, of the twenty collections of table plants staged for competition, the first and second only had the soil covered with *Selaginella*. I should be glad if some abler writer than myself would take up this subject, and I am sure the readers of the Journal would be greatly profited by it.—WM. PLANT.

#### FRUIT NOTES.

BEFORE the interesting scraps about fruit close, I should like to say a word respecting an Apple that is much grown in this neighbourhood (Ashrood Bank, Worcestershire), called the "Woodsill." No such name appears in any catalogue or fruit list that I have seen, therefore presume it must be a "local" sort. No Apple, it appears, is so much grown except *Blenheim Pippin* as a standard for orchards in this district. The trees are not so liable to canker as most sorts. *Ribston Pippin* is, perhaps, the worst; many trees here were so disappointing that they were headed-down and grafted with *Woodsills*, which are now bearing good crops annually. The habit is good, forming abundance of fruit-bearing spurs; fruit good for culinary or dessert, with plenty of colour; in season from September to December; is highly scented. Their presence can always be detected in a room.

I have also a favourite Pear which cannot be found in any list, known as "Green Beurré." This is a sure bearer, of good habit, useful for dessert or baking, very juicy and sweet, and with a little management may be had in use from October to April. Many kinds of Pears have been tried here and found wanting as croppers, and have had to succumb to the grafting-knife to make room for *Green Beurré*. If any reader can oblige with the correct names (if they are known), with any remarks, I shall feel obliged.

The uncertainty of the fruit crop in this district was very singular this season. In some cases, and I am pleased to say mine for one, there has not been so good a crop for many years, while only short distances away it has been almost a failure. In one case a person who rents about twenty acres of orcharding, and who expects to grow several hundreds of pots, told me he had not a pot of fruit in all his orchards. In another case a neighbour who has not probably half as much orcharding, put up, it was estimated, about 150 pots alone of *Blenheim Pippin* Apples, exclusive of windfalls, which he sold for 7s. 6d. per pot; that he considers half a crop, having previously stored three hundred pots in one season, or about 450 bushels. He plants no other sorts now, and the fruit, I hear, is worth 12s. per pot (72 lbs. nett), and cider at the same place is being sold at 1s. per gallon. I mention this in comparison with the statement of "A SURREY PHYSICIAN," on page 466.

I am pleased to see the subject of planting more fruit trees in fields advocated, both in hedgerows and also in the open ground. I have often wondered that land-proprietors do not plant more extensively, which would in a few years certainly enhance the value of their properties; and, apart from the value of the fruit, what looks prettier than an Apple orchard in full bloom, with the various tints of the different sorts? One such sight I have in my mind when visiting Canada a few years ago. It was in the beginning of June, when everything looked lovely from the top of the Montreal mountain; and looking down almost any way, except into the centre of the city, or into the broad St. Lawrence, Apple bloom met the eye, intermingled with the various delicate tints of green. No fancy carpet bedding ever pleased me like the straight lines of Apple bloom in the well-stocked orchards below, some of the fruit from which was probably destined to compete in our own country with local growers, after being brought thousands of miles; whereas in some favoured localities Apple trees thrive so well that they ought to be planted by the thousand at little outlay, and Nature would certainly do her part to provide a crop to compete with American fruit under such disadvantages as freight and various other expenses.

A cheap and simple protection to young trees from cattle I ventured to send, and which appeared in the Journal some two

years ago, consisting of a rough Briar or two and bound round top and bottom with wire. I have just renewed mine which had been on three years, and I found the trees which had previously been mutilated and bruised fast closing over.

Bullfinches should now be caught before they attack the fruit buds. I may be excused from repeating this advice, which I advocated last autumn, and I do not remember to have seen any grumbling since. I hope others were as successful as myself, as I caught about thirty, and my buds were almost untouched. One bullfinch only appeared to have been left, which, over a district, could be tolerated. The last I heard of any of the birds was that a pair were transported to Canada, and were there considered worth about 5 dols., or about £1 sterling. Would that they had many at the price, and that our gardeners could have the proceeds of the sales.—J. HIAM.

[The Apple above referred to is no doubt a local variety, and excellent for culinary purposes. The Pear is, we believe, the Muirfowl's Egg, an old Scotch Pear, hardy and productive as standards.—ED.]

### THE UTILISATION OF SEWAGE.

"YOUR letters in the *Journal of Horticulture* have interested me very much. You say the application of house sewage is still an unsolved problem. Has it not been partly solved by the earth closet system? Any good work on agricultural science would make some reference to 'double silicates,'—*i.e.*, to clay, and its power of combining with other fertilising matters. In the small town from whence I write nearly every inhabitant adopts the earth closet system, but it is evidently not understood by many who use it, and it is consequently not so effective as it might be. The idea with many seems to be that any earth or ashes will do to use in these closets, whereas nothing has the proper chemical effect except a clay of some kind. Of this a small quantity, dried and pulverised, is most effective in forming the desired chemical combination, whereas any other material must be used in much greater quantity, and then it is only a 'smothering' and not a deodorising process. I believe kainite has been made practically useful in a similar manner—*i.e.*, sprinkling it on floors of stables, dung-heaps, &c. Please make what use you like of this, as I should like to see some remarks from you on the subject."

The above communication we received through the Editor from "a teacher of a class in the principles of agriculture in connection with the Science and Art Department." The writer wishes to see some remarks by us on the subject, but, as a matter of fact, we have very little practical acquaintance with any earth closet system. However, there cannot be any doubt but that the problem of how to utilise the present wasted sewage must be solved, if solved at all, on the lines indicated in the above letter. And such a system carried out properly ought to pay. For manures practically the same we annually spend enormous sums; for water to carry away the sewage an enormous amount of wealth has been thrown away, and worse, for not only is water and sewage alike lost, but rivers are polluted, and volumes of deadly gases generated, ready, wherever admitted, to produce serious diseases.

There is no reason why a single sixpence should be sent out of the country for manures; for that which is produced at home, if utilised, would be more than sufficient to double our present crop and maintain our fields, even the poorest of them, in a state of fertility. Within twenty miles of the second city of the empire farmers reap crops hardly half of what they ought, just for want of what makes one of the most beautiful rivers in the country a sink of evil smells. After the drain on our resources for foreign manures and foreign grain tells a little harder on our commerce and our agriculture, possibly we may reform; at present there is an idea abroad that we can well afford to waste as we now do.

At the close of the paper in which appears the sentence referred to in the above letter, we mentioned that trees stunted through poverty were benefited in a remarkable manner by an application of sewage. It may be of use to some of your readers to give a few more remarks in regard to that particular way of applying it. We intended saying something on its use in the vegetable garden by-and-by, but having said this much it may be not out of place to say what value we put upon it in the present place.

Our soil here is peculiar. It is naturally not over 4 inches deep, and under that there is a rusty impenetrable subsoil. Being so thin, it is, of course, very poor. Trees planted on such soil, where the grass is allowed to grow, make no progress, for the grass takes possession at once of the whole available food supply. It took us two years to find this out after we had planted belts for shelter round this place. After finding it out, how to remedy it took us another year to solve. Near us there are large foun-

dries, and in these there are closets conducted on the earth principle. For earth, waste sand from the moulding boxes is used in no stinted quantities. This we found we could have for the carting. A score or so of cartloads were spread over a portion of the plantations and would have dressed the whole. This was in winter. But our employer promptly stopped the proceedings on the score that a plague would be raised. In spring the grass soon covered the dressing, and the trees so treated grew away at once. Next year they made a surprising growth, and as neither smell nor plague followed we had orders to dress the whole of the ground. The results are eminently satisfactory, and for those who may have trees starving, which are wished to grow up for shelter quickly, we here mention this.

We recently saw a gardener lifting an avenue of Limes which had made no progress, though apparently on fairly good soil. The ground was being trenched deeply, and very liberally mixed with ordinary town manure—*i.e.*, street sweepings. This by the boat-load—a canal passes near—was very cheap, and the trees treated to it, hitherto stunted and starving, are now beautiful specimens, growing rapidly and rooting securely. Those whose trees are not growing as they would like, and who are near enough towns to secure such manure as we have named at reasonable rates, would do well to try either or both the above modes of producing such growth as will gladden their eyes; and those who are planting, or are about to plant, trees in small or new places, where a rapid growth is sure to be a desideratum, had better take the hint. Stable-yard manure is much too expensive in many places for such a purpose, and in many districts, indeed, cannot be had; but there are other natural manures besides that, and sometimes one is none the worse for being reminded of the fact.

For the vegetable ground it is also valuable, especially on poor thin soils, or when other manure is scarce. All the Cabbage tribe thrive on it exceedingly, and for Rhubarb nothing comes near it. On ground intended for Cabbages, Brussels Sprouts, Cauliflowers, &c., it is best spread out on the surface and allowed to be bleached in by the rain. It is thus better diffused through the soil than when dug-in at once, and if the soil has been previously dug all that is needed in spring is a light fork-over. The roots at once reach their food, and the result is excellent.—SINGLE-HANDED.

### AREAS OF GLASS STRUCTURES.

WITH reference to your correspondent's comments upon the remarks in my lecture at the Crystal Palace, as reported on page 473 of the *Journal of Horticulture*, had the whole of the remarks

Fig. 81.

been published, which was naturally impossible, it would have been found that my statement that "with the same width and the same pitch a span and a lean-to roof contain the same area" referred most clearly to superficial measurement only, as illustrated by the annexed figure, in which a lean-to, a span, a three-span, and a ridge-and-furrow house of the same length, width, and pitch of roof, each contains precisely the same superficial roof area. See also pages 49 and 50 of my work "Horticultural Buildings." Cubical contents, the measurements relating thereto, and their uses were duly made prominent in another part of the lectures.—F. A. FAWKES, Lecturer at the Crystal Palace School of Gardening.

### DENDROBIUM PIERARDII.

THE above-named plant does not produce flowers at all equal to many other Orchids, not even equal to old *D. nobile*, but there is hardly one more easily grown or more profusely floriferous. More than that, it may be grown in any plant stove and occupies no stage room, for if it is hung near the glass in a basket will produce a fine display of pretty flowers. These are its recommendations, and as it has never been recommended, so far as we are aware, in these pages, we venture to do so.

An engineer on board a steamer secured our plants when in Calcutta, and they arrived along with a harrelful of others mostly useless. Being rather crowded we put the plants two, each with three or four breaks—into mahogany baskets (mahogany does not decay readily, and can be had anywhere), 5 inches square and deep, in a mixture of half charcoal, half sphagnum. In due time the plants commenced growing, and we kept the baskets damp, and were rewarded with pseudo-bulbs quite as stout and

quite as long as the native-grown ones. When the growth was made up we kept the plants rather dry. This treatment caused the pseudo-bulbs to become firm. By February many flower buds were showing. We then began supplying water again. All that was done that year was to remove any old moss and supply some fresh. This has been repeated every spring, and they still occupy their original baskets. They have increased their shoots every year, and the pseudo-bulbs, at first a foot in length, are, many of them, about three, and nearly as stout as those of *D. nobile*. Last spring we had over two hundred flowers, each fully 2 inches in diameter on one plant. Occasionally we dip the baskets in a pail of very weak liquid manure, otherwise they have had only clean tepid water. The treatment in regard to moisture has been the same as the first year.—A. H.

#### THEORIES IN VINE CULTURE.

IN my first paper on this subject I unfortunately omitted to give the distances at which I should plant Vines intended for a permanency, and this to a certain extent misled both opponents and supporters of the system I advocate. On page 452 I mentioned preferring to plant supernumeraries in the body of the house and against the back walls, supporting the former with stakes and the latter with wires, good crops resulting in both instances. In the last vinery I planted the permanent Vines were disposed under each rafter, this admitting of a lateral spread of a trifle over 4 feet. Now, I ask, is not this if well filled, but not crowded, with fine foliage sufficient to meet all the requirements of the young Vines?

In support of his arguments in favour of unrestricted growth Mr. Bardney quotes a description of a remarkable house of Grapes grown in his neighbourhood, and I may point out several good houses of Muscats and other Grapes grown on a different principle. It appears, however, those Vines, the laterals of which are allowed "almost wild extension," are fourteen years of age, and, what is noteworthy, the growth is encouraged at the base more extensively than at the termination of the rods. This is very different to the practice of encouraging wild growth in young Vines.

Mr. W. Thomson is undoubtedly a great authority on Grape culture, but he is not infallible. Like Mr. Bardney, I wonder he has never found out the unsoundness of the system of growing young Vines unrestricted, thereby obtaining a "thicket of growth," only to be cut down to "within a foot of the sashes." I should much like to know if Mr. Thomson in his present circumstances would resist fruiting such rods as he obtained. If he had done this successfully his opinion would have carried more weight, but as it is I fail to appreciate the relevancy of the quotation. Neither do the weights given of crops obtained by Mr. Bardney support his theory.—W. IGGULDEN.

HAVING read the vigorous replies from two of your most able contributors to Mr. Iggulden's article on this subject on page 420, I have looked over the said article a second time to see what there can be in it to deserve such severe condemnation from such very practical men; and I will at once say, that although there are some of the minor theoretical conclusions and deductions which I can scarcely follow to their full extent, yet I consider the practice therein recommended for young Vines as sound as any that was ever penned, and I had no idea till I read the articles of Mr. Bardney and "SINGLE-HANDED" but that such practice was more general than it appears to be. I have no doubt it will look a little inconsistent at first that one who, perhaps, may be excused for fancying he has done something to popularise what is called the extension system of Vine culture, should take up his pen in favour of what your correspondents are pleased to call the restrictive system, but I hope the inconsistency on my part will disappear before I have finished. Of course the term "extension" is only comparative as contrasted with the severely restricted system. No system of indoor Vine culture can be unrestricted if the Vines are grown liberally; at any rate, I should be loth to state the size of house which an unrestricted Vine would occupy in twenty years under the modern generous system of culture.

For a Vine to cover 700 superficial feet in half a dozen years would probably be considered far enough on the road to extension to please most of your readers, but that has been proved to be a very easy matter, even when a considerable amount of restriction was practised. But Vines no less than children should be "trained up in the way they should go." If they are to be grown like Brambles, let them begin to grow like Brambles in the first place, and I have no doubt they will look very pretty; but as "wild gardening," whatever that curious term may mean, is not our object

in this case, I advise a moderate amount of restriction to be begun consistently and carried out consistently so far as circumstances will allow. For the severely restricted system I have nothing to say, as that will soon be a thing of the past.

Mr. Iggulden asks, Why should we allow young Vines to grow wildly for the first season or two merely to be cut back? I also say, Why, indeed? and your two able contributors have failed to answer the question. There is a certain cheap commodity mis-called "science" which used to frighten me tremendously, in the same way as little children are sometimes frightened by unskilful and naughty nursemaids when they are told "the bogies will have them." This bogie tale, no doubt, often does a considerable amount of harm to weak little minds, and should not be resorted to. Happily Mr. Iggulden and myself, if not yet adults, are getting out of our horticultural babyhood; and although I do not wish to be presumptuous, I may say that this bogie has often been proved to be only a paper one, and is not so terrible to me now as it once was. For true science I have the greatest admiration, but not that sort which is gained by reading a few theoretical books and attending an odd lecture, though these are of incalculable benefit when supplemented by knowledge gained from practice and personal observation.

This "all round" sort of knowledge intelligently applied is my idea of science, and without at least a smattering of it a man's ideas are not worth much. Mere theoretical science is very accommodating when successful practice or even failures have to be explained, but it is often sadly behind when we plodding practical men want a difficulty solved, and as often as not we have to grope our way as best we can, and then when success comes the theorist knows all about it and could have told us before.

We are told by your generally very able correspondent, "SINGLE-HANDED," that science is opposed to the practice recommended by Mr. Iggulden. I beg emphatically to say that science is nothing at all of the sort, and that your correspondent is using the term science, unconsciously, no doubt, for what he supposes to be the right practice because many people follow it. Science does not say you will build up a healthy-constituted man by fattening the child as fast as possible, while it can have comparatively little demand on its muscular or nervous systems; neither does it say that growing young Vines Bramble-fashion, however fast it may manufacture roots, is the system best calculated to promote longevity and fertility.

There is a wide-spread notion that a certain area of foliage means a corresponding amount of storage for future use, but this is sometimes misleading. Foliage which is thin, and which cannot be acted on by the light, is not only useless as regards future storage, but I take it to be positively injurious, inasmuch as it assists to manufacture and circulate crude material which it cannot assist in elaborating. I have no doubt it assists in forming roots—not, however, the kind of roots you would be likely to mistake for those of a Box bush, but those gross roots as large as a small quill, which ramble for many a yard without a fibre, and which generally decay within twelve months of their birth; or if they do not decay outright, the central part only lives, and it has to form a new epidermis suitable to its diminished corpulency. Where such stragglers are known to exist a common garden spade is a very suitable instrument to apply to them, but it must be done some time before the fall of the leaf. It would surprise a good many people to see what amount of root-pruning a Vine will bear if it is operated on at the right time. The practice, however, is not necessary for the purpose of inducing fertility. As with other fruits, light, air, and summer-pinching, with the requisite heat, will always bring that about, but it is well for many reasons to know where the roots are.

Not only would I restrict the growth during the first season as recommended by Mr. Iggulden, but I would go further and treat the Vines more in the style that good pot Vines are grown, thus forming a good foundation at the bottom; and if your correspondents will try this plan and carry it out thoroughly they will find there is no necessity to cut the Vines down as low as is usually done, and that a bunch may be carried with advantage both to the Vine and the proprietor when the former is only twelve months old from the bud. Vines so treated will break regularly up the stem for several feet, and these breaks, encouraged to a moderate extent all the way from the surface of the soil, will do more to enlarge the stems and manufacture suitable roots than would half an acre of thicket-like growth at the top.

I do not consider your correspondents have treated Mr. Iggulden fairly when they make him an advocate for the severely restrictive system. If I understand him he merely recommends some restriction during the early stages of the life of a Vine, and I think it quite possible that in the more advanced stages your

correspondents would find him giving more liberty to the growth than they would consider safe. It appears to me, then, that the inconsistency would be on their side. They begin with the rambling fashion, and then come back to what at any rate I should call rather severe restriction. We begin with comparative restriction, and continue that system till stopped by circumstances over which we have no control, such as the non-elasticity of the sides of the house or the garden.—WM. TAYLOR.

[This article was written before the Journal of last week appeared.—ED.]

I HAVE no difficulty in replying to Mr. Bardney's questions on page 500. As to cutting down Vines as recommended by your correspondent, who appears to grow canes 30 or 40 feet long in

summer and removes all but perhaps 3 feet in winter, thus removing all the best buds, I am asked if I do not do the "very same" in pruning restricted Vines? No, I do very differently. My canes are, say, 9 or 10 feet long, hard, strong, and have produced foliage of great texture, every leaf of which has been a working leaf, as is apparent by the prominent eyes, almost down to the base of the rafters. The best buds are not at the top of the Vines, for those formed there are not hard and dormant but have swelled more or less. They only begin to be really sound and satisfactory at from 18 inches to 2 feet from the top; but to make sure I only retain thoroughly sound wood—I remove, say, 3 or 4 feet from the canes and leave 5 or 6 feet according to circumstances. I have plenty of the finest possible buds left, but he has not by his exhausting system. I remove, say, 30 or 40 per cent.

Fig. 82.—VIOLET PRINCESS OF PRUSSIA.

from my canes; he removes more than 90 per cent. from his. He takes above ten times more nutriment out of his border than I do, while I store twice as much nutriment matter in the canes as he does. My practice is therefore very different from his, and I think more economical. Now to results. Vines so treated in their early stages produced when they were fifteen years old Grapes that won prizes both at the Royal Horticultural and Royal Botanical Societies' shows, and the same Vines, now twenty-five years old, yield Grapes of the highest order both in size of berry and quality; but, owing to the wants of a large young family, twice the number of bunches have to be grown than were formerly needed, and these are of course smaller in proportion: but the Vines themselves are in sound health.

I feel convinced I can obtain more and better Grapes by the plan proposed by Mr. Iggulden, with the aid of supernumeraries, than I possibly could do if I crowded the roof with foliage like a "thicket" and then mercilessly burned seven-eighths of the canes for the sake of a peek of ashes. I can get ashes cheaper than

that, and Grapes cheaper too, than by the exhaustive system advocated.

When Vines are allowed to grow in wild luxuriance all through the season they produce yards of growth and hundreds of so-called leaves, that are certainly not feeders of the Vine, but, on the contrary, robbers. This is a point and, I think, a fact, that "SINGLE-HANDED" appeared to overlook in his scientific reply to Mr. Iggulden a few weeks ago.—AN OLD GROWER.

#### VIOLET PRINCESS OF PRUSSIA.

IN Mr. G. Abbey's notes on Violets, published a few weeks since, I saw no special mention of Mr. Lee's fine new Violet Princess of Prussia. Possibly he may not have given it a fair trial. I have had it in cultivation now for about twelve months, and have quite satisfied myself that it is the finest single Violet in my collection, much superior to Victoria Regina and odoratissima. It has been blooming freely since September, and the

plants are still showing signs of keeping up the supply of blossoms for months to come. And such blossoms! as large again as *Victoria Regina*, beautifully shaped, deliciously fragrant, a fine rich purple colour, and borne on stalks long enough and stiff enough for the largest bouquet. The foliage is very fine and distinct, and the whole habit of the plant all that can be desired. I enclose some blooms for your inspection.—R. W. BEACHEY.

[We never saw such fine *Viola*s as those Mr. Beachey sent, and which we have had engraved. They appear to possess all the good properties of the flower—size, form, substance, colour, and perfume—in a remarkable manner.—ED.]

#### PEARS FOR WALLS.

I DID not endeavour to reply to the article of "A. H. H." on page 468 sooner because I found, with regret, that he was under medical care and absent from home, and I was unwilling to impose on him further labour under those circumstances. I hope he is now well and in harness again.

I must now take my readers back to page 327, October 13th, and ask if there was the slightest suggestion of personality in that article, or anything to call forth the smart reply on page 396, November 3rd. This letter, I submit, invited, even demanded, such an answer as I gave on page 428, November 10th, and which your correspondent duly honoured on the page first quoted (468, November 24th.) These dates are collated for convenience of reference to those who are interested in the subject under discussion.

It seems that "A. H. H." disclaims the quality of boldness that I attributed to him in writing as he did after reading the remarks of Mr. Warner (355) and the practice of Mr. Taylor (388) on the subject of Pears on Pear stocks, inasmuch as he had not read those articles when he penned his communication. This is a perfectly satisfactory explanation; but when I asked him to prove that borders 30 feet wide, concreted, &c., were absolutely necessary in ninety-nine cases out of a hundred for such trees as I advocated, his reply is scarcely worthy of him, and if he had written at first what he has written now on this part of the subject there would have been little or any difference between us. Then when he stated that fruit could be grown with a hundredth part of the labour that is necessary under the old system, I naturally challenged the accuracy of the statement; and now, fortified by experience, I do not hesitate saying that what he advanced is absolutely unsustainable, and he has said quite as much as I expected he would say on that point.

It is no fault of "A. H. H." that his experience is less than mine on hardy fruit culture, but at the same time he might credit others older than himself with having striven with the same zeal that he has done to acquire knowledge on this branch of their calling, and he will find it prudent to refrain from applying epithets to those who endeavour to impart information, because he may happen to differ from them in opinion. Although your correspondent cannot adduce results of his own practice, I should not like to suggest, much less assert, that he is no gardener; on the contrary, his letter affords evidence of his capacity in that respect, although, in my opinion, he has yet much to learn on the most economical method of growing hardy fruit.

Several years ago I entertained somewhat similar opinions to those "A. H. H." entertains now. I was young, earnest, and enthusiastic then, and dreamt about the revolution of fruit culture, and of the bountiful harvests that would follow when the improved systems became established. My dreams have not been fulfilled. Millions of fruit trees have been planted at an enormous cost during the last thirty years, but we are more than ever indebted to foreign countries for an adequate supply of useful fruit. This is a fact, and for such "improvements" as have led to it I have no affection. I will go further, and boldly state that if the fashion is continued of planting collections of Apples and Pears—one tree of a sort—on Quince and Paradise stocks, and crippling them by pinching and root-pruning, we shall never become, what we might become, a fruit-producing nation in the most important respect of all—namely, producing an abundant supply of wholesome food for thirty-five millions of people.

This bears directly on the subject on which I first ventured to write. I denounced, and I denounce now, the practice of apeing the French in endeavouring to cover English garden walls with Pears; and I advocated then, what I advocate now, freely grown well-trained trees on Pear stocks, from which the fruit is estimated by pecks and bushels instead of by pounds and dozens. I have no objection whatever to a wall of cordon trees provided a number of each of the best varieties are planted, as these would be equivalent to one good tree grown on the English system in affording a serviceable supply of fruit; but when this is the object

it will never be attained if a hundred trees represent as many varieties; and, in my opinion, this practice is only advisable for experimental purposes.

But cannot cordon trees be grown on Pear stocks? A pretty firmly established opinion exists that they must be on the Quince. This is a fallacy. On many soils they are better, far better, on Pears, will cover the wall quicker, and bear as well as trees can bear if they are properly managed. In many gardens Pears will not succeed on the Quince. I have experienced precisely the same results as Mr. Warner narrated on the page above quoted. I planted two trees of each variety of a selection of Pears—one on the Pear, the other on the Quince—fifteen years ago, and I do not hesitate saying, in fact, I am sure I might with truth say more, that the trees on Pears have afforded five times the quantity of fruit that those on the Quince have afforded, while many of the latter are either dead or dying in spite of every endeavour that has been made to keep them in health. Far more labour has been spent on the trees on the Quince than on those on Pears, yet these latter are now fine fruitful specimens, and will continue so for fifteen years longer, even for thirty, if they are well managed. "But what of the fruit?" "A. H. H." may ask. Well some of it was staged at one of the largest shows in England this year, and had a respectable position there, and it in other respects gives complete satisfaction to a family who are not satisfied with inferior produce.

I notice in the excellent letter of "WILTSHIRE RECTOR" in your last issue that the writer has uprooted *Beurré Diel* Pear because of its worthlessness. With me that Pear was utterly worthless on the Quince, but a tree on the Pear not 10 yards distant produces splendid fruit both in size and quality, fruit which is worthy of a place on any table or in any exhibition. This tree, with others, was planted in an old border, a one-horse cartload of fresh soil being used at the time, and the border has been regularly cropped with vegetables and Strawberries. It has been root-pruned once in a manner that may possibly shock "A. H. H." The soil was removed from near the stem, and two strong roots that appeared to go straight down into the subsoil were chopped off with a small axe and left. That was all. The whole work was done in a quarter of an hour, and if two men had spent a day in lifting the roots carefully and replanting the tree in fresh soil the results could not have been more satisfactory.

On the question of training trees with branches 30 feet long and as straight as gunrods, I wish to say a word. When writers complain of the time that is spent in training and nailing such trees, they always appear to me to publish a certificate of their inexperience. Much less time is requisite for managing a well-trained tree than one that has been neglected or trained in a haphazard manner. Many winters spent in work of this kind enables me to speak positively on this point. A badly trained tree has nearly always far too many branches, and the majority of these are far too crooked; and if a greater number of crooked branches can be pruned and secured to the wall in less time than a lesser number of straight branches can, all I can say is that those who can accomplish this feat are exceedingly clever, and I would go a long distance to see them at the work.

I do not retract one word I said on page 327, that splendidly trained and well-managed specimens of Pears on walls are a credit to any garden and gardener, and they will afford more fruit with less labour than can be obtained from puny trees on Quince stocks that are pinched and root-pruned to accelerate their cropping and shorten their lives.

I am not now writing so much in reply to "A. H. H." as on the general question of fruit-tree culture and management, and he can reply or not as he prefers. I neither invite nor fear criticism. I did not write my first article on Pears for walls without my book, and it is not omitted yet.

On the question of pruning, I cannot refrain from noticing a remark of "A KITCHEN GARDENER" in your last issue. He says on page 491, "I would never allow the leading branches of young strong-growing trees to remain longer than from 9 inches to a foot annually. This will be the means of producing robust well-spurred branches." My remark on this is, that if he does not prune the roots in the same proportion the "spurs" will not be fruit spurs, and if he does so restrict the roots he arrests the extension of the trees needlessly. I dissent entirely from your correspondent on his teaching as applied to Pears on walls. After almost all sorts of experiments, extending over a number of years, I have arrived at the conclusion that there is far more root-pruning and far more branch-pruning practised than is necessary for Pears on walls, and it is because of this that failures are so common and really fine fruitful trees so few.

One word more. If "A. H. H." should reply to this communi-

cation, may I ask him to answer the following questions which he passed unnoticed in my former letter? If the practice of lifting and root-pruning is so wonderfully profitable, how is it that fruit-farmers who pay £5 an acre for their land do not indulge in it? And on the border question will he say why a Pear tree against a wall should require an expensively made and elaborate border when it will grow freely without in an open field or garden?—**JOHN BULL.**

#### PROTECTING ROSES—A WORD OF CAUTION.

ONE advantage of living in our delightfully uncertain climate is that it gives people an opportunity of ventilating all sorts of ideas as the occasion arrives. Thus, a few years ago we had a time of great drought; forthwith out comes a host of letters in the *Times* and other papers on the sinfulness of not storing up our water in wet seasons to provide against the dry ones that may follow. Then came, as we all know to our cost, wet seasons culminating in the woeful year of 1879; and then an equally numerous supply of letters came to light showing how we are to get rid of our superfluous water. It was well the former advice had not been taken, or the latter extreme would have been worse still. Something of this kind occurs to me now. We have had two very severe winters; the losses amongst Roses have been enormous; it was found that those best protected succeeded the best, and hence in all directions we hear of persons making their plants snug, as they call it, for the winter; but what if (and in our uncertain climate more unlikely things may happen) a season as exceptionally mild as the last was severe should come upon us: will not this conduce to too early growths pushing and consequent loss by spring frosts? Already persons are complaining that the lower buds of their Roses are starting; and in the latter end of this, perhaps the mildest November recorded, as I understand October was the coldest one, I have cut Tea Roses from the open; and so far from having as yet given protection, I have rather endeavoured to check growth. About a fortnight ago I told my gardener to put the fork under each of the dwarf Roses and just give them a gentle lift. I did this for two reasons: that which I have already mentioned—giving them a slight check, and so leading them to expend their energy in repairing damages underneath instead of pushing out above ground; and also because I believe it is injurious to the Rose to get sunk down too much, as it will inevitably do. We place a heavy mulching on; this of itself presses on the plant, and then it is dug in and a fresh mulching applied until the point of union is in some instances 7 or 8 inches below the surface.

Considerable difference of opinion has been expressed as to mulching, but it is certainly a good preservative from frost. If, however, growers do not like to use it, then some other protecting material should be at hand to be applied as soon as ever the symptoms of severe weather begin to show themselves. Where mulching is used, then again the material may be at hand and quickly applied. Of course where large collections are grown these remarks do not apply.

I cannot but think that we have too much insisted on the tenderness of Tea Roses, as if they needed special protection. My own experience is that they are as hardy as the Hybrid Perpetuals. Some Teas are doubtless tender, but so are some H.P.'s; but I am convinced that there are a number, and those of the best kinds, quite as hardy as the H.P.'s. Flowers such as Madame Lambard, Contessa Riza du Parc, Bonquet d'Or, Homère, Marie Van Houtte, Souvenir de Jean Pernet, Jean Ducher, and others, are quite as able to bear frost as any of the Hybrid Perpetuals; and I find this confirmed by growers as far north as Darlington, and even at Dunkeld in Perthshire. At the former place Mr. Whitwell assures me that he gives Teas no more protection than he does Hybrid Perpetuals; and at the latter, Mr. Gray writes that he wintered four hundred Teas last year out of doors with as great ease as he did his other Roses.

My advice, then, would be, Do not be in a hurry to protect, but have all in readiness; and when the cold weather comes, as come it will, be ready to apply it.—D., *Deal.*

**POTATOES IN OLD GARDEN SOIL.**—The remarks at page 443 by "PRACTICAL" show how much more clearly some people can put things than others. I thank him for his hints. Like his, the soil here with ordinary cropping and ordinary manuring will continue producing fine crops of Potatoes indefinitely; but doubtless "PRACTICAL" has known gardens, as I have, that produced great crops of haulm and indifferent crops of tubers, while increased manuring only aggravated the evil. Doubtless he has also seen, as I have, applications of wood ashes alone produce on such soil fine crops of excellent tubers. Ours is a particularly favourable Potato soil, although in many other respects a very inferior one. In fact the soil in itself

yields no inconsiderable amount of potash annually—quite sufficient, in fact, to maintain the land in Potato-yielding condition when cropped on the rotation principle and manured with ordinary manure. Manuring is only one phase of the question.—**SINGLE-HANDED.**

It is anticipated that the meeting of the **FRUIT AND FLORAL COMMITTEES AT SOUTH KENSINGTON** on Tuesday next will be a most interesting one. There will be a brisk competition for the prizes offered on this occasion by Messrs. James Carter and Co. for vegetables. Messrs. Carter intend themselves making a large display.

— **HER MAJESTY THE QUEEN** has been graciously pleased to accept a copy of Mr. Fawkes' new illustrated work of reference on "**HORTICULTURAL BUILDINGS**" recently published at this office.

— **AS** showing the **MILDNESS OF THE WEATHER**, "J. W." states that he has a *Rhododendron Nobilcanum* in the open border of his garden, near Liverpool, in full bloom. The blossoms began to expand on the 10th of last month.

— **FROM** Friday the 9th inst. to Tuesday the 13th an **EXHIBITION OF CHRYSANTHEMUMS** will be held at the **ALEXANDRA PALACE**—an unusually late date for the neighbourhood of London, but it is an experiment which is expected to produce fairly satisfactory results. About £40 will be offered in prizes, the principal being those for twelve large-flowering plants in pots.

— **A CORRESPONDENT**, in answer to "J. R.," writes that a report by gardeners who have used **KEEL'S BLIGHT-DESTROYER AND VAPOURISER** has just been published, and may be had on application to Mr. A. Hawes, Walcot Parade, Bath.

— **IN** reply to a Scottish correspondent, on page 450, relative to **GRAPES AT THE EDINBURGH SHOW**, "SINGLE-HANDED" writes that he cannot, for a good reason, supply the information asked for in a public manner, but as he believes our correspondent is an acquaintance of his, he may one day give him the information personally.

— **WE** are glad to learn that the Right Honourable The Lord Mayor of London will preside at the thirty-ninth anniversary dinner of the **GARDENERS' ROYAL BENEVOLENT INSTITUTION**, which will be held at the Albion, Aldersgate Street, on Thursday, June 29th, 1882. His Lordship will be supported by the Sheriffs of London and Middlesex and the Count of the Fruiterers' Company. A successful meeting is anticipated.

— **THE** following are the dates of the **ROYAL HORTICULTURAL SOCIETY'S EXHIBITIONS AND THE MEETINGS OF THE FRUIT AND FLORAL COMMITTEES** in 1882—January 10th, February 14th, March 14th and 28th, April 11th and 25th, May 9th and 23rd, June 13th and 27th, July 11th and 25th, August 8th and 22nd, September 12th, October 10th, November 14th, December 12th; National Auricula Society's Show, April 25th; Great Summer Show, May 23rd, 24th, and 25th; Pelargonium Society's Show, June 27th; National Rose Society's Exhibition, July 4th; National Carnation and Picotee Society's Show, July 25th; Exhibition of British Bee-keepers' Association, August 3rd to 8th; Artisans' and Cottagers' Show, August 7th. The date of the Evening Fête is not yet fixed.

— **THERE** is now in one of the houses at the Royal Horticultural Society's Chiswick Garden one of the finest displays of

BEGONIA INSIGNIS we have seen. Some three dozen plants are arranged to form a bank, which is literally a mass of flowers, the light rosy tint being pleasantly contrasted with brilliant Poinsettias, the bright yellow *Linum trigynum*, red and white Primulas. The Begonias are in remarkably fine condition, vigorous, yet compact and bushy specimens, each 2 feet or more in diameter, and bearing hundreds of panicles of flowers. The plants are all in 24-size pots, and have been grown from cuttings struck early in the year.

— AN Irish correspondent takes strong exception to the remarks on page 468, both as applying to the CHAMPION POTATO and those who esteem it in Ireland. There could be no greater mistake, our correspondent asserts, than to imagine this Potato has "a stone in the heart of it," and only those can give it this character who do not know how to cook it. The references to the typical Irishman are described as at least indiscreet at the present time, even "if only written with the intention of raising a laugh." We can assure our correspondent that the writer to whom he alludes would be the last to intentionally cause pain to the most susceptible inhabitant of the sister island, which no one desires more earnestly to see peaceful and prosperous.

— IN the last issue of Mr. Richard Proctor's new and instructive periodical, "Knowledge," a writer gives some interesting particulars concerning the past "MILD NOVEMBER." "It appears that in London the average temperature of the first twenty-five days of the past month has been as much as 7° above the mean of twenty years' observation; and if it is fair to compare the London temperatures with those of Greenwich the past November has been decidedly the warmest experienced during the present century. Relatively warm Novembers were observed in the following years—1806, 1817, 1818, 1821, 1822, 1824, 1845, 1846, 1847, 1850, 1852, 1857, 1863, 1865, 1866, and 1877. The warmest of these was 1852, when the mean temperature in London was 48.9°, or rather more than a degree lower than that of the month that has just passed away. The maximum readings observed in the month under review have been exceptionally high; and those of the 5th and 10th, when the thermometer in the shade rose to 64°, have only been exceeded once during the present century. This was on November 8th, 1847, the reading being then as high as 67°."

— THE annual dinner in connection with the ASTWOOD AMATEUR GARDENERS' SOCIETY, established some five or six years ago in the interests of horticulture, took place last week. After the dinner Mr. James Hiam read two papers, one on planting fruit trees and the other on planting Potatoes. The subjects were well treated and listened to with great attention. Several new members were admitted to the Society, which meets every Tuesday evening to discuss matters relating to horticulture. A library is attached, the books of which are mostly upon gardening subjects.

— THE *Liverpool Mercury*, referring to FOREIGN VINEYARDS, says—"In presence of the disease which has spread over almost all the vineyards of France, public attention has been latterly directed to the hitherto neglected wine-growing districts of Italy and Greece, which have hitherto been notoriously neglected. Many scientific men believe that the Grape fields of France and Spain have been for the time exhausted, and ought to be allowed to lie in fallow for some years. In the meantime we might be allowed to test the capabilities of the land of Greece and Italy for producing the Vine, for which we have hitherto looked to a somewhat limited district. Neither of these countries has had a fair chance in modern times in competition with France and Spain, although ancient poets sang the virtues of their wines before it was proposed to transplant the Vine to more western climes."

— AN address originally delivered before the Clichester Working Men's Institute, by Lord Henry Gordon Lennox, M.P., entitled "A WINTER IN MADEIRA," has been issued in pamphlet form, containing thirty-seven pages of interesting and instructive particulars concerning that island. The principal physical features, climate, productions, and other matters are discussed briefly but lucidly, and several facts of great interest are mentioned. Alluding to the cultivation of the land the author writes—"The fertility of the soil is truly astonishing, but unluckily much of the island is too arid and rocky for cultivation at all. Vegetables are produced in the greatest abundance, and it was pleasant enough to have Green Peas and French Beans all the winter; but as a rule all vegetables grown in Madeira are inferior in quality to those grown in England."

— IN another portion of the same work the FRUIT IN MADEIRA is thus described—"Fruit of almost every kind is to be found in Madeira, but those which flourish most are from the tropical climes. Bananas grow in greatest profusion, and are of the highest quality. So general is the consumption of this fruit that it might almost be reckoned as among the food of the people. Custard Apples (*Anona*), Mango, Guava, the Loquat, a most beautiful tree bearing deliciously scented white flowers and excellent fruit when ripe; it is in colour yellow, and the shape is of small Plums. Pine Apples are very fine, and are beginning to be largely exported to London, but in Madeira they only ripen under glass, although not requiring any heat beyond the rays of the sun. Oranges, Peaches, Apricots, and Strawberries are also to be found, but the former, owing to deficient cultivation, are very inferior to those coming from Malta, Spain, or Portugal. Peaches and Apricots grow to no size, and have little or no flavour, and Strawberries are only obtained by the expedient of giving the growth of the plants a check or artificial winter by stripping off the leaves and tendrils, and even then they only do well in the colder atmosphere of Comacho and the hills. Besides these there are the Indian Cherry (*Eugenia brazilliana*), the Pomegranate, the Cape Gooseberry well adapted for preserving, and also the Bilberry and Alpine Strawberry, which flourish in a wild state." It is rather strange, however, that the author should refer to *Bougainvillea spectabilis* as having never flowered in England.

— THE culture of the COFFEE PLANT is likely to form a substantial industry in QUEENSLAND. We learn from the *Queenslander* that Mr. Pink of the Botanic Gardens has lately had applicants from the Rosewood Scrub for Coffee plants to an extent far beyond his ability to supply, the stock of young Coffee trees when he took charge of the gardens having been reduced to a minimum. Upon questioning his applicants he is told that there is one German selector in that district who some few years ago planted many Coffee trees. These have thriven well, and are now in full bearing, and the enterprising owner gathers his crop and obtains 8*d.* per lb. for it in Brisbane. So remunerative does this selector find the occupation, that he has expressed his intention of troubling no more with Maize-growing and Pumpkins, but has decided upon planting all his land with Coffee. His neighbours, seeing how successful he is, wish to follow his example, and in order to secure plants have applied to the Gardens.

— THE following GARDENING APPOINTMENTS have been made through Messrs. John Laing & Co., Forest Hill, S.E.—Mr. W. Taylor, late gardener to Prince Christian, Cumberland Lodge, succeeds Mr. F. Allen as gardener to Rev. Geo. Faithful, Storrington Rectory, Pulborough, Sussex. Mr. Charles Rann, late gardener to W. Morris, Esq., Kent Waterworks, has been appointed gardener to J. P. Murphy, Esq., Q.C., Lowood, Upper Norwood. Mr. Albert Early, late gardener to Mrs. Black, Blackheath Park, succeeds Mr. Barnes as gardener to Geo. Rawlinson, Esq., Woburn,

Croydon. The following numerous gardening appointments have also been recently made through Messrs. J. Veitch & Sons, Chelsea:—Mr. P. Hickman, late gardener to C. M. Kennedy, Esq., Newport Tower, Berkeley, has been appointed gardener to C. Willock Dawes, Esq., Burton Hill, Petworth. Mr. G. Butt, late gardener to Sir W. Salt, Maplewell, Loughborough, succeeds Mr. Hovell as gardener to Jas. Thorpe, Esq., Coddington Hall, Newark. Mr. Geo. Parker, late foreman at Cobham Hall, Gravesend, succeeds Mr. Melville as gardener to M. P. W. Boulton, Esq., Great Tew Park, Enstone. Mr. Thos. Dell, recently gardener to the late E. Hermon, Esq., Wyfold Court, Henley-on-Thames, succeeds Mr. Cordery as gardener to Sir John Kelk, Bart., Tedworth, Marlborough; and Mr. Fredk. Moore, late gardener to Prince Lichtenstein, Eisgrub, Austria, succeeds Mr. Pritchard as gardener to H. Woods, Esq., Warnford Park, Bishop's Waltham. Mr. B. S. Williams informs us that Mr. David Long, late gardener to A. Southard, Esq., Bracknell, succeeds Mr. Mitchell as gardener to G. Williams, Esq., Scorrier House, Scorrier, Cornwall. Mr. J. Hughes, late gardener to G. Wilkes, Esq., Chadwick Hall, Temple Balsall, has been appointed gardener to H. F. Osler, Esq., South Bank, Edgbaston, Birmingham. Mr. James Spong, gardener to John Clerk, Esq., Rolleston Hall, Leicester, desires us to announce his address in these pages and in the Horticultural Directory; but, with many other addresses from gardeners and nurserymen, it arrived too late for insertion in the Directory, which is now printed. These shall, however, receive attention in the next edition.

— VICK'S "Monthly Magazine" for November, in recounting a visit to Europe, gives clear illustrations of HYACINTH PROPAGATION IN HOLLAND, with the following remarks upon the methods adopted:—"All who have had experience with Hyacinths know that little pointed bulbs form at the base of the large ones, which, after becoming large enough to form roots, may be removed from the parent bulb and put out to grow to flowering size, which they will do in two or three years. These, however, do not furnish young bulbs as fast as the growers require, and recourse is had to other methods to hasten their production. One plan is to make cuts across the base of the bulb. This is done in June after flowering, and the cut bulbs are replaced in the ground. They throw out around the cuts a great many young bulbs. These are planted in a mass without separation the first season, the second divided, and in three years make strong flowering bulbs. Another plan is to cut about one-third of the base of the bulb entirely away, leaving it somewhat hollow. This is not done until July or August. By this process an immense number of young bulbs are formed from the cut scales, but not as large in size as by the previous process. New sorts are, of course, grown from seed, and seedlings bloom the fourth year."

— AT the second lecture on HORTICULTURAL BUILDINGS delivered by Mr. F. A. Fawkes at the Crystal Palace on the 23rd ult., the various qualities of glass and different methods of glazing received attention. The construction of stages for plant houses, ventilation, and painting were also fully considered, and where necessary illustrated by diagrams. The following remarks upon glazing will interest some readers:—

"Putty-glazing is by no means perfect; the putty is apt to peel off, crack, form crevices for the retention of moisture, and cause the woodwork to rot. Then it is troublesome to renew glass when necessary, as well to put it in in the first instance. No doubt putty-glazing is crude and unmechanical, and horticulturists would welcome any advantageous method of superseding putty-glazing, but for purely horticultural purposes no system hitherto invented has proved a successful rival of putty-glazing, and I cannot conscientiously recommend any of them for glazing purposes. In some cases the glass is held in its place by metallic slips, in others by compressible metallic bars, in others between slips of vulcanite or other elastic substance, the glass and vulcanite being held together by wood or metallic capping and screws; in others the glass drops into grooves prepared to receive it. In all these cases the glass comes in contact

with either a metallic or elastic substance. In the former case there must be a sufficient amount of 'play,' or the glass will break; in the latter case atmospheric influences will rapidly decompose the elastic substance, when there is far more trouble and expense to replace such substance than to reputty a house. If there be 'play' between the glass and its supports hot air has opportunity for escape; the house cannot be properly fumigated; crevices for the retention of water by capillary attraction abound, and the glass is liable to subsequent breaking by the freezing of this water. For other than strictly growing horticultural buildings mechanical glazing may frequently be employed with benefit, but for these structures a puttied roof is safest. If putty cracks it is because it gets too hard, and that may be avoided by putting a little tallow in when made—say nine parts good boiled linseed oil, and one part tallow mixed with whiting to required consistency. It is frequently recommended to employ bottom putty only—i.e., imbed the glass in putty, sprigging it at the top with copper tacks. This will prevent trouble from putty peeling at the top, but is not so sightly as the old plan. If top putty be used it should not cover a large area of glass, and the surface of putty next the glass should slope well, so as not to retain moisture."

The concluding lecture was given on the 30th ult., when the method of heating houses chiefly occupied attention, particulars being given of the quantity of pipes required to produce the requisite heat in different structures, the capacities of boilers, and many other important matters.

### A ROCKERY FOR ALPINE PLANTS.

(Continued from page 490.)

IF the object of a rockery were only the decoration of our garden far more showy plants than those described might be grown upon it; but we have assumed that it is intended to grow plants for which this kind of cultivation is especially suited. If, however, the soil of a garden is stiff, cold, and unsuitable to delicate or capricious plants, there may be many, which will prove hardy and will thrive on the rockery, which will fail in the mixed borders. I have known this to be the case with Hepaticas, which delight in a level well-drained nest amongst stones, in which their roots can penetrate to a great depth without finding water-logged soil. The same may be said of the double forms of the common Primrose. The white *Primula cortusoides amœna*, too, is quite hardy and produces trusses of flowers on my rockery of a size I never saw elsewhere, even in a greenhouse. I have not mentioned the varieties of *Phlox setacea*, which on favoured soils may do well enough on level ground; but even the old white *P. Nelsoni*, the best of all, not excepting the many new varieties, is hardy here only on rockeries. The yellow-leaved form of *Lamium maculatum* may take too much room to be allowed to occupy places for which alpine could be found; but till they are ready try it, and you will hardly banish it after you have once seen how handsome it is.

I regularly grow on my rockery several half-hardy shrubs, raised from cuttings inserted in store pots in autumn and potted in spring ready for planting out. Many of these flower late into autumn. *Abelia rupestris*, with Myrtle-like foliage and waxy white flowers freely produced all summer, is one of the best of these. Two *Hypericums* sold as *H. patulum* and *H. uralum* are treated in the same way and succeed very well. *Cistus crispus*, with flowers of the most vivid rose colour, is another; and the most free-flowering of all the shrubby evergreen *Veronicas*, which I call *V. parviflora*, is now at the end of October covered with lovely sprays of flower. It strikes very readily and grows very fast. All these shrubs are hardy in some parts of the kingdom, but they never survive a winter here if left out, or they might be rather troublesome.

Next there are several biennials or quasi-biennials for which the rockery is the best, if not the only place. *Calandrinia umbellata* is classed as a perennial, but I treat it as a tender biennial, and a good plant of it in bright sunshine in June is a very beautiful object. *Saponaria ocyroides* does best treated in the same way, except that it never wants winter protection; a fine mass of flower is presented by a two-year-old plant in May. *Delphinium nudicaule*, also biennial in most cases, flowers late the year it is sown, and for a long period in its second year. *Convolvulus mauritanicus* is a most easily managed plant. Cuttings inserted at the end of summer may be planted out in May straight from the store pot. They grow fast and flower all the summer, but they should be allowed to extend their growth to the bottom of the rockery.

Several dwarf annuals may be added, especially the many coloured forms of *Leptosiphon roseus*, and a neat little dwarf cruciferous plant, *Ionopsidium acaule*. Of this several sowings

should be made, and it may be kept in flower till Christmas. These annuals may be sown where they are to flower, but may require guarding against slugs with circles of perforated zinc 3 inches high. If the rockery is not yet filled for the season, such dwarfs as *Alonsoa inaeisifolia*, *Mimulus Harrisoni*, *Lobelia Erinus* may be planted in May in the vacant positions.—C. WOLLEY DOD, *Edge Hall*.

#### SPECIMEN-PLANT GROWING.

UNDER the somewhat singular heading of "Responsibilities of Gardeners" a discussion appears to have arisen as to whether plants in pots are better grown in large or in small gardens. Your correspondent "SINGLE-HANDED" appears, as is natural, to consider the best examples are seen in small or moderate-sized gardens, while some "many-handed" contributors, also very naturally, appear to think differently. One of them on page 431 stated that "almost without exception" the plants exhibited at metropolitan and provincial shows were grown "by subordinates." This in my experience is certainly not so; but in saying this I do not imply that those who have the charge of large gardens could not have grown the plants equally well had they been required to do so, and had the opportunity of giving the necessary personal attention to the work.

It is idle for anyone to argue that routine work of the garden is done better in a large place than in a small one, or *vice versa*. The question is often one of means rather than of men, or how would stand the cases of those men who have passed from small to large gardens?

In large gardens the multitudinous duties of a gardener prevent his devoting personal attention to specimen-plant growing, nor are exhibition plants needed in one large garden out of ten. I should doubt even if your correspondents who claim that the best plants are grown in the largest gardens grow exhibition plants themselves; but whether they do so or not, their capacity as gardeners remains the same.

Generally speaking, the best specimen plants are grown in comparatively small gardens and not by subordinates in large gardens. If your correspondent, to whom I have alluded, had seen the wonderful examples of *Chrysanthemum* culture at the chief metropolitan and provincial shows lately he would have found that scarcely any of them were grown by subordinates in great places, but by the exhibitors personally in small gardens. The same rule holds good in respect of exhibiting specimen plants in summer, not 5 per cent. of which come from the so-called "great gardens." Such specimens are of little or no use in the mansions of the great. What are known as "decorative" plants are needed there, and are generally well grown and spoiled quickly. That many young men can grow those plants well goes without saying, or they would not retain their positions; but this is no evidence that the chiefs could not grow them equally well if they could bestow on them personal attention.

It is not wise to contrast the work done in gardens in the way in which the subject has been treated, and I am unable to congratulate any of your correspondents on their judgment in this matter. Many men in both large and small places do well, and would do better if they had the means; and although I have had some experience in showing that satisfied me, I am far from saying that those are the best gardeners who win the most prizes. Some of the most competent men never exhibit, in fact many of them are not allowed to do so. These cannot be judged by the exhibition standard, and asking gardeners to show their cards as a test of ability is not far removed from childishness. Let no one think I am reflecting on the abilities of men who do exhibit successfully. I am not likely to do that. They have the means of showing their work, but they could not show it if they did not do it.

The gardener who gives the greatest satisfaction to his employer, whether by growing huge specimen plants and large bunches of Grapes for exhibition, or by growing smaller plants for house decoration and medium-sized bunches of good Grapes for everyday use, is best contributing to his own comfort and professional reputation, however large or small the garden may be in which he is engaged.—A JUDGE.

**PRUNING GOOSEBERRY AND CURRANT BUSHES.**—As the pruning of small bush fruits is on hand it would be well to know the experience of others on the subject. In pruning these bushes there are two ways adopted by cultivators, and as the best way has not yet been decided a discussion on the subject would be useful to many. I am a young gardener, and the way I have been taught to prune Gooseberries is this:—Leave such branches as contain good firm buds with the bark of the shoots cracked; this is good ripened wood. Small shrunk wood should be removed but not cut off close to the

branches, three-quarters of an inch being left so as to form a spur. As to how many shoots should remain entirely depends on the strength of the branches, two to four being the maximum, selecting those pointing outwards, shortening and leaving them about 8 inches long. Some gardeners cut the shoots smoothly off close to the old wood, and say if the least portion be left it produces useless shoots the next season, and what shoots are left should be left entire. In pruning Red Currants I have been taught to cut back lateral growth to about half an inch, leaving short spurs which are covered with fruit buds, and shorten the leader, leaving it about 6 inches long. Some gardeners trim them well, cutting what are removed clean away, and say the terminal shoot should be left and three or four below it, leaving them entire; the fruit being borne on the previous year's wood, and the clusters of fruit being much finer than those from spurs.—A YOUNG GARDENER.

#### LAWNS IN WINTER.

IN our pleasure grounds of twenty-five acres or more we have much short grass and many trees, both evergreen and deciduous, and from the beginning of October until now the latter keep our lawns in an untidy state; but now the leaves have all fallen we give one thorough cleaning, and this is all that is wanted the whole winter. In cleaning lawns and pleasure grounds all rubbish should be removed. Allowing the leaves to remain under the clumps and bushes will soon produce more work, as the first wind will bring many of the leaves on the grass again; but if all the leaves are raked from round the bushes first, and the lawns swept afterwards, there will be an end of cleaning for several months. Where there are many worms in the turf their casts are now disfiguring the grass, and these should also be swept away. As soon as the sweeping has been done a roller should be run over the surface, and this will impart a very neat appearance to it. If the roller is light it should be taken over the same part two or three times.

When the ground is rather dry is the best time to sweep, but the rolling may be done when the turf is quite soft. Where the grass is very rough it might be cut after it is rolled some days, but it is tough now. We are finishing dressing our lawns for the winter, and they look almost as well as they did in summer.—M.

#### FLOWERS FOR CUTTING.

It is surprising how greatly the demand for flowers has increased in recent years. I know cases where the supply of fruit to the house has been decreased in order to allow much of it to be sold; but there are few cases where the flower supply is treated in the same manner. On the contrary, year by year shows a steady increase in the quantity grown. Quite as many flowers are required and produced in what was called the dull season for flowers as at any other season of the year. Now there is no particular month when flowers may be allowed to become scarce without some danger to the credit of the gardener. As gardeners, we have great reason to thank the florist for the help he has given us. It would have been impossible twenty years ago to cut a hundred trusses a week of brilliant *Pelargoniums* through ehill November, and still have as many at the beginning of December as there was a month earlier. I am not talking of a large collection, but of as many as filled a four-light frame. Then that sweetest of winter flowers, *Bouvardia Veelandi* and its red counterpart *B. Hogarth*, or the deeper-coloured *B. elegans*, which have yielded us six hundred trusses through last month from a score of plants. Or the Chinese *Primula* in its many-hued shades, which, single or double, forms a bouquet of itself, and with its foliage. But what need is there to recapitulate the lovely flowers the present generation of gardeners have at this period? Provided always we have strong-grown healthy plants, the main principle is to keep them growing healthily. This may seem a mere truism, but I have noticed repeatedly that with the advent of short days there also arises a tendency to starve plants in that greatest of all necessities water, and heat sufficient to keep the roots moving. There is no greater fallacy in gardening than that of expecting plants which naturally bloom in summer to bloom healthily and profusely in late autumn and winter without help from fire heat. Let us take the *Pelargonium* as an example. Give it an even temperature of 55°, it may sometimes be a little lower, sometimes a little higher; give water as you would in summer, or whenever you see the soil requires it; keep the plants near the glass, and you will find that active and healthy roots are continually produced. A short healthy growth is produced with a truss from every joint, with large and well-coloured pips. It is just the same with *Bouvardias*, *Primulas*, *Callas*, double *Pelargoniums*, and *Azaleas*. They may vary in some respects, but the same principles hold good, and, if acted on, how satisfactory to everyone concerned are the results.

Then, having the flowers, what about cutting them? Personally I

do not like cutting good flowers, but it has to be done, and cutting them oneself is hardly so bad after all as seeing them cut by someone who has no interest in them beyond securing a gay bloom to be as lightly thrown away as it was lightly gathered. The only safe method of cutting flowers is to gather the oldest and most developed blooms first. That is a point which should always be insisted on. Continuous-blooming plants always repay for hard cutting. You may go once a week, or two or three times a week, to a plant and cut the best-developed of its flowers, and that plant under proper conditions will have more developed when your next visit is made. And then there remains a very necessary

condition in the production of flowers for cutting—you must grow the right sorts. A collection of Pelargoniums or Chrysanthemums may be unique, but the man who relies on a half dozen proved varieties of each will be able to cut blooms when his neighbour with many varieties cannot.—A NOR'-EASTER.

#### TROPÆOLUM SPECIOSUM.

WE have received so many inquiries respecting this beautiful Tropæolum that we have been induced to give an illustration showing the chief characteristics distinguishing it in the form of

Fig. 83.—TROPÆOLUM SPECIOSUM.

the leaves and flowers. As will be readily seen, it approaches *T. pentaphyllum* very closely, but it is far more attractive than that species when in its best condition—*i.e.*, as it is grown in some parts of Scotland. The flowers are marked by a most striking hue—a rich bright crimson inclining to scarlet, and are produced so freely that the plant often appears to be a glowing mass of flowers. It is one of Mr. W. Lobb's introductions, having been found by him in Patagonia, and introduced to cultivation in this country through Messrs. Veitch of Exeter. Mr. Dickson, Arkleton Gardens, Dumfriesshire, with whom the plant succeeds admirably, has favoured us with the following cultural notes.

"This beautiful climber delights in a humid atmosphere, hence one of the reasons why we see it growing so luxuriantly here. I

have also seen it growing and flowering well in various parts of Scotland, in all situations, and also under the shade of trees; indeed, I know of nothing so pretty for covering the bare limbs of shrubs and trees.

"I would recommend those of our friends in the south who have not succeeded in growing it satisfactorily to try it in some part of their ground where it will be shaded from the mid-day sun, or in a plantation or shrubbery, where I am sure it will soon establish itself if left undisturbed for a few years. I have never had any difficulty with it here; it has been in the same position for eight or nine years, and plants are springing up in all directions.

"Whenever I want to increase my stock I lift a few of the fleshy roots (some say it produces tubers, I have never found any), and

plant them at once where they are wanted to grow, and we have very seldom any more trouble with them. The best time for this operation is November or December. It may be grown in pots and trained balloon-shape, or in any other form the grower may wish. The soil I have found it thrive in best is a light turfy loam, say three parts loam, one part river sand, and one part leaf soil.

"I may add that I have seen this plant flourishing in front of a farm house, where no preparation had been made for it whatever, but just planted in the natural soil, which was light and gravelly."

#### ABUTILONS ALL THE YEAR ROUND.

THERE are no plants which will flower with more certainty all the year round than Abutilons. There is not a week in the year in which we do not gather their blooms, and little or no extra care or attention is devoted to them to insure this. So long as they can be kept growing they continue blooming, and this is a simple matter. In summer they will flower freely out of doors or in a cold frame, and now they only need enough heat to keep them growing and flowering. It is also an advantage to have them near the glass, as this makes the wood short-jointed and floriferous. At the end of a Pine house we have two planted out for the winter, and they are more useful than any we have had. Handfuls of blooms are gathered weekly, and unopened buds are on them by the score. The blooms can be gathered singly and used in this way in small glasses, or sometimes the point of a shoot with upwards of a dozen open flowers can be taken. Although the blooms are all of similar shape the colours are varied.  
J. MUIR.

#### SUCCESSFUL CULTURE OF PEARS IN POTS.

IT is a popular though erroneous impression that fruit in the south-west of England and Wales will grow "anyhow." That there are favoured districts in this division cannot be denied, but to assert all alike are exceptionally well adapted for open-air fruit culture is decidedly a mistake. For instance, at Bridgend, Glamorganshire, it is useless to attempt open-air culture of the Pear; at least, such is the case in the gardens at Ewenny Priory, the residence of Col. T. Picton Tuberville. This has led to the adoption of pot culture under glass, with the result of splendid crops of fruit very superior to those obtained in the generality of gardens from trees on walls. The fruit are not merely superior with regard to size, brightness, and clearness, but the quality is of the best description; *Beurré Diel* and *Duchesse d'Angoulême*, for instance, proving delicious. Added to this good crops are invariably secured, the only cost beyond original outlay on unheated houses being for manual labour, water being required in great quantities in the growing season, oftentimes at the rate of four waterings per day.

Two houses are devoted to the Pears, one a span-roof running north to south, the other a lean-to with a southern aspect. In both houses in order to insure well-balanced specimens, even crops, and thorough ripening of fruit and growth, it is found necessary to turn them frequently. Almost every day, in fact, they receive this attention. By this it will be obvious the roots are necessarily confined to the pots, and, as a consequence, require unlimited supplies of water, varied with liquid manure when in full growth. How well Mr. Hawkins, the gardener in charge, attends to this may be gathered from the fact of a tree of *Doyenné du Comice* perfecting six dozen fruit, another of *Beurré Diel* four dozen, of *Duchesse d'Angoulême* from seven to eight dozen, of *Pitmaston Duchess* four dozen, and proportionately heavy crops were borne by trees of *Durondeau*, *Beurré Superfin*, *Beurré Esperen*, *Marie Louise*, and *Brockworth Park*, the fruit in each instance being remarkably fine, many weighing a pound. Some of the best were recently much admired at a meeting of the Royal Horticultural Society, South Kensington; and again at the Bristol Fruit and Chrysanthemum Show, where they would have secured first honours but for over-ripeness. Every autumn the trees are repotted, the ball of roots being reduced so as to admit of repotting into the same sized pots, these varying from 12 to 15 inches in diameter. Rich loamy soil is employed, and the trees are wintered where grown, the precaution being taken of covering the pots with rough litter to prevent injury by severe frosts.—W. I.

CHRISTMAS REQUISITES.—The time is fast approaching when plants and flowers for decorative purposes will be wanted in abundance. Gardeners who have to supply the above generally prepare by having the foliage and flowers in the best possible condition. Many bulbs, *Primulas*, *Cinerarias*, *Calceolarias*, and *Cyclamens*, will be very acceptable, also with the flowers of *Chrysanthemums*, and a few blooms of the *Gloire de Dijon Rose*, which still keeps expanding its fragrant

flowers. There seems to be a plentiful supply of Holly berries this season in many places. Vegetables, too, are as much in demand as flowers at Christmas. Forced vegetables of many kinds are prepared; and as new Potatoes are one of the principal dishes for Christmas or New Year's day they will require a great deal of attention. If the weather continues mild it will be much in favour of the advancement of such crops.—A NORTHERNER.

#### BRENTHAM PARK, STIRLING.

IN these days of steam-driven machinery, steam navigation, steam locomotion, and telegraphic despatches we should not, perhaps, be surprised at the rapidity with which mansions appear. Landscapes are created, even, and great gardens suddenly spring into existence. The evidence that yearly the number of fortune-possessing individuals increases may be seen in every town, despite the assertion of those who think the country is "going to the dogs;" and nowhere is it more evident than in the vicinity of the famous northern town, around which are Scotland's most glorious battlefields. Tourists visit the battlefields and sing enthusiastically "Scots wha hae;" but gardeners seek such gardens as the famous Fernfield, Bridge of Allan, where Dr. Paterson grows such fine Orchids, or the now-famed Brentham Park; and instead of howling ancient hattle cries out of tune or to no tune, clutch their note-book and pencil as an aid to memories somewhat treacherous. At least this is what we did when last we visited the town of Stirling, and of the notes then taken we now make use.

Brentham Park is one of the new establishments to which we referred. Beautifully situated, it commands a splendid view of the Forth in all its river-windings down to where it broadens into the noble Firth bearing the same name. With a grand country on each side, the hills of Fife and the Lothians in the eastern distance, and the picturesque, half ancient half modern town of Stirling, with its high-perched castle to the left, the Wallace monument behind in the foreground, the hare-growing Ochils in the background to the right and the distant Grampians to the left, and the aforementioned battlefields all around. All this is well worth seeing. But as we walk from the town we are more particularly struck with the grand old Elms, centuries old, which line the roadway and turn it into an avenue of which any town might well be proud.

Brentham Park, although quite modern, is a fine building, and, unlike many new places, is surrounded with very fine trees. The house is reached by means of a fine drive, not very long but well kept, and enriched with young and thriving specimens of shrubs and hardy Conifers. The building is one of the best in the vicinity of Stirling, and attached to it is a fine conservatory, at once harmonising with the architecture and yet favourable for the growth of the plants employed for furnishing it. Among others we noticed in it fine robust specimens of *Lapagerias*, red and white. The rest of the houses are situated in the kitchen garden a short distance from the mansion. The first we entered was a Peach house. Peaches covered the back wall and half of the roof; in the centre of the house were a number of healthy Pear and Plum trees in pots. The fruit from these was mostly gathered, but, judging from the health of the trees, we could well believe that the crops both from the Peaches and the others had been good. The next division was also devoted to Peaches and Nectarines, and as this is used for a late house we had an opportunity of judging what Brentham Park could produce in the way of Peaches, and finer fruit we have never seen. The trees, too, were extremely clean and healthy; not a spider, not a thrips, not a green fly to be seen. We asked Mr. Macleod what means he took to keep his trees so clean and healthy. He pointed to a hose attached to a pipe. Once we saw, in an Edinburgh nursery, a man clearing scale from plants by simply laying them on a clean floor and scouring off the insects by subjecting them to a thin stream of water as it issued from the nozzle of a hose affixed to pipes where the pressure was high. Remembering this, we asked no further explanation. "And how do you get the fruit to such a marvellous size?" was our next question. "By spreading a little guano over the borders every time they are watered, and letting them have plenty of it," was the answer; and, he added, "keeping them clean and allowing them to bear plenty of foliage."

On the way to the Orchid houses we passed through three vineries all with good crops of good serviceable fruit; then we enter what was once an ordinary plant stove, now it is an East Indian Orchid house. Most of the plants were not yet very large, but all showed that they have been judiciously cared for. Some fine *Phalaenopses* were in exuberant health. *Vandas*, *Aerides*, *Saccolabiums*, and *Dendrobiums* were in great numbers, extremely clean and healthy, although the house is too wide and the plants rather crowded. In the departments devoted to *Lælias*, *Cattleyas*, and other Orchidaceous plants were many rare and fine speci-

mens. In the *Odontoglossum* house were great numbers not only of *Odontoglossum*, but of other kinds that succeed under cool treatment. All were thriving well, but none more so than the *Masdevallias*, many of which are very rare; indeed the collection is especially rich in the rarest and most expensive species and varieties. We noted a few examples, but on referring to our notes we find that to reproduce all would be to fill the columns of the *Journal* with a large catalogue. To indicate what the collection is like we will give only those that were in bloom at the time of our visit (middle of September).

*Peristeria elata*, *Epidendrum prismatocarpum*, *Acrides quinquevulnerum*, *A. suavissimum*, *A. Thibautianum*, *Dendrochilum filiforme*, *D. glumacum*, *Cypripedium Spicerianum*, *C. Sedeni*, *Zygopetalum maxillare*, *Z. Mackayi*, *Z. Gautieri*, *Dendrobium heterocarpum*, *D. primulinum*, *Cypripedium Haynaldianum*, *C. barbatum grandiflorum nanum*, *C. Schlimii*, *Oncidium fragrans*, *O. incurvum*, *O. macranthum*, *O. leucochilum*, *O. ornithorhynchum album*, *O. tigrinum*, *O. aurosum*, *Odontoglossum Roezlii*, *O. Pescatorei*, *O. Lindleyanum*, *O. Uro-Skinnerii*, *O. madrense*, *O. vexillarium* (many fine varieties, some with very large flowers), *O. cuculatum*, *O. Dawsonianum*. *Cattleya Harrisoniae*, *C. violacea*, *C. speciosissima*, *C. crispa superba*, *C. Mendelii*, *Lælia elegans Turneri*, *L. Dayanum*, *Saccolabium Blumei* (majus (eleven sp ke.) *Acincta Parkeri*, *Stanhopea elegans*, *Mesospinidium vulcanicum*, *Maxillaria grandiflora*, *Restrepia antennifera*, *R. fuscatum*, *R. guttata*, *Dendrobium Jamesianum*, *Masdevallia Veitchii*, *M. nycterina*, *M. Backhousiana*, *M. bella*, *M. ignea*, *M. Shuttleworthi*, and *M. chimæra*.

Scores more were showing spikes, but the names of these we did not take. In conclusion, we only add that a few years hence Brentham Park will be a great attraction to Orchid-growers, for Mr. Smith spares neither trouble nor expense in procuring the very best kinds and in well providing for them.—VISITOR.

#### NOTES ON BEDDING PLANTS.

In reading the article by Mr. Taylor on page 475, November 24th, I, like him, must confess it is difficult to provide variety year after year. Two years ago I determined to try some of the tender plants, but at the same time kept a stock in reserve in case of failure. One bed was to be planted with *Pelargonium Manglesii*, and instead I planted it with *Begonia Rex* edged with *Sedum aizoidium variegatum* and a plant of *Ficus elastica* in the centre. This bed was the great feature of the garden and was much admired. *Colcuses*, *Iresines*, and *Alternantheras* have succeeded well this year, better than last year. *Vesuvius Pelargonium* I find splendid till heavy rains come. Flower of Spring keeps good foliage and is very telling. Robert Fish surpasses all, for it blooms continuously through rain and sunshine. Cannell's dwarf *Ageratum* is a useful bedding plant, and so is *Tropæolum Vesuvius*.

*Calceolarias* and *Verbenas* fail if planted successively in the same soil. The best results are obtained with *Verbenas* when they are planted in fresh loam from an old pasture. I only plant *Verbena Purple King* in the flower garden because it is difficult to obtain other plants with similarly coloured flowers.

I have derived some useful hints on the best fruits lately from notes in the *Journal*, and hope we may have some as useful notes on bedding plants.—W. M. GEDDES, *Thrumpton*.

#### CHRYSANTHEMUM SHOWS.

THESE two northern Exhibitions bring the season almost to a close, for the only one now to be held is that at the Alexandra Palace on the 9th inst., which owing to the late date cannot be expected to be extensive, though we are informed the entries are fairly satisfactory.

##### LIVERPOOL.—NOVEMBER 30TH.

The second Exhibition of this Society was held in much more favourable weather than last year, and on the whole the Show was finer. It was feared, owing to the lateness of the date fixed for the Exhibition, that the supply of cut blooms and *Chrysanthemums* in pots would be limited and poor; but the blooms were as good as are generally seen at Liverpool, and numerously shown. Some of the trained plants, however, showed signs of retarding, and the foliage had begun to suffer. The show of fruit was considerably larger and finer than that of last year, especially the Pears and Apples, but the Grapes were a little behind the usual excellent quality seen at Liverpool.

*Chrysanthemums in Pots*.—In the class for six large-flowering varieties four lots were staged. Mr. J. Stephenson, gardener to Major Pilkington, Windle Hall, took the lead with closely trained plants, the foliage very fresh and the flowers large. The varieties were Miss

Hope, Prince Alfred, Jardin des Plantes, Barbara, Golden Empress, and Mrs. G. Rundle. Mr. J. Hutton, gardener to R. Roberts, Esq., Aigburth, was second, his plants having smaller blooms and not so neat. Mr. J. Hurst, gardener to W. B. Bowring, Esq., Aigburth, was awarded the remaining prize. In the corresponding class for four plants there were again four entries; Mr. C. Finnigan, gardener to W. Burnyeat, Esq., Huyton, leading with fine plants in every respect of Lady Talfourd, Mrs. G. Rundle, Mrs. Dixon, and G. Glenny. Mr. J. Stephenson was second, and Mr. W. Tugwood, gardener to J. G. Morris, Esq., Allerton Priory, Liverpool, third. For six Pompons Mr. W. Tugwood was first, showing neat well-flowered specimens of Prince Victor, Lilac, White, and Golden Cedo Nulli, St. Michael, and Aigle d'Or. For four plants Mr. C. Finnigan took the lead with good plants, followed closely by Mr. W. Tugwood. For one standard Mr. J. Hutton was awarded the first prize for a well-grown plant of Mrs. G. Rundle, the blooms being of a large size. Mr. J. Stephenson and Mr. W. Tunnington, gardener to C. McIver, Esq., Calderstone, Liverpool, took the remaining prizes in the order as named. Only two pyramids were staged by Mr. J. Stephenson and Mr. T. Gowen, gardener to J. Cunningham, Esq., Aigburth, who took the first and second prizes. The prizes for twelve untrained plants were taken by Mr. J. Warrington and Mr. F. Faulkner, gardener to F. R. Leyland, Esq., Woolton Hall, and need no further comment.

*Cut Blooms*.—In the class for twenty-four cut blooms, incurved varieties, Mr. W. Mease, gardener to C. W. Newmann, Esq., Wyncote, Allerton, obtained the first prize and the silver cup. Mr. F. Roberts, gardener to W. D. Holt, Esq., West Derby, was a close second, only being three points behind the premier collection. Mr. J. Jellicoe, gardener to F. W. Gossage, Esq., Wootton, third with rather looser blooms. Mr. Mease's box contained fine fresh blooms of Venus, Princess of Wales, Empress of India, Golden Empress, fine; Queen of England, John Salter, Cherub, good; Hero of Stoke Newington, Bronze Jardin des Plantes, Princess of Teck, Mrs. W. Shipman, Miss M. Morgan, Inner Temple, St. Patrick, and others. For eighteen varieties Mr. G. Mease, gardener to W. Nicol, Esq., Aigburth, was first with fresh, even, and compact flowers, showing well Princess Beatrice, Barbara, and others similar to those above mentioned. Mr. T. Foster, gardener to J. Branker, Esq., Wavertree, second with fresh flowers, but a little looser than those shown by Mr. Mease. Mr. E. Green, gardener to J. Woolwright, Esq., Aigburth, was awarded the remaining prize. Mr. F. Roberts was first with twelve blooms, even and compact; Mr. W. Todd, gardener to J. W. Cropper, Esq., and Mr. T. Foster were second and third, eight stands being staged.

Japanese varieties were shown in better condition and in larger numbers than at this Society's previous exhibition. In the class for eighteen varieties Mr. F. Roberts took the lead, followed closely by Mr. W. Mease and Mr. A. R. Cox, gardener to W. H. Watts, Esq., Wavertree. Mr. Roberts staged fine blooms of Kedive, Peter the Great, Apollo, Cry Kung, Ethel, Striatum, Criterion, Fair Maid of Guernsey, Meg Merrilees, Monsieur Lemoine, Gloire de Toulouse, Nuit d'Automne, Hiver Fleur, and others. Mr. Mease also had fine blooms. For twelve blooms Mr. Jellicoe was first; Mr. R. G. Waterman, gardener to A. Tate, Esq., Wootton, and Mr. W. Wilson, gardener to H. Cunningham, Esq., Gateacre, were second and third, all staging very fine flowers. Mr. E. Green was also awarded a third prize in this class, five collections being staged. For twelve Anemone or reflexed flowers, not less than six varieties, Mr. Jellicoe was placed first, showing Golden Christine, Fleur de Marie, Louis Bonamy, King of Crimson, Mrs. Forsyth, Bijou, Princess Louise, and Acquisition. Mr. A. R. Cox was placed second, and Mr. Faulkner was third, the last-named having all Anemone-flowered varieties, and many considered he ought to have had a higher position. For twelve Pompons, not less than six varieties, Messrs. Cox, Faulkner, and Finnigan obtained the awards, each staging fine blooms.

*Fruit*.—There were three entries in the class for twelve dishes of fruit. Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, took the lead with fine examples. The Grapes were good in every respect both as regards size and finish; the best dishes being Gros Colman, Alicante, Lady Downe's, and Muscat of Alexandria. Pears, Glou Morceau, large and fine; Beurré Diel, large; Duchesse d'Angoulême, Beurré Clairgeau, good. Apples, Ribston Pippin, King of the Pippins, and a good Conqueror of Europe Melon. Mr. J. Ward, gardener to T. H. Oakes, Esq., Alfreton, was a good second, and staged two fair Pines and a dish of Brown Turkey Figs. Mr. W. Pratt, gardener to Lord Hill, Hawkstone, obtained the remaining prize, and staged Blenheim Pippin Apple very fine. For six dishes, Pines excluded, Mr. J. Hurst was first with Muscat of Alexandria and Alicante Grapes, good; Beurré Diel and Glou Morceau Pears; Ribston Pippin and Blenheim Pippin Apples. Mr. Hannagan was placed second with equally good Grapes, a good Conqueror of Europe Melon, much better Pears, and an equally good dish of Apples. Mr. J. Kelly, gardener to R. Singlehurst, Esq., Aigburth, was third. Pines were good, the fruits being very fine. For two, Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, took the lead with good Queens; Mr. Tunnington second with fine Smooth Cayennes; Mr. G. C. Salter, gardener to G. D. Lees, Esq., Oswestry, third. Mr. James Bennett, gardener to the Hon. C. H. Wym, North Wales, and Mr. Tunnington, took the prizes for one Pine. Grapes, as before mentioned, were scarcely so good this year. Mr. Hannagan took the lead in the class for Muscats, and staged well-finished bunches, Messrs. J. Hurst and C. Finnigan taking the other prizes. In the class for

two bunches of any white Grape (Muscats excluded) Mr. J. Wallis, gardener to the Rev. Sneyd, Keele Hall, Staffordshire, was first with fine examples of Golden Queen; Mr. W. Mease second with White Tokay; and Mr. C. Finnigan third with Trebbiano. For two bunches of Black Grapes there were nearly twenty competitors. Mr. Wallis was placed first with Barbarosa, Messrs. C. Finnigan and Goodacre second and third. Mr. Wallis was first in the class for four varieties of Grapes, showing Mrs. Pearson and Golden Queen both good, Alicante, and Gros Colman. Mr. Hannagan was second, showing Mrs. Pince in fairly good condition; and Mr. Goodacre third. There were five entries in the class for eight dishes of Pears. Messrs. Hannagan, C. Dallachie, gardener to Mrs. Zwilchenhoit, Aigburth, and J. Lowndes, gardener to S. S. Parker, Esq., Aigburth, were awarded the prizes as named. The first included remarkable specimens of Beurré Diel, Marie Louise, Beurré Incomparable, Winter Nelis, Beurré Clairgeau, and Duchesse d'Angoulême. For four dishes the same exhibitor was again first. Mr. J. Wollam, gardener to Col. Blundell, Crosby Hall, and Mr. Goodacre, were second and third respectively. Messrs. C. Dallachie, Hannagan, and S. Whitfield, gardener to J. T. Cross, Esq., Aigburth, were the prizetakers for one dish of ripe Pears. Mr. Hannagan was again first in the class for six dishes of dessert Apples, showing Adam's Pearmain, Ribston Pippin, King of Pippins, Blenheim Orange, Golden Reinette, and Beahmwell. Mr. J. Lowndes was a good second, and Mr. Goodacre third. For three dishes the same exhibitor again took the prizes in the order above named. For one dish L. Garrett, Esq., Chester, was first with Cox's Orange Pippin; Messrs. Wollam and Kelly second and third. Mr. Goodacre took the lead with eight dishes of culinary Apples, and staged grand examples of Alfriston, Cox's Pomona, Dumelow's Seedling, Warner's King, Kentish Fillbasket, Waltham Abbey, and Flower of Kent. Mr. Hannagan was a close second, and Mr. Kelly third. For four dishes Mr. C. Dallachie was first with good dishes of Nelson's Glory and Warner's King. Mr. Wollam followed with Pott's Seedling and Lord Derby, fine and large; Mr. Whitfield was placed third. For one dish Messrs. J. Thomson, gardener to J. G. Morris, Esq., Norfolk; T. Jobuson, Lower Bebbington, and J. Wollam, were the prizetakers.

*Stove and Greenhouse Plants.*—In the class for six stove and greenhouse plants, not less than three in flower, Mr. W. Mease secured the first prize, showing some of his well-known plants—notably, Croton variegatus 7 or 8 feet through and well coloured, Croton Queen Victoria equally fine but a smaller plant, Latania horbonica large and fresh, Ixora javanica well flowered, Calanthe Veitchii 3 feet through, and Centropogon Lucyanus the best plant we have seen. Mr. J. Peers, gardener to R. Rayner, Esq., Wavertree, was second, staging a good Pimelea spectabilis and Alocasia Marshalliana. Mr. W. Bromily, gardener to H. Crosfield, Esq., was the remaining successful competitor, who staged a grand Brainea insignis and Clerodendron Balfourianum. Messrs. J. Peers and W. Bromily were the chief prizetakers for four plants. Six stove and greenhouse Ferns, Mr. J. Peers was first with large well-developed plants of Gleichenia dichotoma and Davallia polyantha. Mr. F. Faulkner, Mr. E. Swift, gardener to N. Eckersley, Esq., Wigan, followed in the order named.

Orchids were better and more numerous than the previous year. For three plants Mr. W. Moss, gardener to W. Holland, Esq., Aigburth, was first with Odontoglossum Roezlii, O. Alexandræ, and Vanda cœrulea (good spike). Mr. J. M. Phillips, gardener to Dr. T. S. Walker, Liverpool, was next, having fair plants of Lycaste Skinneri and Lælia autumnalis. Mr. Sherwin, gardener to S. Sparker, Esq., was third. For two Calanthes Messrs. Sherwin and Bromily were the prizewinners; and Messrs. W. Bromily, Peers, and R. G. Waterman for a single specimen. Three Palms or Cycads, Mr. F. Faulkner took the lead, having good plants of Livistonia australis, Geonoma gracilis, and Latania horbonica. Mr. Peers second. For a single specimen Mr. Faulkner was again first. Epiphyllums were good; Messrs. Barber, gardener to Mrs. Barnsley, Aigburth, and W. Bustard, gardener to J. Lewis, Esq., Aigburth, were the chief prizetakers. For six table plants Messrs. J. Ward and W. Pratt were the second and third prizetakers, no card being placed to the first-prize collection.

Poinsettias, standard Mignonette, Roman Hyacinths, and Primulas were all fine, especially the two last named, the Primulas being large and profusely flowered. The chief prizetakers were Messrs. C. Finnigan, T. Gowen, J. Peers, F. Faulkner, and E. Green.

Bouquets were all that could be desired, the chief prize in the nurserymen's class being won by the Liverpool Horticultural Company (John Cowan), followed by Mr. Gore, florist, Huyton. The corresponding class by Messrs. W. Mease, Bromily, and J. Leadbetter, gardener to T. S. Tinnis, Esq., Aigburth. Mr. J. Phythian, gardener to J. Walker, Esq., West Derby, was awarded the first prize for a light tastefully arranged vase; Mr. Phythian, gardener to Lieut.-Col. Wilson, Aigburth, being second, and Mr. J. Ward third.

*Miscellaneous Exhibits.*—Messrs. R. P. Ker & Sons, Aigburth Nurseries, staged a choice collection of stove and greenhouse flowering and fine-foliage plants. The Horticultural Company (John Cowan), had a similar group with a choice collection of bouquets and wreaths. Mr. B. S. Williams, Victoria Nursery, Upper Holloway, London, sent a collection of very fine Cyclamens; Messrs. Cranston and Co., Hereford, sent baskets of Carnations in bloom; Messrs. H. Cannell & Sons, Swanley, Kent, a large collection of Zonal Pelargonium blooms and choice Primulas in pots, the former being much

admired. Mr. Middlehurst, seedsman, Liverpool, had some Primulas of a good strain, the plants fully 2½ feet in diameter. Mr. Kipps, gardener to John Crosfield, Esq., Walton Lea, Warrington, staged a box of Chrysanthemum blooms, a sport from White Globe, named Mrs. John Crosfield. The blooms were distinct and beautiful, being white slightly suffused with pink.

The Committee, Mr. Richardson of the Botanic Gardens, and Mr. Bridge, the Secretary, merit congratulation upon the admirable arrangements of the Exhibition.

#### NEWCASTLE.—NOVEMBER 30TH AND DECEMBER 1ST.

The Committee of the above Show shortly after their late summer exhibition determined to try a Chrysanthemum and winter flower Show, their object being to try if possible to reduce some of their debt. The prize schedule was not very tempting from a monetary point of view, yet the Society threw themselves on the generosity of their exhibiting friends, and, considering that such little time was given, there was a hearty response reflecting great credit on the local exhibitors, who mustered in good force. Speaking generally of the exhibits, it cannot be said that they were equal to those usually shown, but no doubt in another year that defect will disappear.

For a group of Chrysanthemums and fine-foliage plants there were three competitors. Mr. Noble, gardener to Theo. Fry, Esq., Woodburn Gardens, Darlington, was first with a stand neatly arranged, the edging consisting of Lycopods, Ferns, Panicum variegatum, and well-coloured small Coleuses. Mr. Whiting, gardener to E. J. Walker, Esq., was second, and Mr. M. D. Thompson, gardener to Lindsay Wood, Esq., South Hill, third. Both had very good and choice plants in their stands, but their arrangement was deficient in effect. For six miscellaneous plants in bloom there were three collections staged; Mr. E. Adams, Swalwell, being first with a good plant of *Æschynanthus grandiflorus*, *Oncidium flexuosum*, *Ixora princeps*, very fresh; *Stactis profusa*, *Tremandra verticillata*, and *Lapageria rosea*, the latter very beautiful. Mr. Noble was second with a good *Cypripedium insigne*, *Azalea amœna*, and a *Zygopetalum* with five spikes and over twenty-seven flowers open. For six fine-foliage plants Mr. W. R. Armstrong, nurseryman, Benwell, was first with a good *Dicksonia antarctica*, *Croton Disraeli*, *Seaforthia elegans*, *Phormium tenax variegata*, and *Latania horbonica*; Mr. Thompson and Mr. Noble following. For six Ferns Mr. Bullock, gardener to Charles Wilson, Esq., Shotley Park, was first with an even specimen of *Todea pellucida*, *Cheilanthes elegans*, *Lygodium scandens*, *Davallia tenuifolia stricta*, and *Adiantum amabile*.

*Chrysanthemums.*—For six Chrysanthemums, large-flowering, Mr. G. Corbett, gardener to John Liddell, Esq., Benwell, with varieties of Mrs. G. Rundle, Rose Queen, and Mrs. Dixon; Mr. Methven was second with smaller plants, but bearing good flowers. The same exhibitor was also first for three large-flowering, followed by Mr. Bullock. For six Pompons Mr. Methven was also first with white, yellow, and lilac varieties of Cedo Nulli. For three Pompons Mr. G. Corbett was again first, and he was also first with one Pompon, Cedo Nulli, over 3 feet across; and first for one Japanese variety named James Salter. Primulas and Cyclamens were very good for the time of year, Mr. Methven and Mr. W. H. Wilson, Gilesgate, Durham, winning first respectively. Mr. W. R. Armstrong also showed some very fine double white Primulas.

*Cut Blooms.*—For twenty-four incurved blooms in twelve varieties Mr. Methven was first with Queen of England, Golden Beverley, Fingal, Empress of India, G. Peabody, White Venus, and Mrs. G. Rundle; Mr. H. Burn Bykes being second. Mr. Methven was also first for twelve incurved, followed by Mr. W. H. Wilson. For twelve reflexed varieties Mr. W. Sinclair, Oakfield, Low Fell, was first. For twelve Japanese varieties Mr. Methven again scored first with fine blooms of Gloire de Toulouse, Elaine, Bismarck, James Salter, Peter the Great, Fair Maid of Guernsey, and Fulgore. The same exhibitor was also first for six Japanese and twelve bunches of Pompons. For Camellias Mr. Whitney was first. The Chrysanthemums were not as good as is general at London and good provincial exhibitions, but still, considering that they were not grown specially for the purpose, they were highly creditable to the exhibitors.

The following nurserymen sent large stands of plants, which filled the vacant space in the hall—Mr. Jos. Watson contributing an excellent stand of noble plants; Mr. W. R. Armstrong, High Cross, Benwell, had a similar stand; while Messrs. Wm. Fell and J. Robson and Son, Hexham, contributed grand stands of Coniferæ.

**CARBONATE OF AMMONIA v. SNAILS.**—Concerning the solution of carbonate of ammonia, as used for the destruction of molluscs in gardens, I find that from half to three-quarters of an ounce of this dissolved in a gallon of water appears to be safe for the plants, the stronger solution, of course, for hardier species; but in any case it is not advisable to apply it to either stems or leaves, but to the soil; also cracks or crevices in frames might be washed with the liquid. Thus diluted the ammonia is rather beneficial than otherwise to plants, and I daresay it will destroy slugs small and large, though it does not seem to take much effect upon the larger snails. Soot, no doubt from its free ammonia, is also much disliked by them I find, but that is not conveniently applicable. The ammoniacal liquor from gasworks would answer also; unfortunately this requires a

variable amount of dilution, because its strength is uncertain. The Rev. J. J. Wood has strongly recommended the use of ammonia to kill molluscs.—J. R. S. C.

## A WEEK IN LONDON.

### CHISWICK.

WELL may a certain writer in the Journal exclaim "Dear old Chiswick!" Those who have been educated there cannot fail to look back with pleasant remembrances, or point to it as an excellent training school. It is a fine school for gardeners and gardening. No doubt those who live within reasonable distance avail themselves frequently of opportunities to see and make notes of the best and most worthy fruits, vegetables, or flowers in the various seasons. Country gardeners have few such chances, and often have to test a number of novelties before finding a really good one; but by a visit to Chiswick and with a little time on hand the best of novelties can soon be noted, as the majority are tested side by side. Unfortunately time did not permit, or an hour or two could have been pleasantly spent in noticing the young Apple trees which had been worked on the various stocks, in order to test upon which stock various kinds grew and fruited best. The stock evidently makes a greater difference than many are prepared to allow.

The pyramid Pears were grand, the trees being pruned and the branches sufficiently thin to admit abundance of light. The fruit was large in size, and of some varieties was abundant, while others had scarcely any. The crop of Apples generally was good, and one quarter of unpruned trees showed fair crops of fruit, which was rather small, the weight of fruit bringing the branches down into a pendulous fashion, which spoiled the appearance of the trees. The cordon Peaches had an irregular crop, some kinds bearing freely, others scarcely at all. A variety called Merlin was ripening, and appeared to be as early as Early Beatrice, and the fruit much larger. It would be interesting to know the quality of this variety.

The large vinery again contained a heavy crop of well-finished Grapes. In a house of such magnitude (I think it is the largest vinery in England) the sight was imposing. At the bottom the fruit was rather small, but when the stage is ascended the bunches are found much larger and finer in every respect than they appear to be from the bottom. In another house the Vines about three years planted were remarkably strong—the strongest I have seen for a long time, and I should consider them too strong to produce well-finished Grapes. The difficulty must be great to thoroughly ripen wood of such strength.

In one of the plant stoves I noticed many plants of *Pteris cristata* major growing luxuriantly, some of the plants being nearly 4 feet in diameter and in fine condition. *Adiantum Bausei* was numerous and well grown. In the same house *Salvinia natans*, a miniature Fern-like aquatic, was spreading rapidly in a shallow pan of water.

The tuberous Begonias in one of the houses were handsome, and some unnamed seedlings were amongst the best, being profuse bloomers with flowers of large size. *Begonia Martiana*, an upright-growing form with small rose-coloured flowers, was conspicuous and is valuable for conservatory decoration. *Souvenir de Louis Van Houtte* possessed the same character, differing only in having bright red flowers. This is a grand companion plant, and undoubtedly a seedling from the above. Amongst varieties with bright red flowers James McIntosh was striking. *Souvenir de Chiswick* was also very fine. Henry Webb had large bright scarlet flowers freely produced. Walter Davcer, a good variety with deep rose flowers; *Queenie*, a beautiful rose colour and deeper than *Nellie May*; *Pearcei Superba*, the deepest and brightest of yellows; *Chiswick Yellow* was also free and good. Dr. Hogg was a remarkably strong grower, having large flowers of rich dark colour. *Rosca Grandiflora*, good. *Nelly Barron*, a beautiful dwarf free-flowering variety. *Chiswick White* was by far the best white. *Sunshine*, buff yellow, very good.

The Zonal Pelargoniums were next noticed, the best rose-coloured semi-doubles being *Sylvia*, *Urania*, and *Zelica*. *Circe* and *Guide* were best amongst the crimsons, both being dwarf and compact, the last-named having flowers after the style of *Jewel*. Charles Darwin was striking with plum-coloured flowers, having a scarlet-shaded centre. Amongst scarlets *Madame Plaisançon* was grand, but *Delobel* was a little brighter in colour. The best three salmon-coloured varieties were *Pallas*, *La Constitution*, and Dr. Jacoby. *Psyche* and *Bridal Bouquet* were both good whites, but an unnamed variety was much better than either, having a finer truss.

The house of single Zonal Pelargoniums was brilliant and imposing, all the different shades of colour being arranged together, which rendered comparison much easier; the best rich crimsons being Dr. Orton (Pearson), a dwarf variety with a splendid truss. Henry Jacoby, by the same raiser, has been previously noted in these pages. Charles Schwind, Charles Smith, and Rev. S. H. Stanhope were all good but much alike, the first-named being the darkest. *Malcolm* (George), is a dwarf and bright variety. *Plaeci* (Pearson), light magenta suffused with scarlet, a fine flower and truss. *Hettie* (Pearson), light purple magenta, very good. *Trovatore*, by the same raiser, a dwarf and grand variety. *Correggio* and *Onida*, the former having flowers of a crimson purple suffused with orange scarlet, the latter being somewhat similar, but has a small white eye. The best scarlets were the Rev. S. Hey, *Havelock*, Mrs. Storey, *Beatrix*, *Burns*, and *Niobe* (Pearson's). Amongst purple-shaded Pinks Pearson's

varieties again figured as the best, the most noteworthy being Mrs. Ward, very fine; *Lady Bailey*, *Olive Carre*, *Titian*, *Mary Mabel*; the best of the rose-coloured section being *Lady Byron*, Mrs. Wright, Mrs. Leavers (Pearson's), *Madonna* (Denny's), these were all good, but the first-named was most conspicuous; the finest salmons being *Fanny Catlin* (Catlin), *Sophie Birchin*, and *Lizard* (Pearson's); the best white was *Jeanne d'Arc* (Lemoine), the truss was large and the flowers pure white.

In the grounds the Phloxes were magnificent, and intending planters will find the following good and desirable varieties—*Souvenir de Berryer*, bright red; *lilacina*, reddish crimson; *Jane Wilson*, dwarf white with pink eye, good; *Countess Rosslyn*, large truss; *coccinea*, brightest of all, dwarf, flowers dark crimson; *Menotti*, dwarf, lilac and white; *Lothair*, rose salmon, good; *Ada Louise*, dwarf, light with a pink eye; *Souvenir de Naney*, rosy purple, white centre; *Madame Alger*, crimson, fine flower and truss, best of all; *Venus*, dwarf white; *Virgo Marie*, good white. *Begonia ascotensis* was conspicuous in a bed on the shady side of a wall, not only growing strongly but flowering profusely. A bed of *Salvia patens* was also very beautiful. *Lobelia atrosanguinea* made a bright and beautiful bed. *Plumbago capensis* was flowering freely, bedded out, also *Cassia corymbosa*, which looked well with its pretty yellow flowers. I noticed in one of the borders a very fine *Tropæolum* named *Bedfont Rival*, one of the best I have seen for bedding, being a close compact-growing variety, and its flowers were freely produced. A bed of *Verbena Fireball* was very noteworthy, the colour of the flower being bright scarlet. The growth is compact, and in consequence would require but little pegging down. The border of Dahlias were grand. The single kinds were largely grown.

In concluding these notes I must congratulate Mr. Barron upon his good management in rendering the gardens not only attractive but instructive. Unfortunately he was from home the day of my visit, but his able foreman Mr. Thomson conducted me round the gardens, and I wish to thank him for his attention to—A COUNTRYMAN.

## REVIEW OF BOOK.

*A Pocket Guide to British Ferns.* By MARIAN S. RIDLEY. London: David Bogue, 3, St. Martin's Place, Trafalgar Square.

FOR all who are commencing the study of British Ferns this little volume is well adapted, as it gives a clear outline of the principal structural peculiarities of the order, and tabulated descriptions of the species found in these islands. It is also marked by very commendable accuracy both in nomenclature and the general information supplied, which, unfortunately, is wanting in many elementary works upon this and allied subjects.

The intention of the authoress is to supply a want she and others have often experienced, and which is thus described in the preface—"In my own studies I have met with this difficulty—viz., to gather from the published volumes on Ferns what the decided special features or characters are of each genus and species. For while writers mention many peculiarities in detail, some of greater and others of lesser importance, those alone which precisely mark the distinctions are either not sufficiently noted, or so mingled with features of a general kind that the mind fails to grasp the essentials." To aid others in overcoming this difficulty she has reduced the chief characters of every species to a tabular form under the heads of Generic and Specific Characters, Rhizome, Stipes, Frond, Venation, &c., giving the distinguishing features under each. Unquestionably a young botanist would experience little difficulty in determining the name of a specimen by carefully comparing it with the descriptions, and he would by that means also obtain an accurate elementary knowledge of the principal peculiarities of British Ferns.

### KITCHEN GARDEN.

DELAY no longer affording the needful protection to *Globe Artichokes*. We prefer to take out the soil around the crowns about 9 inches in width and 6 inches in depth, and after giving a dusting of quicklime fill up with ashes, covering the crowns about 3 inches deep, with 6-inch mulching of stable litter on the surface. Give a dressing of manure around *Rhubarb* plants, and have the soil between the stools pointed over, and a little placed over the crowns so as to have a neat appearance. In order to encourage a luxuriant growth of the *Rhubarb* the soil may be taken out between the rows as deep as the roots will allow without disturbing them too much, and the

hollow so formed may be filled with decayed refuse or partially decayed manure, the material being brought over the crowns, clearing it from them in early spring, and by watering with liquid manure or guano water (2 ozs. to a gallon of water) after the growth is free the produce will be much finer. Fresh plantations of this and Seakale should now be provided for by trenching the ground as deeply as the good soil admits, loosening that not turned up with a pick, and working in as the trenching proceeds a liberal quantity of vegetable refuse and manure. The soil for Rhubarb, Seakale, and Asparagus can hardly be too rich and friable. Seakale prefers a soil somewhat sandy, as also does Asparagus. The preparation of the ground for these should be proceeded with as opportunity offers, and if the weather be open planting Rhubarb may be continued, selecting divisions from the old plants with one or more crowns. Plant them level with crown, and firm the soil well about them, covering the crowns with vegetable refuse and partially decayed manure. The distance between the rows should be 6 feet, and between the divisions 4 feet. Johnston's St. Martin's is unquestionably the best early variety either for outdoor or forcing, and for the latter purpose the plants need only be 4 feet from row to row and 3 feet apart in the row. For general and market purposes Victoria is pre-eminent, and is good for forcing, and for a combination of size with quality Stott's Monarch has no rival.

Seakale may also be planted now, the healthy portions of the roots detached from plants lifted for forcing in lengths of from 4 to 6 inches making capital sets. Plant them 1 foot asunder in rows 18 inches apart, making the soil firm about them. One or two-year-old plants from seed are also good for forming new plantations, the plants having the crown bud removed with a knife before planting or in spring, so as to prevent seeding. Asparagus should not be planted until late March or early April. Complete the dressing of the permanent beds of these with as little delay as possible.

Jerusalem Artichokes keep best in the ground, also Parsnips and Horseradish, but a sufficient quantity of roots of those should be lifted and stored in damp sand in the root-house or other place, so that the supply be unbroken by severe weather. Similar remarks apply to Celery, which should either be lifted and stored in sand safe from frost, or be covered with a sufficient depth of litter or bracken. Winter Radishes and Rampion are also best from the ground, but they must be protected with litter or bracken to allow of their being taken up as required; but a supply stored in damp sand will keep in good condition some time, and is preferable to daily disturbing them in the open ground in severe weather.

Soils that have long been under vegetable crops and heavily manured will be improved by the addition of fresh loam and a good liming, deferring the manuring until spring or before putting in the crops, or, if this be inconvenient or undesirable, it may be employed during summer as a mulch with great benefit. Heavy soils will be improved by the employment of charred refuse, burned clay, ashes, leaf soil, and liberal manuring, also by a dressing of lime, and should for the winter be thrown up as roughly as possible. Light soils may have a dressing of clay or marl, and after exposure to frost dug in. Deep digging or trenching should be practised frequently where the depth of soil permits, but much of the bad soil must not be brought to the surface.

*Forcing Department.*—Where large supplies of French Beans are required a suitable structure should be devoted solely to them. Where they can be sown or planted out under these conditions they will yield more satisfactory results than when grown in pots, which are often from necessity placed in structures unfavourable as regards position and temperature to their giving satisfactory results. It is essential that these have a position near the glass and a temperature of from 55° to 65° artificially. Single rows may be had in front of Pine beds, forming a border of rich light compost about 1 foot wide and 9 or 10 inches deep, which will yield abundantly if properly watered and a little guano mixed with the water occasionally. Osborn's Forcing is one of the best, but Canadian Wonder gives finer pods, and may be grown where there is plenty of room. Sowings should be made at intervals according to the requirements. Advance successional crops of Asparagus, Seakale, and Rhubarb according to

the demand; and prepare materials for making fresh beds for Asparagus for succeeding supplies. Make beds of leaves and manure mixed, one part stable litter to three or four of leaves, in pits or frames for Potatoes, Radishes, and Carrots, placing about 8 inches depth of rich fine soil for the Potatoes over the bed, putting out the sets when sufficiently sprouted in rows of 18 inches apart, and the sets 15 inches asunder, inserting them about 4 inches deep. Myatt's Prolific and Veitch's Ashleaf are excellent early varieties.

For Radishes and Carrots 4 to 6 inches depth of soil is sufficient, and when warmed through sow the seeds of these in alternate rows, making shallow drills about 4 inches apart, and as soon as the seeds germinate air must be admitted freely. Early Scarlet Forcing Turnip and Early White Forcing Turnip, with French Breakfast and Wood's Frame, are most suitable, and of Carrots French Forcing and Early Nantes. Place more sets of Potatoes in boxes in leaf soil in a house where there is a temperature of 55° preparatory to planting-out the sets in beds. Supply tepid water to Seakale and Rhubarb in the Mushroom house when growth has commenced, also to Chicory, introducing fresh roots of the latter at intervals proportionate to the demand. Introduce roots of Mint in boxes or pots to a house with a gentle heat, also roots of Tarragon. Lettuces and Endive in pits where heat is applied must have regular attention in ventilation.

Lettuce for spring use in cold pits or frames should be examined occasionally, stirring the soil about the plants and dusting with quicklime or dry wood ashes. Similar remarks apply to Cauliflowers under handlights or in frames, ventilating freely when the weather is favourable; but in severe weather neither Lettuces or Cauliflowers will suffer if the coverings are left on for several days. Avoid as much as possible keeping the lights over the plants when the sun is powerful.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—The earliest house, having been closed and prepared for forcing as advised in former calendars, may now have fire heat applied, but the temperature should not exceed 50° by day artificially, nor 40° to 45° at night, until the flower buds are showing colour, and when they are expanding the temperature must be raised 5°, or 45° to 50° at night, and 50° to 55° by day, the lower figures being most suitable when the weather is severe. A somewhat dry atmosphere is desirable after the anthers appear. Syringing as regards the trees must then cease; but when the weather is bright damping available surfaces in the morning and early afternoon will be useful in assisting the development of the blossoms, but if fermenting materials are employed that will seldom be necessary.

*Figs.*—Trees in pots required to give ripe fruit at the end of April or early in May must now be started, the pots being placed on pedestals of brickwork in a pit, and the pit filled with fermenting leaves and litter brought up about the pots so as to afford a genial temperature around them of 65° to 75°. Frequent applications of water at 70° will, if the soil in the pots has been allowed to become dry, be necessary to render the soil thoroughly moist. The trees and available surfaces in the house must be syringed twice daily when the weather is bright; but in dull weather the moisture arising from the fermenting materials will suffice. A temperature of 50° at night and 55° in the daytime artificially is sufficient to commence with, allowing an advance to 65° from sun heat, above which ventilate freely.

*Vines.*—Disbudding will soon be necessary in the earliest house started in November, and should be attended to as soon as the best breaks can be distinguished, doing it gradually, and leaving a number of growths showing fruit in excess of those that will be required for the crop to induce active root-action. No more growths, however, must be reserved than can have full space for development. The temperature can be gradually increased so as to have it 60° to 65° at night when the Vines are in leaf, with 5° more by day, and 10° to 15° from sun heat. With fermenting materials in the house the need of syringing will be reduced. Lose no opportunity of admitting air, avoiding cold draughts or sudden depressions of temperature.

*Strawberries in Pots.*—Where it is intended to have fruit ripe by March, plants of some approved early variety should at once be introduced, if not already done, to a house with a night temperature of 50°, and advancing with sun heat to 60° or 65°. A vinery or Peach

house being started will be a suitable place, assigning them light airy positions near the glass. Never allow the soil to become very dry, and avoid making it too wet. A sprinkling overhead will be of service until the flowers expand, when it should be discontinued. Keep a strict look-out for aphides, and fumigate upon its first appearance.

#### PLANT HOUSES.

*Stove.*—Summer-flowering plants will now be at rest, and, having the wood in a well-matured condition, advantage should be taken of this to eradicate those most troublesome pests, mealy bug and scale. These insects, when fairly established in plant houses where heat is constantly employed, can only be checked by great labour and determined perseverance. In attempting to destroy mealy bug no half measures are of any avail, and, the plants now being at rest and having little soft growth, an insecticide may be used at a strength more likely to effect a clearance without injury to the plants. *Franciscus*, *Gardenias*, *Clerodendrons*, *Dipladenias*, *Ixoras*, *Rondeletias*, *Jasminums*, *Medinillas*, and *Tabernæmontanas* should be dipped or syringed over a vessel large enough to catch the liquid from the plants laid over it, turning the plants on their sides so as to reach every part, and after the liquid has dried on the plants they may be syringed with water at 140° to 160°. Most insecticides at a strength of 4 to 6 ozs. to the gallon of water at 90° to 120° will effect their purpose, such as Gishurst compound, Fowler's insecticide, and nicotine soap. Roof climbers, particularly *Stephanotis*, will need to be taken down, dipped or washed, so that the insecticide reaches every part. Clear out all fermenting or plunging material, the walls being pointed and limewashed two or three times, and the woodwork dressed with turpentine and afterwards painted. With a determination to succeed in destroying the pests their extirpation is only a matter of labour and time.

*Orchids.*—This being the most inactive period in the growth of these plants no more fire heat should be used than is necessary to keep the temperature about 65° by day, and 60°, or 2° or 3° less, at night for the East India house, the Mexican house 57° to 60° by day and 50° by night, the cool house 50° by day and 45° by night, allowing a few degrees rise with sun heat. Very little ventilation will be required now, and though the moisture is at a minimum attention must be given to the atmosphere, water being poured over the benches and paths every morning. The sphagnum and roots growing outside the pots and baskets will require frequent damping, particularly such plants as *Aerides*, *Saccolabiums*, *Vandas*, and *Phalænopses*. Although *Cattleyas* and *Lælias* are rooting freely they require very little water at the roots; the peat in which they are grown should be of a character to allow it to pass away freely. *Odontoglossums* must never be allowed to become dry; they delight in a cool damp atmosphere, syringing lightly overhead on fine mornings, guarding against drip lodging in the young shoots. Sponge the glass inside the house at least once a week, so that the plants have as much light as possible. Adopt precautionary measures to prevent woodlice and cockroaches eating the flowering spikes, which in some of the summer-flowering plants will now be showing. *Cypripediums* and *Cymbidium*s require a good supply of water at their roots. *Dendrobium*s required to be retarded flowering until May should be placed in a greenhouse temperature, very little water, if any, being required until they begin growing, when they must be removed into a warm house to prevent a stunted growth. Procure a good supply of peat and sphagnum, picking out all rubbish, and if laid on a damp floor the sphagnum may be kept in a growing state for several weeks, it being important that it be used as fresh as possible.

## THE BEE-KEEPER.

### DOME-TOPPED STRAW HIVES.

I HAVE noticed these two or three winters how well the cottagers' bees endured the winter about here in small dome-topped straw hives in comparison with my bees, which have been well fed, but are in large flat-top straw hives. The cottagers about here do not understand feeding bees for the winter. Some

give them dry sugar, others beer and sugar in small quantities. A cottager had his first swarm from one of the above-mentioned hives the last day in May. They were placed in a Pettigrew hive and have done well, as the honey season here was in the early part of the summer. My bees did not swarm until the latter part of June, and were not able to gather sufficient honey to keep them through the winter.

I would like to know if there is a better shaped hive for a beginner than the dome-topped one. In an unsuitable district the first necessity is to keep the bees alive through the winter; if the beginner can do that he would soon gain knowledge by experience. His swarms he could hive in improved hives of his own make. In reading this year a bee society's schedule I noticed what little encouragement they gave for the improvement of straw hives; there was only one class for them. Are there any straw hiveists left? If so, I think bee societies ought to assist them as much as they encourage others.—YORKSHIRE.

### BEE-FARMING.

THROUGHOUT life the question of bee-farming has often been before me, and in my younger days I was often tempted to become wholly a bee-farmer. Within the last few years I have been more than once asked to consider the desirability of taking the lead in a projected enterprise to farm bees to a large extent on a wide space of country. About ten days ago a gentleman urged the consideration of the subject, and intimated his willingness to invest largely in such an enterprise. Lately the subject has been partially discussed by Mr. Raitt in this Journal in answer to the letter of a gentleman who wanted to know how £300 a year could be made by bee-keeping. Mr. Raitt fairly and honestly answered the letter. As doubtless in future the subject of bee-farming will be considered by many as a profitable investment, I will now endeavour to convey to the readers of the *Journal of Horticulture* my thoughts upon the subject. In doing this it will be necessary to discuss the subject fully.

If I had in early life adopted bee-keeping as an occupation and farmed bees extensively, I am of opinion that I should have made far more money than I have by gardening; and, moreover, I believe that if I had begun bee-farming when I began the nursery business twenty-two years ago it would have been better for me financially, but through life I have not been guided merely by the love of money.

In coming to discuss the subject of bee-farming as an investment we shall notice the *pros* and *cons*—the encouragements and discouragements connected with it. Taking an average of years—that is to say, good and bad seasons together, the income from bees well managed in a good locality is about £2 per stock hive per annum. I wish it to be borne in mind that this £2 per hive represents income, not profit, for those who made it are not bee-farmers in the strict sense of the word, but cottagers who earn their living by other occupations and attend to their bees after their daily occupations. In managing my bees while I was a nurseryman my expenses amounted to about 10s. per stock hive. This 10s. per hive was spent in feeding, rent, and carriage, for many of my hives were kept in gardens at a distance from home. As there are great differences of pasture and district and great differences in the modes of management, there will be differences of opinion as to what may be reckoned as a fair average income from bee-farming. Many of my youthful companions and friends, after long years of successful bee-keeping, considered that £2 per hive is a fair average yield in their locality. As honey was sold fifty years ago at 1s. per pound, and a similar price is realised now, the results may be stated differently—viz., 40 lbs. of honey per hive, or 40s. worth of honeycomb. Now let us suppose that £100 income is an approximate income from fifty stock hives, and that an expert bee-keeper could manage three hundred hives in one garden, or two hundred hives separated in lots of twenty hives placed in several gardens a mile or two apart. Hives would thus have a wider extent of pasturage and would succeed better than if crowded into a single garden, thus overstocking a locality. In the midst of large orchards, white Clover fields, and good heather, one hundred strong hives standing together would increase in weight fast in honey weather, but we dare not say that one hundred more hives would not overstock the pasture. We think that two hundred hives separated into lots of twenty or thirty hives, and placed a mile or two apart, would be the better way of obtaining most honey out of a given district, and that one clever bee-keeper could manage all.

The cost of two hundred good hives at 30s. each would be £300, and for empty hives and beards and other necessary bee-furniture about £100 more. Thus it will be seen that to commence a bee farm of two hundred hives an outlay of about £400 would be required; and that the average income of such a farm in a good

honey district under skilful culture and active management would be about £400 per annum. What would the expenses per annum amount to ?

Rent, 2s. per hive, odd .....	£25
Carriage of hives .....	5
Bee-keepers' wages—six months .....	60
Feeding, 4s. per hive .....	40
Sundries and assistance .....	20
Interest on outlay of capital .....	20
Deterioration of hives and furniture .....	10
Cover for hives .....	7
	£187

Thus we see that according to the above estimates the profit would be only £213, or rather more than £1 per hive. The estimates of expenses and income is made to the best of my judgment, taking of course one year with another. In contemplating a commencement in bee-farming it is well to look every difficulty fairly and fully in the face. The estimates are made on the supposition that the bee-farmer pays for every item of expense, that he does nothing at all but balance his books at the end of the harvest. If any bee-farmer does his own work the expenses or wages of a manager (£60) would be saved annually, and if the owner of the hives had a garden of his own in the midst of good pasture, part of the expenses of rent would be saved. Mr. Raitt has wisely suggested that persons ignorant of bee-keeping and wishful to make a commencement on a large scale should begin in a small way and continue managing a few hives till they well understand the art and practice of bee-keeping. Those who can afford to serve an apprenticeship of six months duration to a successful man in a large apiary should do so before they make a large venture. An active man would learn more in six months in a large apiary well managed by a competent teacher than he would learn in six years of self-effort and experience in his own garden. Far more can be seen in a garden of fifty hives than in one of five hives, and experienced men have short and easy ways of doing work.

In choosing a district for bee-farming the pasture should be considered. Honey flowers should abound. Fruit trees' blossom in April and May yield much excellent honey. White Clover, field Beans and field Mustard, Sycamore and Lime trees' blossom in June and July yield much honey. Heather in August comes in last. An abundance of these plants makes any district in Great Britain and Ireland a good one for bee-keeping; and it is advantageous for the sale of honey and honey-comb to be near a large town or wealthy people, but this should not be considered a *sine qua non*.

If a bee-farmer has to depend wholly or almost wholly upon a servant managing a large apiary, great difficulty will be found in finding an able and trustworthy man. There are competent bee-keepers now-a-days, and every year many men are becoming expert in bee-keeping, but it is difficult to find such open to engage themselves to others for this work. In all such enterprises far more than I can here mention depends on the ability and faithfulness of the manager. Far more than half the losses and failures in bee-keeping are caused by incompetency and inattention. If I were engaging a man to manage my bees I would offer a fair salary and 10 per cent. bonus on all sales. He would thus have an interest in the concern. I believe that good men are cheap at any price, and incompetent men not worth much anywhere.

One point in bee-keeping or bee-farming I have not noticed in this letter—viz., that of selling stocks and swarms. But this point should not be forgotten. In large apiaries stocks and swarms can be bought, and in bad seasons it is advantageous to sell as many as possible. By selling ten or twenty stocks in such seasons the expense of feeding is met, and thus there is less loss. I know a gentleman in Lancashire who keeps bees for sale, not for honey. He deals in Ligurians, and states that he sells £200 worth annually. If his statements are correct the £200 come from bee-fanciers, not from bee-farmers. An outlay of capital on expensive bees and hives are not on the lines of economical and profitable management.—A. PETTIGREW, *Bowden*.

P.S.—In my estimate of salary for a bee-keeper I have been liberal in allowing £60 for six months' service; but it should be remembered as bees require no attention, or very little indeed from the beginning of October till April—six months, he would have to seek other work during the winter months.—A. P.

#### TRADE CATALOGUES RECEIVED.

James Walker, High Street, Skipton.—*Catalogue of Seeds*.

Putz & Roes, Erfurt, Prussia (Otto Putz, Great Russell Street, London).—*Annual Trade Seed List*.

William Etherington, Swanscombe, Kent.—*List of Chrysanthemums*.

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Disqualifying Chrysanthemums (C. F.).**—The two flowers received under the name of "Ferventa" we think are *Sœur Melainie*, which belongs to the hybrid section, and is most valuable for decorative purposes. It is not a Pompon, and there is no occasion for exhibiting doubtful varieties in small collections.

**Moss on Lawn (J. Freeman).**—Your lawn probably requires draining. As you have tried wood ashes and they have failed we can only advise you comb as much of the moss from the lawn as possible with a fine-toothed rake, and then give it a dressing of lime at the rate of 2 pecks, or nearly so, to the rod of 30½ square yards, and sprinkle over it some fresh soil. Give also a dressing of soot in the spring, on a rainy day if possible, making the surface quite black. If these measures fail, then we should dig up the ground, drain it, and sow thickly a suitable mixture of fine lawn seeds.

**Grubs in Cyclamen (E. C.).**—Your plant has been attacked by the grub or larva of a small beetle, one of the weevils, apparently that of the grooved weevil (*Otiorynchus sulcatus*), which is partial to bulbous and succulent plants. This feeds during the winter and spring, the beetle coming out in April or May according to the season, when it deposits eggs, and should be looked for around the stems of plants where it has already done damage. It is seldom that a plant which has been badly attacked by the grub can recover, but some have advised giving clear lime water to destroy the grubs while young; but this is only of benefit before they have buried themselves in the combs.

**Pear Tree Unhealthy (F. J.).**—The branches dying suggests that the roots of the tree are in wet or ungenial soil, and the wood does not ripen. If this is so you might probably improve the tree by lifting and placing the roots in fresh loam, adding at the same time some calcareous matter, such as old mortar rubbish. A mixture of wood ashes would also be beneficial. If we have not indicated the cause of the unsatisfactory state of the tree—that is, if it is apparently in good soil, and still the branches die, we should uproot it and plant a young tree, as it is never wise to graft on a diseased stock. Train the Vine rod on a level with the wires of the roof; in fact, secure it to them about 6 inches from the front glass, or where convenient.

**Sowing Lapageria Seed (G. S. N.).**—Sow the seeds as soon as they are gathered from the plant in a light compost, the greater part being peat, and place the pots in a temperature of 60° to 65°, keeping the soil regularly moist. Many seedlings have been raised, the result of a cross between the red and white varieties, but the majority of them have proved worthless. Sow the Palm seeds in loamy soil, about half covering them, placing on the surface a layer of moss, which keep moist, in a temperature of 65° to 70°.

**Mushrooms in Cucumber House (Lynn).**—As you "know the spawn was good" we suspect the soil of the bed was unsuitable by being either too light, too wet, or too dry, or the heat of the bed was not suitable. On this point you give us no information, neither do you mention the temperature of the house. The bed should be about 70° and the house about 60°, and if the bed is covered with hay it will not be necessary to cover the glass. Regularity of moisture in the bed is indispensable. You had better remove the soil and make a bed of horse droppings; a layer 6 inches thick will do under your circumstances. This bed must neither be wet nor dry, but of a healthy medium which is easily attainable. If the spawn is inserted in this, and a temperature of 75° is maintained for a fortnight, good spawn will "run," and a heat of 70° to 65° will then suffice. The soil removed may be spread on the bed if it is good, made moderately moist and very firm, the whole being covered with hay. Perhaps, however, your failure is not so complete as you think, and you had better wait a week longer before you disturb the bed.

**Species and Genera (Northampton).**—The question "Are all Palms or all Orchids of one species?" is obviously absurd, and scarcely requires an answer. The plants known as Palms and Orchids form two large families or natural orders, each including a great number of species arranged under their respective genera. A species is ordinarily considered as containing all the individuals descended from one original plant or animal, and therefore agreeing among themselves in certain characters, which also distinguish them from other similar groups of individuals. But in the course of time the variations are so great that it often becomes difficult to assign the exact limits to a species, as the characters seem to merge gradually into each other, thus rendering the definition to some extent arbitrary. A genus is simply a group of species agreeing in their leading characters, genera being grouped under the terms tribes, sub-orders, and orders. Thus, to give an example from one of the families named by you, the Palms, *Chamerops Fortunei* is a species; *Chamerops* is a genus included by some botanists in the tribe Coryphæ, and this in the natural order Palmæ. A variety is a sub-division of a species including individuals that agree in some unimportant characters, such as the colour of the flowers, which are not considered sufficient to entitle them to specific rank.

**Mealy Bug on Coleuses (Park Hill).**—We know of no remedy for exterminating this pest without at the same time staining the foliage, except carefully washing the plants with pure water, using a sponge and pointed stick or an old toothbrush for dislodging the insects. A quicker way of destroying them would probably be to wash them or syringe them forcibly with a warm solution of soft-soap, made by dissolving one or two ounces of soft-soap in a

gallon of water, and adding thereto a wineglassful of paraffin oil. The oil will mix with the soapsuds, but not with pure water, and if the solution is applied warm, say at a temperature of about 120°, it will not stain the leaves nearly so much as if it is applied cold. The plants should be laid on their sides over a vessel to catch the solution, or on a mat and turned round, so that they can be syringed on all sides effectively.

**Exhibiting Plants at South Kensington (F. R.).**—If you write to Mr. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W., and state your case he will give you the necessary instructions for carrying out your project; but we doubt if you send an unnamed plant to the Floral Committee that they will either name it for you or grant it a certificate. If your Fern is really new you can name it yourself, and if it is distinct and so good in the opinion of the Floral Committee as to merit a certificate they will grant one if you place a plant before them. If you send a spray to us securely packed, so as to arrive in good condition, we shall perhaps be able to inform you whether your plant is new or not. You can either adopt this course or write to Mr. Barron, as you prefer.

**Coiling Vines (F. C.).**—If you have placed the canes in the pots properly, only one or two buds being above the soil, they will be quite safe in your orchard house, provided the soil is kept healthily moist—that is, not saturated—until the spring, when they will root more quickly if plunged then in slight bottom heat. We should not plunge them in heat now, as you do not appear to have the requisite conveniences for growing them if started very early. It is immaterial whether the buds are removed or not on the portion of cane in the soil, therefore do not disturb the coils.

**Pines (Idem).**—Pines cannot be grown successfully unless you can insure a night temperature of 60° as a minimum. Leaves and manure form an excellent plunging material. Your form of plunging will do provided the pots are warm; if they are not, sink them deeper. The suckers will not grow in the frame unless it is heated. It is not possible for us to determine whether the piping you name will be sufficient for heating the compartment for Pines without knowing the height of the structure. A flow and return 4-inch pipe the length of a pit 8 feet wide and 5 or 6 feet deep, 3 or 4 feet being occupied with plunging material, would suffice; but the term "orchard house" implies that the structure is lofty, and probably two rows of pipes round the house, if it is a span-roof, would be requisite. If you had sent a clearly drawn plan showing the form and dimensions of the compartment we could have given you a definite reply. It appears to us that you have acted prematurely in procuring plants before you have provided the means for growing them.

**Failure of Chinese Primulas (Jean).**—The most frequent collapse of Primulas results from potting too high. They ought never to require supporting, as in this case the exposed stems are liable to canker, and the plants to fail generally when in full bloom. In your case this is not the cause of failure, but, judging from the facts as stated by you, more probably the decay of the plants is owing to late potting, the subsequent treatment being unfavourable. You omitted mentioning if fire heat was employed in the lateinery where the plants were disposed. Primulas repotted late in October and watered at the same time would require to be placed where a little dry heat could be given, and receive no shade. Given opposite treatment we should expect many to decay. Our latest batch received their final shift about the middle of September, and even at that date we did not water the plants for at least a week, the precaution having been taken to have each and all thoroughly moist prior to repotting. The frame in which they were placed was kept somewhat close till they recovered from the slight check they received. To apply water immediately after repotting, especially if no heat be given, would doubtless ruin many plants. The first signs of injury would be a change in the colour of foliage, followed by flagging on a bright sunny day. On the other hand, if you allow the ball of a newly potted plant to become excessively dry, flagging would be the first sign. In this case the young roots will perish, and a thorough soaking given when too late would also frequently end disastrously. Plants, however, will often recover from the effects of extreme dryness at the roots, but seldom from overwatering. An examination of your failure ought to enlighten you on the subject.

**Various (Inquirer).**—The growths of Clematis Jackmanii which have flowered should be removed down to the prominent buds, which will be perceived on the lower parts of the shoots. Some of these buds may have commenced growing in consequence of the extreme mildness of the weather, and possibly later frosts may destroy them; still, we should leave them, as if they are cut down the lower buds will start in the spring. To cut off the advancing buds now might cause the others also to become too forward, and they had better remain dormant at this season. If the insecticide is used in a warm state it will leave little or no sediment, and consequently it will not be needful to wash it off with plain water. It may be safely applied to the plants you name, but leaves that are "blackened by aphides" ought to be cleansed with a sponge. Cyclamens thrive best in a house in which the night temperature ranges between 50° to 60°. Cut down the Chrysanthemum and keep the plants in a frame or greenhouse; either now or in spring take rooted suckers from the plants and pot them singly in small pots, or cuttings may be struck in a warm house or frame in the spring. When the young plants are established the old ones may be thrown away or planted in the garden. Not knowing the condition of your Rose we are unable to inform you how it should be pruned, but as a rule close pruning of the variety is not advisable; neither is it possible for anyone to advise on repotting without knowing the size of plant and the pot it is growing in. We can only say that this is not a good time for repotting Roses in the hands of inexperienced amateurs.

**Gas Lime for Gardens (Inquirer).**—It is injurious to crops when applied in an excessive quantity, and especially when it is used shortly before sowing and planting. A quarter of a pound, or nearly so, to a square yard may be dug into the ground now, if well mixed with it to a foot in depth, with safety, and this would be useful in extirpating grubs and wireworms; but in the spring half that quantity, or less, according to the nearness of inserting the crops, would suffice. For lightening strong land a heavy dressing of ordinary lime<sup>a</sup> say at the rate of from fifty to sixty bushels per acre, would be safer and more effectual than gas lime. You ought to add ashes, sweepings from roads, vegetable refuse, and gritty matter of any kind, as liberally as possible; also in digging throw the ground up in ridges, and break these up with forks or picks two or three times during the winter when the ground is frozen. You will thus in time ameliorate the soil and render it more suitable for Potatoes and other crops. Mr. Taylor finds no late Potato so suitable for his strong soil as the Champion. Garden refuse of all kinds, even weeds, if placed in a heap with fresh lime and covered with soil, will decay and afford a valuable dressing for your land; and if a portion of this compost, with a sprinkling of soot, is placed in the drills when the Potatoes are planted, the crop will be heavier, and the produce better in quality. You can only ascertain for yourself the precise varieties that are the best adapted for your particular soil, and if the ground is wet as well as

heavy you will find it advantageous to grow the Potatoes on ridges—that is, place the tubers on the surface and cover them with soil obtained from between the rows, which should be wider apart than usual.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*Edward Collins*).—We are sorry we cannot name your Apple. (*A. Barker*).—Pears—1, Arlequin musqué; 2, rotten; 3, uot known. Apples—1, Cox's Orange Pippin, 2, Wormsley Pippin; 3, Gloria Mundi; 4, Somerset Lusting; 5, Hollandbury; 6, Striped Holland Pippin; 7, Bedfordshire Foundling; 8, not known. (*James Searle*).—1, Flemish Bonchrétien; 2, Leon Leclerc de Laval; 3, Beurré d'Arenberg; 4, Winter Franc Real; 5, Forelle; 6, Beurré Sterckmans. (*G. S., Sandbeck Park*).—1, Gloria Mundi; 2, ditto; 3, Minchall's Crab; 4, not known. (*A. Death*).—1, Bedfordshire Foundling; 2, not known; 3, Yorkshire Greening; 4, Cox's Pomona; 5, Rosemary Russet; 6, Cox's Orange Pippin. (*W. S. Mainsforth*).—We do not know the names of either of the two Pears. (*G. C. S.*).—We suspect the Apples you have sent are purely local varieties, of which we do not know the name.

**Names of Plants (W. E. B.).**—Zygopetalum Mackayi. (*Stifford*).—1, Begonia Ingrami; 2, B. fohosa; 3, B. natalensis; 4, specimen insufficient; 5, B. insignis; 6, Gesnera Donckelaari. (*A Young Gardener*).—Your plant is Acacia heterophylla, and requires a greenhouse temperature.

**Do Rhododendrons Kill Bees? (M. Thompson).**—Mr. Pettigrew says the statement sometimes made that Rhododendron flowers kill bees that work on them is not true. Bees have been kept in Rhododendron nurseries with success. For thirty years his bees have been surrounded with gardens in which Rhododendrons have been growing, and he has never known nor feared the loss of a bee from them.

COVENT GARDEN MARKET.—DECEMBER 7.

OUR market is completely stagnant, arrivals of Canadian fruit seriously affecting prices. Good dessert Pears are in demand.

POULTRY AND PIGEON CHRONICLE.

STABLE ACCOMMODATION FOR HORSES.

(Continued from page 508.)

IN the horse boxes to keep the accumulating bedding firm enough to prevent heating, it is requisite to supply a little water once a day with a common water-pot with the rose on, especially round the outside of the box, where the horse does not tread so closely to the division of concrete and boarding. It is also necessary to strew a little dry fine earth over the straw surface daily.

Thus the combined action of the water and earth solidifies the mass of accumulating manure, and effectually prevents fermentation and the escape of any ammoniacal vapour. In the case of the stable to which we have been referring no manure was removed for nine months, and it was only removed then because the dung was required for use on the home farm. In order, however, to ascertain how long the accumulation may be extended without injury or inconvenience, one box was not cleared out until the end of fifteen months, and then only in consequence of some of the manure overlapping the threshold, causing a nuisance on the white brick pathway. We have no evidence to offer as to how long the accumulation may be continued without injury to the horse. In fact, when carried out as we have endeavoured to describe, it is complete in all respects; for the shoeing smith who had shod the horses on the estate for upwards of twenty years informed us, that since the manure had been allowed to accumulate under the animals their feet were in a much better state for shoeing than he had ever seen them at any former period.

It appears very important to inquire, not exactly as to the particular plan or system best adapted for use generally, but that probably each plan would find advocates under the varying circumstances required for stable accommodation. The plan of impervious floors seems admirably adapted for horses in a large town, because the difficulty of obtaining prepared earth would tell against the use of it. The disposal of both liquid and solid excrement is then of the highest importance, in the same way that the sanitary arrangements in towns are requisite for the health of the population, without so much reference to the cost of it. One way, however, to look at the question as it applies to horses is to consider, not only their general health, but the condition of their feet, especially as refers to horses engaged in tramway work and cab horses. These have to travel almost continuously upon the hardest roads, and the necessity of keeping the feet of the horses in an elastic and healthy condition is imperative to prevent serious losses; in fact, the reports of the managers of the tramway and omnibus companies point out the enormous waste of horse power in consequence of the hard stone surfaces they have to travel upon. Horses also frequently suffer in their general health when kept in stables with hard impervious floors, and from these two circumstances alone the average duration of use of these animals is shortened by at least two years. More especially is this the case under the system and circumstances arising from the prevailing style and manner of shoeing the horses it becomes of the highest importance. As securing space for boxes in large establishments would be costly and difficult, it then becomes a question of earth-floored stalls, which may be carried out in most towns by contracting for the supply of prepared earth and the removal of the same after its use and conversion into manure. The saving of straw litter is an important consideration, as at least it would amount to one-half.

The use and advantages of loose boxes with earth floors applies in a forcible manner to all establishments where space and the cost can be afforded, especially as regards hunters, hacks, and carriage horses. But for these the question of shoeing must again be considered; for although the feet will be more elastic and in better condition in consequence of the earth floor, yet it is quite impossible for accidents to be avoided either in hunting or in road-work. When the frog is cut away, as is done in fashionable shoeing, irreparable injury frequently occurs through wounds inflicted by the short spear-like stumps of underwood in the fences and woodlands. Horses on the roads are often thrown on their knees through a stone becoming jammed between the excavated frog and the shoe, whereas in the system of shoeing advocated by Mr. Fleming the defence of the sole of the foot formed by Nature is left perfect, preventing accidents such as

described. This matter is of so much importance that we cannot refrain from quoting Mr. Fleming's observations on the point. He says, "This natural thickness of the sole and frog-horn is an absolutely essential condition for the maintenance of the foot in health and its protection from injury; and in proportion as it is detached by the farrier's knife, so the foot will suffer. Not only does the soled horn play a most important part in protecting the sensitive parts it covers from injury, but the semi-detached flakes it is always throwing off renders great service by acting as so many spring shields when the horse puts his sole on stones or hard unlevel ground, and also by retaining moisture. They are, in fact, a kind of ever-present and natural 'stopping,' which keeps the horn beneath moist and supple; every flake on sole and frog therefore is valuable." In again noticing the loose box with earth floor and its advantages, although the horses' feet will be found in better and more elastic condition, yet they will at certain times require the usual stopping as when standing on impervious floors.

Our third and last system of accumulating manure in the loose box offers all the advantages required in stable reform. The feet of the horses will always be sufficiently moist without the use of stopping, as evidenced by the experience of the shoeing smith before stated. If, therefore, the present style and method of shoeing is persisted in, considerable alterations in stable accommodation and management must be carried out in order to prevent the serious losses to which valuable horses will always be subject without a practical reform is adopted, particularly as regards details of management. We have known farmers who, in the case of accumulation of manure in the loose boxes, have failed in securing a firm footing for the horses in consequence of using too much straw and too little earth and water. In our experience, however, the mass of manure when cleared out has always been found so firm and solid that it could not be removed by a prong in the ordinary way, but was cut into squares for the purpose by the use of a hay-knife. Although the detail of the plans we have proposed are actually more simple and less trouble to the grooms or stable-keepers than any former plan, yet their prejudices and predilections have in many instances proved a bar to any alteration, and in consequence gentlemen have been often induced to yield to their grooms in this respect. While it is the custom to introduce racing horses for use at the age of two or three years old their feet are only growing, or at least not fully developed, we can understand the evil effects produced by the narrow and contracted feet, and can estimate the large number which prematurely break down; or, from the feet being unable to perform their proper office, the legs and feet become subject to splints, side-bones, and ring-bone. Under the present system horses are often ruined before they reach the age of five years, at which time they ought practically to have only just become fully developed. Very few men interested in the welfare of horses will yield to any description from us or others as to the possibility or advantage of change in their horse management, because they have not seen it carried out and experienced the results, and amongst the most prejudiced we must include the shoeing smith or farrier.

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will consist of ploughing and sowing Wheat up to the hurdles where sheep have been feeding off Turnips and Rape, but the ploughing and sowing should be done simultaneously, because at this time of year we either have night frosts or rain; in either case if the sowing is delayed after ploughing it never does so well again. In this case we find the one-horse drill which we use exceedingly convenient, because the land can be seeded close to the plough; and at this time of year we drill 3 bushels of seed per acre, for the plant has many enemies to contend with at this season, the larks and pigeons in particular, but rooks also. The rains have been abundant lately, but will not prevent, when not engaged in ploughing and seeding for Wheat, the fallow-ploughing of land for next year's root crops, which may be continued until finished. In case, however, the horses should be unable to work on the land, carting gravel, &c., for road repairs should now be done. At the same time men should be employed on taking off the sides of the private farm roads and filling into carts to be drawn to heaps either for future use in the cattle pens, &c., or otherwise heaped for mixture with manure from the farmyard to be laid out on the pasture or park land, this mixture being especially valuable for all kinds of grass land, particularly after the mixture has been effected and properly turned and decayed in the heap. The advantage of paring off the sides of the farm roads and making out the water tables is great, for much less gravel is required for repairs when the roads are formed so as to throw off the water quickly. Carting earth from the old heaps and placing in the cattle pens and also at the bottom of the fold yards for sheep or young cattle should now be done, and the manure allowed to accumulate thereon. We have always converted 150 cartloads of earth annually in this way, for when earth is placed under the dung it does

not impoverish it, because the earth only absorbs the liquid manure which under ordinary circumstances is usually washed away and often lost entirely. At the same time the cattle yards and pens always lay drier and more comfortable for the animals. The lambing folds now to be formed should have earth at the bottom, and the land should be rather on the incline to prevent the accumulation of water during a heavy rainfall.

*Hand Labour.*—The flat-lying soils where the Wheat has been sown should be looked over, and any accumulation of water found standing in the water furrows should be let off with the spade to prevent injury to the young Wheat. Men also will be engaged in hedging, banking, also draining if the weather is not too wet, otherwise it had better be delayed until drier weather after Christmas. Paring and forming the outsides of the farm roads will engage some men, because this work can frequently be done by filling the earth into carts at one operation. Men, and women too, may also be employed in pitting the Swedish Turnips in the fields to prevent game and rabbits and wood pigeons attacking the roots; at the same time the roots are preserved in case of severe frosts occurring, or by the depreciation of their feeding value by sprouting greens in the event of a mild winter.

*Live Stock.*—Since we have done cutting up Clover grass for the horses and cattle the horses have received hay and Carrots or Mangold, about 10 lbs. daily of the roots, for in the event of their being fed on dry fodder only the animals are sure to lose condition. We consider that sudden changes from succulent food to all dry fodder should be avoided for all sorts of stock, but more especially for working animals, either oxen or horses. The horned Somerset and Dorset ewes have now completed the lambing season, at least those kept for early lambs; but those breeds kept as stock on the hill farms of Somerset and Dorset are now just lambing, and they require more care from the shepherd. They require a lambing fold fixed like that used for the down ewes, whereas the early-lambing stock only required a shifting fold on lea ground every night for the purpose of keeping the animals together and under the eye of the shepherd. Some of the Dorset down flocks for making lambs ready for Easter have commenced lambing, and as the ewes are in good condition generally this year and freer from lameness than for several years past it is expected that it will prove a successful season. The bullocks intended for sale at the Christmas markets should now be well cared for up to the time of sending them away. We like not only to keep them clean and well littered in the boxes, but they always do better and lie down more when carried with the horse comb. In feeding bullocks, if for Christmas or any other time, we never exceed 4 lbs. of cake and 2 lbs. of bean or barlymeal mixed and strewed over the cut roots. In this way little waste occurs. We advocate a moderate allowance of roots—only 56 lbs. of Mangold and 70 lbs. of Swedes daily, with sweet Oat straw *ad libitum*. We are enabled to show a return of 8s. per week over the cost of food and feeding. In case they had hay instead of straw no return in money would occur, besides which hay-fed animals will often refuse their other food; but when eating straw never, so far as food is concerned, but enjoy uninterrupted good health. Young cattle as stores and also the dairy cows may still be allowed to run on the pastures and parkland, except where flooded, for they not only get a little grass in open weather but they return to the stalls and yards for the night with better health and good appetites for their roots and other food, which may with advantage be pulped and mixed in the troughs with cotton cake meal and Oat straw in chaff. As the earliest Dorset down ewes are now just beginning to lamb, and as with proper care those lambs which fall now will be sold at Easter, both ewes and lambs should be fattened together, for it is a true saying that "fat ewes make fat lambs."

#### THE SMITHFIELD CLUB FAT STOCK SHOW.

THE exhibition of animals that has been held in the Agricultural Hall this week, together with the splendid stands of roots exhibited by the leading seedsmen, also the great display of farming and household appliances, afforded no indication of a depressed agriculture. The animals generally were of excellent quality, and the huge and almost immovable examples of obesity of a few years ago find little favour at the hands of Judges now. Scotland has scored a great triumph this year, the champion beast of the Show being a wonderful animal of the Scotch polled breed exhibited by Sir Gordon Cumming, whose heifer won the silver cup as the best animal in her division; next she took the £50 silver cup as the best heifer or cow in the Show, the male animal winning the £50 silver cup for the best steer or ox in the Show. The final adjudication gave the crowning honour to the heifer—the champion plate of one hundred guineas as the best beast in the entire Show, and her breeder receives the Society's gold medal. Nine times out of the twelve upon which this special prize has been previously given it has, however, fallen to Shorthorns, but only once did it go to Scotland; that was in 1872, when Mr. Bruce achieved the honour with his polled Aberdeenshire steer. Shorthorns were more numerous but not quite so good as on former occasions, Mr. Wortley of Aylsham securing the highest prize. Herefords were splendid, Mr. Lewis Loyd of Beckenham having premier honours, the Queen receiving a prize in the section.

Devons were excellent, Mr. Walter, M.P., taking the chief, the Prince of Wales also being a successful exhibitor. Cross-breed animals were admirably represented, Sir John Swinburne securing the highest award. The sheep and pig classes were filled by animals of remarkable merit, and attracted a large share of attention.

*Roots.*—The display of roots was as usual extensive, all the leading firms of seedsmen contributing imposing and well-arranged stands. Messrs. Sutton & Sons, Reading, had a large stand, in the centre of which were displayed some dozens of silver cups won by exhibitors at various shows of produce raised from seeds supplied by this firm. Among the roots, which were mostly even and of good size, were fine samples of Golden Tankard, Intermediate and Long Red Mangolds, and Champion Swedes. Potatoes were also largely represented, with samples of grasses. Messrs. J. Carter & Co., High Holborn, had similarly handsome samples of roots, their Warden Prize, Tankard, and yellow-fleshed Mangolds, with the Imperial Prizewinner Swedes, attracting much attention. Lincolnshire Red Globe Turnips were also well represented, with fine Cabbages and Potatoes; of the latter Scotch Champion and Magnum Bonum were particularly noteworthy. Messrs. E. Webb & Sons, Stourbridge, contributed a large and attractive stand in the south gallery, the roots as in the others forming the chief feature. Mammoth Long Red, Champion Yellow Globe, Yellow Flesh, and the Kinver Globe Mangolds and Imperial Swedes being represented by handsome even specimens. Messrs. Harrison & Son, Leicester; Thomas Gibbs & Co., Piccadilly; and J. King, Coggeshall, Essex, also had stands, those from the two former being highly creditable to the firms.

## POULTRY AND PIGEONS

#### EARLY VERSUS LATE CHICKENS AT SHOWS.

AMATEURS who are anxious to have their chickens in good condition for the leading shows are often urged to mate their birds early and hatch early—that is to say, in January, February, or March, and not later than April. Acting under this advice I know many who go to much trouble and expense to secure early chickens for the Crystal Palace and other shows, and for some time back I have been wondering if this is really necessary.

After consulting the last Palace catalogue I should say not. Three parts of the cockerels and pullets entered there are not over seven months old, many are only six, and some less than this, while few are eight months, and hardly any nine or ten. The average being seven months proves that April and May must be the favourite months for hatching the best fowls of the season, and this being so I think the fact is worth noting.

If birds of the finest description can be hatched-out generally in April, I think it is a pity that fanciers should go to so much expense in early rearing. All who have had chicks out in January and February know that they require much more attention and more expensive feeding than April and May birds. It is generally thought that large fowls should be hatched sooner than small ones, as it takes them longer to gain maturity; but amongst Cochins, Brahmas, Dorkings, &c., there were more seven-months birds at the Palace than any other age, while in some cases, such as that of the first-prize Any variety Cochin pullet, the age is given as five months and two weeks. That a June-hatched bird should take a first prize is rather suggestive, and probably it may have made others think, like myself, that many of us are in more haste than there is any occasion for in getting chicks hatched for the same season's shows.—J. MUIR.

[If Mr. Muir had many early chickens this year he was more fortunate than most breeders. It is, doubtless, owing to the general failure of early chickens that the ages averaged so low at the Palace—ED.]

#### POULTRY AND PIGEON NOTES.

SOME time ago we heard that a Society for the improvement of the German Toy Pigeons was talked of. We lately received a copy of the rules of the proposed Society, and a list of those fanciers who have sent in their names as wishing to become original members. It includes the names of many well-known breeders, and the Hon. Sec. *pro tem.* is Mr. W. H. Morton of Newent, Gloucestershire. The class for three varieties of Pigeons at the Crystal Palace contained some charming specimens, of which we specially admired the "Fairy Spots" and "Chequered

Priests." If such classes become common they will be a great addition to the attractions of shows. We see that classes are also to be devoted to these birds at the Cambridge and Cardiff Shows.

THE cup Black Red Game pullet at Birmingham, shown by the Messrs. Staveley, was claimed by Captain Heaton for fifty guineas. This is the longest price we remember being given for a single hen.

OF late years White Trumpeters, at least birds good enough to compete with Mottles, have bid fair to become extinct. We were very glad, therefore, at Birmingham to see several fine specimens, shown by Mr. J. C. Wood, Mr. Hutchinson, and Mr. Shaw. The latter gentleman always gives fanciers of various breeds a treat at Birmingham, but hardly ever shows elsewhere.

BREEDERS of Runts as table Pigeons had a good chance of improving their stocks; we never before saw so many large-sized Runts at such moderate prices.

SOMEHOW it generally happens there that quite a different set of Fantails to those successful at the Palace, win at Birmingham. The first White cock (Mr. Stevenson) is a little beauty, and we much admired the immense length of tail feathers of Mr. Serjeant-Son's third White. Mr. Cresswell's little cup hen at the Palace here only received an "hc;" on the other hand Mr. Stevenson's saddleback, he at the Palace, won first in his class.

AS usual, Mr. Tedd won cup with a magnificent Black Swallow, and Mr. Bulley was second with a very good Yellow.

IN Turbits again there were some strange reversals of fortune from the Palace. Mr. T. S. Stephenson's cup Red was only "hc," whilst Mr. Bulley's third Yellow received the cup. Second was one of Mr. Parkins' pretty little Reds, rather unaccountably passed at the Palace.

IN a two-guinea selling class Mr. Yardley was first with a pretty pair of Whiskered Owls, white, with blue tails. We were surprised to see them unclaimed.—C.

### THE SCHEDULE OF THE POULTRY CLUB SHOW.

CONSIDERABLE interest attaches to the forthcoming Cambridge Show. It is the first effort of the Poultry Club in this direction, and, as the schedule is very liberal and well arranged, we trust the result will be such as to lead to the event becoming an annual one.

There are to be altogether eighty-nine classes for poultry; of these, however, four are selling and six local classes. The Show is to be held in conjunction with the Show of Pigeons, Cage Birds, and Rabbits of the Cambridgeshire Ornithological Society, and it is for members of this Society only that the local classes are intended. Throughout the open classes there are six prizes for the varieties which are usually most numerously represented in the show pen, and five prizes for all other classes. Where there are six prizes they run as follows—£3, £2, £1, 15s., 10s., and 5s.; and in the five-prize classes the figures are the same less the £3 first prize. Both sorts of Brahmas, all the varieties of Cochins, and the chief Dorking sections, are respectively divided into three classes, one for cock and hen, one for cockerel, and one for pullet. Asels, the various sorts of Game and Game Bantams, as also Houdans and Crèves, have each a class for cock or cockerel, and another for hen or pullet. Andalusians, the Dorking and French variety classes, the five sorts of Hamburgs, Langshans, the two varieties of Leghorns, Malays, Minorcas, Plymouth Rocks, with the kindred Scotch Greys and Dominiques (these three being classed together), four sorts of Polish, Silkies, Spanish, Sultans, the large variety class, and four varieties of Bantams, as also five classes of Ducks, one of Geese, and one of Turkeys, are to be shown in pairs of any age. There is a class for live table poultry of any pure breed, or first cross between two pure breeds, with a condition that in the latter case the parentage shall be stated. We trust this class, which has five prizes varying from £2 down to 5s., will be more amply filled than is usual with such classes.

The entry fee to members of the Club will be 5s. throughout, to others 2s. 6d. more, except in the selling and table poultry classes, where the fee is 5s. to all alike; and it is announced in the schedule that members elected up to December 16th will be entitled to all the privileges of membership in respect of the Show.

Members of the Club elected at and after the Palace Show are, as our readers are aware, only liable to subscription for 1882.

The Poultry Club rules are, of course, to be observed, and amongst the general rules we notice one (No. 3), apparently especially framed to meet the difficulties as to which the Club recently took counsel's

opinion. This rule provides that exhibitors in the open classes may bid for, and buy-in, or withdraw their birds from sale, but that an entry in a selling class shall be construed as an irrevocable authority to sell the bird or birds entered in the usual way at catalogue price or by auction, and that these exhibits shall not be bought-in or bid for by their owners. This is, as we gather, the intention of Rule 3, and it seems to us to very fairly meet the difficulties which have arisen. Many shows are now adopting Club rules, but even for those which do not it may be worth while to insert a similar rule to No. 3 in their schedules.

Pigeons, cage birds, and Rabbits have numerous classes, but as these are necessarily entirely in the hands of the local Society they are, of course, not provided for on the same scale as the poultry.

We are informed by Mr. Comyns that he is making arrangements to have through vans from all the chief centres to Cambridge, so that the exhibits may escape the numerous shocks incident to the transfer from one truck to another. The London and North-Western have already undertaken to supply through vans to any requisite extent, as well from their own main line *via* Bletchley as from the Great Western *via* Oxford. The Great Northern, the Great Eastern, and the Midland also all run into Cambridge; and as the South-Eastern and Chatham and Dover are in direct communication with the Great Northern, while the South-Western and North-Western have a connection *via* Willesden, and the London, Brighton and South Coast, and the Great Eastern have a connection *via* the Thames Tunnel, there ought not to be any difficulty as to railway arrangements. If there are sufficient entries through vans will doubtless be arranged from almost every principal line in England, Wales, and Scotland direct to Cambridge. Everything seems thus to point to a success, and we hope it may be achieved. The Show is to be held on January 4th and 5th, 1882, and the entries close on the 20th inst.

CUP FOR SILVER-GREY DORKINGS.—As I appealed through your columns for subscriptions to the cup for the best adult Silver-Grey Dorking at the Crystal Palace, may I announce through the same medium that the subscriptions kindly sent to me were as follows:—J. W. Andrews, Esq., 5s.; J. Cranston, Esq., 10s.; The Countess of Dartmouth, 10s.; Thos. Moore, Esq., 10s. 6d.; Miss Pasley, 10s.; Rev. H. R. Peel, 10s. 6d.; P. E. Plummer, Esq., 5s.; Mrs. Radclyffe, 10s.; Wm. Roe, jun., Esq., 5s.—O. ERNEST CRESSWELL.

### OUR LETTER BOX.

**Books (A. D.).**—The essay on "The Horse's Foot and How to Keep it Healthy," can be obtained, no doubt, from W. H. Smith & Son, 186, Strand, London, W.C., but we do not know the price. The latest essay on "The Principles of Horse-Shoeing," by George Fleming, F.R.C.V.S., Army Veterinary Inspector, is the 13th article in the Journal of the Royal Agricultural Society of England, published in Part I., 1881, price 6s. These essays are the best ever published on the subject. The Society's Journal is printed and sold by William Clowes & Sons (Limited), Stamford Street and Charing Cross.

**Fowls Coughing (E. Pearson).**—Get at a chemist's some of the common solution of nitric acid and the like of sulphuric acid. Put ten drops of each to a quart of water, and add sugar enough to take the bitter taste off. Give this to the fowls to drink. You might also try mixing some of Walton's tonic paste with their soft food. Is their roosting place dry? and have they a dry house or shed to resort to in wet weather? If not you must see to this, or medicine will be of no avail.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

27th.—Very stormy, bright sunshine, and heavy showers at intervals; lail 5 35 P.M.

28th.—Rough night and early morning; fine, calm, sunny day.

29th.—Foggy morning, fair but generally hazy.

30th.—Fair, calm, cloudy.

1st.—Dull and rainy greater part of the day; starlight evening.

2nd.—Fine throughout, with some bright sunshine; moonlight night.

3rd.—Fine, but not very bright; sunshine in morning.

Although rather colder than the previous week, the temperature has been considerably above the average, and thus November has been the warmest for at least a quarter of a century. Very heavy gale and very stormy throughout 27th and the early morning of 28th.—G. J. SYMONS.

### LEEKs.

**J**UDGING from what has appeared from time to time, especially last spring, in the *Journal*, recommending Leeks as a good and reliable vegetable, we conclude that they are not generally cultivated in these islands. Indeed, judging from some of the instructions given by the majority of southern growers, we doubt if even those who do grow them have them at all satisfactory, even in that land of Leeks—Wales.

In the northern half of this island Leeks are generally grown, alike in the nobleman's many-acred garden and in the cottager's little patch or "kailyaird," and are appreciated alike by peer and peasant. Possibly the difference in the cooking of the two divisions of the country accounts for the different degrees of popularity in which this esculent is held. In the north vegetables are mostly used in soups, and seldom is the Leek otherwise used. "Cocky-leeky" is a favoured dish among the upper classes, but not among those lower in the social scale and "cocky-leeky" is the only way that we know of whereby Leeks are used simply as a vegetable. In this form the flavour is too strong for ordinary tastes. In soups, even in Leek soup pure and simple, this strong flavour disappears, and is replaced by one which few northern palates do not appreciate.

If a few necessary rules are observed in its cultivation a crop is certain, even in the least favoured positions. It is like Borecole in this, and bleak indeed must be the spot where neither will grow. For this reason it replaces Onions where climatical causes make the latter a precarious crop. It is also particularly free from insect pests, thriving where Onions are destroyed wholesale by maggots. And then every portion of the plant may be used; so it is an extremely economical vegetable to grow where ground is limited or reasons exist for growing only the most productive crop.

It is of no use attempting to grow fine Leeks on poor soil, for when stinted and starved the crop is scanty and the quality poor. The first thing, then, in the successful cultivation of Leeks is to trench the ground at least two spades deep, and to put a thick layer—the thicker the better—of rich partly decayed manure between the layers of soil, especially under the upmost one. This is for ordinary crops, for these are of the most value. To produce extraordinary crops, to furnish examples for exhibition or other extra purposes, such as those exhibited by a Scotch grower at Manchester last year, the soil must be trenched at the very least 2 feet deep and very liberally manured. To thoroughly incorporate the manure and the soil retrenching may be necessary.

The next point is the preparation of the plants, and various ways are in vogue among those who strive to excel. The common way is to sow the seed in a sheltered position on rich soil about the end of February or beginning of March, or later if the weather should not be favourable at the time stated. Battering them into soil at once cold and damp will effectually prevent success. The seed, though smaller than Onion seeds, will germinate under the same conditions; but, although all the plants are to be eventually transplanted, care should be taken not to sow too thickly; indeed we are not sure but the best way is to sow in rows 1 foot apart.

In order to forward a few plants handglasses or cold frames are sometimes placed over portions of the bed. Deep frames should not be used for this purpose, as the plants are apt to be weakened thereby. The seeds are often sown in cold frames for the same purpose.

To prepare a large number of plants in order to secure extra fine crops, we advise those who are ambitious to excel to make a mild hotbed and to cover it with a glazed frame about the middle of April. A strong heat is mischievous, and should be avoided. Rich soil should be used and the seeds sown thinly. Air should be given after the plants are up, and care must be taken that they never suffer by want of water. An occasional supply of weak liquid manure should be given, which will forward the plants considerably. If carefully treated they will be strong and fit to put out by the middle of May—a gain of two months, for plants raised in the ordinary way are not fit to put out till July. Two months of summer weather to grow in make a difference in the crop that needs to be seen to be believed. Leeks so raised will frequently, if put out on rich soil, measure 12 inches round the stem, and we have often had them with a 5-feet spread of tops by October. And Leeks grown thus are always of first-rate quality.

There is yet another way of preparing plants which is practised by exhibitors, by which the large specimens seen at northern shows are grown. About the beginning of February—not sooner, or the plants will be apt to run to seed prematurely—the seed is sown in rich soil in pots and placed in stove heat. As soon as they show the second leaf, by which time they are forming the second root, the plants are placed in 3-inch pots in very rich soil. When the roots are coiling in these they are shifted into 6-inch pots. They are kept near the light, and occasionally given very much diluted urine or a little sulphate of ammonia. By the second or third week of April they will be fit for kitchen use, and should be hardened off. We do this by placing the pots in a frame into which a foot or so of hot manure has been placed. This will maintain a temperature nearly equal to that to which the plants have been accustomed, and as it cools the Leeks will harden. Then ventilation should be increased for a week or two, when the plants will be ready to be put out. Instead of using pots for the plants they may be pricked into boxes, but in transplanting a check will be given, whereas when pots are used no check is given; at the same time we have raised many fine Leeks in this way. Melon pits, Cucumber frames, and other warm structures, too warm for forwarding any other hardy vegetables, will do capitally for Leeks if they can be well exposed to light. A high temperature will ruin Cauliflowers or Celery in a few days, but will benefit the Leeks. Those, therefore, who can neither spare manure to make hotbeds or afford cold frames for this may utilise any spare room at their disposal.

We have heard of Leeks with blanched stems about a couple of feet in length, but have never seen such, except those we have wasted time on. Among most strains "whip-tails," as they are called, appear, the chief characteristics of which are extraordinary length, and leanness of stems and leaves alike. To an ordinary observer these look as if going to run for seed, but really do not. Believing we could make something of these we seeded some, and by deep planting and earthing-up the stems which naturally shot up we have had blanched stems over 20 inches, but very thin and whip-handle-like. We presume those we have heard of must have been similar, for we have never seen them exhibited. The best we ever grew or have ever seen were about a foot in the blanch or a little over. Stout solidity is to be preferred to dangling weakness, although it sounds well to say that Leeks with 2-foot-blanched stems have been produced.

Do not plant the Leeks among the Celery, and do not plant them in trenches like Celery. Earthing them up is a mistake; nobody ever produced good Leeks in that way. Again and again we have been shown Leeks grown on the Celery-trench principle, but they were not satisfactory. The secret lies in obtaining strong plants, put out deeply on well-prepared soil, at a time when ordinary growers are watching theirs coming up.

For ordinary crops there is no better way of planting than the old-fashioned one of making holes with a dibble a few inches deep (that is down to the layer of manure under the upper spade of soil), and dropping the plants into them singly, but putting in no earth except that which falls in of itself. The hearts of the plants will be much below the surface; but that is just what is wanted, for the hearts will come to the surface, and so the stems will be drawn out to the same length as the hole is deep. We need hardly add that the long blanched stem is most valued, but we warn beginners that the stems can only be lengthened by deep planting. When once the plants have grown strong earthing-up will not cause the stems to elongate.

The plants in pots must be placed in holes dug with the spade. This digging loosens the soil, which would fall into the centres of the plants and spoil them, but this can be prevented by putting a stiff paper funnel round each plant. In a week or two the stems will be drawn so that the centres will be at the surface, when the funnel may be removed.

Leeks raised in the ordinary way may be planted in rows 14 inches apart, those on a hotbed 2 feet apart in the rows and one in the rows, pot plants 2 feet each way. A thick mulching in hot summer weather is of great benefit, and when the soil is pretty well filled with roots a thorough soaking of weak liquid manure will produce surprising growth. Nothing is better than diluted urine from stables or cowhouses, but sulphate of ammonia is very good.

The hardiest and most generally useful Leek is the Musselburgh, the largest is Ayton Castle. Most successful exhibitors at the larger Scotch shows, however, grow neither, but possess strains of their own, of which they are generally very jealous. The best way to secure a good strain is to pick the finest plants and save seed. Those who have never done so and will now begin will be considerably astonished at the results, for Leeks are about the worst-selected vegetables we have. In any ordinary half ounce of seed there are at least a score of distinct varieties, and nine-tenths of these are inferior; and yet the Leek comes wonderfully true. Carelessness alone is the cause of its apparent inconstancy. In selecting plants for seed only those of stout vigorous habit should be chosen, and if for exhibition "Onion-headed" varieties should be avoided, for although this Onion-head is really the best part of the Leek, it is objected to.

In preparing the plants for exhibition they should be carefully lifted with all the roots entire, one or two of the outer rinds being removed from the stem, for these are generally yellow, and dirt is almost always seen shining through. This spoils their appearance, and gives them an unsolid appearance besides. Closeness of texture, solidity, purity of white, straightness, uniform thickness, and length of blanched stem, are the points aimed at by those who engage in Leek-growing and exhibiting.

Anyone who finds himself in spring with a number of Leeks

running to seed need not conclude he is going to have a great loss. If the seed stems are pinched out the plants will form bulbs at the roots like Onions. These are by many preferred to either Leeks or Onions as a vegetable when stewed tender and served with roast meat.—A. H. H.

#### ORCHIDS IN DECEMBER.

THE summer-like weather of last month makes us almost forget winter, but it must be remembered that in the course of this month we are usually subject to frosts which are often very severe and frequently of long duration, and that it is therefore necessary to be always on the alert. On no account must the firing be increased in the event of frost. The temperature should rather be kept low and the moisture mopped up, and the doors and all apertures be covered with mats, especially those with a northern aspect. The temperature should be the same as last month's readings. It will be well now to inspect the surfaces of the pots, so as to remove moss from any new pseudo-bulbs or growths which may be too deeply imbedded.

Of the winter-flowering Orchids the beautiful free-flowering *Angræcum eburneum* is now in bloom. Its ivory-white flowers have a fragrance like that of the Poet's Narcissus, and remain in perfection for about five weeks. The flower spikes of this species are subject to the attack of yellow thrips, which soon disfigures the flowers. The best means of destroying it is to apply a weak solution of tobacco water along the stem, two applications being generally sufficient for the purpose. *Angræcum pertusum* is now in full beauty, producing its gracefully pendulous spikes, bearing numerous small white flowers. This plant should always be kept in the warm house with a moist atmosphere, and should never be allowed to be dry. *Angræcum sesquipedale* is expanding its large ivory-white and long-spurred flowers, which have a Lily-like fragrance. It sometimes bears as many as four to seven blooms on one spike, and remains in perfection for several weeks. Formerly these plants were not supposed to flower until they had attained the height of from 3 to 4 feet, and being of slow growth they took some time before they reached these dimensions, consequently they were very expensive and beyond the reach of many Orchid lovers; but, thanks to the many importations, we have now plants which produce from one to two spikes each when only 10 to 12 inches high, and the prices have fallen considerably. Whether this is a different variety or not we cannot say, but the flowers are equally as good as those produced by the larger plants, and where space is a consideration these small plants are invaluable.

*Barkeria Skinneri*, with beautiful dark rose-coloured flowers, twenty to thirty on long spikes, is in bloom; also *Barkeria Lindleyana*, with its long spike of rich purple flowers, with a white blotch in the centre of the lip. The *Barkerias*, the culture of which all have not quite mastered, seem generally to do well suspended on bare blocks near the glass in the cool house; or another good way is to place the block in a pot, with charcoal and sandstone to steady it, where the plant delights to throw out its thick fleshy roots, requiring little or no peat or moss. They must have plenty of water when growing, and abundance of light and air.

*Cœlogyne barbata* is not so well known as it should be. It produces a strong irregular spike, bearing numerous flowers with white sepals and petals, and a dusky brown lip elegantly fringed. It requires to be grown in the cool house with plenty of water, but should now be removed to the intermediate house, and when it has flowered again returned to the cool house. *Cymbidium Mastersi*, with its almond-scented flowers, is in fine condition. This resembles *C. eburneum*, but the flowers are smaller and more numerous. It should always be grown in the Cattleya house. *Cymbidium giganteum* and *C. Lowii* are fine winter-blooming Orchids. *Cymbidium eburneum* is showing its spikes, which will soon bear from two to three flowers of ivory-like whiteness, and with a delicious odour. Careful attention should be paid to see that no water lodges in the axils of the leaves. Those not already showing or strong enough to flower should be kept in a somewhat dry state, just sufficient water being given to keep them plump, their growing season being from April to December.

*Dendrobium nobile*—This floriferous species and its varieties have the buds starting, and should be gradually brought on. *Dendrobium Wardianum* (imported variety) will require the same treatment—that is, if showing its buds. *Lælia acuminata peduncularis* is a beautiful epiphyte, producing from the top of the pseudo-bulbs a long spike bearing six to seven flowers of a rosy colour and with a dark purple centre to the lip. It should be grown on a block in the cool house, and requires the same treatment as *L. alba* and *L. autumnalis*, which, with *L. anceps* and

*L. Perrinii* still render the houses gay and attractive. *Lycaste Skinneri*, a truly handsome winter-flowering Orchid, with its varieties ranging from pure white to the deepest crimson, will now be in bloom, and is invaluable at this period on account of the long time the flowers remain in beauty either on the plant or when cut and placed in a vase. The plants should be grown in the intermediate house and kept rather shady during the growing season, which is from May to October, and should not be allowed to become dry at the roots. Now they should be in a drier atmosphere, so as to prevent the flowers spotting. *Lycaste lanipes* is also producing its numerous greenish white flowers, which are useful for cutting. It requires the same treatment as *L. Skinneri*. The fiery red blooms of *Masdevallia ignea* look well now amid their dark green foliage. *Masdevallia tovarensis*—This, the only white *Masdevallia* in cultivation, is very floriferous, bearing as many as four charmingly pure white flowers on a single peduncle, and blooming from the old spikes as well as from the new ones. It is the easiest of the family to cultivate, and delights in a cool damp atmosphere and placed near the glass. Until lately it was a very expensive plant, but, like *Angræcum sesquipedale*, is now within the reach of everyone. *Maxillaria grandiflora*—This beautiful *Lycaste*-like Orchid will now be in flower. The flower is sweet-scented and of a pure snow-white colour, with a sack-like lip blotched with purple on each side. It is of easy culture and thrives well in the cool part of the *Odontoglossum* house with a plentiful supply of water, but now while in flower should have a little heat and be kept drier, and as soon as done flowering put back into the cool house, because it soon becomes covered with thrips if allowed to remain long in heat.

*Odontoglossum Alexandrae*, *O. Andersonii*, *O. angustatum*, *O. cirrhosum*, *O. gloriosum*, *O. Hallii*, *O. Pescatorei*, *O. radiatum*, *O. Rossii*, *O. Roezlii*, *O. triumphans*, and *O. tripudians* will now be in different stages. These will require careful attention in looking after for slugs and green fly, which attack them now. A good method to protect them from slugs is to have a trough filled with water, into which place an inverted pot, and then stand the plant on the bottom of it. *Oncidium cucullatum*, a very free-flowering Orchid, is in flower and making a grand display with its green chocolate-banded blooms with large rosy lip, and having the additional charm of being pleasantly fragrant. *Oncidium cheiroporum*, with its branching spikes about 8 inches high bearing from forty to fifty small yellow Heliotrope-scented flowers, is beautiful now.—ORCHIDIST.

#### APPLES AND HOW TO USE THEM.

LITTLE by little we make the experiences of others our own in possession and practice, and if not too late I should like, in return for all the information gained from the communications entitled "Scraps about Fruit," to offer a remark or two about culinary Apples.

These, as a rule, unless specially required small, are to be preferred as large as possible. No better example of a profitable and economic Apple as to earliness, size, thinness of skin, colour (in cooking) and texture is to be found than Lord Suffield. The size and delicate skin do not waste the cook's time and temper in paring as smaller and thicker-skin varieties do. Cellini succeeds Lord Suffield, different in shape and colouring, not so free a bearer, but when well grown large and handsome. I have fruits of Cellini now measuring 10 inches in circumference and weighing 6½ ozs. Winter Hawthornden and Stirling Castle follow. With very late culinary Apples I am not so well acquainted, but most table Apples, if a proper proportion of clear cold spring water be added to them in stewing, will turn out juicy. Some sorts require very little sugar, and the tartness of any variety may be increased by the addition of a squeeze of Lemon juice.

As a preserve or compôte Apples may be used in a variety of ways, and are healthful, refreshing, and less cloying for young people than preserves prepared with the full proportion of sugar.

In Germany Apples are much used in open tarts, cooked thus—Pare and core 3 lbs. of Apples, boil them till perfectly soft and free from lumps in an enamelled pan with about half a pint of cold water, boil quickly and beat free from lumps; when quite soft add three-quarters of a pound of lump sugar and boil twenty minutes more. Lemon juice, grated and fresh lemon peel, or lemon candied peel, or a few well-washed and dried Currants may be also stirred in. Apples thus treated will keep good for weeks, and put into open tarts or tartlets with a crisp short crust, or served as a compôte to be eaten with custard or cream, they make a popular variety among sweets.—A. M. B.

**HYACINTHS.**—The appearance of these bulbs is very much improved for room-decoration by planting the surface of the pots with

any of the dwarf Mosses. *Selaginella denticulata* is one of the best for this purpose, pots of which should be previously prepared, so that it may be ready to lift at the time the Hyacinths are placed in the forcing pit. If then carefully lifted and placed round the Hyacinth bulb, in a few days it will look quite fresh and commence growing. I find that the Lycopods are improved by weak liquid manure.—LEADENHAM.

#### NOTES ON POTATOES.

ALTHOUGH "AN OLD TATER" has not been very fortunate in his experience of Potatoes, yet I think he deserves our thanks for introducing this subject. The Potato being one, if not the most important vegetable crop grown, cannot receive too much attention from all who are interested in its growth. As each succeeding year some new varieties are introduced, some really good, others comparatively worthless, it is only by comparing notes that many can form any idea of their merits. Were the selection of a limited number of varieties left to myself I should be content with Myatt's Prolific Ashleaf, Mona's Pride, Early Rose, Dalmahoy, Snowflake, Magnum Bonum, and Paterson's Victoria. I think most growers will agree that Myatt's is an excellent early Potato. Mona's Pride for some reason is not so extensively grown as it deserves to be; I consider it one of the best kidneys in cultivation. Early Rose is a general favourite. Dalmahoy is an excellent variety but somewhat subject to disease (at least such is my experience). Snowflake is a good Potato, medium size, no waste, and when cooked like a ball of flour. We planted a large breadth of it this year, and I do not suppose we picked a dozen diseased tubers out of the whole crop. Magnum Bonum is a good cropper, and is not so subject to disease as some, but as the haulm grows very strong it is not a desirable variety for a small garden. Anyone possessing plenty of room, or an open piece of ground on which they do not desire to plant a second crop, cannot do much better than plant this sort. Paterson's Victoria is a good old sort, though since the introduction of many of the American and other varieties is not quite so often met with, still I believe it to be quite capable of holding its own against any of the new comers. There are, of course, many other excellent Potatoes grown equally as good, no doubt, as the few I have mentioned, and some do better in one place than they do in others, but I can recommend the varieties I have alluded to, as I have seen them doing equally well in several parts of the kingdom. This season we also planted Woodstock Kidney, Schoolmaster, and Scotch Champion. Woodstock turned out fairly well and nearly free from disease; Schoolmaster coarse and ugly, the whole crop diseased. The Champion, no doubt, is excellent for killing weeds owing to the great quantity of haulm it produces, but the produce is coarse and slightly diseased. Some speak highly of this variety. Tastes differ: my opinion is the same as "AN OLD TATER," that when cooked it is coarse in texture and hard in the centre.

With reference to the disease attacking Potatoes, I believe as a rule many plant too late. Were they to plant earlier the probability is that they could have their first and second earlies up before the disease usually appears. Some years ago, when in charge of a garden in the midlands, I trenched a piece of ground early in the autumn, the aspect was a slope to the S.W. Having heard much about autumn planting of Potatoes, I decided to give it a trial. I planted Mona's Pride and Gloucestershire Kidneys. Happening to mention what I had done to our vicar, he told me autumn planting was a common practice in Hants, and I should find that, though the crop would be but little if any earlier than the spring-planted, yet the produce would be better. What he stated turned out correct. I could not wish for a better crop, all of good size, scarcely a small tuber amongst them, and quite free from disease. But while believing that good results may be obtained from autumn planting, I would not advise its adoption unless their ground is high and dry, or is thoroughly well drained. My Potatoes were planted about 6 inches deep, and a slight covering of litter was placed on during very sharp weather. In the following spring, side by side on the same ground, were planted Dalmahoy and Magnum Bonum. Both produced magnificent crops, but unfortunately the disease made its appearance rather early, and I lost about half the Dalmahoy, while the Magnum Bonums were not affected in the least.—CANTAB.

YOUR correspondent on page 492 gives his experience with different varieties of Potatoes, and, as I have grown some of the varieties he mentions, I venture to give my experience of them also.

To begin with Early Rose and Beauty of Hebron. Mr. Abbey finds these are of poor, waxy quality. With me they are not only excellent in quality, but good croppers and quite free from

disease. *Magnum Bonum*, he says, is remarkable for everything but quality. With me it is a great cropper, free from disease, of first-rate quality, and keeps well till late in the season. Schoolmaster he finds very disappointing. It is one of the sorts most grown here, is of good quality, very floury when cooked, and not of such bad shape as your correspondent finds it. We depend on it and *Magnum Bonum* for our main crop. *Triumph*, he says, quality "fairly good;" with us it is very bad in quality, watery, and of bad flavour though free from disease. We shall not grow it again. *Viear of Laleham*, *Victoria*, and *Brownell's Superior*, though of good quality, are very much diseased this year. *Covent Garden Perfection*, though of good flavour and free from disease, is a small cropper here. *Redskin Flourball*, *International*, and *Scotch Champion* are coarse and bad flavoured. *Woodstock Kidney* is a very handsome Potato, with shallow eyes, good in quality, but does not grow very large though a fair size for table. *Snowflake* is of excellent quality, but is a little diseased some years. *Reading Abbey* I do not like; though a good cropper the tubers are of bad shape with deep eyes. *Hundredfold Pluke* is bad in quality and much diseased. *Trophy* is a great cropper; it keeps well, and is of good quality.

The following six varieties I think are worthy of attention, as they are to a considerable degree free from disease—*Magnum Bonum*, *Schoolmaster*, *Woodstock Kidney*, *Trophy*, *Beauty of Hebron*, and *Early Coekney*; the last named for first early, and it is especially suitable for frame culture.—A SURREY GROWER.

#### LIFTING OLD VINES.

I HAVE read with interest the notes on *Marston* and *Longleat*, and especially the references to the Vines at *Marston*. As old Vines I take a great interest in them, and shall be glad to hear through the *Journal* next season how they have behaved. If the wood ripened well this year good Grapes will be sure to follow next season. Many gardeners are afraid to interfere with the roots of Vines, and most of the failures of bad colouring is through the roots being in exhausted soil. You may supply liquid manure and top-dress with manure, but the results are not what would be obtained with good loam and wood ashes. By removing the exhausted soil and applying new we do not lose a crop of Grapes, but improve it the first season. I have lifted several Vines which were thought to be worn-out with bad treatment and age, and I knew before I started lifting them that my employers would expect good Grapes the following season. I will briefly state how I proceeded.

Where the roots were I did not know; we tried in several places and could not find any. At last we found a few black-looking sticks amongst the drainage, which proved to be roots. The soil was prepared previously, and consisted of good loam, brick rubbish, and wood ashes. I may state that ours were lifted in September and October when they were bearing the foliage, but almost equal results may be obtained by lifting now. In fact, where late Grapes are required it is impossible to commence lifting before this. When lifting now choose mild weather, as frost would injure the roots if exposed. Dig a trench about 8 feet deep from the outside wall, cutting off all the old roots. If the roots are inside and out it will be better, as the few roots that are inside will help the Vines to start next season if they are well watered. After the trench is made commence forking the soil out, working very carefully or the roots will break. Do one Vine at a time. If the drainage is defective renew it, and fill up the border to within 1 foot of the surface, and then spread out the roots, cutting off the bruised parts with a sharp knife, and notch them at intervals. Cover the roots with fine soil, and let the upper roots be within 6 inches of the surface. Cover the border when finished with straw to protect it from wet and frost. When ready start the Vines into growth very gently. When the shoots are about 8 inches long, be careful not to hurry them, as it is the stored-up sap that has caused them to grow. When the shoots have made good progress give a good watering with water about 90°. As their roots will be emitted freely let the laterals run a few joints longer than usual, and allow a few to grow at the top and the bottom of the rod to maintain root-action. If this process is carefully carried out and good cultural attention is given, old Vines may soon appear young again, and fruitless rods fruitful.—A BERKSHIRE MAN.

FLOWERS IN AUTUMN.—All admit that flowers are beautiful at all seasons, but the scarcer they are the more they are prized. The old *Monthly China Rose*, as well as the *White China*, are now very beautiful and do us good service for cutting. Spring-sown *Pansies* are flowering freely. *Aster elegans* is a grand object in the borders now, and *Aster dumosus* is highly attractive. *Helleborus atro-rubens*

is flowering in the border and likely to continue for a long time; *H. olympicus* is also in beauty. Both these are worthy of extensive cultivation. Other kinds of *Hellebores* are coming into bloom, with a little protection will be fine for Christmas decoration.—NORTH YORK.

#### ADIANTUM FARLEYENSE.

I HAVE no doubt there are many readers of the *Journal* who would like to grow this lovely Fern, but are prevented doing so through not knowing that it will thrive in a greenhouse with a minimum temperature of 45° through the winter months. Many fail to succeed through continually shifting the plants into larger pots and not supplying sufficient water. It ought on no account be allowed to become dry, but the soil should always be kept moist. The soil used for potting should be sandy loam with plenty of broken bricks and charcoal well mixed and placed firmly in the pots, these being well drained so that the water passes freely through.

By the above treatment fine specimens can be had 3 feet in diameter in a short time, and the fronds will be much more lasting, and carry that beautiful tint on the young fronds which forms such a contrast to the older ones. We find small plants of this Fern are very useful for room-decorating. They last several weeks in good health.

The old fronds are in great request here, and by cutting the mature fronds the plants are continually producing young fronds even in midwinter.—STIFFORD.

[Some fronds accompanying this letter were very fine.—ED.]

#### SOME EFFECTS OF THE SEASONS IN 1881.

WITHOUT reference to meteorological instruments or tables, but judging from observations horticulturally, I am under the impression that the characteristics of the weather in 1881 will include a low average summer and autumn temperature, a deficiency of sunshine, and an excess of cold drying winds; and that this year will, if possible, prove more marked and singular in its effects on vegetation than any of its predecessors in the unpropitious cycle of years, the last of which I trust we are passing through, and which have all had their seasons more or less out of gear.

Notwithstanding the excessively hot days of June and July, it is only on the assumption that the average temperatures, especially of the summer nights, have been low and sunshine deficient, that I can account for the less perfect development and ripening of several plants and seeds than in either of the apparently colder years of 1879 and 1880. From this or some other unexplained cause or causes, the same varieties of *Indian Corn*, sown under at least equally favourable circumstances, have not ripened so well. *Tomatoes* in the open air up to early August looked promising, and with another week's hot weather would probably have mostly ripened as they did in 1880. In early August some showed colour and a few ripened, and for nearly six weeks afterwards remained almost at a standstill. The plants loaded with full-sized fruit were then seized by the *Potato disease* and the crop totally lost. Some tender *Haricot Beans* from the *West Indies*, and a variety of *Physalis* which partially ripened in 1879 and 1880, either never flowered or lost their flowers this year, although grown each year in warm situations. *Ridge Cucumbers* were also an unsatisfactory crop, and showed unmistakable signs of the influence of cold nights; and some early *Wheat*, although sown earlier this year, did not ripen earlier than in the past two seasons.

On the other hand, outdoor *Grapes* have ripened in good time and better than they have done for several years past, and doubtless the concentration or the distribution of heat and sunshine at certain times has contributed to this result, as the Vine is altogether a hardier plant, which will bear greater variations of temperature. Early *Peas* coming in before the expiration of the hot weather ripened very quickly, and the extremely dwarf variety *Minimum* not only ripened a second crop of seed, but these again vegetated, and if the seedlings had been allowed to remain would probably now have been in pod. During the past three seasons I have secured no thoroughly ripened *Rose seed* from the open air, but this year I have obtained a good many ripe heps, the result of cross-fertilisation, the fine open weather of the past month probably accounting materially for this; but all will perhaps be more satisfactorily explained on a comparison of the mean summer and autumn day and night temperatures of the present and past two seasons. The last unusually wet September told very destructively upon the harvest of late *Peas* and other seeds as well as upon corn, and the recent unseasonably mild and moist weather is producing results which might have been anticipated after a

period of protracted drought; and not only are Strawberries fruiting in the open, but Apples, Pears, and Plums are blossoming now at the expense of next year's crop. Asparagus mulched down for the winter is throwing up good heads. Carrots sown in August have come a good crop, and early Potatoes left in the ground have made shoots 2 or 3 inches above the soil. Wall-flowers, Polyanthus, Primroses, Auriculas, Violets, with Phlox Drummondii and Stocks, are in full bloom. Autumn-sown Lettuces, and even spring Broccoli, are coming in, and Parsnips in the ground are running to seed.

Such are a few of the eccentricities of the seasons in 1881; but perhaps the worst feature is that the well-ripened wood of Roses and other shrubs are making young growth, in some cases an inch

in length, almost down to the bottom buds; and I fear that in case of ordinary sharp weather succeeding, this can mean nothing less than total destruction in many cases, and it behoves all gardeners to be prepared for the worst.—T. LAXTON, *Bedford*.

#### BEURRÉ BACHELIER PEAR.

THE Pear, a typical example of which is represented in the annexed engraving, possesses in favourable soils a combination of good properties. The tree grows well without being gross, and bears freely. On the Pear stock it makes a fine wall tree, and on the Quince a fruitful cordon and productive pyramid. It is, moreover, a very hardy Pear, and we have seen it produce

Fig. 84.—BEURRÉ BACHELIER.

excellent fruit on espaliers in northern districts, while in the south we have gathered grand specimens. The quality of the fruit varies considerably with soils and seasons, as also does the period of ripening. In good condition it is juicy, buttery, and richly flavoured, and decidedly ranks as a first-rate Pear both for the home, dessert, and exhibition purposes. The fruit is usually in use in December, but this year we had specimens fully ripe a month before we expected them. The abnormally high mean temperature of November has no doubt accelerated the ripening of this and other Pears, though other causes more or less obscure may have contributed to their precocity. The following is the description of this useful and excellent Pear—Fruit large and obovate, somewhat irregular in its outline. Skin greenish yellow streaked with russet dots. Eye small and closed, set in a shallow basin. Stalk short. Flesh buttery and melting, rich, juicy, sugary, and aromatic.

VAPOURISERS.—In answer to "A LOVER OF HORTICULTURE" allow me to say that my gardeners use a pair of bellows, at the end of which

is a brass ball containing the liquid you want to inject on the plants. The spray is very fine, and the bellows can be worked in any position. My gardeners are very much pleased with them; they are called Soufflet Injecteur Pillon. I obtained mine in Paris at Allez Frères', a well-known shop.—J. FREEMAN.

#### PROTECTING ROSES.

"D., Deal," is more fortunate than me. He writes to warn us not to be too anxious to protect our Roses; rather "unprotect," he says, by putting the fork under them, and so bringing the sap down to inquire what is the matter with the roots. Twelve months ago I wrote to the Journal giving similar advice, and saying, moreover, that the season being so mild, any "cossetting" would increase the destruction should very severe weather ensue. But, unfortunately for me, before my notes were printed a frost of 26° had made itself felt. We all remember the very sudden and extreme change at the end of last year.

But when "D., Deal," says that as many Teas are as hardy as

H.P.'s, he is right, and he is, I think, wrong. He is right when the Roses are grown on high land, and where only dry frosts exist; he is wrong (so I think) when the land is heavy and wet, and the situation low and the atmosphere moist. Where I am now living, on the top of a hill several hundred feet above the sea level, not a standard Rose has been killed during any of the past three winters, neither have they been protected, while a mile below in the "warm" valley not a standard Rose exists. Let me advise those whose gardens are in low situations to protect their Teas, but with light, short, and dry litter. Nothing is better, I fancy, than the Bracken Fern thoroughly dried. And after a thaw, when the Fern is very wet and pressed down by its increased weight, then I get a stable fork and shake it up lightly, so that the effect of breeze and sun may soon dry it; and in mild weather I bring it away from immediate proximity to the plants, and so prevent that "sweating," which, if followed by a hard frost, must be injurious.—J. A. W., *Alderminster*.

#### NOTES ON VEGETABLES.

I QUITE endorse the remark of "E. S." in your issue of November 24th respecting the benefit that would be derived if you were to devote a little space each week to notes on vegetables. In this county (Durham), and in fact the whole of the north of England and Scotland, Leeks are very extensively grown, and yet very few people seem to know how to grow them to anything approaching perfection. I have been told that in Scotland they have been grown this season with 23 or 24 inches blanched, but the largest I have seen measured 14 inches. I have tried again and again, but I seem to make very little improvement. I can manage to get about 8 inches of blanch, but that is the very outside. I have no stint of manure, and think I work the ground well. I sow my seed in a box early in February, and as soon as the plants are large enough I prick them into another one among a good mixture of soil and manure, and finally plant them into the open ground about the first week of May. If any of your numerous correspondents could give a few practical hints on the successful cultivation of Leeks it would enlighten among many of your readers besides—ONE IN THE DARK.

[Our correspondent will find some light on this subject on page 533.]

BRUSSELS SPROUTS.—Taking into consideration all the good qualities of this vegetable—hardiness, productiveness, and quality—it must be regarded, I think, as the best of all vegetables for autumn and winter use. But are not raisers and selectors spoiling it by "improvement?" I have tried different people's "giants," and have been a little proud of the results; but I have noticed the larger I grew the sprouts the less were they appreciated in the dining-room. Their size, colour, and quality are all complained of, and small, round, hard, green knobs are being asked for and pressed for. I have not a doubt there is good reason for complaint, for I must admit that neither in appearance nor quality the big coarse lumps are so good as the smaller, harder, greener knobs that are produced by the older varieties. Since writing the above I find "A KITCHEN GARDENER" (page 511) is of the same opinion as myself on this point. What do others say?—A NOBLEMAN'S GARDENER.

CERTIFICATING POTATOES.—A few weeks ago I observed some second-class certificates were awarded for Potatoes by the Vegetable Committee of the Royal Horticultural Society, and the matter was commented on in one of your notes. Since then the honours thus granted have been much discussed privately, and no one appears to understand what the certificates mean. If the Potatoes were first-class it would seem that second-class honours do not do them justice, while if they are only second-class in quality they are not worthy of a certificate at all. Potatoes are now increasing so rapidly and lists of them are so long that it appears undesirable, to say the least, that such a body as the Royal Horticultural Society should scatter needless honours that can only result in raising the price of seed. It would be instructive to know on what principles the Committee acted when they awarded second-class certificates for Potatoes. At the present the matter is not understood.—A PUZZLED POTATO RAISER.

EPIPHYLLUMS.—These on being introduced into heat may be made very attractive for room-decoration by having a few small seedling Maidenhair Ferns planted in the pot with them. The dark green fronds of *Adiantum cuneatum* have a good effect in contrast with their brilliant flowers, as well as hiding the bare stems of the plants. We had a few in this way last year that were very much appreciated.

When placed in a vase they have the appearance of a fine bouquet. The Ferns are quite at home in the same compost as Epiphyllums, and may have liberal supplies of liquid manure.—LEADENHAM.

#### ROYAL VISIT TO LONGLEAT—LUNCHEON IN THE VINERY.

WHAT dining-room, however bright and gorgeously furnished with all that wealth and taste can supply, could compare with the simple yet grandly proportioned vinery at Longleat for the purposes of a luncheon? The dining, reception, and drawing-rooms of the mansion were undoubtedly splendid by the richness of the ceilings, furniture, and flowers, but luncheon under a canopy of Grape Vines laden with large, symmetrical, bright amber-coloured bunches of fruit must be a treat even for a Prince, for it was under the magnificent Vines that their Royal Highnesses the Prince and Princess of Wales were, with other distinguished guests, entertained by their noble hosts on Saturday last. The Prince of Wales would undoubtedly see such an example of Grape culture as he has never seen before, and would not fail to appreciate the masterly way in which the Vines have been cultivated; and Mr. Taylor, I feel sure, would receive, as he deserves, the congratulations of His Royal Highness, who is always as ready to acknowledge merit as he is quick to perceive it. The table was fixed in the Muscat house, which, although it had supplied dessert in no stinted quantities to over five hundred people at the ball the previous evening, looked still to have a full crop; and the late Grapes, which are all black, hanging in the adjoining compartment amongst foliage of crimson and gold, made such a picture as needed no further ornamentation.

In passing through the vinery in question I was gratified beyond measure by the sight I beheld. Nothing equal to it, I dare assert, can be witnessed at this period of the year in any part of the kingdom. The house and its contents, the mode of cultivation, and many other details have recently been so accurately described by Mr. Wright that I need not here repeat them. I fully endorse all that has been said, and corroborate the soundness of Mr. Taylor's system of cultivation. I have the more pleasure in doing this, as it entirely in the most essential parts agrees with my own views as to the proper mode of Vine culture, which I advocated in the *Journal of Horticulture* many years ago.

If Mr. Taylor's success continues another year—and there can be no doubt if he is spared it will—all who wish to witness the successful cultivation of the Vine, and to learn not only how to grow it but to cause it to produce its fruits in due season in great abundance and of first-rate quality, should make a pilgrimage to Longleat. Even the most sceptical would be convinced by ocular demonstration that the system of Vine culture there adopted is the correct one; and even the sage writers on the cultivation of the Vine and other fruit trees—the systematic pruning, training, and quarter-of-a-degree-temperature-advocating fraternity—would soon find the castles they have built in the air as model structures for the guidance of the coming age of gardeners ruthlessly shattered, and the film which has obscured their vision quickly cleared away by the rarified air of Longleat. They will also find a fund of information willingly imparted by Mr. Taylor on most topics connected with horticulture.

The various other subjects in the gardens described by Mr. Wright bore witness of the truthfulness of his descriptions. The Roses, Tuberoses, Carnations, Pelargonium (*Guillon Mangilli*), Begonia *Knowsleyana*, and Gesneras are wonderfully well grown and superbly flowered, large masses of which adorned various nooks and corners in the mansion. The plants grown in what appeared to be small Orchid baskets, and which were placed on tables, &c., in the drawing-rooms and state apartments, were perfectly lovely. The simplicity of the baskets, and the surface of the soil they contained being covered with bright green moss, much enhanced the beauty of the plants, and made them appear as gems amid the magnificent decorations and works of art by which they were surrounded.—JOHN WILLS.

#### PRIMULAS IN SMALL POTS.

AT potting time in the summer some of our Primulas were shifted from 3-inch to 6-inch pots, and others were allowed to remain in the 3-inch pots, as we had too many to find large pots and room for. Those in the small pots were grown with the others. Lately many of both lots have been blooming, but those in the smallest pots have far surpassed those that were shifted both in the size of their trusses and blooms; in fact, we never saw Primula flowers better than those in the small pots, and for

placing in small vases in rooms they are most convenient. Many Primulas, especially during such damp weather as we are having, are very liable to decay at the base of the stem, but in small pots they rarely show any indication of this, as the pots are crowded with roots, and the plants do not suffer from being over-watered, as plants in large pots with few roots often do. The small plants were the first to come into flower, and they will, I think, be the last to go out, and altogether we are so much pleased with them that I cannot help asking that the plan be generally tried next year.—M.

#### EXTENSION VERSUS RESTRICTION OF TREES AND VINES.

I AM pleased to see this question discussed by your various correspondents who write on "Theories on Vine Culture," also by "JOHN BULL," who caricatures restriction and its inconsistencies, and places the matter in a nutshell when he shows that Pear trees which have the strong shoots cut back to 9 inches or a foot have to be root-pruned also to keep them from doing the very thing that the cutting back is sure to cause—*i.e.*, making a mass of useless wood, and that neither practice is often necessary under proper culture. With regard to Vines, it is for recognised advocates of the cutting down of good young rods to the bottom to come to the rescue of their disciples. I will put it thus, and be glad of an answer. Supposing we have a good young Vine cane one year old stopped at the top of the rafters, and the laterals restrained within reasonable bounds so as to produce fairly good buds and a well-ripened cane, what reason exists for cutting the same down to within a foot of the ground? Is such a practice necessary on the score of either lengthening or strengthening the Vine the seasons immediately following, and if so, why?—EXTENSION TRAINER.

#### AN AMATEUR'S HOLIDAY.

To one imbued with a real love for flowers, the advice so often offered in the columns of the Journal to go and see gardens where the favourites are tended by skilful and loving hands would seem to be wholly unnecessary. Flower shows afford pleasure and evoke wonder, or they may, as they ought, incite to praiseworthy effort and laudable emulation. But, although valuable hints in many departments can there be gleaned by an intelligent observer, such displays can in very limited measure teach us how to effect similar results. For that purpose we must visit the gardens whence come these products of cultural skill. I will now offer to your readers a few jottings of a ramble such as I have annually indulged in for some years, when release from professional duties affords opportunity of seeing old friends and forming new acquaintance.

Circumstances prevented me visiting the great Show at Manchester, and thus I missed what would have been to me not the least of its attractions, Mr. Kelway's display of Gladioli. Our Edinburgh and Glasgow Shows followed. May I offer a few remarks on these? In the former was much that was notable; but there were three exhibits not to be soon forgotten. First, the Rose from Messrs. Cocker, Aberdeen; second, the two lovely baskets of *Primula capitata* exhibited by Messrs. Dickson & Co., Edinburgh; and third, specimens of a pretty plant from the Edinburgh Botanic Gardens, a recent importation from India, where it was found at an elevation of 4000 feet. This was a little Golden Primula, *P. floribunda*. Among all its more imposing surroundings that little beauty fixed my attention. The Glasgow Show eclipsed that at Edinburgh in the extent and quality of florists' flowers. While in the latter there was not, as far as I recollect, a single Pansy, magnificent specimens both of the Show and of the Fancy varieties were present at the former in hundreds, and alone were worth going far to see. Dahlias, Asters, and Marigolds were better at Glasgow; the French varieties of the last were numerous and really splendid. There, too, Gladioli were superior. But in neither exhibition were these at all equal to what we have seen in favourable seasons. I believe the fact that many more amateur florists are to be found in the west accounts in great measure for the very marked superiority of the Glasgow Show as regards the excellence and abundance of florists' flowers.

Next morning I started for Belfast, the attractions of which have more than once drawn me to the Emerald Isle. Accounts of visits to several notable manufacturing and other interesting establishments, or of a run to the Giant's Causeway, would not be appropriate to your pages. No one could fail to admire the wooded beauty of the country at many points on the route to the last. Belmont Nursery claimed early attention, where I spent an hour with Mr. Hugh Dickson, whose Roses have so often delighted visitors to Scottish shows. Heavy demands immediately previous to my call had

rendered first-rate blooms scarcer than I had seen them on former visits, but excellent plants were there in many thousands, great numbers of which will, as usual, find their way to the gardens of Scotland. A collection of Gladioli, extensive and varied rather than select, well-filled houses of table and other plants, and a capital display of Dahlias, were among the numerous features of these extensive and attractive grounds.

Next day a short run to Newtonards took me to the establishment and to the genial welcome of another hero of a hundred Rose fights, Mr. George Dickson, now head of the firm of Alexander Dickson and Son. High expectations founded on previous experience were here fully realised, and a walk through the beautiful nurseries disclosed material in ample abundance for meeting the extensive demands. A large house filled with Tea Roses in pots in splendid health is worthy of mention, and intended efforts in raising new varieties of this class will doubtless, in such hands, be heard of by-and-by.

Calling at the Belfast Botanic Gardens, I formed the acquaintance of the Curator, Mr. McKimm. The *Bougainvillea glabra*, already noticed by a correspondent, was very fine. The wire trellis, 30 feet by 20 feet, which this fills, is, when the plant is not in flower, drawn up near the glass, and the stage below used for other purposes. Mr. McKimm stated that, however splendid the display was when I saw it, the want of sunshine during the season had rendered the bloom much less profuse this year than usual. The Gardens are well worth seeing, and would under other circumstances be much more so. But I confess that to find them more of a people's recreation grounds than strictly Botanic Gardens rather surprised me. Ground for lawn tennis, and a large dancing hall in course of erection, seemed to me incongruous with the purposes of such institutions, and an unfavourable comparison with our well-appointed Botanic Gardens in Edinburgh was inevitable. No skill, backed by whatever enthusiasm, can compensate for the absence of essential facilities; and to have beds trodden down, plants uprooted, and tallies converted into boats in the adjoining ponds by troops of thoughtless or mischievous children, are conditions unfavourable to the proper maintenance, and adverse to the object of botanic gardens, as that term is usually understood.

Duty called me but too soon away from the kindly folks of Ulster. Returning by steamer to Stranraer, I there visited one whom I already knew. The Roses of Mr. Thomas Smith are no strangers to Scottish florists. Here I saw a good many of the new varieties, English and foreign, in flower, and an abundant supply of excellent material awaiting the season for dispersion. These nurseries, as well as those of Belfast and Newtonards, are well stocked with all the requisites for a large and flourishing business in all departments.—A NORTHERN AMATEUR.

(To be continued.)

#### ALEXANDRA PALACE CHRYSANTHEMUM SHOW.

DECEMBER 9TH TO 13TH.

EARLY-FLOWERING varieties of Chrysanthemums are now by no means scarce, and the chief efforts to prolong the season of these easily grown and attractive plants must be directed towards obtaining varieties flowering after the majority have passed their best. It was with the object of showing what can be done towards this end that an exhibition was arranged to take place at the Alexandra Palace at such a late period; and though the display produced was not extensive, and neither plants nor blooms were of remarkable excellence, yet most of the exhibits were better than many expected. With scarcity of materials it is not easy to make an elaborate display, but with the addition of some Tree Ferns and other specimens a pretty arrangement was produced under the superintendence of Mr. J. Forsyth Johnson.

Of the seven classes provided for specimen plants only three were represented, and in these the competition was very limited. For eight Pompons Mr. Butcher, gardener to R. A. Glover, Esq., The Priory, Barnet, was placed in the leading position with dwarf fairly well-flowered compact specimens, Fanny, Marie Stuart, and La Vogue being the most noteworthy varieties. The same exhibitor had the only collection of six Pompons, not in quite such good condition as the others, but with numerous blooms. Antonius, Andromeda, St. Michael, and La Vogue were fair. Mr. J. P. Kendall, Roehampton, Surrey, had the only three standards, gaining the first prize with Dick Turpin and Julia Lagravère.

Cut blooms were more largely shown, and in all the leading stands they were neat in form, though small. The best twenty-four large-flowering varieties were staged by Mr. J. Hill, gardener to A. Savory, Esq., Potter's Park. These included fair examples of Dr. Masters, Princess Teck, Lady Slade, Hero of Stoke Newington, Christine, and Baronne de Prailly. Mr. Kendall followed with less regular flowers, but *Striatum* was well shown. Mr. Butcher took the leading position with eighteen blooms, John Salter, Mr. Gladstone, Lady Slade, Venus, and Jardin des Plantes being especially noteworthy for their substance. Mr. W. E. Clark, gardener to A. Nagle, Esq., Bijou Cottage, Kingston,

was adjudged second honours for fresh bright blooms, Fulton, Yellow Dragon, and Ne Plus Ultra being the best. Messrs. Clarke and Steward, Longford Park, Malden, were the prizetakers with collections of twelve, both contributing moderately good blooms. Pompons were not of first-rate quality; but a creditable stand, twelve Anemone varieties from Mr. Kendall, deserves notice. King of Anemones, Lady Margaret, and George Sands were the leading varieties.

In addition to the Chrysanthemums were the following—A beautiful group of Primulas and Pelargoniums from Messrs. H. Cannell & Sons, Swanley, a group of succulent plants from Mr. Boller, and several collections of large Gourds.

At a General Meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, Major F. Mason in the chair, the following candidates were elected Fellows—viz, J. H. Mangles, Mrs. Edric Bayley, Mrs. Wm. Bevan, Miss Mary Catherine Browne, The Lady Hothfield, Edward Mawley, F.M.S.; Charles Pigott, Mrs. James Travers.

— THE COMMITTEE of the FARNINGHAM ROSE AND HORTICULTURAL SOCIETY, at a meeting held at the Lion Hotel on Monday last, decided to hold their Exhibition next year on Saturday, July 1st. A liberal schedule is in course of construction.

— A CORRESPONDENT who does not favour us with his name and address, has sent us the following note relative to the late DR. DENNY—

“The *Journal of Horticulture* has not a word to say respecting Dr. Denny now he is no more. He certainly did a good deal for one branch of horticulture and deserves some notice.”

If our critic will refer to page 474 of our issue for November 24th he will, perhaps, admit his mistake, as he will find there a reference, however imperfect, to our much-lamented friend and earnest co-worker in the cause of horticulture.

— AT A recent meeting of the chief shareholders and directors of the HULL BOTANIC GARDEN some considerable reductions in the expenses were proposed to meet the rather heavy deficiency. It is suggested that they should engage a man as Secretary and Curator at a salary of £100 per annum, the house formerly occupied by the late Mr. Niven to be let. This was opposed by several influential members, and it was hinted that such a course would be extreme. Unquestionably the prospects of the Society appear to be far from encouraging.

— A CORRESPONDENT informs us that some very fine PRIMULAS are now flowering in the gardens of A. M. Duncombe, Esq., The Cottage, Scarcroft, Leeds. The plants, we are informed, are 18 inches in diameter and the same in height, and many of the flowers exceed 2½ inches in diameter. One of these has been sent to us, and it is remarkable for its size and substance, while the colour is very bright. The variety is Carter's Carmine Beauty, and beautiful it undoubtedly is; in fact, we never saw a finer flower.

— WE are informed that “the decorations on the grand staircase, the principal corridors, and the great hall which served as a temporary ballroom on the occasion of the recent ROYAL VISIT TO LONGLEAT, were entrusted to Mr. Wills, and that a plentiful supply of the large Palms, Tree Ferns, Dracenas, &c., from the establishment of the General Horticultural Company were made to do duty. Many of the plants were splendid specimens; they were tastefully arranged, and it is questionable if they ever showed to better effect than they did in the lofty apartments of this venerable and noble building.” Our correspondent, who was present at Longleat during the festivities, also

obliged us with an account of the luncheon in the vinery, but a description of this, sent by Mr. Wills, was already in type (see page 538) when the letter in question reached us, and it is consequently not necessary to insert it here.

— MR. A. PETTIGREW, The Gardens, Cardiff Castle, Cardiff, informs us that his foreman, Mr. John Lindsay, has been appointed gardener to the Earl of Gainsborough, Exton Park.

— PARTS 31, 32, and 33 of “FAMILIAR GARDEN FLOWERS” (Cassell, Petter, & Galpin), contain coloured plates of the York-and-Lancaster Rose, Lobelia Erinus, the single Stock and Jasminum nudiflorum, the Indian Pink and blue Sage, with the interesting, descriptive, and historical particulars concerning each plant from the pen of Mr. Shirley Hibberd. Parts 54, 55, and 56 of “FAMILIAR WILD FLOWERS,” published by the same firm as the above, give coloured illustrations of the Yellow Rattle, the Hedge Calamint, the Dove's-foot Cranesbill, the Creeping Thistle, the Melancholy Thistle, and the Lily of the Valley, all but the last being fairly well executed. The accompanying letter-press, however, furnishes as much popular information as could be desired about each plant.

— LAST year at this time we received from Messrs. Eyre and Spottiswoode, the Queen's Printers, a packet of CHRISTMAS CARDS, which we noticed in this Journal because of their artistic excellence and the beauty of their execution. They consisted chiefly of floral subjects, and as such called forth our admiration. This year we have received another packet equal in every respect to the former, but the subjects are more varied. And speaking of variety, we have before us a catalogue of these annuals, which contain upwards of five hundred different designs.

— WE have another packet from Mr. Arthur Ackermann of Regent Street, the artistic execution of which calls for the highest commendation. There are three series—Fairyland scenes; the Naval, Military, and Volunteer series consisting of some sentimental and some highly humorous subjects; and the Sporting series, which treats of hunting, coaching, and steeple-chasing in various moods.

— FROM Mr. Ackermann also comes a packet of Christmas cards issued by Messrs. L. Prang & Co. of Boston, U.S.A., in which flowers play a leading part, and which are very faithfully and beautifully executed.

— A NEW serial, of which the first part is now before us, has been issued by Mr. Eliot Stock, entitled “THE BIBLIOGRAPHER, a Journal of Book Lore.” To the student, the bibliophile, and the antiquary this will be an acceptable monthly, for it treats on everything relating to books, printers, and authors since the art of printing was discovered. The first is a very interesting part, and contains an account of the Sunderland library, which is now in the course of dispersal by Messrs. Puttick & Simpson.

— AMONG the most useful annuals which appear at this season we know of none that are more useful than LETTS' DIARIES. A set of these is now before us, supplied by Messrs. Letts & Co., and consist of every size and form, from the small pocket book to that of the folio-sized “Rough Diary” for the office desk. Those most adapted for the merchant's or the library table are No. 8 and No. 13. The former supplies a vast amount of information, and is quite a reference book for commercial purposes, and the latter is well adapted for the study.

— WE have also before us the last issue, part 22, of LETTS' POPULAR ATLAS, of which we have frequently spoken highly, and this number is in no way inferior to any of its predecessors.

— ONE of the extraordinarily sudden CHANGES OF WEATHER that we ever remember to have noticed occurred in the metro-

politan district last week. On Thursday the 8th inst. the day was bright, clear, and spring-like—one of the finest December days ever known. Rain commenced falling at night, and continued for many hours; the next day, Friday, being one of extraordinary gloom, and of a kind not often experienced even in London. The whole day was as dark as night, and lamps were burning indoors and out the same as at night. This was the result of a fog, which was so thick as to completely obstruct the rays of the sun, and the result was almost total darkness. Yet the fog in many places did not reach the earth, hence there was little or no discomfort beyond that incident to the absence of light. A light, silent, oil-like rain fell during the early period of the day, its peculiar softness being the result, no doubt, of passing through the fog that hung like a thick canopy over the City. The next day snow fell thickly for some hours, but melted as fast as it touched the ground. The weather has since been unsettled, and not favourable for planting and ground work generally.

— We learn that growers in California have begun to turn their GRAPES into raisins. Three years ago no raisins were produced, now the crop amounts to 150,000 boxes, and is worth half a million of dollars.

— We have received further communications relative to PLANTS IN LARGE AND SMALL GARDENS, and as we must either publish all or none of these, we choose the latter alternative. We fail to see in what manner the further discussion of a subject of this kind can be profitable. The truth of the matter is that some "single-handed" cultivators grow both hard and softwooded plants admirably; while, on the other hand, we have seen some of the finest examples of culture in the largest gardens in the kingdom. If specimen plants are needed there is no lack of men who can produce them if adequate means are provided; and whether a man does the work himself or instructs another to do it, obviously cannot affect his position as a cultivator.

— At the next meeting of the METEOROLOGICAL SOCIETY to be held on Wednesday, the 21st inst., at 7 P.M., the following papers will be read—"The Rainfall of Cherrapunji, Assam," by Professor John Eliot, M.A., F.M.S.; "On the Meteorology of Cannes, France," by William Marcet, M.D., F.R.S., F.M.S.; "The Principle of New Zealand Weather Forecasts," by Commander R. A. Edwin, R.N., F.M.S.; "Report on the Phenological Observations of 1881," by the Rev. T. A. Preston, M.A., F.M.S.

#### SALVIA SPLENDENS.

"A NORTHERNER'S" remarks on *Salvia splendens* in your issue of the 1st inst., and his mode of cultivating it, has induced me to make a few remarks on its culture here during the past summer. In the spring we struck a batch of cuttings, and potted them and treated them similar to bedding plants, and when bedding-out time arrived we planted them on a sunny border in the kitchen garden about 2 feet apart, giving them water as required with an occasional supply of liquid manure. They grew very freely and were pinched-in so as to form well-balanced heads. At the end of August they were lifted and placed in 10-inch pots and arranged behind a wall with a north aspect until they were established. Towards the end of September they were placed under glass, and at the time I now write (December 5th) they are fine healthy plants, well furnished with good foliage. They are about 3 feet or 4 feet in diameter. On one plant the spikes of bloom are 112 in number. These plants are very showy at this dull time of the year when bright flowers are scarce and valuable.

By this plan of culture much time and labour is saved in watering the plants. Treated in the way described, which will, I think, compare favourably with those grown in pots. They succeed best in a moderately warm house with abundant ventilation in fine weather.—G. R. ALLIS.

OSMUNDA PALUSTRIS.—"R. I. L." writes that this is one of the best Ferns for furnishing purposes. While extremely graceful it stands well, and the beautiful green of its pinnules is contrasted with the red colour of the stems of the fronds, which produces a

lively effect. It is more graceful than *O. regalis*, and is prettier, but it must be regarded as a variety of that plant. Though distinct for garden purposes it is not allowed to be a variety by some botanists.

#### ROYAL HORTICULTURAL SOCIETY.

DECEMBER 13TH.

THE vegetables in the competition for Messrs. Carter & Co.'s prizes formed the chief feature at this meeting, though plants were also well represented, the Council-room being fully occupied. Messrs. Veitch's, Bull's, and Cannell's groups were especially attractive. The weather was, unfortunately, extremely dull, yet this did not deter the members of the several Committees from assembling in large numbers.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Mr. Wallis, The Gardens, Keele Hall, Staffs, sent fine examples of Grapes Barbarossa, Mrs. Pearson, Alicante, Golden Queen, Muscat of Alexandria, and Gros Colman, two bunches, to which a cultural commendation was awarded. Mr. G. R. Alhs, The Gardens, Old Warden, Beds, sent three bunches of Pearson's Golden Queen Grape, remarkably well grown and of excellent flavour, but the Committee are of opinion that this Grape is inferior to Muscat of Alexandria, which ripens at the same season. Mr. Fisher, Bangor Castle Gardens, Bangor, Co. Down, sent a large bunch of Gros Colman Grape, which had been much rubbed in transit. Messrs. Laing & Co., Forest Hill, sent three good bunches of Alicante Grapes, to which a letter of thanks was awarded. Mr. Wilson, gardener to Lord Fortescue, Castle Hill, North Devon, sent four handsome Smooth Cayenne Pine Apples, weighing in the aggregate 24 lbs. A cultural commendation was awarded.

Mr. Thomas Laxton, Girtford, Beds, sent a seedling Apple called Henry Webb, but not considered superior to other kitchen Apples in cultivation. Missouri Pippin, an American Apple, was not thought worthy of any commendation. A seedling Apple, raised in Canada, was sent by Mr. Batters, Hill House, Stanstead, Herts, but it was not considered to be possessed of any merit. Mr. Sidney Ford, Leonardlee, Horsham, sent a seedling Apple called Margaret Henrietta, which was passed. Rev. G. M. Straffain, Tillington Rectory, Peterworth, sent some dishes of Apples, to which a letter of thanks was awarded. Mr. R. Gilbert, Burghley Gardens, sent four brace of Cucumbers—Frost's Prolife, Veitch's strain of Telegraph, Montrose Seedling No. 1, and Montrose Seedling No. 2. A cultural commendation was awarded. Mr. W. Sutton, gardener to J. S. Sassoon, Esq., Ashley Park, sent a brace of Cucumber Model, very skilfully grown, to which a cultural commendation was awarded. Mr. Gilbert also sent specimens of Barr's Large White Cos Lettuce, to which a letter of thanks was awarded. Messrs. James Carter & Co. sent a dish of New Golden Queen Onion, for which a letter of thanks was awarded, and it was ordered to be grown at Chiswick. Mr. Findlay, gardener, Wroxton Abbey, Banbury, sent a dish of Wroxton Onion, raised between White Spanish and Williams' Improved. It was ordered to be grown at Chiswick. Mr. Ewart, The Gardens, Apthorpe, Wansford, sent three dishes of Onions—Nuneham Park, Improved Reading, and Magnum Bonum, remarkably well grown, to which a cultural commendation was awarded. Messrs. Cutbush of Highgate sent good examples of Brussels Sprouts from their stock which they have grown for forty years; they were highly approved, and received a letter of thanks. Mr. Findlay also sent some Brussels Sprouts, but they were considered too large.

Three sorts of Celery were received from the Society's Garden at Chiswick—the Winchester Red, Williams' Matchless, and Leicester Red. The first received a first-class certificate, and was grown from seed supplied by Messrs. Rutley & Silverloek. Mr. Lyon, gardener to Sir Edmund Scott, Bart., Sundridge Park, Bromley, sent a fine dish of Mushrooms, for which a cultural commendation was awarded. The same award was given to Mushrooms and spawn exhibited by Mr. John F. Barter, Lancefield Street, Harrow Road. Mr. Perkins, gardener to Lord Henniker, sent Dell's Hybrid Melon, which was very good for the time of year. A letter of thanks was given. Mr. Lyon also sent a specimen of Parsnip 4 feet 2 inches.

MESSRS. J. CARTER & CO.'S PRIZES FOR VEGETABLES.—The valuable prizes offered by Messrs. Carter induced good competition, seven fine collections being staged. It is worthy of remark that the exhibitors were not restricted as to the particular varieties to be shown, twelve dishes being stipulated for. Mr. J. Austin, The Gardens, Ashton Court, Bristol, secured the leading position with a handsome collection, clean, even, and well grown. Some of the most noticeable were Hathaway's Excelsior Tomatoes, King of Cauliflowers, Carter's Maltese Parsnips, Carter's Scarlet Intermediate Carrots, Improved Reading Onions, Carter's Jersey Lily Turnips, and Schoolmaster Potatoes. Second honours were adjudged to Mr. S. Haines, The Gardens, Coleshill House, Highworth, for good Carentan Leeks, Autumn Giant Cauliflower, Carter's Perfection Brussels Sprouts, Tender and True Cucumbers, and Carter's Naseby Mammoth Onions. Mr. R. Phillips, The Deodars, Meopham, was a very close third with well-grown vegetables. Mr. R. Gilbert, The Gardens, Burghley House, Stamford, was fourth; Mr. R. Lloyd, Brookwood, fifth; and Mr. Goldsmith, The Gardens, Hollands, Tunbridge, sixth; all staging very creditable samples. Messrs. Carters also contributed a fine collection of vegetables, filling one side of the approach to the Council-room. Potatoes were largely represented, including samples

of the leading varieties; Kales, Cabbages, and others being similarly well shown.

**FLORAL COMMITTEE.**—G. F. Wilson, Esq., in the chair. Messrs. James Veitch & Sons, Chelsea, contributed a beautiful group of new plants and Cyclamens. The handsome *Jasminum gracillimum* certificated last year was again shown in fine condition, bearing many close umbels of its neatly formed, powerfully fragrant, pure white flowers. Half a dozen plants of *Begonia socotrana* were also exhibited, the flowers being very bright rosy pink, of good form, and abundant. The bright green peltate leaves are alone very attractive, being so distinct from most other Begonias. The Cyclamens were distinguished by their vigorous compact habit, large flowers, and purity and brightness of the colour, though the bright tints could not be seen to the best advantage owing to the dull weather. Several Orchids and other plants were certificated and are described below. Mr. W. Baldwin, Hassocks Gate, sent a basket of his double Mignonette, with fine spikes of flowers, well showing the very distinct character of the variety. He also sent very fine flowers of *Bouvardia Dazzler*, which have a light-coloured tube and bright scarlet lobes. Mr. W. Bull, Chelsea, exhibited several new plants, but by far the most notable was a group of the double white *Bouvardia Alfred Nenner*. The plants were in small 60-size pots, and some were bearing four or five compact trusses of flowers, very neatly formed and pure white. Among other plants were *Cælogyne harhata* with spikes of whitish flowers with brownish haired lips; *Billbergia formosa*, a species with brown leaves barred with white, the flowers being purplish and the bracts red; and *Odontoglossum polyxanthum pictum* is a variety with large flowers blotched with chocolate. A vote of thanks was accorded to Mr. J. Douglas, Loxford Hall Gardens, Ilford, for a plant of *Calceolaria Burbidgei*, somewhat suggestive of *C. Pavonii* in the form and colour of the flowers and in the form of the leaves, though these are smaller than in the species. Mr. C. Turner, Slough, had a group of Tree Carnations, including several very handsome varieties. Duke of Albany has large dark scarlet flowers of good form; Firfly, smaller but very dark scarlet; Negro, fringed edge, maroon; and Brightness, vivid scarlet.

Messrs. H. Cannell & Sons, Swanley, Kent, staged a group which added largely to the interest of the meeting. Double white and blush Primulas were represented by over two dozen handsome plants most profusely flowered. A stand of fine single Zonal Pelargoniums, the flowers being of remarkable size and substance; indeed, Mr. Cannell has scarcely shown better samples at this time of year. Especially fine was *Czarina*, a variety with white flowers of good form, and over 2 inches in diameter. The double Pelargoniums were similarly good, including more than a dozen varieties. A stand of *Salvia Veitchi* and *S. rutilans* flowers was greatly admired, the bright red of the latter contrasting well with the rich blue of the former. A vote of thanks was accorded to Mr. Cannell. Mr. Herbst, Kew Nurseries, Richmond, exhibited six pots of Lily of the Valley, each with about twenty large spikes of flowers. Mr. Anthony White, Woking, had a box of Primroses, representing many good varieties. Messrs. J. Carter & Co., High Holborn, had a group of their blue *Primula Holborn Gem*. The flowers were large, of good form, and were marked by a blue shade, that unfortunately, owing to the darkness of the morning, could not be seen to the best advantage. In habit the plants are very compact. Mr. R. H. Vertegans, Edgbaston, Birmingham, exhibited plants of *Nicotiana tubiflora*, a form with long pure white flowers; *Phlox Miss Robertson*, a very neat variety with round flowers, pure white in close heads; also plants of *Sisymbrium millefolium* which was recently certificated at Birmingham, and described on page 502. Mr. H. B. Smith, Ealing, Oxon, had plants of a fine Cyclamen Prince of Wales, with very large rich deep red flowers with broad petals. A very beautiful group of plants was contributed from the Society's Chiswick Gardens; Poinsettias, Primulas, Orchids, and *Begonia insignis* forming the chief features. Mr. John Odell, Goulds Green, Hillingdon, staged a group of healthy well-flowered Primulas; Queen Victoria, bright deep red; Alba Magnifica, white, large flowers, and Rubra Improved being the varieties.

First-class certificates were awarded for the following plants—

*Calanthe bella* (Veitch).—A beautiful hybrid between *C. vestita* and *C. Turnerii*, with a spike 2½ to 3 feet long. The flowers are large, 3 inches or more in diameter, with acute bluish-tinted sepals and petals, a broad lip of the same hue, having a rich crimson blotch in the centre.

*Masdevallia ignea Massangeana* (Veitch).—Similar to the well-known type, but the flowers appear slightly darker in colour.

*Cælogyne barbata* (Bull).—An attractive and distinct Orchid, having the flowers in drooping spikes. The sepals and petals are white, of semi-transparent texture; the petals much narrower than the sepals; the lip has the two lateral lobes white, and the centre brownish and deeply fringed.

*Carnation Negro* (Turner).—A variety of the Tree section, with large full flowers, very deep maroon, the edges neatly fringed.

*Carnation Duke of Albany* (Turner).—Another of the same type, with very large flowers of good form and deep scarlet in colour.

*Heliotrope White Lady* (Cannell).—A beautiful variety with remarkably large corymbs of white flowers. The fragrance is very sweet and powerful. The leaves also are large and neat in form.

*Phalangium elegantissimum* (Williams).—A Liliaceous plant allied to

the Anthericums, with narrow leaves 9 inches to a foot long, tapering to the apex, white central streak, and green margin. Attractive and useful for decorative purposes.

*Oncidium Forbesii Carderi*.—A certificate was awarded to Mr. Read, The Gardens, Moat Mount, Mill Hill, for a plant of this very handsome variety, which, however, some members of the Committee thought was inaccurately named. The flowers were very large, 3 to 3½ inches in diameter, deep rich brown in colour, with a crisped narrow yellow margin.

**SCIENTIFIC COMMITTEE.**—*Lilies Attacked by Larva of Brachycerus sp.*—Mr. McLachlan exhibited larvæ received from Mr. G. F. Wilson, which eat into the centre of the bulbs of Lilies.

*Cocoa Nut Attacked by Larva of Hylococcus sp.*—He also showed remarkable larvæ with indurated joint at the head, which penetrates the soft wood of Palms, and observed that the European species attacks hardwooded trees, as Firs.

*Proliferous Cone.*—Dr. M. T. Masters exhibited a cone of *Abies Douglasii*, in which the bracts were foliaceous, but the seed scale partially atrophied, as is usually the case in proliferous cones. He contrasted this with a proliferous state of *Sciadopitys verticillata* (see fig. 46, Veitch's "Manual of Coniferæ"), in which the seed scale became foliaceous, the bract remaining normal. The importance of this latter specimen in relation to the nature of the so-called leaves of *Sciadopitys* and of the seed scale of *Abietinæ* was commented on.

*Embryo Bud of Oak.*—Mr. W. G. Smith exhibited a specimen about 1½ inch in diameter. It was removed from beneath the bark. Such are very common in Beech trees, in which they vary from the size of Peas to that of one's fist.

**LECTURE.**—The Rev. G. Henslow took for the subject of his lecture the "Diversity of Means Utilised by Nature to Secure Similar or Identically the Same End." He illustrated it (1), by the process of "doubling" flowers; (2), by a peculiar method of securing the fertilisation of flowers by means of a lever constructed out of the stamens; and (3), by various methods of colourisation—different organs being coloured, but which secure the same object of rendering the flower attractive; (4), methods of entrapping insects to digest them.

The process of doubling varied in different flowers—thus, the pistil may remain perfect, but the petals and stamens (converted into petals) multiplied, as in Carnations, &c. The pistil may become foliaceous, and the rest of the flower all petals as before. Such occurs in the double Cherry. The petals alone may be multiplied, the stamens and pistil remaining perfect—he had found this in double Stocks; or the whole flower may be converted into a dense ball of more than fifty petals, as in double Wallflowers. Again, a double flower may consist of a repetition of calyx and corolla over and over again as in Rock Rose. Lastly, double Poinsettias are merely a multiplication of bracts, and double Composites a conversion of disk florets into ray, as in Chrysanthemum, Daisy, &c. The peculiar process of fertilisation described was that of the *Salvia*, and the lecturer showed that *Calceolaria Burbidgei* (exhibited) illustrated the same thing; while a similar method obtain in a widely different family of Gingerworts.

As illustrations of coloured organs, the lecturer exhibited Poinsettias and *Euphorbia jaequiniaefolia* as showing how bracts could mimic a true flower. Everlastings were another example. In many cases it was the calyx, as in Anemone and Marsh Marigold.

A *Nepenthes* illustrated a carnivorous habit, and the lecturer made some observations on its structure and the various methods adopted by other plants for catching insects, and alluded to Mr. Francis Darwin's experiments on *Drosera*, which clearly showed that the chief benefit lay in the increase of seed.

#### LUCULIA GRATISSIMA.

**SELDOM** is a large plant of the above to be seen in satisfactory condition. How to account for this I do not know. Its propagation, I must confess, I cannot yet master after many and varied trials. Plants are, however, readily obtained from the trade, and therefore its propagation should not prevent its being more generally planted. I am afraid its beauty and fragrance are not sufficiently known, or it would find a permanency in the majority of large conservatories. It rapidly forms a good bush when planted out. Its cultivation in pots is rather difficult, as it does not do well without abundance of root room. It is a splendid plant for covering a wall, and is even better adapted for this than growing as a bush; however, the latter can be accomplished without much trouble. When grown as a bush its flowers appear to much greater advantage than when grown against a wall. A good plant is a most conspicuous object in a conservatory at this season of the year; it not only, when in flower, fills a house with fragrance, but quickly arrests the attention of visitors. A plant carrying over three hundred trusses open and to open, is a sight when once seen not easily forgotten. Small plants planted out from 6-inch pots are capable of doing this in about six years, thus showing the rapidity with which it grows when once established.

The *Luculia* will endure close pruning, and can therefore be

kept within due bounds and to suit the position in which it may be planted. When well pruned the growths are stronger, more sturdy and compact, and will carry in consequence larger trusses of flower than if pruning is not resorted to.

The treatment which suits Camellias when planted out suits this plant well. If the house in which it is grown can be closed early with a little sun heat while the plants are making fresh growth all the better. After growth is completed Luculias, like Camellias, will do with cooler treatment. While growing abundance of water should be given both to the roots and on the

foliage. The temperature should not be allowed to fall too low in winter. It will do well in any structure ranging from 40° to 50°, according to external conditions.

The soil I have found most suitable is a mixture of loam and peat (the latter predominating), with plenty of coarse sand and a little charcoal to keep the soil porous.

Thrips is the greatest enemy to this plant; in fact, I have never seen any other insect infest it. Care must be taken never to allow the insects to become established, or they soon do much injury to the plants. They are generally kept in check by liberal

Fig. 85.—ADHATODA CYDONIÆFOLIA.

syringings; but, if further measures are needed, sponging the leaves with tobacco water is a safe method of extirpating the pest.—SCIENTIA.

#### ADHATODA CYDONIÆFOLIA.

At one time the genus *Adhatoda* was rather an extensive one, as De Candolle enumerates about sixty species, but Bentham and Hooker admit only six or eight species; the other species being referred to the genus *Justicia*. *Adhatoda cydoniæfolia* may be considered one of the most handsome species of the genus. The woodcut (fig. 85) shows the true character of the flower. The corolla is tubular and divided into two parts; the upper lip is hooded and almost pure white outside, the inner or

under surface is light purple, nearly white; the lower limb is divided into three lobes of a bright purple colour, with a narrow band of white in the centre towards the throat. The flowers are borne in clusters at the termination of each shoot, and are extremely showy, the plant continuing for several weeks in good condition. It is a plant that is easily cultivated, and is worth a place in any collection of plants, and what adds to its value is that it blooms at a season when flowers are scarce. Perhaps its one and only objection is that it has rather a straggling habit of growth, but the way I have overcome this objection is to train it under the roof or up a pillar; in such positions it appears quite at home. The best time to propagate it is in spring when it has commenced growing. The cuttings strike very readily in a little bottom heat,

and should be potted as soon as rooted in a light rich soil. As soon as the pots are filled with roots the plants must again be potted, and when established the tops may be pinched to induce them to branch. After this they may either be grown on in larger pots, or planted out in a border in the stove and trained up a pillar or under the roof. *A. cydoniaefolia* is a native of Brazil, and therefore requires a stove temperature or an intermediate house. My plants have flowered profusely this autumn in a temperature of about 60°.—W. K.

#### SCRAPS ABOUT FRUIT.

**JULES D'AIROLLES PEAR.**—This is not by any means much grown, but deserves to be more extensively known. I have it against an east wall on the Pear stock, on which it is very healthy, fruiting when many other sorts fail; the fruit much resembles Napoleon, but is larger and longer, and carries more colour. It is in season in November and December, and is very juicy, well and briskly flavoured, resembling in that respect Forelle.—G. ABBEY.

**STRAWBERRIES FLOWERING.**—Have any of your correspondents seen at the present season, in the open ground, Strawberries in full flower, just as is seen in summer? The variety President is a mass of bloom. This is grown here largely, being useful for forcing as well as for the garden, and I agree with many gardeners in considering it the best of all the year-round Strawberry. The plants are robust and healthy, and in their third season of growth. The blooms will be decidedly cut down by the first hard frost. No doubt the past mild weather has caused their flowering so prematurely.—H. C. OGLE, *Chilworth Manor, Hants.*

**COMTE DE LAMY PEAR.**—In our light soil this is one of the few October Pears that succeed on the Quince, the tree being healthy, forming a moderate-sized compact pyramid. It crops well, and, though the fruit is only medium-sized it is very rich and juicy with an agreeable perfume, resembling Seakale in that respect. The latter though small is a first-rate sort, succeeding admirably as a pyramid on the Pear, forming a good-sized fruitful tree.—YORKSHIRE.

**THE BEST TWELVE KITCHEN APPLES.**—Duchess of Oldenburg, Keswick Codlin or Lord Suffield, Lemon Pippin, Golden Noble, Cellini, Small's Admirable, Warner's King, Nelson's Codlin, Tower of Glamis, Wormsley Pippin, Hanwell Souring, Gooseberry—twelve and one over, which is easily disposed of. If you have a light shallow soil discard Lord Suffield, if a deep loam retain it. But whatever may be the nature of your soil you will never have reason to regret planting Keswick Codlin, for I have never seen it suffer badly from canker, as Lord Suffield undoubtedly does. Lemon Pippin may be called in question, but I really do not know why, for it is an excellent cooking Apple. The tree is hardy, grows freely, and rarely fails to yield an abundant crop of fruit—so abundant that the sight of a large tree of it in full bearing is not soon forgotten, and yet I do not remember having met with it in select lists. Of the other sorts it may be said that all of them are remarkable for hardiness, sturdy vigour, and abundant produce of sterling quality. Gooseberry Apple, not Gooseberry Pippin, ought to be grown by everybody for the good keeping qualities of its excellent fruit, which is always left upon the trees till late in October, and is then to be had in good condition from the fruit-room in the following May and June.—SUSSEX.

**THE BEST TWELVE PEARS.**—Your correspondent "SUSSEX" gives the names of twelve Pears (page 494) which he designates the best, but it is to be presumed he only means in his immediate locality, and with the qualifications he points out in reference to soil, stocks, climate, and experience in treatment. All these and other circumstances conduce to success or failure. However, I merely wish to remark that at our late show here, referred to in a recent number of the Journal, the three judges and your correspondent, who was deputed to assist them, all agreed, from every point of view, the specimens of Beurré Clairgeau were the best in the show of a large number of varieties. The admitted best at last year's show was Doyenné Boussoch. Though there is not much difference in the climate, &c., neither of these are included in "SUSSEX'S" twelve.—W. J. M., *Clonmel.*

**PEARS NOT KEEPING.**—I noticed what "G. A." said on page 494 under this heading. In regard to Bergamotte Esperen, a Pear which I have been accustomed at the beginning of former years

to place in artificial heat, I am at this time eating it direct from a cold fruit-room in a perfect state of delicious ripeness. Though I never knew it come to table so early, I also never knew it in better condition for the dessert dish. Its usual time is from February to April, and it was therefore only by mere accident that I found it was ripening fast. I make no complaint, as all my crop is, though earlier, excellent. I have, however, been utterly "done" by another Pear—viz., Josephine de Malines. As its proper time is always from February to May I did not pay it the attention of any notice at all. Why look after, or examine, a Pear not likely to be ripe for months? However, when I went and examined the Josephine de Malines, the fruit off two pyramids, the other day, I found them gone too far—from ripeness to rotteness, only a very few being eatable. Not all Pears are thus premature, for Soldat Esperen, a November fruit, is not quite ripe, and will last through this month of December; neither is Napoleon over-ripe. I would note of this fruit that as to flavour it has been overpraised. It is very juicy indeed, but then it is not rich but watery juice. Apples are keeping, as naturally they would, better than Pears, but they are in an unduly forward state of ripeness. In regard to the Malines Pear going off so very soon, I must say that I think part of the reason is that by mistake it was gathered a little too early, whereas those keeping better had their full time on the tree. I should like to know if other cultivators find this true of their Pears. "Hang long keep long" is, I think, a good motto in regard to late fruits.—WILTSHIRE RECTOR.

**RENOVATING OLD APPLE TREES—USEFUL VARIETIES.**—My experience amongst fruit trees in Cheshire was that of obtaining a satisfactory result from old trees on a clay soil. We first thoroughly drained it and then applied manure heavily near the roots. These measures produced a complete renovation. The best old sorts were Golden Russet, Lord Suffield, Manks Codlin, which we always took care to thin-out freely to induce fresh growth of healthy wood (this year I have seen fine specimens in London offered for sale as Newtown Pippins); Nonpareil, "Winter Virgin," a large rosy-coloured Apple, strong tree with a bushy top, which grew tangled and intermixed across, inside, naturally. Fruit large, very red, which about May turned to a russetty yellow pale colour, most beautiful to eat. We called it Winter Virgin, but it is very similar to Ball's Golden Reinette. Gooseberry, New Hawthornden, and Hawthornden. All standards. Since then, in Montgomeryshire, I planted some of the old sorts. On clay soil Lord Suffield planted with some pieces of charcoal and lime under formed a fine tree—only four years after grafting being loaded with splendid fruit. Hawthornden similar, and Manks Codlin and Stirling Castle were surprisingly fine. I tried other sorts which promise well. Royal Pearmain, Oslin, Wellington (Dumelow's Seedling), John Apple or Northern Greening, and Greenup's Pippin. Golden Winter Pearmain is remarkably fine grown near Tenbury on a red clay soil. I have seen rows of trees covered with splendid fruit—a grand sight.—J. C. ANTROBUS.

#### HOMELY HINTS ON CHRYSANTHEMUM CULTURE.

OF the popularity of Chrysanthemums there can be no doubt, nor is it difficult to tell why. Opening into full beauty in November, when so much of vegetable life has assumed the bare aspect of winter, amid gathering mists and murky skies they serve to brighten many a home that would otherwise be bare of flowers, and when brought together in large quantities for exhibition we have a scene so bright as to form no unworthy rival of the gayest gatherings of summer. The large exhibition plants are apt to be regarded by the owners of small gardens as a phase of gardening quite beyond their scope. They see the magnificent cut flowers and ask, "What sort of plants are they cut from? How are they managed? and would it be possible for us to produce anything like them in our little conservatory without the aid of a professional gardener?" Assuredly it would, as I have seen it done for several years in a small garden not far from here—so well done, that there are always plenty of flowers at this time of year of the highest excellence both of size and form.

Now in this garden there is no skilled gardener—only an ordinary labourer—nor has the owner much technical knowledge of gardening. He therefore wisely confines his efforts to the management of a few flowers of easy culture, and of which he has sufficient variety to render his little conservatory gay throughout the year. In this he is most successful, as I have often seen. The stages are always filled with clean healthy plants, but they are never crowded, and the only season of the year when the neat trim aspect of the house is broken up is when the huge Chrysanthemums are brought in, some three or four dozen in number, and are ranged in single

file upon the floor around the central stage, where they remain till the flowers fade, and then as soon as enough cuttings are secured for the next season the old plants are thrown away.

The cuttings are inserted singly in small pots filled with rich loam, and are placed in a cold frame from which frost is excluded by a covering of litter in severe weather, but light and air are given on every favourable opportunity. They make roots slowly but surely, very few ever failing; and when the roots reach the sides of the pots the plants are shifted into larger pots, care being taken to supply water when necessary, and to expose them to the air as much as possible. As the weather grows warm they are again shifted into the large pots in which they are to flower, and are stood out of doors upon a hard level space near a sewage pump. Henceforward throughout summer and autumn sewage is their daily fare, poured into the pots with no sparing hand, for the drainage is carefully done, and so long as that acts well there is no risk of over-watering. The Chrysanthemum is as great a glutton as the Rose, revelling in rich food, and starving without it. Somebody wrote quite recently that the production of fine Chrysanthemum flowers was a difficult matter, understood only by a favoured few. But here is the mystery knocked on the head by the handle of our sewage pump; let it not presume to thrust itself into the way of plain people again.

Stakes are employed for the plants when required, but no pinching is practised. The plant generally breaks naturally into two or three leading shoots, which are tied loosely to the stakes, and all lateral growth is kept under. They attain a height of 7 or 8 feet, stems and foliage all being worthy of the sewage. So, too, are the huge flowers by which they are eventually crowned. Care is taken to disbud as early as possible, the central bud only being retained upon each of the shoots which spring from the end of each stem.—EDWARD LUCKHURST.

### SILKWORMS AND SILKWORM-REARING.—3.

It is with some people a favourite subject, not particularly pleasant to others, though it may prove in the long run occasionally useful, how much is lost or wasted year by year that might be turned to good account. In one of the papers published by the Silk Supply Association there appears the statement that in the vicinity of London are about thirty thousand Mulberries, from which, by judicious rearing of silkworms, there might be obtained 10,000 lbs. of silk annually. Granted the Mulberry trees, I doubt much whether, under the most promising circumstances, such a quantity of silk could be thus obtained near London from silkworms if kept on a sufficiently large scale. But I am tolerably well acquainted with our London suburbs, and do not believe there is anything like that number of Mulberries now growing, old trees or young. Some have been planted in various localities, very seldom, however, in lines or groups; yet many trees have disappeared that were formerly well known owing to the growth of the metropolis. Chelsea Park retains none of its old Mulberries, I believe; nor would it be of any use to seek for remnants of the Mulberry Garden at Pimlico. We may hope that before the end of the present century many more Mulberries will be planted about London and throughout England; for though attempts have been made to rear silkworms upon other food, the Mulberry is manifestly the species in every way best adapted for feeding them upon with satisfactory results. It is in the hands of our gardeners to encourage the culture of the Mulberry, not only as a fruit-bearer, but as supplying leaves for silkworms, and I venture to think they have a degree of interest in whatever may tend to cheapen silk. Gardening pursuits are not, on the whole, unhealthy, still they expose many persons to chills from changes of temperature and contact with damp earth. Flannel as a protective against cold and rheumatism has, in some instances, been proved to be inferior to silk under garments, which do not induce perspiration, but at present they are rather expensive. Perhaps the day may arrive when to some of our nursery gardens there will be attached a silkworm house, the product being reeled on the premises, and, if not supplying an additional source of income, at least furnishing silk textures to the proprietor and his friends.

Before considering the common silkworm in its aspect as a "domesticated animal," if one may so style it, the structure and natural habits of the species call for some brief remarks. In this *Bombyx Mori* we have none of those bright colours during any of its stages which please the eye in other insects of the group. The moths are of a dull white, shading into grey, with a few faintly defined bands across the wings. These, as we know the species, are never used for the purpose of flight; the moths show also little inclination even to crawl about. No native moth of Britain is quite so sluggish as *B. Mori*, yet probably in its original haunts and in a different climate its habits may be more lively. These

moths eat nothing, for a very good reason—they have no organs to bite or suck with, and their sole duty is to continue their race; the life of the males being the shorter, their companions dying as soon as they have deposited their eggs. This is generally within a week after the moths have come forth, though the females may be kept alive longer if they are prevented from following the natural process of egg-laying, for, as entomologists know, all female insects have a strong vitality until that business has been accomplished. The number laid by each moth is variable, seldom less than three hundred, and they are neither piled up nor scattered, but placed side by side with careful regularity all by the sense of touch, for the moth never turns her head to see what progress she is making.

In our country there is only an annual brood of this silkworm, the young larvæ or caterpillars emerging from the eggs during the spring, the date depending upon the season, and they appear in rapid succession. The newly-hatched caterpillars are of a dusky brown hue and hairy, having a horn or appendage above the anus, which, like the colour of the body, undergoes changes, until after the last moult it generally resembles a ridge or hump. Between the time of hatching and the period of maturity four moults occur, which divide the life of a silkworm into five ages.

A rather perilous portion of its life is the few days before the first moult, for it is then small in size, and, eating but little, has not gained much strength. Having cast its skin the silkworm is lighter in colour, less hairy, and shows traces of the crescent-shaped marks, which are subsequently very distinct on the second and fifth segments. The next moult leaves the silkworm hairless and almost white; it has now become about an inch in length and more plump. Between the moults there is an interval of six or seven days, so that the caterpillar is a month old on the average when it reaches the fourth or last moult, which is followed by a great increase of size during the remaining nine days or so of its existence in this stage, when it eats so incessantly as to consume many times its own weight in leaves, and gradually becomes transparent. In fact, to the eaters of caterpillars (for such there are), the adult silkworm presents a tempting-looking morsel, superior, I should say, to the *cozzus* upon which the Romans of old are said to have feasted.

Taking a silkworm for examination when of some size, we perceive the body is composed of thirteen segments, the head counting as the first. This head is horny, and has an upper lip curiously hollowed to receive the edge of a leaf, which is held by it while the jaws cut off slices, which are pushed towards the opening by two little appendages called the "palpi." An under lip closes the mouth, and this has in it a small orifice from which the silken thread is drawn by the caterpillar. There are six jointed legs, which are also found in the moth, and ten membranous legs or elaspers, which belong to the caterpillar only. On the sides of the body is a double row of breathing pores.

At each of the four moults every part of the exterior of a silkworm develops a new covering beneath the old one, which is then cast off by means of a liquid which oozes between the two coats. While this change is in progress the creature remains motionless, seemingly in a condition of sleep, and quits its food for a day or two. It is injurious to the silkworm to be disturbed at these periods. In order, as far as possible, to preserve itself from dislodgement and annoyance, it spins threads across

Fig. 86.—Digestive Apparatus of Silkworm.

a leaf or other object; these, moreover, give a leverage, so to speak, enabling it to pull itself out of the skin that has become too small to allow of its continued growth.

Upon laying bare the interior of the silkworm as exhibited in our illustration (fig. 86), we perceive a beautiful if not highly complicated arrangement. There is a short oesophagus or gullet by which the food is carried into the long stomach, which occupies the greater part of the centre of the body, terminating in a short intestinal canal with the usual convolutions. The nervous system—and this is possessed even by a silkworm—is noticeable as a series of nerve-centres, with radiating fibres, extending from the head to the tail. Along the sides of the stomach are the tubes in which silk is elaborated: it is secreted in the narrow hinder tubes, and becomes thicker in the large tubes nearer the head, where it is stored until required. At the head the ends of these double tubes unite, and the product issues forth as a single thread. Layers of fatty matter lie over and protect these organs more or less.—J. R. S. C.

### NATIONAL ROSE SOCIETY, 1882.

#### ANNUAL GENERAL MEETING.

CONTRARY to some expectations the meeting of this Society at the Horticultural Club-rooms, Arundel Street, Strand, on Thursday the 8th inst., was very well attended, twenty-nine members assembling to aid in conducting the Society's affairs to a close for the year 1881, and to authorise the arrangements for the ensuing season. The following were the members present—H. Appleby, George Baker, Rev. H. A. Berners, Hon. and Rev. J. T. Boseawen, F. Burnside, B. R. Cant, R. B. Cater, Rev. A. Cheales, Capt. A. Christy, J. Cranston, Rev. F. N. Flintoff, Rev. J. M. Fuller, J. House, T. B. Haywood, W. J. Jefferies, J. Mayo, W. Mount, George Paul, G. W. Piper, G. Prince, Rev. J. H. Pemberton, Wm. Rumsey, W. G. Sharp, Arthur Turner, W. M. Westall, E. R. Whitwell, the two Hon. Secretaries—the Rev. H. H. D'Ombraïn and Mr. Edward Mawley, and the representative of the Hon. Treasurer, Mr. G. Lambert. Shortly after 3 P.M. the Hon. and Rev. J. T. Boseawen took the chair, and the business was commenced by Mr. E. Mawley reading the circular calling the meeting. The Chairman proposed that the minutes of the last general meeting be taken as read, which was formally agreed to, Messrs. B. R. Cant and W. G. Sharp being appointed scrutineers of the ballot for the election of the Committee and officers for 1882. The Rev. H. H. D'Ombraïn then read the General Report, which follows—

It is again the pleasing duty of the Committee to offer their congratulations to the members on the continued progress and success of the Society, and to be able to speak hopefully of its future prospects. Their exhibitions have been, on the whole, successful, notwithstanding the generally unfavourable character of the season. More especially was this the case at Sheffield, where their Provincial Exhibition proved to be the best they have yet held out of the London district. Some progress has been made with the Catalogue of Exhibition Roses, which they hope will, ere long, be in the hands of their members. Two handsome challenge trophies, each of the value of about sixty guineas, which had been subscribed for early in the season by amateurs and nurserymen respectively, and presented to the Society, were for the first time competed for at the last Metropolitan Exhibition. The one given by the Rose nurserymen was awarded to Mr. R. N. G. Baker of Exeter, and the other to Mr. B. R. Cant of Colchester. The contests for these two valuable gifts added greatly to the interest of this Show, and the same may be said of the various other cups and pieces of plate offered for competition at both the Metropolitan and Sheffield Exhibitions.

*Financial Statement.*—It will be remembered that the Society began last year with a balance in hand of £104 3s. 7d., and on the strength of this the schedules of the Metropolitan and Provincial Exhibitions were made even more liberal than before, and it was further decided to accept the invitation of the Manchester Botanical Society to hold a third exhibition in connection with their Great International Horticultural Show. These additional arrangements, of course, occasioned a fresh outlay of the Society's funds; notwithstanding which, however, the Committee have now the pleasure of stating that there still remains a balance of £97 9s. 4d. in the Treasurer's hands.

*Affiliated Societies.*—In order to simplify arrangements with affiliated societies, the Committee have determined for the future to charge in all cases alike an affiliation fee of half a guinea, and afterwards to supply the whole of their medals at cost price—viz., for the gold medal £2, for the silver-gilt 12s., for the silver 10s., and for the bronze medal 3s. 6d. They do not desire to place any restrictions on the manner in which the medals should be apportioned, other than that they may not be awarded for any decoration or vase of flowers. It will be necessary for every affiliated society or society desiring affiliation to name early in the year what medals they will require.

*Arrangements for 1882.*—It has long been felt by many of the Committee, and they believe by the members generally, that, notwithstanding the facilities which the Crystal Palace offers for the holding of their Metropolitan Exhibition, the Royal Horticultural Society's Gardens is, after all, the fittest place for the purpose, being

the recognised centre of horticulture in the south of England. They, therefore, felt justified in opening negotiations with the Council of that Society, the result of which is, that arrangements have been made for their first Exhibition being held this year at South Kensington on Tuesday the 4th of July next. The Committee have much pleasure in stating that they are once more in a position to give their members the privilege of a private view of their principal Exhibition, thus affording them an opportunity of inspecting the blooms when in their first perfection, and without the discomfort necessarily attending a crowded Rose show. The Provincial Exhibition will be held at Bath on June the 28th, and from the cordial reception recently given to one of your Secretaries who visited that city for the purpose of making arrangements, they feel assured that the Exhibition to be held there will equal in interest and importance that of last year at Sheffield. As these dates will, to a certain extent, hinder the northern and midland growers from competing at these Shows, it has been decided to attempt a third Exhibition on some day during the third week of July, at a town in the midland counties yet to be selected. At each of these Exhibitions the same right of members to a private view will be secured.

*Members' Privileges.*—Members subscribing £1 will be entitled to two private view tickets, and also to four transferable tickets, admitting at the same time as the general public. Those subscribing 10s. are entitled to one private view ticket, and also to two transferable tickets, admitting at the same time as the general public. All these tickets are available for each one of the Society's exhibitions. To exhibitors pass tickets will be given with their show cards, enabling them to leave and return to the place of exhibition at any time during the day.

The Committee desire, in conclusion, to tender their best thanks to those friends who have so generously and kindly helped them during the past year, to the donors of special prizes, and to the local Secretaries for their continued exertions on behalf of the Society. Their thanks are also due to the President, Curator, Secretary, and Committee of the Sheffield Botanical Gardens, and especially to Mr. Charles Fisher, for their hearty co-operation on the occasion of the Society's Provincial Show; also to our own President for the interesting and valuable address given by him on that day.

The Hon. Secretary further added that, owing to the early dates of the two shows at Kensington and Bath respectively, it was proposed to hold another about the third week in July for the benefit of the northern growers, the majority of whom would be unable to compete at the Southern Exhibitions. They had received an invitation from Darlington, and it was thought that town would be very suitable for the purpose. Some of the members asked if Newcastle-upon-Tyne would not be even better adapted for the Northern Show, but it was explained that the recent exhibitions of that Society had proved so unsuccessful that they were not in a position to give the requisite aid. The report was then formally carried and adopted. Mr. D'Ombraïn next read the Auditors' report and also the balance sheet which follows—

#### BALANCE SHEET FOR THE YEAR ENDING 30TH NOVEMBER, 1881.

RECEIPTS.		£	s.	d.
Balance in hand and at Bankers 30th November, 1880.....		104	3	7

Examined and found correct.

GEORGE P. HAWTREY, } Auditors.

GEORGE PAUL, }

WILLIAM SCOTT, Hon. Treasurer.

Mr. B. R. Cant considered the sum spent in printing the schedules was unnecessarily high, and might be decreased by

Exclusive of the special prizes presented by members and others.

having all the schedules combined in one similar to that adopted by the Royal Horticultural Society, instead of issuing them separately as at present. Mr. Mawley doubted if this would effect the saving anticipated, and it was the general opinion that the advantages to be gained would be comparatively slight, if any. Mr. George Baker then moved the adoption of the report, which he thought highly satisfactory, and also proposed a vote of thanks to the Hon. Treasurer, Mr. W. Scott, and especially to his assistant, Mr. G. Lambert, upon whom much of the labour had devolved owing to Mr. Scott's illness, which they all regretted. Both these motions were carried unanimously. The Rev. J. H. Pemberton proposed a vote of thanks to the Horticultural Club for the use of their room during the year, which was duly seconded and carried, Mr. D'Ombraïn remarking that it was the last occasion of the Society meeting there, as the Club was about to be closed, and therefore the future meetings would be held in Henrietta Street, Covent Garden. A vote of thanks to the Officers and Auditors was carried unanimously, and the Chairman announced that the ballot had resulted in the election of the following as Committee and Officers for 1882. The names of additional members are preceded by asterisks.

COMMITTEE AND OFFICERS FOR THE YEAR 1882.—President: The Rev. Canon Hole. Vice-Presidents: The Hon. and Rev. J. T. Boscawen, James McIntosh, and George Baker. Committee: H. Appleby, J. H. Arkwright, R. N. G. Baker, Rev. H. B. Biron, W. Brockbank, Rev. C. H. Bulmer, T. F. Burnaby-Atkins, Rev. J. B. M. Camm, B. R. Cant, R. B. Cater, Rev. A. Cheales, Captain Christy, J. Cranston, H. Curtis, J. Cutbush, \*C. E. Cuthell, C. Davies, \*Rev. E. L. Fellowes, Rev. J. M. Fuller, Rev. F. H. Gall, T. Gravely, \*T. B. Hall, G. P. Hawtrey, T. B. Haywood, Dr. R. Hogg, C. F. Hore, J. Laing, Dr. M. T. Masters, H. K. Mayor, J. Mitchell, W. Mount, G. Paul, W. Paul, J. D. Pawle, Rev. J. H. Pemberton, Rev. E. N. Pochin, G. Prince, T. F. Rivers, W. Robinson, \*J. Sargant, W. G. Sharp, A. G. Soames, J. T. Strange, J. Tinsley, A. Turner, C. Turner, H. J. Veitch, \*W. Walters, \*E. R. Whitwell, F. T. Wollaston. Auditors: G. P. Hawtrey and George Paul. Hon. Secretaries: The Rev. H. Honeywood D'Ombraïn and Edward Mawley; and Hon. Treasurer: William Scott.

A discussion arose concerning the provincial show for 1883. The Rev. H. A. Berners expressed a desire that the Society would favour the eastern counties, and suggested Cambridge as a suitable locality convenient both for the northern and southern growers. It was objected to this by some members, that the period when the Exhibition would be held would be the long vacation when the town is comparatively empty. Others proposed Ipswich or Nottingham, but no definite conclusion was arrived at, and the meeting terminated with a hearty vote of thanks to the Chairman.

#### HARDY FLOWERS—MEANS OF INCREASING THE PLANTS.

THE propagation of hardy plants is now a matter of more importance than it used to be. We have arrived at a period when it is seen to be needful to keep the great majority of hardy plants in a young and healthy condition, and the propagation of the various species requires timely attention. Many plants propagate themselves naturally by their habit of growth; such are *Phlox stolonifera*, *Hieracium aurantiacum*, many of the *Sedums* and *Saxifrages*, *Campanulas*, of which *C. grandis* may be taken as the type, as well as others. When increasing such plants, all that is necessary is to lift tufts and plant them out, either in the places they are intended to occupy or in nursery lines until wanted. Either spring or autumn is suitable for increasing such plants. Many species are easily propagated by division of the roots. Some of the finest may be thus increased easily and successfully. *Phloxes* of the florist section, *Delphiniums*, *Pyrethrums* of the *P. roscum* type, *Campanulas* such as *Van Houttei*, *C. persicifolia*, and *C. carpatica*; *Asters*, *Hepaticas*, *Christmas Roses*, *Erigerons*, *Stenactis speciosa*, &c., may all be propagated with the best results. The way to set about this work is, in the first place, to lift the plants to be divided, shake the soil from the roots, then divide the crowns to the size wanted. I invariably find that pieces with few crowns make the best plants. Do not leave many roots, which can do no good to the young plants; a few to each piece will be sufficient until new roots are formed. Autumn is the best time for this mode of increase, though for a later bloom spring is suitable. Spring-divided *Phloxes*, for instance, were in flower in the last week of November.

Through the late autumn months many dwarf plants form roots above ground. No better way of increasing such plants can be found than that so provided. The way to manage these is to pull the top growths in pieces according to the size wanted; or, in the matter of scarce sorts, to the number of plants required.

Dwarf and close-growing *Dianthus*, *Androsace carnea*, *Myosotis dissitiflora*, *Aubrietias*, *Arabis albida*, dwarf-growing *Thymes*, such as *T. lanuginosus*, *T. montanus albus*, and *T. cæsius*; dwarf *Veronicas*, such as *V. pectinata*, *V. saxatilis*, and *V. rupestris*, besides many other plants, are easily increased by this means.

Propagation by cuttings is a mode which can be successfully employed with many plants. *Phloxes*, for instance, may be thus increased at almost any season of the year. New *Pyrethrums* can be increased by the same mode. *Asters*, *Campanulas*, &c., are also increased rapidly from cuttings. Such plants as *Phlox frondosa* and its varieties, *Iberis corifolia* and others of that class, *Helianthemums*, and other woody subjects are most easily increased by means of cuttings. The beginning of October is a good time to insert the cuttings. I have raised large quantities of these and many others taken at the above time, merely dibbling the cuttings into the ordinary garden soil and covering them with old sashes until rooted. The plants are ready to transplant in the succeeding spring. Several plants, again, are much better raised from seeds than by any other means. *Antirrhinums* and *Sweet Williams* are cases in point which everybody may be expected to know. *Fox-gloves* and the many beautiful kinds of *Canterbury Bells* are also freely propagated from seeds. These come quite true to colours. Then no better nor quicker means can be adopted to obtain a large stock of *Aquilegias*, *Lupinus polyphyllus* and its varieties, *Delphiniums*, *Campanula pyramidalis*, some of the *Primulas*, such as *P. capitata*, *P. rosea*, *P. cortusoides*, *P. japonica*, &c. *Papavers* are also most easily increased by this means; the beautiful *P. alpinum* in many soils sheds its seeds, increasing freely. *Erinus alpinus* propagates itself by the same means, so does the pretty Alpine *Toadflax* (*Linaria alpina*). The star-flowered *Vittadenia triloba* keeps up a stock itself, and so do many others, provided the seedlings are not cut up by the hoe in a young stage. As a rule, seeds of hardy plants will not vegetate freely in heat. I have found them do very well sown in cold frames early in spring and allowed to come away in their own time. Many of them will flower late the same year, and those that do not flower will make extra strong plants for the one succeeding. Where seed is saved from home-grown plants it is a good plan to sow the seeds when ripe in the open air if before autumn, under protection if later.

It may be noted that in some families the various species of which they are made up must be treated according to their individual necessities. The *Campanulas*, for instance, are a large family, in which are kinds which are most successfully increased by division, others by cuttings, and others by seeds. The interested cultivator is not long ascertaining the best means of increasing the numerous plants in his mixed borders.—R. P. BROTHERSTON.

#### PORTRAITS OF NEW AND NOTABLE PLANTS.

*SYNECHANTHUS FIBROSUS*. (*Nat. ord.*, *Palmeæ*).—"A graceful tropical Palm, one of a genus of three known species, two of them natives of that part of the American continent which, extending from Mexico to Panama, is commonly known as Central America, and which includes Yucatan, Guatemala, Belise, Honduras, Nicaragua, and Costa Rica; the third Colombian. These countries are all rich in Palms, for a knowledge of which we are mainly indebted to Herman Wendland and Oersted, the enterprising botanical explorers of those unhealthy regions. *Synechanthus fibrosus* is an exceedingly graceful Palm, with a trunk in the Kew specimen about 4 feet high, and a crown of leaves as long, from amongst the bases of which the graceful spadices spring, laden with almost microscopic flowers. These are succeeded by the bright orange-red fruits, which weigh down the spadix, and are copiously produced."—(*Bot. Mag.*, t. 6572.)

*BERBERIS SINENSIS*. (*Nat. ord.*, *Berberideæ*).—"This is the most graceful of all the numerous species of *Barberry* cultivated at Kew, the branchlets from the base to the crown of the plants weeping and being loaded with blossoms in the spring. The flowers are, however, the smallest of the genus known, and the berries are smaller than those of *B. vulgaris*. *Berberis sinensis* has been long cultivated in the arboretum of Kew, but was not so at the period of the publication of the second edition of the 'Hortus Kewensis' (1811), where only four species are enumerated as existing in the Royal Gardens. Loudon, however, states that it was found during Lord Macartney's embassy to China, and introduced into England in 1800."—(*Ibid.*, t. 6573.)

*CLEMATIS RETICULATA*. (*Nat. ord.*, *Ranunculaceæ*).—"Clematis reticulata ranges in the Southern United States east of the Mississippi, from South Carolina to Florida. A plant has been grown at Kew in the open border, received from Messrs. Rodger McLelland & Co., under the name of *C. Fremonti*, a very different

species, with very large leaves and no tails to the achenes. The flowers, which appear in September, are much paler than as described in native specimens. The plant was nearly killed by last winter's cold, and is only now beginning to grow again."—(*Ibid.*, t. 6574.)

**OSBECKIA ROSTRATA.** (*Nat. ord.*, Melastomaceæ).—"A handsome plant, and common over a large tract in India. It is a native of swampy districts along the foot of the Himalaya and in Northern Bengal, from Nipal eastward to Assam, Rangoon, and Burma. These were supposed to be the limits of its range up to the period of the publication of the order Melastomaceæ in the Flora of British India in 1879, since which time, however, a perfectly glabrous form of it has been found by Col. Beddome in the Sirumallay hills of the Deccan at an elevation of 3500 feet. As a rule it affects very wet places, and especially Rice swamps, &c., but it sometimes may be found in moist places in the hills. It was introduced into Kew about twenty-five years ago, and flowered first in 1857. It requires stove treatment."—(*Ibid.*, t. 6575.)

**SCHISMATOGLOTTIS CRISPATA.** (*Nat. ord.*, Aroideæ).—"Schismatoglottis crispata is one of the many interesting plants introduced from Borneo by Mr. Burbidge when collecting for Messrs. Veitch, and amongst which the Aroideæ, which have been studied by Mr. N. E. Brown of the Kew Herbarium, are conspicuous for their number and novelty."—(*Ibid.*, t. 6576.)

**ENGELMANNIA PINNATIFIDA.** (*Nat. ord.*, Compositæ).—"A herb belonging to the same great American tribe of Compositæ as the Sunflower, named in honour of the veteran United States botanist, Dr. Engelmann, of St. Louis in Missouri. It is a native of the prairie region of the central United States east of the Rocky Mountains, where it extends from the latitude of Canada to that of Texas. Seeds were received at Kew, collected in New Mexico by Dr. Parry, the plants from which flowered in the second year, and have proved perfectly hardy, having been unprotected in the herbaceous grounds during the last severe winter. It flowers in the month of July."—(*Ibid.*, t. 6577.)

**EUADENIA EMINENS.** (*Nat. ord.*, Capparidæ).—"The genus Euadenia was established by Professor Oliver upon two tropical African plants, of which one, *E. trifoliolata*, *Oliv.* (*Strombia trifoliolata*, *Schum. and Thönn.*), from Old Calabar and Abbeokuta, is an undoubted congener of this plant, though differing in its racemose flowers; the other, *E. Kirkii*, *Oliv.*, from the Mozambique district, is probably a different genus, which is very imperfectly known. *E. eminens* differs from all the other species in the singularly handsome inflorescence, which resembles a candelabrum in its ramification, the yellow petals looking like pairs of gas jets on each branch. It was introduced from West Africa by Mr. Bull."—(*Ibid.*, t. 6578.)

**IRIS MISSOURIENSIS.** (*Nat. ord.*, Iridaceæ).—"This appears to be the commonest Iris of the Rocky Mountains, long known in England as *Tolmieana*. Whether it be more than a montane variety of the Californian *Iris longipetala* of Herbert, which is a very much finer plant from a cultural point of view, is doubtful."—(*Ibid.*, t. 6579.)

#### HARDY FRUIT GARDEN.

FAVOURABLE weather should be taken advantage of to forward pruning, nailing, and tying trees against walls. In pruning old trees—especially of the Apricot and Plum, also Pear—overgrown, old, and barren spurs should be gradually cut back alternately, so as to keep the fruitful buds as close to the wall as possible in order to derive the greatest benefit from its shelter and warmth. The spurs so cut back will generally start at the base if the trees are healthy, and furnish buds for future bearing in due time. By timely pruning the unsightly projections will not be reproduced, a little attention being given to this each season at the summer as well as winter pruning. Pruning Peaches and Nectarines is generally deferred until spring, but the wood being ripe there is nothing gained thereby, and from the press of other matters the work is frequently done hastily and imperfectly. The trees should be loosened from the wall, leaving the main branches secured to maintain the trees in position. The shoots that have borne fruit this year, if they were not cut out after the

fruit was gathered, should be removed, also any old weakly growths that can be replaced with younger wood. The shoots that were reserved at the base of the current year's fruiting shoots for next season's bearing, should be neatly nailed or tied in, and if they be short-jointed and well ripened they will need very little, if any, shortening; otherwise, cut them back to firm well-ripened wood, being careful to do so to a wood bud or triple bud, which will generally have two fruit buds with a wood bud in the centre. Avoid training in too many shoots, the bearing wood being 12 to 15 inches apart, and the branches they proceed from a similar distance asunder. Extensions should not be shortened more than to have the unripened points removed or to originate growths for furnishing the trees. Young trees of Peaches, Nectarines, Apricots, and Plums in course of formation should have the central shoots shortened as necessary to originate growth at the required distance apart for forming the principal branches. In securing them to the wall leave sufficient space in the ligatures for the swelling of the shoots, as any undue pressure or contact with nails or wires may induce canker and the loss of the branch.

#### FRUIT HOUSES.

**Vines.**—Forsing must now be commenced in earnest if ripe fruit is to be had before the end of May. A night temperature of 50° to 55° will not be too much during mild weather, and 60° to 65° in the daytime from sun heat. Syringe occasionally when the weather is bright; but if fermenting materials have been placed on the floor of the house as advised in a former calendar, and a portion stirred daily, syringing, except in the most severe weather, will not be much required. Continue the treatment advised under this head on December 1st for Vines in pots, and as the flowers open increase the night temperature 5°, keeping the atmosphere rather dry. The moisture arising from the fermenting bed will be sufficient to secure a genial condition of the atmosphere. Remove old foliage from midseason and late houses as soon as possible, and prune directly the Grapes are cut. One of the most important operations in Grape culture is early pruning. Heavily taxed Vines cannot have too long a season of rest. Even with late Vines it is advisable to cut the wood away quite to the Grapes, and not retain them on the Vines longer than the early part of the year, which will allow the Vines to be pruned and have some weeks' rest. Outside borders to which the annual top-dressing of fresh loam and bone meal has not been applied may be examined and covered. Generally a layer of hard inert soil forms on the surface and deprives the roots of air and moisture. In such cases the surface soil must be carefully removed down to the roots, supplying the usual compost and covering.

**Figs.**—To have ripe trees early in May the trees must be started at once, and for this purpose cultivation in pots is preferable, as at this season a slight degree of warmth at the roots is highly beneficial, provided it be regular and does not during the early part of the process exceed 70°. The pots should be raised in the bed on pedestals of open brickwork. Three parts Oak or Beech leaves with a fourth of stable litter form a material affording a mild and lasting heat. More than 70° at the roots is not needed, indeed is injurious from inducing growth too rapidly. Commence forcing with a night temperature of 50°, and 55° from fire heat in the day, allowing an advance to 60° or 65° by sun heat. See that the soil is thoroughly moist before the trees are plunged, and if very dry immerse the pots in water until the soil is saturated. Considerable moisture will be given out by the fermenting materials, but when the weather is bright the trees will need syringing twice every day. It is important that the trees have a position where they will be fully exposed to light. Ventilate a little on all favourable occasions, maintaining a free circulation of air after growth takes place, so as to insure well-solidified growth and thick-textured leathery foliage. Ventilate early Fig houses as before advised, and those which are to be started early in January must at once have what attention is yet needed to prepare them. Complete cleaning and tying trees in later houses as opportunity offers, keeping them as cool as possible, frost, however, being excluded.

**Cherry House.**—To have Cherries ripe from the middle of April onwards the house should now be closed. Use no fire heat at the commencement unless absolutely necessary to secure a night temperature of 40°, and 50° by day. Ventilate a little at 50°, and freely

at 55°. A confined atmosphere above the latter degree of heat should not be allowed, and is at all times highly injurious. Syringe the trees early on fine afternoons and at other times when the atmosphere becomes dry, but with the borders kept moist syringing will not be necessary in dull weather.

*Cucumbers.*—The plants showing fruit plentifully must not be allowed to carry too many; if the plants are weakly fully two-thirds of the fruit should be removed, removing likewise the tendrils and staminate blossoms. The roots will need a moderate earthing occasionally of previously warmed soil, pressing it down rather firmly. Be careful in the application of water; a fair soaking once or twice a week according to the weather and condition of the plants will be all that is necessary. Plants growing in pots will require it more frequently, and should have a little extra feeding. The temperature should be 65° to 70° on mild nights, 5° less in severe weather, 70° to 75° by day, and 80° to 85° with sun heat. Ventilate carefully whenever a favourable opportunity offers. If wireworms be troublesome insert baits of Carrot beneath the surface of the bed and examine daily. Woodlice may be caught by baits of boiled potato wrapped in a little hay and placed in flower pots laid on their sides. Toads in the house are useful. Worms must be expelled with lime water, but many may be taken by looking for them at night with a lantern, when they will be found travelling over the surface of the bed. Watch for canker in the old growths and at the collar, applying fresh-slaked lime on its first appearance. Where means do not exist for raising plants for planting in pits or frames, Oak or Beech leaves should now be thrown into a heap with a third of stable litter, turning them over, watering if necessary, so as to have them in proper condition for making a bed for raising plants of these; also Melons for planting in pits or frames heated by fermenting materials. Where, however, there are houses with a suitable temperature for raising the plants a bed can be dispensed with.

#### PLANT HOUSES.

*Forcing House.*—Introduce plants to this structure, or a house with an intermediate temperature. Indian Azalcas, especially of the early-flowering kinds, readily come into bloom in a rather moist atmosphere and temperature of 55° to 65°, and so do most other plants for forcing. Amongst the most valuable may be mentioned *Azalea mollis* in several shades of colour, and the Ghent varieties, with the deliciously fragrant *A. pontica*. *Staphylea colchica*, with its beautiful terminal panicles of white flowers, is highly decorative. Lilac, the common white, Charles X., and Persian are always esteemed. Rhododendrons are indispensable from their great decorative value, some of the finest for this purpose being *ciliatum*, *Early Gem*, and *odoratum* or *fragens* of the dwarf forms; *limbatum*, *Purity*, *Mrs. John Clutton*, *Lady Armstrong*, *Marian*, *coriaceum*, *cardinale*, *Brilliant*, *Michael Waterer*, *Everestianum*, *Mrs. Fitzgerald*, *Scipio*, *Cynthia*, and *Auguste Van Geert*, with *Nobleanum* vars., will come into flower with very little forcing, and all are fine for conservatory decoration. *Prunus sinensis alba flore-pleno* is very pretty, *Deutzia gracilis* being indispensable. *Viburnum Opulus* can be also forced freely, and double Thorns, which are very pretty for wreaths and esteemed for their scent. *Spiræa Thunbergi* is very graceful, and few in beauty rival *Kalmia latifolia*. *Hotcia japonica* is indispensable for decoration, and *Dielytra spectabilis* one of the finest and most graceful.

Roses always take precedence, and are readily forced, especially the Tea-scented varieties, if not brought on too quickly. Clematises have great decorative value, and should never be omitted, some of the best being *Vesta*, *Lady Londesborough*, *Albert Victor*, *Fair Rosamond*, *Lord Londesborough*, *Mrs. S. Baker*, *Stella*, and *The Queen*. Pinks should be placed near the glass and not brought on too quickly, or they will become blind. Lily of the Valley must still have bottom heat, especially single crowns and imported clumps; the temperature about 90° at the roots, and covered until the stalks are drawn to a sufficient length, then admitting light gradually.

Introduce plants of *Richardia æthiopica* to gentle heat, too much heat drawing them up weakly and spoiling the plants, and the spathes are poor as compared with those grown in a temperate heat, 55° to 65° being ample. Keep the plants well supplied with liquid manure.

## THE BEE-KEEPER.

### SOME FACTS ABOUT QUEENS.

I NOTICE in a late issue some suggestive remarks by "COMBER" in reference to his experiences in ligurianising, which induce me to snatch a few moments from some work in connection with our subject which has been very closely occupying me recently. Our correspondent is querying the practicability of inducing Ligurian queens to breed drones early by supplying her stock with abundant brood, in order that queens may be purely fertilised after hatching in the small boxes in which Italian mothers are usually imported.

Experience during several years with work of this kind has led me to discard the use of very small lots of bees as nurses to queen cells for four main reasons. First, weak or imperfect queens are often produced; second, the bees frequently swarm out at the time the queen flies for impregnation, and disappointment follows; third, without great watchfulness starvation is likely to occur; and fourth, feeding is almost certain to lead to robbing. Each of these heads demands a word of explanation. First, very weak lots often produce imperfect queens and drones, and for that matter workers also; and I have little doubt but that the lady hatched minus a wing in the little box of our esteemed correspondent would have been perfect had the cell been allowed to remain with the parent colony. All lovers of Lepidoptera know how likely are chrysalids, cherished with much care in the earth of a flower pot, to produce imagos of faulty development, and excess of dryness almost constantly results in ill-shapen or only half-formed wings. Some experiments I have carried out carefully during two seasons have shown demonstrably that an excess of dryness in the air surrounding a developing larva bee is as likely to injure it as it would a moth. The lamp nurseries of America showed long ago that queens could be raised in cells after sealing apart from bees altogether if the correct temperature be kept up. My experiments have shown, in addition, that a queen may be raised during all the chrysalis state, not only in the absence of the bees, but without a cell at all, if only correct thermic and hygrometric conditions are maintained. This fact is very interesting to the physiologist, as affording an opportunity of watching the progress of very remarkable and instructive changes. The nucleus "of over one hundred bees" would be unable in a "warm glass house" to maintain that moist heat which is required, and so possibly the mischance. That air is also required is manifest from the fact that the sealing of the cell is full of perforations, as the microscope at once reveals. During chrysalis changes breathing in very moderate amount is uninterruptedly continued, and fresh air is slowly supplied by the before-mentioned apertures. The germ developing within the egg of the hen is equally dependant upon a supply of oxygen, and this, no doubt, explains the discomfiture of those early experimenters in artificial incubation when it was the fashion to maintain the temperature at one dead level. The periodical absence of the hen at feeding time permitted the egg to cool, and contracted, as a consequence, the air contained in the ever-growing air vessel, and as a result a new supply was taken in through the porous shell, and so the oxygen, by what seemed an accident (but which is surely more) was constantly given to the little breathing thing within.

Secondly, the liability to swarm at the least excitement is always a great objection to small lots of bees. In more cases than one I have had three or four nuclei simultaneously desert their hives. Perhaps one or two may be subsequently found in ridiculous clusters the size of an egg, waiting the coming of the bee-master with his 20-inch skep, in order that he may suitably hive them. Those who use these small boxes for queen-raising must expect these difficulties, which, perhaps, with ample space and constant attendance, may be bearable through troublesome. When a natural swarm arises, however, the chances of getting an encasement of a valuable queen from the union of a nucleus with it is great enough to make the advantage of small boxes extremely problematical.

The third and fourth objections are simply complements of one another. The less the cluster the greater is the waste of heat, and consequently the larger the relative demand for food. Nuclei cannot consequently maintain themselves, and every attempt at feeding them is (in early spring at least) but a provocative of robbing. I now use one sized frame only, and although the control of impregnation is reduced, advantages accrue which are more than an equivalent. That queen and bees (for the consent of both seems necessary) may be induced to breed drones early by

filling the hive with brood, cannot be doubted, but this involves loss to the stocks supplying the sealed larvæ, and this loss in early spring is often sufficiently serious to tell decisively upon the profits. These early drones may be secured by placing a comb in the very centre of the hive before wintering up, or at any subsequent time that the weather makes interference safe. The free supply of food and the limitation of the hive seem the other two most important conditions. All know that small hives, *cæteris paribus*, swarm before large ones, and so by contraction crowding may be induced, and so lead the bees to contemplate colonisation. The wishes of the colony (if this expression be allowed) will often lead to the selection of cells for ovipositing. I have a frame of comb in my possession which is drone in the centre, but in the centre only. Here the primitive whiteness of the wax is apparent; no larva have been raised in it, while all around is darkened by pupæ cases. It will not be enough, therefore, to give, in the hive-middle, the larger cells; right conditions must by other means be established. This fact brings to mind the caution that if drone comb be excluded for economic purposes, the giving of supers of drone comb is almost certain to attract the queen, and so lead to some detriment by the producing of brood where its absence was desirable.

At some future time I must explain my plan of forming nuclei, so that they can be at once remitted to the parent stock when their work of queen-raising is complete.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

#### WAX-BOILING.

BOILING wax and preparing it for the market is very disagreeable work. All bee-keepers with their wives and servants dislike this work exceedingly, and none dislike it more than we do. Melted wax is easily cooled, and in cooling cleaves to everything it touches, and it is difficult to remove. Combs before being melted are bulky, and therefore have to be compressed before they are placed into a copper to be boiled. When the wax begins melting the pollen of the combs is liberated and mixes with the water in the copper or boiler. There is great difficulty in separating the melted wax from the pollen. Our plan has been to place the compressed combs in a bag of cheese-cloth and boil them, then skim off the melted wax and run it through a strainer or a piece of muslin. But we have never been satisfied with this mode of melting wax. It is troublesome work. After the cakes of wax have cooled some pollen slightly mixed with wax adheres to their under sides, which is scraped off, the cakes being again boiled in clean water and run through a cloth into dishes half filled with clean cold water. We obtain thus wax as pure as it is possible to take it. By running the wax into cold water at the last time of boiling the bottom of the cakes appear to advantage, and look as if they had been moulded. The bottom of our cakes of wax look better than the upper surface, owing to the cold water freezing the wax into various forms as soon as they meet.

Some years ago a bee-keeper at Wigan told the readers of this Journal that this plan of taking wax is too slow and troublesome, and that he had invented another which is easier and better. His plan or mode commended itself to me at the time, but owing to the smallness of our kitchen oven I have never put it to the test of experiment. His plan, if I remember rightly, is to melt the combs in a dry heat by putting them into a wire sieve or strainer or colander, and placing this in an oven sufficiently warm to melt the wax, and over a dish to receive the melted wax as it escapes from the pollen. This appears to me to be a very feasible mode of melting wax, and much easier than the one we have followed for so many years.

Another mode of taking wax—probably the best yet invented—was carried into execution in Bowdon a short time ago. A lady obtained a great boxful of honeycombs; she first took the boney cleanly from the combs, then commenced in a novel manner to manufacture the wax. Instead of taking the wax from the pollen and rubbish, she took the pollen from the wax by washing it in clean water. Then she boiled the wax and poured it into a dish without using a filter. She brought the wax to me to sell for her, which I did at 2s. per lb., and I have never seen better or cleaner wax. This plan makes wax-taking comparatively easy and pleasant.—A. PETTIGREW, *Bowdon.*

BEES IN DECEMBER.—I notice as what is to me a very unusual occurrence, bees busy on flowers in the open air during the last month of the year, especially on some lingering sprays of Mignonette and Wallflowers that have mistaken their season. Violets and Primroses are also affording them exercise, but the beautiful yellow flowers of the winter Jasmine appear to be more attractive to me than they are to them. Will this late feeding benefit the bees?—DOUBTFUL.

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Exhibiting Chrysanthemums (J. H.).**—1, Japanese varieties ought not to be included in a class for "incurved blooms." 2, Japanese varieties are a distinct class, and ought only to be exhibited in their own section, unless special provision is made to the contrary.

**Second Early Potato (E. F.).**—Soils exert a great influence on the Potato, and in the soil in which we planted the tubers you sent the crop was not good, being light in weight, and the tubers small. We will try the variety again on different ground; at present we cannot determine its name even approximately, the true character of the tubers evidently not being developed.

**Sawdust as Manure (A Seventeen-years Subscriber).**—In the way in which the sawdust is prepared—that is, spread in pigstyes and saturated with urine and mixed with manure, it will certainly be valuable for your grass land, and also for your garden, especially if the soil is of a rather strong nature, as it will then have a good mechanical as well as manurial effect. By all means try it, and the probability is that it will do much good and not harm.

**Fancy Primula (Vindex).**—We have seen many varieties of the same nature, some being better and others worse than yours, but as a rule these novel forms possess little decorative value, as, although the plants grow freely, the general effect they produce is seldom satisfactory. You may well preserve your plant and raise seedlings from it and try them, as there is always a possibility of distinct and attractive forms being produced; but the present variety will not, we think, become popular nor prove of commercial value.

**Peach Buds Falling (Inquirer).**—The most fertile cause is a deficiency of water at the roots, and the evil is aggravated by overcrowding the growths in summer and permitting the foliage to be infested with red spider. As you send no particulars relative to the condition of the trees nor the treatment to which they have been subjected, you must decide for yourself which has been the most active cause of the evil in your case, and act accordingly to prevent a recurrence of it another year.

**Celosia pyramidalis (S. H.).**—This is, we think, the name of the plant of which the withered spray was sent to you that you have forwarded to us. It is commonly called the Feathered or Plumed Cockscomb. There are several varieties having crimson scarlet, magenta, orange, and scarlet flowers, and good plants are very beautiful for autumn and early winter decorative purposes. They are raised from seed sown in heat, the plants being grown in rich soil in a temperature not lower than 60°. About May or June is a good time for sowing, as if raised earlier much care is needed to prevent the plants being drawn, in which case they produce small plumes. Strong plants last a long time in beauty in a warm conservatory.

**Jasmine on Wall—Vine Border (E. C.).**—You may carry out the plan you propose, taking care, however, to make a judicious selection of growths for covering the wall. A great number are sure to be naked towards the base, and these would not prove satisfactory. You will no doubt find some having side growths or buds down to the ground, the wood also being firm, and these are what you must retain for covering the wall. Assuming the turf loam and garden soil of which you speak is good, we should not mix the manure with it, but save it for surfacing the border; if, however, the soil is poor, you might mix half the quantity of manure with it, using the other portion as top-dressing. Good Grapes are grown without bones. If you could substitute wood ashes or burnt soil for the tan you would greatly improve the border. We should not use the latter. The lime rubbish will render the border sufficiently porous.

**Potash for Plants (S. S.).**—Our correspondent "SINGLE-HANDED," to whom your letter was submitted, says:—"Potash salts may be had under the name of sulphate of potash, muriate of potash, 'kainit,' and nitrate of potash from most seedsmen and all dealers in artificial manures. Kainit, or crude potash salts, is cheapest, but it only contains about 25 per cent. of sulphate of potash (equal to 13 of pure potash); but it also contains large quantities of other salts which have been found hurtful to vegetation when more than 5 or 6 cwt. is applied per acre, and sometimes even that quantity has done mischief. Sulphate of potash contains about 60 per cent. (equal to 34 of potash), and is, though in proportion dearer, altogether preferable. Muriate of potash contains 81 per cent. of chloride of potash (equal to 50 of pure potash), and is so much more valuable. Sulphate of potash is most commonly used. The nitrate (salt-petre) we have found useful on a small scale—*i.e.*, for pot plants when evil smells would not be tolerated. Our source of potash is the cowhouse. Cow urine contains about 40 lbs. per ton, and much other valuable matter; that of the horse contains about 54. Like you, we are inclined to think that the proper use of potash has not yet been fully ascertained; with nitrogen it is wonderful how long a vigorous growth may be sustained with it."

**Heating Unsatisfactory (B. E. W.).**—Are you sure the pipes are properly arranged? On this point you say nothing, and the evil of which you complain often follows as the result of some mistake that has been made of the nature indicated. If you send us a correct sketch of the boiler, pipes, connections, and cistern, the case shall have our attention. We are unable to answer your letter usefully from the want of sufficient data to enable us to fully understand the matter. Under the circumstances there is nothing unusual in your Thorn tree flowering now. If severe weather follows it will probably be injured,

and rather severe pruning may be needful in the spring to induce early and good growth that will ripen in the summer.

**Sea Sand for Plants (Preston).**—The advantages and disadvantages of sea sand for plants have often been incidentally pointed out by correspondents in the Journal. It no doubt varies in quality, and possibly is not suited alike for all kinds of plants, and, especially if used in a fresh state, it may prove injurious to some. Mr. Brotherton has described on page 350, vol. ii., new series, that his "Alternantheras did not pass the winter well, and in the ordinary pit raise a stock of healthy plants for propagating later on all the cuttings which could be had were taken and inserted. They died in scores, and it was not until others were inserted, and which dampel off at the soil level in the same manner, that the cause was discovered. The sand used, instead of having been laid up for two or three years, was fresh from the seashore, and directly the plants and cuttings were transferred into other sand the losses were stopped." We may also cite what Mr. Cannell publishes in his "Floral Guide"—"Having been called to do duty as judge at the Margate and Ramsgate Flower Show, I was so surprised to see the good result of sea sand compared with the ordinary pit stuff generally used, that I was induced to procure a supply at once, and to my surprise the small portion of salt it contains certainly adds vigour to the whole soil; at all events cuttings strike in it most freely, and it is my opinion that it is far the best sand for floricultural purposes I have ever used, and is in every way superior to the Leighton Buzzard sand." This is the experience of an observant man and excellent cultivator, and it is certain he would not use this sand if he did not find the advantage of doing so. The sand Mr. Cannell uses is without doubt safe, and his store is not freshly gathered. Whether all other sea sand, and especially that recently collected, is equally safe appears to be doubtful, as is evident from Mr. Brotherton's experience above quoted.

**Lapageria not Flowering (K. D.).**—Your plant is still young, and in all probability will flower next year if it has been raised from a layer and not from seed, seedling plants being often shy in flowering. Still, you must prevent the slugs eating the young growths, or those made afterwards will not have time to ripen, and hence will not produce flowers. After the plant has made good growth place it in a moderately sunny position and where it can have plenty of air, as, if the shoots are healthy and solidified, flowers may be expected to follow. We doubt if you would improve it by placing the pot in a saucer of water, as there would be a danger of rendering the soil sour, and the plant would in that case inevitably lose its health and vigour. The white worms in flower pots have been introduced with the soil or manure. Apply clear lime water, which will probably either kill the worms or cause them to come to the surface. The lime water may be made as advised in answer to a correspondent on page 485.

**Chrysanthemum Cuttings (An Amateur).**—It is the custom of some florists not to acknowledge the receipt of orders unless they exceed a given amount as stated in their catalogues. The delay of a week in the execution of an order is not unusual, as cuttings of certain varieties are not always ready on a given day. In sending cuttings they are often accompanied by numbers only, the names corresponding to which and the descriptions of the varieties being given in the catalogue of the vendor. One of the names you have sent is incorrectly spelled, and to an amateur is no doubt illegible, but we have no difficulty in reading it—Maréchal Duroc, a rosy lilac variety. Progne is a reflexed variety, rich amaranth in colour, and fragrant. Mrs. Dixon is one of the most useful incurved yellow varieties in cultivation. We presume this is the information you require, and you could scarcely expect to have such written on the labels attached to the cuttings.

**Conservatory Unsatisfactory (G. P. N., Devon).**—We wish all who seek information on garden structures would send such clearly drawn plans as you have sent, and the replies would be more easy to us and satisfactory to those desiring instruction. Your letter, too, is very clear as far as it goes, but you have omitted to say one word as to the way in which the house is heated. For anything we know to the contrary, the system of heating may be defective, and contribute to the evil of which you complain; further, in houses so situated gas is often burned, and this is prejudicial. But assuming the conservatory is properly heated, there is certainly not sufficient provision made for ventilation, and the ill results arising from this defect are aggravated by the smooth surfaces. The back wall being of glazed bricks, and the floor paved with encaustic tiles, no moisture can be absorbed and given off again as is the case with surfaces of plain bricks and the soil of beds, which vapour is of the greatest benefit to plants. You can only render such a house even fairly suitable for plants by greatly increasing the roof-ventilation at the top of the house. A continuous ventilator to open at the least a foot wide—18 inches would be better—would not be too much there at certain seasons; if you cannot adopt this mode, provide as many separate openings as you can. Then, according to the weather, you must use much moisture. If this cannot be sprinkled on the floor many plants might be stood in saucers of water, and others on pots inverted in saucers, where water in immediate contact with the roots is undesirable. Until you have more moisture in the atmosphere your plants cannot thrive. The ventilators at the top of the house should be first opened, and if sufficient air can be admitted by these without opening the front ventilators all the better, but at any rate do not open these more than is necessary. By acting judiciously on the lines indicated the plants will be maintained in health much better than under present circumstances. No doubt a well-constructed and properly managed house in the position you name would answer either for Vines or plants or both. The plant of which you have sent a leaf is not *Hoya bella*, but *H. carnosa*.

**Trellis for Vinery (F. J.).**—The screws or nuts for tightening the wires are of brass, and are somewhat difficult to describe, but we can perhaps send you one if you will forward to our office your address and stamps to prepay postage. "Eyed straining screw with nut" will also answer for tightening the wires, and may be had of Messrs. Brown & Co., 90, Cannon Street, London. The copper tacks for securing the squares should be three-quarters of an inch long. For each square you will require four tacks—two at the bottom to prevent the square slipping down, and two near the bottom above the glass to prevent its being blown out. When glazed coat well with paint, coming over a little on the glass, but not quite so much as the width of the rebate or bed of the putty beneath the glass. Half-an-inch lap is too much, a quarter of an inch being ample, as the more lap the more water gets in, and the more danger there is of breakage in frosty weather.

**Cesspool (Idem).**—The contents of the cesspool from the dwelling-house may be applied in moderate quantity to fruit trees during the winter, and between the rows of Strawberries, but if strong would be best mixed with soil and applied as a top-dressing. If applied too freely or too strong it will injure if not kill the fruit trees.

**Asters for Cutting (J. A.).**—The same varieties that are grown and flowered out of doors may be flowered also in pots, but they must be grown to a flowering stage under full exposure to the air—that is, either outdoors or in

cold frames with the lights removed except during drenching rains late in the season. The simplest mode is to grow the plants in rich soil and pot them when the colours of the flowers are visible; indeed, thousands of plants are potted when in full flower and sold in the streets of London every autumn. Some of the best kinds for pots and for affording flowers for cutting are Boltze's Dwarf Bouquet, Pompon Imbricated, Dwarf German (early), and Dwarf Chrysanthemum-flowered (late). The best larger kind for your purpose is the Victoria. Seed of the kinds named can be had in mixture or in separate colours, white flowers being generally acceptable. For ensuring late Asters you must sow the seed late. We obtain our latest flowers by sowing seed of the Dwarf Chrysanthemum-flowered kind about the second week in June, and growing the plants in a cool moist position, and before the Aster flowers have faded Chrysanthemums are plentiful.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (A. Y., No. 1).—The Pear you have sent is Fondante de Malines. (James Saurle).—Apple—12, Emperor Alexander; Pear—6, Colmar d'Arenberg. We do not know the names of any of the others. (H. C. Prinsep).—28, Joséphine de Malines; 32, Flemish Bonchrétien. (S. S.).—1, Tower of Glamis; 2, Dutch Mignonne. (Pyrus).—1, Rymer; 2, Wyken Pippin. (T. H.).—8, Hoary Morning; 2, one of the Costards; 3, Striped Beefin; 4, Blenheim Pippin; 5, Devonshire Queen; 6, not known. (G. B. C.).—The Pear is Colmar d'Arenberg, the Apple Norfolk Beefin.

**Names of Plants (F. R.).**—The specimen you have sent is a well-grown form of *Lygodium scandens*, a species that was introduced from the E. Indies towards the close of the last century. Your plant is unquestionably worth preserving, but we doubt if it is distinct enough to merit the award you desire; still, you might submit it to the consideration of the Committee. (C. E. P.).—The large brownish flower is *Cypripedium insigne*, and the small flower is, we think, *Cymbidium Mastersii*, but it could not be satisfactorily determined. (E. W. B.).—Owing to the spray having been wrapped in dry cotton wool and enclosed in a letter, it arrived as much withered as if it had been exposed to the sun throughout a hot summer's day, and was quite unrecognisable. As we have said on many occasions, this material extracts all the moisture from leaves and flowers. Sprays should be packed in something damp and sent in small boxes. If we receive a specimen even in a fairly fresh state we will name it for you. (F. S.).—1, Cotyledon fascicularis; 2, *Sempervivum tortuosum*; 3, *Gasteria verrucosa*; 6, *Enonymus radicans variegata*. The others were too withered to be recognised.

COVENT GARDEN MARKET.—DECEMBER 14.

WE have no alteration to quote this week, trade being very quiet and prices the same.

POULTRY AND PIGEON CHRONICLE.

AGRICULTURAL IMPLEMENTS AND MACHINERY.

WE have from time to time called the attention of the home farmer to this subject, as it is not only a very wide and important one but also continually subject to changes in consequence of the introduction of improvements, or attempted reforms, which may be suitable only under the varying circumstances of farm manage-

ment. One of the chief reasons for our taking up the subject is, if possible, to show the home farmer the benefit of such inventions as may be occasionally offered to his notice. Having not previously given our attention to the use of waggons and carts for general farm work in these columns we now propose dealing with it. It has frequently in times past been discussed by farmers under the heading of "Carts *versus* Waggons," and the discussion amongst farmers and implement makers has contributed in a wonderful degree to the practical application of the various points, for it has removed many old prejudices and preconceived opinions. Reform is required in certain farm implements, rendered imperative by the use of steam power in so many of our farm operations, and it is necessary to consider how far the various suggestions connected with labour-saving machinery has tended towards changes never previously contemplated as regards economy.

Steam power connected with agricultural operations has made such rapid strides, and has enabled the farmers to do so much, that the necessity has arisen to consider the best mode of gathering the crops—whether carts or waggons are the best for this purpose, which is the least expensive and the quickest way of gathering and stacking the various crops. Expedition is certainly a leading point, especially when in a harvest like 1881 and some previous years, in which but short periods of fine weather only occurred, and are circumstances which will not be soon forgotten. In consequence, any reform which can under the head of economy be introduced will be sure to command the attention of the home farmer, and in order to effect the necessary changes in the constructions of our carts and waggons we must enlist the attention and co-operation of the implement makers. We shall first address ourselves to the policy of employing carts or waggons under particular circumstances, and defer our suggestions of the alterations required for a short time.

The advocates of the use of carts in preference to waggons are yearly increasing, and numbers can be found who employ only carts upon their farms, and we are therefore bound to listen with attention to their reasons for this practice. In fact, their arguments in favour of two-wheeled carriages for farm work are all based upon one word—economy, both as regards the first outlay as well as the saving in manual and horse labour. The kind of cart we recommend will be stated further on; but it has been found upon a farm of between 400 and 500 acres that six carts with frames complete and strongly made, in consequence of being convertible from light to heavy framework, have been sufficient to do the whole work. This contrasts favourably with the use of waggons, not only in the first cost but also in the question of repairs. It is found in practice when waggons are used that manure carts are required also for laying out and distributing either yard dung, chalk, clay, and other heavy materials. The saving of manual and horse labour is the next point, and both experienced and practical men make the assertion that more work can be done with the same amount of manual labour with carts than with waggons, and give an instance in their proceedings, stating when it is desired to carry a field of corn it would, supposing the corn to be stacked in the field, require three waggons and five horses to work a double fork, and the two pitchers would work together. On the other hand, if five carts and five horses were used the pitchers would be separate, and boys would lead the horses. It is an accepted fact amongst practical farmers that two men pitching separately will do more work than two working together, so that the same horses and men will certainly carry more corn with carts than with waggons.

There is an article on "The Advantages of One-horse Carts" in the sixth volume of the Journal of the Royal Agricultural Society of England, which states—"When working on the double-hand system the waggon must be set, as well as may be, to accommo-

date both pitchers, and if the man on one side has the wind or the higher ground in his favour the man on the other side must have a corresponding disadvantage; but the single man pitching up to a cart may turn it about as may be most convenient to himself, taking the benefit of the wind or the higher ground as he pleases." Many people object to the use of carts on the ground of their being more unsafe upon hilly land, and the great likelihood of getting the horses hung up. On the other hand, the evidence of numbers of practical men states that they have met with no accidents of this nature, although no farms could be much more hilly, with some of the most inconvenient gateways, than those whereon the carts were in constant use. With regard to the saving in horse labour, which we consider a great item, for a horse in a cart carries part of his load. This, by the amount of steadiness it gives, enables him to draw the remainder of his load with the greater ease. On the other hand, picture two horses between the shafts and two at length drawing a waggon; which, we ask, would appear to the greater advantage? We are quite aware that the opinions upon this subject will meet with many objectors, for we suppose that at the present time, even after the numerous improvements which have been made in both carts and waggons lately, that a large number of farmers would prefer the waggon. This circumstance shows the necessity of our giving the information we possess to the home farmer without favour or prejudice. Still, it is not presumed for a moment that anyone having a number of waggons can be expected to burn them or sell them at a very low price; but it seems important for a young farmer on entering a farm to consider whether it is not of advantage to lay out his money on carts which would accomplish all the purposes of farm work, instead of on carts and waggons as well.

The question is not so much between carts and waggons as whether carts alone could be used instead of both waggons and carts. One great advantage of carts is that they require a less outlay at first; then, from being low, they could be loaded with much greater facility; next, a single horse could no doubt draw a load better with some portion of the load on his back, and with less labour on two wheels than on four, on four wheels there being of course greater friction at the axletrees and a greater draught for the horses to overcome. Some years ago some farmers were in favour of Crosskill's carts, but after a trial of some time they found that the advantages were in favour of two-horse waggons, which demanded less care in loading; for farm labourers are not so careful as they formerly were, in consequence of which it is not unfrequently the case that in the middle of haymaking a load has fallen off the carts, an inconvenience which in a busy time is very considerable. It might very properly be urged, perhaps, that this was not the best description of cart—that is, with a small and narrow bed and extending forward and backward above it, which causes the load to press too much on the horse's back in coming down hill, and in going up hill to become tail-heavy. Various inconveniences named would be obviated by the use of what are called the Scotch carts or frames, which have a long low bed and nearly, or may be made quite, as extensive as that of a waggon both as to length and breadth. These have been in use for many years, and numerous good practical farmers assert that they would not use waggons again on any consideration. It is, however, pointed out by the advocates of the previously named carts with frames that there is a disadvantage in the use of the Scotch framed cart—that it was necessary to have small dung carts in addition, and by their use farmers did not save so much as by making one cart answer both purposes.

The question still remains, Which on ordinary farms is the best to be adopted? Before this can be answered we must refer to a cart which has been exhibited, having a long and low bed and an apparatus for shifting the weight of a load backwards and forwards, thus easing the weight on the horse's back in going down hill, or the contrary in going up an incline. This contrivance is good for the purpose and also very simple, for by screwing the cart backwards or forwards in a horizontal direction the object is easily obtained of regulating the draught when in the haying or harvest time, or when loaded with sacks of corn and travelling on the high roads. We have also seen a very neat and cheap cart exhibited, the only disadvantage of which, if it can be so called, is the exceedingly low wheels and the consequent additional draught and labour necessary. It is, however, a choice of two evils. With low wheels there is additional strength to the vehicle. It was, however, constructed at much less cost, and a moderate-sized horse could draw a ton weight, and the further advantage of low wheels is to allow dung or farm produce to be thrown over the side with greater facility.

(To be continued.)

## WORK ON THE HOME FARM.

*Horse Labour.*—The employment of the horses has lately, owing to the changeable weather which has prevailed, been subject to delay so far as late sowing of Wheat has been concerned; still there has been the fallows to be ploughed, which in various instances have not yet been completed. With regard to Wheat-sowing, as there will be more than usual sown this year in consequence of the idea which is gaining ground that Wheat after all, except on the lightest soils, is the best rent-paying crop of all the cereals, chiefly in consequence of the low price at which Barley is selling, and considering that this has occurred, too, after the repeal of the malt tax, there seems but little hope of Barley commanding so good a price as was expected. In consequence of this we also approve the policy of sowing as much Wheat as can be sown within a reasonable time, which may be said to be from the present time until the second week in February; depending, however, upon the state of the land and the weather. In the event of the land being very dry and light at the proposed period of sowing we should prefer to sow Barley instead of Wheat. When Wheat is drilled with the land very dry and fine the weeds are nearly sure to gain the ascendancy. In fact, a good preparation for Barley is just the reverse for Wheat, as the land cannot be too heavy and wet for Wheat, if it can only be drilled or sown after the press, and the seed properly buried, and the land laid into the required shape as regards the size of the ridges. We must, however, remember that the land should be quite clean and free from couch grass, and otherwise in good condition, so that a full crop of straw may be expected. In case of any doubt existing upon the latter point the spring growth of the Wheat should be carefully watched, and in the event of the plant losing colour  $1\frac{1}{2}$  cwt. per acre of nitrate of soda should be sown broadcast, and immediately followed by the use of the horse hoe, which will not only enable the nitrate to act more quickly and effectually, but destroy a large portion of the weeds. Nothing can show the benefit of wide drilling better than this; and in case the Wheat has been sown broadcast and cannot be horse-hoed, it is but little use to expect the full advantage of artificial manures which may be applied, or the destruction of weeds. In fact, it is frequently hopeless to effect any improvement in the crop in the spring unless the grain is drilled 10 to 12 inches apart between the rows. As regards the time of sowing late Wheat, the earlier it can be done satisfactorily the better; that is to say, December is a better seed time than January, and January is better than February, but especially when the land is close and heavy at seed time, for then the seed lies firm in the land like the early-sown Wheat, and in consequence is less subject to injury by the growth of weeds. It is, however, desirable to sow or drill not less than three bushels of seed per acre at the late season, as the larks, rooks, and pigeons are sure to attack the first sprouts as they appear above ground.

*Live Stock.*—The horned ewes have now finished lambing, and on entering upon root-feeding it is a good plan to divide the flocks, placing all the earliest ewes and their lambs together and feed them both so that they may all be sold fat at the same time. The ewes which lamb later—that is to say, after the middle of November, may, if some ewes are required to be kept over for another season, be maintained in merely store condition, but the lambs may be fed in advance and liberally upon the best of food. In this way the very best of stock will be available for the next season, as the ewes will be sure to lamb early, and may be kept in larger numbers as store sheep going to fold during the summer, and yet be in prime condition early in the autumn when the lambs fall. Young cattle when intended for the dairy should now be carefully fed in the yards and sheds at night time, with a run during daytime upon the pastures. But those calves and yearlings intended to come out as baby beef should be kept entirely under cover and fed in twos or threes according to age, and singly after they reach fifteen months old. We have never found cattle pay better than under the system of early maturity—that is, kept on the best of food and in a fattening state as calves, and so continued on until they go to the butcher, so that when as fat calves they should never lose flesh at any after period. In this way we have frequently sold young cattle, both heifers and steers, at nineteen and twenty months old to weigh 100 stones of 8 lbs. The value of this system of management was well exhibited by some prize animals just over two years old of great weight and prime quality at Islington Hall Show recently.

## POULTRY AND PIGEONS.

### POULTRY IN WINTER.

WINTER has begun, or at least we may expect it shortly to begin. It is well to be beforehand with it in the poultry yard. A few precautions would have saved us many losses and much vexation during the last few terrible winters. We wrote long ago about the necessary autumnal repairs of houses; these we suppose to have been attended to. It is not, however, enough to have warm and watertight roosting houses; if severe frost set in, or, still more, driving frosty fog such as we had last January, the poultry must be confined to them, save in the most sheltered situ-

ations. A very short exposure to it causes the combs of many cocks to be frost-bitten, especially if they have been much shown or kept in warm places. No malady is more difficult to deal with than frost-bite. Its effects are not apparent till the mischief is done, and often not at all to an unpractised eye. The gills perhaps swell suddenly, and the unfortunate bird is thought to have a mere cold, and is placed near a fire in absolute torture; or slight discoloration of the comb is the first sign that part of it is practically lifeless. If once frost touches the comb the bird must be kept in darkness in a moderately cool place, and the parts affected gently rubbed with zinc ointment. Prevention, however, which is not difficult, is far better than cure.

It is, of course, particularly desirable, now that the breeding season is at hand, to keep stock birds in the most vigorous health. With this object in view overfeeding must be avoided. There is no time of year at which poultry are so likely to be injured by kindness as the present. Cold stimulates their appetites, and to the ignorant it seems cruel to stint them. The moult of adults is, however, over, and the growth of young birds—at least, such as are fit to breed from—is almost finished. These two great drains on the system have ceased, and the bird at once begins to put flesh on quickly. This is especially the case with pullets, and must be specially guarded against. Overfat hens never produce strong and healthy chickens.

There are probably just now many of our readers who are about to start incubators. Attracted by the clever inventions to be seen at the Crystal Palace and Birmingham, and their neat workmanship, they have made their purchases or given their orders, and are looking forward to large broods emerging from the pretty egg-drawers. Let us give them a few warnings. To begin with, they probably intend to save up a goodly collection of their choicest eggs against the arrival of the much-talked-of machine. Four and twenty hours will, they fancy, be time enough to study its whole working and regulation, and then in all the eggs will go to the one basket, or rather one drawer, to inevitable destruction and addlement! Let us assure the inexperienced that it takes a long time to master the regulation of any incubator. If early chickens are required the incubator should at once be set to work, and, after a few days, a trial set of valueless eggs be put in and hatched out before really precious ones are tried. The regulation of an empty incubator and one full of eggs is a very different matter, so the trial must be made with some sort of eggs.

Another absolutely necessary precaution is to have the thermometer tested beforehand. Many are faulty, and cause the waste of many eggs and much time and trouble. Last year we spoilt several batches of eggs, which all failed in the second week of incubation, because a thermometer registered  $2^{\circ}$  or  $3^{\circ}$  above the actual temperature. On the first testing nearly every egg seemed good and duly changed, but subsequently the germ ceased to progress.

The subject of testing reminds us of the very useful leaflets we saw at the Crystal Palace by Miss May Arnold's "egg oven," with diagrams showing the various stages of progress and failure in the incubation of eggs. We should advise all novices in incubation to purchase them. It is easy enough after four days to distinguish between clear and fertile eggs, but the difficulty arises subsequently. From various causes the germ fails at different stages of development. We are naturally fearful of ejecting a good egg, but the presence of a bad one is certainly injurious to those containing living chicks. These diagrams will help us much in discriminating between the living and the dead germs.

Similar precautions should be taken to test the working of all artificial mothers. It is not so easy to "cook" the chickens once hatched as the eggs beforehand, still their well-doing depends much upon regularity of temperature. If there is any doubt about the heat to be kept up the safe side is below rather than above the proper mean.

Another point which needs the first care is the storage of the eggs saved for hatching. It is commonly thought that an egg is an egg, and that so long as it is not absolutely broken it must produce a chicken. Its treatment between its production and the time it is placed under a hen or in an incubator is supposed to be quite immaterial. Only those who have ever sold superfluous eggs for sitting have an idea of the ignorance of the public about the conditions under which eggs are or are not likely to hatch.

In frosty weather an egg is very soon chilled after being laid, especially if the nest be upon the damp ground. It is not enough for eggs to be collected every evening when the birds are shut up. Most of them will long ere that have been frozen, and all chance of the germ ever coming to life be gone. The laying hens, generally few in such weather, must be carefully watched, and the eggs collected before they are cool, put deep in bran or dry sawdust. We say dry sawdust advisedly, for the turpentine in wet

sawdust, we believe, damages them. The egg-drawer, too, must be in a moderately warm room. Without such attention to the preservation of the eggs all the care bestowed on sitting hens and incubators is simply labour lost. The three great requisites to ensure chickens at once early and strong, which are the great desideratum of most fanciers, are—1, Stock birds in strong health, well fed and comfortably housed; 2, Their eggs properly stored; 3, The hens which incubate them well attended to, or the artificial incubators carefully regulated.—C.

#### "POLISH FOWLS."

MAY I, through your columns, call attention to the fact that at the forthcoming show of the Poultry Club to be held at Cambridge, there is a class for "any other variety Polish"—*i.e.*, any other variety than the three commonly shown. I have guaranteed the prizes for this class, five in number, in the hope of giving some encouragement to breeders of Padue Chamois, White, or other kinds of Polish, which are now almost extinct in England. I trust that those who possess such birds will be good enough to show them; their chance of winning a prize is better than is often the lot of exhibitors.—O. E. CRESSWELL.

#### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Charing Cross Hotel on Friday the 9th inst. There were present Messrs. H. R. Dugmore (in the chair), T. W. Anns, R. A. Boissier, A. Comyns, J. C. Fraser, S. Lucas, L. Norris, and G. Vigers.

ELECTION OF MEMBERS.—The following new members were elected—Rev. A. S. Davies, Caxton, Attleborough; E. McMorland, Coekett's Farm, Cudham, Kent; Rev. Laxon E. Sweet, Hullavington Vicarage, Chippenham; Sir Henry Thompson, Hurst Side, West Molesey, Surrey; Mrs. G. Ward, Bearnett House, Wolverhampton; R. S. Williamson, Rawnsley, Hednesford. The following new associates were elected:—M. W. L. Brooke, Point Cottage, Attleborough, Norfolk; W. Howard, Holborn House, Shanklin, I.W.; Miss M. F. Symes, Nether Cerne, Dorchester.

CLUB SHOW.—Some final arrangements in reference to the Show were discussed, and the Secretary was directed to issue a special advertisement calling attention to the fact that no entries would under any circumstances be received unless sent or posted to the Secretary of the Show on or before Tuesday, December 20th.

DISQUALIFICATION AT BEXLEY HEATH.—At the previous meeting of the Committee held at Birmingham, a communication from the Secretary of Bexley Heath Show in reference to the disqualification of a pen of Hamburgs shown by Mr. G. P. Pointer, in consequence of the comb of the cockerel having been trimmed, had been under consideration. It appeared that a protest had been lodged by an exhibitor, and that Mr. W. J. Nichols, who acted as Judge, had decided upon examination of the bird that the comb was cut, and that the pen should be disqualified. The rule of the Bexley Heath Show providing for such cases was as follows:—

"All protests against awards must be lodged with the Secretary within six hours after the termination of the judging, and must be accompanied by a deposit of £1 ls. Such protest will be submitted to the Committee of the Poultry Club, who, after hearing the decision of the judge or judges thereon, will decide as to whether such protest is frivolous or made without due grounds, in which case the deposit will be forfeited."

At the Birmingham Meeting the Committee of the Poultry Club decided "that the protest had been made on due grounds, and directed the deposit to be returned to the protestor," but deferred the further consideration of the question of disqualifying the exhibitor from competing at Club shows until the present meeting. It being proved to the satisfaction of the Committee that Mr. G. P. Pointer had purchased the bird at the Crystal Palace, where it had been v.h.c., and that he was thus not directly implicated in the trimming of the comb, the following resolution was passed:—

"It appearing that Mr. Pointer had purchased the bird disqualified at Bexley Heath at the Crystal Palace Show, where it was v.h.c., the Committee of the Poultry Club, while thinking that Mr. Pointer might well have exercised more caution in the matter, do not consider the case to be one calling for disqualification from exhibiting at shows under Club rules."

THE DISQUALIFICATION AT BIRMINGHAM.—The case of disqualification of a pen of White Bantams at Birmingham for having sickle feathers artificially inserted in the tail of the cock, which had been under consideration at the Birmingham meeting, was again before the Committee, and it was resolved that—

"Mr. Sam D. Rhodes be absolutely disqualified from exhibiting at shows held under Club rules."

THE DISQUALIFICATION AT THE CRYSTAL PALACE.—The question of the disqualification of two Malay hens exhibited at the Crystal Palace by Mr. E. M. Le Hurey, and there disqualified, was under consideration. It appeared that the birds had been very properly disqualified at the Palace on the ground that their faces had been cleaned of feathers in the same way as the faces of Game fowl are usually cleaned for exhibition. There was clear evidence before the Committee that the removal of the feathers in this case had been

done under a mistaken impression that the removal of these feathers from the faces of Malays was permissible, and generally recognised to be so. It was also manifest that the feathers had been removed in such a way that their removal would be apparent to a mere novice, and could deceive no one.

Under these circumstances the Committee resolved, "that as the removal of the feathers had been effected by Mr. Le Hurey through ignorance merely, and not with any intent to deceive the Judge, the case was not one which called for disqualification from exhibiting at shows held under Club rules."

SHOWS UNDER CLUB RULES.—A communication from the Secretary of the Liverpool Show as to holding the same under Club rules was read, and a subscription was granted in aid of the funds of that Show.

NEXT MEETING.—The date of the next meeting of the Committee was fixed for Friday, the 16th inst., at Charing Cross Hotel, at 2 P.M.—ALEX. COMYNS, Hon. Sec. Poultry Club, 47, Chancery Lane, London, W.C.

POULTRY CLUB SHOW.—Our readers will note that the entries for this Exhibition absolutely close on Tuesday next, December 20th. Those who have not yet done so should send at once for a schedule to Mr. R. Peters, jun., 7, Downing Street, Cambridge.

ILLUSTRATED BRITISH BALLADS.—Parts 8 and 9 of this excellent work (Cassells) contain several well-known and beautiful ballads, each appropriately illustrated. The principal are—The Five Carlines, Flodden Field, The Forging of the Anchor, The Friar of Orders Grey, Glenfinlas, The Hermit, The Horn of Egremont Castle, and Hugh of Lincoln, with several other smaller pieces.

#### OUR LETTER BOX.

**Crowing Hen** (*Inquirer*).—A crowing hen is in the old proverb associated with a whistling woman, both being deemed unlucky. The origin of the superstition in the former case may be found perhaps in the fact that such hens are frequently unfertile. This is, however, by no means invariably the case, and we should recommend you to give your Andalusian a fair trial before resorting to the extreme measure suggested.

**Turkey Hens Wasting** (*Subscriber*).—We fear your hens have liver disease in an advanced stage. The lameness followed by wasting is an almost infallible sign of this. The disease is contagious, so you had best kill the two hens affected at once.

**Disinfectants** (*B. H. R.*).—If the runs be small dig them over, and in any case sprinkle with carbolic fluid, sanitas, carbolate of lime, or some other disinfectant. Put a few drops of McDougall's fluid carbolate in the drinking water.

**Early Calves** (*A Seventeen-years Subscriber*).—We are not prepared to deny the statement you submit, however extraordinary it appears to be; but the practice of which it is an example is very undesirable, and you are not wrong in describing it as "sheer folly."

**Bromus giganteus** (*M. D.*).—This forage plant will not usually produce like Italian Rye Grass when the imported seed is sown in the autumn and early spring months; and as summer forage we prefer Giant Saintfoin or Lucerne, both for quantity and feeding value, the latter especially when a quick succession is required as green fodder for dairy cows. There is, however, always the question of soil to be considered, and we therefore recommend a trial in the nature of an experiment of these four sorts named in order to ascertain which is the best under all the circumstances of soil and the requirements of the animals.

#### REMARKS.

4th.—Fine and dry, not much sunshine.  
5th.—Very wet morning, but fine afternoon and evening; eclipse of the moon very well seen.  
6th.—Thick fog early, clearing off about noon, afterwards fine.  
7th.—Fine bright day, little hazy in morning.  
8th.—Fine all day.  
9th.—Very dark day, with rain and fog; clearer in evening.  
10th.—Snow in morning, soon melting; rain in afternoon.  
A damp week and cooler; the temperature considerably below that of the previous week, and slightly below the average.—G. J. SYMONS.

## DINNER-TABLE DECORATION.

HAVING recently been much engaged in table decoration, and being out of practice, I at first sought for any remarks bearing on the subject that might have been written in this Journal or its contemporaries; but eventually I had to rely upon my own invention. What resulted I propose briefly to relate. It may occur to some that the devices possess no marked originality or superior merit. Probably not, but they met with the approval of my employers, and might, if imitated, be equally as pleasing to other employers. That, after all, ought really to be the sole aim of gardeners. We are paid to gratify our employers' tastes and not to indulge our own fancies, however superior we may consider them, and I ask would-be critics to bear this in mind.

Mr. Luckhurst has recently written in these pages on "The Arrangement of Cut Flowers," describing several tasteful arrangements; but worthy of imitation as these undoubtedly are, they would not meet our case, simply because we have a different class of flowers and vases to deal with and different tastes to study. In the first place the dining-table here is a large one, the number of persons dining every night varying from fourteen to twenty, and, being also wide, central vases with flowers or plants were insufficient. Added to this the table was lighted entirely from silver branching candlesticks, and, as a coloured shade was disposed over each candle, tall March stands or light-foliage plants would be ineffective. The employment of a great variety of flowers was absolutely prohibited. This to some might appear questionable taste, but the result proved very effective nevertheless, and I should not again resort to a mixed arrangement were I at liberty to do so. Overcrowding had to be avoided, and brightness I soon discovered had to be aimed at. For instance, four flat oval-shaped tin troughs belonging to china vases, filled with the brightest Hawthorn berries and Rose heps, intermingled with the fertile fronds of *Pteris cretica albo-lineata*, and fringed with the shining rich green growths of *Escallonia macrantha*, disposed on the cloth between the dessert dishes, were considered too dull; and but for other flat dishes filled with Maidenhair Fern and white flowers, such as double Primulas, Begonias, double Prunus, Deutzias, Azaleas, and Bouvardias, and highly coloured plants of *Dracæna Cooperi* in vases, the table would have been voted a failure.

On another occasion when there were ten dishes of dessert and three candlesticks employed, on each side of the central and midway between the other two of the latter we stood a good specimen of the silver-variegated *Pandanus Veitchii*.

These were in 5-inch pots, placed on small plates, and good green moss (collected a day or two previous in order to remove the earthy smell and to admit of particles of earth and rubbish being readily separated), was banked from the cloth over the sides of the pots. In this were distributed a few plants of the small hardy wall Ferns *Asplenium Trichomanes* and *Ceterach officinarum*. Among these cut blooms of *Pelargonium Guillon Mangilli* were freely dotted, and next the cloth fronds of Maidenhair Fern were disposed. The dessert dishes were placed one at each end and four on each side, and between these last were alternated two *Crotons angustifolius* and three small flowering plants of *Gesnera refulgens*, these being turned out of their pots, the balls reduced, put into small plates, and banked over with moss and wall Ferns. The plants are not much injured by this rough treatment, and the only objection to this arrangement is the difficulty of working clean with the moss, as, unless arranged before the table is "laid," there is a possibility of rubbish dropping into the salt and glasses. To obviate this difficulty, however, we have had a number of half circular zinc troughs made, and in these next season we hope to have *Selaginella Kraussiana* well established. They can then be rapidly filled with flowers and easily arranged in circles or other forms. For the central plants our tinman has made circular trays, the central space of which is large enough to hold either a 5-inch or 6-inch pot, this being surrounded with a narrow trough. These can then be filled with plants, moss, and flowers, carried to the dining-room and placed in position.

The first night we had these, two were filled as follows:— In the centre a good specimen in a 5-inch pot of the beautifully drooping golden *Croton angustifolius*, the pot mossed over, and at the base were disposed large fronds of Maidenhair Fern, next a ring of white Chrysanthemums, and above this large trusses of a beautiful pale rose *Rhododendron*, obtained by forcing. With these between the candlesticks we employed between the dishes of dessert small plants of narrow-leaved *Dracænas ferrea* and *nigro-rubra* and flowering *Pelargoniums* in 3-inch pots. The pots were stood on Maidenhair Fern and covered with moss, in which were disposed a few yellow Chrysanthemum blooms, which by candlelight really appeared to be white. On another occasion different plants were employed, and sprays of *Jasminum nudiflorum* were advantageously substituted for the Chrysanthemums, and richly coloured leaves of *Mahonia Aquifolium* for the Fern fronds. Red Primulas would have been employed failing the more beautiful *Rhododendron*.

These combination groups may strike critical readers as being rather heavy, and so they are, but not objectionally so; at all events no complaints were made to that effect, quite the reverse being the case. After one of these "heavy" nights a "silver" night follows, and this admits of much of the carefully preserved decorating material being again effectively employed, and in a very different fashion. On these occasions silver is largely employed in the shape of two or four candlesticks, a centrepiece, two cups and two oval-shaped receptacles flanking the centrepiece, in which to place dishes of flowers. The dessert dishes are also of silver, and taller than those in ordinary use. With the exception of the two vases, which in one instance were filled with Maidenhair Fern, white flowers and forced Lilac, and on another with white flowers and *Euphorbia jacquiniæflora*, everything we employed was either laid on the cloth or very near to it. The centrepiece and cups standing on blocks of ebony were not surrounded, but the four

candlesticks on one occasion were surrounded with moss, on this being laid fronds of Maidenhair Fern to form a groundwork for a ring of Pelargonium Guillon Mangilli for the two inner, and yellow Chrysanthemum Peter the Great the two outer. The dessert dishes were festooned with leaves of Coleus Verschaffeltii, with a single bloom of Rhododendron in each. At the points of each festoon between the dishes were stood small glass globes containing a single large bloom, facing outwards, of the yellow Allamanda Schottii and a large frond of Maidenhair Fern. On another "silver" night the bases of two of the candlesticks were surrounded, but at no time covered, with moss, Maidenhair Fern, and fair-sized whorls of Poinsettias, Rhododendrons being similarly disposed round the other two. There were fourteen dishes of dessert, one at each end and six on each side, in the centre of these and in a line with them standing the two flower vases. In each of the spaces between these, or sixteen in all, were placed a small circular patch of moss, a frond of Maidenhair Fern, and a single bloom of Allamanda alternating with a truss of Rhododendron. These were surrounded with the above-mentioned Mahonia leaves, with a spray of Jasminum on each, and an irregular line of similar materials connected the whole, an outward curve being given at the base of each dessert dish. This proved a very pleasing arrangement by candlelight, and when re-arranged the next morning to suit the breakfast and luncheon tables was still more effective, the Jasminum and Mahonia contrasting more beautifully.

At Christmas time a somewhat similar arrangement most probably will be adopted, the materials in this instance consisting of sprays of variegated Holly supporting sprays of berried Cotoneaster Simmondsii or Hawthorn berries for the tracery, Primula trusses in variety being disposed in the centre of the circles, while the bases of candlesticks will be surrounded with branches of Solanums of sorts in full berry. Berries seem absolutely necessary for Christmas decoration, and the Solanums will then be sacrificed simply because they do not find so many admirers later on.

On one occasion we surrounded the bases of candlesticks and dessert dishes with the tips of the stock plants of Iresine Herbstii, running through these a line of Mesembryanthemum cordifolium variegatum. This was a simple yet pleasing arrangement, and might be imitated with the tips of old specimens of many beautiful Coleuses, or, where Holly is plentiful, with berried sprays, with or without a few light-berried or fine-foliaged plants. The above does not exhaust our list of devices, but at the same time we should be glad of a few hints on the subject from others more experienced in the practice.—W. IGGULDEN.

#### PRUNING VINES.

THE performance of this operation will soon be general. Some early Vines may have been already pruned, and very late Vines will not be touched for a considerable time to come; but from the majority of amateurs' vineries the fruit has been removed, and the wood should be well ripened. For various reasons amateurs with vineries generally try to make the acquaintance of the nearest professional gardeners, and it is by them that such work as pruning is done; but many others have to do the best they can themselves, and these are always glad of a seasonable word on this and other matters.

The time to prune is as soon after the leaves have fallen as is convenient. When the wood is hard and brown and the leaves have fallen no injury will occur through using the knife, as all danger of bleeding or doing the work prematurely is past. In vineries where plants are grown more heat than is requisite for the Vines may have had to be maintained at times, and this may cause the Vines to remain growing and the leaves to keep green longer than they would do in an open house, and in such cases it will be well to delay pruning until they have reached the state before indicated.

The most prominent buds are generally some distance from the base of the young shoots, and the smaller buds are found near the old stem. Some think that the best shoots will be secured another year from the largest buds; this induces them to allow the young shoots to remain some inches in length, and this in a year or two forms large spur-like growths on the stems of the Vines which are neither ornamental nor good for fruit-bearing. To avoid this as long as possible every shoot should be cut in to

two eyes from the base. Sometimes when the buds are good only one may be left, but two are always convenient against accident, and the outer one can be removed when it is seen that growth in the other is certain. A very sharp knife should be used in cutting Vinc wood. Sometimes if a young shoot has started from the main rod this may be left to bear fruit, and the nearest spur to it, especially if it is large, may be cut away.

Young canes generally have some small side growths which require cutting from them, and the top must be cut neatly. I do not think there are many young Vines cut in so far now as they were at one time. When a clean, strong, well-ripened cane has been secured it is not cut three parts down, but most of it is retained for fruiting, and this is found to be economical in every way.—A KITCHEN GARDENER.

#### THE PROPAGATION OF HOLLIES.

IT is not easy to understand what becomes of the thousands of Hollies annually raised by seeds, cuttings, and grafting. They, however, find a market, or their propagation would not be so vigorously pursued as it is. The common Holly (*Ilex Aquifolium*) is raised from seed, and other kinds also that produce berries freely. After the berries are gathered they should be allowed to remain in a heap for twelve months until the pulp is decomposed, and then sow them in the early spring. This is a quick and ready way of propagation, but much care is necessary before the young plants attain a saleable size. In some instances the losses are numerous from either drought on the one hand or the severity of winter on the other. In spite of these drawbacks large numbers are raised from seed. August or the early part of September in some large establishments is the time preferred for transplanting seedlings to their permanent positions. Those who practise this contend there are less deaths, and that the young plants start with greater freedom and are much less liable to suffer from drought than if transplanting were deferred until May.

Nearly all good varieties are increased by cuttings as well as grafting, and some few by budding, but the latter I have not seen carried out extensively. *Ilex Hodginsii* is largely propagated, and in the majority of instances by means of cuttings. The young and well-ripened wood should be selected for cuttings. Ripe wood only should be chosen as far as practicable when it is not really necessary for the cuttings to be made with heels. This, however, is looked upon by some of great importance, and wood only is employed that can be furnished with heels. This is of real advantage in the case of any wood inclined to be soft, or in seasons when the wood has not well ripened. But when thoroughly ripe the cuttings appear to root as well without as with a heel. In either case the cut at the bottom should be clean and the operation performed with a sharp knife. The leaves should be trimmed off up the stem about 2 inches, and that part must be inserted into the ground. The cuttings should be 3 to 4 inches long, and must be inserted as soon as made, and a large percentage then root.

Holly cuttings are generally inserted after all the Conifer cuttings have been finished. Glazed handlights or boxes are prepared in the same way as those described for Conifers. Some use good-sized low frames for Hollies, but I consider the boxes are the best, as they fit close down upon the soil and can be kept closer than a frame. Success can be achieved either way. When the cuttings are inserted it is not always wise to give a good soaking of water as recommended for Conifers placed in several weeks earlier, as the material may be moist enough. The autumn is often far advanced or winter approached by the time all these cuttings have been inserted. If water is supplied the soil might be in a saturated state when severe weather sets in, and such a condition is neither desirable nor beneficial. The soil and cuttings often become thoroughly frozen during the winter; no apparent injury results, but it is advisable, in case of very severe weather, to cover the boxes with some protective material.

The spring and summer treatment is exactly the same as that described for Conifers, only the frames may be required to be kept over them for a little longer period of time. Some of the Silver and Golden kinds grow slowly at first, and may be late in making their growth, and in consequence require protection during the second winter. None is disturbed until the second year, when the green and stronger-growing kinds are planted out about 6 inches apart. The weak-growing kinds must remain until large and strong enough for planting. After the young plants are rooted they must not be allowed to become crowded before giving them more room.

The common Holly is used as a stock for the delicate and choice kinds of Golden and Silver varieties; in fact, many green kinds are also largely grafted. There can be no doubt that plants are

obtained quicker by means of grafting than by raising them from cuttings, and grafted Hollies grow well in after years. Grafted plants of *Ilex Hodginsii* I do not approve of, as I consider the plants grow better and faster when raised from cuttings than if worked upon the common variety.

The stocks for next season's grafting should be potted at once or during the spring. The young plants intended for stocks should not be too strong; if about the thickness of a good quill they are of a suitable size. Those with leaders and likely to make good plants need not be selected for stocks. Where quantities are grown plenty of second-rate plants of equal vigour will be found suitable. Stunted plants should be avoided, because they cannot be expected to thrive after they are grafted. The pots for the stocks should be 3 to 4 inches in diameter. One or two crooks at the bottom will be ample for drainage. Any ordinary soil with a little decayed manure mixed with it will be suitable, and must be pressed firmly into the pots. The lower portion of the stem should be trimmed clean for 3 or 4 ins. before plunging them outside. Their after treatment through the summer should be exactly the same as advised for the stocks employed for Conifers.

The operation of grafting (fig. 87) is generally performed as early as convenient after the Conifers are finished; simple splice grafting is, however, generally adopted. They succeed well in a shaded span-roofed house that can be kept close and the temperature

from falling below 50° in their early stages. The plants must be kept well supplied with water, and syringed at least twice daily, until they become united to the stock. I have seen plants afterwards wintered in cold frames, and finally placed outside towards the end of February or early in March. Circumstances sometimes compel this treatment, but it is not to be recommended. Hollies, as a rule, take well when properly grafted. The house in which they have been placed should if possible be devoted to them during the winter. After they have become thoroughly united fire heat need be employed only to exclude frost. They may be gradually hardened by February, to be placed in cold frames where they can be protected for a month or six weeks longer. The top portion of the stock can be taken off when removing them to the frame. The young plants should have a small upright stake to protect the graft from being broken before and when first planted out. When thoroughly hardened the plants can be arranged outside until a convenient time presents itself for them to be finally planted out.—W. BARDNEY.

#### AN APPLE ELECTION.

AS this has been an exceptionally good year for Apples, and brought many almost unknown sorts to the front, I shall be pleased to carry out another Apple election if your readers who are growers will forward me a list of the best twelve kitchen and twelve dessert kinds as a sequence for the season—Blenheim Pippin, when named, to be placed in the former. I shall publish the result in your paper early in February if possible.—LEWIS A. KILLICK, *Mount Pleasant, Langley, Maidstone.*

P.S.—Any notes on the varieties will be welcome.

[We shall be glad if growers will send lists, with such notes as they desire to append, to Mr. Killick at an early date, so as to enable us to publish the results before the close of the planting season.—ED.]

LEICESTER RED CELERY.—The best Celery I have ever grown is Harrison's Leicester Red (the seed from selected heads in original packets obtained through Messrs. Hurst & Son). It is very large and of remarkable solidity, the solid portion being quite 3 inches thick, crisp, and of a fine nutty flavour. Out of many rows planted

out direct from the seed bed on hot sandy land at various times—early and late—through the past summer and autumn, not a single plant has shown signs of running to seed. Better Celery it is impossible to have, and as the circumstances attending its position and growth this season were not especially favourable for the production of good Celery I shall not hesitate to adopt it as a first-rate market sort.—T. LAXTON, *Bedford.*

#### VIOLET PRINCESS OF PRUSSIA AND OTHERS.

IN reply to Mr. Beachey's observation at page 515—viz., that I may not have given Princess of Prussia Violet a "fair trial," I may state that I have it now in alternate rows with Victoria Regina in a frame some 60 feet long and 4 feet wide which contains five rows of plants—i.e., three of Victoria Regina and two of Princess of Prussia, and it was grown in a similar manner last season, my plants being kindly furnished by Mr. Lee in the spring of 1880.

All our Violets are grown under similar conditions—viz., suckers or young rooted runners are planted in spring in well-enriched soil, and in late summer or early autumn are transferred with good balls of roots to pits or frames. The "new comers" have the same fare as the older sorts, hoping thereby to arrive at a satisfactory estimate of the different varieties—some twenty double and eighteen single.

Princess of Prussia had with me this autumn flowers 1½ inch across, exactly the same size as Victoria Regina under the same conditions, and has not produced one-half so many flowers as Victoria Regina, and it was the same last season, hence no more special mention was made of it at page 408 (Nov. 3rd) than was warrantable. Princess of Prussia bears a striking resemblance to Victoria Regina, but is not so hardy nor so free either in growth or production of runners. It certainly is, as your engraving portrays, a fine Violet, but I must say that with me it has not answered Mr. Lee's description as the best Violet for autumn flowering, which was given when the plants were sent in 1880.

Prince Consort has bloomed freely this autumn, yet not so freely as Victoria Regina. Some of the blooms of Prince Consort were 1¾ inch across, with a footstalk 9 inches long; Victoria Regina 1½ inch, and footstalks 7 inches long. Princess of Prussia 1½ inch, and 6 inches in the stem. It is only by comparative experiments under similar circumstances, keenly observing and carefully recording the results, that a correct estimate of the different varieties can be obtained. I have the following varieties, and shall be glad of any other—

*Singles.*—Victoria Regina (Lee), Prince Consort (Lee), Princess of Prussia (Lee), Odoratissima (Lee), Argentæflora (Lee), White Czar, Albiflora, Odorata, O. alba, Obliqua striata, Rubra simplex, Russian (floribunda), Suavis (Russian true), Russian Superb (London), Rubra simplex, Devonensis (?), Crimean (?), Giant (?), Czar.

*Doubles.*—Neapolitans De Parme, New York, Marie Louise (?), Marguerite de Savoie, Venice, Princess Louise, and Duchess of Edinburgh. King of Violets, Russian or double purple, Belle de Chatenay, and its variety cærulea, La Reine, Blandiana, Parmænsis plena, Patrie, Queen of Violets, Rubra plena, Arborea plena (?), and Arborea alba plena (?).—G. ABBEY.

#### POTATOES IN RAISED BEDS.

POTATOES have been so excellent in quality and quantity this year that it would appear on first thoughts useless to give advice to amateur and young growers, much more useless to give our results of the past season's planting; and yet on second thoughts—and second thoughts are often the best—I send to the Journal my experiences, and for this reason—viz., I prepared and planted my beds in anticipation of a possible bad season—i.e., a wet spring and summer.

Nothing, I suppose, is worse for the Potato than ill-drained heavy soil and a sunless aspect. In this belief I planted all my Potatoes this year as follows. A series of beds about 75 feet long by 6 feet wide were thrown up at an angle of about from 20° to 25°. The aspect was south, thus I obtained the maximum amount of sun heat and a natural as well as sufficient drainage. Six beds were thus formed, paths about 15 inches wide intervening. I planted as follows—1, Porter's Excelsior, the premier position nearest the wall; 2, Beauty of Hebron; 3, Snowflake; 4, International Kidney; 5, Magnum Bonum; 6, Rivers' Royal Ashleaf.

Owing, perhaps, to having been planted ten days earlier than the Ashleaf, and profiting also by the close proximity to the south wall, Porter's Excelsior was the first to be ripe. Then followed Rivers' Ashleaf, Beauty of Hebron, Snowflake, International Kidney, and Magnum Bonum in the order named. I had not a single diseased

Fig. 87.

tuber. The quality was excellent. For six varieties at a large show, and where the competition was good, I was easily first, and the show was on the 21st of July. The Magnum Bonums grew after this date of course, but the other five varieties were quite ripe. The varieties I exhibited were the above named, and every tuber came from these beds.

My friends who came to see me in May and early June said, "Ah! this system of yours is all very good in a wet season, but when you have a season like the present, no rain for weeks, it is absurd. Your Potatoes will be no bigger than marbles!" Now my argument is this: If with southerly sloping borders I get a good crop of excellent quality, of fair size, and perfect form, and this in a marvellously dry season, *à fortiori* in a wet season, the results would be still better. In the same field, and immediately following upon No. 6 bed (Magnum Bonum), I continued Magnum Bonums on the level, followed by Schoolmaster, Lapstone Kidney, and Porter's Excelsior, all on the level, and the results were not equal to the former mentioned.

The manure, Hill's first quality Potato manure, was equally distributed, no favour shown. The soil, a light very fibrous loam, pasture land double-dug two years before, so that the soil was good enough and of the proper texture. Very little ground is wasted by throwing up the beds, and but little extra labour required. I am firmly convinced that very many gardeners have yet to learn what very powerful factors in successful Potato-growing are sun light, sun heat, and good and rapid drainage.—J. A. W., Alderminster.

### PEARS

I SEND the following notes respecting our Pears this year. We commenced gathering fruit of Citron des Carmes in August from trees on a south wall. The crop was good and the quality all that could be desired; from espaliers many of them were very much cracked. Doyenné d'Été against a wall with a west aspect had a fine crop, and the fruit of good size and quality. Green Chisel, only fit for preserving whole, a fine crop from pyramids. Jargonelle against a south aspect, moderate crop, fruit fine and of fair quality; from standards and pyramids the fruit was of better quality. Flemish Beauty on a south aspect had a moderate crop of fine fruit of first-rate quality. This fine Pear requires care to have it in good condition. Of pyramids Hesse had fine crops of good quality; it is a useful October Pear. Urbaniste against a wall with a south aspect bore a splendid crop of the finest quality. Louise Bonne of Jersey on an east aspect had a splendid crop of fine fruit and of the very best quality; many fruit on pyramids of this kind were deformed, cracked, and of little use.

Pyramids of White Doyenné only had a moderate crop, but of good size and quality. Duchesse d'Angoulême on a west aspect had a small crop, the fruit large but poor in quality, and only fit for stewing. Marie Louise produced a magnificent crop, all that could be desired in size and quality. From pyramids against a south wall, and espaliers from a wall with east aspect, they have not kept so well as usual, some of them decaying at the core. Vicar of Winkfield on a wall, west aspect, had one of the finest crops I ever saw, the fruits of great size, but not one of them has been useable, for all have been affected by a kind of dry rot, which is a great disappointment. Beurré Sterckmans against an east aspect had a poor crop, not ripening well. Wall trees and pyramids were alike useless. Pyramids of Beurré d'Arenberg had a bad crop and almost useless. The fruits of Knight's Monarch have reached a good size, but instead of ripening have withered. Of Beurré Diel we had a fine crop from trees on an east aspect. We have not had them so fine for many years; from standards and pyramids they were quite worthless. Trees of Winter Nelis bore a grand crop against a wall with a south aspect. It is all that could be desired in every respect, and is worthy of general cultivation. Espaliers of Seckle had a scant crop, but of good size and of the very best quality. It is much esteemed for its musky flavour. Trees of Glou Morceau on a west aspect bore a fine crop, but the fruits have to ripen yet. Espaliers of Althorpe Crassane produced a fine crop of large Pears, but they seldom ripen with us. Easter Beurré had a moderate crop of fair size, but many cracked and useless. Catillac had a shy crop but large fruits from pyramids. Uvedale's St. Germain a fine crop, from half-standards, but not so large as we have had them.—PYRUS, North York.

PELARGONIUM CANDIDISSIMA PLENA.—Referring to the interesting account by "J. W." of a visit to Longleat, in the Journal for November 3rd. If Mr. Taylor has not tried candidissima plena as a double white Zonal Pelargonium I think it will be worth his while to do so. I had it from Mr. Pearson of Chilwell, and out of several double

whites which I have it was the only one which did not become tinted with pink with the summer sun. Amelie Baltet unless shaded was never pure white. I have not enough heat for winter flowers, so cannot say how it would do to depend on all the year round.—SAN JUAN.

### A ROCKERY FOR ALPINE PLANTS.

ALPINES FROM SEED.

(Continued from page 520.)

THOSE who think that the best way of raising rare plants from seed is to imitate natural conditions, must remember how very small a proportion of the seeds of each plant vegetate and come to maturity in their native soil. It is true, that if you could counteract all adverse influences all seeds would germinate more readily if sown as soon as ripe, but as in most cases they would have to remain in the soil from summer until the following spring, and would meanwhile have to contend against many enemies, it is found better in practice to store the seeds until the natural time for their germination arrives. Not but that many seeds will grow at once if sown as soon as they are ripe, but keeping young seedlings through winter is often so troublesome that it is generally avoided except where experience has proved it to be the best plan. On the other hand, the seeds of some plants germinate slowly and sparingly after being stored, and many often remain in the soil a whole year or more before showing signs of life. The question will be asked where to get seeds of alpine, and at present I know of only two persons who keep for sale good collections—Mr. W. Thompson of Ipswich, and Mr. Fröbel of Neumunster near Zurich. It requires an expert and a microscope to test the soundness of small seeds; but when seed fails it is more likely to be from the imperfection of some condition required for success than of the seed.

The hints I am about to give refer more especially to such alpine as are difficult to rear, but may be taken to apply to other choice plants which are delicate in their young state. The seed of all such plants should be raised in pans under glass, and the time of sowing should be early spring—say the middle of March. As a rule I avoid all artificial heat, but especially the heat caused by the fermentation of manure or any vegetable matter. I use the common seed pans about 12 inches square and 4 deep, perforated at the bottom, which should be covered with about an inch of large crocks for drainage. I then fill up with equal quantities of soil and limestone, or other hard stone, broken to sizes from that of a walnut to that of a wild nut. The soil is composed of equal quantities of coarse sand, loam, and peat finely riddled. I do not like leaf soil, as the flat pieces of leaf often obstruct the growth of the seeds. The greatest obstacle I have found to raising small seeds is the growth of fine lichen or moss on the surface of the soil, either before or after the seed has sprouted. The germs of this moss are either in the soil or in the water used, or both. We must do our best to obviate this difficulty. I have tried using burnt earth for a depth of a quarter of an inch on the surface with advantage; but more than this is desirable. It is a good plan when the pans are filled to dip them in boiling water, which will kill the obnoxious germs and seeds of weeds. They must be allowed to dry again before sowing the seed, for although I have seen that some recommend watering the soil before sowing, a dry seed bed is best. Small seed need not be covered with soil; something like a large paint brush passed gently over the surface will bury it sufficiently. We must now consider watering, which is a very important item. For the avoidance of the germs of moss use only water which has been boiled. A gallon will last a long time. The surface should be sprinkled often enough to prevent its ever becoming quite dry; a waterpot with a very fine rose or a fine garden syringe, not aimed at the seed pan, but directed upwards so that the water falls on the soil in fine spray, will be found the best. Some recommend never watering the surface at all, but dipping the pans into water to within an inch of the rim, so that they are watered from below. For the most delicate seeds I have seen a saucer used filled to within an inch of the rim with the finest soil, and a bellglass of less diameter fitted over it. In the angle between the rim of the saucer and of the bellglass wet sphagnum has been laid, which waters the seed sufficiently by the trickling drops from it. Exposure to heavy rain and full sun must be avoided, and slight shading given on bright days, especially when the seedlings are up. Sow thin: when seedlings touch one another they are too close, and if they are not large enough to transplant when they touch they will be damaged. Transplanting is an advantage, even if they are moved only to another part of the same pan merely for the sake of transplanting, as it improves the growth of the roots. Of course air must be given every day.

The after-treatment of alpine must depend upon the kind and

the rate of growth. Some must remain in the pans after transplanting till the second year; others may be transplanted for the first winter to store beds, constructed by raising the soil against a south wall a foot above the ground level, and surrounding it and mixing it with stones. These miniature rockeries make very good nurseries. One word about the time which we must allow before we despair of the seed. If it is choice I keep the pan, sown in March, until April of the following year, and am sometimes rewarded for my patience; but as a general rule the longer it is before seed grows the less likely it is to grow at all. Seed is often condemned as bad when a careful inspection will show that it has germinated and has been eaten by slugs in its earliest growth. The pans should never stand loose in the frame, but be buried to the rim in sifted coal ashes, and the space between the pans, as

well as the inner sides of the frame, may be covered with fine quicklime. If the frame is in a part of the kitchen garden where slugs abound the outside also may be dressed with train oil and soot, for if slugs once get amongst alpine seedlings no pest is more pernicious. Worms inside the pans are nearly as bad, and the depth of the coal ashes must be sufficient to prevent these vermin from rising into the pan through the holes at the bottom.

If anyone has not sufficient frame room for his seed pans pots may be used; a space of 2 inches left between the top of the soil and the upper rim of the pot, and a piece of glass laid flat over the pot. These pots may be buried to the rim in soil, which will prevent them getting too dry; but they must stand upon pieces of slate or tile to prevent the entrance of worms from below. Slugs must be carefully guarded against; and though it must be

Fig. 88.—BEURRÉ D'ANJOU PEAR.

remembered that most alpine seedlings cannot have too much light when growing, they must be shaded from burning sun. Buttermilk mixed with a little lime is useful to smear over the glass for this purpose, but slope the glass off the pot towards the sun, so as to give as much air as possible.—C. WOLLEY DOD.

#### PEAR BEURRÉ D'ANJOU.

NUMEROUS as have been the communications that have been lately published on Pears this variety has had little, if any, attention. Is this the result of its having proved unsatisfactory, or is it because it is not in general cultivation? The fruit now figured was sent to us by one of the most experienced

and successful growers of fruit in this country, and he has a high opinion of Beurré d'Anjou, both because the tree is a good grower and bearer, and the fruit is of superior quality. The specimens submitted to us answered precisely to the description of this Pear in the "Fruit Manual"—namely, "Fruit large and handsome, even and regular in its outline, roundish obovate. Skin greenish yellow, with sometimes a shade of dull red next the sun, marked with patches of russet, and thickly strewed with brown and crimson dots. Eye small and open, deeply inserted in a wide cavity. Stalk short and stout, set in a round hole. Flesh white, very tender, buttery, and melting, very juicy, vinous, and with a delicate rose-water perfume. A very superior Pear; ripe in the end of October, and continues in use till December and

January. This is quite distinct from the *Ne Plus Meuris* of Van Mons."

#### BLUE ROMAN HYACINTH.

SOME months ago I referred to the above Hyacinth as badly adapted for forcing and worthless as a decorative plant. Messrs. Jones & Sons, Shrewsbury, then wrote against my statement and in favour of the plant. After further experience I can now say it cannot be forced nearly so readily as the white Roman, and when potted at the same time and treated exactly the same is several weeks longer before it flowers. I did think it could not be had before Christmas, but must admit I was wrong on this point, for I have plants just opening their flowers. In my former note I said, if I remember rightly, it might be useful for cutting purposes. I am willing to give it that credit now, but as a decorative plant it is useless. You will be able to judge of its merits from the sample I send by this post. They have had the same treatment as white Romans, which are dwarf, compact, and beautiful. I asked your other correspondents to state in these pages about Christmas when they had a good batch in bloom and I would pay them a visit, but I do not now consider the blue Roman worth a short journey to see. Would Messrs. Jones do as I have done—send you flowering plants of this Hyacinth?—

CULTIVATOR OF BULBS.

[The plants received had been shaken from the soil, and their drawn condition confirms our correspondent's estimate of them; the flowers might be useful when cut, but the plants sent are worthless as decorative objects. The leaves are exactly 15 inches long, and the longest spike has seven flowers.—ED.]

#### THEORIES IN VINE CULTURE.

MY name, or rather my *nom de plume*, has been used with much frequency by those who have taken part in the discussion now going on under the above heading in the pages of the Journal; and as much of what I said when writing before on the subject has been misconstrued, much misunderstood, and not a little misrepresented, perhaps you will allow me space to answer some of my critics, to explain what I at first meant, to give my reasons for the opinions I hold, my reasons for holding them, and my practice and its results; for I think that only thus shall we ever be able to perceive each other's meaning clearly, and only thus enable the body of your readers who are interested to understand and to judge which of the opposite systems so keenly advocated by the different sides is best, and which safest to adopt or reject. Perhaps this method, if followed properly, will also enable us to discuss the real question at issue and to avoid the large number of side, or even irrelevant, questions which have been introduced into the discussion as it has progressed, more especially by Mr. Taylor.

First, then, let me "defend a system I am practising" by noticing a few of the points which have been made prominent in the discussion. The first thing I object to is the constant reiteration of such phrases as the following—"A few leathery leaves are preferable to a greater quantity of thin papery foliage;" "foliage which is thin and which cannot be acted on by the light is not only useless," and so on. The only meaning such sentences can have is that one side advocates poor, thin, overcrowded foliage, and the other the opposite. I presume Mr. Bardney can appreciate the advantages of sturdy foliage thinly enough placed to allow of sun and air acting their part; and as for your humble servant, he has often pointed out the necessity for such conditions. That, then, is not the question, for such has never been disputed; neither is the amount of restriction to which Vines ought to be subjected after the structures in which they are grown are filled. Mr. Iggulden's latest on this point, and also what Mr. Taylor says I can agree with at once, and practise similarly so far as is possible under my present circumstances; and as Mr. Bardney has been all along labouring to show the benefit of such a system, with certain but not very important modifications perhaps, I presume he also will agree that neither is that the question.

The question now is whether Vines in the first few years of their existence are benefited by being allowed to make as much growth as possible—that is, fill the house fairly with foliage, or by having that growth restricted to from 4 feet upwards, but never more than two-thirds of the rafter. Having had something to do with both systems, my experience is that the more restricted Vines are incapable of doing the same work as those treated to what one writer calls the "exhaustion system," but which I call the strengthening system. Ten years ago I planted two vineries the borders of which were composed of material brought fully ten miles, and your readers will understand that the expense of

that would scarcely be incurred for inferior material. The borders were mixed and made on orthodox principles, and the Vines planted and trained very much in the way Mr. Iggulden and others advocate. The results were good, but I now think a year or two was lost in filling the house. Four years ago we planted another vinery with Vines struck the same spring. The border was composed of poor material, two-thirds being turfy soil from macadamised roadsides, and the remaining third fibreless loam not quite of the best description. In this was mixed some lime rubbish, horse droppings, and bones, but in less quantity than in the more favoured borders of the other two. The Vines were not allowed to grow exactly "Bramble fashion," but the first year they went to the top of the house, when they were stopped. The laterals were allowed to grow till the house was fairly filled, and all further growth kept down. To fully ripen the growths firing had to be practised far into autumn. Most of the canes were remarkably stout when cut down just when they were about eleven months old, but one or two did only moderately. In planting them we used some decayed weeds and a little manure to give them a start, and round one or two of the Vines the soil produced a fungus which attacked and weakened them, hence their lagging. The permanent canes were cut down to about 18 inches from the soil. Those of your correspondents who have taken sides with Mr. Iggulden will say that I had then only 18 inches of stem left. In the case of the weakly Vines I had not much more, and in the case of the restricted supernumeraries certainly the stems were above ground; but in the case of the incomparably thicker permanent Vines I consider I had much underground stem, and I think Mr. Inglis might have thought what he was writing when he objected to my calling these by their right name. Mr. Inglis evidently prefers wrong names.

Next year the Vines had the same treatment. They were never touched till they were at the top of the house, and then they were stopped. The laterals were again allowed to develop, and were stopped exactly as if they had been fruit-bearing. As Mr. Iggulden says, many of the main stem leaves fell off in consequence of the rapid swelling of the canes after all the growths were stopped. The bark, too, split and tore from the same cause. The falling leaves gave us little concern, for we doubted not that those on the laterals would carry on the work instead, and we were not mistaken.

The difference between the restricted supernumeraries and the permanent rods was the second year very great, and in favour of the permanent Vines. The next year they were fruited, having been in winter cut down to 7 feet. Those who maintain that under such extension as this the lower buds are inferior, will, perhaps, be surprised to hear that the smallest bunch in the house was fully 2 lbs., and several were over 3 lbs., while seven bunches were taken from every cane save two, and one of these was one of those which suffered from the fungus attack. It was only allowed to carry two, and the other carried nine bunches, which, aggregately, weighed 19½ lbs. Two of these bunches were awarded the second prize at one of the largest shows in the kingdom. This was against seventeen competitors. I only mention this as proof that the Grapes were well finished. Such crops I never saw taken from "restricted" canes of the same age. But perhaps your correspondents on the other side will say that the above is not particularly great. I do not say it is, and with my choice of materials for border-making I should not fear to surpass it greatly. Perhaps they will say that the question is, Which system will produce greatest permanent fertility? I am not forgetting.

The next year, in pruning, 6 feet more of rod was left, which was rather too much, for the lower buds on the upper 6 feet did not break so strongly as was desirable; on these no fruit was left, but bunches were left on all the other spurs. I ought to say that the Vines are only 3 feet apart, so, as to give them proper span, the rods are lowered and the laterals trained upwards, and the spurs are thinner than usual. That year the rods carried eleven bunches on an average—fully equal to the first year's. This year the weakest Vines carried thirteen bunches, which weighed together 27¾ lbs., and the strongest seventeen bunches, which weighed 46¼ lbs. Some of the bunches were over 6 lbs. on some of the other, but the aggregate weight I cannot give. The whole was not weighed.

Every year the house has been as full of foliage as if the Vines had been twenty years old, and to this chiefly we attribute the power of the Vines being sufficient to carry such crops. I consider that this year I had a full crop, and cannot hope that the weight will increase even with the increase of laterals, for this and last year the house was as full of leaves as could be fully acted on by sun and air, and I believe their working power was fully taxed.

There is one point in my practice which I have not referred to,

but to which I attach much importance, and which is seldom or never mentioned by cultivators. I have no doubt that the fruit appropriates the materials as fast as the leaves manufacture them. If not, then the crop is not a full one. I consider my Vines are exhausted, temporarily, by the time the fruit is ripe. While they are ripening I take care to feed them liberally on till the leaves turn yellow. As the fruit is rapidly used, I keep on firing after it is ripe and after it is cut on into autumn till they are no more fit to store future supplies. I feel certain that this enables the Vines to recoup their strength to the full. Further, I start them early enough in spring to allow of all this being done with the sunlight of August, September, and October.

So much for this house. And now for the two before mentioned. The only real difference resulting from the different system of treating young Vines is, that restricted Vines are just two years longer in arriving at the full bearing stage, and cannot in the meantime produce so much without exhaustion. In the one case it only takes three, in the other five. Mr. Iggulden grows and ripens a certain amount of growth the first year. I grow and ripen twice as much, taking into account the thicker canes and longer laterals. Mr. Iggulden will certainly do it in less time; but I consider it more economical to keep fire on a few weeks longer, for in the end time is saved. Mr. Iggulden thinks he takes less out of his borders. This is only looking at the surface. In the longer time taken to fill the house quite as much will be cut away before the house is filled as in the other. The one system needs more taking out the first year, but I consider that is hardly worth considering. More, it is no great task to put into the borders exactly what is taken out, for that is easily ascertained. The idea that any great amount of the Vine's food comes out of even the best border is, I think, a mistake. I will endeavour to reply to Mr. Taylor and another correspondent in a future issue.—SINGLE-HANDED.

THERE is one point belonging to this subject which has puzzled me many times, but which "SINGLE-HANDED" in scientific way disposes of very summarily. He says at page 420, "Mr. Iggulden thinks, at least he says, that great masses of roots are useless in spring because they do not move when the buds move. No, they do not, and neither do they when the roots are few. And why should they? What would it benefit a Vine before it has its leaves mature enough to elaborate sap, to be filled with watery crude sap fresh from the roots? Until Vines have made leaves working roots are not wanted; they must both work together." "SINGLE-HANDED" has written so much that is sound and good that we have come to look on him as a scientific authority of late, and treat anything he might say as almost beyond question: that is my excuse for again reverting to the subject.

In the first place let me assure your correspondent that leaves and roots do not always work together in the case of the Vine, but that during one part of the season the leaves are active by themselves, and at another time the roots only are active. This happens, too, with all deciduous plants with which I am acquainted, but as far as I know the Vine is unique in its habit of growing full-sized leaves before root-action commences. The last-mentioned part of the subject is now generally known and acknowledged, but the other part to which I have alluded appears not to be so well known, at any rate it is not known to "SINGLE-HANDED." It is this: that the roots of a healthy Vine continue active long after the leaves have fallen. I am not now speaking of cases where the leaves fall prematurely from bad treatment, as happily I have had no experience with such Vines of late years, but after the leaves have naturally assumed their autumn colours and fallen one by one the roots will be found to be in an active condition, probably more so than at any time of the year. This lasts for several weeks; indeed it often happens that when Vines in pots which have been treated in a common-sense sort of way are placed in warmth for forcing, that the roots are still active and remain so till just before the buds start, when they go to sleep, some of them probably for ever, and a new start is made after some of the leaves are full grown. The leaves themselves are the indicators of the time when this happens, for the bluish colouring matter may be seen in patches before it has mingled with the yellowish material already in the leaves to form the bright green. So you see the question "What would it benefit a Vine before it has leaves mature enough to elaborate sap to be filled with watery crude sap fresh from the border?" does not carry in itself its own answer, as "SINGLE-HANDED" seems to have supposed it would.

That there is circulation and elaboration without foliage I have had ample proof. I can mention the case of a Peach tree which one season was overdosed with an insect-killing compound and lost its leaves before the fruit had fairly stoned, yet this same

tree swelled its fruit buds and carried an excellent crop the following year; and we all know, or ought to know, that the roots of Plum stocks under favourable conditions commence action by Christmas time, and, of course, they cannot be active without supplying the plant with something. Your correspondent's reasoning on this head is a remnant of the old resting-and-drying theory, which has hindered the progress of horticulture for ages, and which I had fondly hoped was all but exploded.

Another remnant of it is elinging to "SINGLE-HANDED" when he says, "The idea that Vines when extending their shoots in spring need support, leads many to supply liquid manure to their borders when neither leaves nor roots are at work." Allow me to inform your correspondent that winter, after the cuts from pruning have healed, is a very good time to apply liquid manure to an inside border, and that it may be used stronger than is safe at any other time.

A Vine border should never be allowed to become dry, especially in autumn or winter, and nobody ought to know better than your correspondent that the manure is not poured into the Vines as if you were pouring soup into the stomach of a sleeping man. It is applied to the border, which, if well made, has the power of getting rid of surplus water and retaining the solids for future use.—WM. TAYLOR.

#### THE CLASSIFICATION OF CHRYSANTHEMUMS.

I QUITE agree with Mr. Moorman in his able and interesting remarks upon the Chrysanthemum (page 365) that a new classification of the Japanese varieties is necessary, but I would class them in three divisions as follows—Ribbon varieties, Twisted varieties, and Thread varieties.

The first or Ribbon varieties would comprise those of which the florets are reflexed and droop below the calyx—namely, *Meg Merrilees*, *Baronne de Prailly*, *Fulgore*, *Gloire de Toulouse*, *Triomphe du Nord*, *Fulton*, *Elaine*, *Madame C. Audiguier*, *Arlequin*, *Rosa Bonheur*, *Triomphe du Chatelet*, and others. The second or Twisted varieties would include *Yellow Dragon*, *Grandiflora*, *Hero of Magdala*, *James Salter*, *Chang*, &c. Thirdly, the Thread varieties would be such as *Cossack*, *Gold Thread*, and *Madame Godelet*. Then we have many of our best varieties with their florets erect or partly so—namely, *Sarnia*, *Ethel*, *Fair Maid of Guernsey*, *Peter the Great*, *Daimio*, *Madame Lemoine*, *Jane Salter*, *Soliel Levant*, *Erecta Superba*, *Oracle*, *Diamond*, *M. Maney*, *La Nuit*, *Bouquet Nationale*, and others. The beauty of the Japanese consists in their great diversity of colour and form, and these characteristics are making them worthy rivals of the incurved varieties. There are two varieties of Japanese, or rather now classed as such, which might with advantage be added to the large Anemone-flowered—namely, *Duchess of Edinburgh*, and a variety I bought under the name of *Minnie Chate*. The former has pure white guard florets with a pretty mauve centre, the latter has lilac guard florets with lilac centre.—W. ETHERINGTON, *Swancombe, Kent*.

WE are informed by Mr. T. Jackson, the Honorary Secretary of the KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY, that the Exhibition for 1882 has been arranged to be held on November the 16th and 17th. The Society has also voted £30 of the balance of this year's funds towards a second challenge cup, to be competed for on similar conditions to their first, which is now limited to three competitors. The first challenge cup was contributed by the President and Vice-Presidents, and we think the executive have made a very wise provision for their future prosperity by offering a second cup.

— LIEUT.-COL. HILL writes to us as follows—"A gardener here tells me that he gathered ripe fruit of EARLY ASCOT PEACH six or seven years ago on a garden wall the first week in June. Poor Early Beatrice is nowhere. I should like to hear through the Journal if anyone else has done such a thing. He also tells me that a Weymouth gardener did the same. I intend seeing him

on the subject. The tree was on a south wall in a village in Dorset."

— WE have on several occasions referred to the new dwarf *TROPÆOLUM EMPRESS OF INDIA*, and a coloured plate sent us by Messrs. J. Carter & Co. represents a plant of this variety in very good condition. The compact habit of the variety, the dark-coloured foliage and the richly coloured flowers, are very fairly portrayed; and if the flowers are as well borne above the foliage the variety is unquestionably a valuable one, and will soon be a favourite for bedding purposes.

— WE are informed that, in accordance with the wishes of the late Mr. JOAD of Oakfield, Wimbledon, his herbarium and a large portion of the fine collection of hardy and cool house plants grown in the garden and houses there, are to be presented to the Royal Gardens, Kew. These additions to the national collections will undoubtedly be highly valued.

— THE locusts are committing such ravages in the ISLAND OF CYPRUS that a plan for the extirpation has recently been sanctioned by Lord Kimberley, which it is estimated will cost £23,000.

— CONSIDERABLE success, we are informed, has attended the experiments of M. Thiollière de l'Isle at Tain, in France, to check the RAVAGES OF *PHYLLOXERA* by planting his Vines in a soil specially prepared with sulphide of carbon.

— THE annual dinner of the BIRMINGHAM CHRYSANTHEMUM SOCIETY was held on the 14th inst., after which a combined business and sociable meeting took place. Several special prizes were liberally offered by gentlemen present, the highly satisfactory balance of £30 being announced as the result the past year. Great interest continues to be manifested in the progress of the Society.

— CASSELL'S ILLUSTRATED ALMANACK FOR 1882 is quite up to its usual high standard, being most profusely illustrated, and containing a great variety of useful and interesting matter.

— THE lessees of the Alexandra Palace announce a CHRISTMAS SHOW OF FRUITS, PLANTS, AND FLOWERS, to be held from December 24th to January 7th. Liberal prizes are offered in twelve classes, varying in value from £5 to 10s. In addition to classes for Grapes, Apples, Pears, and a general collection of fruits, provision is made for hardy berried plants, hardy ornamental shrubs, Rhododendrons in flower, Everlasting Flowers, Limes, Lemons, Citrons, Oranges, &c. For the year 1882 a liberal programme is announced, comprising a permanent exhibition of appliances used in horticulture, with numerous special and monthly exhibitions devoted to Hyacinths, hardy Azaleas, Clematises, pot Roses, Rhododendrons, Gladioli, Gourds, and Fruits. Particulars will be supplied by the Horticultural Director, Mr. J. Forsyth Johnson.

— MR. EDWARD LUCKHURST writes—"We have pleasant evidence of the genial influence of the MILD WINTER in the catkins of *Garrya elliptica*, which are now in full beauty and are very fine. It is planted here in the shrubbery borders and also among the climbing plants upon the house, answering well in both places; but the catkins are not freely produced till the plants have become well established in the soil and growing into large slightly specimens. *Lonicera odoratissima* is giving us plenty of its pretty little sweet-scented flowers, and the curious blossom of *Chimonanthus fragrans* is opening in unusual abundance, and is highly valued, a handful or two put in saucers filling a room of considerable size with rich perfume. Russian Violets, too, are almost as plentiful out of doors as under glass. Globe Artichokes in December are so great a rarity as to be worthy of notice. The remarkable mildness of the weather has caused several plants to put

forth flower stems—not mere abortive growth, but stout vigorous stems worthy of the finest summer weather, crowned, too, with such fine 'globes,' that I was able to cut a dish for table to-day (December 17th). Nor is this a solitary instance, for I have just been told of a similar case in the garden of J. W. Larking, Esq., at Lee."

— A CORRESPONDENT in the south of Perthshire sends the following respecting *TROPÆOLUM SPECIOSUM*—"So far from any difficulty being experienced in inducing this climber to grow here, it thrives so luxuriantly that precaution would rather appear necessary to prevent its becoming a nuisance. If planted near a cottage it soon bears a profusion of beautiful flowers, and it would seem advisable to confine the roots in boxes or by insertion of stones or slates to prevent detriment to other plants near it. This autumn I saw a case in point. It had been employed with other climbers to cover the retaining wall of an extensive terrace. It had not only fulfilled its purpose, but the Roses and other contiguous plants were being enveloped in its masses. Beautiful as it is, no one could wish it to become master of the situation to such an extent. Another graceful and beautiful flower, *Dielytra spectabilis*, grows rampant in the same locality."

— A CORRESPONDENT informs us that "Mr. G. Harris, gardener to H. W. Tugwell, Esq., Crowe Hall, Bath, and previously foreman at Syon House, has been appointed successor to the late Mr. A. Ingram as gardener to the Duke of Northumberland at Alnwick Castle. Judging by the satisfaction Mr. Harris has given in his previous positions, and the energy he has displayed in his profession, he is likely to well maintain the credit of the establishment now under his management." Messrs. J. Veitch & Sons, Chelsea, inform us that Mr. E. George Yeatman has been appointed gardener to Mrs. Miles, West End House, West End, Kilburn, N.W.

— SEVERAL good examples of that beautiful bulbous plant *FREESIA REFRACTA ALBA* are now flowering in an intermediate house at Orsett Hall, Essex. Six or eight bulbs are grown in a 32-size pot, moderately light turfy loam being employed as soil with plenty of drainage, as water is required rather freely during the growth of the plants. One specimen has a dozen scapes of white deliciously fragrant flowers, some quite expanded and others fast advancing. Mr. R. Castle, the gardener, finds that a moderate degree of heat suits the plant better than a cool house, and a light position is very important to obtain it in the best condition. The flowers are particularly valuable for cutting owing to their pleasant fragrance, which is somewhat suggestive of a Primrose perfume. This *Freesia* undoubtedly deserves to be better known than is the case at present. The woodcut on page 171 of the last volume of this Journal well represents the scape and flowers.

— FRAGRANT flowers are general favourites, and any improvement upon those we already possess must be welcome to all. This Mr. H. Cannell has unquestionably provided in the new *HELIOTROPE WHITE LADY*, which was shown in excellent condition at Kensington last week and awarded a first-class certificate. The chief characteristics distinguishing it from other varieties of the well-known plant are the great size of the corymbs, the large individual flowers which are quite white, and the fragrance is powerful even for *Heliotrope*. The habit, too, is compact, and the plant appears to be sturdy and floriferous in no mean degree.

— AMONGST the abundance of seasonable fruits in Covent Garden Market at the present time some examples of the *APPLE-FRUITED GRANADILLA*, or *SWEET CALABASH*, are especially notable. They are the fruits of *Passiflora maliformis*, a native of the West Indies, and are very distinct in form from the

common *Granadilla* (*Passiflora quadrangularis*), approaching *P. edulis* in form, but differing considerably in colour. They are indeed suggestive of the fruits of the Egg Plant, being ovate in form, pointed at the apex, 2 or 3 inches in its longer diameter, and when ripe is of a dull dark yellow colour. The rind of the fruit is comparatively thick and hard, but the internal substance is a yellow gelatinous pulp possessing a rather agreeable flavour.

— A DAILY paper remarks that "the birds are becoming bewildered by the mildness of the season. A gardener at Hampton in Arden discovered a day or two ago a sparrow sitting upon four eggs in her nest."

— A CORRESPONDENT sends the following note respecting FERN DENE, GATESHEAD, the seat of Alderman Newall—"In the numerous glass structures, which are under the superintendence of Mr. Milner, the following Orchids are blooming well—*Sophronites grandiflora*, eighteen blooms; *Cælogyne cristata*, sixteen spikes; and *Dendrobium Wardleanum*, ten spikes. The extensive collection of Pitcher Plants were also throwing up well. The grand corridor, 60 feet long, was extremely gay with *Chrysanthemums*, the plants and flowers being remarkably fine."

— A NORTHERN correspondent observes that "CHRYSANTHEMUM SHOWS IN THE NORTH OF ENGLAND have never been customary, although horticulture in all its branches is so well represented at the spring and summer exhibitions. The Newcastle Society, however, inaugurated a Show at Low Fell, Gateshead, last week, and although the prizes were not large several good collections of cut blooms were staged. The flowers were, however, unnamed, a defect which will no doubt be remedied another year, and the Exhibition is confidently expected to improve."

— NOTWITHSTANDING the great size it attains, and its somewhat straggling habit, DAHLIA IMPERIALIS is aptly named, and might advantageously receive more attention than is at present generally accorded it. The flowers shown by Mr. Wheble of Bulmersh Court, at South Kensington last week, well indicated what fine results can be obtained with a little care. The plants from which these were gathered were said to be about over 8 feet in height, and were growing in a Peach house where they had produced their blooms in the greatest profusion. At Kew and some other establishments plants may also be seen in good condition, but as a rule the culture of this handsome Dahlia is greatly neglected. Certainly it is chiefly adapted for a large house, as then only can its beauty be seen to the best advantage, but for a conservatory its value cannot be over-estimated.

— THE schedule of the BIRMINGHAM SPRING SHOW SOCIETY announces that the Exhibition for 1882 will be held in the Town Hall on Wednesday and Thursday, April 19th and 20th. Prizes are offered in sixty-two classes, especial encouragement being given to exhibitors of Hyacinths, Tulips, Lilies of the Valley, *Spiræas*, *Diclytras*, *Deutzias*, *Azaleas*, *Cinerarias*, *Primulas*, *Cyclamens*, and other spring-flowering plants. Special prizes are also offered by Messrs. J. B. Thomson, Hans Niemand, Bank & Hughes, Morley, Tonks, Jenkins, Spinks, and Redfern. Every provision has been made to ensure a good show, and it is to be hoped that the financial results will be more satisfactory than last year.

— A COMMITTEE has been formed with the object of providing prizes for a GRAND NATIONAL DAHLIA SHOW to be held at the Crystal Palace, Sydenham, in September, 1882, and to this end the following prospectus has been issued—"Though the Dahlia is acknowledged to be the queen of autumn flowers, no

great show, such as were accustomed to see in former days, has taken place for several years, and as a consequence the warm-hearted zeal which used to be generally manifested in regard to the cultivation of this flower has in great measure died out. In order to revive this flagging interest it has appeared desirable to several of the admirers and growers of the Dahlia that a great exhibition open to the United Kingdom should be held in or near London next season (1882) in order to give the public an opportunity to see the many beautiful varieties of all classes which are now to be found in collections of Dahlias, whether cultivated for exhibition purposes or for garden decoration. The Directors of the Crystal Palace Company, it has been ascertained, will give a handsome sum in aid of the prize fund; but to enable the Committee to issue a really liberal schedule, such as will insure a truly great show, by inviting Dahlias of every class, and by holding out proper encouragement to all growers, both those with limited and those with extended opportunities, a considerable sum will have to be raised. The Committee therefore hope to have the hearty co-operation as well as the liberal support of all who are willing to aid them in their undertaking." Subscriptions have been promised by a number of the principal florists, and further contributions will be gladly received by Mr. George Smith, New Villa, Hedge Lane, Edmonton, the Hon. Secretary and Treasurer of the fund. If the Committee receive the generous support that may be confidently expected, no doubt a magnificent show will be produced.

#### AN AURICULA COLLOQUY.

THE scene is a certain grand exhibition in the north of England, at which were assembled from all parts of the kingdom those most interested in the various departments of horticulture. Here were the most famous Grape-growers, the best plantsmen, the ablest gardeners in the kingdom. There, too, were rosarians of renown, Dahlia growers who scoffed at the mania for single flowers which had recently been developed, the famous Gladioli grower of the south meeting formidable competitors in the north; and amidst all these various interests there was a little knot of lovers of the Auricula who, shut out of the battlefield by reason of the time of year, could only talk over the past and conjecture about the future. To this came he of the merry eye and ruddy cheek which did not belie the genial warmth within, whom I will designate as Hibernius. There, too, was the Jupiter, the Hercules, the Titan of Auricula growers, who, hailing from the Yorkshire wolds, we must call Eborensis. There, too, was he of the murky town, who has shown that no disadvantages can outweigh perseverance and determination to succeed: we must call him Cultrarius. There, too, was the knight of the rueful countenance, who, albeit he hailed from the sunny south, looked as if a whole colony of woolly aphids had settled on his face: him we must call Cantus. While from a county close by to where we met was one who had lately joined the brotherhood; and although his hair was grey, yet did Castriensis show all the zeal of a neophyte. The conversations are no imaginary ones like Landor's; but, although I cannot give the *ipsissima verba*, yet the sentiments were expressed pretty much as I have given them. A wide field was ranged over. Exhibitions, modes of culture, value of varieties were discussed, and with that degree of zeal which profane outsiders call "crackiness."

CAST.—Well, I think now I have at last completed my collection, and believe I have got nearly every variety worth having.

HIB.—Have you George Lightbody and Prince of Greens?

CAST.—Yes, all of the good sorts, and many of them in quantity; in fact I am going in for them. I don't see why these better sorts should be so dear as they are, and I mean to try if I cannot cheapen the market. I am going to grow them all in frames ["bravo!" from Hibernius]. I don't believe in these heated pits or houses for a plant like the Auricula, I am sure you must injure the constitution of the plant; and if I am told that I must do it if I want to exhibit in the south, then I say Bother the south; the north is good enough for me.

EBOR.—Well, we must all be glad to welcome a new claimant, and one who is evidently determined to succeed. I am inclined to think that he is right, too, about forcing Auriculas ["Hip, hip, hurrah!" from Hibernius]. I shall never again subject mine to the heat that they have had. I have, in order to get them in for the London shows, given them as much as 55°, but I shall never

give them more than 45° [at this Hibernius shook his head]. Why, there is our old friend Cultrarius had three hundred blooming plants last season, and he forced them so that he could only find thirty fit for showing, all the rest were sacrificed to this; in fact, I have written to say that it is very improbable that I shall exhibit in London again unless the date is altered, for we can hardly ever have our Auriculas in time for their show unless we force them, and that I do not intend to do again.

HIB.—I am delighted to hear that some of these new ideas about forcing, and pits, &c., are condemned on such high authority. I have always looked on Manchester as the capital of florists' flowers, and its dicta are always to be regarded with respect. I stand in very much doubt as to influence of London on the true taste for florists' flowers. When one sees size and number of pips looked upon with favour, and refinement a secondary matter, I cannot but fear; for an Auricula without refinement is like a fair woman without modesty. You see I am a bachelor, and am therefore allowed to express myself thus. But what says my friend of the rueful countenance—my poor woolly-aphis-consumed hero?

CANT.—Aha! rueful countenance by no means. I need to be especially jolly when I hear these sages of the Auricula world thus expressing themselves. What amount of scorn have I not been subjected to because I have advocated these very things; because I have said that to force Auriculas was a heresy that no real lover of the flower would for long tolerate; that it was impossible to fix a date for a show that would combine north and south; that the southern taste was not a good one; that it went in for "wallops" and "chaney's" rather than for purity and refinement; that it gave a first-class certificate to that jaunty impostor Col. Champneys, who has not one good quality of an Auricula about him; and now to have all this confirmed by such high authority may well shake off all my ruefulness. I have heard nothing said about my own particular *bête* (not *noir*, but) *blanc*, woolly aphis, nor has anything been advanced as to the value of varieties.

EBOR.—As to woolly aphis, I don't mind it a bit; we all have it. There's old Cultrarius's plants are white with it. Eh! old friend, is it not so? [Yes.] And I fancy when Cantius thought his plants were killed by it that there must have been something else the matter. As to varieties, well, I am now raising such seedlings as I think will make me independent of named sorts, specially amongst green edges.

HIB.—I think I may say I have not got woolly aphis; but I hardly think a beast like that can be anything but injurious. It must live upon something, and if it extract the juices from the roots they must suffer. I am glad to hear about Ebor's seedlings. We do want some good green edges, as we have not one first-rate one. Col. Taylor is angular, Prince of Greens has a watery eye, Imperator is long in the legs and rarely first-rate, and so we might go on. If we could only get a George Lightbody green instead of grey! That would be something.

CULT.—Well, Ebor and I have had many a talk together about our seedlings. We talk and talk, we examine carefully, and I do think that between us we shall have something good to show by-and-by. I hear a friend who is raising seedlings has lost some very promising green edges.

CAST.—I don't pity him. If a man grows Auriculas in glazed pots he deserves it.

CANT.—Come, friend, that won't do. I have seen that collection, and I have no hesitation in saying that it is impossible to see a finer, more healthy one, than it is; and, to speak truth, these seedlings were not in pots, so that could not be the case. This conversation has been a very pleasant one, and before I go I should like to lift up my hands against the system that prevails in the south of putting stakes to the blooms. It is like using bearing reins. If a horse pokes his head people use them; but when they take it off down goes his head again. Now these poor things have been so forced and coddled that they can't do without them; take them away and the bloom falls down on the pot. So I say, Away with them. Let us have the rule of the older and better florists, that the stem should be stout and well able to support the trusses. "Hurrah!" "Yes!" "Certainly!" from all, in the midst of which the party broke up and the colloquy came to an end.—D., Deal.

LEEK.—At page 533 the following occurs—"To prepare a large number of plants in order to secure extra fine crops, we advise those who are anxious to excel to make a mild hotbed and cover it with a glazed frame about the middle of April." April should have been February, as no doubt attentive readers would understand; but

others might make a mistake, being misled, and we therefore hasten to make this correction.—A. H. H.

### TROPÆOLUM SPECIOSUM.

I OBSERVE much writing in connection with this plant, so very common in some parts of my country, and, although I make no pretensions to a knowledge of horticulture, I beg to offer you some of my observations regarding it. Some twenty years ago I first saw this plant (not in flower), in a small pot in the hands of a gardener, who explained its beauty and rarity, and, of course, price; but not for five years after—some fifteen years ago—I saw it in all its beauty and luxuriance. At that time I took a four-days trip north, by Loch Tay and Loch Earn. Having arrived at Aberfeldy by rail I spent a morning among the grand and lovely "Birks o' Aberfeldy," then getting the forenoon coach started for Killin. This coach runs through Kenmore, a small village in which the principal entrance to Taymouth Castle is situated. It is an old-fashioned village, very small, and can be seen at one view. One side is crescent-shaped and the other angular, the houses all one storey high except the little inn. As we neared the village (the coach road runs through it), the place looked *en fête*. All the windows and doors were festooned with bright scarlet ribbons as we thought, the rustic doorway of the inn was in a blaze of scarlet colour. Still all was quiet, almost no one going about. What could all this be? No sooner did we draw up to the inn door for a change of horses than I jumped down and examined what I then saw to be a very beautiful creeper twined round every support it could get hold of. Neither landlord, waiter, nor anyone about could tell me the name of it, nor was there time to beg or steal a root. Well, steal! it was growing wild. As we drove off and looked back we concluded that no art however high could have decorated that or any other place as that simple plant had done.

Driving along the margin of Loch Tay we at length reached Killin, one of the loveliest spots on earth. This small village consists of an hotel and about half a dozen thatched cottages as well as three or four new villas. On nearing it the first thing that caught my eye was the north end of the hotel ablaze with the same plant. Some trouble had been taken here. A large number of strings had been fastened to the eave of the house, two storeys high, and then pinned in regular order to the ground, and around each string twined a plant about 10 feet high at that time. The flowers of course all turned to the light, looking northward (the strings being 6 or 8 inches from the wall), and in such profusion that the leaves could hardly be seen. I did not attempt to get a root here. Next morning in walking round I saw the same plant twined round some long rods in front of one of the new villas, and, observing a gentleman working in his garden, went in and asked him the name of plant, when he told me it was *Tropæolum speciosum*, quite common, he said, in this part of the country.

That forenoon I was taken to an old garden about a mile off, on the banks of Loch Tay, which had belonged to the late chief of the McNabs, and for many years was the property of that family. There I saw a Vine in one great house—such a Vine as I had never seen. An English gentleman who was with me said it surpassed in size the celebrated Vine at Hampton Court. Another thing I saw in this old garden which may interest your readers was a Gooseberry plant, a single stalk trained up the corner of an outhouse and running along under the eaves of several houses (used for potting, &c.) for at least 18 or 20 yards, and at each joint hung a large berry, putting me in mind of some of those Dutch fringes I have seen on bed curtains. I had never seen anything like it, and could not believe it was one plant till I had traced it from root to point of branch. On going round this garden we came upon a man toiling with fork and spade at the side of a wall digging out the *T. speciosum*. He said it was a "wretched weed," and he could not get rest for it. It had gone under the wall and had come up on the other side as well. He had half a wheelbarrow load of its roots on the gravel walk ready to be thrown out. Thus is this beautiful plant prized at Killin.

The same afternoon we drove down Wild Glen Ogle and arrived at the hotel at the head of Loch Earn. There I found the same plant growing in great profusion in the garden of the hotel and also trained up the sides of the house. The landlord kindly gave me a handful of roots. Leaving this comfortable house we reached St. Fillan's Hotel at the foot of Loch Earn, another of the lovely and grand spots on earth unfortunately little known to tourists, being off the beaten track of railways. There I found this beautiful plant growing close to some small thatched cottages, and just under the eaves of the houses; those plants were not only in full flower but also abundantly loaded with purple berries

quite ripe, a lot of which I secured as well as more roots. The seed of the berries though quite ripe did not grow with me, and, having no botanical box, the roots were all shrivelled when I reached Glasgow; still, one or two of them grew the following spring, but did not—could not—flower in such a sulphurous atmosphere. How some of our gardeners would rejoice to see those plants, as I have seen them, in all their luxuriance—not a tender thing in a pot or greenhouse, but by the roadside, where, if crushed by the foot or nearly dug up, will spring again with renewed vigour.

Now the sequel of my observations is: You need not care a fig

what sort of soil the plant is put in, and it seems to me to grow like the common wild *Convolvulus* once rooted and established; but I noticed that in all places it was most luxuriant close to a wall. At Kenmore by the rustic porch of the inn it was growing up through the hard beaten ground. At Killin it was growing through the gravel spread round the hotel, many times relaid, no doubt, and beaten down; and at St. Fillan's, in the little plots before the cottages, where it was covered with berries, plots which I daresay never had a spade put into the ground. The roots are not unlike those of the wild *Convolvulus* and will grow when allowed, inserting themselves between the stones of the wall. If it does

Fig. 89.—*BEGONIA KNOWSLEYANA.*

not grow in England, where almost everything else grows better than in Scotland, it must be the temperature, not the soil. I never found the roots at any great depth, and they must be frozen hard in winter, yet they spring again each year with renewed strength. I have seen it growing equally well with any aspect, but I should prefer to give it a southern one, as the plants I saw bearing fruit were exposed to the south. I trust this paper though prosy may be interesting to the readers of the Journal.—**JAMES HUIE.**

**MILD WEATHER AND THE LARVÆ OF INSECTS.**—It will be interesting to note the results of the past unusually mild November

upon the subterranean-feeding larvæ. Probably the growth of some or most of these will be accelerated, to the injury of the roots, &c., they attack, but they may not be more likely to survive the winter should frosts set in hereafter.—**J. R. S. C.**

#### **BEGONIA KNOWSLEYANA.**

THIS is not a new plant, but till within the last few weeks I have never had a name for it, and as not many people care to grow a plant without a name it has not come into cultivation so much as it deserves.

I first became acquainted with this *Begonia* at Knowsley, the

scat of the Earl of Derby, some twenty years ago, and it has been one of my companions ever since; but I must own I have only discovered its merits as a decorative plant for winter within the last two or three years. It has always been treated as a plant that was useful for affording flowers during winter when we could not obtain sufficient of others, or to afford a little variety when there was apt to be too much sameness; but it was never thought of great value, and its total loss a few years ago would have occasioned little regret. Its great merit, however, is its adaptability for small specimen plants in 6-inch pots, where they grow from 15 to 18 inches through and a foot high, producing flowers at every tip and from most of the axils. The flowers are nearly white; they have just a tinge of pink in places, which gives them when growing the appearance of being blush white throughout. They are produced in abundance all through the year, but they are most useful in autumn and winter, and it is for these seasons that they are grown and recommended. The leaf is smaller and the habit better than *B. insignis*, a beautiful old pink variety which everybody should grow, but which I believe is difficult to obtain true now, there being spurious forms of it in cultivation. I have often observed seedlings of *B. Knowsleyana* growing where plants have stood in the previous year; and although I am not sure that I have grown any of these seedlings to flower them, yet they are always in appearance so much like the parent that there can be no doubt it comes true from seed. I am of opinion that it is a distinct species imported by one of the collectors of a former Earl of Derby, who used to collect both plants and animals, more especially the latter, in large numbers. Knowsley at one time was celebrated for its menagerie, but the only remnant of it at the time I speak of was an aviary. I often heard the labouring men speak of a botanist or collector who used to be allowed to attend to some of his own pet plants in the gardens. I forget his name, but it was a well-known one. Was it Nuttall? Mr. Barron of Chiswick took some cuttings of this *Begonia* back with him when visiting Knowsley, and I have little doubt but that it found its way from Chiswick to Kew, where I am glad to see it has been thought worthy of a name.

Its culture is very simple. Cuttings are struck in March or the beginning of April, potted into 6-inch pots in such soil as would suit *Pelargonium*s well; they are kept in what may be called cool stove temperature—*i.e.*, with a minimum of about 55°, and when the pots are filled with roots liquid manure is occasionally supplied, or, what I consider better, they have a teaspoonful of Standen's manure placed on the surface of the soil. This once repeated, if care is taken not to wash it over the sides of the pot when watering, is sufficient to carry them through the winter.—WILLIAM TAYLOR.

#### SCRAPS ABOUT FRUIT.

VIRGIN WINTER APPLE.—I shall feel greatly obliged if Mr. T. C. Antrobus will kindly tell me where the above variety can be obtained true to name, either trees or grafting scions.—ROBERT WARNER, *Broomfield, near Chelmsford, Essex.*

SECKLE PEAR.—Where did "WILTSHIRE RECTOR" obtain the sample of this Pear which was so "very small and of a vulgar sweet taste?" I very confidently venture to predict that not many of your readers will be found to agree with him. In the first place, it is not very small under good cultivation. I have seen and tasted fruit of it this season in Sussex quite as large as Louise Bonne of Jersey, and of most delicious flavour. But then, perhaps, it is the very exceptional aromatic richness for which it is so famous that offends the delicate palate of "WILTSHIRE RECTOR." If Seckle is to be condemned on the score of size, what are we to say about Winter Nelis, Comte de Lamy, Zéphirin Grégoire, or Dana's Hovey? all of them in my opinion indispensable sorts, and all having small fruit. The crop of Seckle was this year a heavy one, so heavy that the unthinned fruit was doubtless small and probably of inferior flavour; but is the result of such practice to be used to assail the high character of a fruit of such world-wide repute?—E. L. O.

SELECT APPLES.—Recently I had the pleasure of examining in a nursery in Essex a number of Apple trees in full bearing. I append a list of the sorts I thought worthy of cultivation as standards or pyramids—Tower of Glammis, the most extraordinary fruit I ever saw. Two years since in Covent Garden Market 6*d.* each was the price of them. Winter Majetin is everything we could desire as a late fruit. Golden Russet, Norfolk Stone Pippin, Northern Greening, Cox's Orange Pippin, Wellington (Dumelow's Seedling), Lord Suffield, Hawthornden, Manks

Codlin, Stirling Castle, Nonpareil, Golden Winter Pearmain, Winter Pearmain, Blenheim Pippin, London Pippin, Boston Russet, Allen's Everlasting. King of the Pippins and Summer Pearmain, two early Apples, were past when I visited the nursery. Scotch Firs afford an ornamental as well as useful protection to fruit trees in exposed positions.—T. C. ANTROBUS.

RED CURRANTS.—This is one of the most prolific of all fruits. The Red Dutch is very good, but Raby Castle is much superior both in size of bunches and berries, and keeps much longer. We had it fit for tarts on bushes in the open throughout October without any covering other than ordinary fish nets. White Dutch is a good companion variety.—SOMERSET.

BERGAMOTTE ESPEREN PEAR.—I find this one of the best late Pears, coming into use when most other kinds are over, and with care may be kept until spring. All late Pears require to be kept cool and not over-dry, or the fruit is apt to shrivel, which spoils the juiciness and melting character of the fruit. It is a free and certain bearer, succeeding admirably on a west wall on the Pear stock, trained either horizontally or fan-fashion. It succeeds well on the Quince, but as a pyramid is not profitable, as the fruit in ordinary seasons does not attain to perfection; indeed it is only against a wall that it can be had fine in North Yorkshire.—G. ABBEY.

RIVERS' EARLY PROLIFIC PLUM.—There was an omission in my previous note about this Plum which I hasten to make good. The pyramidal trees are of an average height of 13 feet, and are 10 feet in diameter at the base. I may add for the benefit of those who are unacquainted with this Plum, that its name of Early Prolific is faithfully descriptive of its remarkable property of earliness and abundance. A really good Plum which is ripe in July must command the market, and is a sound investment for those who are planting for profit.—A KENTISH GROWER.

BLACK CURRANTS.—*Apropos* of planting for profit I may usefully call attention to the important fact, that in Kent Black Currants prove more profitable than any other fruit. The better the soil the stronger the growth, the finer the fruit, and the heavier the crop. You cannot give them too much manure, and, mark this! you cannot lose money by doing so. But do not disturb the roots of thoroughly established bushes. Surface-dressing is the best way to apply manure, and if you have plenty of sewage pour it about among them frequently, and you will have plenty of sturdy shoots from the ground, and a constant renewal of youth and vigour.—K. G.

THE BEST TWELVE PEARS.—Beurré Clairgeau invariably affords me some fruit, and usually bears a full crop. This year it was a heavy one, and the fruit was remarkable for its beauty of both form and colour; but it was so poor in flavour, and really good Pears were so abundant, that not a dish was used for dessert. Doyenné Boussoch, too, was very fine and plentiful, but it was only used for stewing. It bears such noble fruit that I always regret its invariable poverty of flavour. Were I to select a second best twelve for dessert, neither of these Pears would be included therein. I very confidently venture to assert that had "W. J. M." and his co-judges tasted Beurré Clairgeau and compared it with, say, Fondante d'Automne, they would not have come to a decision so erroneous and so misleading. I may add that the soil here is so largely impregnated with iron that the fruit of Beurré Clairgeau is always very highly coloured, and is so beautiful that I once took some of it to Dr. Hogg, who much admired its brilliant appearance, but made no remark about flavour, nor was I surprised, for what saith the "Fruit Manual?" "A handsome and showy Pear; ripe in November. Its appearance is its greatest recommendation."—SUSSEX.

#### GOLDFUSSIA ISOPHYLLA.

THIS plant is by no means so popular as it deserves to be, and for a late autumn and winter-flowering plant none could be more useful and ornamental. The colour of the flowers is indeed very pleasing, being of a pale lilac. Its uses are numerous, and for conservatory decoration, when a rather dry atmosphere is maintained, it is a great acquisition. In the case of Goldfussia, as in many other plants that belong to *Acanthaceæ*, the individual flowers are of rather short duration; but fortunately they do not all expand at the same time, and if a little care is exercised to remove the decayed flowers the plants will keep in good condition

for a considerable time. When a constant succession of flowers is to be maintained Goldfussias do good service, and with a number of plants the flowering season may be prolonged for several weeks.

If cuttings are inserted about March in a little bottom heat they very readily form roots. As soon as struck they may be potted off singly into 60-size pots and kept in the stove till they are well established. When they have filled their pots with roots they should be shifted on into 48-pots, employing a rich compost. After they have commenced rooting in the new soil the tops should be pinched out to induce them to branch; one, or at the most two pinchings, will be quite sufficient. Good bushy plants can be grown in 48's, but if plants are required of a larger size another potting will be necessary. I grow my plants in a cold frame through the summer fully exposed to the sun, and in autumn they are removed to an intermediate house.

I find it the best plan to bring the plants on gradually into flower, for if they are forced into bloom they do not as a rule last so long. It is undoubtedly the best plan to strike young plants each year and grow them on as described above. I have on one or two occasions kept the plants a second year. After they have done flowering I cut them back and treat them like Pelargoniums, reducing the roots, and pot them in rich soil, after which they receive the same treatment as the spring-struck plants. As a rule plants grown the second year are not nearly so satisfactory as young plants.—W. K.

### A WEEK IN BELGIUM.

[THE FOURTH DAY.]

HAVING referred to Antwerp with its antique features and quaint customs, glanced at the character of the horticultural exhibitions, also the domestic floriculture of the old city, and briefly described what may be termed the town and country nurseries of one of the oldest and most esteemed of Belgian horticulturists, I pass to a change of scene and spend the fourth day in

#### BRUSSELS.

What Edinburgh is to Glasgow, and Bath to Bristol, Brussels is to Antwerp. On the one hand we have business with all the attendant excitement and an apparent money-earning community; on the other we have luxury and ease represented, and what seems to be essentially a money-spending population. Antwerp is the great Belgium emporium of commerce. Brussels, the seat of much trade no doubt, is essentially a city of pleasure-seekers from many lands. Antwerp is flat and generally unpicturesque. Brussels occupies a position more or less undulated, and there are several standpoints from which beautiful views may be had of a beautiful city—all the more enjoyable because there is no smoke. It is in consequence of the practical smokelessness of Belgian coal that the cleanliness of the buildings is to be attributed. All the principal edifices are white and clean as if painted yesterday—a striking change from the dingy bricks of London. The trees, too, are as fresh as in the open fields; the park in the centre of Brussels being the rendezvous of thousands, who enjoy the shady walks, for shaded indeed they are, and the open air concerts; the boulevards, too, are extensive and enjoyable promenades.

When it is incumbent on the visitor to see as much as possible of the city in the least possible time, he cannot do better than engage a guide who has a horse and small open carriage behind him. There are numbers of them, and much may be seen in an hour or two—the palaces of the King, Comte de Flandre, Duc d'Areberg, the ancient Hôtel de Ville, and the modern Palace of Justice—the latter approaching completion. The New Law Courts in London are unquestionably extensive, and many think them imposing, but they represent a conglomeration of pepper-boxes in comparison with the massive grandeur and rich architecture of the noble building in Brussels, on which something like three million pounds sterling will be expended before the work is finished.

If time permits for a suburban drive it will be enjoyed—say, for instance, about two miles in one direction to the Wiertz Museum for an inspection of the paintings, which for marvellous conception and dash in execution are, perhaps, unequalled as the work of one man. There are few visitors who do not experience a keener sense of the sublime and the ridiculous in this building than they have experienced before. In what way the latter is accomplished it would scarcely be fair to tell—all who have been will know, and those who go will find out, if they see all that is to be seen. The artist must have been intoxicated with his extraordinary imagination and his conspicuous talents. About the same distance in another direction is a terminus of a very different character—the Bois de la Cambre. This is a beautiful wood and park combined, and for boldness of treatment and the

diversified character of the scenery it is unique. Both these popular places of resort can be reached by tramcar from either of the railway stations. English visitors who have a day at disposal can spend it interestingly by a visit to Waterloo by coach, a distance of twelve miles; but having been to the historic field on a former occasion I turned in another direction—namely, Laeken; first, however, spending half an hour in the

#### BOTANIC GARDENS.

These are situated quite close to the Station du Nord, the station for Antwerp; and as the boulevard alongside of them, the north side, is much higher than the Gardens they show to great advantage, sloping as they do to the south, the glass structures occupying the higher ground, forming the northern boundary; in fact the gardens are so thoroughly overlooked that they can be and are enjoyed by thousands without entering them at all. The principal range of glass is very extensive, very old, and very ill adapted for the growth of plants. It is in the old orangery style, having a front of masonry with windows, but a roof of glass domed in the centre. It is more imposing from without than attractive within, still it contains many gigantic Palms; in fact, it is a forest of Palms, which are kept as healthy as the place and circumstances permit. A very large fernery is more attractive, as it is furnished with many fine and choice specimens in excellent condition. There are also long, low, span-roofed houses crowded with a varied botanical collection of plants, which are evidently well cared for and cultivated. Outside the grounds are rendered attractive by various kinds of bedding plants, Orange trees in tubs, and a garden of hardy plants. There appears to be little of everything, including carpet bedding, and there is something to meet the tastes of all. The Superintendent, M. Lubbers, is admitted to be one of the most accomplished gardeners in Belgium, and any of the British fraternity who visit him will find his ability equalled by his courtesy; but they will find the pleasure enhanced if they can speak the French or Flemish languages, for there is nothing much more awkward than the meeting of a Belgian and Englishman each ignorant of the other's tongue, and both smiling and bowing their best to render themselves agreeable. We now pass on to

#### LAEKEN.

There is a station at Laeken on the line to Ghent—in fact two stations, one for the Royal family and the palace visitors, and the other for the public; but it is as well to go by tramcar, the distance being only about two miles. Those who were acquainted with Laeken two or three years ago, and visit it again now, will be astonished at the great alterations and striking and costly improvements that have been made by His Majesty. The approach formerly was through a village the reverse of picturesque. The road was narrow and cramped by old cottages on one side and the dead park wall on the other. Now all is changed. The King purchased the property, pulled down the old tenements, and converted the site into a handsome park, which he has presented to the people of Laeken and Brussels. It is a right royal gift. Nor is this all. The park is only separated from the royal demesne by an open iron fence, so the palace grounds can be seen by the public, and since the improvements have been effected they are certainly worth seeing. The Royal Family have also a corresponding advantage, for an extensive and picturesque view of the public park is obtained from the palace; a prominent object of interest to all being the Leopold Memorial, an elaborate structure, somewhat in the style of the Albert Memorial in Hyde Park, erected in memory of Leopold I. This public park has been most skilfully designed and planted by M. Delabarrière, a student of M. Alphande in the parks of Paris. M. Delabarrière has also been engaged in remodelling a great portion of the royal pleasure grounds, and he has certainly accomplished his work in a masterly manner—created, in fact, quite a transformation. It is not surprising that the King, in recognition of work so well done, should desire to retain the services of one who has proved his competence, and in all probability both the public and the private park will remain under his superintendence. Boldness and freedom characterise the whole work, and Art and Nature have been so happily merged that it is impossible to tell where one ends and the other begins. Laeken is richly wooded, and abounds in glades and vistas that render the surroundings of the palace highly picturesque.

#### THE WINTER GARDEN.

From a gardening point of view this remarkable structure towers above all else at Laeken. It stands alone in all its majesty, and is quite unlike anything we have in England. It is circular, with two corridors or wings attached. The roof is a vast dome, resting on a wall of masonry 3 or 4 feet high and terminating in a lantern with movable lights for ventilation.

The diameter of the house is nearly 200 feet, and the height to the top of the lantern 80 feet—a vast space to fill ornamentally, but it has been accomplished. The interior of the wall on which the roof rests is faced with rockwork and planted with Ferns, Begonias, and other suitable plants, by the side of which is a broad walk all round the house. About 20 feet from the side is a circle of thirty-six stone columns 20 feet high and 30 inches in diameter for supporting the roof. These massive columns and the architrave are rather obtrusive, but none of the structural parts of the edifice must be covered with plants; no climbers even must touch the roof, in obedience to the law of the architect, otherwise Mr. Wills would without doubt have found means to partially cover this and the masonry, and have made the house, as a garden, even more ornamental than it is. Between the outer wall and the pillars a series of semicircular beds are being formed, and in each is being planted a single Palm—if I remember rightly, *Phoenix reclinata*—and handsome specimens they are. Hitherto they have been in tubs and other plants grouped round them, but they now demand more space, and their appearance will be much better when the work of planting is completed.

We now come to what may be termed the inner circle of the garden—the space enclosed by the pillars. This is simply divided into two large semicircular beds by a promenade some 20 feet wide of mosaic pavement. The beds are planted in a free irregular manner so as to resemble a tropical forest, and the idea is admirably carried out. Magnificent Palm trees and Tree Ferns tower aloft forming a grand canopy of foliage, the undergrowth comprising dwarf Ferns associated with ornamental-foliaged Begonias. The Begonias thus grown in all their native vigour are most striking. Such plants cannot be produced in pots, and the subdued light is precisely suited for bringing out the richness of their markings. These plants, 6 feet or more in diameter, with huge leaves in richest colour, show with great effect from the mass of luxuriant Ferns—*Aspleniums*, *Adiantums*, *Pterises*, &c., *P. argyrea* being especially striking, and the whole scene is as complete in its way as could be desired. To enumerate the Palms would be too great a task, and is not needful, but a few cannot be forgotten. *Sabal Blackburniana* from the Duke of Arcmberg's is magnificent, and one wonders how such specimens could be removed and placed in their positions, for the weight must amount to many tons. *Livistonia australis* and *Sabal palmata* are similarly grand. *Astrocaryum rostratum* with its prickly stems is the finest plant in the kingdom. *Corypha australis* has a stem 10 feet high and a head 20 feet in diameter. *Caryota Rumphiana* is of the same size. *Phoenixes* are numerous, *P. sylvestris* 20 feet high being deservedly valued, and the rare and valuable *Cocos australis* with its remarkable sharply hooked leaves commands attention, the specimen being valued at £500. *Kentias*, *Attaleas*, *Arengas*, *Braheas*, *Chamærops*, *Latantias*, *Livistonias*, and, in fact, all the choicest and the best kinds that could be obtained, are included in the forest, and all are in the best of health. They are such as a king may be proud to own, and it is evident his skilful gardener M. Ingelrelst cherishes them. This is a meagre description of a remarkable structure, which alone is worth a journey from England to see, if the sea is not too rough and the visitor can speak French, as all cannot expect to be so fortunate as I was to meet His Majesty's English valet, Mr. Murray, whose presence rendered my hour at Laeken peculiarly agreeable.

#### THE ORANGERY.

Connected with the winter garden is the orangery, at one end of which is the King's private theatre. This orangery is a huge building 250 feet long and 25 feet wide. The sides are glazed between buttresses of masonry, and the roof is ceiled; still it appears to answer the purpose of preserving the Orange trees and Camellias in the winter, these being placed in the open air during the summer. A correspondent "VINDEK," referred on page 383 to the light soil in which Belgian Camellias are potted as insufficient to maintain them in good health. I do not know what he would have said had he seen the Laeken specimens in tubs, and not very large tubs either, the foliage being of the richest character and the buds in thousands—even thousands on one specimen, for some of the plants, or trees, are apparently 30 feet high, perfectly furnished from the tubs upwards, the specimens being cone-shaped, or rather split-cone shaped, for they are flat at the back for arranging against the walls of the orangery, every portion of which between the windows they cover from the floor to the ceiling. In August they were in the open air arranged on the north side of a close belt of lofty trees, and consequently quite shaded from the sun during the greater part of the day. Shade is evidently considered essential for Camellias in Belgium, and is provided by cultivators in private gardens and nurseries. Great judgment is requisite in watering such specimens as these, and

they are certainly well attended to, or they would not be in the excellent condition they are. The soil in the tubs is black and sandy, resembling decayed leaves or manure mixed with sand, and clear liquid manure is given occasionally.

Fine as the Camellias are, the Orange trees are still more striking. As arranged in rows outside the house they formed quite a grove. Many of them are historic specimens and are greatly and worthily prized. There appeared to be about two hundred of them in tubs about 4 feet high and 5 or 6 feet square. The stems of many of them appear to be 18 or more inches in circumference, and the heads, which are globular and very handsome, range from 8 to 10 or even 12 feet in diameter. Several of these trees are, I believe, considerably over a hundred years old, yet, generally speaking, they are in excellent health, the foliage being clean and glossy and the fruits numerous. In the spring Orange blossom at Laeken must be about as plentiful as Apple blossom is in an ordinary English garden, and the perfume in the orangery must be overpowering. A few of the trees have lost their vigour and are being renovated. This is done by reducing their heads, cutting the branches "hard in;" buds and fresh growths soon follow, and new and fresh heads are formed. The specimens are unsightly for a time, but not for long, and eventually there is a satisfactory compensation in the renovated trees. This is the best mode, too, of treating old Camellias that need renovation—cut them boldly down, and they will repay by strong and healthy growths if the plants are otherwise rightly treated, as I have often seen in Belgium, and seen also and practised in England. The Orange trees in question are worthy of Laeken, of the royal possessor of them, and of Belgium—more need not be said.

From the Winter Garden we enter a semicircular conservatory adjoining the theatre, and from thence a long glass-roofed corridor that conducts to the palace. This is a great work, and mostly below ground, except, of course, the roof. On the sides are rockwork, and the walls above are wired, but hitherto they have failed to cover them. Even the *Ficus repens* scarcely makes any progress, and *Selaginellas* assume an abnormal character. There is a great desire to cover the walls, and in all probability a collection of Ivies would be as likely to succeed as anything, while many of the varieties are unquestionably beautiful—to wit, Sir Henry Peek's wall of them at Wimbledon House.

There is thus much of interest at Laeken—much that is good, even grand; but I must record a great want. The winter garden, as I have said, stands alone. There are no preparing houses for the supply of plants that would complete its adornment. There is a venerable range of lean-to houses of little use for plant culture, and a few rough frames. Ranges of span-roofed houses or pits appear to English eyes simple necessities under the circumstances, and perhaps in due time they will be provided. Until then it is an absolute impossibility for any gardener to furnish the huge building in the most attractive manner; but with such aids and competent assistance, a spectacle of floral grandeur might be effected such as would be difficult to equal in any country.

I shall not soon forget Laeken, nor the courtesy and kindness of M.M. Ingelrelst and Lebarrière, Mr. Murray, and my good friend and able interpreter Mr. Charles Van Geert, jun., who was my efficient guide and genial fellow traveller during the fourth day of my week in Belgium.—J. WRIGHT.

#### PEARS FOR WALLS.

I HAVE carefully read "JOHN BULL'S" latest under the above heading, and, anxious to satisfy him as far as is in my power, I again revert to the subject. Your correspondent thinks that we may be shocked to know that he root-prunes with an axe. Whether shocked or not, we certainly think that had the tree he speaks of been properly planted, and the roots properly cared for afterwards while the tree was young, the work would not have been greater, and the practice would have been more worthy of being held up for imitation.

The only thing "JOHN BULL" asks me to answer is—"If the practice of root-pruning and lifting is so wonderfully profitable, how is it that fruit-farmers who pay £5 an acre for their land do not indulge in it? And on the border question, will he say why a Pear tree against a wall should require an expensively made border when it will grow freely without it in an open field or garden?" I have already answered the latter question in the following words—"I did not say that Pear trees would not grow without having borders made for them. But I said, and say still, that first-rate results need not be looked for from trees trained as advocated without good borders. That they will grow we are all aware, but we want something more than growth. We want fruit, and not only fruit, but good fruit, and we have yet to learn

that good Pears can be produced all over these islands from trees the roots of which are allowed to run in cold clay or cankered gravel. Here and there, especially in favoured spots, conditions favourable enough may be found, but few are so favoured." This reply your correspondent does not seem to have noticed.

My lot never having been to work in orchards I will not presume to understand their usual management; but if root-pruning and root-lifting are unknown among fruit-farmers I do not hesitate to say that, even on the best of soils and in the best of climates, fruit-farming is capable of improvement, for care of roots is of more importance than care of branches. But, more important still, I will venture to say from my own experience that it is only favourable soils that command £5 an acre, and that when such land at that price affords profit it must be good. Orchards, generally speaking, are confined to certain districts known to be favourable, and in such districts great results are obtained with next to no skill. Gardens, on the other hand, are placed anywhere. The soil may be quite unfit for further culture and the climate bad, but the gardener is expected to furnish fruit and vegetables from it. Even the best skill may fail under such circumstances if the example of the plant-and-let-grow plan as advocated is followed. Perhaps your correspondent has never had serious difficulties to contend with, and as yet he has said nothing to justify us in thinking that he merely plants his trees, and, beyond severing a tap root occasionally, attends to the tops, and reaps first-rate results. His book is not yet emptied, however, and it is possible he may have the best part of it in store for us.

In our native county there is a small district almost wholly occupied by orchards, the people having found that all kinds of fruit thrive with no attention. In no other district do Pears attain the size or quality of the Pears in that spot under natural conditions. On such a soil (it is heavy gritty loam from decayed trap to an unknown depth) no preparation of borders would be necessary, and such trees as advocated by "JOHN BULL" would be satisfactory to everyone concerned. In the garden where the first three years of our gardening career were spent the soil was of a very different kind. A better stocked garden as far as fruit trees went we never saw, and the old gardener was one after "JOHN BULL'S" own heart. Just such trees as he admires covered the walls, but great numbers were prone to produce wood rather than fruit. In good seasons immense crops were produced, but between their produce and that of the orchard district the difference was great. They were not over half the size and the quality was not equal, neither did they fruit year by year with the same regularity. The finer kinds were scabbed and often cracked and inferior. The roots of the former were in healthy material, ours in poor sand.

Part of the wall was much swayed, and that portion was covered with young trees not nearly full grown. It was determined to rebuild the wall, and to accomplish this the trees had to be lifted. This was entrusted to me. Strict orders were given us to lift the trees with balls; but the roots were clean and straight, and we could not get an ounce of earth with them. We transplanted them temporarily against another wall. All lived, and when one year after they were transplanted against the new wall the fibreless roots had become magnificent wigs; but the growth of the branches was effectually checked. The following year the newly planted trees produced more and finer fruit than I believe was ever produced from an equal space in that garden before. On revisiting the garden some years afterwards I was assured that the trees referred to were the most satisfactory on the place. That fine trees bearing fine crops of first-class fruit could be produced by making expensive borders I quite admit, and such was the practice in that country fifty years ago. Without the borders such results could not be obtained. If the tree must be produced, then, also, so must the borders. Now we think the borders quite unnecessary, for by careful lifting and root-pruning the best results may be produced on even bad subsoils; but lifting and root-pruning in inferior soils means smaller trees, which will cover the walls equally well if planted closer: and medium trees would be equal at least, at very much less labour and much less waiting, than larger trees necessitating the making of wide deep borders.

Axe-pruning we know little about, and should hesitate to sever large down-going roots for fear that decay might be induced, which might creep up and kill the trees. Large trees we have assisted to improve by lifting first one half of the roots one year and the other the year following; but again we say that the labour required in such cases is much greater than is expended in keeping the roots of properly trained medium trees out of the subsoil. Still, were we to find ourselves in charge of trees barren or producing inferior fruit by reason of the roots going into bad or cold soil we should certainly lift the roots; and if such trees

turned out bad sorts, still we would not destroy them if they were healthy, but cut back every branch and crown-graft them with sorts known to be good and suitable for the locality. Many bad sorts have we thus replaced.

We have helped to cultivate trees successfully when others let alone would not live even. Not many years ago we had a lesson on a soil very similar to that of the London basin. These trees grew well with no trouble, and produced excellent results. On similar soil the results were exactly opposite. This may look strange until we add that the garden is five hundred miles further north. The matter of climate alone made the difference. There we helped to plant a number of trees in prepared soil. So long as the roots kept in the prepared soil the fruit was very fine and never failed to ripen. When the roots reached the cold under-soil the effect was exactly as if the climate had changed much for the worse. What would "JOHN BULL" do in such a case? The gardener in charge lifted all the roots and thus restored the trees to their former fertility, but the operation checked the growth to begin with, and the heavy crops afterwards. Part of the more easily managed—that is, smaller—trees on the walls were similarly treated with like results. Others there are "splendid and splendidly trained," which bear well in alternate years, but the fruit is not good in ordinary seasons; and in bad years—and they have occurred rather too frequently in that locality lately—the fruit is very inferior and many kinds fail to ripen fruit at all.

I hope I have now made clear why I prefer small to large trees, and why I advise others to "seriously consider" what they are doing. I said before that much more labour was necessary to produce a given amount of fruit from a given space of wall, and though the terms I used were exaggerated (I confess that); my experience tells me that that is so. On a healthy soil and in a good climate perhaps I might be inclined to raise such monuments to my name as "JOHN BULL" admires, but hitherto I have not been favoured with the necessary conditions. In what latitude does your correspondent practise? He might give us a hint, for surely he will go on drawing upon his "book," now that he has begun. Although I have used words I should not have used, for which my apologies are due to "JOHN BULL," his object, I am sure, is to benefit his readers as mine is, and no one will read what he has to say with greater pleasure than will—  
A. H. H.

#### PLANT-COLLECTING IN TROPICAL COUNTRIES.

AS, doubtless, many of your readers who fully appreciate the many beautiful plants annually sent out by the leading nursery-men have but faint ideas of the dangers incurred in collecting them, I give the following brief indication of the course pursued by men so engaged, the substance of which I have gathered from conversation with many travellers in the tropics.

Having received his instructions as to the chief objects of his search, and the districts where they are most likely to be found, the collector proceeds to the port nearest to his destination and thence to the most convenient town as a basis for his operations. After a few days he is well on the road, and seeks to engage some assistance in the shape of a boy, this boy being often nearly as old as himself. After the promise of a few dollars the boy is engaged, or as many assistants or boys as the collector requires, and start, each man carrying his own knapsack. In a short time they are all busily engaged, provided everything is favourable, tearing the plants from the trees or rocks, and making some preparation to keep them alive till they have collected sufficient to form one consignment to be taken down to the seaport and packed ready for shipment. All this may appear a charming life to those uninitiated, and so it is; but this, of course, is the brightest part of it. The drawbacks are tenfold compared with the pleasures. The climate is perhaps the most dangerous of all to any European, and what a collector suffers from most is fever. This is brought on to a very great extent by exposure. It often occurs that when a collector is exploring a wild out-of-the-way district that he is too far away to go even to the nearest house or hut to sleep, consequently he has to construct a hut himself, and thatch it with leaves to keep out the wet. It is when a collector is smitten with fever that he finds himself in an awkward position. He then has to doctor himself, his chief medicine in case of fever being sulphate of quinine. I was informed by a collector not long since that on more than one occasion he would willingly have given his twelve months' salary to have been free from fever and back home again. Generally speaking, they live very hard, too, when they are travelling; their staple food is boiled rice, with any other delicacies they are fortunate enough to obtain. Wild animals and poisonous reptiles are frequently met with, to say nothing of the annoyance of monkeys, croaking frogs, ants, and other things

too numerous to mention. Nor do their troubles end here, for in many parts the natives are very untrustworthy, and much care and constant watchfulness are required to contend with them. These are only a few of the troubles and dangers to which plant-collectors are exposed; but sufficient has been said to enable uninitiated readers to perceive that the beautiful plants which adorn their stoves have not been obtained without much danger, discomfort, and expense.—W. R.

#### KITCHEN GARDEN.

ADVANTAGE should be taken of weather unfavourable for outdoor operations to examine the roots, especially Potatoes, which owing to the mildness of the autumn are sprouting fast. This more particularly applies to the early kinds, which of those intended for planting should be placed thinly on shelves or other suitable places so as to retard the sprouting as much as possible and to render the growth stout. It will not do to remove the first growths of the early kidney varieties, as they do not start freely into second growth. They should be kept as cool as possible, merely excluding frost. The later kinds of Potatoes are not keeping very well, except Champions, which have scarcely any diseased, and these should be sorted, removing any diseased tubers. Onions are keeping fairly well, but all bad bulbs must be removed, whilst those which have been bunched or strung should be placed in a dry cool shed where they will obtain plenty of air to insure their keeping sound to a late period in spring.

During weather unfavourable for ground operations the rubbish heap must have attention, separating the crude material from that in an advanced stage of decomposition. The last should be placed in readiness for employment in enriching the ground. The crude material may have a little lime and salt mixed with it, as it is thrown into a heap, which will hasten decomposition and help to destroy vermin. Any dressings of trees or prunings should be burned, the ashes being valuable as top-dressing for fruit-tree borders, and are peculiarly valuable for ground intended to be cropped with roots, such as Onions and Carrots.

Cauliflowers and autumn or winter Broccoli should be looked over frequently, cutting all heads that are of suitable size, and keeping them in a cool place safe from frost. Any not large enough to be cut, but having heads about the size of a teacup, may be lifted and planted in pits or frames protected from frost. Any that have heads neither large enough for cutting nor lifting should have the outer leaves broken over them. Hoe between autumn-sown crops of Onions, Cabbage, Spinach, and Lettuces to destroy weeds, and remove decayed foliage.

*Forcing Department.*—Continue to prepare well-fermented material, such as dung and leaves, in the proportion of one of stable litter to two or three of leaves, to afford material for lining beds containing Potatoes, should severe weather set in, and for making beds for successional plantings of Potatoes, also for Cauliflowers, Carrots, Lettuce, and Radishes as may be necessary to the supply of the establishment. See that good successional supplies of Asparagus, Seakale, and Rhubarb roots are introduced. French Beans will require sowing at intervals, earthing-up those plants advanced in growth, and supplying liquid manure. Cauliflowers under handlights or in pits or frames must have air on all favourable occasions, similar remarks applying to Lettuces and Parsley, providing sufficient covering as protection in severe weather.

#### HARDY FRUIT GARDEN.

Apples and Pears, whether grown as espaliers, bushes, or pyramids, may now be pruned to advantage, staking and tying where required. To make handsome and fruitful trees pyramids and bushes should be moderately well thinned, as where hard summer pruning is practised the wood is likely to become crowded so much as to seriously affect

the prospect of a crop of fruit; but wherever the condition of fruit trees is unsatisfactory the roots must be carefully examined, when it will generally be found that remedial measures may be adopted with success. Excessive luxuriance is a frequent cause of fruit trees not bearing, and can generally be remedied by judicious root-pruning, which should, however, be carefully performed, using a sharp instrument for severing the roots, as bruised roots die back considerably and cause fungus in the soil. In cases of weakness or exhaustion the surface soil must be carefully removed to expose a considerable portion of the roots, removing the soil from amongst them carefully, also any dead or decayed portions of roots. Work in good turfy loam, to which has been added a fourth of well-decomposed manure; make it firm and cover the roots with 3 or 4 inches depth of the same compost, and if the soil is dry tread it down moderately firm and mulch with light manure.

When the weather is open planting fruit trees may be brought to a close as soon as possible, and as soon as the trees are planted they should be secured to stakes, or, if against walls, lightly tied or tacked to the wall to prevent injury by wind, deferring securing the shoots in their proper positions as well as shortening the growths until spring. Mulch well over the roots.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—Owing to the unusually mild weather very little fire heat has been required in the house, to which it is usually applied early this month. Heat has only been needed on wet days to promote a circulation of air, which is always desirable, particularly in the early stages of growth. Continue the temperature at 50° to 55° by day, turning on the heat in the morning to effect this, allowing a rise of 10° from sun heat, accompanied with a free circulation of air, the night temperature being maintained at 45° to 50°, which will be quite sufficient for bringing the trees into flower without unduly exciting them. Syringe the paths and borders in the morning and early afternoon, and the trees also if the blossoms are not more than half expanded. If upon examination the borders are found dry give a thorough soaking with water at 80°. The house to which fire heat is to be applied early in the year must be closed, damping the trees in the morning and afternoon, ventilating when the temperature reaches 50°, and employ fire heat at night if necessary to exclude frost. Supply the inside borders with water at 80° repeatedly until they are thoroughly moistened; but if the lights have been off water will not be required for some time to come. The outside border must be protected with a good layer of leaves and litter to prevent their being blown about. Complete cleansing the trees in succession and late houses, also cleansing and painting houses that require it. Watering must be attended to in succession and late houses, as, should there be any deficiency of moisture at the roots of the trees now, it is likely the buds will be cast later on. When the weather is mild the ventilators must be open constantly, closing only when there is frost.

#### FLOWER GARDEN.

Beds of Hyacinths and Tulips should be covered with a mulching of cocoa-nut fibre refuse 2 or 3 inches thick to protect the bulbs from severe weather, similar attention being given to other plants that are likely to be injured. Rose borders should be well mulched with litter. Standard Roses must be protected if necessary with hay or other light material wrapped about the head, and make secure to stakes. Teas must not only be protected with soft dry material, but be covered with mats as a further protection, the ground being well mulched previously. Cannas left in the ground should be well mulched with straw or bracken; and all plants of doubtful hardiness, such as *Chamærops humilis* and *Fortunei*, *Aralia Sieboldi*, and Bamboos, must be protected with mats. Delphiniums and Pyrethrums often have their young shoots eaten beneath the surface by slugs, and to avoid this the soil may be taken out around the crowns, a dusting of quicklime being given, and the space filled with ashes. Shrubs, such as *Ceanothus* and *Magnolias* against walls, should have a double mat tacked in front of them in severe weather, and similar protection will be necessary for such Clematises and Roses which are in a dangerously forward condition, and, unless protected, will in all probability be severely injured if the winter prove severe. Herbaceous borders may receive a good dressing of leaf soil, well-reduced refuse, or manure,

which will enrich the soil and form a suitable protection for the plants. Christmas Roses should be covered with handlights, for which they amply repay in the size of the flowers and purity of colour. Spring bedding plants must be examined, firming the soil about such as require it. If a mulch of cocoa refuse be given between the plants it will impart a neat appearance and enable the plants to pass the weather safely.

**Bedding Plants.**—Plants in cold frames need frequent examination, removing every particle of decayed foliage, dusting any infested with mildew with flowers of sulphur, fully exposing to the weather on all favourable occasions, and when frost prevails keep them well protected. If the plants become frozen they must not be exposed to the sun until they have thoroughly thawed, which they should be allowed to do in darkness. We have had Calceolarias closely matted for ten weeks; they have been frozen all the time, and not a plant failed. Be very careful in the application of water, giving it only to such plants as absolutely require it, and in the early part of fine days only Verbenas should be frequently examined, and if mildew is observed apply flowers of sulphur, and those with Petunias and Ageratums should have a dry airy position with a temperature of 40° to 50°, and no more water than to preserve the plants in health. Pelargoniums must have a temperature in which they will be kept slowly growing through the winter, and a light position to insure sturdy growth. A temperature of 40° to 45° at night, and 50° by day, ventilating freely on all favourable occasions. Plants wintered in this way will be in much finer condition in spring than those starved through the winter. Variegated and other Pelargoniums, the stock of which is in arrear, should be kept in a warm airy house, and they will soon furnish cuttings which strike freely on a shelf kept rather dry in a temperature of 60° to 65°. Tender plants, such as Coleus, Alternantheras, and Iresines, should have the temperature above indicated, with no more water for the present than will keep them in health. Succulents must have any decayed parts removed; keep the soil dry, but without causing the plants to shrivel, and protect from frost.

#### PLANT HOUSES.

**Greenhouse.**—*Tropæolum tricolorum*, *T. Jarratti*, and *T. pentaphyllum* being now in active growth, should be kept in a light position with the shoots regularly trained, which, if not attended to frequently, soon become so entangled as to prevent their being made to look well, being careful in all instances to cover the bottom of the trellis with young shoots before they are allowed to ramble to the top. Keep the soil in a moist condition, but not too wet, or the plants are seldom healthy. *Lachenalias* also must be near the glass and not overwatered.

**Pelargoniums.**—The Large-flowered, Spotted, Regal, and Fancy Pelargoniums are not so much grown as they were before the improved forms of the Zonal varieties came into cultivation; but this is certainly a mistake, as, desirable as are the Zonals from their continuous habit of blooming, the others, from flowering so profusely when most of the spring-flowering greenhouse plants are over, are particularly acceptable for conservatory and general decoration. Moderate-sized plants are most suitable, not formally trained, but no pains should be spared to grow them well, and employ no more sticks and ties than are needed to keep them shapely. Plants intended to flower early in May should now have the requisite number of sticks placed to them, and the shoots trained thinly so as to allow light and air to reach the centre of the plants. Unless unduly vigorous they need not be pinched. Old plants certainly will not need stopping. Later plants will require to be potted, making the soil quite firm, as when lightly potted they produce much foliage and do not flower satisfactorily. At potting it is advisable to place as many sticks as are likely to be required, as when this is deferred until later on their insertion mutilates the roots. Arrange the plants in a good light position as near the glass as possible, and ventilate the house freely except when frost prevails. Keep a strict look-out for aphides, and fumigate upon their first appearance.

Herbaceous Calceolarias will require shifting into larger pots before they become root-bound, or they will not grow freely afterwards. Pot rather firmly in a compost of three parts loam, one part leaf soil and well-decayed manure, with a sprinkling of sand. It is essential that the plants be kept cool and moist.

Cinerarias for spring bloom should be shifted into large pots, employing the same compost. Plants in small pots for later flowering should not be allowed to become root-bound, but must be moved to larger pots as they require it, giving the final shift early in February, and they will bloom when spring is well advanced. The temperature of the greenhouse will need to be kept at 40° to 45° by artificial means, ventilating if the day is likely to be fine. Water should be supplied in the early part of the day, and must be given liberally to plants requiring it, too frequent waterings being highly prejudicial.

**Conservatory.**—Chrysanthemums will, if plants have been specially prepared for late flowering and retarded in a north house, still form an important part of the decoration of this structure. The general stock of these plants should be removed and the house made as gay as possible. If due preparations have been made there will be abundance of flowers, such as the following—Camellias, Indian Azaleas, Rhododendrons of the early-flowering section, *Azalea mollis*, Lilac, *Acacia platyptera*, *Coronilla glauca*, *Cytisus racemosus*, Epacrises, winter-flowering Heaths, the glowing Poinsettias, bright-coloured early-flowered Cinerarias, Primulas, Cyclamens, Zonal Pelargoniums, Roman Hyacinths, Roman and Paper White Narcissus, *Helleborus niger*, *maximus*, *orientalis*, and *olympicus*; common Primroses, Snowdrops, the indispensable Crocus, lovely Violets, Lily of the Valley in quantity, Heliotrope, stately Richardias, bright *Schizostylis*, Pinks, Forget-me-not, Mignonette, *Eucharis*, *Epiphyllums*, and equally brilliant Euphorbias, *Luculia*, *Daphne indica*, *Jasminum grandiflorum*, *Lapageria*, *Cestrum aurantiacum*, and Roses, of which *Niphetos* is especially notable. These with others, if tastefully arranged with foliage plants, make an effective display.

#### DESIGNS IN HONEYCOMB.

IN his article on bee shows on page 366 Mr. Pettigrew urges the introduction of more variety and novelty at exhibitions as a means of making them "more gratifying and sensational." I am not sure that I can plead for the "sensational," even although our shows are meant for public attractions, so much as for the educational so far as bee-keepers are concerned. As it so happens that the fancy designs, stars, mottoes, &c., for which he pleads are at the same time highly attractive to visitors and capital exercise for the skill of the bee-keeper, I therefore take up the somewhat novel subject, and shall first of all describe a few of the more striking designs which have adorned the exhibitions of the East of Scotland Society at Dundee during the past few years. The idea originated in 1875 with an Arbroath gentleman, who offered a guinea for the best star in honeycomb, with five points and not less than 12 inches across. If I remember rightly it was two years before a star was produced worthy of the prize. Meanwhile other prizes had been offered for designs, no special form being stipulated, and drew a magnificent turn-out at the 1878 show. Some of these designs were exceedingly elaborate. The most imposing of all was a beautifully shaped vase full of purest comb surmounted by the star above referred to. This was passed over by the judges because of its being built into vase shape by the bee-keeper rather than the bees. The vase had been obtained and filled in sections a few inches deep, which were afterwards built together, the joints being covered by ornament. The idea, however, is a good one. Dealers in glass shades have frequently to cut them down for special orders, and the cuttings or rings of various diameters and depths, when covered by a circular plate of glass may, when finished, be built into towers, pillars, &c. There were two designs in the form of a cross 18 inches high, each consisting of six separate designs, crosses, stars, hearts, &c., built together after being worked by the bees. Here, again, the bee-keeper was considered to have had too great hand in the design. The first prize was awarded to a design, beautiful in its very simplicity—viz., two concentric circles of very fine honeycomb. For protection there was a wooden rim round them, but they were at no point attached to it or to each other. The prize, a honey extractor value 30s., went to a working bobbin-turner near Banchoy. The second prize went to the same house for a beautiful star of six rays worked in a shallow "cogie." The third was of similar design. Since 1878 we have had no chance to get designs finished in Scotland; they require especially good

seasons. Nevertheless, I have seen several promising attempts exhibited—a spread eagle, part of a motto, concentric rings, &c. Mr. Pettigrew may rest assured we are not so far behind as he seems to think, and if he will offer anything tempting at his next Manchester exhibition it will not be our fault if Scotland does not win the day.

I shall now, for the instruction of novices, give a few hints on the art of obtaining designs. The use of shade cuttings I have already explained. I shall, therefore, take the next easiest form of design—viz., that cut out of a block of wood, the vacancy being filled by the bees with comb. For this purpose take two pieces of soft pine wood large enough to contain the design wanted, and each about seven-eighths of an inch thick. Lay them so that the grain of the wood will cross and fasten slightly together by driving a few clean wire nails through both at points that will not interfere with the design. Now draw the shape wanted, whether a letter, a cross, circle, heart, or star, and with a fret-saw cut out the piece. Before placing in the hive separate the two thicknesses of wood, place a sheet of super comb foundation between, and again nail them together. Such designs are best worked when hung in bar-frames, either at the sides of a hive or in an upper storey, and this must be borne in mind when deciding on the size and shape. Tin or other separators must be used to ensure smooth finish. I have worked many such designs, and have been astonished to find the bees working so nearly alike on both sides, though having no “pop-hole” between.

I cannot help thinking, however, that such designs are too mechanical—that is, man's hand is too much seen. I therefore prefer the following method. A board is taken, which is to be the top of a super, round, square, or oval—say a circular glass cutting 3 to 4 inches deep. On this board the design is drawn—a star, concentric circles, or such like—and strips of comb foundation half an inch less in depth than the super are secured along the lines, care being taken to avoid crowding. Vacant corners outside the design may have guides attached in such a way as to secure their being filled with detached and regular combs, or blocks of wood or other material may be temporarily attached, partly acting as separators and partly as stopgaps till the comb is worked. The rim of the super need not be added till the foundation is fixed, and even then only lightly secured to the lid; for sometimes a design will turn out that will be seen to much greater advantage without the rim under a glass case.

There is still another class of designs which are very striking, but which I have not yet succeeded with owing to bad seasons—viz., combs embossed with monograms, geometrical patterns, figures of birds, beasts, &c. To get these a rich honey yield is needed. The slab of comb, say in a large section or an ordinary frame, is first allowed to remain in the hive till perfectly finished. It is then removed, and the design wanted is pricked on its surface. Every cell within the design is now carefully uncapped, and the comb returned to the exact place it occupied in the hive, only it is pushed back nearly a quarter of an inch from its former position. Honey being abundant the bees will lengthen the uncapped cells, seal them over afresh, and leave the design embossed on the comb. By using as separators boards carved out with hollow designs like butter prints, we may have our embossing done without the necessity of removing the comb during the process. The bees will naturally cause the surface of the comb to bulge into all the hollows of the pattern, which, however, must be of a bold type.

Monstrously thick combs are obtained much in the same way as the first style of embossing just mentioned. The bees are allowed access to a space that will serve them for one comb only in the centre of a case that may be from 4 to 12 inches across. This space is enclosed by moveable separators, and as soon as the one comb is nearly worked out, but before it is at all sealed, the separators are pushed back little by little day by day. The bees know no better than to lengthen their cells, which they will continue to do till the box is filled with a single comb. All these operations require considerable attention and no little knowledge and dexterity; but the pleasures of success and an experience extended even by failure are worth the attempt. The winter evenings may be employed in elaborating the designs so far as they are mechanical; let us hope the summer to come may be such as to ensure their perfect completion.—WILLIAM RAITT, *Blairgowrie*.

#### BRITISH BEE-KEEPERS' ASSOCIATION.

At the monthly meeting of the Committee, held at 105, Jermyn Street, on the 14th inst., there were present Mr. T. W. Cowan (in the chair), Rev. G. Rayner, Mr. D. Stewart, Mr. J. M. Hooker, Mr. W. O. B. Glennie (Treasurer), and Rev. H. R. Peel (Hon. Sec.). The Hon. and Rev. H. Bligh was also present, and discussed with the

Committee his proposals for a competition with the view to the better promotion of cottage apiaries throughout the United Kingdom. It was the general opinion of the meeting that such a competition should be limited for the first year to the six home counties, and that a sum of £21 should be offered in prizes of £6, £5, £4, £3, £2, and £1, “for the best managed and most profitable poor man's economic department of an apiary, such department to be worked with a limited number of hives, upon any principle or combination of principles.” It was resolved that the question be adjourned for further consideration at the next meeting, and that in the meantime a set of rules be drawn up for the management of the competition.

A letter was read from the Secretary of the Royal Agricultural Society, approving of the draft schedule of prizes for bees, hives, honey, and bee-keeping appliances, to be offered for competition at the Royal Agricultural Show to be held at Reading in July next, and stating that the Royal Agricultural Society would be pleased to grant the sum of £30 to the British Bee-keepers' Association to enable the Committee of that Society to carry out the proposed Exhibition. It was resolved that a vote of thanks be sent to the Council of the Royal Agricultural Society for their increased support towards the promotion of bee-keeping.

#### APIARIAN APPLIANCES AND BEE PRODUCTS AT THE BRIGHTON HEALTH CONGRESS.

WE are glad to be able to note that various societies, whose aims are to assist in the production of good and cheap food for the people, are giving prominence to the exhibition of honey and appliances in connection with bee-keeping, as tending to the increased production of an article of nutritious food and the revival of an almost neglected industry.

The Council of the Brighton Health Congress invited (through Mr. F. V. Hadlow, the Chairman of the Food Department) the Committee of the British Bee-keepers' Association to make a display of honey and bee-keeping appliances at their Exhibition, which commenced on the 12th inst., and allotted space free of charge for the purpose. The exhibition of honey, &c., was under the able management of T. W. Cowan, Esq., the Chairman of the Committee of the British Bee-keepers' Association. Bee hives and other appliances were kindly sent by Messrs. Neighbour & Son, Mr. S. J. Baldwin, Mr. A. Rushbridge, Mr. T. B. Blow, and Mr. Wooldridge. Specimens of small sections of honey in the comb and extracted honey in glass jars were contributed by T. W. Cowan, Esq., J. M. Hooker, Esq., Mr. R. Scott, Mr. Baldwin, Mr. Rushbridge, and Messrs. Neighbour & Son. Hundreds of visitors visited the Exhibition, and much interest was displayed in the department allotted to bee hives, honey, &c. The uses of the various exhibits were explained by T. W. Cowan, Esq., Mr. Baldwin, and Mr. Rushbridge.

The Congress sat daily, and various papers were read on the promotion of health and the production of food. At the meeting held on Thursday, the 17th inst., J. R. Holland, Esq., M.P., in the chair, Mr. T. W. Cowan read a paper on honey as food, which we received too late for insertion this week.

The Judges awarded a certificate of high commendation to the exhibits of the British Bee-keepers' Association.

#### TRADE CATALOGUES RECEIVED.

Frederick Roemer, Quedlinburgh, Germany.—*Price List of Flower Seeds.*

J. Carter & Co., High Holborn.—*Vade Mecum, 1882, with Coloured Plates.*

Ernest Riemschneider, Altona, Hamburg.—*List of Flower and Vegetable Seeds.*

Hennequin, Denis & Cie., Faubourg, Bressigny.—*Catalogue of Flower and Vegetable Seeds.*

Richard Dean, Ranelagh Road, Ealing.—*Catalogues of Potatoes, Primroses, Auriculas, Pansies, &c.*

Sutton & Sons, Reading.—*Amateurs' Guide, 1882, with Coloured Plates.*

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**The Cottage Gardeners' Dictionary (J. N.).**—This will be more useful than the other work you name, inasmuch as it gives full cultural details on all the most useful kinds of fruits, also kitchen garden crops, and stove, greenhouse,

and hardy plants. We do not know a work of its nature more useful for an ordinary gardener.

**Potatoes** (*E. F.*).—Your letter was answered last week on page 550.

**Removing Limewash** (*A Constant Subscriber*).—We know of no better mode than washing it off the wall, using long-handled hard brushes and plenty of water, commencing at the top of the wall and working downwards. By scrubbing the wall vigorously you will soon effect your object.

**Winchester Red Celery** (*W. M. T.*).—The address you require is 412, Strand, London. We can give no opinion as to the merits of a new variety which we have neither grown nor tasted.

**Selection of Chrysanthemums** (*E. T. H.*).—You will find the following half dozen good Pompon varieties—Mdlle. Marthe, Rosinante, St. Michael, Boule d'Or, White and Lilac Cedo Nulli. The Anemone Pommoms best suited for the purpose named are Antonius, Firefly, Madame Montels, Marie Stnart, and Dick Turpin.

**Collection of Chrysanthemums** (*San Juan*).—The varieties you name are all good, and we should suggest that you add M. Declaux, rich maroon, and Fulton, bright yellow, to the Japanese; with Mdlle. Marthe, white, and St. Michael, bright yellow, to the Pommoms.

**Peculiar Primula** (*T. W. T.*).—The strange appearance of the Primula flowers you sent is due to the calyx having become foliaceous—that is, it has assumed a leaf-like form closely surrounding and extending beyond the corolla. We have not seen the peculiarity so strongly marked in varieties of Primula sinensis before, though similar changes occur in allied plants, such as the old and singular Jack-in-the-Green or Gallygaskiu Polyanthus. We thank you for letter, and reciprocate your good wishes.

**Tous-les-mois** (*Lorrimore*).—The kind of meal or starch known by the above name is obtained from the rootstock of a species of Cannia, by some supposed to be *C. coccinea*, and by others *C. achiras* or *C. edulis*. The substance is prepared in the island of St. Kitt's, and it is said its manufacture is attended with much difficulty. It is highly nutritious.

**Protecting Holly Hedge** (*J. G.*).—We know of no more effectual plan for preventing rabbits injuring the newly planted Holly hedge than protecting it with galvanised wire netting. A good mode of fixing the netting is to bend about 6 inches along the bottom at right angles with the remaining portion, burying the bent strip about 2 inches deep, this facing outwards or towards the point of attack, and very few of the animals will succeed in burrowing underneath it, as they certainly would do if either this or a better method of fixing were not adopted. It is not enough to simply sink the lower edge of the wire a few inches into the ground in its natural upright position. If any of our readers can suggest a better, simpler, and cheaper plan for the purpose indicated we will readily publish their experience.

**Tropæolum speciosum** (*J. L.*).—It is perfectly hardy and needs no protection whatever when once it is established, as you will perceive by a communication in another column. It is important that the roots be kept moist in transit, damp moss being a good material in which to pack them. Light loamy yet gritty soil will be suitable for planting them in, and a moist and cool position is preferable to a hot and dry one. This *Tropæolum* evidently enjoys plenty of water, as some of the districts in Scotland, where it grows luxuriantly, are remarkable for a heavy rainfall; this, however, passes away freely, and the soil is not stagnant. It should always be remembered that a rainfall of 30 inches in a low flat district liable to floods is equal in effect to a fall of 60 inches in a hilly district or where the ground is of a porous nature through which the rain passes rapidly. A liberal supply of water, therefore, with free drainage, would appear to be essential to the free growth of this beautiful climber; that is to say, the ground should be moist yet not waterlogged in consequence of defective drainage.

**Lime for Gardens** (*B. H. R.*).—Though often nearly white, the magnesian limestone is generally of a yellow colour. It cannot by the eye be distinguished from common limestone of a similar colour, but is characterised by containing a carbonate of magnesia, sometimes in large proportion, hence is injurious to plants. The simplest method of detecting magnesia in a limestone is to dissolve it in diluted muriatic acid, and then to pour clear lime water into the filtered solution. If a light white powder fall it is magnesia. The relative proportions of magnesia in two limestones may be estimated pretty nearly by dissolving an equal weight of each, pouring the filtered solutions into bottles which can be corked, and then filling up both with lime water. On subsiding the relative bulks of the precipitates will indicate the respective richness of the two varieties in magnesia. There is little or no magnesia in either the white or the grey lime in your district, and we should prefer the former for using in gardens.

**American Blight** (*L. J. K.*).—We received the box sent previously, but were not able to determine by whom it was forwarded, hence the absence of any reply. The whole of the malformations on the spurs have been caused by the American blight. If the tree were not particularly prized we should have advised its destruction, especially if the others were clean, but as it is a favourite we should endeavour to extirpate the pest that is the cause of so much injury. You have evidently destroyed a great number of the insects, but not all, as we find several fine specimens on the spurs you have sent. Mr. Speed of Chatsworth has found the following remedy effectual—"Take a pint of gas tar and mix with it a pint of dry powdered clay. Form the whole into a paste by adding by degrees a gallon of warm soft water. If this is applied with a brush during winter it effectually destroys all insects, while it does not injure the trees." Another good plan is to mix a wineglassful of paraffin with a gallon of strong soapsuds, and with this paint the trees, remembering that as much depends on the manner of its application as on the power of its dressing. Unless it is brushed thoroughly into the crevices of the bark the effects of this or any other insecticide will not be satisfactory. We have no doubt the tree may be cleansed by applying the dressing in a thorough manner and as frequently as is necessary. You will find much information on paraffin as an insecticide, and the right mode of using it, in the "Gardeners' Year-Book" that is just being published.

**Nertera depressa and Other Plants** (*R. C.*).—The plant labelled No. 1 is *Nertera depressa*, and is not difficult to grow. Do not remove the growths. If you keep the plants quite close to the glass in a very light house or frame, and water them copiously, they will flower freely and produce an abundance of berries. This plant cannot well have too much water and sun during the growing season. The best berried plants we ever saw were plunged in ashes on a warm south border from April onwards, and watered daily, often twice a day during hot sunny weather. They were well hardened before being plunged, and were protected with mats when the nights were frosty. But in your district the plants would probably be best plunged in a very light frame; but they

should only be a few inches from the glass, and the frame-light might be drawn off entirely during favourable weather. No. 2 is *Chlorophytum orchidstrum variegatum*, and succeeds very well in a basket of light turfy soil suspended in a cool house. No. 3 is a *Canna*, and requires to be kept dry during the winter if in pots, otherwise store the roots in a dry cool place safe from frost. In the spring the plants may be transferred to the flower garden, and if planted in rich soil they would grow strongly and form an imposing bed in a suitable position.

**Exhibiting Chrysanthemums** (*Competitor*).—"At a recent exhibition a class was provided in the schedule for 'Twelve Pommoms, not less than six varieties, to be shown in bunches of three, with foliage.' The chief prize was awarded to an exhibitor with three individual flowers of each variety. The second prize was awarded to another who staged three trusses of each variety, each bunch of three trusses probably containing over a dozen individual blooms. According to the reading of the schedule ought not the latter stand to have been disqualified?" We state this question in order that our reply may be better understood and of more service generally, as the subject has much more than a personal significance. The second-prize stand referred to could not have been disqualified, as "bunches" certainly were staged—a "bunch" meaning a cluster. A number of the same kind growing together, or a number of stems containing single flowers tied together, would form a bunch. In the Kingston schedule the stipulation is "Twelve bunches of Pommoms, distinct, three stems as cut to form a bunch (*Anemone Pommoms and Hybrids excluded*)."  
Mr. Moorman was rightly adjudged the first prize in this class, each of the stems having six or more fine flowers. According to the extract from the schedule first referred to, the judges might, perhaps, have disqualified the first-prize stand, as blooms, not bunches, of three varieties were staged, but they no doubt, as judges usually do, exercised their discretion in reading ambiguous conditions. According to the Kingston schedule they could neither have disqualified bunches of three single blooms as cut from the plant nor bunches containing several blooms on one stem. Whatever is meant by committees should be stated. Either "three single blooms to form a bunch," or "three bunches of flowers as cut, number of blooms not limited," would make the matter plain to all.

**Grafting Fruit Trees** (*A Beginner*).—Apples are grafted on the Crab and Paradise stocks, the former for orchard trees, the latter for hedges. Crab stocks are raised from seed, Paradise stocks from layers and cuttings inserted in the autumn. Pears are grafted or budded on Pear stocks for standards and trees for free growth generally; on Quince stocks, for smaller trees and early fruitfulness, the stocks being raised as above mentioned. Plums are budded or grafted on Plum stocks, and Peaches or Nectarines are budded on stocks of the same kind. Grafting is done in the spring when the sap commences rising, and it is an advantage if the stocks are in advance of the grafts or scions, by the latter having been retarded by cutting from the trees before any signs of growth are apparent, and storing in soil in a cool position. There are various methods of grafting; for young trees Baltet's system of crown grafting, as represented in the accompanying figures, being simple and good. The stock A

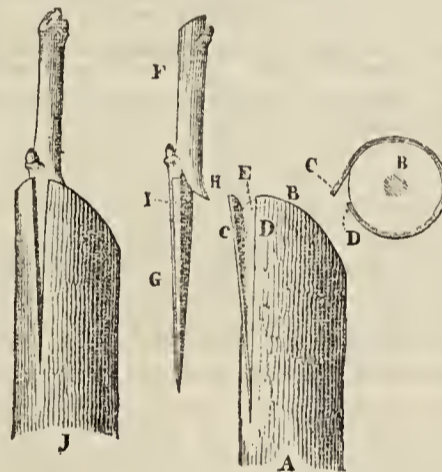

Fig. 90.

done but the waxing and tying. We add the plan of the stock, B, the portion of bark, C, raised from the wood, and the other, D, which remains untouched. These slight variations, which may be infinitely increased according as reason and practice dictate, have for their object the hastening of the union between the graft and the stock. A small work on grafting that would be useful to you is published at 170, Strand, London, the price, we think, being about 1s.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*Reader*).—The Apple is an imperfect example of the Blenheim Pippin. (*H. H.*).—1, Reinette Diel; 2, Stamford Pippin. (*James Searle*).—13, Probably Northern Spy; 14, Margil; 15, Lucombe's Pine Apple; 16, not known; 17, Dumelow's Seedling; 18, Kentish Fillebasket. (*G. Picker*).—The large conical Apple is Catshead, which we think we have named for you before; 1, Trumpington; 3, Gloria Mundi; 6, Court of Wick. No numbers were attached to the others, therefore we cannot name them. Numbers should be firmly secured to the fruit.

**Names of Plants** (*G. P.*).—1, *Pteris argyrea*; 2, *Polystichum aculeatum*; 3, *Pteris serrulata cristata*; 4, *Adiantum pubescens*; 5, appears to be a *Nephrodium*, but the specimen was not sufficiently mature to enable us to determine it with certainty; 6, *Helleborus foetidus*. (*Reader*).—It is impossible to name Conifers with certainty from small sprays unless information relative to the character of the specimens accompany them, and we can only say that No. 1 resembles the male form of *Juniperus chinensis*, and No. 2 *J. virginiana*, the Red Cedar. (*C. E. M.*).—1, *Taxidunaria clephantipes*; 2, not recognisable; 3, *Euonymus japonicus latifolius variegatus*; 4, apparently a *Francoa*, but the specimen was insufficient for identification without flowers; 5, *Sedum carneum variegatum*; 6, *Alonsoa incisa*. (*T. J. H.*).—*Adiantum macrophyllum*. (*R. C.*).

—1, Nertera depressa; 2, Chlorophytum orchidastrum variegatum; 3 a Canna, for particulars of culture see above.

**Bees in Winter (H. R.).**—If you had the stock from a successful bee-keeper he probably gave you good advice. The weight of the hive is an indication of this, and you had better let the zinc remain as it is.

COVENT GARDEN MARKET.—DECEMBER 21.

OUR market presents a different appearance to what it usually does during Christmas week, everything being dull with an absence of the class of stuff we expect at this season. Grapes are in good supply, but show signs of bad keeping, while Pears are nearly off the market, samples being confined to small arrivals of French and Californian Easters, which are selling at excessive rates.

POULTRY AND PIGEON CHRONICLE.

AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 552.)

THE next point to be considered is between the use of carts or waggons for the various works on the farm, at least as the advocates of each state their opinions and experience. Having, however, given the most practical and useful observations of those farmers who prefer carts, let us now hear what those who use waggons in preference have to say. It is stated in their favour that light two-horse waggons are preferable to one-horse carts, but more especially upon hilly land or on the strong soils where small ridges and deep water furrows prevail, as the loads are not so liable to fall off at harvest or hay time in very dry weather; and that tying the load is more effective than with carts. The light waggons most approved in the southern and south-western counties are those made in Dorset, Wilts, and Gloucestershire; for, in fact, some of the makers in these districts offer us a light waggon adapted for one horse capable of carrying a ton and a half burden, and by the same style and pattern others capable of carrying a load varying up to three tons, the difference only, or chiefly, being the width of the wheel tire. These for the most part have wheels so high in front that they do not turn as required; but the waggons for one or two horses as furnished by the Bristol Waggon Works Company are made so that the front wheels will lock under the body, and can then be turned in its own length. These are furnished at a moderate price, and will

carry a load up to four tons with wheels of wide tire in proportion, the horse power being regulated of course by the weight to be drawn.

We shall now give our opinions upon the subject, and endeavour to recommend to the home farmer, as well as the implement makers, what style of waggons and carts we think most likely to meet the general requirements for work on the home farm, and at the same time to be adapted for use in connection with all the improvements which have lately been obtained by steam power in our labour-saving machinery. The latest improvements in waggons have somewhat altered our opinion, although we have contended for many years that single horse carts or frames for harvest hay-carting were the most economical. They are on some farms, but for general purposes, such as use on hilly land, in water meadows, and on arable land with small ridges and deep furrows, as also in carting corn and other merchandise on the high roads, we think one or two-horse waggons are the best and safest, although the first investment or purchase would be rather greater than for carts. There is, however, one qualification we must make in the advocacy of any observations connected with this subject, that we now as ever have always recommended the use only of horses standing not less than 16½ to 17 hands high, with weight and activity in proportion; in which case we expect, under ordinary farm work either on the field or high road, each animal to be master of a load of from 25 to 30 cwts., and under these circumstances the use of waggons adapted for one or two horses are to be preferred to carts. For ordinary animals, however, only capable of drawing about 20 cwt. loads, the Scotch harvest frames we think best. It must be quite understood that we recommend two sets of implements, for, whether waggons or carts are preferred, those tipping carts fitted for carting dung, chalk, &c., must also form an important and indispensable part of the farmer's stock of implements in preference to the use of carts for all purposes with convertible apparatus of ladders.

We must ask the implement makers to consider the subject of certain reforms in the farm implements in our opinion rendered necessary in connection with steam power and machinery. The first point is that nearly all the work which was formerly overhanded, such as unloading corn and hay at the stack, and was the severest manual labour done on the farm; but since the introduction and use of the elevator in raising the hay and corn to the rick underhand labour is only required of the men by casting it into the elevator, in consequence there is no advantage in having carts and waggons made high in order to assist or diminish the labour of unloading. Implement makers should, therefore, consider how much the carts and waggons can be lowered in their build without adding to the draught to an appreciable extent, and thus favour the labour of loading. It may be also asked how far the tipping carts for manure, chalk, and heavy substances can be lowered so as to facilitate the work of loading and yet to maintain the power of tipping unimpaired; for it seems to us that the crank axle is worth attention in connection with the improvement of dung carts without interfering with the advantage of tipping, which is of course indispensable. Again, in the case of harvest frames it is worth consideration how far these can be lowered without disadvantage in order to save labour in loading. We consider those changes which are now coming largely into operation, such as tying the crops into sheaves by the improved sheaf-binding harvesters, is greatly in favour of harvest frames; for if no corn is carted to the stack in loose condition the load would require no tying, especially if the frames, waggons, or carts were made as low as possible. We think that any of the harvest frames we have noticed, either offered by the Bristol Company or other makers, may be lowered with benefit, even if it necessitated bent shafts.

Before quitting the subject of carts we must notice that light spring milk carts are becoming of more importance as the supply of milk is continually on the increase. The Bristol Company offer light vans and milk carts, but we think that they are each set up too high. More in accordance, however, with the requirements for the transit and delivery of milk is the spring milk cart exhibited at the Derby meeting of the Royal Agricultural Society, and made by Messrs. Vipan & Headley of Leicester. It appears a well-made and practical cart either for delivering milk in a town or for conveying railway cans to and from the farm to railway stations. In its make we notice a cranked axle secures a low body, of great importance in saving labour, and strong springs prevent undue jolting. For carrying cans to the railway four cans holding twenty gallons can be carried easily, and probably six if required. For milk-selling in towns a removeable framework allows of two swinging cans being carried, from which the milk is drawn through taps. For filling the delivery cans the shafts can be raised, thus bringing the cans to the proper level,

and avoiding the necessity of lifting them when full. This is highly spoken of by the Judges at the Exhibition, and is therefore worth the notice of the home farmer and implement maker. Messrs. Hornsby & Son, Limited, exhibited a novel Turnip cutter at Derby, which actually cuts the last slice, and thereby avoids a certain amount of waste which has hitherto occurred in ordinary machines owing to the last slice passing into the skep or basket—a large piece all, or nearly all, rind, and which is refused by sheep and wasted. The improvement in the cutter is obtained by the addition of a perforated guard or shield fixed underneath the barrel, so that any piece which may escape uncut from the front cutting-plate is prevented from falling into the basket, and is carried round to the hopper again to be forced through the knives with the other roots. The action is perfect, and the result is a great practical improvement in the economy of cutting roots, especially for sheep fed in the open field in troughs. Messrs. Perkins of Hitchin have made important improvements in their corn screen. The original polygon form is now replaced by a circular frame which is made to revolve eccentrically, thereby securing a much more efficient action, which is a contribution of a rotary and longitudinal motion. The frame is also capable of carrying various screens which are easily removed and replaced. The screens are stamped out of metal plate, so that the openings cannot vary in size. This screen has a number of indents on the inner surface. These receive the weed seeds and carry them round till overcome by the force of gravity; they fall into a sloping receptacle in the lower portion of the screen, whence they are discharged.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—The work attendant upon Wheat-sowing is now nearly concluded, and the sooner it is completed the better, December being better than January, and January being better than February for the completion of sowing. The best kind of Wheat which we know as a red berry is the Nursery, and the best white Wheat the Club-headed Rough Chaff. Although the latter is usually sown at the autumn seed time, yet on all dry soils and in favourable climates, like the southern and south-eastern counties, it will do better than any other white Wheat. It will not only tiller well and keep plant in the spring, but yield grain of fine quality.

Chalk-carting for all soils which require it should now be done, and also clay-carting for the sandy and gravelly soils. Now these substances, although they cannot always be laid out at the time they are brought on the farm, yet they may with advantage be deposited in heaps in or near to the field, and then carted out and spread as soon as the weather will admit of the work being done. This chalking of land is a matter of the first importance, for we are through our own experience quite satisfied that no land can be profitably cultivated in the absence of a proper amount of either chalk or lime. We have inspected large tracts of land lately, and in many instances we found that the fields were quite out of chalk, as evidenced by the weeds, which will immediately be noticed by those who are acquainted with their habits of growth.

*Hand Labour.*—The men are now employed in filling dung from the boxes to be heaped in readiness for application to the Clovers as soon as it can be drawn on the land; but it should be spread directly, in order that the rains may fix it on the soil, and also carry the soilage of the manure to the roots of the Clover plants. The water furrows on the Wheat land will require looking to, and be relieved of any accumulations of soil, which may be spread thinly on each side of the furrows. Trenching in the pastures may now be done if it is not intended to turn the cattle thereon during the winter months. If cattle are to feed on the pastures in the following summer we prefer to make out the trenches in the spring, and the proceeds burned as soon as dry. This will furnish good ashes either for laying out on the pastures or to be held in reserve for drilling with corn or Mangolds or other root seeds.

The men may now be employed in the woodlands cutting underwood and converting for various purposes, such as hoop rods, Hop poles, also bavins, but putting on one side the bushes, &c., with certain rods as stakes and for making dead hedges. Pitting Swedes and Carrots may be carried on during mild and open weather. This is usually done by casting them together into small heaps and covering with earth. Upon any dry land, such as sand, gravel, or chalk, it is a saving of labour to open a space with the plough by turning out three furrows each way twice and cast the roots into the trench or double furrow thus made, and then returning with the plough the reverse way will nearly cover the roots, the completion of which is best done by shovelling a portion of earth on the top to a point, with a slight trench on either side. In ordinary seasons the roots are found to keep well in this way, and are easily put together and more easily distributed or cleaned for use in the spring. The women may assist the men in pitting root crops, also in forking out the lumps of Couch grass in the root crops and in the young Clovers; for we maintain that it is advisable to attack the Couch in this manner, as it prevents the roots spreading over the land, and eventually saves considerable horse labour at a comparatively trifling cost.

*Live Stock.*—The Somerset horned ewes have now finished lambing, some of the earliest of which have been sold to be killed for Christmas lamb. The greater portion of these flocks will be sold between the middle of the months of January and March. The west county and Dorset down ewes are now fast yearning their lambs, and will require the shepherd's constant attention. They should be prepared with remedies for the young lambs suffering from the white scour; the use of a few drops of tincture of opium in a little water is the safest and quickest remedy, and may be repeated every three hours until the diarrhoea has ceased. The ewes will require treatment after a severe or protracted lambing time; carbolic acid is the remedy used by many flock-masters to be applied to any injured parts, and thus prevent gangrene or mortification. The latest advised remedy, however, to be used in the same manner is a solution of salicylic acid. Bad and inflamed udders, however, should be treated with sugar of lead ointment; but if likely to mortify the verdigris ointment is a safe and sure remedy if taken in time.

There is no branch of our stock farming which requires so much attention, care, and nicety in detail as the fattening of early lambs and ewes simultaneously. Our mode is to feed the ewes and lambs, whether of the horned or down breed, in the open field; but although it is often done where the land is rather flat and becomes dirty, yet if the climate should be good, either in the southern or eastern counties, they will then do well without shelter if judiciously and regularly fed as follows. As soon as the lambs begin to eat we give them a little of the finest Dutch Clover hay, which should be grown on purpose for them. We have grown it as fine and perfect as a sample of hops, without any other grasses in admixture. The root-feeding should be white Belgian Carrots and the white hearts of the Champion Drumhead Cabbage, quartered into the Gardner's cutter and passed through twice, which reduces the Carrot roots into small pieces like dice, and the crisp sweet Cabbage is also reduced very fine, and easily taken up and eaten by the lambs when they first begin to eat; and it is of great importance that they should eat early, and as they eat but little it should be of the best and most forcing quality, because it relieves the ewes, particularly when they have twins. The Carrots and Cabbage, after being cut fine as described, should be powdered over with cake meal, by which means the lambs take cake before they would eat it in any other way, the aroma from the Carrots being very enticing and agreeable. They have also oil-cake in the covered troughs, cracked and passed through a riddle to make it as small as cracked beans or peas, in which state cracked peas are mixed with it, and for lambs we prefer American bag or barrelled cake with grey peas. The bullocks which we usually sell at this Christmas time we frequently buy in store condition in the month of May, from which time until the first week in October they are placed in boxes 10 by 12 feet and fed with Clover, Saintfoin, or Lucerne cut fresh from the field daily, and the bullocks in addition receive also 4 lbs. of cake each per day. From October 1st until sold they get cut roots, about 56 lbs. of Carrots or Mangolds being preferred per day, and 4 lbs. cake and 2 lbs. bean meal mixed with the cut roots daily, and sweet oat straw *ad libitum* in the racks in the ordinary state. We have given the mode of feeding somewhat in detail in order that it may be understood that bullocks, not being overfed with hay and large quantities of cake, will yield a clear profit of from 3s. to 3s. 6d. per week, all expenses paid and charged.

## POULTRY AND PIGEONS

### BANTAMS PAST AND PRESENT.

THE formation of a Bantam Club has drawn new interest to these old favourites. It is high time that it did so, for to few varieties of poultry has more harm been done by fashion. The extended classification which under the Club's auspices is now being given to them at shows, will give encouragement to many who hitherto have only been able now and then to trust their birds to the somewhat hazardous chance of the variety class; others will, we hope, be choosing a breed in the hope of improving it. We will, therefore, look back some thirty years, and see what the Bantams have been and what they are.

Time was, long before general poultry shows were thought of, and when a vision of the present long lines of pens at the Crystal Palace or Birmingham would have seemed the wildest dream, that many real fanciers amused themselves with breeding pigmies, aye, and formed societies for showing them too, but of these we have little record. It is about eighty years since Sir John Sebright began the production of his exquisite little laced Bantams; thirty years later the variety may be said to have been established. In the days of the earlier poultry shows, roughly speaking thirty years ago, it was exhibited in great perfection. We have not since that time made such advance in the Bantam line as we might, but we will try to see where there has been progress and where falling-off.

What has been lost and what gained in this particular variety? Probably birds are now to be found as accurately laced as ever, and the pure white ground colour of some strains of Silvers has been an addition of later breeders. But what has the sacrifice been? To begin with, we can remember Sebrights little more than half the size of the present exhibition birds; truly, in Bantams this is a great retrogression. Then the characteristic hen-tail of the cocks is seldom now seen in anything like perfection. But more than all, the beautiful coxcombical Bantam carriage has been much lost. Let any fancier with an eye for form look at the lanky ungainly tucked-up creatures now often in a prize pen, and then read descriptions of Sebright carriage a quarter of a century ago, and his only rational conclusion will be that much has here been lost. What says Dixon, whose book was published in 1850:—"Here is a little whipper-snapper! His ample tail, from which sickle feathers are absent, is carried well over his back. His dependent wings nearly touch the ground. He is as upright as the stiffest drill sergeant, or more so, for he appears now and then as if he would fall backwards, like a horse that over-rears himself." What again writes Mr. Hewitt, in Tegetmeier's Poultry Book?—"In the carriage of these birds we find the very extreme of pride, vanity, and self-importance. The feet are raised in walking much more than in any of the other Bantams, and planted again with the greatest deliberation and precision. When alarmed their deportment is most striking; the wings drop to the ground, not listlessly, but as if determined to make the most of their tiny proportions; while the head is thrown back and the tail raised, so that they nearly meet." Other writers lay stress on the nervous motion of the Sebright cock's head being almost like that of the Fantail Pigeon. These descriptions are hardly that of the Sebright of 1881. A large field, it seems to us, is open for the improvement of the breed by intelligent fanciers in smallness and carriage.

On the other hand there has been a great gain in the production of the whole family of Game Bantams. At many a show now they are the chief feature of the Bantam classes. The most numerous by far, yet at the great metropolitan shows of 1852 and 1853 we believe there was not a single pen. Their failing seems to be a tendency to revert to the size of their Game ancestors. Time ought to improve this, for we have often observed that in the case of those varieties of Bantams which have been exhibited from time immemorial no amount of over-feeding seems to increase their size. The great point still to be tried for in Game Bantams is, as it seems to us, the combination of really gamy carriage and characteristics with tiny size. Competition is, however, so close that the fancier is bold who starts with the determination to make himself a name for Game Bantams.

White and Black Rose-combed have, we fancy, on the whole been much improved; a little has perhaps been lost in carriage, but much gained in comb and earlobe, and brilliant gloss of the Blacks. There is room still for improvement in the Whites, and we should be glad to see a fancier or two, who have accommodation to keep white birds clean, and who know how to show them, taking up the breed.

Nankins have always been among our favourites, and so once were Partridge Bantams, their cousins of a darker shade of colour, but the latter are extinct. There are quite enough Nankins here and there to be picked up still to form the nucleus of new strains. They are undoubtedly an ancient race, and are no exception to our rule as to the size of the older breeds being kept down without difficulty. Japanese are entirely a new importation. We cannot find a trace of them thirty years ago. Doubtless they have been bred small for ages in Japan, and even originally reduced from a fowl still common there of larger size, conspicuous for its enormous tail. Pekin Bantams, too, the result of the sacking of the Chinese Emperor's Summer Palace, have been gained, and are now practically lost again. To the best of our knowledge their existence hangs on the slender thread of one yard, the possessor of which will not sell a bird or egg. It would take very many years to produce their like by judicious crosses of small Cochins with other Bantams. It might probably be done, and the attempt would be worthy of some second Sir John Sebright, to be immortalised in the poultry yard. Cuckoo Bantams are probably far better than they ever were before. One or two exhibitors have by their enthusiasm made them almost invincible in Bantam variety classes, whence they very properly are passing on to classes of their own. It is a misfortune when any one breed of large or small fowls monopolises too much attention in general variety classes and hinders the exhibition of other and new kinds. Booted Bantams there were long ago and are still. There seems formerly to have been more variety in their colour than we have now, or at least than we have in good specimens. They had become well nigh extinct, but a suggestion, we think in Wright's Poultry Book, that they would be a pretty "fancy" for one in search of such, caused the revival of the White

variety. For some years they flourished in clever hands, but have again almost disappeared. The difficulty of keeping their foot feathers in good trim is a drawback to them; but a Bantam fancier should be able to attend to such detail in his yard, and have plenty of small pens in which his pets will live happily through the exhibition season and keep in good condition. There were formerly many quaint and pretty Booted Bantams—buff, and speckled and spangled, but few survive. Here, too, is a field for an enterprising breeder. Blacks are often still seen, generally with some red about their wings, but quite good enough to merit attention and improvement. About the last addition to the variety class are tail-less; we have lately a very pretty pair, like miniature tail-less Leghorns. Rumours, too, have reached us of Brahma Bantams one day to proceed in perfection from a famous Brahma yard. An American correspondent has described to us, too, White Polish Bantams—exquisite little creatures, if only the imagination of the New World does not unduly magnify their charms.

Such are the Bantams which we know or have known—enough for many fanciers to choose a *spécialité* and improve it. We wish the Club every success in extending its sphere of operation.—C.

### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at Charing Cross Hotel on Friday, 16th, at 2 P.M. There were present Messrs. S. Lucas (in the chair), T. W. Anns, and A. Comyns.

NEW MEMBERS.—The following members were elected:—Frank Barnes, Farnham, Surrey; R. R. Fowler, Prebendal Farm, Aylesbury; Hon. Mrs. C. Ives, Moyns Park, Birdbrook, Halstead, Essex; H. J. Gunnell, Shelford, Cambridge; F. C. Lawson, Bell Street, Reigate, Surrey. The following new associate members were elected:—J. Bloodworth, Wycombeville, Cheltenham; J. F. Hills, Sudbury, Suffolk; A. Johnson, St. John's, Woking Station, Hants; R. Feaks, Covent Nursery, Cambridge; E. E. St. Quintin, Lee Hall, Lee Road, Lee, Kent. Mrs. Ricketts, Knighton Vicarage, Radnorshire, late an associate, was elected a member.

CLUB SHOW.—The Secretary was directed to communicate with the various railway companies with the view of obtaining cheap return tickets for visitors to the Show to be held at Cambridge on 4th and 5th January.

DISQUALIFICATIONS.—One or two important cases were discussed, but as the meeting was a small one and the matters were not quite ripe for decision it was thought best to postpone the further consideration of them.

NEXT MEETING.—The date of the next meeting was fixed for Thursday, January 5th, 1882, at the Club Show, Cambridge, at 10 A.M.—ALEX. COMYNS, *Hon. Sec. Poultry Club, 47, Chancery Lane, December 20th, 1881.*

### OUR LETTER BOX.

Early Chickens (*W. J. E.*).—Early chickens are easy to rear if you have a barn or outhouse with an earthen floor in which to keep them. They require protection from rain, draughts, and cutting winds; they also want to be warm during the long nights of winter.

### REMARKS.

11th.—Frost in morning; dull day, with slight rain in evening.  
 12th.—Dull and gloomy; drizzling rain greater part of the day.  
 13th.—Fine but misty during the day; thick fog in evening.  
 14th.—Foggy early; moderately fine day.  
 15th.—Dull and rainy.  
 16th.—Wet morning; fine latter part of day; starlight night.  
 17th.—Wet morning; bright for short time in middle of day; very stormy afternoon with heavy rain; gale at night.

A damp week with heavy rain on the last day, temperature lower than last week and below the average.—G. J. SYMONS.

### GARDEN MANAGEMENT.

**Q**UESTIONS on this subject are frequently asked by owners of gardens, also by young men taking charge of gardens for the first time; and certainly the subject is one of great importance to all concerned with horticulture, no matter whether they may be owners, lessees, gardeners in large places, single-handed men, or workmen generally. All have, more or less, to do with the management of the garden, and the subject deserves and requires much study if the best has to be made of everything.

It is not my intention now to enter fully into the question of profit and loss, although there was never a time when this was taken more into consideration than now. In my opinion money properly expended in labour and other things connected with cultivation is amply returned in the produce; however, be this as it may, we may all rely that money spent in gardens at the present time is being weighed and considered by owners, and economy should be the rule with all. But doing with less labour and buying fewer plants and seeds are not the only ways of saving. Bad management is the most serious part of garden expenditure. Loss and dissatisfaction are the only accompaniments to this, and it will eventually do more harm than anything else.

There are many ways of managing things badly. Carelessness and neglect are two prominent features in it. Abusing confidence and allowing third or fourth-rate culture to take the place of first-rate work are other forms. Idle habits and a general course of large or small deceptions by anyone connected with a garden may also be included as important items in bad management. Good management, on the other hand, is a simple matter, easily accomplished by all. An unwavering desire to keep time and do everything in the most conscientious manner are good signs; and while they give pleasure to those who perform them, they are also very gratifying to employers.

Conscience is the helm or regulator of a successful routine. A head gardener should have a large share of this, and those under him should not be wanting in it, or good management will be difficult, at least for a time; but those with a determination to persevere in rectifying errors both in themselves and others generally succeed in placing things right.

To induce those employed in the garden to work properly is the first and most important step to good management. A gardener may have the best intentions, but if those under him are otherwise inclined all will not go right. The workmen we have found worst and dislike the most are those which make a

great show before the face and are the most idle behind the back. If they think their employer is about they will keep their time to a second; but if he is known to be away, one hour or more behind is looked on as nothing. Before-the-face work will be done most particularly; behind-the-back work will only be carelessly done. Trenching will be turned into digging, and where there should be a heat of 80°, 50° may be the figure. Tools, which should all be placed in one house, will be left in out-of-the-way corners, many of them, perhaps, never to be found again until they are spoiled. All such practices as these indicate bad management. All lead to loss, and in the end a reduction of the money devoted to horticulture, as it is out of all reason to suppose that anyone would continue to spend money to uphold such courses.

Reason in everything and for everything is what is much wanted by all to insure perfect garden management; but it is not always the gardener who is lacking in reason. We have known employers who expected more from one man and one acre of ground than could possibly be had from three men and as many acres of land. Others, again, with two or three vineries could not understand why they had not Grapes all the year round when such and such a one had them, but forgetting all the time that in their case the number of vineries were double or more those of their own. With such employers the most skilled managers would never succeed. Still, while many know of cases of the kind I have just mentioned, it is also well known that kind and liberal employers are often greatly deceived and robbed by those under them, and this may not be so much by giving things away or selling them, but the time lost through idling, inattention to proper hours, and similar failings amount in the course of twelve months to a greater loss than many imagine. To lose half an hour in the morning, five minutes at breakfast time, ten minutes at dinner time, and leave off work fifteen minutes before time at night, may not appear much day by day, but calculate what those odd minutes and half hours will amount to in a year, or, further, ten years. This is the true way to look at the matter, and we must act accordingly.

Poor cultivation may sometimes indicate want of experience, at other times neglect on the part of assistants; but if time is well kept in the case of the former, and everything is done in reason, there is more hope of success eventually resulting than with the latter. When we see a young man who knows little, but is always at his work diligently in working hours, we feel more satisfied, and have more hopes of him than some which may be more forward but less genuine. From Mr. Pettigrew and others much good advice has lately been given to young gardeners, and on this account I will only remark that much of the garden management depends on them. In watering, firing, cultivating the soil, and many other duties, they can do their work well or most indifferently. They can also be persevering, and by painstaking may save the head gardener much trouble; and of this they may rest assured, that as they conduct themselves so will their success in life be. Nothing is too much for considerate employers to do for deserving workmen, and the opposite is the case with the other class.

Many employers who have found from experience the importance of having workpeople thoroughly trained have offered suggestions on the subject, and a correspondent from county Wicklow suggests remarks on early rising, doing work regularly, placing tools away properly, and other useful matters,

all of which must be attended to if garden management has to be creditable. In some gardens young men are expected to be up for hours before the usual time and work all day besides; but with this we do not agree, as gardeners have no more right to work more hours than any other class of workmen, nor have they any licence to be behind them any or every day. No good will ever result from loose habits in time. Our greatest factories would soon come to a standstill were their workmen as unpunctual as many of those in gardens. In this respect we had a grand lesson while employed in Kew Gardens many years ago. There the bell was rung punctually at 6 o'clock A.M., the entrance door was kept open for five minutes afterwards, when it was closed, and all those shut out had to remain out until breakfast time, when a quarter of a day's pay was deducted from their wages. Defaulters were entered in the book, and at the end of the year it was easily seen who were the careless men. Deducting the money for time lost besides the black mark had a wonderful effect on many, and if this plan were more adopted we know of some estates where hundreds of pounds would be saved and the management would be better. So long as employers have to bear the loss of such conduct matters are difficult to improve; but when a just master deals fairly between man and man, and makes those who lose time lose the money too, a better lesson is given than all that could be spoken or written in any language. In many places fines are imposed for leaving tools where they ought not to be, and of this we also approve when words have no lasting effect. Our remarks have so far mainly applied to gardens where there is a number of men employed, but small places do not differ from large ones in their general management. Punctuality must be observed in them too, and all the other details must be adhered to, only on a smaller scale.

Next in importance to managing the men is arranging the work, and this devolves chiefly on those in charge. No person should ever be kept waiting and losing time until another job is found for him after finishing his last; indeed, before this men should be told where to go next, dividing them if needed, according to the work in hand. Much time is often lost in having more hands at certain work than there is room for. A good manager will see that this never occurs, and the work will be done in season and according to weather. In going from home sometimes, when it may be fine in the morning, we never forget to state what has to be done should it rain. This we find forwards the work wonderfully, as doing the dry-weather work in dry weather, and wet-weather work when it rains, is the means of placing the work generally in an advanced state. In fact, where a garden is fairly manned, no matter whether its size may require two or a dozen men, if the work is only done according to the weather there need seldom be anything behind. Thinking it is not worth while going out when it is fair, as it is sure to rain again soon, is not the way. Time is then lost which may never be made up in dry weather. "Go in when it is too wet and come out whenever it becomes fair," is our order to all; and were it not for such orders as this we should want one or two more hands to keep our garden in its present state.

Respecting the proper hours to work in a garden, we think ten per day is right, beginning at 6 o'clock in the morning and leaving off at 6 o'clock at night, with one hour for breakfast and the same for dinner in summer, or so long as light admits of full time being worked; and when this cannot be done work from daylight to dark, with half an hour for breakfast and the same for dinner in the shortest days. For long there were no short Saturdays in any garden, but now they are rather general, and on that day work is given up two hours sooner than during the rest of the week. To those who do their work properly no one will grudge this; in fact, really deserving men we always like to treat liberally in this matter, allowing them a day now and again as it is wanted and can be spared, and not being too hard in stopping every hour off their wages which they might chance to lose through sickness; but it is only those who try to make up for this time when they are at work that we treat in this manner. Shirkers and those who will not do five minutes' important work after their hours are up are dealt with after their own ideas. This is how most

gardeners with numbers under them treat their men, and it is generally how amateurs with only one gardener treat him.

In dealing with a number of men their different characters and dispositions are soon apparent, and work should be arranged accordingly. Two or more who are known to be inclined to be talkers should be put together as little as possible. An industrious man and one of the above kind will do better. Men should never be put to do boys' or women's work, if such are kept. The most able-bodied should always be given the heaviest work, and the most experienced should do the particular things. Trying how well and how quick everything can be done is our frequent advice. A thorough interest in all that is done will make everything light and pleasing. Fancy jobs do not need doing daily. Rough work is enjoyable enough if only done in proper weather, which will always be the case if everything is well managed.

In small gardens it often happens that there are one, two, or more old men and women employed through the kindness of the owner. This is very commendable; but when such are not qualified to do a full and reasonable day's work, as is often the case, this fact should be taken into consideration when the gardener's doings are being spoken of. One garden with three young men might be better kept than another with four or five old ones, but it is hardly fair to consider them man for man.

Where there are numbers employed there is generally jealousy, some men thinking that others are getting easier work than they, or are taken more notice of by the heads, and in many cases this may be so, as we can say personally that those men who always try to do most for us are most esteemed and most favoured; but it is simply from their work and actions we judge them and favour them. This is the case generally; so that those who may think they are not getting justice have only themselves to blame for it as a rule. Everyone who has work to do knows too well the advantage of having a person who will do it thoroughly in every sense of the word, to value their services lightly or treat them differently from what they merit.

In conclusion I may just briefly repeat what cannot be too much impressed on the minds of all—that loose ways, inattentions, and every description of irregularities and deceptions, whether they be small or great, all directly detract from good management in all gardens; and those who indulge in them, whether they be master or man, may rest assured that, although they may pass unnoticed and unchecked for a time, they will only lead to their own loss of character, place, and esteem.—  
M. M.

#### ARRANGING PLANTS FOR EFFECT.

OWING to a certain extent to what has been carried out at the metropolitan and provincial shows of late years, a revolution has been effected in the art of arranging plants. The orthodox much crowded, much mixed, and very neat arrangements seem now to be giving way to a lighter, less mixed, and more natural disposition of plants. We get into a certain habit, however; and although we see and read of superior methods it does not always enter into our heads to reform, until perhaps a friend, for friend he or she is, upsets all our preconceived notions of what is best to be done under the circumstances. This was what not so very long since occurred to me. Our conservatory was set out, and, as I thought, the best had been done with the materials at hand. My "eye opener" soon convinced me of our mistake. It was much too flat to please him, especially as the house was tall, being built like so many similar structures, more with regard to external than internal effect. Tall plants we were short of; but says he, "Why don't you elevate the most suitable you have at intervals on flower pots and arrange the others up to and around them?" We did so, making them central plants of groups, thus forming an irregular, higher, and more effective arrangement.

Critics tell us one colour "kills" another, and no doubt they are correct; but if each bright colour is arranged in groups, and these groups divided with the negative white, there is less fear of offending particular tastes, and the general effect is enhanced. That I am not alone in this idea is very evident from the encomiums passed on the conservatory here as lately arranged, and I also find a much-respected neighbouring gardener was in no way overcome by my discovery, having practised it for some time. To further illustrate my argument I will briefly describe the above arrangement, merely adding that we did the best with materials

at hand, and that for the future we intend to grow plants specially for this method of arranging.

The space on which to arrange the plants, considering the height of the house is much limited, the raised beds being divided by wide central paths. A broad band of Selaginella is established at the front of the raised borders. On one side next the door a good specimen of *Dracæna ferrea* was stood on a 12-inch pot, and a conical group formed around consisting of rosy pink flowers, such as *Salvia Bethelli*, *Begonia weltoniensis*, also *Pelargoniums* Master Christine and *Amaranth*, these being fringed with small flowering plants of the same coloured *Pelargoniums*. The next was the central group, and this consisted entirely of silver-variegated foliage, white-flowering plants, and Ferns, the central plant being a good specimen well raised of *Pandanus Veitchii* surrounded by white *Chrysanthemums*, *Callas*, *Pelargonium* White Princess, *Begonia semperflorens grandiflora*, *Eupatoriums*, and *Primulas*. The end group had for a central plant a specimen of *Dracæna indivisa*, the remainder of the group consisting of crimson *Celosias*, the free-flowering *Pelargonium* Guillon Mangilli, and small plants of single *Pelargoniums* of the same shade. The spaces between these groups were occupied by Ferns, principally *Adiantums* of sorts, and midway between each principal group a small group of the beautiful blue *Browallia elata* was disposed.

On the other side of the house entrance and in a line with the last-mentioned raised group a similar group was arranged. Next came a group of yellow flowers, such as *Celosias*, *Chrysanthemums*, and *Coronillas* surrounding a raised plant of *Chamærops humilis*. The end group had for a centre *Yucca aloifolia variegata*, about this being arranged *Salvia splendens* and *Pelargoniums* Wonderful and *Vesuvius*, Ferns being worked around these groups also. The bed opposite to these was sufficiently long to admit of fine groups being arranged. The central group consisted of a tall well-elevated specimen of *Blechnum brasiliense* surrounded by *Celosias*, *Epiphyllum truncatum*, Guillon Mangilli *Pelargoniums*, and red *Primulas*. On each side of this the groups consisted of white-flowering plants, Ferns, and a central erect-growing green *Dracæna*. One outside group had for a centre *Dracæna ferrea*, surrounded by light pink *Pelargonium* Mrs. W. Paul in different sizes and blooming freely, and Reading Pink *Primulas*; the other was composed entirely of free-flowering scarlet *Pelargoniums*, with *Yucca aloifolia variegata* for a centre. Ferns large and small divided the several groups.

It is not necessary to enter into further details, beyond stating how effective a number of *Begonias* of the Rex type and flowering freely were when grouped under a large *Latania borbonica*, and a group of richly coloured *Cinerarias* showed to advantage with a few *Callas*. The white flowers and Ferns form the most attractive groups; *Adiantums* such as *cuneatum*, *formosum*, *concinnum*, and *tenerum* being most suitable for the purpose. A bank recently arranged in a small heated verandah, and consisting of *Centropogon Lucyanus*, scarlet *Pelargoniums*, *Poinsettias*, and tall *Euphorbia jacquiniæflora*, surrounded by *Eupatoriums*, *Callas*, double white *Primulas* and Ferns, is remarkably effective, especially when viewed by lamplight.

The temperature of the conservatory ranges from 50° to 60° by day and 45° to 50° by night, and occasionally still lower, and this and the supplying tepid water seems to maintain floriferousness and health in the various kinds of plants arranged in the structure.  
—W. IGGULDEN.

#### IS POTATO CULTURE PROFITABLE?

A FEW weeks ago one of your correspondents complained of the price of Potatoes, and asked if Potatoes could be grown at a profit at 4*d.* per stone, the price at which he was then selling. The Editor replied that it would depend on the crop which could be obtained. The price mentioned, 4*d.* per stone, would work out to £2 13*s.* 4*d.* a ton. This seems an absurdly low price. It is the price at which Potatoes used to be sold wholesale in Scotland nearly thirty years ago, when the expenses of cultivation and rent and taxes were much lower than they have been of late years, and before the losses by disease were so serious.

I have tried growing Potatoes on a large scale, and I do not think I could make them pay at the price mentioned. The cost of cultivation is considerable; and although the rent of land is less, the rates and taxes are still very high, and the cost of labour more than it was twenty years ago. But besides the expense of cultivation there is the outlay in storing and moving the crop, and the cost of carting to the market; and when the price is low the buyer is more particular in the sample and asks for the small tubers to be picked out.

With regard to a large crop, it may be obtained from land in good condition, but I have not been able to get large produce

without a considerable outlay in manure, which of course adds to the expense; but then comes the question, Why does your correspondent sell at 4*d.* per stone? Depend upon it the dealers who give that price do not sell for less than double. If we allow 2*d.* per stone for selling, the seller would make 50 per cent. profit. Why should not the grower take a share of it? I did when I had Potatoes for sale. I found a dealer who sold for me on commission at 2*d.* per peck. If I could not find one I should send someone round myself. In making these remarks I do not wish to discourage the growth of cheap Potatoes. I think the people have reason to expect them at a cheaper rate as long as the *Magnum Bonum* and other disease-resisting Potatoes hold out, but that the grower should endeavour to lessen the cost of cultivation to meet the reduction in price, and claim a share of the profit when sold to the consumer.—AMATEUR, Cirencester.

#### AN AMATEUR'S HOLIDAY.

(Continued from page 539.)

WHILE thankful that he is not one "who hath no music in his soul, or is not moved by concourse of sweet sounds," but grateful that he can reap much pleasure from, and even contribute, however indifferently, to the same, the writer confesses his inability so to grasp or adequately to appreciate music of the highest class as can be done by those of greater natural endowments and high scientific musical culture. He is aware that in this, as in the domain of the sister art of painting, there is to him a world of unexplored beauty and unappropriated delight—a *terra incognita* far beyond the confines of which he cannot penetrate. Of the sermon thus far preached the application will be obvious.

Conscious of my inability to do justice to such a subject, with great diffidence I proceed to mention my visit to Castle Kennedy. A "WYLDE SAVAGE" would here have a theme "worthy of his steel" pen or graphic quill. I shall endeavour to avoid inaccuracies, but my visit was too hurried; and writing from unaided memory, I can hardly hope to give your readers any idea of what is certainly the most lovely place I ever saw.

The grounds are open to the public on Wednesday and Saturday. I would in your columns again tender my thanks to Mr. Fowler, to whose frank courtesy it is due that, calling as I did on another day, I was not only granted admission, but that I had through this veritable fairyland the conduct of the presiding genius of the whole.

Castle Kennedy, the seat of the Earl of Stair, is in the parish of Inch, about four miles from Stranraer. It possesses all the essentials of beautiful landscape—hill and valley, wood and water, picturesque ruin and imposing modern mansion. The old castle, the remains of which form a striking feature in the picture, was built about the time of James VI., and was held by the Earls of Cassilis. During the reign of Charles II. it came into the possession of Sir John Dalrymple of Stair, and was burned by accident in 1715. The present splendid mansion, in the Scotch baronial style, occupies a commanding site surrounded by a wide amphitheatre of hills. The extensive grounds are laid out in a series of numerous terraces, and include two lakes, the Black and the White Loch, respectively a mile and a mile and a half long by half a mile in breadth. These are really connected, but seem to be detached, and the castle stands on the westmost peninsula that divides them. The whole demesne has in all details been embraced in one grand comprehensive scheme, including the surrounding hills, which also have been laid out for reciprocal effect. In carrying out this extensive undertaking a hundred hands were engaged for several years, and the minimum staff now consists of thirty gardeners, while upwards of a dozen foresters are in constant employ. It is almost unnecessary to add that only by the division of the men into squads, each having its particular quarter assigned, could it be possible to maintain such neatness and order as obtains everywhere. The slope of one of the terraces has been converted into the semicircular auditorium of an open-air theatre, and here concerts are occasionally held, this being one of the ways in which the temperance movement in the district is laudably encouraged. What a place for a rendering of the "Gloria in Excelsis" or the "Hallelujah Chorus" worthy of the surroundings!

I had often heard and read of Conifers; but as I traversed those spacious glades deeply lined with rare specimens, their dark foliage lit up with the beautiful cones, I felt how insufficiently any attempts at description could convey an idea of the beauty of the scene. Nor had I any idea of the variety of habit and appearance assumed by *Araucarias* till there I saw those deep and long lines, more striking to one who had hitherto seen comparatively little more than isolated specimens. Then *Rhododendrons* by, I should imagine, tens of thousands, the addition of

new varieties worthy of admission swelling the already enormous aggregate. It seemed to me that Mr. Fowler had a special love for these, and he seemed to know most of them, as we say, by headmark. Interspersed were Fuchsias of great size in flower. "Come and see us when the Rhododendrons are in bloom." No greater treat could be more frankly offered, and no thanks more sincerely given. Before I mention a few things more within my humble ken, I may say that the arrangement I have tried to indicate, of walks of great breadth between trees of such sorts as I have mentioned, remains in my memory as a characteristic feature of the grounds.

In the short time I had at command I had to hurry past much well worth observing. But I saw, of course, the well-cropped Vines which had made Mr. Fowler so famous as a grower of Grapes. He has for some years, so far as I have observed—certainly not without ample means to further victories—left to others the field where his laurels were so nobly won. On entering the garden my eye was arrested by two long lines of a yellow Viola that I have not seen surpassed. The lines were of considerable breadth, and the dwarf compact foliage was surmounted by a dense uniform mass of bloom. I found *Ageratums* a speciality, and was astonished at the number of seedling varieties and the charming effect of their various shades when grouped and blended as they were. The favourite variety Cupid was raised here. One bed, in the flower garden at the castle, of a lilac bordered by one almost white, was extremely chaste and attractive. A slightly greyish tint is to be eliminated from the latter to secure a pure white, and a step is secured towards a crimson or scarlet. But many of the numerous seedlings would please all but a taste so fastidious as to colour and habit. Two plants of *Yucca gloriosa* in flower were striking objects on one of the terraces. One of these I found to be nearly 9 feet in height. From this plant a limb had accidentally been severed. This had been inserted in the adjoining shrubbery, and was also far advanced in flower. I was much struck with the beauty of the *Chrysanthemums* in bloom in the garden, and was surprised to learn that these stood out all the year, the severest winters seldom necessitating the filling-up of a gap; but, as Mr. Fowler observed, Castle Kennedy enjoys a climate scarcely to be found elsewhere in Scotland.

But my time—evidently not the patience or the courtesy of my conductor—was rapidly becoming exhausted. As I walked on I turned frequently to glance up those beautiful vistas, and felt that I was leaving a scene such as I fancy Scotland at least has little to match. I have seen much of her beauty and her grandeur—something, too, of her sisters, and a little beyond; but Castle Kennedy is unique in the combination of natural advantage and artificial adornment, and the beauty must be seen to be realised. An apology should almost be offered for giving so meagre a notice; it cannot be called a description. To the visitor of an after generation it may well be said of Mr. Fowler, who has spent thirty-five years at Castle Kennedy, "*Si monumentum queris, circumspice.*"

At the station, which is just beyond the gates, I found a number of beautiful Roses kindly forwarded by Mr. Smith of Stranraer. A friendly wave from the obliging station-master, and I sped on with these towards Glasgow, where on more than one of the tables of one of the public institutions they would be, as my own flowers had frequently been, the objects of an admiration—if covetousness entered who will call it sin?—such as those who have the love for flowers but are denied our opportunities for gratifying it, alone can know.—A NORTHERN AMATEUR.

(To be continued.)

NOTES ON POTATOES.—I see that some of your correspondents, in giving their experiences of Potatoes, speak well of certain varieties while others do not, therefore I should like to give the result of my observations. Early Sandringham is the best cropper of early kinds. I grew Rivers' Royal Ashleaf three or four years ago, when the disease cut down the early ones. More than half the Rivers' were diseased, but the Sandringham was quite free from disease. It is a good cropper, good in quality, and very dwarf in growth. Beauty of Hebron is a great cropper of good quality, quite free from disease, far better than Early Rose, for the tubers of the latter are red all through while the others are not. International is good for exhibition, but has poor flavour and rather close substance. Magnum Bonum about here is better in quality than it used to be; the tubers do not grow so large as they did when the variety was first brought here, that is why I think they are better. Snowflake I am puzzled about. Is it a kidney or a round? However, it is a good Potato, though sometimes it is diseased more than others. Of King Noble and Porter's Exeelsior I have only grown a few this year for the first time; they turned out well and free from disease. Schoolmaster, Mr. Abbey says, is poor and waxy; with me it is not only excellent in quality but a good cropper and quite free from disease, indeed one of the best. Johnston's Downshire is light-coloured, and of a Victoria

type. I planted 3 lbs. and dug 50 lbs. good sound tubers, only three or four diseased, also of good quality. Victoria is an excellent variety and good in quality. Champion I do not like, because when cooked it is hard inside. I know many people who will not plant this variety on that account. The following is my selection—Sandringham, Hammersmith, Beauty of Hebron, Snowflake, Schoolmaster, Johnston's Downshire, and Victoria. Can any reader tell me what are the best varieties for light poor soils?—F. WALKER, *J. of W.*

#### DINNER-TABLE DECORATION.

THIS is a matter which many take great interest in, and to which they devote much attention. Like all other fashions it needs to be changed to retain admirers. When the numbers at dinner vary and the tables are changed in size accordingly, plants of different size can be worked in, and a change of the plate or chief centrepieces affords the same chance. Alterations of the kind are always favourable to those who decorate, as none of us like to have the table the same night after night before the same company.

As a rule lightness is always appreciated. Plenty of green with a few bright colours is generally most effective. Small glasses are, to our mind, much more pleasing than spreading the decorations on the cloth, and the main pieces should always be done well. Of these we have arranged many, but one of the best we had recently. The stand has a massive silver base some 2 feet wide, and on this stands for figures holding a flower basket over their heads. This basket is about 18 inches across, and is sometimes filled with plants and sometimes with flowers. On the occasion we refer to there was a good plant of *Cocos Weddelliana* in the centre. A quantity of a small green *Selaginella* covered the pot of this and filled the basket. As a fringe *Adiantum farleyense* was used, and white Chinese *Primula* and Roman *Hyacinth* spikes were cut and placed, not too closely, over the surface of the green. The effect of this was more pleasing than any centre we have made. The *Primroses* and *Hyacinths* looked as if they were growing on the little green mound, and the graceful *Palm* spreading over the whole made the combination complete.—M. W.

#### ADNITT'S PEA PROTECTORS.

MR. ADNITT, The Gardens, Sylvia House, Caterham Valley, has submitted to us a cheap, simple, and useful protector. As some such appliance as this cannot fail to be of great service in all gardens, we submit a greatly reduced figure of the article in question (fig. 91), showing the protector, and (fig. 92) a section. These with the following instructions will enable anyone to make these protectors at a trifling cost. "I make them," writes Mr. Adnitt, "of three-quarter-inch boards 4 inches wide and 6 feet long; make the groove, A A (fig. 92), for the glass to slide in, chamfer the top edges of the boards, and nail pieces of sheet iron on the ends, cut the exact width of the frame, with two nails on each side. I nail a

Fig. 91.

piece of wood 1 inch by 2 across the middle of the inside where the dotted lines are. This is feather-edged at the bottom, and prevents the sides from warping. The top of this cross stay is made flush with the underneath side of the glass. A hoop-iron handle three-quarters of an inch wide is secured with half-inch flat-headed nails. One nail an inch long is driven through the top, where it is bent over the wood. I paint the wood with anti-corrosive white paint and black the handles. These protectors have been in use all the year round for four years, and appear as if they will last four more years without painting. I nail a piece of zinc across the ends of some of them to prevent mice from getting in. The glass is cut so as to work freely in the groove, the two end pieces to fit tightly.

"I have found them of the greatest use in protecting and forwarding early Peas. For the last twenty-five years I have tried raising early Peas out of doors, but as yet I have found no plan approaching this. The protectors are very easily moved from one place to another. A man can carry two in each hand (a length of 24 feet). They are easily stowed away if not in use, which is very seldom, and they are very cheaply made.

"The plan I adopt with these protectors is this: I prepare the ground as is usual for Peas; draw straight drills, sprinkle a little fresh lime and soot in them to destroy any slugs that may be

there; sow the Peas so that they shall be all inside the protector, then cover them with soil, and give a good sprinkling of lime and soot on the top. I then place on the protectors, having one at each end that has a stop to prevent mice and birds from entering. No further attention is needed until the Peas reach the glass, with the exception of an occasional search for slugs. But the protector should be firmly pressed into the ground an inch or so to keep out mice and slugs. When the Peas reach the glass the protectors can be easily raised a few inches by placing them on earth drawn to the rows; this can be done from time to time until the cold cutting winds of spring are past. When the protectors are removed the rows are all that could be desired, and the Peas make rapid growth. Those who sow Peas in November will find these the best of protectors, for when sharp weather comes litter, leaves, &c., may be laid over them, and as easily removed without damage to the plants beneath. I find the best size for Peas is 8 inches wide and 4 inches deep. I make them from 6 to 14 inches wide; these larger are used for forwarding such crops as Radishes,

Fig. 92.

small salads, Lettuces, and Horn Carrots which never come too early.

"Many gardeners in this neighbourhood have seen the protectors in use, and all speak highly of them. Gentlemen who delight to attend their own gardens and sow seeds in the morning before going to business, will find them quite safe on their return in the evening if protected in the manner indicated."

Mr. Lumsden and other good gardeners use protectors of this nature and find them of great value, but we have never seen any simpler, cheaper, and more serviceable than those used by Mr. Admitt; anyone can now make them of the width and depth that may be desired.

#### MIGRATORY BIRDS—A STRANGE WINTER VISITOR.

On Saturday the 10th inst. I was very much surprised to see a chiffchaff here anxiously seeking insects among the ice-covered Ivy. It was nearly starved, and could only fly a few yards at a time. It had, no doubt, been lured over by the previous unusual mildness of the season. The earliest I have ever heard or seen one was on the 13th March this year, and the last I heard was on the 30th September last.

If it is not too tedious to read, I will give an instance of the usefulness of this class of birds which came under my own observation. I was sitting in my garden waiting for my bees to swarm, and having a field glass, as usual on such occasions, I turned my attention to an old willow wren which was feeding three young ones in a row on an Apple tree a few yards distance in my orchard. This, as a rule, would be just half the family, and probably the other parent bird had the other half to attend to, to make matters fair. I took out my watch and noticed them for a quarter of an hour, and during that time the single old one fed them exactly eighteen times, on caterpillars chiefly, collected from the surrounding fruit trees. I will not carry out tedious figures to show the vast amount of good effected to rear a single nest of young, and I think I may defy a single charge being lodged against them, unless it is occasionally breaking off a Rose bud in their work of collecting green fly and grubs.

As it appears from the correspondence the Journal circulates through the length and breadth of the land, I for one reader should be glad to see any notes upon the arrivals and departures of our migratory birds in different localities. Last autumn we

had large flocks of redwings and fieldfares, but scarcely any berries for them, consequently the greater portion appeared to perish, as I only saw a straggler or two in the spring, while this year we have abundance of berries and no birds worth naming to eat them. So far I have only seen three fieldfares and very few redwings. Our resident British birds are almost as scarce. A few years ago thousands of starlings might be seen morning and evening going to and fro to their roosting place, now it is a rarity to see one. In consequence of this great change in nature, caterpillars have committed sad havoc both on fruit and timber trees, and during last summer it was no unusual sight to see trees looking as bare of foliage as in the dead of winter. I shall read with pleasure any remarks from others.—J. HAM.

#### THEORIES IN VINE CULTURE.

(Continued from page 561.)

MR. TAYLOR (page 514) has a very curious theory as regards what determines the character of roots. It is this: If I pinch as he says I ought, my roots will be such as might be "mistaken for those of a Box bush," but if I allow them to get overcrowded they will be "gross roots as large as small quills." Has this been ascertained? If so, it is one of the most singular things I ever heard of, and I will thank Mr. Taylor for particulars.

Another theory is, "that thin foliage which cannot be acted on by the light . . . assists to manufacture crude material which it cannot assist in elaborating." Is this also ascertained? The old idea is that under diffused sunlight leaves act more feebly than under bright sunshine; but that they manufacture a different kind of material which has a special mission, and that mission is the manufacture of fleshy roots, is another new theory—at least to me. Mr. Taylor does not like "cheap science," but only science can clear up such points as are here raised, and I await enlightenment.

My idea is that the character of the border has more to do with the character of the roots than anything else. Nor do I think that the roots of a Vine 20 feet long will differ, except in quality, from one of 10 if both are in similar soil and equally ripened.

Mr. Taylor introduces here the practice of root-pruning, but that need not be here further noticed, as it is away from the point and is not under discussion. As for the fattening of children, unless he beheads them at a certain stage, there is no analogy between growing children and Vines except this, that undue pinching and restriction is good for neither.

I will now refer to Mr. Taylor's letter in your last issue. Your correspondent has the better of me in this controversy, for he "knows what he knows," as Josh Billings would put it, and he also knows what I know, or rather what I do not. At page 561 he says, "It is not known to 'SINGLE-HANDED' that the roots of a healthy Vine continue active long after the leaves have fallen." Not only am I aware of this fact, but his assertion to the contrary, along with another equally unfounded, that I believe in and am an advocate of the "resting-and-drying theory," tempts me to anticipate what I meant to embody in another paper, and refer to a large number of experiments more fully than I can do now; but few as are the words I will use, I think they will sufficiently answer Mr. Taylor.

Several years ago, where I then was situated, the Gooseberries were sadly infested with small mouldy-looking insects. The bushes were not in health, were infested badly with green fly in summer, and next to useless. In the month of November when we were digging the ground I lifted a number of rooted suckers from these bushes and potted them. To see whether the vermin might not be killed and the bushes manured at the same time, one-half of them were watered with cow urine, one-fourth with urine much diluted, and one-fourth had nothing. These were stood outside for two months, when they were carefully examined. Those that had nothing were dead, and so were those that had the diluted urine. Strange to say those that were soaked with the pure urine were growing, while all the insects were dead. Since then I have potted-up all sorts of roots, including Vines, for the purpose of finding out whether pure urine applied to soil full of roots would do harm. It never did, and I have profited by the knowledge thus gained. So far as I am aware our work in this direction has been original, and when I have made further experiments of the same nature under different circumstances I will give the world any benefit that might be derived from it; at the present I have felt compelled to write somewhat prematurely, and more briefly than I intended, on a subject of such importance.

I manure my Vines and outdoor trees with liquid in winter, and had Mr. Taylor seen me soaking the inside border not more than

a week ago with ice-cold water from melting sleet perhaps he would have grown happy over my mistake, as did two smart neighbours who called when I was so engaged; but if I had told him, as I did not tell them, that I was sure (from experiments I had conducted for years that my Vine roots inside were extending themselves at the expense of the rods, owing to the too high temperature of the Vine borders), that a lowering of border heat in winter was as necessary as the lowering of the temperature above, he might have written the article in question, but would have been obliged to attribute the false opinion in it to someone else. But this is anticipating what I have to say on "how, when, and why" I manure my Vines.

I had intended answering what has been written by Mr. Iggulden and "AN OLD GROWER," but Mr. Taylor's second letter intervened; perhaps the two cultivators referred to will find their remarks answered during the progress of this discussion even if they are not personally alluded to. The question at issue is not one of names, but of principles. Possibly as they read further one of the contributors may find there is such a thing as founding an argument on false premises, and the other may have a suspicion that assumption may be mistaken for fact.—SINGLE-HANDED.

#### PRIMULAS IN SMALL POTS.

I COULD not help thinking, when reading "M.'s" notes on Primulas in small pots, which appeared in the Journal of the 15th inst., that however commendable may be the practice of making a 3-inch pot a final receptacle for a Primula to those who have few larger pots and but little room, the general trial he solicits of that system would end in a very general and speedy return to former paths of culture.

I am far from denying that some excellent results may accrue from blooming Primulas in such pots, but when I read that within those circumscribed limits better blooms and larger trusses are obtained than by devoting to them pots of twice the diameter, it appears to me that some mistake has been made. Indeed my experience of Primula-growing convinces me that such is not the case.

I had this summer, like "M.," a batch of well-rooted plants in 3-inch pots, which, being ready, instead of engulfing them at once in 6-inch pots, I chose the more gradual process of transferring them to pots of an intermediate size, in which a few weeks sufficed to fill the soil with roots. I then proceeded to give them their final shift into 6-inch pots, taking care to drain these well, and shaking some light rich soil round the balls until the pots were sufficiently filled. I then gently settled the whole, and placed them on the shelves of a warm greenhouse, where they have grown luxuriantly. Fine sturdy plants they are now, studded with crowns, from the centre of which spring huge trusses laden with fine blooms about the size of an old-fashioned penny, and the soil in the pots threaded through and through with white ramified roots, which, peeping from the surface, appeal as eloquently as ever did toper for "something short in their liquor."—AN OLD PRIMULA GROWER.

#### LEEKs IN WALES.

I HAVE read the remarks by "A. H. H." on page 533. By him Leek culture is represented to be most complicated and not well understood, but it will certainly not be his fault if this continues. He is under the impression that in Wales Leek culture is unsatisfactory. Will he state distinctly where he learned this? I can say Leeks are as common in Wales as they are in any county in Scotland, and their culture, as a rule, is on a par in both parts.

To grow Leeks under the directions on the page quoted a man would need to have a supply of handglasses, cold frames, and hot-beds. He must also sow seed in pots, place these in stove heat, pot singly in 3-inch pots, shift the plants into 6-inch pots, harden them off, and so on; planting out 2 feet each way, and watering with sulphate of ammonia. These are instructions which I call superfluous, and I am sure the majority of Leek-growers throughout the country will say the same. An "Onion head" is said to be the "best part" of the Leek, but it, too, is "objectionable." All "A. H. H.'s" teachings prove that he wants us to grow one batch of fine Leeks for show, and another inferior one for the table, and this is a course I wish to discountenance.

Size is evidently the first and only consideration with your correspondent. It is a pity he did not give the weight of what he considered a good and perfect Leek, and say if moderately strong soundly grown examples are not as acceptable and well flavoured as those grown in a stove and forced as described.

Anyone wishing to grow what may be termed excellent Leeks for the table from November until May, will secure them if seed

is sown on rich ground at the same time as the spring Onions. In fact, they require no more attention than the Onions except in earthing up.—J. JONES.

#### TORTOISES IN GARDENS.

FROM a barrow in the London streets I purchased some two or three months since a tortoise, which the bill exhibited by the vendor informed me was of African extraction, and "good for killing all manner of garden insects." I conveyed my tortoise home, and ensconced him in my garden, which, being surrounded by a brick wall, ensured the tortoise's safe custody. Since then I have watched the horny gentleman on many occasions, but I have never seen him kill or devour insects. During the summer he confined his attentions principally to young Lettuces and Clover, of which latter edible he appeared extremely fond, and conscientiously nibbled every bloom to be found on the lawn. To all appearances he has enjoyed life up to the present time in a leisurely manner, burrowing in cold or wet weather beneath the Rhododendrons in a peat bed, and apparently contented excepting in frosty times, when he appears to become perfectly torpid and remains immovable for several days. Can you inform me whether I ought to remove him from the garden during the winter and give him a corner by the kitchen fire, or otherwise protect him from the frosts and rains of our climate? And if so, what I ought to feed him on until the warmth of spring will enable him once more to pick up a living in the garden?—TESTUDO.

[The reply we gave to a correspondent early in January last appears applicable in this case:—"There are a great number of species, most of which are natives of warm regions of the globe; but those that live in colder climates burrow and sleep during the winter. They are quiet inoffensive animals, extremely tenacious of life, and remarkable for longevity. Individuals are stated upon good authority to have lived upwards of two hundred years! The common tortoise, or tartaruga, Testuda græca, is a native of the south of Europe, and almost all the countries bordering on the Mediterranean. It is found in the islands of the Archipelago, Corsica, Sardinia, and in Africa, and is thought to be more common in Greece than elsewhere. It is from 6 to 8 inches long, and weighs about 48 ozs. This species is often brought to this country, and kept in gardens. One was brought to the archiepiscopal garden at Lambeth, in the time of Laud, in 1633, where it lived till 1753, owing its death more to neglect than the effect of age. You had better place your pet in the greenhouse, or other suitable place, and supply it with food. They live mostly on vegetables, but will eat almost anything, including bread soaked in milk."]

#### SECKLE PEAR.

"E. L. O." asks "Where did 'WILTSHIRE RECTOR' obtain the sample of this Pear which was so very small and of a vulgar sweet taste?" I reply that I had that sample, many dozens indeed, from a tree in my own garden, which tree I had from Messrs. Smith & Co. of Worcester, and also others from a large espalier near me. I have known the Pear for years, and was some time before I made up my mind to denounce it. I live in a grand fruit country, being less than a dozen miles from Bath. I ask, Why grow such a small Pear of what I consider a vulgar sweet taste, fit only for a huckster's shop, when you can grow a large, handsome, and magnificently flavoured one, such as Beurré Hardy, ripening at the same time? I think if we are to compete with importers of fruit it is by only growing the best, and not allowing our gardens to be crowded with, or even to have any, inferior varieties in them. I am daily having at dessert the old Golden Pippin and Cox's Orange Pippin. But how inferior the former is to the latter! It might have been the best Apple in its day, but that day is over. Just so, too, of Juneating and Irish Peach. Why grow the former when you can the latter? We need to clear our minds of old fancies and preferences, and see what is the best, and grow only the best. When at Worcester I saw perfect battalions of Dumelow's Seedlings and Lord Suffields, while only thin ranks of older and now proved to be less valuable sorts of Apples. I say, Choose carefully the best, and gradually advance new claimants to the first rank as they deserve it, but away with the second-rate sorts. I only know of two small Pears that are indispensable—Winter Nelis and Monarch, and the latter is not very small.—WILTSHIRE RECTOR.

CHRYSANTHEMUM SPORTS.—Remembering that some of the best show Chrysanthemums we have were originally obtained as sports—for instance, Mr. George Glennay and Mrs. Dixon, from Mrs. George Rundle, the following extract from a letter just received with a box of blooms from a lady in Sligo may be of interest—"I enclose you

a curiosity—pure white, and bright pink blooms from the same specimen Chrysanthemum, Miss Mary Morgan, or, as it is sometimes called, Pink Perfection. Three stems bloomed early, and produced blooms similar to the pure white; while later on two other stems gave blooms of the correct "Pink Perfection," type, as they have hitherto done. I cannot think of any reason for this except to consider it a sport, which it will be of interest, if I can fix permanently, as it is deserving of being perpetuated."—W. J. M., *Clonmel*.

#### THE DIAMOND TUBEROSE.

THE accompanying woodcut is a reproduction of an engraving published in the "American Gardeners' Monthly" for December,

Fig. 93.—Tuberose The Diamond.

1881, and portrays a plant of most remarkable character, and if faithfully shown one that will prove of such value, that it deserves the attention of our readers. It is, we understand, one of the novelties sent out by Messrs. Nanz & Neuner, who, it will be remembered, sent out the double Bouvardia a short time since,

and which has proved fully equal to the descriptions given of it. We may, therefore, expect the Diamond Tuberose to maintain the credit of the firm, and to be a plant of real decorative value. The very dwarf habit is the most remarkable character of the variety, and it is stated the plants "grow from 5 to 8 inches high and yet produce as many flowers as the ordinary kind." For culture in pots it is, therefore, extremely well suited, and no doubt we shall soon see it in cultivation in Great Britain.

#### EARLY POTATOES IN POTS.

DURING many Decembers we were in the habit of making up long hotbeds of leaves and manure on which to grow our new Potatoes for Easter and Whitsuntide. When the weather all through was fairly mild and good a satisfactory crop which amply paid for labour was generally secured, but in bad springs the opposite to this was the rule. If the frames had to be kept covered for days, and sometimes weeks together, owing to severe frost, when exposed again the young shoots were generally white and weak, and after this the crop was never abundant. In wet weather the manure and the frames were full of moisture, and the young growths not unfrequently decayed at the surface of the soil.

Taking one season with another, we came to the conclusion that to grow early Potatoes on dung beds was not profitable, and often disappointing. At last we thought of growing all early Potatoes in flower pots, and these we have found answer the purpose much better than the frame; 10-inch pots are the best, a hundred of these will give many dishes of fine early Potatoes, and when properly managed there is no risk with them. A crop may be relied on at all times with no more trouble nor expense than was required with the beds and frames. A quantity of roughish loamy soil should be collected, and a little decayed manure mixed with it. Each pot must have a little rough drainage placed at the bottom, and afterwards be half filled with the prepared soil. This should be made level and firm, and the sets can then be placed on it. Two, three, or four sets may be placed in each, keeping them as far apart as possible, and afterwards covering to the depth of 2 inches or more with the soil.

A cool house or frame protected from frost are suitable places for the pots at first, as with a little water the sets will soon produce growth above the soil; and the cooler and nearer the glass the plants are kept at this period the more robust will they remain, and this is a great point gained. Later on they are placed in early vineries or Peach houses, and there the tubers form plentifully and swell quickly. As the weather becomes warmer, about the end of March and beginning of April, they may be placed in frames with the lights over them.

Where there is no room to grow many a few dishes may be had from one or two dozen pots, and when they are turned out I feel sure all will be satisfied with this easy and certain mode of securing early Potatoes.—A KITCHEN GARDENER.

#### THE CHRYSANTHEMUM.

(Continued from page 466.)

IT may be truly said that there should be three main objects kept in view in growing the Chrysanthemum—viz., specimen plants, blooms for exhibition, and plants provided for conservatory decoration only. Specimens are plants trained in globular form from 2 to 5 feet or more in diameter, with the flowers regulated with precision and kept in position with delicate supports. Blooms for exhibition are obtained from untrained plants, and the size and substance of the flower take precedence over quantity or the beauty of the plant. The skill and judgment of the cultivator is here severely exercised in disbudding. A display for conservatory decoration may easily be obtained by growing the plants untrained as for cut blooms, but allowing them to carry as many clusters of flowers as possible. This plan may also be termed a slovenly one, as, grown under the second method, plants are equally as useful for the conservatory, and, indeed, the finer the quality of the flower the more effective must be the display; but, whatever object the cultivator has in view at starting, it is first necessary he should commence with

*Propagation.*—Cuttings should be taken from around the base of the plant as early as possible after the plants have bloomed. Insert three or four cuttings in each 60-pot, employing a light soil and silver sand; place the pots on a bed of ashes in a cold frame, protecting them from frost by covering with mats. Although most successful cultivators prefer the earliest cuttings, they may be taken during January and February with equal success; but if taken very late it is a good plan to place them in moderate heat,

but cuttings struck in heat are by no means so sturdy as those that are placed earlier in a cold frame.

*Potting.*—When the cuttings are well rooted—which, if inserted at once, will be about February—they will require potting singly, still using light soil, and return them to a cold frame as before, placing the tallest at the back of the frame and the shortest in the front, drawing the lights off on all fine mild days to keep the plants dwarf and sturdy. About April the plants will be benefited by another shift, this time into 6-inch pots, or 32's, using more loam in the soil than in the first potting, returning them again to the frames until all fear of frost is past, when they may be placed out in an open space to await their final potting about the middle or end of June. For untrained large-flowering plants to supply flowers for cutting for exhibition a 16-size pot, or 9 inches in diameter, is very suitable; specimens may require a larger size, according to the strength of the plant. Pompons will thrive and bloom freely in a 24 or 8-inch pot; indeed, some may be successfully grown even in smaller pots, and will be found useful. Employ a compost of two parts good yellow loam, one part of well-decomposed manure, and sufficient sharp sand or road grit to make the whole porous; a little bone dust or pounded oyster shells will be found a valuable addition. Efficiently drain the pots, and place a layer of the roughest portion of the compost over the potsherds before filling in the soil. Pot firmly.

*Stopping.*—Some cultivators like to stop the growth of their plants once about the time they give them their first shift, and doubtless good flowers may be produced in this way, but as yet I have failed to see that they produce finer flowers than from plants that have never been pinched at all. An advantage can be gained in the height of the plant, and for a home display, or for the arrangement of groups, plants that have had the leading point of the shoots taken out at the time of the first shift have a decided advantage on account of their sturdiness; but if large flowers only are desired my advice is, Never pinch. If specimen plants are required select the strongest plants at first, and commence to lay the foundation of the plant by early stopping it, and at intervals afterwards take out the extreme points of the longest shoots until the last week in June, or at the latest the first week in July.

*Training, Staking, and Watering.*—As soon as the plants are transferred into 32-sized pots a small willow or other light stake should be placed to them in the case of single stems to prevent them being blown off by the wind, and for specimens each branch should receive the support of a neat stick of sufficient length to answer the required purpose. When the plants are fully grown great taste and regularity are needed in tying out so that the training is not made offensive to the eye, like the flat specimens often met with at exhibitions; the growths twisted and distorted so as to destroy all beauty. When the untrained plants have received their final potting they will require a stronger stake, which will also in time require to be secured to a horizontal wire or stout string to prevent the plants being blown about. The gales at the end of September are generally very destructive to Chrysanthemums unless they are well secured, for it is very easy in these gales to lose the whole of a season's efforts. Chrysanthemums require water frequently, especially if the plants are arranged along the edges of a hot garden walk or in an open position, for it is not considered a wise plan to plunge the pots, more especially if the plants are left to root through, which will check them and prove injurious to the flowers. On hot days it is a good plan to damp the foliage well. Clear water will suffice for them until the end of August, when most of them will be disbudded and the flower buds formed, then they will stand in need of something more stimulating than clear water. Clay's and Standen's manure are very good and easily applied. The former manure is now generally used for softwooded plants, and I have frequently heard successful prizetakers of Chrysanthemums say that they believe their success has been mainly due to the use of Clay's fertiliser. Guano and sulphate of ammonia are also good, but must be used cautiously. My own choice has been the diluted drainings of farmyard manure and soot water, supplying it frequently and weak, with a few supplies of guano or patent manure during the time the buds are swelling.

*Disbudding.*—About the middle of July it will be observed that the plants when grown in a natural manner have only one straight shoot, at the extreme point of which a flower bud will appear. It is not this bud that must be retained, but from just below this flower bud there are four leaf buds, which will commence swelling; and in the course of a month, if the plants are in a healthy condition, these three or four breaks will each have a flower bud, and then disbudding must be resorted to if large flowers are required—merely leaving the centre bud and pinching away the other shoots below, which if left would again throw out other growths and

flowers, but these flowers would be found both late and small, and therefore useless for exhibition.

*Housing.*—Any dry and open greenhouse is a suitable place for housing the plants. Usually about the first week in October is a good time. Early frosts are scarcely then sufficiently sharp to do much damage to the advanced buds, but if there is a prospect of frost house them at once, as all the lower petals will be so damaged as frequently to cause the calyx to decay also. I had some plants that were out in two sharp frosts in the early part of October this year, and they suffered considerably. Two plants—Miss Mary Morgan and Jardin des Plantes—were killed, while my friend Mr. Jordan told me that he lost grandiflora and one or two others in the same way. A Peach house is well adapted for aiding the further development of the flowers. No one would scarcely credit the difference it makes between good flowers and bad in housing plants in a light, open, and well-ventilated glass structure, and lofty dark and gloomy conservatories. Here again, it is not a wise plan to stand them too thickly, and if a little heat can be applied on damp foggy days it is a great advantage.

*Insects.*—At all stages of their growth the Chrysanthemum is very liable to the attacks of green fly, which infest the extreme points of the young growths. In the case of young plants it is a good plan to dip the points in tobacco water, but with larger established plants a dusting of tobacco powder after rain or heavy dews should be tried. This can easily be washed off after a day or two. Earwigs are also destructive generally at night, damaging the foliage, but more frequently the flower buds and growing points. Pieces of Broad Bean stalk or small rolls of paper placed between the stem and the stalk will frequently entrap them, when they can be blown out in the morning and destroyed. Notes on dressing the flowers and a selection of the best varieties in each section will be given next week.—J. W. MOORMAN.

WE are informed that the date of the Exhibition of the REIGATE ROSE ASSOCIATION has been fixed for Saturday, 1st of July, 1882, and that an attractive schedule of prizes will be duly announced.

— THE HORTICULTURAL EXHIBITIONS at the Royal Botanical Gardens, Manchester, Mr. Bruce Findlay informs us, will be held in 1882 on the following dates:—14th March, 4th April, 2nd May, at the Town Hall. The National Horticultural Exhibition opens at the Gardens 26th of May; Rose Show, 14th and 15th of July; Show of Gooseberries and Dinner-table Decorations, 7th of August; Cottagers' Show, 8th and 9th of September; and the Chrysanthemum Show at the Town Hall, 21st of November.

— PROBABLY it is not generally known that the COLLECTION OF FERNS AT KEW includes more than eight hundred species and varieties, excluding the numerous forms of British Ferns and many doubtful ones amongst exotics. This is one of the finest representative collections of the great Fern family in the world, and it is surprising how so many plants from such widely different situations and climates can be maintained in satisfactory condition. Even those pretty but fastidious genera the Cheilanthes, Nothochlaenas, and Pellaeas appear to be improving, though the two former are rarely seen thoroughly healthy. Further accommodation might be advantageously supplied to the Fern collection at this establishment, for neither of the houses open to the public are constructed in the best possible manner.

— THE plants of Messrs. J. Carter & Co.'s "BLUE PRIMULA HOLBORN GEM," shown at the last meeting of the Royal Horticultural Society, were in better condition than they have previously been exhibited, being dwarf and compact in habit with neat trusses of flowers. The very distinct tint marking this variety could not, however, be seen to the best advantage owing to the

partial darkness prevailing at the time ; but it was apparent that the bluish colour is being improved and deepened. The ultimate result if this progress be continued will, no doubt, be a very distinct race of Chinese Primulas.

—WE recently announced that it was intended to make a PRESENTATION TO MR. E. S. DODWELL on the occasion of his removal from the neighbourhood of London in consequence of his failing health. The Committee then formed with that intention obtained subscriptions to the amount of £108 6s. 6d., which enabled them, after deducting £3 6s. 6d. for expenses, to present Mr. Dodwell with a cheque for a hundred guineas.

— PART 3 of ICONOGRAPHY OF INDIAN AZALEAS, which we have received from M. Auguste Van Geert, contains coloured plates of Mdlle. Louisa de Kerchove, Camille Vervaene, and Roseo Pieta, the last a very attractive variety with large well-formed flowers, white prettily streaked and dotted with bright rose. It is of German origin, said to have been obtained by M. Schultz from seed. The colouring of the flowers in each case is good, but the foliage has a rather unsatisfactory tint.

— A PRIMULA GROWER writes as follows upon SUPPLYING WATER TO PRIMULAS—"I find it very difficult to induce my young men to give proper attention to watering these plants, and as I grow a large number carelessness in this respect leads to rather serious results. With many plants the chief danger to which they are liable is a too liberal supply of water ; but in the case of my Primulas it is the opposite, for I believe they more frequently suffer from the soil being dry than from excess in the other direction. The leaves of an apparently healthy plant will be seen to be drooping quite suddenly and unexpectedly ; it then in all probability receives a thorough watering, and the consequence is that when subsequently turned out of the pot and examined the soil is found to be completely saturated and the roots apparently decayed. Now I consider that the roots are destroyed by the soil becoming too dry, and an application of water is then too late to enable the plant to recover. The rule I endeavour to enforce is that plants should be watered every morning when the soil is at all dry, and at this time of year at least once a week give them a thorough watering—that is, first select those which are dry, and then give them all an equal supply."

— AMONG the papers read at the last meeting of the METEOROLOGICAL SOCIETY was one on the "Rainfall of Cherrapunji," by Professor J. Eliot, M.A., F.M.S. Cherrapunji is notorious for its excessive rainfall, larger in amount, it is believed, than at any other place, so far as is known. Cherrapunji is a small Indian station, situated in the south-west of Assam on a small plateau forming the summit of one of the spurs of the Khasia hills. These hills rise on the south with exceeding abruptness, and have the Bengal plains and lowlands at their base. Cherrapunji stands on the summit of one of these hills at an elevation of about 4100 feet. The hill on which it is situated rises precipitously from the lowlands of Cachar and Sylhet, which are barely 100 feet above sea level. During the S.W. monsoon the lower atmospheric current advancing across the coast of Bengal has a direction varying between S.S.W. and S.E. in lower and central Bengal. In thus advancing almost directly towards the hills of western Assam the mountain ranges cause a very considerable deflection of the current. One portion is forced upwards as an ascending current with a velocity directly dependant upon the strength of the current in the rear, and upon other conditions which need not be enumerated. The rapid diminution of temperature which accompanies expansion due to ascensional movement of air is usually followed by rapid condensation in the case of a moist current, such as the S.W. monsoon current. The normal annual rainfall in Cachar and in the plains of northern Bengal is about 100 inches.

The average annual rainfall of Cherrapunji is 493 inches, that is 393 inches in excess of that at the foot of hills on which it is situated. The rainfall of Cherrapunji is not due to any abnormal local conditions of atmospheric pressure, air movement, &c., but simply and solely owing to the presence of a vast mechanical obstruction, which converts horizontal air motion into vertical air motion.

— A WRITER in "The Gardener" gives the following note upon a little-known plant:—"Of neat and pretty little trailing plants for a window or cool greenhouse I have one now in my mind's eye (and, thanks to Mr. Moore of Glasnevin Gardens, in the greenhouse also), and that is of all things to be desired. I allude to the 'BLUE-FLOWERED SHAMROCK' (anent which English name I am confident, having had it direct from the maker thereof), or as it is known of the botanist, *PAROCHÆTUS COMMUNIS*. For the benefit of those who do not know the plant under either of the above names I will liken it in habit to a plant of white Clover, also supposing that instead of the bossy heads of many white flowers only one bloom is produced at each axil of the creeping stem, and that one blossom of the size and colour of that of the 'Chick Pea' or Chickling Vetch, yeleft *Lathyrus sativus* in Latin, as opposed to the vulgar tongue. Now small blue Sweet Pea-like flowers, borne on slender stalks 2 or 3 inches high above a Clover-like tuft of Trefoil leaves, is, as I take it, a great if somewhat old-fashioned rarity, and as such I hereby most heartily commend it to all who care for plants of interest apart from bold colour effects."

— WE learn that Mr. G. Bailey, late foreman at Trentham, succeeds Mr. Dell as gardener at Wyfold Court, Henley-on-Thames. Mr. J. Ellicott, late foreman at Syon, succeeds Mr. Harris as gardener to H. Tugwell, Esq., Crowe Hall, Bath.

— WE are informed that the following SPECIAL PRIZES will be offered by MESSRS CARTER & Co., Seedsmen, High Holborn, London, at the various meetings of the Royal Horticultural Society during next season—At the great summer Show, May 23rd, for the best fruit of Carter's Blenheim Orange Melon—first prize, £2 2s.; second prize, £1 10s.; third prize, 15s.; fourth prize, 10s. 6d.; fifth prize, 7s. 6d. At the Pelargonium Society's Show, June 27th, for the best four dishes of the following Peas (fifty pods each)—Carter's Stratagem Pea, Carter's Telephone Pea, Carter's Pride of the Market Pea, Telegraph Pea—first prize, £5; second prize, £3; third prize, £2; fourth prize, £1; fifth prize, 10s. 6d. At the Show of the Association, August 3rd, of British Bee-keepers, for the six pots of Tomatoes as follows—Carter's Golden Drop, Carter's Grapeshot, Carter's Red Currant, Carter's Dedham Favourite, Carter's Greengage, Carter's Holborn Ruby. At the winter meeting, December 12th, for the best twelve dishes of vegetables, to comprise twelve Onions, Golden Queen; twelve Onions, Silver Ball; twelve Onions, Golden Globe; twelve Turnips in variety; three Cauliflowers, three Celery, fifty Brussels Sprouts, twelve Potatoes, six Carrots, six Parsnips, three Red Beet, six Leeks. First prize, £5; second prize, £3; third prize, £1 10s.; fourth prize, £1; fifth prize, 10s.; sixth prize, 7s. 6d.

— A CORRESPONDENT sends the following respecting DAMAGE TO FRUIT TREES AND OTHER CROPS BY SMOKE—"At the Sunderland County Court on Friday 16th inst., before Mr. Meynell, the County Court Judge, and a special Jury, Messrs. R. Gibson & Sons, market gardeners and nurserymen, sued Messrs. J. G. Kirkby & Co., brickmakers, for damages to their crops, alleged to have been sustained by the fumes and smoke of defendants' brick kilns in Tunstall Lane, Sunderland. Mr. Strachan, barrister-at-law, instructed by Mr. W. M. Skinner, solicitor, was for the plaintiffs, and Mr. Atherley Jones, barrister-at-law,

instructed by Mr. Bowey, solicitor, appeared for the defendants. Mr. R. Gilson, A. Balfour, nurserymen of Newcastle, Mr. Crament, gardener to Mrs. Backhouse, Ashburne, Sunderland, and other witnesses spoke as to the injurious nature of the smoke coming from the defendants' works; and Mr. Balfour estimated the damages done to the complainants' fruit trees and other crops at £35. Mr. J. Thompson, nurserymen of Newcastle (principal of the firm of Thompson & Son, Ravenside), and Mr. P. Ferguson of Mere Knolls, Monk Wearmouth, both attributed the unhealthy state of complainants' fruit trees to the presence of red spider, and the loss of the Onions to the attacks of the Onion fly. Both witnesses also spoke as to the unusual severity of the late frosts, particularly in early June, when the destruction of early vegetables was general in the county of Durham. Both witnesses were also agreed that the slight damage sustained by the complainants' trees was ascribable as much to adverse weather and the close contiguity to the town as to the fumes of defendants' brickworks. In summing up the Judge said that there could be no doubt that wherever manufactories of this sort went on vegetation generally was sure to suffer. The Jury found for complainant for £30. The case attracted considerable attention in the neighbourhood, there being many gentlemen's gardens round the district where the brickworks are."

#### PEAR NOUVELLE FULVIE.

LIKE the Pear we submitted last week, this variety receives little attention in the current literature pertaining to a fruit on which so much, yet not too much, is written, for the Pear is beyond question the most important of all hardy dessert fruits. Although Nouvelle Fulvie is not one of the most handsome of Pears, it is nevertheless one of the best of its season. The fruit is usually ripe in January and February, and is of delicious quality. Like most other late Pears the trees need the shelter of walls, and it is only in the southern counties that satisfactory fruit is produced on trees in the open garden. A Pear of such excellence is worthy of a place amongst late Pears, and hence we give it more prominence than it has hitherto received. The following is a description of this good Pear—Fruit medium-sized, pyriform. Skin green, changing to yellow, and thickly dotted all over with russet; when fully exposed and in a warm climate it has a red crimson cheek, which is bright when the fruit is at maturity. Eye half open, with dry horny segments, rather deeply set. Stalk about three-quarters of an inch long, occasionally fleshy, and united to the fruit by some fleshy folds. Flesh fine-grained, melting, very juicy, with a rich and exquisite flavour. It was raised by M. Grégoire, of Jodoigne in Belgium, in 1854, and named by him after one of the members of his family. Our figure on p. 587 represents a very fine specimen of this Pear.

#### CHRISTMAS AT CHELSEA.

It matters little what month the visitor may choose for a journey to the world-famed nurseries of Messrs. J. Veitch & Sons, Chelsea, he always finds abundance to interest him. However dull or cold the weather be, the numerous houses are thronged with handsome plants, forming a series of exhibitions of the most select and beautiful character. Winter has no dullness there. Perhaps the superb collections of Orchids are not quite so strongly attractive as at other seasons, when they constitute such a grand feature in the nursery; but even in December they contribute in no mean degree to the general effect, and many other plants scarcely less choice or showy amply supply whatever deficiency may be observed in that class. Few indeed but those who well know the resources of the establishment would think it possible so much of interest and beauty could be provided in a nursery in the third week of December; but winter-flowering plants have in recent years received so much attention, so many new introductions are annually sent into commerce, and such care is given to the selection of varieties in certain classes of plants to prolong their particular season, that we shall soon have at command as great a diversity of floral beauty at this season as at any other period of the year. Indeed, some of Messrs. Veitch's most recent and most useful novelties are plants specially adapted for winter decoration, among which it is only necessary to mention *Jasminum gracillimum* and *Begonia socatrana* as examples, each of which will undoubtedly take a place amongst the most popular plants in cultivation; but the following

notes, though necessarily brief, will give some idea of what were specially attractive in these nurseries at Christmas, and they will also indicate how easy it now is to render cool or warm houses gay in no mean degree at what is considered to be horticulturally one of the duller periods of the year.

ORCHIDS.—Though there was not the abundance of flowers which will render the houses devoted to these plants so brilliant a month or two hence, yet, as might be expected, in such a rich, diversified, and well-grown collection there was much that was noteworthy. Greatly improved varieties of well-known species, beautiful hybrids, new introductions and rarities, provided plenty of interest for the increasing number of Orchid lovers and growers. Foremost amongst the novelties was *Calanthe bella*, a very beautiful hybrid, the result of a cross between *C. vestita* and *C. Turneri*. It is quite distinct from both parents, being extremely vigorous, producing a very long spike, frequently 3 feet in length, the flowers being arranged on the upper half. One very remarkable quality is the great size of the flowers. The sepals and petals are broad, white tinged with rose; the lip is particularly large, of a similar hue, but having in the centre a rich crimson blotch, which imparts a great attraction to the flowers. The outline is very even, and there is a general appearance of great substance. The Floral Committee of the Royal Horticultural Society recently signified their appreciation of its merits by awarding it a first-class certificate. Another handsome *Calanthe* is *C. Sedeni*, with pink flowers and a deep rose blotch in the centre, while the several varieties of the useful *C. vestita* and the valuable *C. Veitchii* were still attractive. The last-named scarcely needs a word of praise; it is now so well known and is so thoroughly appreciated that it has become almost indispensable wherever Orchids are valued.

Cypripediums have received much attention at Chelsea, and many beautiful hybrids have been obtained, which, together with the numerous species and their varieties now grown, constitute a collection of great value and interest. At this time of year the old but useful *C. insigne* is in its best condition, and when represented by some of the best varieties, such as *C. insigne Maulei*, which was there in excellent form, it is one of the best of the genus for general culture. One unnamed variety had surprisingly large flowers, the white margin of the dorsal sepal being broad and pure, and the lip was also of good colour. The very distinct and pretty *C. Sedeni* with its rose-tinted flowers was noteworthy, as were also the following—*C. euryandrum* [*C. barbatum* × *C. Stonei*], a handsome form with imposing flowers; the dorsal sepal broad and streaked; the petals long, slightly hairy at the margin, and darkly spotted. The lip is suggestive of *C. barbatum*, but usually surpasses it in size. *C. selligerum* [*C. barbatum* × *C. lavigatum*], is also a distinct form with large flowers; the dorsal sepal broad, white with dark streaks; the petals are long, moderately broad, faintly streaked with crimson, spotted with a darker shade, and slightly hairy. *C. vexillarium* [*C. barbatum* × *C. Fairrieanum*], one of Mr. Dominy's raising, was very attractive, its fine flowers and dwarf habit rendering it a fine addition to the garden form. The dorsal sepal is purple streaked on a whitish ground, the petals broad, and the lip neat in outline, and resembling the pollen parent. *C. cenanthum* [*C. insigne Maulei* × *C. Harrisianum*], though not bearing such large flowers as some of the others already mentioned, this is a very beautiful form, and when seen in a good light is particularly striking owing to the peculiar glossiness of the blooms. The dorsal sepal is about 1½ inch in diameter, nearly circular in outline, the greater portion being thickly spotted with shining deep claret purple, running into streaks near the centre, a narrow but evenly defined margin of white relieving the darker centre. The sepals are nearly 2½ inches long, about half an inch broad, with a slightly undulated margin, the glossy purplish hue being evenly spread with the exception of a few spots near the base; the lip is small but neat, and of similar colour to the petals though rather brighter. Several others were also flowering, *C. pyenopterum*, and *C. Harrisianum* being the most noteworthy, the former a distinct hybrid, and the latter an older but beautiful form of hybrid origin.

Odontoglossums are grown in thousands, and several of the advance guard were already flowering. One very fine variety of *O. Alexandræ* had seventeen flowers of excellent form in a spike. *O. Halli* was represented by a superbly coloured variety. *O. odoratum* was flowering freely. *O. tripudians*, a comparatively recent acquisition, with neat bright brown-barred flowers, the diminutive but pretty *O. blandum*, the magnificent *O. triumphans*, and *O. limbatum* with others were all flowering well. Phalænopses of all the best species and varieties were showing an abundance of flower spikes, but recent fogs have done them much mischief, though, doubtless, they will as usual produce a fine display later on. Cattleyas also give great promise, innumerable sheaths being

produced. Many other Orchids were flowering, but sufficient have been enumerated to indicate the chief attractions in that department.

**PITCHER PLANTS.**—It is within the memory of many when *Nepenthes* were represented in very few British gardens; indeed until quite recent years they have been regarded as so extremely difficult of culture that they could be only included in those collections where houses could be specially devoted to them, but it is now becoming known that many can be had in satisfactory condition in an ordinary stove or Orchid house. The consequence of this is a great increase in the demand, and to meet it numbers of new forms have been introduced, and hybridising has been

resorted to with encouraging results. The houses appropriated to *Nepenthes* at Chelsea may be fairly considered the head quarters of the forms in cultivation, and probably it would be impossible to find a collection to rival it in Europe. Scores of plants suspended from the roof bore hundreds of pitchers, representing great diversity of form. From the long pitchers of *N. distillatoria*, which in the Glasnevin variety are much finer than the ordinary type, to the broad massive rounded pitchers of *N. bicalcarata*, there are numerous gradations, the colours and markings being similarly varied. The last mentioned species is at present far ahead of the others in general strength of habit, the broad leaves matching the capacious pitchers very well. *N. Rajah* is still young, but it is

Fig. 94.—PEAR NOUVELLE FULVIE.

developing satisfactorily, and good provision has been made for its continued progress. In *N. madagascariensis*, too, the pitchers are not fully developed, but the fine deep red colour marks it as one of great promise. But certainly one of the most distinct and one which might be easily recognised among any at present known is *N. Veitchii*, which is remarkable for the very broad brown or yellowish green margin to the mouth of the pitcher, the body being long and green shaded with brown. *N. Mastersiana* with neat and bright-coloured pitchers; *N. Morganiana* streaked with red; the richly spotted *N. Hookeri* and the deep-coloured *N. sanguinea*, and the old *N. Rafflesiana* with others innumerable, are all

growing and "pitchering" admirably, in some cases perhaps better than they would in their native habitats.

**STOVE PLANTS.**—Among the vast numbers of these it is difficult to select a few for note, as all are good; but chiefly confining ourselves to the novelties we still have abundance. Foremost among these the beautiful *Jasminum gracillimum* deserves notice. When shown at Kensington for the first time last year it attracted much attention, and the plant exhibited at a recent meeting of the Royal Horticultural Society fully confirmed the high opinion that was generally formed of it, and proved that the first-class certificate awarded was well merited. Several specimens of good size in one

house admirably indicate the character of the plant. The long slender arching or drooping branches produce fine clusters of pure white fragrant flowers from nearly every axil. On one we observed about a dozen clusters showing, which develop successively from the apex of the shoot downwards. A plant so graceful in habit and so floriferous at this season of the year is extremely valuable, and will undoubtedly soon become a general favourite.

Another handsome new plant of special utility for this season is *Begonia socotrana*, which has been flowering for the past two months, and is still in good condition. This has been frequently mentioned in the pages of the Journal, and it fully deserves all that has been said in its favour. It is one of the most distinct species of a large and useful genus, the rich rose hue of the neatly formed freely produced flowers, the compact habit, and the large, thick, bright green, circular, shield-like leaves rendering it unique. The leaves vary a little in shape, but the majority are suggestive in form of small *Nelumbian speciosum* leaves, and on this account the plant is attractive even when not flowering. It will succeed either in a stove or intermediate temperature, the latter, we think, being rather preferable, as the flowers last longer and the growth is more robust.

Crotons are largely represented, and have their distinctive colours finely developed. *C. Hawkeri*, which has been figured in your pages, is very handsome, and in its way is quite unrivalled. The contrast of light yellow and dark green in the foliage is very striking, and several plants having now attained a good size show in the best possible manner how well the characters are preserved and even improved with age. *C. Evansianus* is quite a different type, with broader leaves richly marked with crimson, and *C. Cronstadtii*, with voluted leaves, is also highly coloured and beautiful; indeed, these form a capital trio worthy of cultivation in every collection.

The charmingly elegant *Asparagus plumosus nanus* was in beautiful condition, several scores of plants being alike marked by the same dwarf habit, which renders it so valuable for decorative purposes. The finely divided leaves, the segments of which resemble fine hairs in size, closely interlaced to form a gauze-like delicate leaf somewhat triangular in outline. These are admirably adapted for bouquets or buttonholes, and for table decoration small plants are especially well suited. Like other ornamental forms of the genus *Asparagus* this one can be grown in a lower temperature than that of a stove, though it appears to thrive either way; but probably the cooler temperature would be preferable where the plants are to be employed for decoration.

Turning to the Ferns, of which a large and choice collection is grown, there are many worthy of note, but two of the leading novelties can only be mentioned now. The first of these, the pretty *Gymnogramma schizophylla* (figured in this Journal page 277, last volume), is making good progress, the largest specimen well showing the distinctive characters of the species. As grown in a basket, with the long finely divided and forked fronds gracefully arching, the merits of the plant for such purposes cannot be over-estimated. Another good Fern, well suited for culture both in pots and baskets, is *Lastræa Richardsi multifida*. This when in good condition is a very beautiful variety with broad bright green fronds, the apex of which, with the tips of the pinnae, are neatly crested, imparting a very distinct appearance to the Fern. The fronds have a fine arching habit and are of good length, frequently reaching 3 feet. It is of robust constitution and free growth—in fact, a really useful addition to the list of cultivated Ferns.

Greenhouse plants were as bright as could be desired, many interesting old and new plants being in flower; but they cannot be referred to now, as these notes have already acquired considerable length, and to do justice to the occupants of the cool structure would need at least an equal length. However, readers may conclude from the preceding that Christmas at Chelsea was far from dull in a horticultural point of view.—SAXON.

**PETRIFIED FORESTS.**—An American gardening magazine recently published the following:—"In 1871 the petrified remains of a forest of Redwood, Oak, and other trees, thrown up from a lower level by volcanic action, and deeply imbedded in tufa, still with many portions of trunks some feet above the surface, were still to be found midway between Golden Pass and the Ute Pass, in the Rocky Mountains. It is now said to have disappeared, at least so far as anything is to be seen above the surface. It is said that another of these wonderful pre-historic series of remains in Sonoma, California, is fast disappearing before the zeal of relic-hunters. It is to be regretted that these wonderful remains of the mysterious past could not be preserved, and it may not yet be too late for the State to do something towards that end. The one in Colorado must have been buried very deep by the volcanic dust, as at the time referred to one of the trunks was hollow, and a string and a

stone at the end was let down and found to go many feet beneath the surface. No doubt if this old forest could be dug out to the original surface of the ground many interesting relics of plants and animals might be brought to light."

#### PERISTROPHE SPECIOSA.

THIS may be considered as one of the most useful and ornamental winter-flowering plants, and one that cannot be over-estimated for room and conservatory decoration. The flowers are bright purple and of moderate size, thus making themselves quite conspicuous amongst flowers of a duller colour. Most gardeners will know it under the name of *Justicia speciosa*; but our botanical brethren are not satisfied with old-fashioned names, but must be constantly altering them, so in order to keep pace with the times we must adopt the new one. *Peristrophe speciosa* was introduced to this country about 1826, and forms one of the greatest ornaments of the forests in the interior of Bengal. It is a plant easily propagated and easily grown, and should find a place in every garden where winter-flowering plants are appreciated. The individual flowers, like many other members of *Acanthaceæ*, do not last very long, but one point in their favour is they are not all produced at one time, so that a plant lasts in beauty some few weeks in a cool airy house. I have tried the same plants two years in succession, and have come to the conclusion that they are far from satisfactory the second year. The best way is to grow a new batch every season. When the young plants are fairly established the old ones may be thrown away.

The best time to insert the cuttings is the latter end of February or beginning of March. If placed in a little bottom heat they soon form roots. The cuttings may be inserted singly in thumb pots, or four or five in large 60-size pots, in any light sandy soil. As soon as the cuttings are rooted they may be potted into large 60's, and kept a little close for a few days till they begin to root, after which the ventilation must be increased. When they have filled their pots with roots the tops should be pinched out to induce a bushy habit. A few days after pinching they should be transferred to 48-pots, employing rich soil, consisting of good fibry loam, well-decomposed manure, a little leaf soil, and a dash of river sand. My best plants this season, and plants that flowered most profusely, were grown in 48-size pots; but if plants of a larger size are required, then the third potting will be necessary into 32's. It will be necessary to again pinch the points out of the leading shoots after they have become sufficiently long. Stopping them twice is all that will be required to insure good bushy plants. When the season is far enough advanced, and the plants well established, they may be grown in a cold frame for three or four months during the summer. By growing them cool, near to the glass, and well exposed to the sun, using no more shading than is absolutely necessary, I find they make stouter and shorter-jointed wood than when grown in heat. About the end of September if the weather is cold they should again be housed, giving a fair amount of air and liberal supplies of liquid manure. During their season of growth they should not be allowed to become dry at the roots; if so, they soon lose their lower leaves and look unsightly when in flower. By introducing them to a little more heat they can soon be brought into flower; but I find those plants that expand their flowers in a temperature of about 60° last longer in perfection than those that have been subjected to a higher temperature.—W. K.

#### SILKWORMS AND SILKWORM-REARING.—4.

(Continued from page 546.)

HAVING described briefly in the preceding article the growth of the silkworm (*Bombyx Mori*) from the egg until it has arrived at maturity (fig. 95), I remark further that, owing to the fact of the grand increase in size taking place after the last change of skin, any deficiency of food during the conclusion of the caterpillar life inevitably stunts the growth. It may not prove fatal, but it would tend to reduce the size of the cocoon or to impoverish the silk. The worms appear to feed at this time, with little cessation, by night as well as by day, and if we are in a room that contains a number of them busily engaged, the noise caused by the quick movements of their jaws can be distinctly heard. Now, too, as the growth nears completion, the delicate creamy tint of the skin begins to be displaced by a hue of yellow or yellowish brown. There is also observable a greater transparency. As in a multitude of other caterpillars, the disinclination it showed to move while food was plentiful around it is changed for a singular activity. The silkworm now crawls hither and thither in a way that seems purposeless, having ceased to eat, and shows a particular wish to climb up any vertical objects that may happen to

be near. From this propensity the breeders of silkworms call the period between the cessation of their appetites and the commencement of cocoon-spinning the mounting or ascending season. This desire to wander is brought to an end by the discovery of a suitable nook or resting-place where the cocoon can be fixed.

At the beginning of its task a silkworm throws threads on different sides of the space chosen in a rather irregular manner. Some of these are stoutish cords, serving to fix the cocoon; others are spun loosely, being a sort of floss silk, forming an envelope for the compact structure which is thereafter woven with such regularity as to allow the thread to be unwound entire if care is exercised. Coiling itself round, and employing its body as a measure, the worm draws out and works in the thread until all its silk is exhausted, this operation taking about three days. For a time its proceedings can be watched, but as the silk accumulates on the cocoon the worker is hidden from view. The calculating Robinet, in his comments upon this species, tells us that according to his reckoning a silkworm has to move its head three hundred thousand times in the construction of its cocoon. Say the average time is three days—that is, seventy-two hours, by a process of reduction we discover that there must be about sixty-eight movements in each minute. Another naturalist has informed his readers that the thread of forty thousand cocoons joined together would pass a silken band round our earth at the equator.

Fig. 95.—Adult Silkworm (*Bombyx Mori*).

Its labours being completed, the silkworm then assumes an attitude of repose, the body thickening, and the legs disappearing, until in two or three days more it undergoes pupation, and the larva skin is thrown off. There are curious and exceptional instances of a couple of worms uniting to form a double cocoon; from these the moths are apt to emerge more or less crippled. In two or three weeks' time, the chrysalis or pupa contains a moth ready to be developed, and on bursting its shell the insect liberates itself from the silken prison by applying a liquid to the walls. M. Guérin-Meneville, on dissection, found a gland in the head from which this is emitted by the newly emerged moth; and then having well moistened the cocoon, it is able to open up a passage to the outer world. The threads are by this process disunited, though not actually broken, therefore the moth is never allowed to proceed as far if the cocoon is to be utilised. We may observe here that the cocoons vary in colour according to the race. The com-

Fig. 96.—Full-sized Cocoon of *B. Mori*.

Fig. 97.—Small Indented Cocoon of ditto.

moner colours are white and yellow. White cocoons produce a silk which is considered to be of the highest value and greatest beauty; the bulk of the silk is, however, obtained from cocoons of various shades of yellow. One race of silkworms yielding yellow silk has a particularly large cocoon, but the silk is not esteemed as much as that afforded by cocoons of medium size. Then there are races whose cocoons are greenish white or decidedly green. Still more singular is a breed belonging to Tuscany, with cocoons of a rosy tint (figs. 96 and 97).

It has been already stated that the East appears to be the

native region of this species, *B. Mori*, and that from Turkey the culture of the silkworm passed into other European lands, Italy and France having in the eighteenth century had the pre-eminence, and the latter country retaining to the present hour its importance as a nursery for the silkworm, in spite of fluctuations arising from domestic disturbances or failures in rearing the species. We shall hereafter notice more minutely the details of silkworm management in France, its successes and its difficulties, since these have an important bearing upon the experiments that have been made, or may yet be made, in Britain. Leaving this for the present, we would note that recently the rearing of the silkworm has been tried with good results in so many lands, that it may really be styled a cosmopolitan insect.

India, which has within its boundaries such varieties of climate, offers fine opportunities for silkworm culture in many extensive districts. Large Mulberry plantations have been made in the Mysore territories, and much excellent silk produced by this silkworm has been sent into the market, especially from Bengal. Though in some parts of India the Mulberry is found to grow with too great rapidity, in most of the provinces it flourishes quite as well as in the colder regions of the West. And it is favourable for the extensive rearing of *Bombyx Mori* that its suitable food may be obtained in all inhabited countries, save a few tropical ones, by the planting of Mulberry trees, a circumstance which does not belong to the history of other silkworms, where, though a species may be "acclimatised," a substitute must often be sought for in place of the natural food plant.

The vast island of Australia appears likely to furnish us with good supplies of silk in course of time. A recent statement from Melbourne is that its climate admirably suits the growth of the Mulberry and the development of the silkworm. In other parts of Australia the settlers have shown themselves anxious to try the culture of silk. The Sandwich Islands and the West Indies have been suggested as suitable for this purpose. Persia, one of the early homes, probably, of the silkworm, has districts with large plantations of Mulberries where silk might be easily produced in quantities, but at present only a little is obtained every year. From California we get the report that the silk-growers have already planted nearly ten millions of Mulberries, and they have succeeded in getting two or even three broods of the silkworms in a season. A lady resident at the Cape of Good Hope has discovered that the Mulberry thrives in the colony and the worms are reared easily; further north, in Natal, silk of first-class quality has been obtained. The modern Chinese, however, intent upon pushing their fortunes in foreign lands, have rather neglected one industry of their ancestors at least. Travellers report that in many localities the hills are covered with Mulberries where no silkworms are reared.—J. R. S. C.

#### HARDY FRUIT GARDEN.

As soon as pruning and nailing wall trees is finished standard trees should have attention, removing all superfluous shoots and branches, thinning out the spurs where too crowded, in order to freely admit sun and air to mature the crops of fruit. Only trees that are much crowded with wood should be treated in this manner. Trees infested with moss and lichen should have the bark scraped so as to remove the moss, and may be afterwards dressed with strong brine, and young trees should be pruned, removing any shoots crossing each other or likely to interfere with the formation of symmetrical open heads. Trees which have attained considerable size and are unproductive, or if the variety is of inferior quality, may now be headed down, and in spring grafted with varieties that experience has proved suitable to the soil and situation. Soil and locality have much influence upon the health of the trees and the quality of fruit, some kinds of Apples and Pears being excellent in some parts whilst in others they are practically worthless. Therefore in forming new plantations of fruit trees it is always advisable to plant largely of the kinds succeeding in that locality, and to plant moderately of other kinds, until their suitability becomes known.

Bullfinches are already appearing and will require close watching,

or their attention to the already prominent buds of fruit trees, especially Plums and the Gooseberry bushes, may prove destructive of next year's crop. Shooting them is the only sure remedy. Gooseberries and Currants are often neglected in pruning at this season on account of the depredations of these birds, the work being delayed until a period when the pressure of other matters is considered of more importance, which is not favourable to the production of fine fruit. In pruning Gooseberries it must be remembered the fruit is borne on the young wood of the present year's growth and on spurs where the young wood has been shortened-in. The bushes, therefore, should have the young shoots moderately thinned, spurring in the side shoots on the main branches to a couple of eyes, the longer and stronger shoots shortened so as to form a symmetrical bush. Varieties of pendulous habit should be encouraged upwards by keeping a clear stem and shortening the points of the lower shoots. Black Currants bear on the young wood, and being erect in growth, only require thinning, removing old growths and encouraging young shoots from near the base or as low as possible, shortening the upper shoots as required. Red and White Currants do best when spurred-in to the main branches, which should not be more numerous than to form a symmetrical bush with the centre open. When pruned and the ground cleared a good dressing of manure may be given, and lightly dug or pointed in, except for young trees between which the ground is cropped, and may be dug more deeply. Deep digging only induces deep rooting and strong half-ripened shoots which produce little fruit. Cut down autumn-fruiting Raspberries close to the ground, mulching the stools with decayed manure. The fruit is borne on the young growth of the current season, hence the necessity of cutting the canes close so as to direct the energies of the plant to produce vigorous growths for the autumn crop.

#### FRUIT HOUSES.

*Vines.*—The earliest-forced Vines in pots are now well advanced for flowering, and should have a night temperature of 70°, falling to 65° in the morning, or during very severe weather to 60°, keeping the heat at 70° to 75° by day, with a rise of 5° to 10° from sun heat, moderately ventilating on favourable occasions, keeping up moderate moisture by damping available surfaces in the morning and early afternoon, and this with the moisture arising from fermenting materials will afford ample moisture in bright weather, that from the fermenting materials being sufficient in dull weather. Allow a fair extension of lateral growth, but do not allow more to be formed than are to remain, as a severe reduction of foliage gives a check disastrous to the swelling of Grapes and their finishing well. Keep the roots well supplied with tepid liquid manure, and the heat steady about the pots at 75° to 80°. Early-started Vines planted out have commenced growth, and the temperature should be maintained at 60° to 65° at night and 70° to 75° by day, with a few degrees advance from sun heat, ventilating carefully above 75°. Disbud as soon as the best breaks are distinguishable; and although it is advisable to leave more growths than will be allowed to carry bunches, no more shoots should be encouraged than when fully developed will have space for full exposure to light and air. Do not be in a hurry in stopping, allowing the shoots to make two or three leaves beyond the bunches before taking out their points.

Syringing must be practised in the morning and early afternoon of fine days, turning over a portion of the fermenting materials every morning, renovating with a little fresh stable litter as may be necessary, or keep the evaporation troughs regularly charged with liquid manure—guano water at the rate of 1 oz. to the gallon of rain water. Cease syringing when the bunches are clear of the foliage. Vines started early in the month are breaking freely, and should have the temperature gradually raised to 60° at night and 65° to 70° by day, with 5° to 10° advance from sun heat. Syringe two or three times daily, but only to provide a genial condition of the atmosphere, as an excess of moisture induces thin flabby foliage, long-jointed wood, and aerial roots from the rods. See that fermenting materials on outside borders are not allowed to become cold, but replenish with fresh materials as necessary. The Vines intended to afford ripe Grapes early in June will need to be started at once. Those that have been subjected to the process in previous seasons will start

readily into growth; indeed, they are now breaking, but those not so treated will need a temperature of 55° artificially day and night, advancing to 65° from sun heat, whilst those before alluded to should only have 50° at night, 55° by day, and 65° by day from sun heat. Syringe the Vines twice, and if the weather be bright three or more times a day, allowing them to become dry at night. Young Vines will need the rods depressed to insure the buds breaking regularly. Push forward the pruning and dressing of Vines from which the foliage and crop have been removed, cleansing, and if necessary painting the house.

Late Vines with the Grapes still hanging require the atmosphere as dry as possible, maintaining a night temperature of 40° to 45° for Black Hamburgs, and ventilating freely by day in favourable weather. Muscats must have a temperature of 50° and a little air admitted constantly, as a close cold atmosphere soon causes the berries to spot and decay.

*Cucumbers.*—The weather has been very favourable for the growth of the winter-fruiting plants, and they are more robust and healthful than is the case when the weather is such as to render extra firing necessary. Light is a very important element in Cucumber cultivation. It is essential, particularly at this season when the days are at the shortest, that the glass be kept thoroughly clean both inside and outside. In dull weather avoid giving liquid manure freely, as it tends to induce flabby unhealthy growth. Be careful not to overcrop the plants now, and do not allow the fruits to hang too long, as it greatly weakens the plants. The fruit cut will keep fresh several days if the neck end be inserted in saucers of water and kept in a moderate temperature. If canker is noticed in the old growth press quicklime well into the infested parts. Continue the instructions given in our last calendar in regard to temperature, &c.

*Pines.*—If a sufficient number of plants failed to form fruits in October or November of such kinds as Black Jamaica, Montserrat, Smooth-leaved Cayenne, and Charlotte Rothschild, plants starting now into fruit will not be ripe in May and June; and as that is an important time to have ripe fruit, efforts must be made to induce plants of other kinds that ripen more quickly, such as Queens, Enville, and Providence, to start into fruit at once. If a fair proportion of the successional stock has been subjected to a somewhat dry and cool treatment a selection from such plants can be made, choosing those which have developed an enlarged base with a tendency to open in the centre. These should be placed in a light house and have a brisk bottom heat of 85° to 90°, the top heat varying from 60° to 70° at night according to the weather, and 5° more by day and 10° from sun heat. Maintain a genial condition of the atmosphere by sprinkling the plants once or twice weekly and occasionally damp the cool surfaces about the house, but avoid steaming by damping highly heated hot-water pipes or syringing the surface of the bed between the plants. See that the soil at the roots is sufficiently moist, employing tepid water with a little guano in it, applying it copiously when needed, which in the case of healthy plants will be about every ten days, but a weekly examination of the plants should always be made. Continue the temperatures as before advised to other stock in their several stages.

#### PLANT HOUSES.

*Stove.*—Although bottom heat as a medium for plunging the pots of stove plants in is not so much employed now, there can be no doubt that a bed of fermenting materials, such as a bed of tan, is highly favourable to the growth of the plants, and causes a considerable saving of fuel. A bed of tan will maintain a temperature of at least 90° for two months. To render assistance in this way no time should be lost in preparing the material, all fresh tan being decidedly preferable; but where this is difficult to procure Oak leaves form the best substitute, having a good reserve to add as the heat declines or the material subsides.

*Clerodendron Balfourianum* is one of the most useful decorative plants. It flowers quite freely in a young state, the wood being well matured, plants in 6-inch pots being very useful; but it should be grown in quantity, as successional plants can be had in flower at almost any season by plants in different stages of growth. To rest the plants they must be kept dry at the roots, even so as to cause the

leaves to flag rather freely before any water is given, and then only a little to enable them to recover somewhat, and keeping in a temperature of 55° at night. After a few weeks' rest they will start freely into growth and flower in a brisk moist heat, and, the ball being dry, immerse it in tepid water until saturated.

*Orchids.*—Be careful not to excite these into growth at this season, as rest is of the greatest importance to Orchids; and as this is the dullest and usually the coldest period of the year the temperature should be the lowest, not employing more fire heat than is absolutely necessary to keep the heat in the East India house at 60° by day and 55° at night; the Mexican house 55° by day and 50° at night; the cool house 50° by day and 45° at night, allowing a few degrees rise by sun heat. Cool treatment at this season will result in a more vigorous subsequent growth. Although attention must be paid to the moisture of the atmosphere, a saturated atmosphere now causes serious injury, but, on the other hand, it must not be allowed to become so dry as to cause the stems and leaves of the plants to shrivel. A little water poured on the benches and paths every morning when the weather is fine will be sufficient. Dendrobiums intended for late flowering, such as *D. Farmeri*, *D. densiflorum*, and *D. macrophyllum giganteum*, which are easily retarded, should now be placed in a cool house and kept dry, similar remarks applying to *D. nobile* which it is desired to retard until May should be placed in a greenhouse temperature, giving little, if any, water until they begin growing, when they must have heat as well, as it is prejudicial to check any plant after it has started into growth. *Dendrobium nobile* is one of the most useful Orchids for decorative purposes, and it is very easy to keep up a succession of blooming plants. Those grown in 6-inch pots are useful for filling vases, &c., from January to May by calculating each batch of plants to last in flower about three weeks. Those that completed their growth early have their buds in a forward state, and if placed in heat and supplied with a little water they will flower in a short time.

## THE BEE-KEEPER.

### HONEY AS AN ARTICLE OF FOOD.

WE have much pleasure in publishing the following excellent paper read by Mr. T. W. Cowan, F.G.S., of Horsham, at the Brighton Health Congress:—

Mr. Cowan said that bees in olden time were extensively cultivated for their honey and wax, and it was remarkable how frequently allusion was made to these products by ancient writers. We read that the land where Abraham dwelt was one "flowing with milk and honey," and that in the Mosaic law there were many statutes regulating the ownership of bees. Solomon recommended the use of honey in the words, "My son, eat honey for it is good." About 600 years B.C. bees seem to have been regularly cultivated, for Solon made a law requiring bee hives to be placed 300 feet apart in cultivated fields. The Persians, Grecians, and Romans made use of honey extensively, and it was used for sweetening their beverages. It was mixed with wine, and to this day it is used by the Spaniards in sweetening "Malaga wine." It was used up to the seventeenth century when sugar was introduced, and as the use of this increased the use of honey decreased. On the continent of Europe bee-keeping had been carried on more extensively in former times than in England, and for a long time we had been depending on foreign supplies.

In the olden times, when bees were destroyed by brimstone, different ways were adopted for separating the different qualities of honey. The light-coloured combs were pressed and strained to get the best quality, and the inferior honey was used to make "*pain d'épices*," a sort of gingerbread sold in every town in France. Large quantities were imported into this country from Cuba, Chili, and, lately, extracted honey from California. It was not until the formation of the British Bee-Keepers' Association in 1874 that really much progress was made in developing the honey resources of this country. Bees are no longer destroyed to obtain their honey, but are induced to build straight combs in frames, and these are taken out, and, having the cells uncapped, are placed in an extractor, by which means the honey is obtained in a pure state, and very different to the heterogeneous mass of honey, pollen, and crushed brood which was formerly known by the name of honey. He stated that there was great economy in being able to return the combs to be re-filled, inasmuch as it took 20 lbs. of honey to make 1 lb. of comb. He wished it to be understood that bees did not make

honey, but that they collected it from the nectary of flowers, and that each flower yielded honey of its own peculiar flavour.

The climate of England was particularly suited for the purpose of bee-keeping, and there was no country where it could be produced better in flavour than in this. He said pure honey should be used by every family. It was no longer a luxury only to be enjoyed by few, but was sufficiently cheap to be within the reach of all. It had properties which made it a valuable food. It differed from alcoholic stimulants, which dull the intellect, as it produces a bright intellect. Children were very fond of honey, and one pound of it went further than a pound of butter. It had the peculiarity of keeping good, whilst butter would become rancid, and thus is injurious to health.

In recommending honey as an article of food caution must be used, as there was much foreign honey that was adulterated. Pure honey would granulate and become solid on the approach of cold weather; it could, however, be made liquid by placing the jars containing it in warm water. The adulterated honey was always liquid and transparent, and would not granulate. He read an extract from an American paper, in which Mr. Murth stated that one gallon of honey was mixed with ten gallons of glucose. Glucose had no flavour of its own, but partook it readily from this small admixture of honey. He would always look with suspicion upon honey said not to granulate. He would recommend consumers to purchase pure English granulated honey, and reduce it to its liquid state themselves. He was glad to say that adulteration had not yet commenced in England, and from the vigilance of the Bee Associations he did not think it would be attempted.

Associations were being formed in many counties in connection with the British Bee-Keepers' Association for the purpose of spreading a knowledge of bee-keeping and developing the honey resources. There were fourteen county associations; and if those who are in a position to do so would take a deeper interest in aiding this particular work, he was sure they would not only find it a healthful exercise, but would be pecuniarily benefited, at the same time being able to procure a wholesome article of food.

[We trust the Associations referred to will receive the well-merited support of the public in furtherance of objects at once so important and commendable.—ED.]

### BOILING WAX.

HAVING read Mr. Pettigrew's remarks on the above subject (page 550), I will refer to the plan I adopt, and which I find to answer well with the smallest amount of trouble and waste. I send these particulars for the guidance of any reader who may wish to follow the plan.

First procure a piece of fine copper gauze, No. 36, as large as convenient to use, turned up a little all round to hold as much comb as possible (the piece I use is 13 inches by 10); second, a dish to hold the gauze and to receive the wax as it melts; third, another dish or tin a little larger partly filled with water for the smaller dish to stand in and to keep the wax from burning. Squeeze the combs together so that more may be put on at once, and fill the gauze with as much as it will hold and place it in a good hot oven; refill with combs as it melts down, and empty the dish into moulds.

This year I did not take the combs to be cleaned by the bees on account of the commotion it always makes amongst them, but those that were not worth draining with the other combs I put with the others on the gauze, the honey in them running through with the wax settling at the bottom, which I put into a feeder and gave it the bees in that way at night.

In my plan the combs need no washing to remove the pollen, &c., as mentioned by Mr. Pettigrew in the latter part of his letter, which must be an unpleasant task. All the dirt remains on the top of the gauze, which only needs emptying off in the fire now and then after all the wax has run through. I feel sure that anyone who tries the above plan will be pleased to see how comparatively easy it is in comparison with the boiling plan.

I am glad to say this season has been a very good one here in comparison to the previous two seasons, when I did not get an ounce of honey, but had to feed liberally. This year I had 80 lbs. from one hive and two supers.—P. RAINFORD, *Wigan*.

### TRADE CATALOGUES RECEIVED.

E. Webb & Sons, Wordsley, Stourbridge.—*Spring Catalogue, 1882 (with coloured plates).*

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Gesneraceous Plants.*

W. M. Crowe, Upton, Essex.—*Catalogue of Miscellaneous Plants.*

B. S. Williams, Upper Holloway, London, N.—*Illustrated Catalogue of Flower and Vegetable Seeds.*

Harrison & Sons, Leicester.—*Illustrated Catalogue of Flower and Vegetable Seeds.*

Diekson, Brown, & Tait, Manchester.—*Catalogue of Flower and Vegetable Seeds (illustrated).*

James Vick, Rochester, New York.—*Floral Guide (illustrated).*

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Flower and Vegetable Seeds (illustrated).*

Bruant, Boulevard Saint Cyprien, Poitiers, France.—*Catalogue of Novelties.*

Charles Sharpe & Co., Sleaford, Lincolnshire.—*Catalogue of Vegetable and Flower Seeds (illustrated).*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Correspondence (Z. W. P., and Others).**—Owing to the great pressure upon our columns, your letters with a number of other valuable communications we are compelled to hold over until next week.

**Gros Colman Grape (Amateur).**—We do not advise you to include it in a "small collection in a very small house," because the Vine requires as much if not more space than any other variety, it being a very strong grower. A lateral spread of 4 feet should be afforded, or fine well-finished fruit cannot be expected to follow with certainty.

**Poinsettias (L. O. E.).**—We shall shortly publish some cultural notes on this brilliant winter decorative plant from a gardener who grows it successfully and has afforded us proof of his skill. If, after reading the article in question, you require further information we will readily supply it if you will specify your wants.

**Ivy for Fence (York).**—No doubt Ivy would be as suitable as any other evergreen for covering your fence, but it will need to be secured with nails and shreds, as it will not adhere satisfactorily to boards whether they are tarred or not. The tarred fence when dry and sweet will not prevent the growth of the Ivy. The spikes issuing from your *Cælogyne* are no doubt flower spikes. The plant will not require shade at this season, and a genial minimum temperature of 55° to 60° will be suitable. With a moderately moist atmosphere syringing will not be required, as too much moisture causes the spikes to decay.

**Leaf-miners on Cineraria (C. E. M.).**—These leaves have been attacked by a small maggot, the larva of a fly in the genus *Tephritis*. The species is uncertain till the insect can be reared to maturity. It is allied to the well-known Celery fly (*T. onopordium*). That, however, quits the leaf and descends to the earth to undergo pupation, while on this species the larvæ, when adult, have secured themselves to the leaves. We fear there is no mode of dealing with this pest by way of precaution, but all leaves that have tracks or burrows should be removed and burnt.

**Midseason and Late Peaches (J. E.).**—You do not state the number you require. The following are better varieties than those you name:—Mid-season—Early Grosse Mignonne, Old Grosse Mignonne, Bellegarde, Noblesse, and Royal George. Among the best later Peaches are Barrington, Princess of Wales, and Gladstone; the last-named was exhibited in fine condition and successfully at the Manchester autumn Show. Lord Palmerston is a noble-looking Peach, but often inferior in quality and seldom first-rate. The best yellow-fleshed Peach is Early Crawford, an American variety. The best late Nectarine is the Victoria. Very late Peaches are not usually satisfactory; one of the best is Desse Tardive, which you may safely include in your collection. If you do not possess Mr. Rivers' work, "The Orchard House," you would find it useful. It is published by Longmans, and can be had through a bookseller for a few shillings. If you can give us an approximate date of the article to which you refer we will endeavour to find it, but the number may be out of print.

**Persimmon (J. R. L.).**—The tree known by the above name is *Diospyros virginiana*, very common in the middle and southern States of America, and is there called Persimmon. When ripe the fruit is round, of the size of an ordinary Plum, and of a dark yellow colour, containing a soft yellow pulp, in which the seeds are enclosed. When green the fruit is very harsh and astringent, but when perfectly ripe, and after it has been subjected to frost, it is sweet, glutinous, and agreeable. It is said that in the southern and western States it is made into cakes with bran, and used for making beer, with the addition of water, hops, and yeast. A spirituous liquor is obtained by distillation, the infusion has been fermented. The unripe fruit contains tannic acid, sugar, malic acid, colouring matter, and lignin; and it has been used advantageously in diarrhoea and chronic dysentery. The wood is very hard, but brittle and white, and is very good for joiners' tools, such as planes; but it soon rots when exposed to the weather. The bark has been employed as a febrifuge.

**Grapes Shanking (H. M., Paris).**—The following extract from the "Cottage Gardener's Dictionary" will answer your inquiry—"Shanking is an ulceration or gangrene, attacking the footstalks of the bunches, and appears to be occasioned, like shrivelling, by the temperature of the soil being too much below that in which the branches are vegetating; and, consequently, the supply of sap to the Grapes is much diminished, and the parts which thus fail of support immediately begin to decay. This is an effect always the consequence of a diminished supply of sap, apparent either in the leaves, flower, or fruit. The coldness of the soil causes this torpidity in the action of the root; and this perhaps at the very period when the greatest demand is made upon it to sustain the excessive perspiration which is going on in the leaf, and to furnish fresh matter for elaboration, to both which ends it is frequently quite inadequate, owing to drenching rains. If the young fibre be examined at such in-

ment periods it will be found somewhat discoloured, and in some cases quite rotten. Shanking, we conceive, is generally caused by the unnatural disagreement of temperature between the root and top, independent, in the main, of the question of moisture. It generally occurs with Vines which have been somewhat forced; seldom on open walls—seldom with Vines forced in pots or tubs."

**Mignonette in Pots (T. P. C.).**—The following instructions, which were communicated by a first-rate cultivator, will perhaps be of service to you—"Mignonette, which is a general favourite on account of its delightful fragrance, is seldom seen in good condition except in market-growing establishments. It is of easy culture, and within the reach of everybody. September is the best time to sow the seed for raising plants for spring blooming. The most useful-sized pots are 48's, and the most suitable compost two parts of turfy loam and one of decomposed cow manure, with a sprinkling of old lime rubbish. Place over the crocks about 2 inches of decayed manure (as the Mignonette delights in a rich compost), and fill the pots with the above compost; press the soil in firmly, sow the seed rather thinly, and sprinkle a little soil over it; plunge the pots in a cool frame in ashes within 3 inches of the glass, supply water rather sparingly till the seed germinates, after which the plants should have very little water. Thin the plants out well, retaining about six or seven in each pot. Ventilate freely night and day to keep the plants sturdy, leaving the lights off altogether on all favourable occasions. Discontinue watering from the middle of November till the end of February. This is the secret of success, as if the plants are watered through the winter they become weakly and drawn, and the result is never satisfactory. Do not mind the plants flagging a little, which sometimes they will do when the sun is rather strong. About the first week in March they will require to be watered rather more, never allowing them to become dry; ventilate freely, and when they show bloom water with liquid manure. Place a neat stick to each plant, so that the air may circulate well amongst them." Seed may also be sown now and onwards for producing successional plants, placing the pots in a very light position in a pit or greenhouse. We are unable to give you the address unless we know for what purpose you need it. See our request at the head of this column. If you require any particular information we are quite prepared to supply it if you will state your wants fully and clearly.

**Cypripedium spectabile (A. James).**—You have been correctly informed. The plant is quite hardy, but it is admirably suited for growing in pots and large shallow seed pans. There cannot be too much said in favour of this lovely Orchid, as it possesses merits which should make it a general favourite with all plant-growers; and when its perfect hardiness is taken into consideration with its present inexpensiveness there is no reason why everyone should not possess one of the very best perennial Orchids. The plant is easily distinguished from all others. It grows from 1 to 2 feet high, the stems being more or less covered with leaves of a light green colour and conspicuously veined. The flowers, which are borne singly or from two to four on the stems, are very showy; the sepals and petals are spreading, ovate in form, the petals being much the widest, pure white in colour; the lip is very much inflated, of a rich rose colour, sometimes nearly crimson. The soil best suited for it is good peat and coarse sand, with some sphagnum chopped up fine and mixed with the peat. If grown in pots several should be placed in a large pot and kept plunged in moss or fibre in a shady place. When well-grown it is a most beautiful plant for exhibition purposes, and it can be readily forced. It can be equally well grown if planted outside in peat and sand in a shady place or on the rockery, where it is quite at home with many of the Primulas, Dodecaedrons, and Ferns. It forms a lovely companion for Ferns. The stems springing up from among the light green fronds of the Lady Fern are exceedingly attractive, and the plant thoroughly enjoys such a home. We have had it planted in old stumps with other rarities, when it seemed to be peculiarly happy.

**The Cashew Nut (Lorrimore).**—The Nuts to which you refer are produced by *Anacardium occidentale*, a small tree 16 feet high, a native of the East Indies, the West Indies, and South America; but it is supposed that the East and West Indian are two distinct varieties. The fruit of this tree is formed by the enlargement of the footstalk of the flower, and is about the size of a large Orange, with an agreeable subacid flavour and a slight astringency. It is sometimes of a yellowish and sometimes of a red colour. The juice expressed from it and fermented yields a pleasant wine, which, when distilled, a spirit is drawn from it superior to arrack or rum, making an admirable punch, and acting powerfully as a diuretic. They are eaten when ripe, and frequently roasted for mixing in punch to give it a pleasant flavour. At the end and on the outside of this fruit grows a kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of two shells. The outer is of an ash colour, and very smooth; under this is another which covers the kernel; and between them there is a thick black juice, which is very caustic; but the kernel when fresh has a most delicious taste, and abounds with a sweet milky juice. They are eaten like Chestnuts, either raw or roasted. These Nuts are what are known as Cashew Nuts. The juice which they contain is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation followed by blisters, and it has often proved very troublesome to those who incautiously put the Nuts into their mouth or break the shell.

**Nucleus Hives (Inquirer).**—We have a letter on this subject from Mr. Cheshire which did not reach us in time for insertion this week; it will appear in our next issue.

#### COVENT GARDEN MARKET.—DECEMBER 28.

LITTLE or no business is doing in our market on account of the holidays, and there is no quotable alteration in prices.

POULTRY AND PIGEON CHRONICLE.

AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 575.)

THE next implement to which we shall allude is a hay press, and it is of some consequence to notice this, for we find it reported that hay has been recently imported into Glasgow from parts of the American continent, and in certain seasons when the hay crop is very deficient here the supply may be very considerable from abroad after being pressed in the smallest space. About two years ago we noticed a sample of hay in a corn exchange in a southern county; it was evidently grown on cultivated land, and was composed chiefly of Timothy Grass. It was imported from Canada, and beautifully bright and well made, and the aroma from it was agreeable and perfect. This shows that under certain circumstances, when hay is scarce in this country, that we may be furnished from abroad with a superior article. But hay at the best is bulky, and always will be; but the bulk may be greatly reduced by pressure and packing, as may be seen by the hay stored on board the steamers. Anything which will compress hay into a less compass than usual must be of great importance, not only for storing in our own shipping, but especially when imported from other countries.

The American implement makers are generally alive to any invention which may answer their purpose; in fact, numerous instances show that they are an inventive race, for we owe to their genius the first introduction into this country of articles of high repute and numerous agricultural implements and machines now in general use. The press to which we now allude is called the Perpetual Baling Press, and is an American invention, which was shown in its present identical form at Philadelphia in 1876. It was then described as Dederick's Hay Press, from the name of the patentee. In the absence of illustrations we wish to convey, if we can, a correct idea of this machine. The hay is fed into a hopper by the attendant, and that at regular intervals when the traverser is withdrawn a fork or board descends and forces the loose hay into a chamber below the hopper, where it is subject to the compressing action of a reciprocating traverser. The hay, after it has been forced down by the fork or board preparatory to its being driven forward by the traverser, is subject to the combined action which causes each section of the bale to be folded up. The pressing is accomplished by the reciprocating traverser moving backwards and forwards underneath the hopper, which presses against the compact hay, and forcing beyond its traverse at each revolution all the hay pitched into the hopper. The chamber into which the hay is forced is provided with steel springs, which retain all the hay forced beyond them and prevent expansion backwards when the traverser is withdrawn. The size of the chamber is 12 by 15 inches, and this of course regulates the dimensions of the bale, which can be made of any convenient

length, although the usual size is 3 feet, by the insertion in the hopper of wood followers with slots on their surface, through which the wires are passed for tying the bale as it passes through the chamber. The wires of proper length being first prepared, an attendant below passes the wires through the slots in the followers, and brings the ends together on one side of the truss with pincers. The liberation of the truss from the discharge end of the chamber, by allowing some lineal expansion, tightens the wires. The mouth is adjustable, so that by turning a nut the bale is released or held, thus forming light or heavy bales as required. Two men only are required to work the machine, the hay being supplied on to a platform which is level with or slightly above the top of the hopper. One feeds the machine whilst the other attends to the wiring of the trusses or bales.

It will be understood from this description that the bale consists of a number of independent sections pressed closely together, so that when the ties are removed each section may be taken off without pulling the bale to pieces, and without that waste inseparable from the distribution of a homogeneous mass. This is a point of considerable importance. The sections can be piled up as so many blocks ready for use, or the bale can be placed on end and gradually reduced by the removal of consecutive sections. As these observations are taken from the report of the Judges at the Derby meeting of the Royal Agricultural Society, we find that they weighed a truss 12 by 15 by 36 inches, which scaled 1 cwt. 1 qr. 16 lbs., being about 42 lbs. to the cubic foot, whereas the machine could if required compress 45 lbs. to the cubic foot, which would allow 1 ton of hay to be packed within 1 ton measurement of 40 cubic feet.

In a time test it was found that 3 feet 8 inches of hay was discharged in two minutes. As this weighed 191 lbs., and the work is continuous, it follows that the machine can bale about 2½ tons per hour; whereas the Pilter Press, which makes a circular truss and which was awarded the silver medal at the Kilburn meeting of the Royal Society in 1879, bales only 1 ton per hour. The Judges considered that this machine has merit and utility for the following reasons:—The rapidity of execution, and the small cost of manual attendance: the peculiar way in which the hay is passed in sections: the simple action of the presser, minimising waste: and the advantage of the rectangular form of truss for stowage as compared with cylindrical trusses. The exhibitor claims that this machine can be applied to comparatively green hay in the fields, and that such compression would prevent fermentation, even if the hay were packed in a much greener state than that in which it is usually stacked, and this opinion was shared in by Mr. Scotson, one of the Judges, who is an extensive hay seller, and who held a strong opinion that through its agency hay might be secured from the field in a much greener and therefore more valuable condition than when stacked and sweated as in ordinary practice. The fact of hay being so closely packed would, by excluding the air, prevent heating; moreover, the bales could be so stacked in barns or sheds as to secure ventilation between them. One machine capable of pressing 2½ tons per hour could deal with the crop as rapidly as by ordinary stacking, and the hands employed less numerous. There are various points of great advantage which the home farmer as a practical man will see at a glance and the inexperienced may study with benefit in the foregoing statement, and for this reason we have made a more than usual copious extract from the Judges' report.

We must next refer to a new style of plough exhibited at the Derby meeting called a gang plough, introduced by a Mr. Cooke, and is quite a novelty when compared with the implements to which the home farmer has been accustomed, but they have been in use in America, constructed upon a similar principle, for some years. It appears to us that this plough, which is made to turn two or more furrows, will soon undergo great improvements; we shall, therefore, only make a few observations on its construction. The plough consists of a strong main beam composed of angle iron and wood combined, and to this is attached by large screws another beam of iron carrying the front frame, which is adjustable according to the width of the furrows that are desired. Between and above the beams in front the pole is attached, being carried on a plate about 2 feet from its lower end. The pole rocks loose on this plate. According to the present arrangements the pole is necessary in order to steer the plough, two or three or more horses may be yoked abreast. The driver has a seat fixed between and above the wheels slightly behind the axles, which balances the apparatus. The driver can regulate all matters relating to the depth of the work, the turning at the ends of the field, &c., without leaving his seat. Coult's forcefeed drill is a comparative new implement, and a departure from the ordinary formation of English drills. It is so arranged that whenever the forcecups are filled with seed, and the drill put in motion, a

regulated quantity shall be discharged from each cup; and this must take place in whatever direction or pace the drill travels. Thus there is little or no difference in the delivery, whether the drill is travelling on the level or on a hill side. Through a simple arrangement of geared wheels working an index on a disc, the land is actually measured in the act of drilling. In front of the seed box is a small drill for sowing Clover and grass seeds. The whole apparatus is strong and simple, and the delivery will be formed more accurate than with the old disc and seedcup arrangement. The implements we have alluded to are all illustrated in the last issued Journal of the Royal Agricultural Society of England, and we advise gentlemen to furnish their home farm managers with a copy.

#### WORK ON THE HOME FARM.

*Horse Labour.*—All the land to be fallow-ploughed should now be finished, and in case of strong wet soils it should be carefully water-furrowed, and made with a sufficient fall to carry off the surface water quickly. On the driest soils where clean we note that some farmers are laying out the manure direct from the farmyard, to be ploughed in as fast as it is spread. This is a good plan, for on dry land it is ready early in the spring to be worked down fine, and drilled with whatever crop we may require. In the case of planting with Potatoes, it may be ploughed shallow with light one-horse ploughs, and planted as fast as ploughed; and any additional manure required should be Peruvian guano, strewed in the furrow with the sets. Wheat-drilling will in some cases be continued, but must be done as fast as the land is ploughed, otherwise the work is sure to be interrupted by rain or frost. Sowing by hand is, however, rather better at this period, for the land can be seeded close up to the ploughs, thus securing the seed being covered in should rain occur at any time of the day. Carting chalk will be going on, and laid into heap to be drawn out and spread in the first favourable weather which may occur, so that the night frosts may break down and reduce the coarse portions into a state fit to plough in without the expense of breaking by hand. This is a very important operation, for unless the chalk is buried in the soil it is exposed to the drying winds of spring and summer, and becomes very hard and loses its value to some extent. We use chalk also for drilling with root crops instead of ashes, and have this week directed the carting of chalk to a large barn mow, and desired the teamsmen to bring the finest chalk they can obtain. If, however, the weather becomes dry enough we shall send men to the pit where the chalk is within a few miles or a day's carriage, and screen it with an ash screen, then fetch it away and keep it dry in a shed or barn ready for use in spring and summer. This plan is the best surety against clubbed roots in the bulbs of Swedes, Turnips, Cabbage, Kohl Rabi, Thousand-headed Kale, and Rape. Mangolds and Carrots, however, seldom suffer from clubbed roots.

*Live Stock.*—The weather has been too wet for the sheep which are fattening in the field upon root and cake-feeding. They not only do but little for themselves, but tread the land to its injury for the next crop. They are in many cases, too, breaking out with the epidemic lameness and footrot; but our remedy is so perfect that in case each animal is treated the second day after breaking down, it does not suffer in the same foot again during the season. We were lately present when the feeding of dairy cows was the subject discussed, the points being the best and most economical food at this period for the production of butter, and also for the increase of milk intended for sale, or for suckling calves for veal. We have on certain occasions recommended the home farmer as to the feeding of his cows under both these circumstances. We consider nothing better for the production of butter of good quality when the cows are not fed upon grass, than bran and Potatoes, with a little sweet park hay, especially that which contains the Sweet Vernal kind of grass which gives the hay such an agreeable aroma, for this is sure to contribute a better flavour to the butter. As regards the economy of feeding with Potatoes, it will depend upon their quality, soundness, and cost. The large field Potatoes of the Red Giant growth will give a heavy acreable weight in the crop, and answer well, not being generally so much damaged by disease as many other varieties, and should be grown if it is intended to feed for butter-making. We know farmers who are now feeding cows with wheat meal; this is of course better than bran only, as the meal maintains the animals in better condition during the milking period. Where Potatoes cannot be had cheap enough we use Mangold or white Belgian Carrots, but it does not make butter of the like quality as Potatoes. In feeding dairy cows for the purpose of yielding quantities of milk only for sale, &c., we know of nothing better than distillers' grains, and the large Drum-head Savoy Cabbages. The Robinson's Champion Cabbage are very good, but they often decay partially at this period, whereas the Savoys are not affected by frost, and therefore maintain not only their feeding value, but will remain sounder for a longer time, and will not injuriously affect the milk. The Champion Cabbages will now be invaluable for ewes previous to and during the lambing season.

DONCASTER AGRICULTURAL SOCIETY.—I beg to inform you that the date of our next Exhibition is fixed for Wednesday and Thursday,

June 28th and 29th, 1882. The entries will close Saturday, June 3rd.—GEORGE CHAFER, *Secretary.*

#### CELEBRATED POULTRY YARDS.

WOOD END HOUSE, GRAVELLY HILL, BIRMINGHAM.  
(H. TOMLINSON, Esq.)

DURING our stay at Birmingham in the Show week we had an opportunity of making a long-intended visit to the yards of Mr. Tomlinson, who has been for so many years known as one of the leading exhibitors of Cochins. Twenty minutes' run in the train from Birmingham brought us to Gravelly Hill station, and a pleasant walk through the country for another quarter of an hour found us at Wood End House.

This is one of those charming old-fashioned residences which are unfortunately becoming somewhat rare in the neighbourhood of our large cities. It is situated in sloping grounds, attractively wooded, and having a piece of ornamental water at the foot of the slope.

The appearance of the premises from the outside hardly suggests the presence of the vast number of birds which one would expect to find in the yards of so noted a breeder, and we wondered somewhat as we walked up to the hall door where such a number of birds were hidden away. Our subsequent chat with Mr. Tomlinson in the library explained this mystery. As a matter of fact, Mr. Tomlinson only keeps such of his birds as are immediately wanted for exhibition, and those which are for sale, at Gravelly Hill, the breeding stock being distributed amongst various cottagers, who each take charge of a yard of birds, and hatch the eggs and rear the chickens until they approach maturity.

The system which Mr. Tomlinson adopts is an extremely fair one, and must tend to foster amongst the cottagers who have charge of his birds a rivalry which is not without its advantages to the owner of the stock.

At the commencement of the season Mr. Tomlinson distributes his breeding stock without partiality amongst the cottagers already referred to. He exacts a rigid account of the number of eggs laid and set, and a weekly visit enables him to see how matters are progressing. When the chickens approach maturity he buys them from the rearers at a fair price; and as an example of what may be made by those who have charge of the breeding stock, we may say that Mr. Tomlinson during the past season paid to one rearer an average of £1 each for all the chickens reared. Mr. Tomlinson, also offers for competition a cup of some value, which is given to the cottager who rears the bird which is most successful at the Birmingham Show. That this plan as carried out here is capable of being successfully adopted the splendid chickens shown by Mr. Tomlinson abundantly testify.

Notwithstanding the narrowing of dimensions established by the means already indicated, Gravelly Hill is not without a considerable poultry establishment of its own. Almost facing the visitor as he turns to the right from the hall door are an old stable and coach-house. In a large room on the ground floor of the stable we found a numerous and goodly assortment of pullets of several varieties. Buff and White Cochins were most numerous, but Dark and Light Brahmans were not without their representatives. Mr. Tomlinson limits himself to the Asiatics, and is chiefly known as a breeder of Cochins, but many Brahmans in this yard were of considerable merit. The Cochin pullets were an even lot, round, fluffy, and amply feathered. In another part of the same building we found a range of pens, in which were confined a number of cocks and cockerels of the various breeds indicated, intended we believe for the auction which was to take place in Birmingham the following day to that of our visit. In the same building were also to be found the workshops where Mr. Tomlinson's well-known incubators are made, and the business offices connected with this branch of the establishment. We cannot attempt now to enter upon any discussion of the appliances which were to be seen here, but must reserve them for a future article.

Emerging from the back of the incubator factory and turning to the left, we found ourselves opposite a range of some dozen houses constructed upon a plan which seemed to us worthy of imitation. We are enabled by Mr. Tomlinson's kindness to put before our readers illustrations of these houses (p. 395), showing the plan (fig. 98), section (fig. 99), and elevation (fig. 100), which will give them a better idea of their construction than any words of ours could. In front of each house is a yard neatly gravelled of the same width as the house and about 12 feet in length. These houses and runs are here simply used for housing show birds, but they would be capable,

with the addition of a few grass runs, of being adapted for breeding yards of any of the Asiatic varieties. Most of their usual inhabitants were at the time of our visit in the show pens at Birmingham, but there were some few fine specimens left at home.

Returning past the house to the opposite side to that occupied by this range of runs, we found ourselves in a large run with an

adjoining house, occupied by some dozen white Cochin cockerels. These were very uniform in type and promising, but were too young when we saw them to form any accurate estimate of their ultimate qualities.

Further on still we came upon another good-sized run filled with Cochin and Brahma hens in various stages of moult. In conse-

Fig. 98.

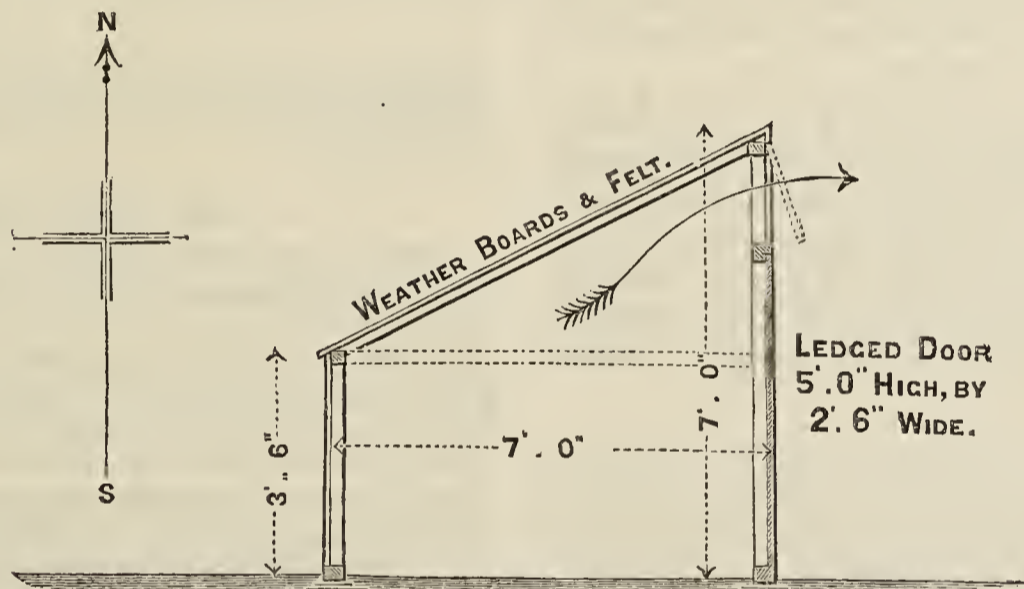

Fig. 99.

Fig. 100.

quence of the transition of plumage the Buffs were hardly so even in colour as at other periods of the year; but we were so much struck with the beauty of type as regards shape of the Cochins, that we shall, by Mr. Tomlinson's kindness, submit in a future number an engraving of his Buff Cochin hen "Empress," which our readers may well take as a model of true Cochin shape and character.

Further on still we came upon a lot of Buff cockerels, amongst which we noted several promising birds; and beyond these again a lot of raw young Dark Brahma cockerels, which, though hardly as pure in colour as we like, were of great size for their age, and had neat heads and combs and that sweeping outline which is so characteristic of this breed.

Beyond these again were some other houses built upon a somewhat similar plan to those of which we give illustrations, with this difference, however, that they were in pairs, and that the central part between each of the two houses was left as an open shed. We noticed here a wire running in front of the doors, which was rather suggestive to us of a thief alarm; and found upon inquiry to Mr. Tomlinson that our conjecture as to this was correct. This wire was in connection with an alarm gun placed near the house; and while it says something for the poultry-fancying proclivities of Birmingham, it does not say much for their honesty that Mr. Tomlinson finds it necessary to constantly employ a night watchman, watch dogs, and every other available means to secure the safety of his pets.

So ended our round of this celebrated yard, which when taken with the arrangement distributing the breeding stock amongst cottagers to which we have already referred, made up as complete an establishment as a fancier could well desire.

#### NOTES ON THE BELFAST SHOW.

BELFAST Show is the great event in the Irish fanciers' year. It came off last week, and though in numbers hardly up to some former years, yet the quality was remarkably good. The Belfast Committee are enthusiasts in the matter, and the Hon. Secretary is more than equal to all the duties of his post. We never, however, were at a show where there was less public support in the way of visitors. The same few familiar faces were to be seen eagerly scanning the exhibits and criticising the awards, but that was all. Mr. Leno, assisted by Mr. Mulligan for the local classes, judged the poultry, and Mr. Fulton the Pigeons, and the awards were generally well received.

WE were struck with the number of English and Scotch names in the catalogue, and took the trouble to count up the exhibitors, exhibits, and prizes belonging to the Green Isle and this side the Channel respectively. Out of 132 exhibitors sixty-nine were Irish and sixty-three were not. The Irish exhibitors showed 604 pens—their visitors 251. Of 129 prizes and eleven cups offered for forty-three classes of poultry some forty-eight prizes and eight cups went across the water. Of 111 prizes and eleven cups for thirty-seven classes of Pigeons, some forty-three prizes and three cups again left the Green Isle. The Show may, therefore, be said to be as much an English and Scotch as an Irish one, and the honour of winning is about equal to that to be gained at a good English show.

THERE is, however, another side to the question. Does not this large influx of English and Scotch exhibits deter a number of Irish fanciers from competing? We incline to think it does. There is no doubt that in a general way the Irish fancier is not on an even footing with his brother on this side the Channel. There are almost daily shows here during the season and large prizes are offered. A big price for a bird can be afforded when there are a few ten-guinea cups for him to win. The sixty-guinea Brahma, for example, has won back for his owner a considerable part of his price already. In Ireland, however, shows are like angels' visits, few and far between, and high prices cannot be afforded for birds merely intended for home competition. A few Irish fanciers compete successfully in England, but they labour under great disadvantages as respects cost of carriage and through their birds being exposed to the risk of rough passages. The Belfast fanciers choose to admit all comers, and perhaps they are right; but there is, we think, something to be said in favour of limiting the competition to Ireland.

COLOURED DORKINGS were few in numbers, but of really first-rate quality. Messrs. Smyth showed three hens that we have not seen surpassed anywhere this year. Silver-Greys were numerous but not up to the English, or perhaps we ought to say Scotch standard. Brahmans were, through the liberality of a fancier who has during the past two seasons guaranteed the prize money, provided with eight classes. The eup Hull bird (second Palace) here took the cup for Darks. All the prizes for hens and two of the three for pullets went to Mr. Comyns, while Mr. Erskine kept up to his good beginning last year by taking the three prizes for cockerels with birds which but for their being slightly tanned might have won anywhere. They were all bred, Mr. Erskine told us, from the winning cockerel of last year mated with the eup hen of last year purchased from Mr. Comyns. Lights were not so numerous nor quite so good as the Darks; Messrs. Birch were as usual the chief winners. In pullets, however, they were beaten by a very large well-feathered bird of Mr. Ward's, and two well-shaped heavily feathered birds shown by Mr. Comyns, who made his first essay with the Lights here.

COCHINS were not so liberally classified as Brahmans. Mr. Ward's splendid pair of Whites were first in the old classes respectively, and the cock took the Cochin cup. Mr. Robertson and Mr. Pye each showed some good first-rate Buffs. In Buff chickens Mr. Kellsall

was deservedly successful. The cup for Spanish went to Scotland to an old cock of Mr. Street's, and the same exhibitor also took all three prizes for hens.

MR. J. A. MATHER was most successful in the Game classes, the winners being birds which have also taken prizes in England recently. Mr. Pickles was to the front in the three Hamburg classes, while the cup for the French, Polish, or "Any other variety" went to a fine pen of Houdans of Miss Carter's. Mr. Ward stood first with Crèves, and Mr. D. Sullivan in Polish. Messrs. Bradbury won easily in Plymouth Rocks and Leghorns respectively, the Poultry Club cup going to the latter. These classes were very poorly filled.

THE Bantam cup went to Mr. G. Coulthard for Black Red Game, Mr. G. Anderton and Mr. Pickles winning in the other Game Bantam and other variety Bantam classes respectively. In the other variety class the first were Malays, second Minorcas, and third Sultans. Mr. Robertson took the Duck cup with a fine pen of Rouens; he also won several other prizes in these sections, as also did Mr. Mullan and Messrs. Birch, the latter gentlemen as usual heading the list in Turkeys and Geese respectively.

PIGEONS were a wonderfully good show. Space will not permit of our going into details, but we must mention the Red Jacobins, which were wonderful classes. Mr. Fulton awarded two equal thirds and four equal fourths to the cocks, and three equal fourths to the hens, and said he could easily have awarded more prizes to birds which could win almost anywhere.

POULTRY CLUB SHOW.—We are pleased to hear that the entries of poultry for this Show number nearly 1300. Pigeons, Cage Birds, and Rabbits will also be numerously represented, and bring the total up to 2250.

#### OUR LETTER BOX.

**Cayenne Pepper for Canaries** (*A. G.*).—It is mixed with the food of the birds and given to them to deepen the colour of the plumage. An equal mixture of egg, biscuit, and pepper is prepared by many fanciers, and the birds eat it readily.

**Ox Cabbage Plants** (*Yokel*).—Although the seed was sown in the spring, the plants, if they are very small and weak, may be pricked out in February, if the weather is favourable, thickly in newly prepared soil. After a few weeks' growth those inclined to run to seed will be seen producing long stems, the remainder may then be planted in the field. Plants thus raised and treated often produce the largest heads which can be grown.

**Earth Floors for Cow Stalls** (*Idem*).—If made quite level with fine dry earth rammed down hard, and the footpath behind is raised 3 or 4 inches above the floor, all the urine will be absorbed instantly by the earth floor, and only the solid excrement will be required to be removed. Much less quantity of straw will be required for litter by this than by any other plan; but the stalls should be narrow enough to prevent the animals from turning round; the dung will then fall only at the end of the stall, which will soil but little of the straw litter. As the urine is absorbed by the earth floor, and the ammonia fixed and deodorised, the air will be pure; when it becomes offensive the earth must be changed.

#### REMARKS.

18th.—Frost in morning; bright cold day and windy.

19th.—Fine bright morning; rain in afternoon.

20th.—Gale in early morning; fine bright day with much wind; rain in evening, gale at night.

21st.—Fine and bright throughout.

22nd.—Fog in morning; fine day.

23rd.—Frost in morning; fine bright day; thick fog in evening.

24th.—Fair, but thick all day.

Temperature nearly the same as in the previous week, and rather below the average. Very low barometer on 20th, and gale of wind.—G. J. SYMONS.
