The advice which follows on the general management of poultry is very good in its way, though we must confess that most of it seems culled from books and articles, and might, we fancy, have been put together in a rather more methodical and forcible way. If we might make a suggestion to so august a body as the Royal Agricultural Society it would be that they should publish cheap leaflets on such subjects as "eggs" and "chickens," with some reliable statistics and practical advice showing the loss which the importation of eggs and poultry annually entail upon the country, and methods by which part of the sum annually paid for such foreign produce might remain in English pockets. Hence, then, we are inclined to differ a little from Mr. Pope, as when he says "perches should be broad and flat enough for the fowls to roost comfortably upon them." After much observation we have come to the conclusion that fowls do best on perches that they can clasp, neither broad nor flat. These are some illustrations of simple coops, and the author says, "The old-fashioned coop with a slanting roof to shoot off the wet, and with strong upright bars in front, answers every purpose." We do not think it sufficiently answers the purpose of keeping wet out, and prefer a coop of our own with a slanting weather board in front, which makes a great difference in the state of things inside during a period of bad weather. We are also told "it is well to have a close front to shut up securely by night." Close fronts are most undesirable; only those can know the evil of them who occasionally get up early and open their own coops; the wonder is that chickens can exist—healthy they cannot be—in coops so closed up. The fronts should only reach to about 4 inches from the top; good ventilation is absolutely necessary for health. The observations on diseases are decidedly good, and the directions given for operating upon chickens suffering from gapes sound practical. "A common pipe, stable bucket, a cloth and a smoker, are all that are necessary, with tobacco. Place the chickens in the bucket, cover them up, pass in the stem of the pipe, blow in the fumes till the sufferers are heard falling about, then turn them out at once. Repeat in two days. We use boxes and bellows, so that women may operate!"

The remarks on Ducks, Geese, Turkeys, and Guinea Fowls are really too brief to be of much practical use, and we cannot but regret that the author gives no hint of the great advisability of causing poultry to migrate over a farm in moveable houses both for their good and that of the land. We have candidly pointed out what we think errors or omissions in the little work; there is much that is good and useful in it, and we hail its publication as a step in the right direction.—C.

### OUR LETTER BOX.

**Fattening Fowls (M. D.).**—No operation connected with the poultry yard requires greater attention and experience than fattening fowls in coops. Oatmeal and barley meal alternately, mixed with milk, and occasionally with a little dripping, is good food. The feeding troughs, which must be kept constantly scoured, should be placed before the birds at regular intervals, and when they have eaten sufficient it is better to remove them, placing a little gravel within reach of the coop to assist digestion.

### REMARKS.

- 21st.—Fair, but dull morning; rain at 0.45 P.M., and heavy showers during afternoon; fair but damp evening.  
 22nd.—Fine bright morning; afternoon overcast, with sprinkle of rain; evening fine.  
 23rd.—Morning fine; heavy rain in afternoon; dull gloomy evening.  
 24th.—Shower in forenoon, thunder 1.5 P.M. to 1.25 P.M.; rest of day fine, bright, and breezy.  
 25th.—Dull and gloomy; rain throughout.  
 26th.—Heavy showers, with fine bright intervals.  
 27th.—Fine, bright, pleasant day.  
 Temperature near the average, but rainfall greatly in excess. —G. J. SYMONS.

### THE PROPAGATION OF CONIFERS.

**T**HE propagation of Conifers scarcely belongs to the ordinary routine work of the practical gardener, and many in consequence never trouble about it. This apathy may be sufficient to satisfy a certain class, but with the intelligent gardener and horticulturist the case is very different. He not only tries to grasp all the information possible on any subject pertaining to gardening, but is anxious to obtain a knowledge of how nursery stock is raised. Unfortunately many know nothing about this work, which is rarely if ever treated upon fully in any of the gardening periodicals, and young gardeners are at a loss for information on the subject. To obtain a knowledge of Conifers and their propagation I had to sacrifice the more pleasant work of a private garden for the laborious duties of a nursery before my wish was achieved.

Before passing to the subject of these notes I must say that young gardeners are frequently too anxious when they are in a nursery to get out again, as if there was nothing to learn there. This is a great mistake, and they should seize every opportunity of extending their knowledge of nursery work whenever a chance presents itself.

At no period of the year is the propagation both of hardy flowering shrubs and Conifers carried on in nurseries with greater rapidity than from the present time onwards. The majority of Conifers are propagated by means of cuttings and grafting, many Pines excepted, and a few common varieties of Cupressus, which are readily raised from seed. The system adopted where the work is carried out on a large scale entails much labour. Narrow beds are formed about 2 feet wide, with a row of bricks placed edgewise on each side of the bed, leaving the tops of the bricks just above the soil. Handlights or small glazed boxes about the same width, and about 3 feet 6 inches in length, are in readiness before the cuttings are inserted. A heap of coarse river or red sand is placed at hand, and a good proportion is mixed in the soil, the surface being covered about half an inch in depth, after which it is ready for the cuttings. These, when the wood is fairly ripened, are frequently taken from the plants intended for sale, and others from stock plants kept in borders for the purpose. Some care is necessary in taking them so that the plants be not disfigured. The portions intended for cuttings should be so taken that when dressed each will have a heel. It is necessary that the cut be cleanly done with a sharp knife. The cuttings should be made clean for about an inch of the stem near the base, and should be from 2 to 4 inches in length,

but the length matters little provided a good heel is left and the wood is in a proper state of ripeness. This mode of making the cuttings applies with equal force to all the Cupressus, Thuias, Retinosporas, and many others, but such kinds as *Cryptomeria elegans*, *Retinospora ericoides* and others equally free strike readily without a heel.

The cuttings are inserted as thickly as possible under the handlights on the prepared border, making the soil firm around them. A good watering is then given and the handlights placed over them. These miniature frames are generally arranged in rows, leaving about 2 inches between each bed to allow room for the frames to be removed as occasion may require. Little trouble is necessary afterwards, only giving shade if the sun proves very hot for a time after the cuttings are inserted. It is scarcely necessary to again lift the lights before the early spring, as the cuttings seldom need water before then. Sufficient will soak in round the handlights during wet weather, and keep the soil moist during the winter. The cuttings should be kept as close as possible until they are well callused, which will be the case in spring, as if air is given in their early stages many of the cuttings may damp off. During winter the only attention that is needed is to cover the frames with mats or other protecting material in severe weather. It is better if they can be so covered as to exclude all frost, but this is not absolutely necessary. I have seen the soil frozen hard for a long time and little or no injury has resulted therefrom.

Another course of propagation can be effected by placing the cuttings in pots in the Conifer house, which is generally kept at a temperature of 40° to 45° during the winter. This system is practised to a large extent because smaller cuttings can be employed, which is often convenient with new and choice varieties. The pots employed are about 8 inches in diameter; they should be half filled with drainage and the remaining portion with sandy soil, covering the surface with sand. The house best adapted to the propagation of Conifers is a span-roofed structure with a walk down the centre and a bed on each side. The beds should be covered with lights so as to convert them into a frame in which to place the cuttings. It is usual to give a slight bottom heat to these beds, which is of the utmost value in propagating many Conifers, especially those that are grafted. The cuttings inserted in pots are at once plunged into the side beds half their depth amongst cocoa-nut fibre. Considerable attention is needed when propagating Conifers in heat, much more so than when they are placed outside. They require dewing nearly every morning with the syringe, especially when first placed in the pots. If the roof of the house is not well shaded the frames in which the cuttings are placed must be shaded as soon as the sun shines upon them. When in these frames they are generally kept close during the day, and the lights lifted at night. They are, however, liable to damp off in considerable numbers, and every particle of decayed matter must be promptly removed. No doubt the better system is to keep them close for a time without opening the frame except to give water, and this will be seldom required if the soil is well soaked at first.

The cuttings, as a rule, are a long time before they are callused, but when they once attain that stage there is but little fear that they will afterwards be lost. In the spring when those in pots have commenced rooting they are removed to frames. In cold severe weather a little warmth should at

first be given, and the frames kept very close until the plants can be gradually hardened. It will be understood that those in pots will be rooted first, and ready for potting singly into 2 or 3-inch pots about the month of May. Those under handlights require a little different treatment in spring. As soon as the sun has power the small frames are shaded, and during showery weather the lights are removed. If this can be carried out once a week, or at short intervals, the cuttings improve considerably. If dry weather sets in the young plants must be well supplied with water. As the season advances a little air must be given daily on favourable occasions, as the roots are generally produced when growth commences. It is surprising what a time some of the varieties take to form roots, and often the season is far advanced before this is accomplished. Some are ready for potting off during the month of June—such, for instance, as *Cryptomeria elegans*, which roots quickly. *Retinospora ericoides* is even freer in this respect, while *Thuopsis borealis* and *T. b. compacta* are a very long time before they are rooted, and are often left the second season. As a rule when they are well rooted the different varieties are potted off singly, and any cuttings that are not rooted are placed thickly together in 8-inch pots, and remain in them in cold frames through the following winter. After the plants are potted they are placed in frames and kept close for a time until they commence rooting again. They are then turned out and stood closely together in narrow beds, and cocoa-nut fibre refuse is placed amongst the pots and about an inch in depth over the rims. The plants may have to stand in this position through the winter, but in the majority of cases the strongest are planted out, and only the weakest plants and those potted late are kept and wintered in pots as described.—W. BARDNEY.

(To be continued.)

#### FANCY PANSIES.

SINCE my notes on Fancy Pansies were written I have been unfortunate with my stock of plants. The hot weather we had during the latter part of July was very favourable for the fly, and my stock has been sadly injured. In order to insure a supply of cuttings, therefore, I have taken off the shoots which are infested with the fly, and the little shoots at the base of the plants will soon be strong enough for the purpose. As Pansies everywhere are much infested with the well-known enemy to Pansies—the red fly—it may be of advantage to note here the remedy I am trying. Softsoap is dissolved in water, using half a pound of soap to two gallons of water, and the plants are watered through a fine rose. As we are having very showery weather in this locality it is necessary to apply it several times a week, as the rain soon washes off the solution.

It must be borne in mind that if a fine display of blooms is required a fresh stock of Fancy Pansies must be propagated every year. The most suitable cuttings are those taken from the base of the plant; by this is meant the fresh shoots which spring up round all roots of Pansies at this season of the year. The leading stems which have flowered may be struck, but the flowers from them next season would be worthless compared with plants raised from the small offsets, which as yet have not flowered. If it is not convenient to winter the stock in a frame the cuttings should be taken at once, and they will then be well established by winter. If the plants are not producing a sufficient quantity of fresh shoots I remove a few of the leading stems, and in a very short time I have an abundance of cuttings.

Of late years I have propagated them in the following manner. Among the new growth at this time of the year I shake a little finely sifted soil, which encourages the formation of roots, and I have rooted offsets to plant either in the open border or in frames. About the end of September the frames are prepared, a mixture of good loam with a liberal quantity of well-decayed manure and a little sand being the compost used. The cuttings are planted about 4 inches apart, and for a few days the frames are kept closed and shaded. During the winter as much air as possible is given in mild weather, as from experience it has been found that this is the best method of keeping down insect pests. In the case of plants which are to be wintered outside, a border is chosen which is protected either by a wall or hedge, but every care is taken that the plants will not be injured by excessive wet from drip, &c. If plants are placed out at once they will be well established by winter. In selecting cuttings for this purpose I obtain the strongest of the fresh growth—rooted if possible.

These are planted on a small prepared bed, each cutting being pressed firmly down. As rooted offsets are used for this purpose they become well established by winter, and there is no danger of the frost disturbing them. The plants are allowed to remain in the frames until they begin to show flower in the spring. It is wise to choose mild weather for transplanting, so that the plants are not checked in growth. If plants or flowers are required for show it is the best plan to leave them in the frame, giving abundance of air on suitable occasions, and shading on very hot days.—VINDEK.

#### PEACH-TRAINING FOR AMATEURS.

A FRIEND has kindly sent me a copy of a contemporary, in which I have the honour to be criticised thus—"Mr. Taylor of Longleat has set himself a task in attempting to prove that the fan system of training stone fruits is wrong in principle according to all our notions of vegetable physiology." Happily this is not a very difficult task. Mr. Robert Thompson in the original edition of the "Gardeners' Assistant," at page 550, says, when writing of the Peach, "The fan method is the best, yet it requires particular care and some knowledge of the physiology of the tree, otherwise the latter will become weak at the bottom and too strong at the top, as well as exhibit irregular growth throughout." Here, then, are two important admissions: first, that the system is not a perfect one, and secondly, that to carry it out the operator requires both theoretical and practical knowledge as well as to be particularly careful. The first justifies me in recommending a system which, if not absolutely perfect, has not so many disadvantages as fan-training, and the second goes a long way towards corroborating me when I say that "seven-eighths of the men (including labourers, specially mentioned in the preceding line) brought up in gardens never could be trusted to attend to fan-trained Peach trees." If that is too sweeping an assertion I shall be glad to modify it on proof being adduced to the contrary by responsible practical men, but at present I have nothing to withdraw, and am of opinion that the fact is too evident to require argument. Even amongst those who call themselves young gardeners I wonder how many can honestly say they understand the fan method of Peach-training. I say this without any disparagement to the young men in question, for it is a difficult lesson to learn, and the attention given to hardy fruits of late years has been small compared with that spent on less difficult subjects.

I am taken to task for presuming to think that my own particular notions on vegetable physiology are "all our notions." Now the only physiological question here is whether branches at different angles from horizontal to perpendicular have all the same chance. According to my notions of vegetable physiology the lower branches, being horizontal, have a very poor chance indeed. I have no objection to except my critic, but with that exception I shall still be so presumptuous as to assume that that agrees with "all our notions." Granted, then, that in fan-training the force is equally divided from the fact that no two branches on one side of the tree have the same angle, a plan which will give the same angle to every branch, and which is simplicity itself, ought not to meet with any formidable opposition. It is nothing to me that "every noted cultivator has recommended fan-training," and has spent a decade in attempting to carry it out if his trees have lived so long; noted cultivators have recommended things and systems before which are now obsolete, and it is possible that fan-training as far as the Peach is concerned will follow in their wake. In these economical days we must move along and not wait from six to ten years for that which need only take two and cost comparatively little. If those who grow Peach trees for sale would only train them much in the same shape as they do their horizontal Pears, which as I have pointed out in a previous paper can be done in the second year from the bud, we might always reckon on having a crop of Peaches the second season after planting, should it be a favourable one.

As to the objection that with this system there would be more bare wall at the bottom than there is when the fan-training is carried out, it is not worth much, for the lower branches in my case are equal in vigour with the upper ones, and barring the frosts, which have a special liking for lower branches, will carry an equal crop. In fan-training, on the contrary, the lower branches are the weakest; and although I have had the advantage of being employed in more than one garden where there were some of the best fan-trained Peach trees in the country, I have never seen a great weight of fruit gathered from within 3 feet of the ground, even though flued walls were used in some cases. Training merely for the sake of covering a wall with fruit trees is a thing of the past with most of us, our employers preferring rather to look at the produce than at the training. Nevertheless, apart from its

economical aspect, I maintain that the system I have recommended is when fairly carried out equal in appearance to any other, and that as the greater part of the wall is covered in two or three years there is less waste of space than there is with fan-training.

I have no doubt my critic considers himself witty, and enjoys giving a sly poke at me and my "extraordinary ignorance;" but that is not gardening, and were I ever so clever in retort there is no room for banter and gossip in the *Journal of Horticulture*. Such dainties are better suited to the columns of "Truth" and the "Cuckoo;" but I may hint that my friend's arithmetic is a little faulty, also that I have the results of my Peach-training to show, and shall be glad to hear where I can see his, or, in the case of that being amongst the invisibles, where I may see outdoor fan-trained Peaches at the present moment which approach the models drawn in the standard works on gardening, and which are equal in vigour throughout.

I think the term "oblique training" is not appropriate to a system which has upright stems, though we have the authority of that estimable man and clever pomologist, Mr. Robert Thompson, for calling it by that name. Would not "fish-bone training" be better?

How is it that Dr. Hogg Peach, which used to be early, has with me for several years now been a midseason Peach, as late as Bellegarde, or even later? Early Ascot is the only one I have to follow closely after Hale's Early and Early Rivers. Lord Napier Nectarine and Early Ascot Peach are ripening simultaneously. Will other growers kindly say what Peaches they have ripening at the same time, and immediately after this fine Nectarine?—WM. TAYLOR.

#### WINTER CUCUMBERS.

It will be an advantage if plants are already established, yet Cucumber seed may still be sown to obtain plants for fruiting in winter, therefore a brief record of my practice may be useful. The seeds should be sown singly in 60-sized pots placed near the glass. The best variety for winter is, I believe, Rollisson's Telegraph; some recommend Cardiff Castle, but as it was only tried here last summer I cannot speak as to its winter bearing qualities.

The soil in which the plants are to be grown should consist of about one-half loam and the rest of decayed manure (that from an old hotbed being preferable), and leaf soil. The compost must be well mixed and placed in the house at least two days before planting is to be done, so that it may be warm quite through. The glass and woodwork should be thoroughly cleaned previously, both to give light to the foliage and to destroy any insects that may be in the house.

When the plants are to be turned out of the pots care should be taken that the soil is thoroughly moist. They may be syringed twice a day except on very wet days to check red spider and thrips, and if the syringing is done thoroughly no insects will appear. As soon as the fruit commences swelling it is advisable to apply liquid manure water in a tepid state to the roots; this should be weak and applied often.

The temperature should range between 65° and 75° Fahr., but on bright sunny days with a little air it may be 5° higher; in fact with a little extra fire heat it will be well to have the ventilators open every day. The atmosphere as well as being warm should also be moist, and for this purpose water must be thrown on the floor occasionally, but not too often, because in the dull winter months the leaves are liable to be attacked by mildew, which, if it appears, should be promptly destroyed by dusting with sulphur.

If too many fruits appear all but the best should be removed, as too heavy a crop at first exhausts the plants. The shoots must be stopped at every second joint when the trellis is sufficiently covered, and some of the old wood can be cut out to allow the young growths room to develop.—A. R. P.

#### GAILLARDIA PICTA VAR. LORENZIANA.

MR. CHR. LORENZ, seedsman of Erfurt, Prussia, sends us the annexed figure of a new and remarkable variety of Gaillardia, which exhibits a phase of floral transformation that is occasionally observed in other members of the natural order Compositæ. The central tubular florets are developed to such an unusual extent that the flat ligulate florets at the circumference are either not produced at all, or so imperfectly and so small that they are scarcely perceptible. If the flower heads are produced as large and full as that shown in the woodcut the plant will undoubtedly prove an acquisition of considerable value, and will merit the attention of all who grow hardy plants. Mr. C. Lorenz also

gives the following account of the plant, and states that it will be shortly sent out:—

"Gaillardia picta is generally appreciated as one of the most beautiful garden plants, and though in mild climates biennial and even perennial, it is generally cultivated as an annual. The corollas in the circumference of the flower head are ligulate, three-toothed at the edge, at the upper part yellow, the lower portion purple, the disk florets tubular and five-toothed. In the course of the time several varieties have been obtained—viz., var. grandiflora, var. albo-marginata, var. sulphurea, and others; but eight or ten years ago the species showed the propensity to transform the ray florets and sometimes those of the disk into much-prolonged infundibuliform, regularly four or five-cleft tubular flowers; but only a few flower heads of this form were then to be seen, and they were developed very imperfectly, mostly with only two rings of such tubular florets. Attempts to improve this form and raise it to a certain degree of constancy were for a long time unsuccessful. But in Gaillardia picta var. Lorenziana we have at last attained our object. The form is distinguished not only by a regular development of tubular florets constituting a beautiful globular head, but a satisfying degree of constancy has also been secured. From this we have raised six beautiful varieties, which show the colours of the ordinary varieties in a different arrangement. 1, Claret or purple tube, the segments tipped with white; 2, amaranthine tube, the segments tipped with gold; 3, golden tube, throat claret; 4, gold tube, throat amaranthine; 5, purple tube,

Fig. 36.—Gaillardia picta Lorenziana.

segments tipped with gold; and 6, pure yellow. Also these varieties are constant in a certain degree. The flower heads are 3 to 4 inches in diameter."

[We shall be glad to receive a flower-head of one of these Gaillardias equal to that represented in the engraving.—ED.]

#### SOUTH SHIELDS FLOWER SHOW.

THE South Shields and Wistoe Floral Society held their thirty-eighth Exhibition in the cricket field, Westoe, in a spacious oblong marquee 80 feet by 40. The interior fittings of the marquee were very neatly covered with Heather in full bloom, which was interspersed with Asparagus foliage, causing a most pleasing effect.

The Show, with few exceptions, was much superior to that of last year, the entries being greater and the quality of the exhibits generally much superior. The Society is divided into open (or gentlemen's gardeners', amateurs', and cottagers') classes. For six stove and greenhouse plants in bloom the Society offered £15 divided into five prizes averaging from £6 to £1 each. For these there was a very strong competition. No less than six lots were staged. Mr. John Thompson, nurseryman, was first with a superb plant of *Lapageria alba* with over two hundred flowers open. He had also a good specimen of *L. rosea*, remarkable for its large superbly coloured flowers. His best other plants were *Stephanotis floribunda* and *Bougainvillea glabra*. Mr. Appleby, gardener to H. Craven, Esq., Briery, Sunderland, was second with much smaller plants, but even and well flowered, consisting of *Erica Marnockiana*, *Erica superba*, *Bougainvillea glabra*, *Dipladenia amabilis*, and *Phœnocomia prolifera* Barnesii. Mr. Battensby, Hagg Hill, Blaydon, was third, his best plant being

*Erica Marnockiana* about 5 feet through, the same in height, and superbly flowered from the base to the top. Mr. Smailes, gardener to W. C. Stephenson, Esq., M.P., was fourth. Mr. Charlton, gardener to J. Hedley, Esq., West Chirton, was disqualified for having two *Bougainvilleas* of the same variety. He had a *Lapageria* resembling closely a cross between *alba* and *rosea*, the flowers being of a delicate flesh colour. Altogether the plants were good for the time of year in all the stands.

For three decorative plants Mr. Smailes was first, and Mr. Watson, gardener to J. Eltringham, Esq., second. For three fine-foliage plants Mr. Appleby was first, *Croton majesticus* and *Cycas revoluta* being his best plants. Mr. Thompson was second. For the best six Zonal and Tricolor *Pelargoniums* Mr. Smailes and Mr. Watson were first and second, and second and first respectively, in each class. For three exotic Ferns Mr. Appleby was first with creditable examples of *Gleichenia Mendelli*, *G. rupestris*, and *Davallia Mooreana*; Mr. Smailes being second. *Coleuses* in this class were well shown, although scarcely as good as last year, Messrs. Watson and Smailes showing them well. Florists' flowers were remarkably good, but, except the premier stand of *Gladioli* of Mr. Thompson, none of them was named. This is one of the worst features of the Show. The same applied to many of the plants as well. The Society ought to more severely enforce the rule as regards naming the plants. Mr. Harkness of Bedale and Mr. Walker, Gateshead, won the principal prizes for *Dahlias*, the former showing excellent flowers. For *Picotees* and *Cananions* Messrs. Scott, Newcastle, and Flowdy, Gateshead, were respectively first. *Asters* were good, so were *Marigolds*, which were principally contributed by Mr. Spoor, Swalwell, and Mr. Robson, Birsley.

FRUIT.—The show of fruit was not large, but the *Grapes* from Mr. Smailes were certainly such as have not been seen at Westoe before. For a collection of fruit, *Pines* excluded, Mr. Smailes was first with superior bunches of *Black Alicante* and *Buckland Sweetwater*. These bunches were each about 2½ lbs. in weight. The *Alicante* was finely finished, being large in berry, fine in form, and exquisite in colour. His other best dishes were *Jargonelle Pears* and a good fruit of *Victory of Bath Melon*. Mr. Charlton was second. For two bunches of *black Grapes* Mr. Smailes also proved invincible with *Black Alicante*, the same exhibitor having the best white *Grapes*—two fine bunches of *Muscat of Alexandria*. For the heaviest bunch Mr. Smailes won with *White Nice*, weighing about 6 lbs. Mr. Watson and Mr. McPherson, Clevedon House, also contributed fruit.

Vegetables were very good, Mr. Robson winning the prize for the best collection. Mr. Spoor showed six very handsome *Leeks*. Mr. Appleby contributed a dish of *Peas*—a fine sample of *John Bull*.

The amateurs' classes, as in most north-country shows, were very good, the exhibits being creditable. Plants, florists' flowers, and vegetables were good, the latter particularly so; Messrs. Battensby, Kennedy, J. J. Attrely, and Bennett being the principal exhibitors. The Secretary, Mr. Dobby, and the Treasurer, Mr. G. Easton, were strenuous in their exertions to render the Show a success. The latter gentleman was the founder of the Society, and has been connected with it for thirty-eight years.

#### NOTES ON THE GLASNEVIN BOTANIC GARDENS.

I HAD a short time to spare on my way to the Manchester Exhibition, and took advantage of it to have a run through those fine gardens of which Irishmen are so proud, and I am indebted to the courtesy of Mr. Moore, the Curator, for seeing many rare plants not otherwise accessible. The note of "*D., Deal*," page 179, which caught my eye in the *Journal* on my return, reminds me that one of the beauties of the cool conservatory for nearly two months here has been *Disa grandiflora*, which many have failed to flower satisfactorily in this country. There are large numbers here, and although many are in small pots they bear three, five, and several plants even seven blooms to a spike. Peat and sphagnum are largely used as potting material, but I understand the plants are not found to dislike a mixture of leaf soil and decomposed humus. Most of the best were out of bloom, but a treat remained in those left.

The Palm house was especially attractive. It contains many specimens, said to be the finest in Europe; in fact, it was so when I first saw it twenty years ago with the late Dr. Moore. I need not refer to the collections of *Orchids*, stove, succulent, or greenhouse plants. They have been frequently noted by other writers; but we cannot pass without a note the great *Victoria regia*, which had five monster leaves, and very promising flowers, models of healthy growth, while not less interesting was the aquatic collection around.

I was, in the short time I had, more anxious to see the outdoor bedding and border plants, but before coming thereto I may be permitted to cursorily refer to the fernery, situated partially shaded behind. My greatest surprise here were the large pans of *Filmy Ferns*, *Todeas*, *Hymenophyllums*, and *Trichomanes*. Not least noticeable was the more generally known *Davallia Mooreana*, for which the Fern world is indebted to the present Curator's late father, Dr. David Moore. Here, too, were some of the newer

*Lastreas*, *Lomarias*, and *Microlepias*. In the same range is what may be called the nursing exotic department for all the newer and rarer introductions, among which the fifty fine specimens of *Nepenthes* were grand.

In the border in front of the long range I was just in time to see a few fully expanded blooms of *Crinum Moorei*, also introduced by the gentleman named above. It is far superior to *C. capense*, which had just ceased blooming. Both were fine after having endured last year a temperature nearly down to zero. I hope the new promised *Crinum* about to be introduced by Messrs. Henderson (C. Powell), a cross between those two, will be equally hardy. I was, however, a few days late to see a fine companion outdoor border flower, needlessly grown under glass—*Amaryllis Ackermanni*, with scarlet blooms 7 inches long, so welcome now when flowers are scarce. There was also a fine display of the showy single *Dahlias*, *Phloxes*, *Campanulas*, *Zinnias*, *Pansies*, *Asters*, early *Chrysanthemums*, the *Dianthus* family, *Fuchsias*, *Gladiolus*, *Pelargoniums*, and many other effective flowers now in bloom. I was glad to hear from Mr. Moore that he intended to cultivate even more extensively all the more common flowers for the instruction and example of the visiting public, such as most of them could imitate at home.—W. J. M., *Clonmel*.

#### ARTIFICIAL MANURE AND TOMATOES.

TOMATOES are now becoming so popular that many growers find it difficult to meet the demand, and consequently any hint respecting specially successful culture is acceptable to those engaged in the culture of this excellent fruit. During a recent visit to the establishment of Mr. Wiggins, nurseryman and market grower at Tottenham, my attention was drawn to a striking instance of the benefit derived from a judicious application of some artificial manures. A span-roofed house 120 feet long has three beds, the central one occupied with young *Vines* and *Tomatoes*, the two side beds with *Tomatoes* alone, planted about a yard apart and not trained to the roof, but with the shoots sufficiently thinned and spread out upon the soil. The central bed, having been specially prepared for the *Vines*, contains a substantial compost, while the side beds have only ordinary soil with a small proportion of manure; yet the contrast between the plants is remarkable, those in the side beds bearing from two to four dozen large handsome fruits, the growth and foliage being also proportionately vigorous, yet those in the centre have only small fruits, some of which will not be worth gathering, though the variety is the same in both cases—viz., *Trophy*. This difference is thus explained by Mr. Wiggins—The plants were placed out late, and as they seemed to be making very slow progress he determined to assist those in the poorer soil (the side beds) with a little artificial stimulant. About half a bushel of *Clay and Levesley's* fertiliser was applied and washed in, the result being soon apparent in the growth and subsequently in the greater size of the fruits. It would be interesting if Mr. Wiggins record the relative weight of fruit obtained from a similar number of plants of each, but judging by appearances the weight from the assisted plants will be at least three times that from the others.—R. C. S.

#### CANTERBURY ROSES.

PEOPLE staying at Dover naturally visit Canterbury, consequently I have carried out the usual arrangement, having the extra inducement of a visit to my colleague this year and last at the Crystal Palace, in search of the best *Rose*. The line from Dover very naturally runs up-hill. It was a sad sight this hapless harvest time, the sheaves hopelessly dripping on the hill sides, and the long swathes of mown corn almost grown into the ground. The beautiful *Hop* plantations were the only cheerful objects, and these had been abandoned perforce by the hop-pickers. Of course the first object at Canterbury is the Cathedral. Presently I was standing on the precise spot on which *Becket* was murdered. One particular slab has had a piece cut out of it, deep dyed with the blood of the Saint, which is reported to be at Rome. Dean Stanley, however, with that marvellous power of observation which never deserted him, when shown the relic at once perceived that the piece cut out was larger than the hole that it came from, which presents an obvious difficulty.

I may not dwell further on the Cathedral's many other objects of interest. Upon this followed my visit to the City Rose Garden. I have been allowed to describe in these columns on two several occasions model town *Rose* gardens at Reigate and at Croydon. Here I found in a city one surpassing them both. First in respect of size. It is marvellous, as I have shown, how small a space is sufficient for a *Rose* garden if science and money are there to

make the most of it. This garden contains an excellent supply of Hybrid Perpetuals, sufficing to insure the second prize for eighteen at the well-contested local Show. It has also a good-sized Tea Rose house entirely devoted to Maréchal Niel, several side beds of Tea Roses, and the pride of the place for its elegance and novelty—a Tea Rose glass arcade, 57 feet long, 8 feet high, and 10 feet wide, which comes nearer solving the problem of how to grow Tea Roses in our climate than anything which I have seen yet. The basket of Roses I was most obligingly presented with contained Teas that would have held their own at any country show; while E. Y. Teas, A. K. Williams, Marie Baumann, and others were also very fine indeed for the time of year. The size of this garden is just 21 perches! and Roses have been grown here for seven years no less successfully. Part of the secret was to be seen near the entrance gate in a high heap of rich loamy soil, also in a large barrel on the banks of the beautiful trout stream which bounds one side, well filled for occasions with liquid manure. The rule is with every Rose that is fresh planted to fill in at least a foot square of entirely new soil. The result, when I saw the plants, was a high state of autumn excellence; but the Teas under the glass verandah, with open ends and side, were more healthy than those in the Tea Rose house. I believe it is now generally accepted by the best authorities that, if these houses are to answer, the roofs must be made moveable, so as to be off at least half the year.

I think I may promise a hearty welcome to any brother rosarian who shall visit No. 2, Palace Street, Canterbury; certainly he will hardly find anywhere a more interesting and instructive city Rose garden.—A. C.

#### A WEEK IN BELGIUM.

[THE FIRST DAY.]

"CHANGES" and holidays have certainly become fashionable now-a-days, and are, indeed, regarded as necessities of our being. Without doubt constant monotonous toil is enervating, and a short period of cessation from labour has a wonderfully rejuvenating effect on most constitutions. Yet possibly holiday-making is occasionally overdone, and changes do not always result in benefit. It is a question if the mechanics' Saturday afternoon is a benefit to all, as with many, unfortunately, it only affords facilities for the waste of that which might be utilised. But gardeners, at least, have no Saturday afternoons at their disposal, and on few Sundays can they find complete repose for mind and body. They, if any body of men do, earn a change and need it; such a change they occasionally have, or ought to have, by visiting shows. Even the break of a day from mental and manual labour is beneficial; besides, at those gatherings most men gain hints that they afterwards turn to profitable account. Several years spent between garden walls enable me to speak practically on this point, and I plead that others may have what I once had the privilege of enjoying—an occasional holiday.

Flower shows have no longer special charms for me, for my visits to them mean labour, not rest; nor do those in England at any rate afford much change, for they are strangely alike year after year. Foreign shows at least possess some novelty, and the late Antwerp Exhibition attracted me over the water, or perhaps, to be more candid and exact, it afforded me an excuse for spending a week amongst old friends and revisiting old scenes in Belgium, for I confess I cared little about the Show itself, beautiful as it undoubtedly proved. I simply wanted "a change," and had one, pleasant, refreshing, and complete.

Those gardeners and horticulturists who can command a week's holiday may spend it interestingly in the thrifty little kingdom in question, and as inexpensively too, as travelling from one side of England to the other, or sauntering by the seaside watching the waves and getting melancholy. I never see the sea but it reminds me of the walls of a prison and I want to be over, and a week at the side of it would certainly make me miserable. The facilities for crossing are great, and, considering the provision made for the comforts of passengers, wonderfully cheap. It is, or rather used to be, the opinion of some foreigners that Englishmen "take to the sea like ducks;" but all of them do not do so, and it is astonishing how great is the fear of many of what the French call *mal de mer*—the English, sea-sickness. I am able to give some idea of what this is like, and perhaps some day may do so; in the meantime let no one be deterred by it from crossing the "silver streak." If the weather is fine they will not have it if they do not fear it; if it is rough they probably will fall victims, and then they will very decidedly have "a change."

Desiring to have all the time possible in Belgium I elected to travel by night, and how quickly and comfortably it is done! In London at 7 P.M., Harwich at 9, and in Antwerp at breakfast

time next morning. As I know very well a little description of the journey will be as acceptable as a disquisition on Orchids, Ferns or Cabbages, I shall not confine myself to strictly gardening matters. Of gardening exclusively most readers have enough; some, and probably not a few, too much.

From Harwich the sea passage is something under a hundred miles, and is crossed in about eight hours, the distance from Flushing to Antwerp up the Scheldt being sixty miles. Whatever class a person may travel by rail I cannot advise him to cross the sea in the "steerage." I once saw in a storm about 150 people "all of a heap" and something more, in that uncomfortable part of a steamer, and I determined to avoid that part for ever, and to advise others to do the same. The steerage is cramped and comfortless, the saloon large and almost luxurious, and the cost between the two is trifling. Our ship was the *Princess of Wales*, which is evidently popular, for every berth was taken. The saloon is like a well-furnished hotel, even to plants and flowers on the tables, and everything required can be had at moderate prices. It may perhaps not be generally known that the trade in plants for ship decoration is a very great one, and that attractive plants are a necessary part of the appointments on all ocean-sailing passenger ships. Mr. Bardney could perhaps tell us something about the extent of this trade at Liverpool. But to proceed. Of the sea we saw but little; it being a wet night and dark we "turned in," went to sleep and dreamt, at least I did, some cantankerous man was bent on quarrelling with me; first he pointed at me scornfully, then touched me, then struck me, once, twice, thrice, each time harder than before. Although I trust of a peaceable disposition it behoved me to exercise an Englishman's privilege under those circumstances, and my antagonist fell screaming. The noise awoke me, and my assailant proved to be the sides of the berth against which I was being knocked, and the scream was the cringing of the ship as she battled with the waves. I have known pleasanter moments, but it was better than *mal de mer*, and the day was dawning, and Flushing near.

The Scheldt is a noble river that creeps through a fertile land like a huge serpent. Its curves are so numerous that the distance to Antwerp, as has been said, is sixty miles, while an Antwerp Pigeon would find its way home in twenty-five miles. The width varies from five or six to one or two miles. No one can inspect the banks of this river and, as well as he is able, the land beyond, without being struck with the great work that was accomplished in times past by the enterprise and industry of the Dutch. The river is raised high above the land for miles, so high that in some places only the tops of the trees are visible and the spires of the churches. On each side thousands of acres have been reclaimed of the most fertile soil in Europe. The scenery is not picturesque, for there is nothing to be seen but long lines of Poplars skirting the sides of the ditches, that are, however, invisible from our standpoint, and here and there a village with its gables and church steeple peeping over the banks. We have none of Nature's grandeur to command our admiration, but the works of man, with their comparative tameness yet great utility, predominate. An American traveller was astonished at what he saw. "Ours is a great country," he said, "but Nature has made it. Our Rocky Mountains are magnificent and awe-inspiring; but we have nothing in America like this, and the people who have done this work are a great people." This work of land-reclamation has been there so long and passed so frequently that it is probably unnoticed by hundreds of voyagers, but unless it was of some magnitude it could not have astonished an American who had visited all the capitals on the continent of Europe; and his verdict must be acquiesced in, that the country through which we passed is a monument of the industry of a "great people." But we glide past some rather formidable fortifications and are at Antwerp.

Before leaving the steamer the traveller should have some money changed, if he did not make the necessary provision before leaving England. The steward, who is obliging in all things, and does not hang about you like a railway porter as if he had lost something, will readily give you a full Belgian equivalent for English coin. True, anybody in any country will take English sovereigns, but there is often a difficulty in the way of change, and it is well to be provided for all emergencies. You appear to have more money in Belgium than in England, for you receive 25 francs for every sovereign, and in many things the francs go there as far as shillings do here. They certainly go as far in railway travelling and much further in cigars. They also go as far in cab fares, or rather you can go as far for 10*d.* there as for 1*s.* in London; but the hotel charges are about the same in both countries, except as regards soap, and this you had better take with you, or you will certainly either have to go without or purchase rather dearly. Water is plentiful in Belgium and they use

it freely, for they wash the outsides as well as the insides of the houses; but soap, in the hotels at any rate, appears scarce. My friends of the gardening fraternity ask me far more questions on the customs, &c., of the country than about plants, therefore I make no apology for mentioning these matters here. There was a time when I should have been glad of such information, and hence I conclude it may be useful to others, for, to speak paradoxically, it is certain that a number of persons go to Belgium every year "for the first time," and in all probability the numbers will increase. I will, however, say something about plants by-and-by, for I have a headful of them which I shall be glad to have emptied.

Cabmen are, I think, generally pretty smart all the world over, and my Belgian jehu, though youthful, was old enough to take his observations before taking me. I hailed cab after cab on landing, but the drivers looked straight over my head. I soon perceived that I was neglected because alone. The more passengers the more money, and the "parties" were first picked out, individuals having to wait their turn. They appear to know just a little English—"shillings" for instance, and are good enough to take them in lieu of francs if you are not better provided. The first time I went to Belgium I neglected to provide myself with Belgian money. My first cab fare was, I knew, 3 francs—2s. 6d., but nothing but 3s. would satisfy. A half-crown did not appear to be understood at all. It was "tree francs—tree chillings," and by the want of the former I was chilled out of sixpence.

Antwerp is a city of extremes; you find the roughest of people about the quays, and the most polished and polite in the town. You find the oldest and some of the ugliest buildings imaginable, and also modern erections of an imposing character. You find the narrowest and most angular of streets you can think of, and broad, open, and gracefully curving boulevards. You find the dingiest of "estaminets" or taverns, and the most beautiful of cafés and best of hotels. You find all sorts of religious tableaux sculptured and gilded on the corners of houses, and not one per cent. of the people going to church. Sundays are as other days, except being more gay, in this good old Catholic town, and those who are very strict in their devotions go straight from mass to secular concerts. The cathedral and churches are very beautiful, and appear to be always open; and even there you may see contrasts—in the intense devotion of some visitors and the play of the children, who rush in and count their beads—making a race of it—and out again at the r games, apparently enjoying the fun immensely. You find excellent horses in the drays and miserable hacks in carriages, and the only dogs fit to be seen are yoked either singly or in pairs or running tandem in vehicles of various kinds, especially milk carts. The utility observable is very stern. Even dogs do the churning; and the pleasures of the people, when they do indulge in them, are earnest too. At the communal fêtes it would seem as if all the pleasure fairs in the country had congregated together in the city, and had the weather been finer there would have been quite a carnival.

The horticultural show, that has been described, was a prominent feature, and the nursery of Mr. Charles Van Geert, one of the oldest and most esteemed of Belgian horticulturists, was a centre of attraction to many, and his hospitality to his visitors was worthy of the occasion. Some account of this and other nurseries, and of the winter garden and improvements at Laeken, must be postponed, as they do not pertain to the "first day" of any "week in Belgium."—J. WRIGHT.

#### DOUBLE HELICHRYSUMS.

No half-hardy annuals have afforded me as much pleasure this season as a collection of double Helichrysums. It is much to be regretted that they are not better known. I know nothing that will give a richer and more serviceable return for so little trouble. I am now having a rich harvest of beautiful flowers from a two-shilling collection of seed. This was sown early in spring in a box, and after well hardening the young plants they were dibbled out 2 feet by 1 apart, in a good rich soil. They are more beautiful in a large mass like this than when dotted about. Of the many improvements of all classes of flowers of late, I see nothing more striking than with these. We now have almost every shade of colour possible. Looking at a mass of the flowers before quite open, we are reminded of the Persian Ranunculus. I must yet speak of one or two invaluable properties of this neglected Everlasting. Not the least is the long time it keeps in flower. The last three weeks has been a trying time, and most garden plants have been woefully disfigured. Not so these. At night and on wet dull days their shell-like petals are closed up (without the flower is old), and only induced to unfold by warmth and sunshine. They are the best of Everlastings, gathered just when

half open and hung up in any shaded airy room. We use them largely for church decoration. Lastly, I find these Helichrysums have not only been wonderfully improved in colours but also in character of growth. They formerly were tall lanky plants (and there are many such now), but I am glad to find that most of them are of a dwarf branching habit. This is a great acquisition. Many grow not more than 8 to 10 inches high and as much through, while others run to 2 to 3 feet high. The dwarfs are exquisite and will yet shine in the ribbon borders and flower beds. I mean to try them there next summer. I have only now to thank our continental friends for the improvement they made in this lovely flower, and ask them to select us a good strain of a dwarf compact habit and distinct colours; for such there will be a ready sale.—JOHN TAYLOR, *Hardwicke Grange, Shrewsbury.*

#### THE ART OF COLOURING GRAPES.

THERE is no doubt that "SINGLE-HANDED" is right in saying it is the want of air that prevents Grapes colouring which are situated far away from the ventilators, while those which are near colour perfectly. One would think at first sight, that when the ventilators are open both at the back and front sufficiently to keep a house comparatively cool, there would be a perfect current of air which should be ample for all purposes. But I am convinced that colour is not produced by any particular degree of temperature, neither will a certain number of cubic feet of fresh air per minute always produce it. The colouring agent, whatever it may be, is extracted from the air by the foliage, and it is natural to suppose that as the quantity is limited, that foliage with which it first comes in contact has the best chance of getting a supply; and there is no doubt that, though all the fruit in common depends on the roots and the foliage in general for its supply of raw material, yet local fruit depends on local foliage for its quality and finish. This being so, large panes of glass with puttied laps are not so likely to produce good colour as smaller panes with abundance of small apertures, and I think this will be found to be so in practice where there is no effort made to counteract the effects of the almost airtight glazing. Black Grapes of the Hamburgh class I consider want more air to colour them perfectly than other Grapes do. Taking one season with another, I have never seen Hamburgs exhibited with such colour and finish as Mr. Henderson of Cole Orton used to exhibit them, and I have always understood that his houses were glazed with small panes, and that they were far from being weather-proof. I am not, nevertheless, going to advise a return to the small panes, but of that more anon.

Most Vines I believe are trained too near the glass. All the foliage which is most exposed to the light, and which ought therefore to be of the greatest benefit to the Vines, has its upper surface pressing close to the glass, and is thus to a great extent prevented exercising its natural functions. Thorough ventilation of dormitories is of little use where the occupants will persist in covering their heads with the blankets, yet some of us act almost as inconsistently as this with our Vines. We give air no doubt to the house, but to be successful we must go farther than that—we must do as sensible people do when they distribute charity, see that it goes where it is most needed. I have said that the leaves pressing against the glass are unable to perform their natural functions; they are not only rendered impotent themselves as regards inhalations and exhalations, but by preventing the circulation of air and obstructing the rays of light they deprive a great portion of the plant of its vital necessities.

The remedy, then, for bad colouring with Grapes otherwise so well managed as those described by "SINGLE-HANDED" is more air in such a way that the foliage can have the full benefit of it. Four feet apart is quite near enough for Vine rods—mine have more space than that—and 2 feet from the glass is not too far; the upper portion of the Vines under my charge have a space of 6 feet between them and the glass, and there being nothing to prevent the air gaining direct access to every leaf, merits and demerits as far as colouring is concerned are equally distributed.

There is another advantage in having Vines trained further from the glass than they generally are which is worth noticing. Everyone knows how difficult it is to tie the young growths down in spring, and when tied as we think safely during the day they will often snap off when they become more rigid at night, and leave a piece of bare stem. "SINGLE-HANDED" and others recommend training them in V-fashion. I leave them alone with the exception of stopping the points till the Grapes are ready to thin, when they are easily bent to any form, and are tied down as we proceed with the thinning.

Besides a saving of time and some branches there is no doubt that the upright natural position is favourable to the setting of the

flowers. I observed last May that Mr. Barron was following the same practice in the large house at Chiswick, where, although the Vines are not a great distance from the glass, the sides of the house being almost upright, the leaves cannot press against it with their whole surface, as they do in comparatively flat houses. It has been noticed by many that, although there are very great disadvantages to contend against in growing Grapes in this said house, yet it generally finishes off a heavy crop marvellously well; indeed, very much better than the best practitioners amongst us would predict if we had not seen what can be done there. Good attention aside, may not the position of the leaves I have mentioned—*i.e.*, not pressing their surfaces against the glass—have something to do with it?—WM. TAYLOR.

### IRISES.

(Continued from page 331, Vol. I., New Series.)

To conclude the brief review of the chief species in the beautiful genus *Iris*, only one section, the Pogoniris or Bearded kinds, now remains to be considered, and though this contains a number of really ornamental forms, and some of the best known in English gardens, the most distinct can be described in few words. In treating the genus systematically—that is, under the several divisions to which the numerous species have been allotted, there is one disadvantage—namely, that the order of flowering cannot be so clearly indicated as might be desired by some growers. To rectify this, however, the list at the conclusion of these remarks will probably be found useful, as the most attractive or interesting forms in flower during seven or eight months of the year are there named.

In the classification adopted by Mr. Baker, which has been followed throughout these notes, the division Pogoniris is defined as including those species that have the falls bearded down the claw and the standards beardless, the root, like many others in the genus, being a rhizome. The various species are then arranged in five groups, chiefly distinguished by their relative dwarfness of habit, the typical forms chosen being *I. pumila*, *I. biflora*, *I. variegata*, *I. germanica*, and *I. pallida*. As each of these includes several species of more or less interest and beauty we may devote a few remarks to them in the order named.

First respecting the *I. pumila* group, which is marked by very dwarf habit, the flowers being produced early in the spring, and includes several species; but one of the best known is the type *I. pumila*. This is one of the dwarfest of the genus, scarcely exceeding 5 inches high, with short tapering leaves, and is compact in habit, bearing bright purple flowers which are very attractive in spring, generally April, though they are of short duration. This may claim a place amongst the oldest of our garden plants, for it was known to Parkinson, who described it in his "Paradisus" as the "Lesser purple dwarf Flower de Luce," and also enumerates six varieties, more even than are found in cultivation at the present time—at least, really distinct forms. One of the most pleasing varieties now known is *I. pumila cœrulea*, which has a preponderance of a bright blue tint in the flowers. The species is a native of hilly situations in central and south-eastern Europe, but it is not at all particular as to soil under cultivation, thriving in any that is not very heavy or wet, and it is easily increased by division of the roots. Passing *I. chamæiris*, which does not possess remarkable beauty, *I. olbiensis* is the only other form in the *pumila* section that needs special notice. This, though ordinarily regarded by growers as a distinct species, is considered by Mr. Baker as simply a variety of *I. chamæiris*. However, that is a matter of small importance, especially as several of the forms in this section come near in characters. It is something like a slightly enlarged *I. pumila*, having rich purple flowers, which in some cases are varied by the introduction of bright yellow hues that contrast very strikingly. The flowers, moreover, possess a very agreeable fragrance—a quality of no mean importance.

The *I. biflora* group has similar characters to the preceding, only a few unimportant botanical peculiarities serving to distinguish them. The type named above is the most attractive in the group; it is of medium height, rarely exceeding a foot, and has pretty flowers, the falls being veined with lilac or various shades of purple, some very rich on a lighter or nearly white ground. It has been not inaptly described as a dwarf *I. germanica*, for it bears some resemblance to that well-known species. One variety, *I. biflora gracilis*, well merits its name, being slender in habit and delicate in colouring, the tints being lighter than in the ordinary form. Other species in this group are *I. lutescens* and *I. arenaria*, neither very beautiful, the latter being chiefly noteworthy for its spreading roots and the dry sandy positions in which it is found growing naturally.

The *I. variegata* or *I. aphylla* group is not a very remarkable

one. The plants composing it are better known than those of the two previous groups, sometimes reaching nearly 2 feet, the flowers being borne on stems that are but little taller than the leaves. The chief garden form is *I. variegata*, and this has received much attention by growers, something like twenty named varieties being catalogued and described by various firms. It also is one of the "kinds of Flower de Luce" known to the old writers. Parkinson mentions it and says, "The yellow variable Flower de Luce loseth his leaves in winter contrary to all former Flower de Luce, so that his roote remaineth underground without any show of leaf upon it; but in the beginning of the spring it shooteth out faire broad leaves." Continuing his description of the flower he says, "The falling leaves are of a reddish purple colour, and the three that start upright are of a smoakie yellow." This is not a very glowing description, but is truthful as applied to the

Fig. 37.—*Iris squalens*.

original form, though some much more richly coloured varieties are now in commerce, the standards being various shades of yellow, and the falls crimson or purple veined or mottled in a very diverse manner. The peculiar tinted *I. lurida* takes its position in this group, but now so many brilliant Irises are known such as this can well be dispensed with in most collections, except where it is desired to have as many representative species as possible.

The *I. germanica* group includes several of the best in the whole Pogoniris section, the first-named alone being entitled to a high position amongst garden plants, and perhaps there is no other species in the genus that is so largely represented in town gardens, especially in the neighbourhood of the metropolis. The varieties, too, are now very numerous and beautiful, but as a selection was given some time ago when considering another section it would be unnecessary to refer to them again, and the type is so well known that it does not need description. Unquestionably it is a useful addition to any garden, fine bold clumps having a

telling effect in suitable positions during the short time that the plants continue in flower. Perhaps some readers may, however, not be aware that it has been known in England nearly three hundred years, most of the old herbalists having described or figured it. It is from the macerated flowers of this species that the pigment Vert d'Iris, Verdalis, or Iris Green is said to have been prepared. *I. sambucina* is principally noteworthy for the Elder-like fragrance its flowers possess, to which quality the specific name refers. The flowers are somewhat dull in colour, or as the author of the "Paradisus" observes, they "are of a pale or bleake colour tending to yellownesse, shadowed over with a smooke purplish colour." The fragrant *I. neglecta* must not be omitted, for it and its varieties are general favourites wherever hardy flowers are cherished. In the typical form the standards are blue, the falls having a yellow crest and being veined with violet, but this is considerably varied in some forms. The only other species in the sections deserving special mention is the one represented in the woodcut (fig. 37)—namely, *Iris squalens*, one of the early-flowering kinds of moderate height, very easily grown, bright and pretty. The standards are yellow, brown, orange, or purple tinted, the falls being neatly rounded in form; crimson or purple of very rich shades, often prettily veined or netted with a dark hue on a light ground. In the one figured the veins were violet or purple on white, the standards being yellow tinted with purple. It is a charming species, and is now represented by many handsome varieties, of which a dozen good distinct forms could be selected.

The last group to demand notice is that of which the chief species is *I. florentina*, the violet-scented roots (Orris or Orrice) of which were formerly used in medicine, but are now principally employed in perfuming various articles for the toilet. The plant itself is a handsome one, the large white flowers having a fine effect in combination with those of darker hues, and therefore it is well worth a place in any garden both for its beauty and historical interest. *I. pallida* and the orange-scented *I. plicata* are both pretty, the former especially, of which over a dozen varieties are grown, including some beautiful shades of blue, purple, and crimson.

This concludes the brief review of the genus; and as an aid to intending growers, the following list will convey some idea of the order in which the principal species flower, commencing with the end of December, from which time till March, *alata*, *stylosa*, *reticulata*, *persica*, *caucasica*, *tingitana*, *Kolpakowskiana*, *Reichenbachiana*, and *iberica* come into flower, some of them often appearing in frosty and snowy weather outside; *reticulata* and *persica* being especially suited for culture in pots, and when grown in cold frames they are obtained in flower a week or more earlier than outside. During April, May, and June the bulk of the Irises are attractive, most of the section just described being at their best in April or May. Following these are the Apogon Irises, the strangely coloured Spanish Irises, the richly tinted English Irises, and finally the magnificent Japanese Irises, the now varied forms of *I. Kämpferi*, that often continue flowering until August, which may be considered the termination of the Iris season.

It may be well to remind amateurs that the present month is a very suitable one for planting the bulbous forms or dividing the rhizomatous kinds, but as the season is a wet one the work had better be completed as soon as possible.—L. CASTLE.

#### DEATH OF MR. CHARLES LEE AND MR. W. E. RENDLE.

It is with much regret that we have to announce the death of two well and widely known horticulturists which occurred last week—Mr. Charles Lee of Hammersmith, who died on Friday, the 2nd inst., and Mr. E. Rendle, who expired on the following day.

MR. CHARLES LEE.—The death of this gentleman was lamentably sudden. While driving in his chaise on his way to his country nurseries the horse became troublesome, and caused some nervousness and excitement that had a most melancholy result, for whilst Mr. Lee was sitting in the vehicle in the High Street, Hounslow, and giving some instructions to his coachman, he expired suddenly. On the following day an inquest was held at Crosby House, Hounslow, when Mr. Bullock, surgeon, said the cause of death was apoplexy, and a verdict was returned in accordance with the medical evidence. The deceased was head of the firm of Messrs. Charles Lee & Son. The business at Hammersmith, which is the head quarters of an extensive nursery trade, has been conducted by three generations of Lees, and Mr. Charles Lee was the representative of the fourth. On the retirement of Mr. John Lee, early in 1877, the deceased attained to the position that he occupied until his death. Although seventy-

three years of age Mr. Lee was remarkable for his activity and his great business capacity. He was skilled in his calling, hospitable, and kind; indeed, he was a fine example of a British nurseryman, and his death will be mourned by all who had the privilege of his acquaintance.

MR. W. EDGCOMBE RENDLE.—Mr. Rendle died at Eastbourne after a long and severe illness. He was borne on February 10th, 1820, at Compton Giffard near Plymouth, and was thus sixty-one years of age. His father was a nurseryman of repute, and established the Union Road Nursery, Plymouth. The deceased succeeded to this business in 1840, and shortly afterwards invented the tank system of heating, which for a time was somewhat extensively adopted. We are informed that Mr. Rendle was the first to publish descriptive catalogues of seeds and send them through the post all over the country, and also the first to introduce the artificial manure business in the west of England by shipping guano from Peru. About 1852 a large portion of his grounds were secured by the railway company, and shortly afterwards the gardens were used for flower shows, concerts, &c. In 1861 Mr. Rendle removed to London, where he was engaged in various mercantile pursuits. In 1868 he again turned his attention to the horticultural business, and invented some wall-protectors; and on this principle he erected structures for the Duke of Portland to the amount of £10,000. Eventually his system of glazing attracted the notice of the railway authorities, and the plan has since been applied to several large stations, the Westminster Aquarium, and large buildings in different parts of the country.

THE SEVENTH INTERNATIONAL POTATO EXHIBITION, to be held at the Crystal Palace on the 20th and 21st, under the patronage of the Lord Mayor, is expected to prove the most interesting of the series. The first International Potato Show was held in the year 1875, consequently the forthcoming meeting will be the seventh. Hitherto every succeeding year has witnessed an improvement both in numbers and in the selection of varieties and samples. The promoters are practical men, who, having put their hands to the plough, are not likely to look back.

— AS an example of the demand that exists for PYRETHRUM GOLDEN FEATHER and the mode adopted by growers who send large quantities into the markets, we cite the following passage from a communication recently received—"In one of the medium-size market-growing nurseries in the neighbourhood of the metropolis, one of the specialities is a supply of Golden Feather, which is provided in the following manner—Shallow light wooden boxes are employed specially manufactured, about 15 or 18 inches long, a foot wide, and 2 inches deep. These are filled with light soil, and the seed is sown at the present time so as to obtain the plants strong before winter. When of sufficient size and before they become crowded the young plants are pricked out, a hundred in each box, which are then placed in a cool house as near the glass as possible, so that sturdy plants are secured by March, at which time the greater portion is sent to market. It is said these boxes when ordered in large quantities cost about 1½*d.* each, and the highest price obtained for a box containing a hundred plants is 1*s.*, which must leave a large margin of profit. The grower now referred to sends four thousand such boxes to London every year, and he says that had he the space to accommodate them he could dispose of twice that number."

— A SIDMOUTH correspondent will be glad if any of our readers can inform him how to destroy HORNETS' NESTS, of which he has two—one high up the brick wall of the garden, and the other between the laths and plaster and brick wall of an outhouse.

— A RECENT visitor to Ireland sends the two following notes:—"One of the most historic and picturesque isles in the

Killarney Lakes, ROSS ISLAND, is covered with *Osmunda regalis*. There is about 10 acres of it in one spot; no other Ferns are near. All seem to give place to their more princely and royal compeer. Many of the fronds are over 5 feet high."

— "IN the same place, called THE MEETING OF THE WATERS, immortalised by Moore, near the old Bridge of Weir, the water is skirted with a fringe of *Osmunda regalis*, not very high, which here and there peeps out a bunch of common *Erica*, forming, as it were, one grand natural bouquet, which would be hard to imitate. The Killarney Fern (*Trichomanes radicans*) is becoming very rare."

— MESSRS. JAMES VEITCH & SONS have received from Mr. McLachlan an example of his strain of COCKSCOMBS, the head measuring 2 feet 9 inches from tip to tip, and 18½ inches in breadth. In richness of colour, too, the head was one of the finest we have seen.

— WE regret to learn that the veteran florist and well-known raiser of Carnations, MR. E. S. DODWELL, is compelled by ill health to remove from his present residence, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W. His surplus Carnations and Picotees, including unbloomed seedlings, also his garden appliances of various kinds, are offered for sale, and must be disposed of early in October.

— MESSRS. CLAY & LEVESLEY of 174, High Street, Homerton, desires us to state that, in order to facilitate their expanding business, they have erected offices at their works, Temple Mill Lane, Stratford, London, E., where all communications should be addressed.

— IN reference to the recent MANCHESTER INTERNATIONAL SHOW, Mr. Bruce Findlay informs us that on Saturday the 27th ult., when the weather proved bright for a few hours, about fifteen thousand persons visited the Show, the total number being about 40,000, which, considering the very unfavourable weather that prevailed during the greater part of the time, was a much larger company than could have been expected. We learn that medals were awarded to Messrs. Leech Bros. and Hoyle of Manchester, for the best mowing machine and the best garden seat. We are also informed that Messrs. R. Halliday & Co. of Manchester were awarded the gold medal for general collections of hothouses, frames, boilers, &c., not Mr. R. Holiday, as stated in the report.

— MR. CHARLES TURNER of Slough announces that he intends exhibiting a LARGE COLLECTION OF DAHLIAS AT SOUTH KENSINGTON next Tuesday. All the chief sections will be well represented by selected varieties.

— "IN the Botanic Gardens, Belfast," writes a correspondent, "is a *BOUGAINVILLEA GLABRA* that fills a curvilinear house, 30 feet by 20 feet. It is trained on a wire trellis. When in full bloom, as it was at the time of my visit, it is very handsome."

— THE same correspondent observes—"At KILLARNEY HOUSE, the seat of the Earl of Kenmare, the gardens and pleasure grounds are undergoing most extensive alterations and improvements. Miles of walks are being made; new carriage drives in every direction, adding much to the charm of the lakes, the resort of so many visitors during the summer. Rhododendrons and Pines grow very freely. The extent of the planting may be judged from the fact that seedling trees sufficient to plant over 4 acres of nursery ground are bought every year. These are planted out the following year in their permanent quarters. The whole is under the charge of Mr. Kelly, who, in addition to his abilities as a general gardener, seems to be skilled in the art of landscape work."

— WE have received particulars of the following recent

GARDENING APPOINTMENTS—Mr. R. Billiald, late foreman at Leighton Hall, Welshpool, succeeds Mr. Salter as gardener to A. Sillem, Esq., Laurie Park, Sydenham; Mr. John Bottrell, late foreman at Trentham, succeeds Mr. Harris as gardener to Lord Vernon, Sudbury Hall, Derby; Mr. Thomas Hill, late foreman at Brodsworth Hall, Doncaster, succeeds Mr. Woolley as gardener to H. Berens, Esq., Sidecup, Chislehurst; Mr. Henry Downing, recently gardener to Lord Huntingfield, Heveningham Hall, Yoxford, succeeds Mr. Smith as gardener to A. Brasscy, Esq., Heythrop Park, Chipping Norton; Mr. H. Wilson, recently in the service of J. E. Barton, Esq., Prescott House, Stourbridge, as head gardener, succeeds Mr. Downing in the same capacity to Lord Huntingfield, Heveningham; Mr. Alexander Todd, late gardener to H. Miles, Esq., Ham Green, Bristol, has been appointed to a similar position in the service of J. Theobald, Esq., The Bedfords, Havering, Romford, Essex; and Mr. R. H. Taylor, late gardener at Kingwell Hall, Bath, has been appointed gardener to James Watson, Esq., Langley House, Slough.

— IN the course of Sir John Lubbock's excellent address at York on the opening of the Jubilee Meeting of the British Association for the Advancement of Science, he made the following remarks upon the ALTERNATION OF GENERATIONS, which are not devoid of interest to horticulturists:—"It has now been shown by Bassett, and more thoroughly by Adler, that some species of insects are double-brooded, the two broods having been considered as distinct genera. Thus an insect known as *Neuroterus lenticularis*, of which females only occur, produces the familiar Oak-spangles so common on the under sides of Oak leaves, from which emerge, not *Neuroterus lenticularis*, but an insect hitherto considered as a distinct species, belonging even to a different genus, *Spathogaster baccaurum*. In *Spathogaster* both sexes occur; they produce the currant-like galls found on Oaks, and from these galls *Neuroterus* is again developed. So also the King Charles Oak Apples produce a species known as *Teras terminalis*, which descends to the ground and makes small galls on the roots of the Oak. From these emerge an insect known as *Biorhiza aptera*, which again gives rise to the common Oak Apple. It might seem that such inquiries as these could hardly have any practical bearing. Yet it is not improbable that they may lead to very important results. For instance, it would appear that the fluke which produces the rot in sheep passes one phase of its existence in the black slug, and we are not without hopes that the researches in which our lamented friend Professor Rolleston was engaged at the time of his death, which we all so much deplore, will lead, if not to the extirpation, at any rate to the diminution, of a pest from which our farmers have so grievously suffered."

— THE following observations upon DIMORPHISM IN PLANTS in another portion of the President's address are noteworthy—"It had long been known that the Cowslip and Primrose exist under two forms, about equally numerous, and differing from one another in the arrangements of their stamens and pistils; the one form having the stamens on the summit of the flower and the stigma half way down; while in the other the relative positions are reversed, the stigma being at the summit of the tube and the stamens half way down. This difference had, however, been regarded as a case of variability; but Darwin showed it to be a beautiful provision, the result of which is that insects fertilise each flower with pollen brought from a different plant; and he proved that flowers fertilised with pollen from the other form yield more seed than if fertilised with pollen of the same form, even if taken from a different plant. Attention having been thus directed to the question, an astonishing variety of most beautiful contrivances have been observed and described by many botanists, especially Hooker, Axel, Delpino, Hildebrand,

Bennett, Fritz Müller, and above all Hermann Müller and Darwin himself. The general result is, that to insects, and especially to bees, we owe the beauty of our gardens, the sweetness of our fields. To their beneficent though unconscious action flowers owe their scent and colour, their honey—nay, in many cases their form. Their present shape and varied arrangements, their brilliant colours, their honey, and their sweet scent, are all due to the selection exercised by insects. In these cases the relation between plants and insects is one of mutual advantage. In many species, however, plants present us with complex arrangements adapted to protect them from insects; and within the last few years Darwin, Hooker, and others have shown that many species have curious and very varied contrivances for supplying themselves with animal food."

#### BEDDING PLANTS AND THE WEATHER.

ALTHOUGH, perhaps, of secondary importance, it is, to say the least, very annoying to see the labour of many months not merely spoilt but positively rendered unsightly by the continued prevalence of wet weather, and this, too, at a time when many of us are most anxious to have things at their best. The start made in the first instance was not very encouraging, as many of the more tender kinds were much injured by the late frosts; next, the long spell of dry weather militated against many kinds; and now, when everything was beginning to brighten, comes the "damper." The result, with a few notable exceptions, such as *Violas*, *Verbena venosa*, and *Begonias*, is the absence of bloom, especially in the case of *Pelargoniums* and *Petunias*, and unusual and unwished-for vigorous growth in the case of *Lobelias*, *Ageratums*, *Verbenas*, and *Heliotropes*, the whole presenting more the appearance of breaking-up time than August. This, no doubt, is the general experience, though perhaps those in more open and drier positions do not look so woe-begone as in our and other cases, where the gardens are hemmed in with trees and otherwise sheltered, thus inducing a less sturdy and floriferous growth.

My object, however, in penning these lines is not because I am in a grumbling humour, but more especially with the intention of directing attention to the carpet beds, which in our case are the only bright spots in the general desolation. Carpet beds we were bound to have; and although at one time I begrudged the time and space necessarily devoted to the propagation and putting out the plants, I am now very glad I carried out my employer's wishes to the fullest extent possible. The comparative superior attractiveness of the carpet beds, ordinary as they certainly are, was apparent some time since, but was most strikingly so on my return from a week's trip in the midlands. Among the various plants employed in these *Pyrethrum Golden Feather* was the only kind to fail, these having damped off largely. *Lobelias* I seldom use in carpet beds. *Echeverias* of sorts, *Pachyphytons*, *Kleinias*, *Mesembryanthemums*, *Sedums* in variety, *Coleuses*, *Iresines*, and *Alternantheras*, all appear uninjured. Of the latter, and which are really indispensable, *A. spectabilis* is the brightest in colour—a very effective rich crimson; and *A. paronychioides aurea*, a comparatively scarce variety and a great favourite in Hyde Park, of which I fortunately had a good stock, is also decidedly effective, being bright yellow in colour and of neat habit. *A. paronychioides major* is also well coloured, but the same cannot be said of *A. paronychioides*. To these varieties I hope next season to add *A. versicolor grandis*, this being vigorous in growth and rich in colour, and therefore suitable for filling-in central figures.

It must not be inferred from these brief remarks I am an enthusiast on the subject of carpet beds. On the contrary, I would reduce the number of these in many gardens, turf over all elaborately planned flower gardens, and disperse a few plain beds about the grounds, whether this be strictly in keeping with the surroundings or not. Some of these should then be filled with carpeting plants, both because agreeable to employers' wishes and also because most pleasing to the generality of visitors, of whose good opinion I am not yet disposed to affect indifference. There is no disguising the fact that carpet beds are the first to be attractive and the last to succumb to the effects of unfavourable weather whenever experienced.

**MESEMBRYANTHEMUM PROPAGATION.**—In my remarks on "Autumn Propagation of Bedding Plants," page 171, I omitted mention of *Mesembryanthemum cordifolium variegatum*, and as this is deservedly a popular bedding plant I will now rectify the mistake. The cuttings of these in common with other plants of a similarly succulent nature will, if subjected to a close moist atmosphere and shaded, invariably damp off. Our plan is to fill well-

drained 5 or 6-inch pots with light sandy soil, and to dibble in the cuttings thinly. They are then placed on a shelf exposed to the sun in a heated house, and no water given till the cuttings are seen to be freshening up or are callused. To water them before the cuts are healed would undoubtedly result in a bad strike. I ought perhaps to state the cuttings are about 3 inches long. Many kinds of succulents may be placed on a shelf till the cuts are healed, but the *Mesembryanthemums* would curl, thus rendering it impossible to dibble them in. An ordinary stove temperature is suitable for wintering them, and they will not require much moisture at the roots; still less must be given if the attempt is made to keep them in a cool house.—W. I. M.

#### MR. A. PETTIGREW.

AS both gardeners and bee-keepers have frequently requested us to publish the portrait of Mr. Pettigrew, who has for many years been a contributor to our gardening and apiarian columns, we submit what to a great number of visitors to the Manchester Show will be a recognisable likeness. We insert this in our gardening columns, because, as will be seen by the following autobiography, Mr. Pettigrew is at least as much a gardener as an apiarian, and what he has written has been intended especially for the perusal and benefit of young gardeners, who may presumably derive some useful lessons from a long, varied, and not unsuccessful career.

#### AN AUTOBIOGRAPHY.

Though fully convinced that biographies and autobiographies are, generally speaking, imperfect, I have, in a moment of weakness, consented to give a short account of myself in the pages of the *Journal of Horticulture*. At once let me say that it is a hard task for me to think about, a difficult work for me to perform.

Some time after the battle of Waterloo I first saw the light in the village of Carlisle in the centre of Lanarkshire. My father was from the age of twenty to thirty a common labourer, and it may be safely stated that during those years he was the most advanced and most successful bee-keeper in Great Britain. During those ten years he saved, as the results of bee-keeping, £300 or £400, wherewith he bought the "Black Bull Inn" and commenced the business of selling drink. The surroundings of my early life were, therefore, disadvantageous. I had to live in an atmosphere not favourable to the growth of moral feelings or tending to give direction to enlightened pursuits. As I grew up I disliked nothing so much as school lessons, and was a great dunce, almost always at the bottom of the class. When I was about eight or ten years of age my father became a butcher, and sold beef and mutton as well as whiskey, and I assisted in the business. Thus my early days were spent. My father continued to keep bees, and his success encouraged many around him to do the same. Ever since his day (he died in 1843), and during his time, bee-keeping has been a source of pleasure and profit to many working men in Carlisle and the adjoining parishes. The bee-keepers there now are numerous and successful, and the annual yield of honey is satisfactory. In early life I imbibed my father's love of bee-keeping, and learned all he could teach me, and eventually the management of his bees was left to me.

When about the age of eighteen I went to Carstairs House to learn gardening, paying £5 as an apprentice fee. During my three years there I was permitted to dig, mow, and to do the routine work of the gardens, but no encouragement to read and study was given me. My first master at Carstairs had been head man for fifty-six years. He had three apprentices at a time, and was not satisfied with having their £5 fees, but he kept 6s. a week of their wages. This was discovered, and the old gardener was dismissed on a pension of £20 a year. He died in a few weeks after. It is now forty-six years since I went to Carstairs, and I look back with regret to the three years I wasted there, chiefly by my own folly and partly by the want of interest on the part of my two masters.

I left Scotland a conceited young man. Arriving in London in the beginning of 1839 I was sent by Mr. Hugh Low of Clapton to Lord Mansfield's garden near Hampstead, and there I found young men—apprentices of nine months' standing—that knew more of gardening and possessed more intelligence than I did. This discovery was healthful and stimulating. Fortunately for me "Cobbett's Advice to Young Men" fell into my hands about this time. Opportune and good advice it gave me—the first advice I ever had. It made me thoughtful, and induced me to study English grammar, so that I could speak in a passable manner. Before I saw this book I could not put three sentences together correctly. I owe much to Cobbett's "Advice to Young Men" and his "English Grammar," which latter book is meant to teach the sailor and ploughboy how best to use their mother tongue and speak correctly. That was the turning point of my life. I began to study horticulture in books as well as in the garden, and read the best writers on the subject. My desire for knowledge increased. My evenings were spent in reading scientific works on gardening and farming. The latest works on chemistry, physiology, and natural philosophy were greedily read. Theatres and public houses were neglected. Two years of "my glorious youthful prime" were spent but not wasted at Hampstead. I was fortunate in know-

ing Mr. William Thomson in Scotland, who afterwards took charge of a large garden establishment near Barnet. I left Hampstead to serve under Mr. Thomson at Wrotham Park, and there I spent four happy years as his foreman. I owe a great deal to Mr. Thomson of Clovenfords—more to his first wife, who was an excellent woman and interested in my welfare.

In 1844 I commenced writing for the press, and began to think I was qualified to take charge of a gentleman's garden. Mr. Thomson commended me to the notice of Dr. Lindley, who sent me to serve a gentleman in Yorkshire. Though there was a disquieting element in this situation I resolved to bear it, serve the gentleman to the utmost of my ability, and stay at least three years. The gardens were not

walled, the house servants knew well the best fruit, the housekeeper was a great favourite of my master, and he allowed her and her friends to take what fruit they liked. This to me was the disquieting element of the place. My predecessor on leaving the place told me what would happen. One Saturday night at ten o'clock I caught a housemaid cribbing an apronful of Apricots. One year some Ribston Pippins were taken. My under gardener was suspected, and my employer would not listen to my pleadings on his behalf, and caused me to dismiss the best man that ever served under me. I did not engage another to take his place, but gave my employer notice to leave myself, and I did the foreman's work till I left the situation.

I returned to London, whence I was sent to Manchester to serve

Fig. 33.—MR. A. PETTIGREW.

Edward Loyd, Esq., banker, of Cheetham Hill. The situation was a comfortable one, and my employers exceedingly kind. Not a word of discontent was ever uttered by employers or employed. There I married and there my family was born. Owing to the long illness of my wife the household expenses were very heavy, greater than my salary could meet, and I told my employer that the considerations of health constrained me to think of seeking a change of climate. He would not, however, accept my resignation, said he wanted to find a house and garden in the south for himself. At last he consented to my going if I would find a gardener for him. This was done, and I went back south to fill a situation in Middlesex, in which I did not stay long. Mr. James Veitch of Chelsea then sent me to serve a gentleman in County Down, Ireland, in the joint capacity of

land steward and gardener, and we got on well, and had everything in good condition. My employer, however, resolved to have both a gardener and land steward, and I was offered either of the posts. I preferred giving my employer two months' notice, very much to his surprise and regret. He afterwards asked me to continue as I was, and promised to let me have the joint situation for life.

Returning to England I was engaged to serve a nobleman in Oxfordshire. This situation was entered on with a determination to make it my last, for as I had not failed to please other employers I would please here too. Fever entered my house and cut down my eldest boy: this frightened the lady I served so much that she speedily sent us from the place. I then resolved to take no other situation as gardener, but to commence business as a nurseryman

somewhere in England. After two months' search we found a field at Rusholme near Manchester, which we rented, and there we pitched our tent. We know that there is in this world a living for everybody who likes to go out to fetch it. I now became my own master, and this I liked very much, for I am somewhat afflicted with impatience under restraint. In my nursery at Rusholme I built a dwelling-house and greenhouse, worked hard for thirteen years, and did very well. My place at Rusholme was sold for building purposes, and I went to Sale, built a dwelling-house and three large vineries, and grew Grapes for eight years. This year I sold the place to Messrs. Stansfield, retired to Bowdon, one of the finest towns in England, most beautiful for situation, and here we shall keep bees, sell honey, and enjoy life as much as we can by helping others. And now I have to beg the reader's pardon for writing this long letter about myself. All I wanted to do has been simply to write for the benefit of young gardeners some lessons I have learned in my time. These lessons can be given in a second letter.—A. PETTIGREW.

P.S.—I may add that while an apprentice at Carstairs and a journeyman at Wrotham Park I kept bees in the woods and plantations, and when I became head gardener to gentlemen I managed their hives, wrote papers and treatises on the subject of bee-keeping, and noticed all that was going on in the apiaries around me. With one or two breaks while acting in the capacity of head gardener, I have managed bees for fifty years.—A. P.

#### NOTES ON CIRCUIT.

I IMAGINE that no Rose lover who had the pleasure of being present at the National Rose Society's Sheffield Show is ever likely to forget it. They have probably seen larger displays of flowers, they can recall stands which perhaps surpassed any that they saw there, and they may easily have recollected shows where the flowers remained longer in perfection, for with the thermometer at 80° they had but little chance in a tent; but there was a freshness and heartiness in all the arrangements which told upon everybody, and made them feel that the object of their affection was being honoured in a way that satisfied them of the pre-eminence accorded by universal consent to the queen of flowers. From the very first day that the idea was entertained the good people of Sheffield, to whom flower shows are a somewhat unusual sensation, entered into it *con amore*. The then Mayor (Mr. Alderman Tozer), Mr. Marshall the Secretary of the Botanical Gardens, Mr. Ewing the Curator, and last, not least, Mr. Charles Fisher of the firm of Fisher, Son, & Sibray, were the leading spirits of the enterprise, and the Committee of the Gardens readily entered into their plans. Everything was done ungrudgingly. A grand schedule was arranged, while what may well be called an additional one had been prepared by the townspeople. The cups, so liberally given, were no make-believes, but real, solid, substantial ones; and the prize for a seedling Rose offered by Messrs. Maples & Son, and which unfortunately was not won, comprised the most splendid set of garden tools I ever saw. By-the-by, this eminent firm have most liberally offered the same prize at the Bath Show of 1882. Two disappointments only can I deplore. One was that I failed in my attempt to see Ben Simonite's garden. I attempted it on the evening of the Show, but he was not at home, and after a weary tramp I had to abandon it. Of course I have been there, but it is always a pleasure to talk with so enthusiastic a florist, who is at the same time so thoroughly honest and genuine, working under difficulties which would discourage most men, and succeeding where few could hope to succeed.

It was a great comfort, after all the fatigues and anxiety of Sheffield, to be accosted on the morning of the Wirral (Birkenhead) Show—"I have had a message from the office to say you are not to trouble yourself about the Exhibition to-day, as I am here to report it;" for it is not an easy matter, after one has been engaged as I was, to have to take notes and then write off a report of the Show. I had reached Rock Ferry the day before, and there with my good friend Canon Hole we had somewhat rested from our labours. We saw in our host's (T. B. Hall, Esq., of Lambwood) garden the most abundant evidence of an enthusiasm in Rose culture which will account for the success he has already obtained—an augury, let us hope, of higher awards. He has built a house for Tea Roses which has succeeded admirably, and which has enabled him to show them in great beauty. His Hybrid Perpetuals were very vigorous in growth and gave fine blooms, although he had been hit hard by mildew. Roses abound, and I doubt not will soon overflow into the farm, where there is a grand piece of fine loamy soil, in which they would thrive. He encourages by his words and his success his neighbours to increase their growth of Roses. He can show what can be done in the windswept promontory of Birkenhead, and Rose houses are springing up around him. Canon Hole told him that it was all very well to say the new room he had just added to his house was a library. Nothing of the sort, he said; it was simply a room in which he

would set out his Roses the day before the Show. In fact, he said, all the arrangements of the place—cowsheds, piggery, poultry houses, &c., were only secondary. The grand point was how they could help forward his Rose culture.

I have mentioned what I saw and heard with regard to the Nottingham in respect to the low ideas of honesty entertained by the artisans there. Let me give an instance of a contrary character. "I want," said Mr. Hall, addressing Canon Hole and myself, "to introduce you to one of our most successful florists;" and forthwith brought forward a steady-looking bricklayer, who in a few words told us his history. "I was," he said, "one of the wickedest creatures on God's earth, and now, thank God, I am happy and comfortable." He had seen the folly of his ways. He took to gardening and a good wife. "And now," he said, "I should like to show you my little place." "Well," we said, "we must go up and see you. Is it far off?" "Oh, no!" he said; "but there, gentlemen, if you will come I'll stand the cab for you." This delightful, honest, and simple speech took us by storm; and although we did not accept his offer made in the overflowing of his heart, we went next morning to see him. He lives at Higher Bebington, and there in a small garden he has achieved an honest independence. He is the best bricklayer in this country side. He bought a piece of ground, on which he says he discovered a gold mine—a bed of building sand. He is a nurseryman too in a small way. He and his son have built their greenhouses, where he grows Fuchsias, bedding plants, Pelargoniums, &c., and after the plants are out Cucumbers. "They hardly pay," I said, "do they?" "Well, if I cuts sixty or seventy dozen a week and gets 3s. a dozen for them, why it do pay," was the practical reply. Out of doors Pansies, Dahlias, and Roses were well grown; and as to the latter, pointing to where the excavation had been made for the sand—"There," said he, "is a nice spot, warm and sheltered, where I should like to put up a nice house for growing Roses, and shouldn't I like to beat Mr. Hall? but there, they wo'n't let me do it because I sells." He introduced us to his excellent hardworking wife, who quietly laughed at him and said, "Ah, John! there'll be no speaking to you; now that these gentlemen have come to see you the house wo'n't hold you." Whether it be the elevating influence of a garden, or that a man is what a woman makes him, or both combined, certainly the history of John Lee of Bebington is an illustration of what can be done, and may well encourage others to imitate his example. He was not a little proud when he took at the Wirral Show the second prize for a bouquet of Roses, in the construction of which I should imagine his excellent wife had a good share.

That same Wirral Show has been so fully reported in the columns of the *Journal of Horticulture* that it may seem superfluous to say anything at this distance of time, but still there are some few things connected with it that I would like just to allude to. As a whole it was not equal to the grand Show of 1880. There was not the quantity of Roses which made that Show so memorable a one, nor was there such a grand box as that one of thirty-six which Mr. Jowitt exhibited then; but this was easily accounted for. The intensely hot weather (would that we might have had some of it in August) had had such an effect on the Roses that the more distant growers—Messrs. Paul & Son, Mr. Cant, Mr. Hawtrey, and others—could not venture to come with theirs. A journey in such weather would have been disastrous. There was, however, a marked improvement amongst the local growers. Mr. Hall's flowers, especially his Tea Roses, were much in advance of those he had previously shown, and I was particularly struck with the zeal and energy with which the subject of Roses and Rose culture was discussed; and if only one-half of the projected plans is carried out we shall see a great impetus given to the Exhibition at Birkenhead. I would have given something to have seen the bloom of A. K. Williams exhibited by Mr. Jowitt when he cut it the day before; and I can well believe that, as he said, it was the grandest Rose he ever cut. It was fully 5 inches across, most perfect in shape and substance, and altogether a most wonderful flower. There was another in his stand—a bloom of Dr. Andry, which was certainly very remarkable, so much so that several Rose-growers questioned whether it could be of that variety. There was, however, no doubt about it, and this judgment was confirmed by a lady whom I cannot but think about one of the best judges of Roses I ever met—Miss Watson, the very able coadjutor of Mr. Prince; but I do not think that anyone ever saw this fine old Rose shown in such form. Mr. Cranston's new Rose Mrs. Jowitt was shown by him in excellent form, and promises to be a very grand and useful Rose. It seems to be constant and of a very vigorous constitution.

In one thing I was certainly disappointed—the attendance of the general public. The day was fine, the place of meeting convenient, and one might naturally have expected a large concourse

of people; but perhaps we are too sanguine in this respect. After all, Roses have principally their charm to those who really love the flower: to the great mass one Rose is as another. Our hope must be that the public taste may be educated, that a more general appreciation of the flower may follow, and then a larger concourse of people to see them. Those who are endeavouring to foster this taste, as our friends at Birkenhead are doing, are worthy of all commendation, and I trust will have their reward in an increased public appreciation of the beauty of the Rose.—D., *Deal*.

#### TROPÆOLUM SPECIOSUM.

WITH the above I have succeeded far beyond my expectations, having had it well established and in flower in two places—at the foot of a north wall, and in a north-west angle near a rain-water tank: in both these positions it is doing remarkably well. I also planted two other patches at the foot of a south wall and west wall. The one near the south wall is barely alive, while on the west wall it is doing better, and was the first to flower; it is quite evident it is at home in a cool, moist, shady position. Through ignorance I planted the roots too thickly, and now they are established I hardly like to disturb them. My supply of roots came direct from Douglas Castle in a biscuit tin this last spring. From what I have seen I do not think it would be a hard task for any nurseryman to establish it in pots as mentioned by your correspondent “J. W.,” provided he could obtain a good supply of healthy roots such as I received from Douglas Castle. I tried a few roots in a pan in case those planted outside failed, and they grew and have succeeded fairly well. It would be wise to plunge the pots in ashes or cocoa-nut fibre at the foot of a north wall.

That it is a beautiful climber is beyond a doubt, and seen as described in Scotland it must be a sight never to be forgotten. I intend to try and induce it to grow with *Tropæolum peregrinum*, as that does well with me. I have it growing on arches made of long hazel poles over the kitchen garden path, where it has a good effect.—A. J. SANDERS, *Surrey*.

#### RECOLLECTIONS OF MANCHESTER.

GARDENERS, amateurs, and all, however slightly interested in horticulture, who visited the late great Show at Manchester, must now be in possession of many pleasing recollections of the grandest garden Show England has seen. The three days we spent at it will ever be periods agreeable to our recollections. The marvellous productions of fruits, flowers, and vegetables must have made us happier and wiser men—happier in observing such unmistakeable evidence of the care devoted to the objects of our chief attention, and wiser in the varied lessons which might in many ways be gathered from them. Apart from all this, too, the meeting was a true gardeners' one, where old acquaintances were warmly greeted and new friends firmly made. Of the Show itself too much good cannot be said. Nothing whatever was wanting except a bright sky and a dry atmosphere, and even the opposite of these lost their depressing influences to a great extent. Amongst gardeners it was said there was nothing there of a startling character, but collectively the uniformly high quality of the exhibits had no parallel. In visiting gardens and shows we may often see a few things well done or well shown, and much inferior produce, which detracts from that agreeable impression of general satisfaction. But there was nothing of the kind felt at Manchester. Of the fruits, plants, vegetables, or cut flowers it was difficult to tell which to admire most.

In giving a few notes we will, however, first refer to the fruit. As is now pretty well known, the large collections, winners and losers, were of high merit; a really bad dish, far less a bad collection, could not be seen. The positions gained by Mr. Coleman were ungrudgingly admitted to be deserved; his Grapes, Pines, and Peaches were especially fine examples of culture at home. Care in transit and taste in “setting up” Grapes, Pines, and Peaches were the leading features of all the minor collections, and it was observable that other black Grapes were better finished than Black Hamburgs. Of Grapes the great centre of attraction was the collections competing for the prizes offered by the General Horticultural Company (Mr. John Wills). Here the competition was what an aspirant from the Edinburgh neighbourhood termed “fast and furious.” Where the champion might come from was a matter of much speculation. On the forenoon of the 23rd suspicion rested on the Scotch east coast, a little beyond Berwick-on-Tweed; later on it was circulated that something strong had come from the north of the Tay, while after sundry peeps under the cautiously lifted lids of the long boxes a heavy lot was said

to have come from the temperance side of the Border; but few had any idea that all the time the most dangerous lot were resting under the table on the fancy-covered stands which figured so conspicuously at the International Show in Manchester in 1872. That Mr. Hunter was clearly first all noticed before the tents were cleared for judging, and much satisfaction was expressed at this gentleman being again in his old position. The Lambton Grapes were certainly highly finished, and the handsome size of the bunches added much to their merits. There was no disputing about the justice of positions in the Grape classes, excepting, perhaps in the Veitch Memorial class for three bunches of black Grapes. Muscat Hamburg was the favoured kind here, and some—a very few—thought the Madresfield Court should have been preferred. Both were fine, and we are quite prepared to give our vote in favour of the decision of the Judges, as we never saw a finer lot of the Muscat Hamburg. Although the berries might have been thought small the bunches were really grand, and their bloom and finish perfect. Nothing striking appeared in the new Grape class. The first-prize kind is not distinct enough in appearance, but is said to be of good flavour. Many Pine-growers had evidently kept away their fruit under the impression that the competition would be strong.

The Peaches were highly satisfactory in numbers, size, and colour. Apples and Pears, too, were not inviting in ripeness, but otherwise no fault could be found with them. In the fruiterers' competition the first-prize lot belonging to Mr. Mason of Manchester was admirable in quality and extent, and its arrangement was unique. It occupied about 30 yards of a wide table, and every dish was as near perfection as possible; indeed, the home-grown Pines, Black Hamburg, Muscat, and Duke of Buccleuch Grapes, were equal to any of the prizewinners.

In the plant department it was difficult to find anything bad enough to condemn, all being so evenly good that exception, could hardly be taken to any of the specimens. As usual the group from Messrs. Veitch of Chelsea was excellent, every plant being choice and faultless in culture. We have seen Mr. B. S. Williams exhibit larger specimens, but never more promising. It is not often that we see the Edinburgh nursery firms venture beyond the boundaries of their own borough, but it is evident there is enterprise in some of them, as Messrs. Ireland & Thomson of Craighleith entered in some of the most popular classes, and were very successful, especially with Crotons and new plants. The Crotons from Edinburgh which gained the first prize in their class were the finest we have seen for many a day. In health they were luxuriant, in colour brilliant, and altogether most creditable to the firm who sent them. Croton Thomsonii, which gained the prize for the best new fine-foliage plant, we preferred to any of the new forms shown from France. For artistic arrangement and a large quantity of healthy clean little plants of the choicest kinds nothing surpassed the group from the General Horticultural Company. Here Crotons and Dracaenas were used in great profusion to embellish a gradually inclining bank of great extent with grand effect. *Dipladenia hybrida*, which gained the Veitch Memorial prize for the best stove plant in flower, is, we were informed, much hardier than the other varieties. This will be good news for many who have not enough heat to grow the others satisfactorily. In speaking of the Veitch Memorial prizes many there could not understand why one or more of the ten £5 prizes were not given in the vegetable classes. As these prizes are supposed to encourage and reward the production of the most valuable occupants of our gardens vegetables should certainly be included, and we hope they will next time they are offered.

Since the last great Show at Manchester Tuberous Begonias have made great strides, and many of them were tellingly used in the groups of plants competing for effect. Of Roses those in pots from Messrs. Paul were the grandest lot that the Manchester people have seen in the autumn. They were chiefly Teas, and the number and quality of their blooms were surprising. Amongst the cut flowers we met our friend “D., *Deal*,” so we expect that every impression worth having will be given to readers of this Journal. We were especially pleased with the bouquet and single Dahlias. Of the latter there was a magnificent display from Messrs. Ware and Cannell.

Of the vegetables much might be said, as their numbers and quality have never been surpassed. New varieties, such as Culverwell's Giant Marrow Pea, Sutton's Marvel Cabbage Lettuce, Carter's Jersey Lily Turnip, the Reading Exhibition Sprout, and many others are sure to be frequently seen again. The Potatoes were quite a show in themselves, and indicated abundant crops all over the country. Onions, too, were remarkably fine; so fine, indeed, were the spring-sown ones that we heard one of your poultry writers remark that he thought some of them, like many

spring chickens, had been "hatched last autumn!" Tomatoes were disappointing, about the worst in the Show being awarded the first prize. Thus far I had written when our Journal of September 1st came to hand, and the report there is so full and just that I will not seek to take up more of your valuable space, except to say that the excellent likeness of Mr. Bruce Findlay was a pleasing surprise, and probably would be the same to thousands of your readers.—WELSHMAN.

BEFORE the Manchester Show is forgotten in the hurry of everyday routine I should like to note some few facts which struck me as worth remembering. First, by way of protest, let me point out the difficulty (to put the matter in as easy an aspect as possible) there was for gardeners to inspect the produce in the crush of visitors which thronged the tents after the Exhibition was opened. I went chiefly to see what hints I could gain that would be useful to me in my daily garden work, and had I not been so fortunate as to take my notes before that crush I am afraid my journey would have been fruitless. The Edinburgh "Internationals" are the only shows conducted for the benefit of gardeners. There gardeners of all classes are admitted at a uniform rate of 1s. for an hour or two before the general public. This is as it should be, and what the other managers ought to follow.

Amongst the plants, what I most admired was the collection of Crotons so artistically arranged by the General Horticultural Company, and the first-prize group of Mr. C. Smith, gardener to J. Rylands, Esq. This group struck me as being the most effective in the whole Show, not excepting the above-mentioned group of Crotons. It was certainly the embodiment of an attainment which any gardener might be proud to copy.

Turning to the fruit tent, the most remarkable object there was the display of Grapes. True, one might criticise the greenness of the Muscats and the general unevenness of the various collections; but that aside, there was no difficulty in finding very many fine examples of Grape culture. The six varieties from Mr. Elphinstone, Shipley Park, were really superb examples, the finish being perfect. The bunches were not large—just a good family size. I thought more highly of these than any other collection in the Show. Then remarkably fine were the Muscat Hamburgs from Mr. Boyd of Falkirk; and as a finish to the whole, what could surpass the magnificent display of fruit which Mr. Mason of Manchester set up? It had only one fault—the Pine Apples and Grapes were so fine as to put the other fruits entirely in the background. Few of the other fruits were above mediocrity, the Apricots being especially poor. I was interested in Peaches and Neectarines, and found many of the finest fruits old and well-tried sorts. Of Peaches Stirling Castle, Royal George, Violette Hâtive, Bellegarde, Grosse Mignonne, and Noblesse were fine; Princess of Wales was extra large; and fine dishes of Chancellor and Mr. Gladstone, varieties which I had not before seen, were also staged. The finest Neectarines were Lord Napier, Pitmaston Orange, Prince of Orange, Victoria, Violette Hâtive, and Elruge.

Amongst the abundant vegetables Snowdon's Nonesuch Peas, shown by Mr. Snowdon, Thirsk; and Livingstone's Perfection Tomato, shown by Mr. Iggulden, were all I noted out of the common, unless perhaps it was in the judging. The cottagers' Celery was very fine. Florists' flowers are obviously at a low ebb near Manchester; a good many were shown, but obviously they are only advancing to better things in this class of flowers. Some of the finest Show Pansies I have seen this year were staged, but these came from the north, and anything up to the mark of special merit came from a great distance. But even amongst these I found something worth drawing attention to; these were the fine Verbenas from Messrs. Cannell & Son, and the Zinnias from the same firm. They had also a strain of Cockscombs superior to anything I have seen. In the stand of single Dahlias from Mr. Ware, besides older sorts were attractive varieties well worth a place everywhere; these were Vivid, Mauve Queen, and Heeter.

One of the most interesting departments in these large exhibitions is that devoted to implements. In this department I thought highly of the "Allerton Priory Boiler." This is a flued saddle; in principle it is the same as the two at Norris Green, the difference being that in the latter the smoke passes through tubes and the boiler is rivetted. In the former two flues are used in place of tubes, and the boiler is welded. Both are good, though I should prefer those of the Scotch firm. The only other articles I considered better than we have been used to in this department were the frames from Foster & Pearson. Any gardener who has the offer of 100 feet or more of these should most certainly accept them. I would prefer the 8 feet wide size and build a brick foundation for them; they may be very efficiently heated. Their system of substituting iron instead of wood for the rafters of vineries and greenhouses is also a plan worth following.

Durability and lightness are very cleverly combined.—R. P. BROTHERSTON.

#### SANDY AND DISTRICT HORTICULTURAL SOCIETY.

FINE weather and Sandy Show have become proverbially concurrent; and the thirteenth annual Exhibition, held on Friday the 26th ult. in the beautiful grounds of J. N. Foster, Esq., Sandy Place, following the most miserable day in harvest probably on record, was no exception to the rule, and, taking advantage of the agreeable change, many thousands of visitors attended the Exhibition. Favoured with sunshine and under the auspices of an excellent executive, increasing prosperity has attended the efforts of the Society; and Sandy has gradually emerged from an infantine village show to become the heyday and holiday, not only for Bedfordshire, but also for a large portion of the neighbouring counties of Hunts, Cambs, and Herts.

The objects of the Society include the advancement of horticulture—the staple of the district, bee culture, poultry, birds, and agricultural produce; and some idea may be formed of the work and responsibility falling upon the staff from the number of entries for vegetables alone, which exceeded eleven hundred. Of course in a market-gardening locality vegetables are an important feature, and at few shows are they shown in such good form or so largely. An excellent display of these was made on Friday last, and scarcely less important were the departments of fruit and cut flowers. About twenty marquees and tents were erected on the ground, three of them, including one 100 feet long, being filled to overcrowding chiefly with vegetables and fruits. Plants, although not shown largely, were in very fine condition for the season, but at Sandy do not appear to the best advantage, as the antiquated, risky, and expensive lofty stage is still in vogue, and as the sides of the marquee are also utilised the narrow space left is totally insufficient to enable the crowds of visitors to compass the plants.

In the open class for ten stove and greenhouse plants in flower Mr. James Parker of Rugby took the £15 prize with very superior specimens, showing good health and excellent cultivation, but little novelty was observant. Mr. W. Rabbitt, gardener to Lieut.-General Pearson, The Hazells, Sandy, secured a very respectable second position. In the gardeners' class for six stove and greenhouse plants the first prize fell to Mr. G. Claydon, gardener to J. H. Aske, Esq., Woodbury Hall, St. Neots; whilst for foliage plants, Coleuses, and Zonal Pelargoniums Mr. Rabbitt, who is an excellent cultivator of the latter, was well to the front; and in the same class Mr. Tillbrook was first for six Ferns, including a very handsome Dicksonia.

For forty-eight cut Roses in the open class Mr. J. House of Peterborough was first and Mr. Laxton second, but the wretched weather of the previous "cutting" day allows little to be said in commendation. For the President's prize for twenty-four blooms the Rev. E. L. Fellowes, Wimpole Rectory, Royston, was first; and for a stand of twelve C. E. Cuthill, Esq., of Dorking, Surrey, took first place. The best amongst the newer varieties were Harrison Weir, Charles Darwin, and Louis Doré; but the noticeable feature in Roses, and a remarkable feature in the Show, was a stand of forty-eight blooms of Gloire de Dijon staged by Mr. Fellowes, but not for competition. These were shown in the cleanest and most beautiful colour and condition—not ragged, pink, overfull, and quartered as one usually finds the "Glory," but the blooms, although large, were cupped, shell-petalled, and incurved, of a rich cream colour, nearly all being perfect exhibition blooms. Mr. Fellowes informed me they were grown on a wire trellis in the open air. Does not this teach us the true way of growing these pendulous Teas and other delicate-tinted Roses, such as Gloire de Dijon, Maréchal Niel, &c? Shade and shelter seem necessary, a loose and pendant habit being the natural and only suitable mode of growing them, instead of the erect and mathematical mode of nailing and training usually adopted. "Heads downwards" is evidently also the natural position of those glorious Roses, which are ill adapted for withstanding rain and hot sun. French Asters from Mr. Tillbrook, a successful grower of this flower, were very fine for the season, as also were Quilled Asters and African Marigolds from Dr. Swaine of the Arlesey Asylum. Dahlias are evidently not yet at their best, and were inferior to those usually shown at Sandy.

The table decorations were an unusual source of interest. For the first prize a very elegant table was laid by Mrs. Richardson of Sandy Rectory, who secured a cheerful yet well-toned effect by combining Plumbago and dark Coleus as a base for the border, the centre being proportionate and light; Taesonia, Rhodanthe, and Zonal Pelargonium blooms being judiciously introduced. But perhaps a more successful or beautiful arrangement has rarely been attempted than the design of Mrs. and Miss Orlebar of Withington Rectory, which was formed entirely of wild flowers, berries, Ferns, and Grasses interwoven on an elegant wicker framework. This table, to which the second prize was awarded, is the only instance which I have seen of a satisfactory design in indigenous flowers, berries, &c.

Fruit was shown in large quantity, and upon the whole good. Excellent Grapes came from Mr. Tillbrook; from Mr. J. Day, gardener to Mrs. Seymour, Norton Hall, Daventry; from Mr. Shephard, gardener to T. Murpin, Esq., Great Staughton, Hunts; and Mr. Allis, gardener to J. Shuttleworth, Esq., Old Warden, who each secured prizes in different classes. The President's prize for the best collection of ten varieties of fruit fell to Mr. Rabbitt, whose collection

included Pines, good Black Hamburg and Museat of Alexandria Grapes, Bellegarde Peaches, Stanwick Elruge Nectarines, and Jefferson Plums. For the collection of six varieties, Pines excluded, Mr. Day took the lead.

The President's prize for twelve varieties of vegetables was taken by Mr. G. Vines, gardener to H. Thornton, Esq., Kempston Grange; Mr. H. Fahey, Goldington, coming in first for the eight varieties. For the collection of Potatoes, eight sorts, the Rev. J. D. Hawkesley, Arlesey Asylum, was first, and Mr. J. Richardson of Boston second. In the market gardeners' class Mr. R. Simpson, Arlesey, was first for the collection of Potatoes and also for the collection of Onions. For white Spanish Onions Mr. Laxton took the first place. Ridge Cucumbers were remarkably well shown, several of the exhibitors staging clean, straight, and well-coloured specimens upwards of 18 inches in length. The prizes for separate dishes of Potatoes were awarded for white kidneys, chiefly for Myatt's Prolific, International Kidney, and Paddy's Pride, a very large and somewhat coarse flat kidney of the White Elephant type. In round whites Schoolmaster was in almost all classes the predominant prizetaker. Amongst coloured kidneys Beauty of Hebron and Late Rose were prominently successful in the prize list, and Manhattan as a coloured round. Amongst other new sorts Suttons' Reading Hero and Fillbasket created a favourable impression, but as grown in the Girtford Garden the latter variety has, with the Champion and other vigorous late sorts, shown a tendency this season to grow out.

The Show was altogether most successful in all departments, the tent of the British Bee-keepers' Association being on the ground. The honey, too, was remarkably good.—T. LAXTON, *Bedford*.

#### SINGLE v. DOUBLE FLOWERS.

In Mr. Brotherston's last contribution on the above subject he appears rather more concerned about baving the last word than in treating me fairly, and as his remarks upon wild flowers verge on the infinite I leave the subject, in the meantime at least.

Mr. Hibberd must have a very short memory when he asserts that he in his lecture referred merely to "a mythical Caliban," which is only "an abstraction" and a "characterisation," and not to any "existing individual." He there stated, "There are now amongst us, even in the bright world of flowers, those who profess to be æsthetes, and who propose that we should undo and utterly waste the work of centuries, and allow Nature to assert herself according to the original pattern of things as on the third day. Yes; they dare to doom our double flowers to an ignominious oblivion, and they fondly hope we shall destroy our proper garden flowers, and plant in their places those that Nature cultivates so nicely in the woodlands and on the mountains," and so on. Mr. Hibberd now asks that we believe that "they" and "those" were nobody in particular, and this at a time when the subject of "Single v. Double Flowers" was being discussed, not in the Journal only, but elsewhere. And then to end by saying he only referred to a mythical personage, an "abstraction," &c. ! Surely Mr. Shirley Hibberd is the incarnation of "abstraction!"—SINGLE-HANDED.

#### GROSSE MONSTRUEUSE DE LIPARI FIG.

A FEW years ago I received cuttings of a Fig under the above name; and although the fruit is of great excellence I am extremely doubtful if the name is correct; and on applying to two good gardeners my doubt is not removed, for one of them says the name is correct and the other says it is not. We have sent a fruit for your inspection, and shall be glad if you will settle the point.—F. R. H. S.

[The fruit was, as Figs usually are that we receive from a long distance, crushed beyond identification; but the accompanying figure and description will aid you in your object, and will bring a good variety to the notice of our readers. Fruits large, roundish-turbinate, much flattened at the apex. Skin light brown or chestnut, shading off to dark, and with dark-coloured ribs, with occasional dark spots, the whole covered with a thick bloom. Stalk short, thick. Eye large, closed. Flesh dull red, thick, juicy, and pleasantly flavoured. Habit of plant robust, and very prolific. A very meritorious variety, and suitable for cultivation either in the open air or under glass.]

COOLING'S NE PLUS ULTRA DWARF FRENCH BEANS.—In response to your question (page 209), I have grown this Bean in

pots during the past winter and spring. It is very productive, and has fine pods. It is in no way superior to Osborn's for forcing, but is quite distinct from Fulmer's. I do not think anyone will be disappointed by giving it a trial. Those grown in the open ground have produced an excellent crop of good-sized pods, and I have no doubt this new variety will give satisfaction to any who may grow it.—D. WALKER, *Dunorlan*.

#### SHADING CAMELLIAS.

I HAVE been much interested in the controversy on this subject, and I fully decided last year to give it a trial when the subject was similarly raised in favour of shade. I grow these plants in pots, and since I have employed shade they have improved in health, and the foliage is now nearly black; but when grown without shade, as I used to grow them, the leaves at the end of the season were rather yellow in colour. Perhaps one of the strongest points in your correspondent's remarks about shading these plants is, Will they do without shade when in flower? At this point Mr. Muir's assertions fall to the ground. If not shaded in spring when in

Fig. 39.—Grosse Monstrueuse de Lipari.

flower one day's sun is sufficient to take the colour from the flowers, and what good is a flower when its colour is gone?

The last statement on this subject from "R. P. B." rather puzzles me. Does he mean that vigorous growth is not needed in the successful cultivation of Camellias, or that as fine flowers are produced from a plant that grows weakly as from one that has vigorous growth and large dark green leaves of great substance? His statement appears to me much like staging a green Croton by the side of the same variety in good condition and well coloured. I think I know which would be placed first at an exhibition.

I must maintain, notwithstanding what "R. P. B." has said on this subject, that dark green glossy foliage is much to be desired in Camellias. I am proud of my few plants in pots, which have improved wonderfully in this respect since I shaded them, and my brother amateurs express a wish that theirs were of the same beautiful colour. Those who have only a few plants for their small greenhouses will be on the safe side when they shade their

Camellias judiciously, as Mr. Bardney advocates. Not only are the Camellias improved, but slight shade preserves the other flowering plants that are, or may be, blooming in the house at the same time. Pelargoniums and such plants when in flower used to fall quickly before I shaded, and now they keep their colour better and last much longer before falling.—AN AMATEUR.

## KITCHEN GARDEN.

CABBAGE as a spring crop is one of the most valuable, as, though a constant supply throughout the year may not be indispensable, the lack of a good supply in spring and early summer would in most places be a serious drawback. As soon as the plants are ready transplant them at once in rows about 18 inches asunder, with the plants 15 inches apart, but those from later sowings will require more room, 2 feet between the rows and 18 inches apart not being too much. Attend to the plants from the August sowing in keeping them free from slugs, dusting whilst damp with quicklime, dry wood ashes, or soot; avoid keeping the plants too thickly in the seed beds. Winter Spinach will soon require thinning, which should be attended to before the plants become too large, allowing sufficient space between the plants to prevent damping-off in bad weather, keeping the surface soil between the rows well stirred. Take every opportunity in favourable weather to use the hoe amongst all growing crops, so as to prevent the necessity for hand-weeding. Thin-out autumn-sown Onions to about 3-inch distance apart, which will allow of every alternate plant being drawn in spring for early use as needed. Take up the main crop of Onions, exposing them for a few days before storing away in a dry cool room or on shelves, stringing or tying in bunches such as are available for that purpose.

As ground becomes vacant fill it with late plants of Coleworts, Endive, and Lettuce according to probable requirements. Any pits or frames at liberty should have Endive or Lettuce pricked into them for winter use, keeping them duly supplied with water if the weather be dry, not putting on the lights until there is likely to be frost. The Lettuces from a sowing made at the end of July, planted in frames now, will do much better than when deferred until the season is more advanced. Late Turnips should be moderately thinned so as to allow due development. Keep up a supply of small salading by sowing at intervals proportionate to the requirements. Radish seed must be sown on sheltered borders; and where sowing has been deferred of such varieties for winter use as China Rose and Black Spanish, the seed may yet be sown, protecting the plants in severe weather; they will afford good roots during severe weather, and more crisp than those taken up and stored. Select fine days for tying-up Cos Lettuces and Endive, also for earthing Celery. Any Potatoes in the ground should be lifted at once, except late sorts, which should not remain a day after the foliage shows disease spots. The haulm should at once be burned, instead of being allowed to decay on the ground or on the rubbish heap. Globe Artichokes should have all useless stems cut away, and all decayed leaves removed, so as to admit of light and air to harden them at the base. Remove the leaves from over the clusters of Tomatoes in order to advance the ripening process, cutting the most forward, and hanging them in a dry airy house, which will give the later-set fruit a better opportunity of maturing. A first planting of French Beans should be made in pots, 10-inch pots being most suitable; half a dozen Beans being placed in each, standing them as close to the glass as practicable in a house with a night temperature of 60°, and 70° to 75° by day. Osborn's Forcing is a suitable variety.

## HARDY FRUIT GARDEN.

Wall trees should be examined now for the purpose of stopping such shoots on Pear, Plum, Cherry, and Apricot trees as have made secondary growth, pinching them back to one joint, so as to keep the spurs close to the wall and to allow of sun and air having free access

to them, so as to secure as far as possible the ripening of the wood. Extensions must be secured to the wall as they advance in growth; and the shoots of Peaches and Nectarines, also Morello Cherries required for next year's bearing, should also be secured with twigs, nailing or tying as may be expedient. Be careful not to have them too crowded. They should be so distributed that the sun and air can act freely on the foliage, as upon this depends the ripening of the wood and its fruitfulness another season. These growths should not be closer than 12 to 15 inches apart, keeping the sub-laterals pinched to one joint. The fruit of Peaches and Nectarines are now generally ripening, and will require attention daily. Later kinds require attention in turning the leaves aside or shortening them, so as to expose the fruit to the sun to give colour and flavour. Pyramid, bush, and espalier trees of Pear, Plum, Apple, and Cherry should be given, so far as the summer pruning is concerned, a final stopping and regulation of the shoots, attending to the gathering of Apples and Pears as they become ripe.

## FRUIT HOUSES.

*Peaches and Nectarines.*—The fruit in the latest houses will soon be all cleared off, and to insure the proper maturation of the wood all shoots not required for next season's bearing or the extension of the trees should be cut out, so as to admit all the sun and air possible to those retained. The foliage must be kept free from red spider by thorough cleansing with the garden engine, syringe, or hose, well watering the inside borders, and where the lights are moveable remove them as soon as the wood is well ripened. The trees in the earliest-forced house will soon shed their leaves; the shoots may then be loosened from the trellis in order to have the house painted and otherwise thoroughly cleansed. Soil should now be procured and stacked for future use. Peaches and Nectarines do best in strong turfy loam, and if of a chalky or calcareous character so much the better; but if not, add to it a tenth of old mortar rubbish or pieces of chalk, and the trees with proper surface dressings will afford fruit of the finest quality. Where early forcing is contemplated the trees should be planted at the latest by the end of this month. The best Peaches for early forcing are Alexander, a new fine American sort coming in earlier than Early Beatrice, Hale's Early, A Bec, Royal George, Grosse Mignonne, Noblesse, and Stirling Castle. Those will give a succession extending over several weeks, but where there is a number of houses the three latter may be omitted from the earliest house. In Nectarines—Lord Napier, Advance, Elruge, and Violette Hâtive are good and reliable for early forcing.

*Pines.*—Suckers obtained from the summer-fruiting plants will soon be ready for repotting. Shift the strongest plants into the fruiting pots, 10 or 11-inch, according to the variety, giving them a light position, and keeping them steadily growing through the winter months; these will start in May or June, affording a good supply of early autumn fruit. The remainder of the plants should be wintered in 7 or 8-inch pots, and be transferred to the fruiting pots so soon as ready in spring; and these, in conjunction with Smooth-leaved Cayenne and Charlotte Rothschild started as suckers last March, will afford a successional supply through the winter months, being aided by Queens and Jamaicas started with those already referred to in March. It will be necessary about this time to re-arrange the plants, especially those started as suckers last autumn, and which now have fruit swelling off. The plants that have completed their growth will start into fruit more readily if now subjected for about six weeks to liberal ventilation. Scarcely too much air can be given when the temperature exceeds 80°, that being a sufficient temperature also for the roots.

*Figs.*—The wood of the trees in the earliest-forced house is now ripening, and watering should be discontinued. Where the trees grow too vigorously it is a good plan to root-prune them and circumscribe the borders, making them only 3 feet in width. A good surface dressing may be given after the root-pruning, using rich loam with a little bone meal intermixed. If there be any doubt about the drainage it will be necessary to lift the trees when the leaves are falling, root-pruning and replanting in good soil. About a foot of brickbats with old lime rubbish screened should be employed for drainage, loam with about a tenth each of old mortar rubbish and road scrapings intermixed forming suitable soil, which should be

made very firm about the roots. With fresh compost as surface dressings, mulching and feeding with liquid manure, the trees will produce abundant crops. The trees in narrow borders need little pruning, whereas when growing in wide rich borders they grow luxuriantly and do not fruit satisfactorily.

## PLANT HOUSES.

*Stove.*—Dipladenias required to flower early in spring should now be kept drier at the roots for a few weeks and then be cut back, giving them at the same time a thorough cleansing. When they have started into growth about half the old soil may be removed, replacing in the same pots in good fibrous peat. The young shoots as they extend should be trained on strings run up near the glass through the winter, and when advanced for flowering secure them to the trellis. Stephanotis intended for a similar purpose should have the shoots trained in the same way. Plants having completed the growth should be kept drier at the roots, only sufficient water being given to prevent the loss of the foliage. Started early in the year they will in a brisk moist heat grow and flower freely in a light position. Clerodendron Balfourianum that flowered early will be making strong growth, and should be encouraged by liquid manure during the present month, the growths ripening well later on with plenty of light and a diminished water supply. Plants of this, also Bougainvilleas and similar plants that have been in cooler quarters for flowering, must now be moved to a warmer position, but not to excite growth, having a drier atmosphere, and withholding water yet not so as to cause the premature falling of the foliage, but to gradually harden the growth. Ixoras that have been used for conservatory decoration must be returned to the stove now, placing them in the warmest part. If infested with mealy bug or scale thoroughly cleanse the plants by dipping or syringing with an insecticide, removing all their old flowers.

Clerodendron fallax is never so satisfactory as when raised from seed. The seed should be sown now or as soon as ripe, sowing it in small pots and shading. When the seeds have germinated the pots should be placed on shelves near the glass, afterwards shifting the plants into 6-inch pots, employing good fibrous loam, with a fourth of leaf soil and a little sand. Old plants that have flowered should be cut back, keeping them in a warm place and damping every afternoon until growth has commenced, then remove some of the roots and place in smaller pots for the winter.

Amaryllises are fast completing their growth, and they can be kept much cooler when at rest. They should have a cool stove or an intermediate temperature, with plenty of air and light to secure the solidification of the growth. Although a lessened supply of water will, consequent on the time of year and cessation of growth, be necessary, extreme dryness must be avoided, it being important that the soil be kept moist so as to prevent the loss of the roots. Pancratiums making growth after flowering should be encouraged with plenty of moisture, and increased root space if needed, supplying them with liquid manure, and growing them in a light position.

Euphorbia jacquiniæflora removed to cooler quarters some time ago must not remain too long, or they will, especially if kept too moist, lose their roots and do little good afterwards. They should now have a house or pit kept at a minimum temperature of 55° with plenty of air and light. Poinsettias should also have position near the glass in a similar temperature. Any that have been planted out must be lifted carefully, potted in fibrous loam, and kept rather close until they begin to root, when they must have more air. Other winter-flowering plants must be in plenty of light, so as to insure a stout solidified growth. Achimenes that have nearly done flowering should be continued in a temperature similar to that required to grow them in, giving water as required until the tops die, as they should gradually. Gloxinias require similar treatment, the soil being kept a little moist until the tops have died down. Gesneras are brilliant winter-flowering plants, and they must be kept in an active state of growth by repotting those that need it, and top-dressing others that are in the pots in which they are required to flower. They enjoy a light position and a moist atmosphere, but hot sun and water from the syringe are injurious to the foliage.

## SUGARS IN RELATION TO THE COMPOSITION OF HONEY—BEE FOOD.

SOME time since I remarked in the columns of the Journal that "sugar (especially grape sugar) is a true food." This sentence has suggested to one of our well-known correspondents a series of questions, which cover ground of such general interest to the educated bee-keeper that I have determined to treat the subject at somewhat greater length than the correspondence columns would allow.

It is no doubt the common idea that sweetness in all dietary articles is due to the presence of a substance which is identically the same, whether revealing itself to the taste in the grape, in milk, in honey, or in the sweetmeats of the confectioner; but chemistry teaches us that this error is a grave one, for the word "sugar" is applied to a class of bodies present having a common likeness with very marked differences, and that in the examples cited the sugar of each differs widely from the sugars of all the rest. This question has much to do with honey and bee-feeding, as we shall presently see. The sugar of our tea table is named by the chemist sucrose, and is derived usually from the sugar cane, although its source may be the beet or maple, while it is also found mixed with other descriptions of sugar in many fruits. The characteristic with which we have here most to do is the facility with which it crystallises into oblique six-sided prisms. It is on this account sometimes distinguished as crystallisable sugar.

The nectar produced by different plants varies not only in flavour but in the kinds and proportions of the kinds of sugar it contains, and in consequence honey similarly varies. Where much sucrose is present the honey shows a strong tendency to candy, while the artificial addition of uncrystallisable sugar will permit it to retain its clearness almost indefinitely. This artificial addition is most undoubtedly to all intents an adulteration, and I should not have referred to it had it not been argued by some American honey dealers that here "the end justified the means." But this knowledge may have a most practical application. I remember—but I must not be too circumstantial—at a competition of supers the judges disqualifying a very fine specimen because part of the super was candied and part not. They declared that this was distinct evidence that the super was the work of two years instead of one, or that part was honey and part syrup; but the knowledge that supers often are marbled, so to speak, with honey of different tints because gathered from different sources, and that with the source may vary the disposition to candy, should have shown the judges (?) that they were not giving "righteous judgment." But to proceed. By far the greater portion of the solid constituents of honey consists of that kind of sugar which is found in quantity in the grape, and has received the commercial name of grape sugar, although the vine is almost always innocent of its production. The chemical and more accurate name glucose has now passed into commercial use, and indicates a kind of sugar which is usually manufactured from starch—commonly maize starch—by boiling with sulphuric acid. The transforming hand of the chemist can, however, prepare it from any form of cellulose, so that woody fibre, nut shells, calico, paper, pawn tickets, &c., can all be changed into "grape" sugar. And if the process be properly performed and the conversion complete there is no reason why this "grape sugar" should not be a perfectly good article for bee food, the strong statements made in some quarters to the contrary notwithstanding. Unfortunately, however, the conversion is often incomplete, and a not inconsiderable amount of dextrin, or half-converted starch, remains. The white solid known as "brewers'" glucose is quite unfit for feeding bees, as the chalk which is used for taking up the sulphuric acid has not been separated from it, as its presence in its new form of sulphate of lime is beneficial in brewing.

Glucose again is separable into at least two di-tinct kinds of sugar, known as dextro and levo-glucose. The former is mainly found in sweet, and the latter in acid fruits—Oranges and Lemons by example; and here again honey may exhibit marked differences, according to the flowers which have supplied it.

The relations subsisting between sucrose and glucose are very important to the advanced bee-keeper, and will repay careful attention. Sucrose passes very readily into glucose. When cane sugar is taken into the mouth the saliva immediately sets up this transformation. Boiling does the same. The sugar refiner would have to boil his syrup at 230° Fahr. did he not carry on the process in what is called a vacuum pan, by which 150° evaporates his syrup readily. He thus saves the loss to which he would otherwise be exposed by the change of his crystallisable into uncrystallisable sugar.

He does not perfectly escape, for treacle, one of his waste products, contains scarcely a trace of cane sugar; it has almost wholly been converted into glucose by the necessary heat employed. What will those say to this who tell us that no boiling of cane sugar for bee food is needful? It is needful; it converts the cane sugar, in part at least, into honey or grape sugar, and prevents its crystallising, and so saves much trouble, and may save much mischief. The addition of a little acid aids in the process, hence the recommended vinegar; but the work would be done more perfectly by sulphuric acid afterwards neutralised with chalk, but for this method some technical knowledge is desirable. We see this very matter in the case of a fruit tart; if sugar be added by the cook before baking the heat and the acid of the fruit transform sucrose into glucose. The flavour is more agreeable and natural; but more sugar will be required, since two measures of sucrose have as much effect on the palate as five of glucose. The reason of my statement that sugar, especially glucose, is a true food is now apparent. Cane sugar is changed into the latter in our case as the first step towards assimilation, and it probably would be so changed in the bee's body at its passage into the true stomach. The alteration is brought about by the absorption of a portion of water, so that, strange as it may appear, 342 lbs. of sucrose become 360 lbs. of glucose. The sugar cane is largely eaten at harvest time by the blacks, and they thrive upon it wonderfully. In addition to its sugar there is in it a little nitrogenous matter. This is also true of honey, which, apart from all aroma and delicacy of flavour, contains the essentials of one part at least of a scientific diet table.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

#### TRADE CATALOGUES RECEIVED.

Charles Turner, Slough.—*Catalogue of Carnations, Picotees, and Bulbs.*

Hooper & Co., Covent Garden, London.—*Catalogue of Bulbs (Illustrated).*

George Bunyard & Co., Maidstone, Kent.—*Catalogues of Fruit Trees and Roses.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Bulbs.*

E. S. Dodwell, 11, Chatham Terrace, Larkhall Rise, Clapham.—*Select List of Seedling Carnations and Picotees.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Coke v. Coal as Fuel (Kittie).**—You cannot do better than refer to page 150 of the issue of the Journal of February 27th, 1879, where you will find a record of some experiments made by Mr. Luekhurst on the relative value of anthracite coal, coke, and a mixture of the two for heating a plant structure, the fuel being consumed in a saddle boiler. If you do not possess the number referred to it can be had in return for 3½d. in postage stamps, sent to the publisher with a request that he send you No. 935.

**Spent Tan (Ramatho).**—Such old "rotten" tan as you describe has very little manurial value. If the tan is in a friable state it may be applied beneficially to very heavy land, such as clay or strong loam, but no benefit will result if it is mixed with ordinary light garden soil. Some pastures we have known to have been benefited by a heavy dressing of old tan, and this is possibly the most likely way in which your heap may be utilised—that is, if you have no heavy garden ground that requires to be made more friable.

**Shifting Young Pelargoniums (Inquirer).**—If they are Zonals they should, when the small pots are filled with roots, be transferred to 6-inch pots, potting firmly, placing them in a light position, and with a little heat the plants will flower in winter. If, however, they are of the Show, Spotted, or Fancy section, they may also now be repotted and have the shoots stopped so as to induce a branched habit, keeping them near the glass and the house freely ventilated.

**Carnations with Flowering Shoots (Idem).**—It is hardly likely that plants with no "grass" now will form any this season sufficiently strong to flower another season, but the roots will possibly survive the winter and make plenty of growth next season, and flower well the following year. The cuttings should not be torn off the stem, but cut so as to have one joint clear of the

crow leaves, and being cut transversely below the lowest joint they should have the leaves from it removed. Insert the cuttings in sandy soil under a handlight, and keep them shaded until rooted. For answers to other queries see the following reply.

**Placing Roses in Pots Out of Doors (R. T. L.).**—It is not necessary at this season to place Roses outdoors that have been grown in an airy greenhouse for the ripening of the wood, as that will, if the plants have had plenty of light, be thoroughly perfected, and the only good that exposure would effect would be in inducing rest, assigning them a sunny position, and housing before the weather becomes severe, the pots being plunged in ashes to the rims. The Cactuses should between now and the end of the present month be placed indoors, or before the soil becomes soddened with wet or the plants injured by frost.

**Grapes at Manchester (G. C. Ramsden).**—Our report of the heaviest bunch classes is, we believe, correct, and it agrees with that of the *Gardeners' Chronicle*. According to those reports Mr. Roberts placed his heaviest bunches in competition. In another paper we observe a mistake, and if this is the paper to which you refer you had better write to the Editor. We could have replied more satisfactorily if you had quoted the papers in which you allege there is such discrepancy. Have you not made a mistake? You quote words and weights which you say appear in "other papers," that are in no way of the gardening papers now before us.

**Dahlias with Open Centres (Amateur Florist).**—This is very common this season, and is probably a result of the prolonged dry weather in the early part of summer, the plants being weakened by over-propagation, so as not to make a strong early growth. Want of proper supplies of water and liquid manure is also a frequent cause of the flowers having few petals. Nothing tends so much to encourage fullness in flowers as high culture, and it is to absence of this that we should attribute the sparseness of the petals.

**Removing Plum Tree (A. Byle).**—You cannot adopt a better plan than the one you propose. In all probability the trees will have some roots approaching more or less a vertical position, and they must be severed, half of them this year and the other half the next. If you can place a quantity of light gritty vegetable soil in the trench, packing it very firmly round the roots, it will be of great value in promoting the emission of a number of short fibrous roots that are so desirable for the quick re-establishment of the tree. It will be an advantage rather than otherwise to prune the tree by shortening the luxuriant branches.

**Gooseberries Unhealthy (A. J. S.).**—We think there must be some other reason for the branches dying. The galvanised netting we presume does not touch the bushes but is elevated above them; and further, if this netting was the cause of the injury we should scarcely expect the Currants to remain healthy in the same quarter. We know of Gooseberry bushes that have been covered with galvanised wire netting for a number of years and not the slightest injury has resulted, the netting being fixed 6 feet from the ground. The soil is perhaps too hot and dry for Gooseberries, and we should mulch it in summer to retain the moisture.

**Sphagnum for Orchids (A Constant Reader).**—The moss should be used in a living state, as when dead it causes an unsuitable stagnation about the roots that is very unfavourable to the plants. The most suitable work for you will be the "Orchid Growers' Manual," published by Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, from whom it can be obtained post free for 6s. 6d.

**Grass Seeds for Renovating Permanent Pasture (Robesten Walthen).**—The most likely Grasses to succeed where there is great drought in summer and heavy rains in winter are *Festuca duriuscula*, *F. ovina*, *F. rubra*, *Cynosurus cristatus*, *Dactylis glomerata*, *Lolium perenne*, *Poa pratensis*, *Phleum pratense*, *Holcus lanatus*, and *H. mollis*, with the leguminous plants *Medicago lupulina*, *Trifolium filiforme*, and *T. repens*. Of Clovers the last-named is most likely to succeed, and of it we should employ 4 lbs. of seed, and the others in proportion as follows:—*Medicago lupulina*, 4 lbs.; *Festuca rubra*, 2 lbs.; *Cynosurus cristatus*, 2 lbs.; *Dactylis glomerata*, *Holcus lanatus*, *H. mollis*, *Phleum pratense*, and *Poa pratensis* each 1 lb., *Lolium perenne* being employed alone with those named at the rate of 4 lbs. per acre, or 21 lbs. altogether if the pasture be very bare. If the situation be high add 2 lbs. of *Festuca duriuscula*, and 1 lb. of *Festuca ovina*.

**Planting out Stephanotis (Subscriber).**—The plant will succeed in the position you name, the growths being trained in a light position near the roof, and the temperature of the house and general management being suitable. So far as we can understand your case, which you have not made by any means clear, we should grow the plant to a larger size before planting it out; on this point, however, you must judge for yourself. A suitable compost will be about two-thirds or nearly so of rather light turfy loam and one-third of turfy peat, the whole to be broken by the hand and used in a somewhat lumpy state, pressing it down firmly; to the soil add broken charcoal liberally, with sand or gritty matter to render the soil porous. Planting should be done in the spring. In regard to the other question, if you have quoted the conditions correctly, the question answers itself, and all you have to do is to stage the "largest and heaviest" fruit you have.

**Various (F. C.).**—There was no Peach leaf enclosed in your letter. We scarcely understand the condition of your Grapes, as you do not say whether the warts are on the leaves or berries; please send us a small sample of the foliage and fruit to which you refer, and we will endeavour to aid you. If the Vines are free from insects we should not syringe daily, but should sprinkle the walls and paths on bright days for obtaining atmospheric moisture. Cherry stocks are usually raised from seed. Quince and Paradise stocks from cuttings inserted in October, or by layers pegged down at the present time. You cannot have a more easy method of raising Plum stocks than the one you describe. The Black Damask or Morocco Plum is a good and very old variety, and ripens in August; fruit medium-sized, roundish, very dark purple, and with a sweet brisk flavour. The budded stocks should not be headed back until growth has commenced in the spring. When Rose buds are inserted the shorter the shield is below the bud the better is the union, and only sufficient need be left for tying the bud down to the stock. When the shield below the bud is lengthy there is an unsightly space between the stock and the bud, and the latter is more liable to be blown out than when it unites to the principal stock of a standard Briar. If the bud is inserted as low on the stem as possible, as it should be, the transverse cut must be above it, and in no case would it be better below.

**Mealy Bug on Vines (A Disappointed Grape-Grower).**—Your Vines have not had the attention they needed or they would not be in their present state. You cannot destroy the insects until the crop is out. We advise you to remove the fruit as soon as possible, and then violently syringe the Vines daily for a week. This must be no ordinary sprinkling, but a thorough and

forcible washing. If you can wash off the protective mealy covering from the pests they will be at your mercy. So long as this remains on nothing will destroy them. These heavy syringings will at least check the increase of the insects, and if the work is thorough will reduce their numbers considerably. As soon as the leaves turn yellow remove them from the Vines with the hand and burn them, you will then destroy thousands of the enemy: shortly afterwards prune your Vines and burn the laterals, then must follow a cleansing process. "Ordinary" measures, as you describe them, are of no use; the cleansing of the Vines and house must be of an extraordinary kind. The Vine rods must be washed with an insecticide. It is not of such great importance what this is as the manner in which it is applied. Gishurst compound, fir-trec oil, nicotine soap, or softsoap and tobacco water may be used, and any or all of them will be of service if rightly used. The solution, of the strength recommended by the vendors, must be brushed into every crevice with a spoke brush until you are certain that not one insect is left. Go over the Vines twice, and spare neither the solution nor the brisk action of the elbows. Wash also every portion of the woodwork of the house wherever this may be, and let paraffin penetrate every chink wherever it is situated. Cleanse the walls similarly and limewash them. Remove all the soil from the border in the house (if any), and add fresh, and in fact adopt every possible means of exterminating the enemy. After all you can do some insects will probably appear in the spring, and must be searched for daily and promptly destroyed. Mealy bug in vineries is one of the worst foes that the gardener has to deal with, yet it is conquerable, but only when the battle is fierce and persistent, and you can only succeed in your object by adopting some such measures as we have suggested.

**Names of Fruits (R. D., Lancashire).**—We are unable to identify your Apple from the specimen sent. In all probability it is a local variety. (*Flora*).—The Apple appears to be the Red Astrachan. We are unable to inform you of the origin of the local name which is applied to the fruit in your district. (*G. B. C. W.*).—We have little if any doubt that your Plum is the Victoria. We have seen thousands of fruit of that variety of the form of those before us, and it is not improbable that another year you will have longer fruit. We have frequently gathered long and almost pointed fruits, and others like those you have sent, from the same tree.

**Names of Plants (G. O. S.).**—*Polygonum euspdatum.* (*G. L.*).—The fungus you send appears to be a small and immature specimen of the Giant Puff-Ball, *Lycoperdon gigautum.* (*Miss Riddell*).—It is not a *Spiraea*, but one of the Bugworts, *Cimicifuga spicata.* (*C. M. Major*).—*Zea Mays.*

COVENT GARDEN MARKET.—SEPTEMBER 7.

THERE are still large quantities of Grapes arriving from the Channel Isles, causing home-grown fruit to realise low prices. Very little demand for best grown fruits.

introduction. By so doing we may be enabled to understand the benefits to be derived from a departure from the harvest customs which formerly prevailed.

We have been induced to some extent to take up this subject now in consequence of the serious aspect of the weather. It must always be difficult, however, to characterise and calculate upon the weather occurring during haying or harvest, because there is quite a difference of a month or six weeks in certain parts of the kingdom. The haying season in the early districts lasts from the first week in June until the middle of July; in the latest climates, however, such as the north-western and northern districts, it extends from the first week in July until the middle of August. In like manner the harvest period for corn in the early southern or eastern districts generally commences the first week in August and continues until the middle of the month of September; whereas in the northern and north-midland counties and Scotland the harvest period extends from the 1st of September until the middle of October. Such, however, is the variation of climate and seasons that we have occasionally to record exceptions to any general period of time for either haying or harvest, and notably we may mention 1853, 1860, and 1879, without going back to the years 1829 and 1830. In these exceptional seasons in various parts of the kingdom there was absolutely no time when the produce, either hay or corn, could be harvested in fair saleable condition by the old-fashioned mode of drying and storing in sunny and dry weather. The new implements—such as the mowing machine, the tedding machine, the horse rake, &c.—enable an amount of work to be done in the shortest period, and thus reducing the risks in ordinary management which formerly attended the saving both of hay and corn crops. In respect of the saving of field hay, and also of meadow or pasture hay, we could extend our observations and remarks to great length; as this is not our intention we must refer our readers to the subject as treated in this Journal on the 20th and 27th of June and 4th of July, 1878.

We must not omit the notice of certain modes of preserving and securing both hay and corn by two separate devices. The first to be noticed is the machinery invented by Mr. Gibbs, which for a time attracted but little attention on account of the cost being a very serious item. The late untoward seasons, however, as well as the present one, will cause more inquiry into this mode of saving hay and corn, for it must be remembered that certain circumstances will favour the use of the machine, which are of great importance. The first is, that in seasons when but little hay can be saved by the ordinary means the value of that portion got up in condition reaches a higher value, and the same observation applies also to the saving of corn, especially in those districts where the rainfall is nearly always heavy. Again, in preventing waste of the leaf of Clovers and Saintfoin, and in saving corn without sprouting or shedding, especially upon large occupations, or in climates usually adverse to haying and harvest operations, the purchase of one of these drying machines may be really judicious and economical.

We must now refer to the latest proposal for the practical saving of hay under certain conditions. It is called the self-harvesting of hay and corn, of which the following report was given in the *Times* of August 11th. The originator is Mr. R. Neilson of Halewood, near Liverpool, who farms 300 acres on the estate of the Earl of Derby. This system has also been taken up by an enterprising gentleman, Mr. R. M. Knowles, J.P., of Colston Bassett Hall:—"Mr. Knowles, we are informed, has several farms in his own hands, but upon his home farm has put up permanent hay sheds made of corrugated iron roofing upon iron pillars, the breadth 20 feet, and the length forming a series of square bays. Along the middle of each shed is laid in the ground an air-tight drain of sanitary pipes, having an aperture in the centre of each

POULTRY AND PIGEON CHRONICLE.

A WET HAYTIME AND HARVEST.

THE lessons taught by a wet haytime and harvest are many and sometimes very serious as regards the conducting of a home farm; still, when we look back and review our own experience in the hay and harvest field for a period of many years we may probably be able to bring to the notice of the young men and beginners not only some of the most exceptional seasons, but also how they were encountered, as well as the advantages to be obtained by the use of means which are of comparatively recent

bay, these being opened or closed by slides, so that any one can be worked without using the others. In stacking the hay a vertical air shaft or chimney is formed over each aperture by the common method of drawing up a sack of straw or a round chaff basket as the building of the rick proceeds, but these ventilating flues are carried up to only half the height of the stack. The new plan of making the hay consists in tedding the grass as fast as it is cut and exposing it to the withering action of the air, whether there be sunshine or occasional showers. In about two days without any further labour upon the crop, and whether it be wet or not (a dry day, of course, being preferred for the operation), the green hay, in a condition of not more than half made, is collected into rows by the horse rake, carted, and stacked. The rick at once begins to ferment and heat, and this heat naturally generated is made use of to change the moist grass into properly dried hay; in fact, the hay makes itself by its own heat, without the cost of field manipulations, and without the risk inseparable from employing the sun's heat for the same purpose; the business being a certainty in any weather whatever, and the quality of the product cannot be beaten, as witness the cut stack now remaining in the rick-yard at Colston Bassett, from the hay made by the process in the wet of last year.

"Everyone knows that half-made hay put together in mass quickly heats to a point at which if left to itself it will completely spoil, and probably fire. This is, however, prevented by the use of an exhaust fan set in motion, and drawing the heated air from the pipe at the base of the rick, which is connected with the chimney in the centre of the stack, and by that means rarefying the air in the chimney; the replacement of that air, however, can come only by currents penetrating the rick from the outside walls and roof, and gradually converging into the chimney in the centre. By this suction of hot air and moisture out of the mass cold air is induced to enter the stack at all points, and to seek the central flue, bearing with it the excess of heat and the moisture, and cooling the whole substance of the rick. Mr. Knowles' five-horse-power steam engine drives the fan with sufficient force when giving out a mere fractional part of its power. One horse, however, working a fan by means of an ordinary chaff-cutter, horse gear, and intermediate speed gear, will do well; or two men turning a corn-dressing machine fan arranged in connection with the air tube have been able to accomplish all that was wanted for cooling a stack. With a gentle exhaust the atmospheric air is caused to permeate every part of the rick in ample quantity for keeping down the temperature of the fermenting grass. Mr. Knowles has brought the internal temperature of a large rick for 130° down to 90° in the short space of forty minutes. In the rick while building he lays at various heights wooden tubes of bore large enough to admit a thermometer to be introduced by a lath, these tubes reaching horizontally from the outside to the centre, and thus the heat of all portions of the stack can be examined. A temperature of 100° is considered the maximum at which it is advisable to let the fermentation work, the fan being set in operation at any heat approaching this. The same provision of air ducts, and a manually operated exhaust fan, have been employed with advantage in keeping barley and other corn stacks from heating." In concluding our extracts and quotations from this interesting and valuable report we beg to state that on a future occasion we intend to give our opinions upon this matter in comparison with that of others, and our mode of proceeding at former periods, &c.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will now, when not employed in connection with harvest, be engaged, together with any oxen which may be kept for farm work, upon land intended for Wheat, such as laying out the dung upon the Clover leas. This may be spread immediately with the view of being ploughed in, for it is quite the exception where land at this period is too wet for ploughing out of lea. On the contrary, it will be all the better for being rather close when ploughed. The autumn fallowing, which after the seeding of Trifolium, Rye, winter Tares, and winter Beans, must have immediate attention whenever the ground is dry enough for cultivating either by the steam tackle, horse, or ox labour, and proceed with the farm work at any period previous to the cultivation for Wheat, except upon strong cold fallow land. In that case the sooner the dung is laid out the better; but what is more beneficial is that dung should not be used on fallow'd, strong, flat-lying land and on fields distant from the homestead, for we prefer to use guano in the autumn and nitrate of soda in the spring. In this way we dress the land without fear of the manure producing weeds, as much of the farmyard dung does. Even where all the stock on the farm have earth under their beds for absorption of liquid manures, yet when dried peat is used we have an earth adapted for absorption; yet it never produces weeds, being composed of decayed vegetation. The autumn period for cultivation is the foundation of all good farming, for whether the land comes in

for Barley after Wheat, or Mangold, Carrots, Cabbage, or other early roots, it should be cultivated as soon as the crop is cleared. We never hesitate about delaying the season for Wheat a little if the land is found in a state fit for cultivation, because as soon as the autumn rains commence, which they usually do about the middle of October, no more cultivation can be carried out. After the Wheat is all sown the land previously cleaned on the surface may with advantage be deeply ploughed before the winter frosts commence. The lifting of the Potato crop must soon be done, and will go on easily if a strong horse is used to one of the Potato-lifting frames attached to the frame of the double mould plough followed by an active party of women and lads, for this is strictly women's field work, as some of them will do more at it than men.

*Hand Labour.*—Men will now be required in trimming fences, such as the Whitethorn or quickset hedges, especially where they were not trimmed once in the summer, for this wood hardens very quickly and thus becomes almost like wire, in which case it is not easy to keep a handsome and good fence when not trimmed both in July and September. Filling dung into the carts, laying out and spreading, will be continued, also hoeing and finishing the late Turnips, which, owing to the heavy rains lately, have not made such good progress as usual upon the mixed soils. Young Turnips cannot receive so much rain as older crops without injury. The labour in wood-cutting may commence on the home farm about the 20th of the month, for it has been a practice on various estates as long ago as we can recollect that underwood sold may be considered ripe for cutting on the 13th of this month; and many buyers prefer to begin early, because the wood cuts softer and makes up into hoops with less labour than wood hardened by winter weather. When the cutting of underwood commences it ought to be thought of whether trees for timber are to be reserved, and if so should be marked with red or white paint previous to the woodmen beginning their work. The home farmer, too, must remember, if it falls to his lot to mark the trees for timber, not to reserve any stems or those which have been previously cut off as underwood, but reserve those Oak plants only which have grown direct from the acorn and the Ash from the seed.

*Live Stock.*—When horses are reared on the home farm with the view of future employment in the tillage, &c., the foals will now be weaned, or very soon according to age, and at such a time we advise that they should be as a rule kept in sheds and littered yards, and fed carefully with good hay and Oats, or Maize. At such times they do best kept in pairs, for they enjoy companionship, and do not so much miss their dams, and when they have always access to water and rocksalt they are sure to do well. Cattle which have been grazing for the butcher on the pastures will soon be ready for sale, at least the forwardest in condition. The past summer has, however, been so dry and the grass in some cases very deficient, that the bullocks are not so early in condition as usual, still they will pay for receiving supplementary food, such as cotton cake and Bean or Barley meal; for in consequence of the late abundant rains the grass has sprung up so suddenly, and it is not so nutritious as grass of slower growth, hence the animals require other food to maintain them in advancing condition. The dairy cows on the contrary are doing very well on the short young grass, and are yielding a satisfactory quantity of milk. These animals, however, would be benefited by an allowance of bran and Maize at milking time night and morning, especially the cows kept for making butter, otherwise for yielding milk for sale cotton cake answers a good purpose, except where animals are kept stalled and a supply of grains can be obtained from the brewery or distillery. The sheep on the home farm are not likely during the coming autumn to be in want of grass either in the meadows or parklands. The grass in the water meadows should be fed by dairy cows, as it is never safe for sheep after a succession of wet weather. The young cattle, both calves, yearlings, and heifers, will now find abundance of grass under a well-regulated system of stocking; but as the nights are getting longer and colder great care should be taken for them to lie high and dry at night if possible, this being the time of year when young animals full of condition are very liable to quarter-ill and splenic diseases. The breeding ewes should now have the rams with them, as in the midland districts the plan is to have the lambs to fall earlier if possible than formerly, because it is on very few farms where they depend upon pasture only, and it is now thought best to have a rather larger portion of arable land under culture, at any rate where a considerable stock of breeding ewes are maintained.

#### DAIRY AND POULTRY FARMING.

ALTHOUGH dairy farming has been less injured during the period of agricultural depression than arable land farming, still there are various points requiring attention, in order that dairy products may be turned out of the best quality, whether of cheese, butter, or sale of milk, for this is almost the only way that foreign importations can be competed with successfully. We do not consider at present any particular districts have the monopoly of supplying the large towns as formerly with dairy products, because managers of out-lying farms away from the railway stations or towns can turn their attention to the rearing of calves for veal; in fact, it is well known that various dairymen have given up butter and cheese-making and

taken to the rearing of calves, and when properly attended to veal meets with but little foreign competition, for the quality of veal made from shorthorned cows by suckling calves of the Devon and Hereford breeds is unrivalled by any portion of the foreign supplies. The feeding of cattle for beef will probably pay as well in the future as in the past, notwithstanding the large importations of foreign meat; but we advise the home farmer to calculate which will pay best at the commencement of winter—whether to put up so many steers for fattening, or take so many Shorthorn dairy cows which have recently calved and keep them at the same cost as the steers in fattening, and sell the milk or suckle calves for veal. We think the cows would pay better than the steers, for if well bred they would be making beef during the whole milking period. It will be advisable in the future in most cases for the home farmer to breed his own live stock, whether of cattle, sheep, swine, or horses. We recommend the large Yorkshire pigs to be crossed with the Berkshire; this cross will give large farrows, which will quickly become of early maturity, and furnish the best of meat at any age.

Poultry and eggs next demand the home farmer's attention, as the importations are immense. For eggs alone we pay the foreigner two and a half millions of money annually. Why not breed more poultry, and produce eggs enough for the requirements of the people? Surely we can do it as cheaply as any other country if we give it thought and attention, and utilise our own farm produce. The economy of the homestead will require more attention in the future than is often bestowed upon it. For instance, all the cart horse stables, cattle and pig pens, and covered yards may be floored with earth instead of bricks and stones. We hope to see in the future farm produce of every kind sold at farmers' or co-operative stores in all towns, where also the home farmer may be able to purchase all he requires for use, including manures.

#### VARIETIES.

THE MANCHESTER BEE SHOW.—“A LANCASHIRE BEE-KEEPER” writes to us in somewhat disparaging terms relative to the above Show, and in rather strong language denounces what he terms the “plucking off” the wings from bees and marking the queen with a string round her waist. These practices our correspondent describes as “cruelty to animals,” and consequently in direct opposition to the teachings of those who have written on the “humane treatment of bees.”

— THE HARVEST.—Come what may in the shape of sunshine, the harvest of 1881 will have to be ranked with its four immediate predecessors, as not alone below an average so far as yield is concerned, but also as regards quality. In Ireland the actual situation is not quite so disastrous, for in many districts a spell of fine weather might yet remedy the mischief that has been done; but from Cork and Tipperary we hear that great quantities of Wheat and Oats fit for reaping are shedding, whilst corn in stock is rotting and Potatoes are blackening. At home the outlook is still more generally disheartening. In Durham the rivers have risen and flooded the surrounding country. In Hampshire the sheaves in many fields are becoming green, and it is estimated that produce is already damaged to the extent of from 6s. to 8s. per quarter. Lancashire has been one of the heaviest sufferers from the deluge—hundreds of acres have been flooded in the fertile districts in and around Furness and the Fylde. A good harvest this year was the last chance of many a farmer who has been struggling manfully for years past against the weather and the American. If we could only get a few weeks of sunshine the crops might be still saved in some parts in tolerably fair condition, and some corn was housed before the rains came, but at best the outlook is a gloomy one.

— A FAMOUS BUTTER COW.—Notice has already been taken of the run on Jerseys, and the high prices obtained for some sold at public auction this year. One of the best of the herd died recently, Jersey Belle of Scituate—pronounce minus the “c”—owned by Mr. Charles O. Ellms, of Scituate, Mass. The cause of death was milk fever. At the time of her death she was just ten years and one day old. In her seven-year-old season she was tested for a year with a result of 705 lbs. of butter in the 365 days. A year ago last month she was tried on extra feed, and in one week the return was 25 lbs. 3 ozs. of butter. One peculiarity of her cream and butter was its rich colour, never varying summer nor winter. Her first calf, dropped in 1874, went to the butcher. It was then seen what a

milker she was, and better care taken of the remainder, of which Mr. Ellms has three heifers, and Col. H. S. Russell of Milton, Mass., one.—(*Live Stock Journal*.)

— HARVEST PROSPECTS IN EUROPE.—An international grain fair has been opened at Vienna. The representatives from the various countries of Europe gave in official reports as to the harvests in their respective States, which the *Daily News* correspondent telegraphs as follows:—Wheat: Hungary—below average; Hanover—excellent; Rhine Provinces and Silesia—below; Saxony—doubtful; Bavaria—above; Italy—considerably below; Holland—average; France—below, importations expected to be necessary; North Russia—below; Central Russia—average. Barley: Bavaria and Prussia—above the average, and of fine quality; elsewhere—fair. Maize: Bessarabia—expected large; other Danubian Provinces—short and poor.

— FOOT-AND-MOUTH DISEASE IN WILTSHIRE.—Nearly eight hundred sheep, several head of cattle, and a few swine were reported last week to be suffering from foot-and-mouth disease in Wilts, but as the Executive Committee have decided that at present there is no necessity for imposing restrictions on fairs and markets, the Clerk of the Peace for the county has been instructed to apply to the Privy Council to release all areas in which affected places have been set free by the local authority. The Wiltshire cattle and sheep fairs and markets will consequently be held as announced.

— TOBACCO CULTIVATION IN IRELAND.—Among the Irish business to be brought before Parliament next session will be a Bill to repeal the Acts in force prohibiting the cultivation of Tobacco in Ireland. During the recess arrangements have been made for the collection of information and statistics on the adaptability of the Irish soil for the growth of the plant. It is not proposed, should the cultivation of Tobacco be resumed in Ireland, to exempt it from duty.

— THE HARVEST IN WALES.—The *South Wales Daily News* contains a report of harvest prospects in Wales and the west of England from upwards of one hundred of its correspondents in agricultural counties of its districts. The general result is surprisingly satisfactory. In only one district is the report altogether bad. From nearly all districts the reports show that the present fine weather has saved almost everything, and that harvest will be much above the average of the last three years.

— PROTECTING HORSES FROM FLIES.—Writing on this subject to the *Irish Farmers' Gazette*, Dr. J. J. Ridges says—“Before harnessing a mixture of one part of crude carbolic acid with six or more parts of olive oil should be rubbed lightly all over the animal with a rag, and applied more thickly to the interior of the ears and other parts most likely to be attacked. This application may need to be repeated in the course of the day, but while any odour of the acid remains the flies decline to settle, and the horse is completely free from all their annoyance. Whether the dreaded tsetse of Eastern Africa would also fight shy of similarly anointed animals I cannot say, but it deserves a trial, and if successful would be an incalculable boon. It might also prove obnoxious to mosquitoes.”

## POULTRY AND PIGEONS

#### POULTRY NOTES.

AN American breed of poultry which has hardly of late years received as much attention as it would appear to merit is the Dominique. This breed, according to a writer in a contemporary on the other side of the Atlantic, is of considerable antiquity, having been imported into America about the year 1800 from the island of Hayti in the West Indies, and taking its name from the eastern part of that island which is called St. Domingo. The writer first heard of them when he was ten years old, and as he is now in his seventy-eighth year—that would be about the year 1813. He then saw a cock and ten or twelve hens, said to have been hatched from eggs purchased from the original importer of the breed. “These birds were about the size of the present Plymouth Rock, altogether larger than the common hen, with nicely barred plumage, yellow legs and beaks, and fine rose combs. The hens were great layers and good courageous mothers.” Some few

specimens of the breed have been imported into this country, and a good illustration of a pair of them appears in the *Illustrated Book of Poultry*, but they do not seem to have made much way here. This is a pity, as they are hardy, excellent layers, and good for table. The chickens are said to grow rapidly and mature early. The plumage is of the colour known amongst fanciers as "cuckoo"—that is to say, a ground colour of very light blue-grey pencilled or banded across each feather with darker blue-grey bars. The ground colour is sometimes pure white, in which case the bars are of comparatively light blue-grey. On the other hand the bars are sometimes almost black upon a rather dark blue-grey ground. The margins of the two colours which are on each feather are not clearly defined, but are shaded or run off into each other. The general shape and style are very much like that of the Dorking, although the hens are rather more down by the head and jaunty in carriage than the Dorking generally is. In America the breed has hardly had fair treatment of late years, and has been somewhat overshadowed by the newer Plymouth Rocks, but it is now being taken up again; and the writer from whom we have already quoted recommends that the standard of weight should be increased to that of the Plymouth Rocks—viz., from 9 to 10 lbs. for cocks, and from 7 to 8 lbs. for hens.

OUR American contemporary, the *Poultry Bulletin*, a short time since boasted of the superiority of the American poultry illustrations in general, and its own in particular, and even referred in terms of censure to some of the plates in the *Illustrated Book of Poultry*. It is not a little amusing after this that the illustration of Dominiques given last month should be a mere reproduction in black and white of the coloured plate in the English work to which we have already referred. It reminds one of Mr. Burnham's coolness in running down the English Brahma as being vulture-hooked, &c., and then reproducing the engraving of the Dark Brahma cockerel in Mr. L. Wright's work on the Brahma fowl, and describing it as a specimen of the Brahma as bred by Mr. G. P. Burnham. It is rather strange, if it be true that the old country is so much behindhand in the matter of poultry illustrations, that an American journal in illustrating an American breed should have recourse to an English work as a source from which to obtain an illustration of that breed.

PLYMOUTH ROCKS have during the last few seasons made great strides in popularity on this side of the Atlantic. They are of comparatively modern origin, and, except that they are somewhat larger in size and have single combs, they are almost identical in appearance with the Dominiques. They are said to have been originally produced by a cross between Dominiques and the black Java Fowl, which we recently described. The smaller size and Cochin character of the tail and the greater abundance of fluff are also points of distinction between the Plymouth Rock and the Dominique. These latter characteristics seem to indicate that a Cochin cross has been resorted to; and as the Plymouth Rock is more Asiatic in type than either the Dominique or the Java Fowl, it is probable that a cross of Cuckoo-Cochin blood has been employed to improve the original cross. It is perhaps as well to note, in order to avoid risk of confusion, that the name Plymouth Rock was some thirty years ago applied by Dr. Bennett to a mongrel fowl which he produced "by crossing a Cochin China cockerel with a hen that was herself a cross between the fawn-coloured Dorking, the Great Malay, and the Wild India." The modern Plymouth Rock has, however, no connection with Dr. Bennett's wonderful production, which has, we believe, long since disappeared.

THE modern Plymouth Rock is, as we have already stated, becoming firmly established here. A Club has been formed to support it, and it will this season have classes at Birmingham, the Palace, the Dairy Show, Oxford, and several other exhibitions. A standard of excellence has been issued by the Club. A leading fancier of the variety informed us some time since that he had orders for more than double the number of eggs for hatching which he could supply during the past season. It would thus seem that the Plymouth Rocks are having a fair trial, and we shall be glad to learn the results of their experience of the breed from any of our readers who may have kept them. It is a pity that our American friends should have such a fancy for yellow legs as to insist upon their presence in all their breeds. There is a prejudice against yellow legs in the English markets for table poultry, but if the birds be of sterling merit for table purposes that prejudice will doubtless ere long be overcome in their favour. That they are in the first rank as layers is generally accepted, and

the table of laying results which we extracted last week from an American contemporary fully bears out this view.

STILL another American variety seems to have recently received renewed attention. Jersey Blues were apparently "made" some years back, but after a while passed out of notice, and have only of late been again taken up by some leading fanciers. They betray an undoubted Andalusian origin in their colour and marking. The ground colour is a deep slate blue, and the pencillings are almost black, as also are the saddle, hackle, and tail feathers of the cock. The earlobes are red, the legs black. They are squarely made, full-breasted, thickset birds, and weigh from 8 to 10 lbs. in the case of the male bird and from 7 to 9 lbs. in the hen. Their tails and combs are of medium size; and as they are said to be excellent table fowls, and, indeed, "to have been frequently eaten as Turkeys, and pronounced good ones too," it is not unlikely that the Langshan may have something to do with their origin. A cross between good-sized Andalusians and Langshans as free of leg feather as possible would probably produce a fowl not unlike the modern Jersey Blue; and as the birds are reported to mature very early and to be exceptionally hardy, it may be worth while for some fancier or farmer to try the effect of such a cross.

#### OUR LETTER BOX.

**Incubators (Mrs. M.).**—We have had no personal experience of the incubators you name; they are, we believe, identical in principle with, and merely vary slightly in detail and perhaps in quality from, Christy's. We think the business of the firm you first refer to was taken over by the other maker you mention, so that there is really only one incubator in the market. We have amongst our readers several who have used Christy's machines with success, and should recommend you to obtain his pamphlet, also Brown's work on incubation, published by Messrs. Cassell, Petter, & Galpin.

**Plymouth Rocks (L. S.).**—You will find some notes in reference to this breed in another column. It is of American origin, and the birds are esteemed and found profitable by many poultry-keepers—at least, so we find by reports in the American papers.

**Hens' Feet Swollen (L., Baltimore).**—We have never before heard of the ailments which you describe affecting Hamburgs. If your roosts are very high lower them, and if there is any broken glass lying about remove it. If pus have formed in the swellings on the feet they must be lanced and the matter squeezed out, and the parts fomented with warm water. Some few days after the matter (if any) has been extracted, or at once if there be no matter to extract, apply lunar caustic daily to the swellings on the feet. Until a cure has been effected the birds must not be allowed to perch, but should sleep on straw. The scales on the legs may be removed by scrubbing well with a hard nail-brush and soap and water, and then applying an ointment made up of flowers of sulphur and lard. Repeat this process daily until a cure is effected.

**Prickly Comfrey (Hans F. Hamilton).**—In November the plants may be divided into as many pieces as there are crowns, reserving a portion of root to each division, planting in rows 30 to 36 inches asunder, and 24 to 30 inches apart, burying up to the crown in loose soil. The ground should have been deeply trenched, and the more manure is worked-in the better the plants will flourish. A good dressing of manure should be given about the crowns after planting, and this should be pointed-in early in spring. The deeper and richer the soil the more space should be given the plants. Comfrey does best in deep damp soil, but the moisture must not be stagnant. Propagation is also effected by cutting the roots into lengths of about a couple of inches, and dibbling them in at the above-named distance apart, November and February being suitable seasons. Guano, nitrate of soda, and salt are good surface dressings, applying in March.

#### REMARKS.

28th.—Fine, dry, and cool.  
29th.—Wet morning; latter part of day squally; heavy rain in evening.  
30th.—Fair day, with a very heavy shower at 2 P.M. and a little rain in evening.  
31st.—Fine, but with scarcely any sunshine.  
1st.—A cloudy day, with occasional sunshine in morning.  
2nd.—Fine pleasant day without much sunshine.  
3rd.—Cloudy morning, fine bright afternoon and evening.  
A dull cloudy week, with a good deal of rain in the first half. Temperature rather below the average.—G. J. SYMONS.

### THE ARRANGEMENT OF CUT FLOWERS.

**I**T is quite an exception to my ordinary experience to find a gardener able to arrange cut flowers really well," was the extraordinary expression that fell quite recently from the lips of a lady whose exquisite taste in the treatment of cut flowers is indisputable, who, moreover, is the owner of a large garden, and whose experience of the doings and capabilities of gardeners is sufficient to impart great weight to words not lightly spoken. A feeling of regret to which they gave rise prompts the inquiry, Is this so? and if it is, What can be done to effect a general improvement in a matter of such importance?

That the prizes given at flower shows for dinner-table decorations and for bouquets have done something in this direction is undoubtedly true, but ought we to rest content with this? The inspection of finished work is instructive by conveying a general idea of how it should look when done, but how to do it is the question to which the sight of it so frequently gives rise. "Can I ever attain to such excellence as this?" is the unspoken thought of many a puzzled but aspiring beholder. It would be misleading to assert that it is possible to render proficient all or even many of those who aspire to the mastery of an art for which, just as in landscape gardening, there must be a natural taste—an intuition that readily adapts itself to the refining influence of artistic training, and originates and brings to perfection conceptions of its own different from others, and yet devoid of all that offends the highest taste and culture.

Let not those be discouraged, however, who are sensible of the non-possession of such natural gifts, and who can never hope to achieve great things in this direction, for all flowers are so beautiful and lend themselves so readily to graceful combinations, that a knowledge of what colours may best be used together, and when, with a few lessons—actual practical demonstration by an accomplished artist—would suffice for ordinary purposes. But where are such lessons to be had? Machinery in motion, working dairies, bee-driving, and many similar methods of popular education are established facts at public exhibitions, but floral decoration has advanced no further than a mere exhibition of finished work. If the managers of horticultural societies wish to add a feature to future exhibitions that will attract the public and afford greater gratification than anything that has yet been tried, let them secure the services of a good floral decorator—a man who cannot blunder at his work, of fluent speech and polished

address—a lecturer, in point of fact, and let him have a large table with vases and flowers of his own selection, so placed in an enclosure that as many persons as possible may look on. Then let him show how cut flowers can be made to look best in vases and other vessels suitable for sitting-rooms, corridors, and wherever they are required, in a variety of ways for dinner-tables, and also in hand and buttonhole bouquets, explaining the reason of all he does, and answering the very numerous questions with which he is quite certain to be assailed. It may very safely be predicted that this would be a step onwards so highly appreciated that the lecturer and not the public would tire first. It would, moreover, tend more than anything else could do to instruct and aid many a willing anxious learner, rendering his duties in floral arrangement easier to himself and satisfactory to his employers.

Tasteful combinations of flowers and foliage that harmonise not only in colour but in form, are our chief aim in this work. Avoid mixtures of gaudy colours: if scarlet is the chief colour use no yellow shades, but rather choose white for contrast. For example, just now the bold scarlet flowers of *Vallota* are plentiful, so also are the lovely white flowers of *Anemone Honorine Jobert*; try them together, using the *Vallota* blooms singly for a groundwork, out of which springs the white *Anemone*, also single, yet with the flowers gracefully clustering. This is a charming mixture for a dinner-table, and serves to illustrate my meaning both in its application to form and colour. In so treating a Marsh stand lately the *Vallota* flowers in the bottom saucer had a bold fringe of Fern fronds, a few small sprays of Maidenhair Fern rose among the mingled white and scarlet flowers, and around the glass stem was twined a spray of *Selaginella cæsia* with the lovely bluish metallic hue well developed, partly hidden by tufts of half-opened *Anemones*, dried Quaking Grass, and a couple of leaves of *Geranium pratense* which clustered around the base. The same flowers were repeated in the tops with the addition of bold clusters of scarlet-flowered *Begonia fuchsioides*. Had this stand been for a daylight decoration some spikes of single blue branching Larkspur might have been used with excellent effect. But blue never answers for lamp light, and is never used because it looks black, just as yellow becomes an unsightly shade of white under artificial light, and is, therefore, always avoided for dinner-table work.

Before turning from the blue flowers a recent success with some may be noteworthy. A large glass fish bowl had its edge boldly but not heavily fringed with Fern fronds, through and between which the clear, flashing, transparent water was visible. Upon the Ferns rested broad circles of *Gloire de Dijon* Roses in clusters; between the Rose clusters the white flower spikes of *Ligustrum japonicum* projected irregularly, two or three being made to droop downwards upon the green fringe, and the centre was entirely filled with spikes of single branching Larkspur, principally of blue shades, with a mixture of pink, a few curved deep blue spikes bending charmingly over the Roses, while a dozen or two clusters of dried Quaking Grass (*Briza minima*), springing irregularly out of the central flowers imparted a pleasing air of sprightliness and finish to the whole. This was for a daylight repast.

Pink and carmine are excellent colours for the groundwork of lamp-light decoration, and it should be added they are equally effective by day. *Coleus Sensation* from the rich carmine centres of its foliage answers admirably for the dinner-

table; Maidenhair Fern, Anemone Honorine Jobert, and white Begonia flowers being all that are required with it to form a chaste combination that lights up well. Some shades of pink are not liked so well as others, the deep purplish-pink of Anemone japonica being avoided for brighter shades, such as we have in the flowers of the old variegated bedding Pelargonium Manglesii. Insignificant as these are in a bed, yet they are of so much use for all arrangements of cut flowers as to be eagerly sought after whenever they are in bloom. Nothing can be more lovely than a groundwork of pure white Roses with Pelargonium Manglesii flowers mingled with and springing out of it. For the dinner-table it, perhaps, is most liked in tall slender glasses managed in this way: Each glass first has four sprays of Selaginella caesia put in so as to be gracefully pendant, and most of it long enough to rest upon the tablecloth, then come six or eight of the small pink Pelargonium trusses, two or three very choice little fronds of Maidenhair, and half a dozen clusters of dried Briza. Sufficient slender glasses must be so dressed to form a double chain around a cup or whatever is used for the centre of the table. Care is taken not to crowd the glasses, and the pendant chain is formed by twining two sprays of Selaginella together, so as to gracefully connect the glasses. The last time I so used them was for a small table, and only about a dozen glasses were required, but above them five small transparent fish-bowls were suspended by very fine wire from a chandelier, four of them forming a circle, with the fifth suspended a little lower from the centre. Much longer streamers of Selaginella were used in the bowls, a pendant chain being made from bowl to bowl just as from the glasses below, only it was much bolder in character. White Fuchsias with bright pink corollas were used with Maidenhair Fern in the four outer bowls, and another Fuchsia with large rosy pink flowers in the central one. Briza maxima was used in the suspended globes instead of the smaller variety, to give due importance to the central group.

Of white flowers there are many which are found most useful whenever they are to be had. Lily of the Valley is so exquisitely graceful that it would seem impossible to arrange it badly, and yet it may sometimes be seen woefully crowded. Roman Hyacinths, too, are very lovely and answer admirably for slender glasses. Stephanotis reigns supreme from spring till autumn, and may be used in a variety of ways. What can be more suitable for a boudoir-table than a basketful of its sweet-scented flowers mingled with delicate Fern fronds? Not long ago I used it for a small dinner-table successfully in a somewhat novel manner. Three small transparent glass bowls were put in the form of a triangle upon a flat stand covered with crimson plush, a fourth glass was placed on the top of the others in the centre, and then they were dressed with Selaginella caesia, Stephanotis, and dried spikes of Briza minima. Four flowers only of Stephanotis were required for each of the three lower glasses, and six flowers for the upper one. Four of these little groups were prepared, each upon its crimson stand, and they were so placed upon the table that the Selaginella sprays met upon the cloth. The effect was very chaste and lovely.—EDWARD LUCKHURST.

#### HARVESTING ONIONS.

SOME Onions which were sown early in spring and formed good bulbs in July and August now have their top growths bent over and the bulbs hard and dry. All such should be drawn from the soil at once, but they should not be taken under cover yet. Some allow them to lie on the ground where they were grown, but we think they do not dry quite so well or quickly as if spread out on a gravel walk, especially in wet weather. The bulbs should be removed to the walk and be placed in a single layer. After remaining in their first position for two dry days they should be turned over, and this operation may be repeated until they are all firm and dry. Those which are smallest in the neck at drawing time will dry first, and if really good winter-keeping Onions are wanted it is well to select the smallest-necked bulbs, drying and storing them by themselves. Those with very thick green sappy necks should have a good part of the top growth cut away, and the remainder well twisted round to press the sap out. These thick necks are easily selected from the others, and they are easily seen in the beds, as they remain standing straight up after the

others have fallen. Some weeks before the roots are to be drawn it is a good plan to examine the beds and bend all the thick growths. This stops their growth and assists the ripening. Those who give a little attention to Onion culture, however, have seldom many of these objectionable thick-necked bulbs in their beds by the autumn, as many are taken out at the spring thinnings and for use throughout the growing season.

A dry day should be chosen for removing the Onions from the ground, and it is better to leave them out far into September to secure this than to take them in wet. When suitable weather cannot be secured the best way of dealing with them is to take them into some open shed or loft and dry them there. They are improved by being exposed to the sun, if it is only for a few days at first, and they may be finished off in sheds afterwards. In any case they ought to be well dried before being placed in their winter quarters, and the larger the bulbs the more drying they require. Green tops should never be seen on them when being stored. I daresay others besides myself have noticed that the flavour of Onions in winter is influenced greatly by the way they are harvested. If not properly dried and they are afterwards stored in heaps or in a close place they appear to ferment to a certain extent, and lose much of their original flavour.

As to the length of time needed to dry Onions thoroughly, much depends on the state of the bulbs and the weather. As before hinted, small-necked bulbs are often nearly dry and ripe before being pulled, and they do not require to lie long before being ready for storing. As a rule we allow our Onions to remain in the open from eight to fourteen days, and if the weather is dry at the end of the time they are moved in at once.

As to the best keeping Onions, no variety we have tried has lasted in good condition so long as James's Keeping. Improved kinds of Onions we have in numbers, but their introducers have evidently had nothing but size in view when they were selecting them. The place to store Onions in winter generally depends on the accommodation each cultivator has; some having excellent places for them, others having to do the best they can. Any shed, whether it be well lighted or nearly dark, is suited for keeping Onions in, always providing it is dry and cool. Frost or a high temperature soon causes decay, and heat does more harm than cold. In the spring of 1880 we sowed some favourite Onion seed along the bottom of a wall with the intention of securing bulbs from which to save seed, and these remained out all last winter, exposed to 20° or more of frost without being injured, as at the present time we have a fine lot of seed on them. In winter our Onions are given much the same treatment as our Apples and Pears, and we always manage to keep them well until they are plentiful in the open quarters again.—A KITCHEN GARDENER.

#### THE ART OF COLOURING GRAPES.

THE principal art, it appears to me, that is requisite in imparting to Grapes a rich dark bloom, consists in the negative exercise of following Nature. "SINGLE-HANDED" is undoubtedly right in presuming that a full and free circulation of air is necessary during the colouring process. The condition of outdoor Grapes in autumn tells us this; and they tell us further, as plain as berries black as Sloes can speak, that a high night temperature is not so essential as we artists think for finishing black Grapes, at least so far as regards their appearance. What is really essential is powerful root-action, and this, in the case of outdoor Vines, is in fullest force when colouring commences. Some shade, too, is also needful, for black Grapes that are shaded by the foliage are almost invariably better coloured than those exposed to the sun—hence the reason of the general want of colour on Grapes this year that ripened during June and July. No one visiting the exhibitions that were held during the hot period could have failed to observe the brown or mahogany hue that was visible on most dark Grapes, and the same character was apparent in the windows of the best fruiterers' shops. Those who were "on the move," too, during the period indicated would find that the Grapes, as a rule, were much better coloured in the western counties than in the eastern, the reason of this being that the heat in the former district was not nearly so prolonged as in the latter.

The Vine, it may be well to remember, is not a climbing plant as many suppose, but a trailer, and its fruit hangs beneath the leaves and is not exposed to the sun. This fact ought to teach us that it is a very easy matter to remove too many laterals from Vines just before the Grapes change for ripening. If the weather proves very hot it is far better to remove no sub-laterals at that time, and if there is a fear of these unduly shading the principal leaves, let the laterals be drawn downwards and hang down among the bunches, and down the back wall. These growths have not an exhausting effect but rather the reverse, for they

are great incentives to root-production; and if the chief leaves are kept clean and are fully exposed to the light, and air is admitted freely, they will always elaborate the additional sap that is provided by the additional roots consequent on the free growth of the laterals, and the Grapes profit by the additional food and natural shade.

There appears to be two extremes in Vine-dressing that are extensively indulged in. One is permitting too many primary or fruit-bearing laterals to extend, and consequently there is no thoroughly developed and perfect foliage; the other is thinning the chief laterals sufficiently, and then rigidly, often too rigidly, stopping the subsequent growths regardless of the state of the weather.

Overcropping, or in other words defective root-action, is the primary cause of defective colour. A Vine may be overcropped even if the bunches are few and small. The fruit alone does not afford sufficient evidence for determining the point as to whether Vines are overcropped or not. One Vine may be lightly cropped with 30 lbs. of Grapes, and another too heavily cropped with 15 lbs.: in this matter everything depends on the root-action, the food, and the working power of the foliage.

It is a long time since I have seen so many brownish-black Grapes as I observed at the June and July exhibitions this year, which I attended in the capacity of—A JUDGE.

#### DISBUDDING CHRYSANTHEMUMS.

It is a most difficult task to select the proper buds to produce good flowers. The present is the time to disbud, and whether the crown bud or the terminal bud be chosen depends in a great measure on the strength of the plants and the experience of the grower. Weakly plants that have been stopped once or more now have several shoots. On examination these will be found to have a small bud in the centre of two or three young growths—this is what is known as the crown bud. If the growing shoots are removed at once this bud will in most cases swell and form a large flower, and from this crown bud many exhibitors obtain their largest flowers, more especially in the Japanese section. If, however, the shoots which appear with and around the crown bud are left the bud will not swell, and the young growths will perfect themselves by making about another foot of growth, and each bearing buds at the point. These are what are termed terminal buds. The difference in this case is, that instead of the centre bud being surrounded by young growths as in the case of the crown bud, they are surrounded with other flower buds, as it is natural for the Chrysanthemum at that time of the year to bloom in clusters. Good flowers of many varieties are obtained from the so-called terminal buds, but of others there is not substance enough to be obtained from a terminal bud for an exhibition flower. Experience and observation will soon enable anyone to determine what bud to retain.

I purpose fully considering this important autumn flower, and hope other correspondents will assist me by supplying any information in determining the various sections. A large field of observation is open, and much good may be the result.—J. W. MOORMAN.

#### DESTROYING HORNETS' AND WASPS' NESTS.

IF your Sidmouth correspondent will try the following plan he may destroy the hornets he complains of, although the position of the nests seems rather difficult to deal with. The one high up the brick wall I would deal with as follows. At night, when all the hornets are supposed to be in their nests, get say a pint of turpentine and a garden syringe with rather a coarse rose and forcibly syringe the nest; by this plan the nest will be cut into shreds and the hornets killed or dislodged, as they cannot endure turpentine, which causes almost instant death to those it touches. If, however, there is anything trained against the wall in question, it would be well to nail a mat or something of the kind on the wall before syringing. I have this season destroyed a hornets' nest similarly situated. The nest between the lath and plaster and brick wall I would treat as follows. Well saturate some cotton wool with turpentine, and with it stop up the crevices of the lath and plaster. This must be done when the hornets have ceased working for the day. For wasps or hornets in the ground the same method is applicable, but in light soils there is sometimes more than one outlet, and the application may have to be repeated.—G. R. ALLIS, *Old Warden Park*.

IN reply to a Sidmouth correspondent, I submit an easy way of destroying wasps or hornets, and one which I have not found to fail. I took a wasp nest on Friday last, and I have found that

the insects are not merely stupified by the plan I adopt, as they are by some other methods, but are killed. I obtain three pennyworth of spirits of turpentine in a small bottle and cork it up closely until it is used. The cork is simply withdrawn and the bottle forced into the entrance to the nest. Whether the turpentine all runs out of the bottle or not does not matter, provided the hole is stopped up and air is excluded. By this plan the insects are destroyed, and no fire nor anything else is needed.—J. B.

#### CIMICIFUGA SPICATA.

THE accompanying woodcut represents a portion of the flower spike and leaf of a *Cimicifuga* growing in Mr. Ware's nursery under the above name. It is similar to *C. racemosa* in general form, the flower stems being several feet in height, and bearing

Fig. 40.—*Cimicifuga spicata*.

the small white flowers closely packed on lateral and terminal branches. Being late in flowering it forms a conspicuous object in the borders during August and early September, and may advantageously receive the attention of cultivators. Ordinary garden soil suits it very well, and when large clumps have been formed the plant is really a valuable addition to the list of effective hardy plants.

MINT V. MENTHA.—When recently visiting an English public park my attention was attracted by a bed containing apparently two forms of the now popular dwarf Mint, *Mentha Pulegium gibraltarium*, one much darker in colour than the other. Desiring to ascertain the name I accosted the nearest workman, and thinking to make my question as intelligible as possible I asked, "What Mint is that in the centre of the bed?" "That ain't a Mint, sir; it's called *Mentha pruleja*." With which rather surprising piece of intelligence I was obliged to be content, reflecting

what a promising recruit my informant would make for the ranks of those who advocate a general adoption of English plant names.—SIMPSON.

### STRAWBERRIES.

THE present is a very good time to make a new Strawberry bed. The soil is moist and the runners are unusually well rooted. The land should be deeply dug, and some well-decayed manure added if the soil is poor and of a light nature; if the soil is of a heavy character the manure need not be much decayed. The strong-growing Strawberries, such as Sir J. Paxton, should be 2 feet from plant to plant and 2 feet apart in the rows. Keens' Seedling need be only 1 foot 6 inches from plant to plant. It is not at all a bad plan to allow 2 feet 6 inches after every third row, which will allow more space for gathering the fruit; you can pass along the wider space and gather one row and half another, then go to the other side and finish the other row and a half. If a large quantity of fruit is wanted in a short time the plants may be set out much nearer together, and some of them taken away after the second year. In this case Sir J. Paxton and other large sorts need be only 1 foot apart either way. The ground should be trodden firmly before being planted, particularly at this time of the year, for if it is not left firm the frost frequently draws the plants out of the ground in winter. A little manure spread over the surface of the ground is very useful in checking this. The other day I saw Forman's Excelsior recommended as a valuable acquisition. If any of your readers have tried it I should like to hear their opinions.—AMATEUR, *Cirencester*.

NOW is the time for transplanting Strawberries. All ours were put in new pasturage a fortnight since, and they are now fully established. It has been a rule here to change the position of Strawberries every two or three years, and the consequence has been that we always have very large crops. The plants do not die in the old beds, but the soil becomes exhausted and the crops are light. I have observed this to be the case if the plants be kept in the same spot over two years. Our plants are twelve years old, but they are in the greatest vigour. The inner crowns no doubt gradually die, but there is always a large supply of strong crowns on the outside. This plan is of great importance where a man has 100 acres of this fruit.—PHILODENDRON.

### CINERARIAS AND CALCEOLARIAS.

ALTHOUGH I have for many years grown Cinerarias and Calceolarias it is only comparatively recently that I could fairly understand and meet their requirements. At one time, in spite of every attention, a great percentage of plants would persist in dying, often without much warning and no matter how well established. Of course the knowing ones are thoroughly acquainted with the cause and its cure, or rather prevention; but I failed to discover it, and have to thank a more experienced friend for the remedy. "You keep them in too hot a position," said he, and ever since, instead of growing the plants in frames with a slope to the south, they are located in frames near a north wall and sloping to the north. Even in this position they are lightly shaded when the sun is bright, care being taken not to shade any longer than is absolutely necessary, and also to ventilate freely both night and day in order to maintain sturdiness of growth. Calceolarias are not of much service here, but of Cinerarias we are growing about two hundred, some already giving signs of flowering, and others are receiving their final potting. Not a plant gives signs of a collapse, neither will they unless when they are transferred to the houses and heated pits some of them are injuriously affected by the fire heat. We keep them in frames as long as possible.

A slated or gravelled staging, or both as the case may be, well removed from the hot-water pipes in a house where only sufficient fire heat to dispel dampness or keep out the frost is employed, will be found to agree with both kinds. Where there is a conservatory to be kept gay, then the general effect has to be studied; but where Cinerarias and Calceolarias are grown more as a hobby, then by no means place them with greenhouse plants generally, but rather arrange them in groups. By these means they are far less liable to be infested with insect pests, and as the colours and markings are very diverse the beauty of one is enhanced by contrast with another, the rich green foliage, which ought always to be preserved, being sufficient greenery.

Other cultural details, which I will briefly touch upon, I really regard as of minor importance. The seed for the earliest batch of Cinerarias is sown towards the end of March or early in April, and two more sowings are made at monthly intervals. Large shallow pans well drained are employed, filling these to near the

surface with light sandy soil, and finishing off with a layer of sand. A watering is given with a fine rose, and in a few hours the seed is sown thinly, pressed in with the clean portion of a flower pot, and very slightly dusted over with sand. The pan is placed on a cool greenhouse shelf, closely covered with glass and well shaded with paper till the seed has germinated. The glass is then tilted, shading being applied when necessary, and when the seedlings have their second leaves they are transferred to a cold frame. The seed being sown thinly pricking-off is unnecessary, but before they are much crowded and when easily handled they are potted singly into 3-inch pots, and from this size and before becoming much root-bound they are finally transferred into either 6 or 8-inch pots. The last pan of seed, I ought perhaps to state, is placed on the north side of a wall in the open air, and every good seed invariably germinates. Nearly half leaf soil may be used for the plants in the earlier stages of growth, and for the final potting about three parts of loam to one each of leaf soil and decayed manure may be given, using some sand in each instance. Rough fibrous loam for the last potting is preferable, but good Cinerarias are often grown in fibreless loam, more than ordinary care in this case being taken with the drainage. The pots must always be clean and well drained, and the plants should be potted rather firmly and up to the collars, weak liquid manure to be given frequently when the flower heads are developing. Aphides form the greatest enemies to this class of plants, and must be destroyed by frequent mild fumigations with tobacco paper. Heavy fumigations prove very injurious; and although dipping the plants in a tub of some insecticide in solution is a thorough cure, it also is liable to disfigure the foliage, the settlement being especially objectionable. Much may be done with a small hair brush if used in good time for the removal of insects.

Much of the foregoing is also applicable to the herbaceous Calceolarias. We make one sowing of these at the end of July or early in August in a manner similar to the latest sowing of Cinerarias. The seed being minute is with difficulty sown thinly; consequently the seedlings when large enough to handle are pricked off in pans of light soil and placed in handlights behind a north wall. Before becoming crowded they are potted singly into 3-inch pots and returned to handlights or a frame still under the wall. Here they are kept somewhat close till established, and before becoming root-bound the strongest are shifted into 8-inch pots, and the weaker into 6-inch pots, and returned to a cold frame. To give them a good start they are again kept close for a week or ten days, lightly damping the foliage on clear days. At no time should Calceolarias be dry at the roots, and they are all the better for standing on a moist base. If wintered in frames air should be given on all favourable occasions. If it is preferred to have them in a cool greenhouse place them near the glass, covering the shelves if possible with a layer of moss. By potting the strongest as they require it, the batches will form a succession; but if it were required to still further prolong the display more seed would be sown late in September, and from the two sowings the flowering season would extend from late in April till July. For ordinary decorative purposes it is not advisable to pinch out the bloom heads of either Cinerarias or Calceolarias, and if either kind are allowed to become root-bound in small pots premature flowering will result.—W. I. M.

### ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE autumn Show of this old-established Society was held, as usual, on the first Wednesday and Thursday of the present month in the Waverley Market, Edinburgh. There is always a thinness apparent at these autumn shows, fruit constituting the main feature of the schedule, and plants holding a secondary position. From having the fruit, vegetables, and cut flowers mainly on the one side of the building and the plants on the other the thinness of the material was more noticeable than it otherwise might have been. Dividing as it were the Exhibition into two halves were a series of large tables down the centre of the Market, mainly filled by nurserymen. The most striking of these groups was that from Messrs. Ireland & Thomson of Craighleith Nursery. Several of the Crotons which secured them first honours at Manchester were effectively set up in telling positions; two grand Pitcher-plants were conspicuous at each end, and many fine new Dracaenas, &c., were freely used in the arrangement. Messrs. Downie & Laird, West Coates Nursery, filled another of the tables with huge Lantanas and other Palms, and many smaller fine-foliage plants on the sunny side of the table, while on the north side were representative collections of cut florist flowers. Another table was furnished by Messrs. T. Methven & Sons, of Leith Walk Nurseries, similar in style to the one just noted, but without flowers. Messrs. Dicksons & Co., Waterloo Place, made up the end table with a collection of plants, conspicuous amongst which were some grand Dicksonias, two large basketfuls of *Primula capitata*, very quaint-looking in the mass, and a collection of the fine Pinks for cutting which this firm is working up. The other central table was filled with

competition Ferns, and other plants in competition. At the west end of the building The Lawson Seed and Nursery Company had an oval arrangement on the floor of the Market, in which flowering Lilies, fine Phormiums, and other foliage plants were conspicuous. Many Palms, as well as other foliage plants dotted singly about the Market, were supplied from the Royal Botanic Garden. A table which attracted attention from the same garden was occupied with economic, medicinal, carnivorous, and other curious plants.

In the plant classes the chief prizes were offered for a table of plants artistically arranged. Two competitors only came forward; A. Paul, Esq., Gilmore Place, being first with one in which Orchids helped the arrangement greatly, the other table being deficient in flowers. The stove and greenhouse flowering plants and the Heaths were fine for the lateness of the season. In the class for six stove and greenhouse plants in flower Mr. John Paterson, Millbank, was first with a very good specimen, Mr. Paul, Gilmore Place, being second with scarcely inferior plants, though wanting in Heaths. In the class for three of these the same exhibitors were again first and second. For two Mr. McFarlane, Moredun, was first; and Mr. J. Shearer, Merchiston, second. A really grand *Lapageria rosea* was one of the second-prize plants. For three Cape Heaths Mr. Paterson was first and Mr. McFarlane second, both with good half-specimens. The foliage plants were rather weak on the whole. Mr. R. M. Reid, Edinburgh; Mr. Paterson, Mr. G. McLure, Trinity Grove; and Mr. S. Graham, Kibrassock, being the principal prizetakers. Ferns we have also seen better, but it is interesting to note that one of the most successful exhibitors was a letter carrier, Mr. A. Anderson, of 19, Pilrig Model Buildings. He took first prizes for Todeas, Filmy Ferns, dwarf-growing Ferns, and British Ferns. The Orchids were not numerous, but some good pieces were staged, a grand plant of *Oncidium incurvum* with four spikes being notable. Mr. J. McLeod, Brentham Park, Stirling, Mr. Paterson, and Mr. Paul were the prizetakers. The other classes were not specially noteworthy.

**FRUIT.**—The exhibits in these classes were arranged on three tables, and formed one of the best shows seen in Edinburgh during the past few years. The Grapes were not so large as many that were set up at Manchester a fortnight previous, but they were well finished generally. The Peaches and Apricots were much finer than at Manchester. For a collection of fruits, twelve sorts, Mr. McIndoe, The Gardens, Hutton Hall, York, and Mr. McIntyre, The Glen, Peebleshire, were the only exhibitors, the first prize going "over the border." This was an even and good collection, the Duke of Buccleuch, Golden Champion, and Gros Guillaume Grapes being well finished; but Black Hamburgs were rather deficient. Barrington and Alexandra Noblesse Peaches were also very fine. For eight sorts, Pines excluded, Mr. McKelvie, Broxmouth Park, Dunbar, was first, his collection containing very finely finished Muscat of Alexandria and good Black Hamburg Grapes, with fine Peaches and Nectarines. Mr. McIndoe was a remarkably close second, his smaller fruits being decidedly better, whilst his Grapes were weaker than those in the first collection. Mr. McIntyre was third.

For twelve bunches of Grapes, six white and six black, Mr. McKelvie was first with fairly good examples of Alicante, Gros Colman, Muscat of Alexandria, and Buckland Sweetwater among others. Mr. McIndoe was again a very close second, Gros Guillaume, Trebbiano, and Duke of Buccleuch being specially good. Mr. Mackie, Woodlands, Darlington, was a good third. For eight bunches Mr. McIndoe was the only exhibitor, and obtained the first prize with some well-finished Grapes. For four varieties the competition was very keen. Mr. Kirk, Norwood, Alloa, being first with Gros Colman, grand; good Black Hamburg, and Mrs. Pince and Muscat of Alexandria in good order. Mr. McKinnon, Melville Castle, Lasswade, was a close second; Mr. Boyd, Callander Park, Falkirk, being third with small bunches but grandly finished. In the two bunches of one variety the first-prize Black Hamburgs from Mr. Kirk, the Mrs. Pince from Mr. Brodie, Glen Mayrie, Galashiels, and the Muscat of Alexandria from Mr. Calderhead, Wemyss Castle, Fife, were particularly good. In the single bunch classes the competition was keen. Mr. Calderwood's Muscats were again fine here, so were also the first and second Black Hamburgs from Mr. Kirk and Mr. Boyd; the Gros Colmans from Mr. Lees, Hillsborough Castle, Ireland, and from Mr. Boyd; the Black Alicante from Mr. W. Collins, Walkerburn, and from Mr. Boyd; and the Lady Downe's from Mr. Kirk and Mr. Boyd. A fine bunch of Duke of Buccleuch came from Mr. Scott, Carbery Tower. The finest-flavoured white Grape was Duchess of Buccleuch from Mr. Calderhead, and the finest-flavoured black being an Alicante from Mr. Boyd. Mr. Simpson of Wortley near Sheffield exhibited a collection of Grapes stated to have been grown in a night temperature ranging between 35° at the bursting of the buds to 65° at the ripening of the fruit. The varieties were Muscat of Alexandria, Lady Downe's, Mrs. Pince, Alicante, Black Hamburg, Raisin de Calabre, and Gros Guillaume. They appeared to have been badly packed, and in consequence had been considerably rubbed on their journey; but apart from that they were not in good condition, and the gardeners present were not impressed with the economy of the system.

Pine Apples were not largely shown, Mr. Murray, Maybole, being first in the class for two Smooth Cayennes, and Mr. McIndoe second. For any other sort Mr. Murray was again first, showing Lady Beatrice Lambton. Peaches were not numerous either, but the size of many of the fruits was surprising. The Judges selected quality and colour, as the smaller fruits were placed first. Mr. Ewan Cameron, Moffat,

was first for twelve, and Mr. Bunton, Gilmerton, Drem, first for six fruits. In the Nectarine classes Mr. McLeod was first in the one and Mr. McLean, Vintner's Park, Maidstone, in the other. Figs, Pears, Apples, Gooseberries, Currants, &c., were fairly well shown, and some good hardy fruit was shown in collections of ten sorts; Mr. Brunton, Gilmerton, being first here, and Mr. Barrie, Salton Hall, Tranent, second.

Vegetables were fine indeed in the classes for particular sorts; we have never seen better exhibits in Edinburgh. The collections were scarcely up to the usual standard. Celery was quite equal to that at Manchester, which is saying a good deal, Mr. James Brown, Crieff, taking first. Leeks from Mr. McKelvie, Broxmouth Park, were first, and were a grand sample; some of the longest blanched Leeks we have ever seen were passed over, the want of corresponding thickness being against them—quite 15 inches in length was perfectly blanched in these. The Onions, Lettuces, Beet, &c., were all fine. Potatoes were not a large show, for twelve sorts Mr. McKinnon occupying first place with the finest examples, though perhaps overweighty for many fanciers.

In the cut-flower section was much of ordinary quality, at the same time many fine collections were staged. The Roses were good for the lateness of the season, those from Messrs. Cocker & Son, Aberdeen, causing quite a sensation on account of their size and brightness of the blooms. This firm showed boxes of fine blooms of Alfred Colomb, Comtesse d'Oxford, Marie Baumann, and La France. Many of the blooms in their first-prize twenty-four were equally grand. Messrs. H. Dickson, Belfast, was second with very creditable blooms; Mr. T. Smith, Stranraer, also showed well. Mr. A. Hill Gray, Dunkeld, was first in the class for twelve with a fresh and clean lot. For twelve Quilled Asters Mr. T. Menzies, Carbery Manse, Musselburgh, was easily first with handsome blooms, large, full, and globular, and clear in colour; the Victoria Asters from the same exhibitor were also fine; Dahlias were generally good. Messrs. Downie & Laird being first for twenty-four Show and twelve Fancies; Mr. J. Walker, Linlithgow, for twelve Show; and Mr. Black, East Calder, for six Show and for twelve Fancies. Phloxes were good, Mr. Ewan Cameron being first. Zonal Pelargoniums in trusses of three were bright. Hollyhocks were poor, also Gladiolus. Amongst miscellaneous exhibits were a couple of flowers of a very fine variety of *Cattleya gigas* from the Brentham Park collection. Messrs. Tod & Co., Maitland Street, had an assortment of bouquets, crosses, &c., and a centre plant arranged with flowers for dinner-table—a beautiful exhibition. Mr. Kilgour, Kilmarnock, showed a few good Gladiolus, and a stand of Phloxes and Pentstemons; Messrs. Downie & Laird a seedling *Lobelia* named "Miss Duncan," for which a first-class certificate was awarded; it appears to be a cross between *speciosa* and *compacta*, and is clear blue in colour. Messrs. Ireland & Thomson had a similar award for four new Crotons, these were C. Thomsoni, C. Duke of Buccleuch, C. Whittoni, and C. Houldsworthi. Mr. Turnbull, Bothwell Castle, also had a certificate for a new *Erica* named Thomsoni, a beautiful and distinct variety in the way of *E. linioides superba*, and from its habit and style of flowering is likely to prove useful for decorative work.

The general arrangements were as usual most efficiently carried out by Mr. Young and his assistants. A very large number of gardeners visited the Show.

#### FRUIT-GROWING AT WIMBLEDON.

FACING the Common, and near where the camp is held, is situated Fieldheim, the residence of F. Rodewald, Esq., a small but very neat and clean establishment, and conveying a lesson respecting what may be done in a small garden. Fruit is the principal attraction, and accordingly we find a range of half-span houses devoted to it which are very light and suitable for the purpose. The first compartment is 30 feet long, and is used as the earliest vinery. Mr. Bennett, the gardener, stated he had cut about 130 bunches, averaging 2 lbs. each, from the house, and commenced cutting on the 24th of May. The next house is 40 feet long, also a vinery, with a fine crop of good useful fruit of such varieties as Black Hamburg, Lady Downe's, Muscats, and Alicante; some bunches of the first-named were remarkably good in size of bunch, berry, and colour. In all there were about two hundred bunches. Another vinery also contained a fine crop, bunches about 2 lbs. each. Under the Vines were some fine Peaches and Nectarines, including excellent specimens of Noblesse, Barrington, Grosse Mignonne, and Late Admirable Peaches; of Nectarines Elruge seems a great favourite; there are also Hardwicke Seedling, Rivers' Orange, Pine Apple, and Victoria. About forty-two dozen fruit has already been gathered in this house, but there still remain numbers of fine fruit. A small compartment in the middle of the range is devoted to Bananas, which are successfully cultivated. 46 lbs. of fruit were taken from a plant in June, and another appears likely to produce a similar crop.

There is also a later house, about 60 feet long, adapted to the culture of Vines and Peaches. The varieties of Grapes are principally Black Hamburg, Gros Guillaume, and Alicante, bearing about 200 bunches, averaging 1½ lb. each, in good condition.

Under the Vines are Royal George, Late Admirable, and Golden Eagle Peaches, and Elruge Nectarines. These trees are heavily laden with fine fruit of excellent quality, Elruge Nectarine and Royal George Peach being the most noteworthy. The back wall is covered with Brown Turkey and other Figs. An adjoining span-roofed Peach house, about 60 feet long by 20 feet wide, has six trees covered with promising fruit, Royal George carrying about fifteen dozen, Noblesse ten dozen, Millett's Mignonne eighteen dozen, and Elruge Nectarine again with twelve dozen remarkable fruits.

A long span-roofed house with several partitions is devoted to Melon and Cucumber growing. From one compartment 250 Melons have been cut, some of which were exhibited at Wimbledon, and though not for competition were highly commended. Reid's Scarlet-flesh and Golden Perfection are held in high esteem. Another very promising crop is coming on. In another compartment are some very fine specimens of the most useful Orchids, also a good collection of table plants, which seem in strong demand at this establishment. Some of the Crotons were very highly coloured. A good collection of Zonal Pelargoniums are grown for flowering in pots. A fine lot of Azaleas and other plants were noticeable, also a collection of healthy Chrysanthemums.

The kitchen garden although small is well stocked, not a spare foot of ground can be seen. Some fine pyramid Apple and Pear trees are well laden with good even fruit. The flower garden and lawns are neat, and a fine conservatory attached to the dwelling contains healthy Camellias and other plants, the Fuchsias trained to pillars being remarkable for the profuseness with which they flower. Good management reigns throughout, reflecting much credit upon the gardener.—J. P.

#### GREENHOUSE RHODODENDRONS.

FOR some time this useful class of plants was much neglected in private gardens, but during the past two or three years their cultivation has extended. The demand was small for a time, but it is now almost difficult to obtain plants of some useful kinds. The more recent introductions, of which Princess Royal is the type, are beginning to be plentiful; while Princess Alice, one of the very best, can scarcely be obtained except as very small plants, which require to be grown two or three years before they are of much service for decoration.

These plants are amongst the most useful we possess either for cutting or other kinds of decoration, and should be largely grown in every garden. Some of those classed as greenhouse varieties are very nearly hardy, and would, I feel confident, stand our winters in some parts of England and Wales. Rhododendron Gibsoni, R. Princess Alice, and R. ciliatum I have left outside all winter—not during one of our severest winters—and the plants were not injured in the least. It is not advisable to subject them to this treatment if the best results are looked for. If no better accommodation can be given a cold frame will suit them well. Some kinds do best when grafted, others succeed best on their own roots. Rhododendron Gibsoni does well worked on the common R. ponticum or any variety for a stock; while Princess Alice does not take well to a stock, but strikes readily with care and proper management, and grows well upon its own roots. R. jasminiflora does well either way, but grows strongest when worked. Princess Royal, which grows most luxuriantly and strikes freely, would no doubt make a capital stock for the more delicate growers.

When propagation is effected by means of grafting, clean stocks should be selected and established in 2 or 3-inch pots ready for grafting in the spring, say about the month of February. The tops of the previous year's wood should be used for the scions. The system of grafting should either be saddle or side grafting, similar to that employed for Roses or fruit trees. The former I consider the most successful mode. Little art is required in saddle-grafting. The cut of the stock or scion must be clean and done with a sharp knife, so that the two fit exactly together, being made secure by means of worsted. Some employ clay or grafting wax round the union after the scion and stock are placed together, but this is optional, and by no means indispensable. After the operation of grafting is performed the plants should be placed in a close frame where a slight bottom heat can be given, and the top heat maintained at 45° to 50° until the stock and scion are thoroughly united. The plants must be shaded from bright sun, kept well watered, and dewed with the syringe twice daily.

When the stock is increased by means of cuttings they can be inserted at once, selecting short growths of nearly ripened wood. Pots 8 inches in diameter should be prepared by half filling them with crocks, and the remainder with sandy peat pressed in firmly. About half an inch depth of silver sand must be placed over the

surface. Place the tallest cuttings in the centre and the dwarf ones round the sides, leaving sufficient room for the bellglasses, which should be placed over them after a good soaking of water has been given. The pots containing the cuttings should be plunged amongst any moisture-holding material in a cold frame until cold weather sets in, when the temperature if possible should be maintained at from 40° to 45°. The bellglasses will not require to be removed for a long time, as but little water will be needed, and sufficient can be given by syringing over the glasses occasionally. As soon as the cuttings are rooted they must be potted singly in small pots, and kept close in a frame until they have commenced to root afresh, and must then be exposed to more air to gradually harden them to be grown under cool treatment. The grafted plants when the scion and stock are thoroughly united may be treated similarly.

The hardening process must be gradual, or a severe check is sure to follow. The operation must be done with much care, then the young plants will continue growing. When severely checked in their early stages they often fail to grow satisfactorily. When they have been hardened to cool treatment and have filled the small pots with roots the plants should be transferred to 5-inch pots. This size will be large enough for the first season after grafting. The plants should be wintered in a greenhouse or frame, where free ventilation can be ensured.

The second season the object should be to obtain two growths, which can be accomplished by starting them early in the season by means of a little heat, giving at the same time sufficient air to cause a sturdy growth. The first growth should be completed by the beginning of July, and must have for a short time abundance of air until the flower buds are visible, which is sure to be the case with free-flowering kinds such as Princess Alice. The flower buds must be removed and the plants kept close again until they commence growth, which must be pushed on until completed. Flower buds may by chance be formed upon this second growth, and can be allowed to develop if deemed necessary. This is not altogether advisable when the plants are small; in fact they will make greater progress the following year if not allowed to flower. The freedom with which many kinds flower render them in a small state very attractive for vases and decoration generally. Where plants for such purposes are in request, and good-sized specimens are needed, they can be allowed to flower and only make one growth a season. Moderate-sized plants are best for greenhouse or conservatory decoration, and should, until they attain a fair size, make two growths a season. This is an advantage and saves valuable time.

Potting must be done carefully from time to time as the plants require it. To grow greenhouse Rhododendrons successfully every attention must be paid to this matter, as if allowed to become rootbound the wood hardens, and in consequence growth is weak and slow. They must not, however, be overpotted, or the evil will be as great as if the plants are in too small pots. The pots must be well and carefully drained and the soil pressed firmly in. The soil most suitable is good fibry peat with plenty of coarse sand to keep it porous. They also do well in a mixture of loam and peat, but the former is preferable.

Watering must be carefully done, especially after the plants are first potted, but they must not suffer by the want of water during any season of growth. If allowed to become dust-dry they soon fail to do satisfactorily; they also refuse to grow luxuriantly if water stagnates about their roots. During the growing season the plants should be liberally syringed, which will keep down thrips, the only insect I know that attacks them. Cultivators of these plants will not grow them satisfactorily upon dry shelves, where I have seen them placed in more than one garden. They should stand upon some cool moisture-holding material, such as ashes or gravel. During the summer or growing season plenty of water should be thrown amongst the pots and the atmosphere kept moderately moist. Under such treatment the plants grow rapidly and luxuriantly.—W. BARDNEY.

SHADING CAMELLIAS.—Perhaps the short note I wrote about Camellias was rather loosely constructed. I certainly do not mean to say, as "AN AMATEUR" assumes, that as fine flowers are produced from a plant in feeble health, and which in consequence makes a weakly growth, as from a plant of robust growth and in perfect health. I quite agree with him as regards shading. All our Camellias are shaded, and necessarily so, because they would not thrive in our structures without shade. However, they are to be found thriving in gardens without any shade during summer, consequently it is a question that no one can draw a hard-and-fast line about. Some growers, for instance, manage Orchids without shade. I have tried both plans, and find I can keep the plants healthy with less labour grown under

shade throughout the summer. I have seen Mr. Bardney's Camellias, and I acknowledge they have foliage much more beautiful than my plants have. Such plants must produce fine blooms. At the same time our plants always prove good flower-producers.—R. P. B.

#### OBJECTS OF SEX AND OF ODOUR IN FLOWERS.

[Read by Mr. T. Meehan before the American Association for the Advancement of Science.]

(Continued from page 135.)

BUT perhaps the most remarkable fact of all is that the statement of Dr. Gray, that anemophilous plants have flowers mostly destitute of odour, is probably incorrect. Certainly there is odour in a large number of anemophilous plants. In monoecious and dioecious classes colour or fragrance is usually present in the male flowers, and often both are there, but wanting in the female, unless in flowers with a conspicuous corolla, such as in Cucurbitaceous plants. In these cases the degree of fragrance is equal. But odour to a greater or less degree exists in the Willows, Poplars, Maples, Rhus, Spinach, Indian Corn, Palms, Sweet Chestnut, and others, but always in the male and never in the female flowers. Instead of anemophilous flowers being mostly destitute of odour, I have not been able this year to find any male flowers of this class that have not odour, with the single exception of the common field Sorrel (*Rumex Acetosella*). The Sweet Chestnut (*Castanea americana*) is indeed remarkable for the prodigious amount of odour and other material which, under prevailing notions of individual good, must be regarded as absolute waste, but which comes to be looked on as the height of wisdom under the laws involved in variation. As the branch grows the axillary buds which in many plants remain dormant till spring, and then perhaps make a new branch, push at once and make a spike of male flowers. A bunch of these will fill a room with fragrance. There are about fifty clusters of these flowers in a spike, five flowers in a cluster, five spikes to a branch; and hence twenty-five hundred male flowers, and these all fall before the female flower with its attendant male spike is formed, and which appear at the termination of the growth instead of at the axils. There is no conceivable use for this immense crop of precocious male flowers with its attendant fragrance under any law of reproduction; but if we take into consideration the immense number of minute creatures on the earth, in the atmosphere, in water, everywhere—and the evident design of Nature that they should be fed, we may understand under the laws of variation how even a Chestnut may be made to scatter this food in profusion through the atmosphere, even though not the slightest benefit to itself or to its race should follow the act. Even the views of Professor Huxley that the coal measures of England are the product of pollen which fell during thirty thousand years in the carboniferous era, are explainable under the operation of this law of variation for the purpose of ultimate universal good, but under no theory of individual benefit from natural selection that I can see.

In pursuing our studies of the odours of flowers, we shall find many difficulties in believing that they were developed for the chief reason of attracting insects for the purpose of cross-fertilisation. Not the least of these difficulties is the fact of many genera of showy-coloured flowers existing, which may have one or two species highly odoriferous and the rest destitute of scent. The Violets of Europe are of this class. *Viola odorata* is very sweet, the Pansy less so; the rest are comparatively scentless. American Violets show the same characteristics. I am familiar with many species, but I only know of *Viola primulæfolia* and *Viola blanda*, two nearly allied species, that would be called sweet. Has fragrance given these sweet species any advantage in the struggle for life? If so, it is, at least, not apparent. On the other hand, observation will show that the scentless flowers of this genera are just as freely visited as those which have odour. Of the many species of *Reseda* I only know of one that is fragrant, the common Mignonette. In my garden *Reseda undata*, wholly scentless, is as freely visited by bees as its sweet sister species. Again, it is a fact that among the sweet Mignonettes some are less fertile than others, and that the least productive have the most odour. Another remarkable case in which colour and fragrance in inverse proportion to productiveness is afforded by the genus *Rubus*—the Blackberry and Raspberry class. *Rubus odoratus* is beautiful and fragrant. How rarely its fruits is notorious. *Rubus cuneatus* is not high-coloured, but it is fragrant; not half the flowers produce anything usually, and many of those that do give but a very few carpels. *Rubus canadensis* has very showy white flowers but no odour, and its "berries" are generally more or less defective. *Rubus villosus* is less attractive than the last, and is more perfectly productive. But the most fertile of all the species is *Rubus occidentalis*. I do not know that I ever saw a flower that did not make a perfect fruit, and yet it has no odour, scarcely any petals, and these of such a green shade of white as to be actually inconspicuous. On the ground of variety in which fragrance is to play its part, and which must of necessity permeate all things, we can understand its uses; but we are lost when we attempt to explain such facts as these by any hypothesis that has for its foundation mere individual good.

May we not, then, logically say that sex in Nature is not primarily for reproduction, but to insure variation; that questions which properly come under this law of variation have but a remote relationship to questions of natural selection, but are referable to some external

power governing universal good, with which the individual governed has little but co-operation to do, and which as often tends to the destruction of individuals or races as to their preservation?

#### CHELONE OBLIQUA.

"TURTLE-HEAD" is the fanciful name applied to this plant in North America, and the generic name has a similar origin, both referring to the peculiarly arched upper portion of the corolla. Several *Chelones* are known in gardens, but the one of which a spray is shown in fig. 41 is probably the most generally grown by those who make a speciality of hardy plants. It has no pretensions to be considered a novelty, for it was found in Virginia by a Mr. Clayton more than a century and a half ago, about which time it was sent to England, and it was cultivated by Mr. Miller in 1732. In addition to the undoubted hardiness of the

Fig. 41.—*Chelone obliqua*.

plant, at least in the neighbourhood of the metropolis, it possesses another valuable recommendation—namely, that it produces its bright purplish crimson flowers at the end of summer and in the beginning of autumn when the flowers are becoming scarce and the borders unattractive. Almost any soil or situation suits it, though it thrives most satisfactorily in rich moderately light loam. It can be very readily propagated by dividing the plants, preferably about the present time or a little later, as, if the operation is deferred to spring, results are not always such as might be desired. Increase may also be effected by means of seeds or cuttings.

*C. glabra*, though formerly regarded as a distinct species, is now considered to be merely a variety of the preceding, which it resembles in most of its characters. *C. Lyoni* is also another form of the genus with pretty purplish flowers, and is well worth growing. Several other plants commonly seen under the name

of Chelones are really Pentstemons, to which the former genus is very closely related.

Several specimens of *Chelone obliqua* amongst many other pretty plants were a week since very attractive in Mr. Ware's nursery at Tottenham, and from one of these the spray was obtained from which the accompanying engraving was prepared.

#### THE OLD WEIR, HEREFORD.

I AM sure that many of your readers will regret to hear that this classic home of the Rose is no longer to be connected with the name of the present tenant, Mr. Jowitt. Indeed as a place associated with the queen of flowers it will no longer exist. My good friend leaves it in November; his fine collection will be disposed of, and he himself is seeking a new residence. His long list of triumphs will not be added to so far as the Old Weir is concerned, and the wondrous blooms he has delighted us with will no longer grace our exhibition tables. I am sure that many will regret this, and only hope that in some new spot where he may pitch his tent he may initiate a new collection which shall still bring him to the front. By-the-by, does anyone want a thoroughly good gardener, especially as a Rose-grower? Then I may say Mr. Jowitt's gardener is open to an engagement in November. —D., Deal.

A GENTLEMAN who has facilities for seeing the best examples of fruit culture, writes as follows relative to MR. THOMSON'S VINEYARD AT CLOVENFORDS—"I called at Clovenfords last week. The sight is magnificent. Those great houses that have been described so often in the Journal are this year more grandly furnished than ever they have been, the Vines bearing the heaviest crop they ever had, and every bunch is perfect. I never saw such a sight. The crop of the Duke of Buccleuch is all gathered except a few bunches, and these are very fine, the flavour of the fruit being delicious."

— WE learn that arrangements have been made for discontinuing the practice of charging visitors a penny each "for the gardener" for inspecting the GREAT VINE AT HAMPTON COURT. We observe that the old Vine is showing signs of diminished vitality, and in all probability a good portion of the top of it will die either this year or the next. An endeavour, we believe, will be made to impart fresh vigour to the Vine, and we have little doubt that it might be done, since the fact has been ascertained that a good portion of the feeding roots are not far distant from the house, the popular idea that they are in the Thames having little to support it. By breaking up the ground near the house and using liquid manure and rich compost freely, reducing the crop for a year or two and increasing the foliage, the old Vine, we think, might be improved, and efforts ought certainly to be made to arrest its decay. Mr. Knight, who has for many years had the charge of the Vine and the private gardens at Hampton Court, will shortly retire, and will be succeeded, we understand, by Mr. J. R. Stirling, gardener to H. H. Vivian, Esq., Park Wern, Swansea, he having been nominated for the position by Mr. Jones of Frogmore, who has the chief control of all the Queen's private gardens around Windsor. Mr. Stirling is known to be an excellent gardener and cultivator of fruit, and he is unquestionably competent for the efficient fulfilment of the duties pertaining to his new charge.

— WE regret to hear from MR. BRUCE FINDLAY that he is suffering so much from exhaustion after his great efforts at the International Show at Manchester that he has been compelled to retire from his duties for a short time to recruit his health. This we can easily realise; but we are told that some of the prizetakers

at the Exhibition are impatient for their prize money, and that their importunities penetrate even to Mr. Findlay's well-earned temporary seclusion. Mr. Findlay desires us to announce that at the end of this week or beginning of next they will all be attended to. We are happy to announce, for the information of many who will be glad to hear, that Mrs. Findlay and her daughter "are much better."

— COLBURN'S MAGAZINE (E. W. Allen, Ave Maria Lane) of the present month contains an excellent lithograph portrait of MR. G. F. WILSON, F.R.S., who is so well known and highly respected in horticultural circles. A copious biography of Mr. Wilson also appears in the Magazine, in which his parentage and early life are sketched, his discovery of the distillation of glycerine noticed, his capacity for and success in business chronicled, and his connection with and works in horticulture narrated.

— MR. J. MUIR of Margam has sent us some sprays of CAMELLIAS GROWN WITHOUT SHADE, which are as fine as any cultivator could desire; yet they are not superior to others that have been sent to us which have been grown in partial shade. It is not necessary to publish further letters on this subject at present. We know that Camellias will grow without shade under certain conditions, as we have seen them in the open air in England, and even in Italy; but it is equally certain that under different circumstances judicious shade is beneficial, especially to plants in pots as grown by the majority of amateur cultivators.

— WE are informed that the GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY held their annual Show on the 6th inst., and was on the whole a good show, the cut flowers, Grapes, and plants being abundant. The best produce always goes to Edinburgh, and it altogether appears bad management to have what might be two good shows on the same day.

— A CORRESPONDENT observes, "In most of the London parks the new ALTERNANTHERA PARONYCHOIDES MAJOR AUREA has been used freely this season, and when judiciously employed it is very effective. To my mind, however, a mistake has been made in many instances by placing *Alternanthera amœna* next to it in the carpet bed designs; the two colours do not harmonise, and several otherwise pretty designs are rendered unsatisfactory by this means. In one instance, by an unaccountable piece of bad taste this yellow *Alternanthera* was placed next to a line of Golden Feather, but this was quite an exception. The best mode of employing it that I have seen is where some soft grey or whitish plant is next to it. The silvery *Leucophyton Brownii* or *Sedum acre elegans* are particularly suitable associates."

— "L. D. W." writes, "At Chiswick VILMORIN'S DWARF WHITE ASTER was recently very conspicuous for its dwarf habit and the profusion in which its flowers are produced. This variety is by far the finest white I have yet seen. The flowers individually remind me of Mrs. Geo. Rundle Chrysanthemum; they are pure in colour and of much the same shape as the flowers of that variety. Benary's Dwarf Chrysanthemum Aster was also very striking, the flowers being a very bright crimson."

— "SCIENTIA" writes that "BOUVARDIA JASMINIFLORA FLAVESCENS has flowers of a beautiful straw colour, and is quite distinct from any other variety. The trusses of flower are not large, but the plant is worth growing for the pleasing colour. *Bouvardia Reine des Roses* is also a very desirable variety with rose-coloured flowers, which resemble miniature trusses of *Ixora* blooms. The trusses are large and very freely produced early in the season. Where *Bouvardias* are appreciated these two varieties should be grown, especially the latter."

— VERY noticeable in Covent Garden Market at the present

time is the quantity of SCARLET SIBERIAN CRABS or CHERRY APPLES exposed for sale. These pretty little fruits are the produce of a species of *Pyrus*, *P. baccata*, and are valued by many persons for the pleasant preserve prepared from them. In Siberia, the native country of the tree, a kind of punch is made from them. A dish of well-ripened fruits is a decidedly ornamental addition to the dessert at this season of the year, and the flavour though slightly acid is by no means unpleasant.

— A FRENCH writer, M. Roman, has recently stated that the cultivation of the SOJA HISPIDA has of late years been largely developed in Austria-Hungary, Italy, and parts of France. It is said to grow in any soil, and while the leaves and stems make an excellent fodder for cattle, the beans form a nutritious food for man. When roasted the seeds form an excellent substitute for coffee, and M. Roman thinks that the plant will pay better than the Potato. At present the retail price of the Soja Beans is 6*l.* per lb., but as the plant becomes more extensively cultivated they will no doubt be reduced in price.

— A MONTHLY MEETING OF THE SCOTTISH HORTICULTURAL ASSOCIATION was held on Tuesday evening the 6th inst. in St. Andrew's Hall, Edinburgh. A paper was read from an Australian gentleman on the culture of florist flowers; and Mr. Priest, Newbattle Abbey Gardens, read a paper on the colouring of Grapes, his opinion being that the more equable and uniform the temperature the better would the fruit be in colour and quality. The insufficient ventilation of hothouses came in for a share of the blame in the discussion which followed; while the nature of the soil, it was pointed out, had a very great effect indeed, some Grapes thriving on a given soil where others could not be induced to flourish.

— THE correspondent of a daily contemporary describing the Electrical Exhibition in Paris, thus refers to the INFLUENCE OF ELECTRICITY ON PLANTS—"Flowers appear to be in sympathy with Queen Electricity. The tall Palms and tropical Ferns look to peculiar advantage when she is holding her court at the Palais de l'Industrie at night. There is a greenhouse of black glass into which no solar ray penetrates. Electricity stimulates the vitality of plants there and brings them to bloom and bear flowers. They are in a thoroughly healthy condition, and do not appear as if they ever wanted to go to sleep at night. All the twenty-four hours they are exposed to the rays of strong electrical lamps. It would appear that to some extent the chemical action of this light will enable gardeners to dispense with manure. In another example the light is produced in elegant vases suspended from the ceiling at a height of about 8 feet above the floor, and out of which beautiful plants are growing, made doubly luxuriant by the powerful properties of the light. The light being thus concealed in the midst of the vase does not reach the eye directly, but is reflected to a white tightly stretched circular sheet in the ceiling, from which it diffuses a mild and yet powerful light through the whole room."

— AN excellent herbaceous plant flowering in August and September is *ACHILLEA RIGIDA*; the flower stems rise to about 5 feet in height, and its large flat flower heads at the top are from 3 to 6 inches in diameter. The flowers are golden yellow, and the plant thrives in ordinary garden soil.

— A CORRESPONDENT, "W. M. S.," will be obliged if any of our readers can give a good receipt for PRESERVING MELONS in an early issue of the Journal.

— WE are informed that the AUTUMN EXHIBITION held by the Royal Horticultural Society of Ireland last week proved very satisfactory, plants, cut flowers, fruit, and vegetables being well represented. In the plant classes some of the principal prize-takers were the Rev. F. Tymons, Mr. Smith of the Vice-Regal

Gardens, and Messrs. Westby, Wilson, Vaughan, and Watson. Cut flowers were contributed by Messrs. Dickson of Newtownards in fine condition, Messrs. Rodger, McClelland & Co., Newry, staging a fine group of new and rare plants. Grapes were especially good in the fruit classes.

— THE September issue of the *Gardener* gives the following particulars of the LARGE VINE AT SPEDDOCK, DUMFRIESSHIRE. "At Speddock, near Dumfries, there is a very remarkable specimen of the Black Hamburg Vine. It is distinguished for its size, but not more so than for the splendid Grapes it bears annually. As far as we are aware it has no equal in this country, if its size and the quality of its produce are considered. The Vine at Hampton Court, as well as those at Cumberland Lodge and Finchley, are all larger; but the produce of these is not so fine as the Speddock Vine. This Vine is about eighty years old, and until a few years ago it occupied a much smaller vinery than the one it has now nearly filled, and which is something over 60 feet long and 20 feet wide, with a lofty back wall, and consequently a long rafter. The Vine is planted at the extreme east end of the house, so that its growth is entirely to the west. Last year it bore 600 lbs. of Grapes of superb quality both as to size and finish. This year it has fully 700 lbs., every bunch from end to end and top to bottom being a model one; and while some are quite 3 lbs. weight, they will average at least 2 lbs. each. They are large in berry, conical in shape, and jet black. Mr. Smith, who manages all his Vines in four vineries with great care and skill, wings all the bunches, so that they are all remarkably uniform in shape. This grand Vine is in a most vigorous condition, and if the vinery were added to 60 feet to the east, it would soon fill it all; but the nature of the ground prevents extension in that direction. The border is liberally manured annually."

— THE following GARDENING APPOINTMENTS have been recently made—Mr. S. Burge, recently gardener to Col. Calvert, Ockley Court, Dorking, is now gardener to D. Davidson, Esq., Somerset Lodge, Wimbledon Common; Mr. J. Robinson, late gardener to Baron de Worms, Milton Park, Egham, succeeds Mr. Pierce as gardener to the Dowager Lady Howard de Walden, The Mote Park, Maidstone; Mr. James Jordan, late foreman at Oakfield, Wimbledon Park, has been appointed gardener to J. Moray Brown, Esq., Florian, Torquay; and Mr. J. Gadd, late of Thorndon Hall, has been appointed gardener to Sir T. Barrett Lennard, Bart., Belhus Park, Aveley.

#### ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 13TH.

ONE of the best meetings that has been held for some time was that of Tuesday last, when numerous members of both Committees attended, and the exhibits in each department were sufficiently numerous to keep them well employed for an hour or more. Dahlias were, however, the great feature of the Meeting, and better representative collections have rarely been seen. The Council-room and vestibule were fully occupied, the numerous bright and varied flowers affording a pleasing and attractive display that has not been exceeded at some exhibitions held this year.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Mr. G. Hawkins, gardener to Col. Turbervill, Ewenny Priory, Bridgend, Wales, was awarded a cultural commendation for some dishes of fine fruits gathered from trees in pots. Beurré Hardy Pears were good, said to be from a tree with four dozen fruits. Coe's Golden Drop and Reine Claude de Bavay Plums were both finely ripened, the former from a tree with six dozen, the latter from one with nine dozen fruits, both in cold houses. Lord Palmerston Peaches were also large. Messrs. G. Bunyard & Son, Maidstone, were accorded a vote of thanks for the following fruits—Frogmore Prolific Damson, a small black variety, comparatively sweet. Worcester Pearmain Apples were very notable for their even shape, good size, and bright colour, and it was stated that they were gathered from trees two years old in the nursery rows. The same was stated of some Grenadier and Ecklinville Apples, both fine. A vote of thanks was also accorded to Messrs. J. Veitch & Sons, Chelsea, for fruits of three varieties of Raspberry Belle de Fontenay, October Red, and October Yellow. A similar recognition was accorded to Mr. Gilbert, The Gardens,

Burghley, for an example of his Netted Victory Melon, fairly well netted and of excellent flavour, the Committee expressing a high opinion of the variety, and desiring to see the fruit again. Some Cucumbers were also shown by Mr. Gilbert. Messrs. T. Rivers and Son, Sawbridgeworth, had a collection of Apples, Peaches, and Nectarines, and were awarded a vote of thanks. Mr. R. Dean, Ealing, had a collection of Apples, which was accorded a similar acknowledgment. Mr. Burnett, The Gardens, Deepdene, Dorking, sent some fine examples of the Red Astrachan Apple. Mr. Hughes, gardener to Colonel Cartwright, Eydon Hall, Byfield, sent several examples of Beet, but were not considered sufficiently distinct from those already in cultivation. Mr. T. Laxton, Bedford, sent pods of his new Runner Bean, very long and broad. Mr. W. H. Brown, Uppingham, exhibited some Red Shallots, and for comparison some Mammoth Russian Shallots, which were much larger than the former. Mr. George Ockenden, Cuckfield, staged fruits of a new Fig called Ockenden Seedling, of good size, and dark purplish in colour. The Committee expressed a desire to see it again. Mr. Wilson, gardener to the Duke of Norfolk, Arundel Castle, sent a large multiple crown of a Pine Apple, comprising some dozens of small ones closely packed in a globular mass. Messrs. Cheal & Son, Crawley, sent several Apples and Melons, but not of special merit.

Messrs. W. Paul & Son, Waltham Cross, were awarded a silver Banksian medal for a collection of Apples and Pears, comprising 120 dishes of the former and eighty of the latter, together with several examples of ornamental Crataeguses and Pyruses.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair.—Mr. Charles Turner, Slough, had a remarkably handsome collection of Dahlias, occupying considerable space in the vestibule. All the bedding, Pompones, and single forms were arranged in clusters in boxes of moss, and thus had not the formal appearance of the Show varieties on the flat trays. Of the Pompones varieties the best were Lady Blanche, white; Dora, very light yellow; Prince of Lilliputians, deep crimson or maroon; Fireball, scarlet; North Light, scarlet and rose; Perfection, bright purple. Among the fancy varieties the following were noteworthy—Mrs. Sanders, very large, yellow tipped with white; Peacock, crimson, tipped white; Annie Pritchard, very large, white streaked with purple; and Grand Sultan, yellow streaked with crimson. The most striking Show varieties were John Laing, bright scarlet, good form; Canary, rich yellow; Pioneer, deep maroon, nearly black; Annie Neville, white; Prince Bismarck, rich purple; Emily Edward, blush white, brown florets; Robert Burns, maroon, good. A medal was recommended for this collection.

Messrs. H. Cannell & Son also had an extensive collection of Dahlias, representing all the sections—single, Pompones, Show, and Fancy varieties. Of the single varieties Alba, a large pure white flower, Brightness, orange-scarlet, The Star, deep orange, and Paragon were the most noteworthy. In the Pompones White Aster, Barcelona, deep crimson, Voltaire, and Sensation, yellow, were the best. Of the very numerous Show and Fancy forms it is almost impossible to make a selection, as nearly all the best in commerce were admirably represented. A medal was also deservedly recommended for this collection. Mr. J. T. Riches, Tooting, sent a collection of pretty and choice hardy plants, among which were the early-flowering Chrysanthemums Scarlet Gem, dark red, Jardin des Plantes, yellow, Précocité, yellow, and Nanum, white. Several Pentstemons were notable, Robert White, with large bright red flower and a white throat, being one of the best. Among other plants were Solidago virgaurea, bright yellow; Arum pannonicum, with purplish Thistle-like heads; Campanula lactiflora cœrulea, Dracocephalum canescens, and Rudbeckia Newmanni. A vote of thanks was accorded to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, for a large and beautiful collection of single Dahlias. The most noteworthy variety was White Queen, flower head large and of good form, the outer florets pure white, broad, and rounded. Among many others the following were especially good—lutea grandiflora, pale clear yellow, large and symmetrical; Yellow Queen, very neat and bright; gracilis perfecta, deep rich scarlet; Paragon, and a sport from it entirely deep maroon without the lighter bands; glabrata, the light and graceful form with mauve-coloured flowers; Beauty of Cambridge, deep red with a slight purple tint, very distinct and fine. Mr. Temple, gardener to J. Donaldson, Esq., Chiswick, sent about two dozen plants of a brightly coloured Amaranthus. The leaves were richly marked with yellow, crimson maroon, and green in about equal transverse bands. The young leaves were particularly fine. Mr. H. Eckford, The Gardens, Sandywell Park, Cheltenham, sent a group of seedling Coleuses, several bright and pretty, but not considered sufficiently distinct to merit the award of certificates. He also sent some seedling Pansies and Dahlias. Mr. John Fraser, Lea Bridge Road Nursery, Leyton, sent a handsome specimen of *Ixora venusta*, about 4 feet high, and bearing abundant trusses of bright orange-scarlet flowers. Some small plants of *Ixora regina* were also shown, and certificate was awarded for it. It is described below. Messrs. Jones & North, Lewisham, sent several seedling Fuchsias, but not marked by special excellence. Messrs. J. Carter & Co., High Holborn, exhibited two new Crotons, one named Bealii, with neat leaves, bright yellow in the centre and green margins. The other was named Dunnetti; the leaves were veined freely with yellow. Plants of *Gaetonia candicans* were also shown.

A vote of thanks was accorded to Mr. B. S. Williams, Upper Holloway, for plants of *Stephanotis multiflorus* flowering very freely.

They were in 60-size pots, and were each bearing one or two trusses of flowers. A vote of thanks was accorded to Mr. R. Dean, Ealing, for a plant of the new dwarf French striped Marigold, compact in habit and very free. Some fine African Marigolds were also shown. Messrs. Wm. Paul & Son, Waltham Cross, sent six boxes of Roses in excellent condition for the season. Beauty of Waltham, La France, Souvenir de la Malmaison, Alfred Colomb, and A. K. Williams were particularly fine. Messrs. Watson & Son, Islington, were accorded a vote of thanks for a group of early-flowering Chrysanthemums. Souvenir d'un Ami, pure white, was one of the best. From the Society's garden a large and handsome group of plants was exhibited, comprising Gomphrenas, Celosias, Begonias, Bouvardias, and Torenias. The neat Capsicum Little Gem was especially noteworthy for the dwarfness of its habit and the number of small bright scarlet fruits it bore. The Scabious in pots were also very bright and flowering well. A handsome specimen of *Begonia Martiana* was shown with growths 3 or 4 feet high thickly studded with bright rosy flowers, and some dwarf Cockscombs were exhibited with fine compact bright crimson heads. The variety was one of Vilmorin's, and is named President Thiers. Four boxes of Dahlias were contributed, chiefly Pompones, representing a large number of varieties from English and continental growers.

Messrs. Heath & Son, Cheltenham, sent an Orchid said to be from Central India, with peculiar white flowers, the lip being deeply cut into narrow divisions. It was a terrestrial species somewhat in the style of a *Disa*, but the flowers were furnished with a spur. It was determined by Mr. Croucher to be *Bonatea speciosa*, a Cape Orchid. Mr. J. McDonald of Chichester exhibited fruits of his Golden Crab, said to be the result of a cross between *Pyrus floribunda* and the common yellow Crab. The fruits were of a very bright yellow colour. A vote of thanks was awarded.

First-class certificates were awarded for the following plants—

*Sarracena Courtii* (Veitch).—A very pretty and neat hybrid between *S. psittacina* and *S. purpurea*. The pitchers are deep red in colour and form close rosettes 4 to 5 inches across, in some instances there being a dozen pitchers. It is a curious and attractive form, evidently intermediate between the parents named above, partaking largely of the *S. psittacina* habit.

*Adiantum Oweni*.—This, which is said to be a hybrid between *A. amabile* and *A. cuneatum*, was shown by Mr. Owen of Yewdon, Henley-on-Thames. It has large fronds, and is graceful in habit; the general form of the pinnules and appearance of the plant justifying the recorded parentage.

*Ixora regina* (Fraser).—A variety which is chiefly remarkable for the dwarfness of its habit and its floriferousness. Some plants in 48 and 32-size pots were 12 to 18 inches in height, bearing from three to six close trusses of bright orange or salmon-tinted flowers.

*Pelargonium Miller's Mrs. Miller* (Laing).—A silver-edged tricolor variety of great beauty; the leaves being of neatly rounded form, the centre green with concentric bands of maroon, crimson, and white. It appears to colour remarkably well, and is of good dwarf habit, yet free in growth. We understand that the variety was raised by a gentleman at Ramsgate, who has had it bedded out, in which way it colours extremely well.

*Pellionia Daveana* (Bull).—A neat and pretty plant of trailing habit, with ovate leaves 1½ inch long, oblique at the base, light green or silvery in the centre, and with broad dark green margins.

*Euonymus latifolius* (Veitch and W. Paul).—Similar to the well-known *Euonymus europæus*, having fruits of a bright red colour produced in large numbers, and when fully ripe they open, exposing the bright yellow seeds, the effect of the contrast being most striking.

*Pitcairnia Jacksoni* (Royal Horticultural Society).—One of the Bromeliads, with narrow tapering dark green leaves half an inch in width; the flowers being bright scarlet, 3 inches long, in a raceme 9 or 10 inches long.

*Capsicum Little Gem* (Royal Horticultural Society).—This is one of Mr. B. S. Williams' novelties for the forthcoming season, and appears likely to be a general favourite for decorative purposes. The plants are dwarf and compact in habit, scarcely exceeding 9 inches in height, and in small 48-pots make pretty little specimens. The plants shown had abundance of small ovoid or globular fruits, bright scarlet in colour.

*Dahlia Pioneer* (Turner).—A Show variety, with blooms of good size and form, of an intense deep maroon colour, velvety, and nearly black. It is one of the darkest varieties we have seen, and in substance and form is well worthy of the firm that exhibited it.

*Dahlia Miss Batchelor* (Keynes).—Also a Show variety, the flowers being of moderate size but exquisite in shape and substance, finely rounded in outline, and with no approach to flatness in the centre. The colour is a brilliant scarlet.

*Dahlia George Rawlings* (Rawlings).—Another Show variety, globular in form, large, 5 inches in diameter; deep maroon, nearly black in the centre of the florets, but shading to a deep rich crimson at the margin. It is a handsome massive bloom.

MULE PINKS.—A gentleman sent me a letter through your office offering me cuttings of Mule Pinks. When I essayed to write him to accept his kind offer his note was not to be found, and I have forgotten the address of the writer. It was Cambridge

I know, but do not recollect either name or street. Can you help in any way?—R. P. BROTHERSTON.

MR. CHARLES LEE.

LAST week it was our melancholy duty to announce the death of this gentleman, whose portrait we now submit as that of a kind and genial man, an earnest and skilful horticulturist, and for the last four years the head of one of the oldest and most important nursery firms in this country. Mr. Charles Lee was, however, a

partner in the firm for fifty years previous to the retirement of his brother, Mr. John Lee, in 1877, so that his term of labour has been long, as it has admittedly been honourable; but that of his brother, who we are glad to say is alive and well, was still longer, for he had been engaged in the business for fifty-six years at the time of his retirement above mentioned.

The portrait of Mr. James Lee, the founder of the Hammersmith Nursery, where Mr. Charles Lee was born on February 8th, 1808, appears in vol. xxxii. of this Journal, page 65, January 25th, 1877. As is there stated he was born in Scotland in 1715, and was for

Fig. 42.—MR. CHARLES LEE.

some time under Philip Miller at the Chelsea Garden, and afterwards gardener to the Duke of Argyle at Whitton, Middlesex, who was a great importer of exotic trees, and for that reason only invidiously nicknamed by Walpole "a tree-monger." In conjunction with Kennedy, then gardener to Lord Bolton at Chiswick, Lee commenced the business of a nurseryman at the Vineyard, Hammersmith. He was patronised by a great many of the nobility and gentry, to whom he became known by his extensive knowledge of natural history; and his garden became particularly rich in plants from the extensive correspondence he kept up with Linnæus and other contemporary botanists. He died August 25th,

1795; and after an interval of a few years his son, Mr. James Lee, became the sole proprietor, and died in 1824. It was stated last week that Mr. Charles Lee was the representative of the fourth generation of Lees as conductors of the nursery; what was meant was that the firm was first Lee & Kennedy, next Mr. James Lee, then John & Charles Lee, and last, Charles Lee & Son—the son, Mr. Wm. Lee, at present occupying his lamented father's position.

The Hammersmith Nursery is not what it once was, although it is still the head-quarters of the business. The irresistible growth of London has effected a marvellous change, and the Addison Road railway station, Kensington, now occupies a portion of

the grounds of the Royal Vineyard establishment; but the loss of this ground is most fully compensated for by the important branch establishments at Isieworth, the propagating ground for choice Conifers under the care of Mr. Marslen; the arboretum, which almost adjoins, where Mr. Webb has charge of the fine collection of ornamental deciduous trees; at Feltham, where Mr. Dixon manages the evergreen and Conifer department; and at Ealing, where fruit trees, Roses, &c., are grown by Mr. Cannon.

It was over this great business that Mr. Charles Lee so ably presided until the time of his lamentably sudden death. He married a second time only a few years ago, and leaves a widow and two young children to mourn his loss and receive the sympathy of a host of friends.

#### THE HYACINTH.

HAVING on page 248, last vol., described the method of cultivation adopted in Holland I will now refer to the system pursued in England, first noting their culture in glasses. Under this system Hyacinths will be most likely to find favour with those who cultivate them in dwelling-houses, in consequence of their presenting a more ornamental appearance, taking up less space, and requiring less attention than when grown in pots. Having prepared the glasses by well washing them, nearly fill them with clear soft water, in which place one or two small pieces of charcoal; this keeps the water pure for a long time and is beneficial to the plant; place a bulb in each glass and fill up with water until it almost touches the base, then place the glass in a cool dark room or cellar in any airy situation, the object being to encourage root-action, which is more rapid than when exposed to the influence of light. In about a fortnight most of the bulbs will emit a number of roots, which, if the bulb is a good one, will be in an unbroken circle round the outside of the base. They should be allowed to remain until the roots have almost reached the bottom of the glasses and the flower spikes are about an inch in length, when they must be removed to the light, which should be subdued for the first change; afterwards bring them gradually into full daylight, when the spikes will change from a pale yellow to a green colour, increasing in depth. At this period they must be placed in a window as near the glass as possible, in order that they make a healthy growth.

When the bulbs have been started a week or two examine the water to see if it is pure and sweet, also take out the bulbs one by one and carefully remove off the brown shiny substance that will be found in the inner circle of the rootlets; this, if permitted to remain, is often the cause of the water becoming turbid. Care must be taken in doing this not to injure the young roots, which are very brittle. Change the water whenever it becomes in the least impure. As the roots descend they must be watched, as a whitish film occasionally forms upon the ends. This, if permitted to remain, will turn them black and destroy the tip; it is easily remedied by taking the bulb out of the glass, holding it in the left hand with the roots in a bowl of water, and carefully drawing them through the fingers of the right hand. I have found the film form much more frequently when charcoal is not placed in the water. For some time after the plants are brought to the light they should have the coolest and most airy situation that can be given them, but they must not be allowed to remain in any heated atmosphere until the flower spike is well advanced, when they may be hastened into bloom by being kept for a few days or a week in a room where there is a fire; care must, however, be taken to avoid their being unduly drawn and weakened. As soon as the flowers are well open they are best in a cool temperature, and by attending to this rule they may be kept fresh, and will last double the length of time that they would if permitted to remain in a heated room. As the flower spikes advance keep turning the glasses round, so that each part of the plant is equally exposed to light. Many will require supports, as, the roots having nothing to hold to, the plant soon becomes top-heavy, and the flower spikes would frequently break if not properly supported.

In growing Hyacinths in pots I prefer a mellow loam enriched with well-decayed manure from an old hotbed rendered porous by an addition of sharp sand, say loam three parts and manure one part, well mixed together. If not easily procurable I do not hesitate to use the best compost I have at command, not being very particular in this respect, although I would always advise the use of good loam. As I can produce almost as good blooms in water as in soil, I am convinced that it is not so much the quality of the soil we employ as the previous treatment we have to depend upon for the desired result. The embryo bloom being properly developed in the bulbs before we obtain them, their after treatment differs materially from that which must be pursued in order to produce similar results in floriculture generally.

Having prepared the soil, take some clean 5-inch pots, the deeper the better; place not less than an inch of crocks or charcoal broken to the size of hazel nuts for drainage; then fill up with the coarse part of the soil to within about an inch of the rim, shake it down by knocking the pot upon the potting bench, sprinkle a little sand on the surface, place the bulb in the centre, press it gently down, and nearly cover it with the finer portions of the soil. A little care is necessary, for if the soil is too firm the bulb will rise out of its place as the roots are emitted, and if too loose the roots are liable to injury by the soil frequently becoming dry. When the whole batch is potted give a slight watering, which consolidates the soil and fixes the bulbs. Many growers do not advise watering at this stage, but I have always found it beneficial. Those who have the convenience should place the pots upon a bed of ashes, covering with not less than 6 inches depth of cocoa-nut refuse, fine charcoal, or ashes, sloped to throw off the rain. I prefer the former, which being light does not easily injure the spikes, but if used it should be pressed carefully down to make it rather firm. Those who have not the convenience for plunging the pots out of doors may place them in a packing box and cover with either of the above materials, or they may invert a small flower pot over each bulb in lieu of plunging, and place them in a cool dark cellar or outhouse, which answers the purpose equally well. No further care is needed for some time. In about two months the bulbs will produce plenty of roots, and the pots should be cleansed, and plants gradually brought to the light. The after treatment should also be the same as for those in glasses, except that liquid manure or soot dissolved in water may be given occasionally with advantage, as the flower spikes advance and begin to show colour. Attention must be given to the soil, which should never be allowed to become very dry, or the roots will shrink and be injured. In watering take care that sufficient is given to moisten the whole.

It must be borne in mind that Hyacinths cannot be cultivated so successfully in dwelling-houses as in greenhouses, no matter what care and attention you may bestow upon them; still I know no plant that can be so well grown in rooms, and that will adapt itself to circumstances as it does. Amateurs who possess a greenhouse may follow the treatment described but with better results.

Hyacinths grown in rooms frequently become very dusty, when the leaves must be sponged or given a gentle watering overhead with a can with the rose on; this is often very beneficial, as it softens the outer coating of the bulbs which the dry air renders hard, particularly round the collar of the spike. When the flower buds are about to open this process must be discontinued. In all cases avoid extreme temperatures and sudden changes, and bear in mind that, as a rule, the longer the period of growth the better the blooms.

The Hyacinth being a hardy plant will bear much frost without injury, though it is not desirable that it should become frozen; if, however, the water in the glasses be frozen during severe weather, with care in thawing little or no damage will result. I have had the water frozen solid and the glasses broken, in which case I took the plants with the ice firmly attached to the roots and placed them in water a few degrees above the freezing point, and allowed them to remain until sufficiently thawed to be able to remove them without breaking any of the roots, afterwards I placed them in the coldest water I could procure, and kept them very cool for a few days, when they grew and bloomed as usual and did not appear to have sustained any injury.

October is the best month for starting them into growth, but this may be deferred until December. I would not, however, recommend this being done later than the middle of November, as some of the earlier sorts will begin to push up the spikes, and when this has taken place they do not root so freely, consequently the blooms are not so good, and disappointment is occasionally experienced from this circumstance. For forcing and for glasses the single varieties are the best, although some of the double varieties succeed very well in glasses. For pot culture all varieties are suitable.

In conclusion I would remind all who may be desirous of cultivating the Hyacinth of the danger of attempting to follow implicitly any instructions they may receive without first considering their requirements and facilities, which vary so much that it is impossible for the most elaborate and exhaustive treatise to meet every case. A little sound judgment coupled with care and attention is all that is needed to become a successful cultivator.—  
JOHN HAIGH.—(*Read before the Sheffield Horticultural Society.*)

THE CYPRESS GROVES OF MEXICO.—A writer in an American journal describes these as follows:—"There are in the park probably not less than a thousand fine Cypress trees, whose

planting by the Toltecs (Nephites) antedates, perhaps, many centuries the rise of the Aztec empire. Some of these are nearly 50 feet in circumference, and from 100 to 125 feet in height, with huge limbs extending all round to a great distance, and being always clad with dry, bronzed, and fresh green leaves, mingling with drooping silvery Mosses, form the most enchanting bowers imaginable. The arrangement of these trees is in groves and double rows, sometimes crossing at right angles and affording splendidly shaded narrow avenues. An exceedingly fine spring of pure water gushes from the rocks of the south side of the hill. Three hundred and seventy years ago the waters of this spring were conveyed by the Aztecs to the city through an aqueduct of masonry constructed for the purpose. A portion is now forced with a steam pump for use in the gardens of the palace above, while the remainder still flows to the capital."

#### WHAT PLANTS USE.

(Continued from page 183.)

HAVING made a few remarks on the gases used by plants, we will now turn our attention to the mineral matters which they require, and which are found in the soil only.

When wood is thoroughly burnt there is always left behind an ash which will not burn. This ash is wholly mineral, and is as absolutely necessary to the plant's growth as are light and air. The elements, which may be present in small quantity only, are as necessary as are those which are present in much greater quantity. For instance, potash is present in the ash of Asparagus to the extent of only six per cent., while soda bulks as largely as thirty-four. Still we cannot say that soda is of more importance to the Asparagus plant than potash, for it will no more thrive without a due proportion of the latter than it will without the former. At the same time, a soil rather poor in potash, but with eight times more soda, will afford sufficient of both of these compounds. In the case of the Potato the case is quite different. Potash is present in the ash of Potatoes to the extent of fifty per cent., while soda seldom amounts to one per cent. Even the tyro will understand that a soil may be very suitable for Potatoes and yet fail to grow Asparagus, and *vice versa*. He will also understand that in ordinary soils Potatoes will make a heavy demand on the potash, and the Asparagus on the soda. He would also conclude that potash salt must be good for Potatoes, and soda for Asparagus, and would probably end by sprinkling kainit on his Potato plots and salt among his Asparagus. This is a common practice, and chemical science has shown how it is that salt is so appreciated by Asparagus. This much to enable the uninstructed reader to understand what follows.

Many elements enter into plants by the roots and are necessary to plants. These elements are chiefly in the form of compounds. We have already mentioned potash. Now potash is not an element, it is "hydroxide of the metallic element potassium." Again, soda is also a compound, and common salt a still more complicated one, in which the metallic element sodium and the gaseous one chlorine play important parts. We shall mention many others, but every one are compounds of elements. We will take each compound as they are generally placed in analytical tables. By the time we are done we hope our readers, who have hitherto given no attention to the subject, will understand the value of the tables which appear from time to time in the Journal and other publications.

*Potash.*—This is present in the ash of Potatoes to the extent of from forty-five to over sixty per cent., according to the soil and the variety. Many other plants contain large quantities, while others contain very little. Speaking generally, it is a good plan to insert plants which require only a small amount of any given mineral compound which may have been demanded in large quantities by the previous one grown on the same soil. Rotation of crops on this basis is proper and profitable; as generally carried out it means nothing and does not secure the end aimed at.

Potatoes may find enough of potash in the soil on which they are planted, or in the manure which is added, to bring one crop or more to perfection, and yet exhaust the soil of potash to an extent that would make Potato-growing unprofitable on that particular position until potash had again collected in the soil, either by its free application, by chemical manure, or in the ordinary way, being left there by other crops which do not require it, and therefore only take other matters from the freshly applied manure, leaving the potash. As a rule, plants which have a large percentage of potash in their ash have little soda, and *vice versa*. It seems that the soda takes the place in one plant that potash does in another. Both are alkalies: both have many properties in common, yet the one cannot replace the other in the economy of any given plant except in rare cases. We have therefore potash

plants and soda plants. Soda plants, as we have called them, affect the seaside. Plants which affect inland districts generally contain potash instead. This rule is, however, by no means absolute. Here is a list of commonly cultivated garden plants which contain potash in large proportion, and therefore demand it in the soil. Potatoes, 45 to 50 per cent.; Potato tops, 23; Apples (fruit), 35; Artichoke (Jerusalem), 44½; Broccoli (leaves), 22; (heart), 47; Beetroot, 39; Beet tops, 21; Beans (common), from 27 to 38; (kidney), 35; (runners), 49; Cherries, 51; Cabbage, 34; Cauliflower, 34; Celery, potash 22, and chloride of potassium, 33; Cucumber, 47; Endive, 37½; Gooseberries, 38½; Plums, 59; Grapes, 70; Vines (Grape), 34; Lettuce, 46; Leeks, 33; Onions, 39; Pears, 54; Pine Apple, 49; Peas, 36; Rhubarb stalk, 59½; Strawberries, 21; Turnips (Swede), 33.

The foregoing list of plants and fruits contain soda in their ash in much less quantity—sometimes only mere traces—and seldom more than 8 per cent. The exceptions are when the potash is present in less quantities than 40 per cent. The more soda the less potash, and *vice versa*. For instance, Apple ash contains 35 per cent. of potash and 26 of soda. Artichokes contain 44 of potash and only traces of soda. Kidney Beans 36 of potash, and 18 of soda; while Grapes, which have only 3 per cent. of soda in their ash, have as much as 70 of potash.

The following plants contain more soda than potash. Asparagus 34, and also 12 of common salt. Strawberries 27. (In Strawberries potash and soda are nearly equal: they contain 21 of the former.) Spinach 34, and 8 of common salt; Poppy 33; Corncockle, 22. Occasionally lime takes the place of both potash and soda, but it is generally in the parts of fruit or vegetables or grain-producing plants which are not used for food that lime is thus largely present. The parts which are used generally contain most potash. Thus Apples contain 35 per cent. of potash in their ash and only 4 of lime. Apple wood contains 63 per cent. of lime in its ash and only 19 of potash. Potatoes contain, off and on, about 50 per cent. of potash in their ash and only one of lime. The haulm contains 23 per cent. of potash in its ash, and as much as 43 of carbonate of lime.—(Liebig). Peas contain 36 of potash and only 10 of lime, while the haulm contains only 4 per cent. of potash and 47 of lime. We might enumerate many more cases, but this would only take up space. It is a rule, however, which is very uniform. Nourishing matter in vegetables, fruits, or grains has always a large proportion of potash and phosphoric acid associated or bound up with it. Mere woody fibre, or useless (for food) tops of any kind, have a greater amount of lime and less potash. This rule holds so good that one may say that the nature of mineral food required by any plant may be ascertained by the use for food or otherwise the plant is to animals.

*Phosphoric Acid.*—This is one of the principal compounds which plants use, and which is largely present in the ash of all plants cultivated for food. We append a list of plants and fruits with the per-centage of phosphoric acid found in their ash. Apple, 12; Asparagus, 18; Artichoke, 10; Broccoli, 24; Beans (common), 35; (French), 26; Cabbage, 12; Celery, 11; Gooseberries, 14; Grapes, 20; Onion, 20; Pears, 14; Peas, 31; Potatoes, 11 to 15; Rhubarb, 15 to 20; Radishes, 40; Strawberries, 8½; Spinach, 7¾. What we have called soda plants contain a less amount of phosphoric acid than potash plants, and less animal nourishment.

In addition to the above plants require sulphur (which is generally present in the form of sulphuric acid in combination with some of the alkalies), magnesia, silica, and iron, which are present in very considerable quantities in most of our cultivated plants, but not to the extent of what have been called the more important compounds. Still they are necessary, and no soil can be fertile, or manure perfect without them.

There are others which we have not even named. They are still less important: some of them are not considered necessary at all, but even when found in plant ash to be only accidentally present. To enumerate them all in a very elementary article like this would be out of place.—SINGLE-HANDED.

(To be continued.)

#### CANWELL HALL,

THE SEAT OF A. B. FOSTER, ESQ.

THIS is situated near the Tamworth and Birmingham Road, midway between the former place and Sutton Coldfield. The Hall is approached by two carriage drives, one from the Lichfield and the other from the Tamworth Road, at each of which entrances commodious and elegant lodges have been recently built.

Entering by the Tamworth lodge we do not proceed far along the well-kept carriage drive, which is nearly a mile long, before the eye is arrested by the charm and variety of the scenery. Looking to the right the landscape is really beautiful. Hill and

dale, grand old trees, many bushes of Hawthorn dotted about (which must look fine in spring when in bloom), golden corn and grass of emerald green, combine to make up a picture not easily forgotten. In the distance a glimpse can be had of Drayton Manor, the seat of Sir Robert Peel, Bart., and which, horticulturally speaking, is one of the finest country seats in the kingdom, and is entirely the creation of the present popular baronet. Winding our way slowly onwards we pass some old giant Ash and other trees, many of them measuring from 17 to 20 feet round the stem and from 70 to 100 feet in height: they must be many centuries old. As we approach the Hall it is impossible to pass by the noble-looking old clump of trees planted in the valley below without a note of admiration and praise. In looking at them a doubt arises in the mind whether the gardening, like the architecture of antiquity, was not more noble and grand in its conception and execution than that of modern times. It may be considered presumptuous to criticise a work so old and so grand as the planting of these fine groups of trees; but the effect to my mind would have been better had the old gardener fringed the skirts of these groups with an occasional Scotch Fir, so as to brighten with its silvery glaucousness the too sombre and heavy colour of the deciduous trees. A short way before reaching the Hall a walk to the left leads to the kitchen garden. In passing I noticed some new plantations in which many of the recently planted trees had succumbed, as in many other places, to the unusually cold dry spring we have this year experienced; but the gardener, Mr. Morewood, who seems to possess the happy knack of making the best of difficulties, had planted the ground with Scotch Champion Potato, which no doubt, in a measure at least, will compensate for the loss of the trees. Following the same way, and passing by the garden offices, &c., we come to the gardener's house, which is roomy, comfortable, and light, and forms part of a fine new block of buildings consisting of stables, coach houses, &c., and which is close to the kitchen garden. Finding Mr. Morewood at home I was first shown into the kitchen garden, three acres of which are enclosed by high and substantial walls, with a central one dividing the garden into two.

Entering at the higher end of the garden the glass houses, which are numerous and in excellent condition, many of them being new, are arranged right and left conveniently together, no doubt with the object of economising labour and to facilitate work. Immediately before us in the centre of the garden was a walk leading to the lower end flanked on either side by a flower border, which was gay at the time of my visit with herbaceous and other interesting plants. The vegetable quarters were bearing heavy crops of all seasonable fruit and vegetables, this being the season that the demand is heaviest at Canwell. I was particularly pleased to find on a north border some Gooseberry and Currant trees loaded with fruit; they were carefully netted, and no doubt will afford a good supply well on into October. It is seldom also we see a finer wall of Peach and Nectarine trees than the central wall of this garden, furnished as it is with grand young trees in vigorous health, and showing careful and intelligent culture. Many of the trees are bearing good crops, but I doubt very much if the fruit will ripen without we have much warmer and better weather than we have been having lately. They certainly deserve a covering of glass. The kitchen garden proper is surrounded by another vegetable garden of about three acres, where the coarser vegetables, herbs, &c., are grown. It has not often been my privilege to visit a kitchen garden more replete than this in every article necessary for the supply of a large establishment, or where scrupulous order and cleanliness are better attended to.

The glass houses next claim attention. We first entered a Peach house, in which the fruit had been recently gathered. The trees are mostly young and in vigorous health. It is proposed to divide this house into two, so as to prolong the supply of fruit. In front of this are two new ranges span-roofed, each about 30 yards long (divided, one into two and the other into three sections), erected by Messrs. Richardson of Darlington. They are light roomy houses, in the construction of which every recent improvement has been introduced likely to facilitate successful culture. The first section is a stove, which contains a choice selection of healthy plants grown chiefly for house decoration and for cut flowers. For the latter purpose I was pleased to meet an old acquaintance which has of late years been elbowed out by younger but less worthy objects. I refer to *Hedychium acuminatum*, which was well bloomed, the Gardenia-like perfume from its snowy white flowers filling the house with its fragrance. The greenhouse was filled with plants chiefly useful for home decoration. The other three sections are used for growing Melons, Cucumbers, and Tomatoes. The Melons are good, the varieties being Victory of Bath and William Tillery. The latter in my opinion will become a standard variety; it is good all round. There are four vinerics

mostly planted with young Vines, which are in a healthy condition and bearing good crops of moderate-sized bunches, which are more aimed at here than larger bunches. The varieties are Black Hamburg, Black Alicante, Gros Colman, Madresfield Court, Muscat of Alexandria, Duke of Buccleuch, and Golden Champion. Mr. Morewood speaks highly of the latter as a summer Grape, being seedless and very luscious. Certainly there are good clusters of it here, although affected as usual with the spot.

Leaving the kitchen garden and houses we return to the pleasure ground, and on the way pass a venerable Yew tree. A little further down we come upon one of the grandest avenues and groups of Spanish Chestnuts it has ever been my pleasure to behold. They are the pride and glory of Canwell. Many of them measure 20 feet in girth of stem, and tower up to the height of 100 feet and more. They are truly magnificent giants, and to a lover of trees are worth a long journey to see.

We proceeded along the carriage drive which leads from the Lichfield lodge, and came in sight of the north-west and entrance side of the mansion; it is a noble-looking building, and has been much improved by its present owner. In the front is a fine expanse of park rich in many trees of great magnitude and beauty, additions to which have been judiciously and liberally made by Mr. Foster since he bought the property about seven years ago.

Passing to the right we come upon the south side of the Hall, where the flower garden, lawn, tennis ground, &c., are situated. The former is arranged on a sunk terrace immediately adjoining the mansion. It is prettily designed, and this summer is very effectively planted, the colours being harmoniously and pleasingly blended. The centre bed encircling a massive vase may be particularly mentioned as one out of many samples of very artistic and effective carpet bedding. Other beds that pleased me were Pelargonium Miss Kingsbury and Calceolaria Bertha Baron planted promiscuously in masses, the rich dark velvety colour of the Calceolaria contrasting beautifully with the light bright colour of the Pelargonium. This is one of the very best silver variegated Pelargoniums for bedding purposes, being much brighter and more distinct than such varieties as Flower of Spring, Flower of Day, Bijou, &c.

Another pretty bed was Pelargonium Maréchal MacMahon and dwarf Ageratum planted in the same way. For harmony of colour and general effect this simple way of massing plants in my opinion is far more effective than the system of using many varieties in one bed, which, without great skill is exercised, often results, as far as general effect is concerned, in a complicated and confused maze of colour.

The general view from the terrace on this side of the house is both extensive and varied, the eye taking in at a glance twenty miles or more of interesting scenery, conspicuous to the left being the ancient and historical borough of Tamworth with its venerable and grand old church and castle.

Leaving the flower garden we return by a cool and shady walk through a forest of fine trees, highly pleased with our visit, and much impressed by the many additions and improvements substantially and thoroughly carried out within the past six or seven years by Mr. Foster, not only in the garden but in every department of the estate.—COUNTRYMAN.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 28. NEW SERIES.

WE are not certain that the spiders of our islands are regarded either by gardeners or by the people generally as our most useful group of insects. Much might be said in favour of the bestowal of this title upon them when their outdoor proceedings are considered; and though within doors their webs are too disfiguring to be tolerated by most persons, they would, if left alone, impose a check upon the housefly and other annoying species. As it is we usually resort to artificial modes of keeping these under, and in our gardens spiders' webs are seldom left undisturbed in prominent positions, only those that have set their snares in nooks and corners escape, often only by accident. The æsthetic individual may indeed affect to be delighted at a tree or shrub the branches of which display the webs of spiders of various sizes and set at different angles, especially when these are glistening with dew-drops; but the horticulturist who prefers to see vegetation free from these traceries of silken cord, with their carcasses of slain insects, has something to urge on his side.

Yet it is far from advisable to make a point of clearing away every web that is seen, although at the decline of the season these seem to add an element of untidiness to gardens and shrubberies just when it is difficult to keep up their summer attractiveness. Fortunately there are many spiders that do not make webs but hunt down their prey, and these usually escape being meddled

with. One circumstance that ought to be in favour of spiders is this, they chiefly destroy insects in their perfect or imago state. In so doing they frequently stop the deposition of those eggs that would develop into a future brood of tormentors; and as the lives of some spiders last two or three years, though they may be more or less torpid during the depth of winter, each individual spider in these instances must kill many hundreds of insects during its period of existence.

In some parts of the continent the utility of spiders is recognised by gardeners, as is the case with the species called *Theridion benignum*, abundant in autumn almost throughout southern Europe. The cultivators of the Vine believe that its webs, which are often so numerous distributed over the branches as to leave scarcely any of the bunches of Grapes exposed, keep off a variety of insects large and small. This does not occur in Britain, although we have native species of that genus. The specific name was given to record the fact that this spider is of an amiable disposition, free from the cannibal tendencies notorious in others, where the smaller males are apt to fall victims to their larger female relatives.

It is not altogether unnecessary to state that there is no reason to apprehend any ill effects from the bite of a British spider, even of the larger species, supposing one succeeded in piercing the skin, which is hardly possible, at least I have never heard of an authenticated instance. In hotter countries it is different. If we reject the story of the Tarantula—as well we may, for the tarantula dance of Italy is evidently a kind of epidemic connected with a nervous derangement—there are still spiders that are certainly venomous. One of these which occurs in Spain has the inelegant appellation of *Latrodectus malmignatus*, and it might be imported by chance were it a house or garden species; but fields are its resort, where it seizes grasshoppers and locusts, killing them instantaneously, and though it is small in size its bite has proved fatal to human beings.

We have not said all that might be said in favour of spiders as a group when we have commended them as insect-killers. The silk they produce has been tried for manufacturing purposes, but the difficulty has been to obtain a sufficient quantity to work upon; it was also found almost impossible to clear the silk from extraneous substances so that it could be carded. It is not likely to rival the silk obtained from the Bombyx tribe, but the stouter threads are really serviceable in another way. Placed across the divisions of the micrometer they serve to measure minute spaces. To the web of the spider a medical or surgical value is attached in some places. There are still districts of England where these webs, formed in a sort of bolus, are swallowed as a cure for local fevers and ague, and it is a fact that applied to small wounds the material acts as a styptic. To those of us who are engaged in horticultural pursuits it is especially interesting to find that spiders have the repute of being "natural barometers," and their movements or their inactivity at various seasons of the year have been taken as indications of approaching changes in the weather. A degree of uncertainty, however, is connected with all prognostics drawn from the animal world. To give a familiar instance, birds hover low and are restless before rain, so it is said. Quite true, but they will manifest this uneasiness in the presence of a heavy cloud, which, from some cause does not produce rain, and passes over to another locality. I have noticed that in winter, when spiders are observed to be on the move during mild weather, it is probable that no immediate fall of the temperature is impending. In the summer or autumn a renewed activity on their part subsequent to rainfall may be deemed a hopeful sign, for they seldom attempt to repair their webs while the weather is unsettled.

It will be observed that spiders have been referred to as insects, and insects they will, I doubt not, be styled by the majority who are not naturalists. Even the students of their structure and habits are doubtful whether they are insects or crabs, hence they have by some been exalted into a separate class—the Arachnida. Their natural affinities certainly bring them near the insects, although there is an absence of distinct transformations, the growth of spiders proceeding by means of successive moults. Nor do we discover in the body the threefold division into head, thorax, and abdomen, the head being merged in the thorax. The legs are eight in number, whereas insects having attained to the imago stage can only display six, but then the first pair in spiders appear to be "palpi" or feelers somewhat modified. The integument or skin of a spider closely resembles that which is noticeable amongst all orders of insects, and its breathing is performed by organs in the abdomen, which are like the tracheæ or air-tubes of insects. The spinnerets of the Arachnida are in many respects peculiar, and different from the organs by which some insects secrete silk.

Owing to the diminutive size of many spiders, the dexterity with which others conceal themselves, or the resemblance in colour they bear to the substances amongst which they are to be found, few persons are aware how abundant spiders are in every direction. On and under the bark of trees are numerous spiders at all seasons of the year upon their foliage, and upon the leaves, flowers, and fruit of almost every plant these insects spread their snares. Walls, palings, and old buildings are well-known resorts; stones, large or small, serve also as hiding places, and many spiders are constantly running over the surface of the earth, heaps of dead leaves, or rubbish.—J. R. S. C.

#### THE LOUGHBOROUGH BOILER.

THIS new boiler that has just been brought out by Messrs. Messenger & Co. of Loughborough, has been designed for heating the small structures of amateurs satisfactorily and economically. The advantages claimed for this boiler are that it is portable and does not need setting in brickwork, hence is a tenant's fixture; further, no stokehole is required, the boiler being placed on the ground at the end of the house inside, the face of it, or feeding portion, being flush with the outside, and consequently fed from

Fig. 43.—The Loughborough Boiler.

the open air. All that is necessary is to place the boiler in position and connect the pipes, flow and return, with india-rubber rings, and take them along the front of the house under the stage. The boiler, being inside the house, might be utilised for supplying bottom heat to a propagating case that could easily be fixed over it, such aids for striking cuttings being always of great service for amateurs. The boiler, we are informed, works admirably, and we direct attention to it as it promises to be of great service in heating small structures in villa gardens. The feed syphon is at the extreme end of the pipes, the outlet for smoke being in the front of the boiler (as may be seen in fig. 43), to which a pipe is attached that reaches above the roof or as high as is needed. Further particulars of this boiler will doubtless appear in advertisements, or may be had from the makers at the address above given.

#### HARDY FRUIT GARDEN.

EXCEPT attending carefully to ripening fruits, little requires to be done in this department at the present time. Trees against walls ought to be examined every morning, and all Peaches, Nectarines, Plums, and Figs removed as soon as ripe, not allowing them to become dead ripe, as it is generally considered that the fruit of the Peach and Nectarine with the finer Plums are improved in flavour by placing them for a few days on the shelves of a well-ventilated fruit room. The earlier Apples and Pears should be gathered as fast as they become ripe, handling the fruit carefully. Some judgment must be exercised, for if gathered too soon they will shrivel, and if allowed to remain too long upon the trees the fruit is deteriorated, not unfrequently being mealy and flavourless. Late Plums, Peaches, and Morello Cherries should be securely netted up. Remove or stop for the last time all unnecessary growths on espalier, bush, pyramid and cordon-trained trees, also trees trained to walls, so as to give the ripening fruit the benefit of the sun and air, also to accelerate the ripen-

ing of the young wood and spurs. Autumnal Raspberries will soon be ripening, and will require, where birds abound, the protection of nets. This crop is a valuable one, but is not so much cultivated as it deserves. All that is needed is an open situation with liberally enriched soil; and as soon as the crop is over the canes should all be cut off close to the surface, selecting in spring about half a dozen of the strongest canes to each stool, pulling up or cutting off all that are weak or superfluous. Recently made plantations of Strawberries should be kept free from runners and weeds; and those formed of plants which have been forced will probably have set their fruit for an autumnal crop; indeed we have now very fair fruit of Vicomtesse Hericart de Thury and Pioneer from plants that fruited in April. They will need protection from birds, with a mulch of some clean material.

#### STRAWBERRIES IN POTS.

Some of the plants that fruited last April or early May were reserved and partially shaken out and potted or surface-dressed. They were then placed on the north side of a wall until re-established, being afterwards transferred to an open situation and well supplied with water and liquid manure. They have now set a plentiful crop of fruit, and when this is swelling they can be placed in a pit or other light well-ventilated structure, with a temperature of 50° to 55°, and 10° to 15° rise from sun heat by day. The fruit will swell to a good size and be of fair flavour; indeed they are much appreciated where there is not much variety in fruits for dessert in October and November. Vicomtesse Hericart de Thury is one of the best for this purpose, also Sir Harry and Pioneer. Later batches for autumn fruiting may be continued out of doors until frost, when they may be placed in cold pits and transferred to the houses in October and November, so as to afford ripe fruit in November and December. Runners layered in the fruiting pots some time ago should be kept free from runners and weeds, and be well supplied with water and liquid manure to encourage vigorous growth, affording them plenty of room.

#### FRUIT HOUSES.

*Vines.*—The earliest-forced Vines must now be pruned, it not being necessary to wait until all the foliage is down, for if the wood be brown and hard and the leaves are turning yellow early rest will be induced by the pruning. Both the house and Vines should be given a thorough cleansing; the woodwork being brushed with soap and water, and the glass thoroughly cleansed both inside and out with water. If necessary the house should be painted. The loose bark can be removed from the canes, and then wash them with a brush and tepid water, and dress them with an insecticide. Remove the loose surface soil from the border, and supply good loam with about a fortieth part of bone dust and a similar proportion of wood ashes. Any Vines in an unsatisfactory condition should be partially lifted, carefully laying in the roots near the surface in fresh compost, but this process is best done whilst the Vines are in leaf. After pruning keep the house cool, closing only when there is likely to be frost. Vines in pots to be started in November should now be fully ripe, pruned, and at rest. Owing to the wounds on young Vines not healing quickly they should be dressed with styptic or patent knotting; keep them comparatively dry at the roots, but excessive dryness must be guarded against, as that would prove injurious through causing the fibres to perish. Later batches of Vines can, as soon as the wood is mature, be placed outdoors to ripen, having the canes secured to a wall or fence to prevent injury by wind. Young Vines that have made a strong growth take a long time to ripen properly, and should be assisted with a little fire heat accompanied with constant ventilation, continuing this until the wood is brown and hard. Late Grapes not yet ripe require extra heat, 70° at night and 80° to 85° by day, accompanied with free ventilation. If the roots of late Vines are in outside borders it will soon be necessary to protect them from heavy rains by means of shutters, tarpauling, or straw. The Grapes keep much better when the roots are not chilled by the autumn rains. When the Vines are planted inside it will only be necessary to guard against excessive moisture in the border, such as will cause mischief by its evaporation, which may be prevented by covering thinly with clean straw or a double thickness of mats; the covering also prevents the soil cracking.

*Peaches and Nectarines.*—Late kinds have the fruit swelling and

ripening fast, and the house should be freely ventilated day and night; if the weather be cold and wet a little heat by day will accelerate the ripening process and improve the quality, for late Peaches from being long in ripening through cold are very often poor in flavour though of good appearance, which causes them to be in ill repute, but when well ripened they, like some late Grapes, are very different. As the fruit is gathered in the latest houses cut out the wood that has borne fruit this season, not being extensions, and if necessary thin the wood well out so as to admit of the foliage and young wood having full exposure. In the case of trees having strong wood and green a little fire heat will be necessary to ripen it properly, with a somewhat drier condition at the roots than is advisable for trees in a less vigorous condition. Trees that ripened their fruit in July now have the wood matured, and should where practicable have the roof lights removed; this will tend to prevent the premature development of the buds to which trees long subjected to forcing are prone. Occasional syringings will be necessary to keep the foliage free from red spider, and if scale infests the trees syringe with an insecticide at a temperature of 120° to 140°. Brown aphides sometimes attacks the wood at this season and later, and must be promptly eradicated by fumigation, or syringing with an insecticide.

*Pines.*—Young plants at this season invariably present a luxuriant condition of growth. Great care will be necessary to prevent the growth becoming soft and attenuated. To consolidate the growth a drier condition of the atmosphere will need to be maintained, even if fire heat have to be resorted to in unfavourable weather. Syringing the plants should only be done occasionally early in the afternoon of sunny days. Afford a plentiful supply of weak guano water in a tepid state. Ventilate above 80° liberally, especially on sunny days and secure a minimum temperature of 65° at night. At the close of the present month the plants most likely for starting into fruit early in the ensuing year should be chosen from those started last March, bringing them together where they can be subjected to a comparative rest for about six weeks. All fruiting plants should be placed in a suitable structure for ripening, which will now depend greatly on artificial heat, encouraging them with a liberal supply of moisture ranging the night temperature from 70° to 75°, and through the day from 80° to 90°, closing rather early at 85°.

#### PLANT HOUSES.

*Stove.*—The dull weather lately prevailing has necessitated the removal of flowering stove plants from conservatories to their winter quarters; and as they have been kept somewhat dry at the roots, which with the lower temperature has checked growth, care must be taken in moving such back to the stove that they are not excited into growth. To prevent this withhold water, so as not to injure the foliage, and keep the atmosphere somewhat drier than in the season of active growth; indeed the temperature of this structure for the next two months should be kept at its lowest, 60° to 65° at night and 70° to 75° by day being ample. Stove plants as a rule do not require a long season of rest, but, if anything, should have the season of growth extended. The best season of rest is unquestionably the autumn months, and this will admit of the temperature being raised at the commencement of the new year; the plants will then start into growth and have the advantage of a long growing season. Resting them early induces a disposition to start early. Allamandas, Bougainvilleas, Ixoras, and other plants that were started latest into growth at the beginning of the season will naturally continue flowering the longest, and at no time are they more acceptable than through the autumn; hence they should be placed together at the warmest end of the stove. Those that were started early can be placed at the coolest end, keeping them as dry as they will bear without injury. Where there is a partition in the stove, so as to form two divisions, there will not be any necessity for an arrangement as above pointed out, as one compartment can be kept for such as require a high temperature and the other for those that do not need more than a cool stove or intermediate temperature. Shading, except for the tender-leaved foliage plants, can now be discontinued, and the glass both inside and out should be thoroughly cleaned. The woodwork also must be cleaned, and a thorough overhaul of the plants made

for insects, especially mealy bug and scale, fumigating repeatedly to exterminate thrips.

Caladiums, Gesneras, and Gloxinias, as their leaves begin to discolour and evince symptoms of the growth stopping, should have the water gradually withheld, allowing them to flag slightly before giving any, and then only enough to slightly freshen them, keeping them in a light position and in a stove temperature. Placing them in a lower temperature, so as to stop their growth and starve them to rest, prevents the proper ripening of the tubers, which will be so weakened as to result in an enfeebled growth the following season. When the leaves have died the plants should be stood in the pots, where they will receive a little moisture, and have as regards the Caladiums a temperature of about 60°, but the Gesneras and Gloxinias will winter safely in a temperature of 45° to 50°.

## THE BEE-KEEPER.

### EXAMINATION OF HIVES.

SEPTEMBER is, perhaps, the best time for a thorough examination of stock hives of all kinds. In this month their strength and condition can be well seen and understood, diseased hives condemned and removed from the apiary, and weak hives united. Having set aside fifty-six hives for sale and stock, I am now engaged in a careful and painstaking examination of them, our watchword being "excellence." Whatever is found objectionable is noted and condemned. If a single cell of foul brood is detected the hive is condemned and removed from the apiary. If hives be found weak in bees two are united, making one good hive; and if the combs of stocks are too old and black the bees are driven from them, and placed either in hives with young sweet combs, or into empty hives and fed into stocks. As this is important work nothing should be left to chance. Good hives are invaluable, and autumn is the time to make them strong. Several hives have been condemned owing to their combs being old. Last year, being an unfavourable one in Cheshire for honey, several hives were allowed to stay in the apiary a year beyond the usual time. This year they have been condemned, their honey taken, and in a few days their combs will be melted. We think that, generally speaking, combs that have been in use for two years should be condemned and melted. Early swarms generally fill their hives with combs, and their combs with brood, in the first season. These make capital stock hives. Next season their combs are so often filled with brood that they become tough and discoloured, and thousands of the cells in the central combs are cloyed up and made useless by pollen. The accumulation of a superabundance of pollen is common in old hives, and is a very great hindrance to prosperity. Every square inch of brood comb yields, or should yield, fifty young bees per hatch—*i.e.*, every three weeks during the breeding season, but in pollen-bound combs the yield is not half so great. Combs made useless for breeding purposes by pollen stored up are nearly useless for storing honey. Besides, all this pollen in honeycombs is a great nuisance in the time of harvest, rendering it difficult to obtain pure honey. Often old combs are found so full of pollen that they appear like a piece of gingerbread. The retention of old combs in hives, and the practice of removing them from one hive to another, cannot be too strongly condemned. Among young combs bees thrive faster—that is to say, they breed faster, swarm earlier, gather more honey, which is more easily taken in a clean state from the combs than it can be taken from tough pollen-bound combs.

There is the question, too, of foul brood, which, though it is an incurable disease, need not frighten any bee-keeper. It has often been said that foul brood is an awful and destructive disease, and frequently have we repeated the same statement. If allowed to run its course ruin and destruction will result, for the disease itself admits of no cure. But in apiaries of young combs this disease is seldom known, and if it exists at all it cannot do much harm and never becomes a plague. The renewal of combs every second year at most in every hive, is the best possible way of preventing foul brood from injuring the apiary. In examining hives at this time the eye of the bee-master should run over the sides of the combs to see if any of their cells are covered with lids—that is to say, sealed up. If cells are seen covered with lids there is reason to fear that foul brood exists. By using a pointed stick or knitting needle the cells can be broken and their

contents exposed to view. Foul brood thus exposed is more like the gravy of meat or good beef tea than anything else. If a particle of foul brood be detected, both judge and executioner should do their work without delay—that is to say, the bees should be driven from the hives as soon as possible and put into other hives.

The work of uniting swarms is now a very simple affair. Formerly we used to take great precautions to prevent fighting and the destruction of life. Bees know each other and strangers by smell, and non-intrusionists naturally. In a healthy normal condition they fight and kill all strangers that enter their homes, often killing whole swarms as they have been cast into their hives. Nutmeg grated, minted syrup, and other strong-smelling substances have been used in uniting swarms in order to prevent bees smelling which are strangers, and thousands of unions have been effected without the loss of lives. This year we are doing the work differently and doing it well. By using brown paper or calico rags dipped in a weak solution of gunpowder or saltpetre and dried, the bees are subdued and mastered at the moment of union. The fumes or smoke from such paper or rag blown into the hive to receive the bees so disturbs and distresses the bees that they can think of nothing but their own safety. They run hither and thither to save themselves. While doing so we turn the hive upside down, and cast a swarm or half a swarm amongst the bees and comb, speedily replace it on its board, give them a sniff more of saltpetre, and shut all in the hive for a few minutes. All our unions this autumn have been successful, and all have been done as above described.

If combs are too old they can be removed and the hives have fresh combs built in their stead. If the combs are diseased the bees can be put into new or other hives and fed into stocks, and thus saved from ruin; and if hives are weak two can be united and thus made strong. If short of food, sugar syrup is easily administered. Whatever is needed to make hives strong for the winter should be done now. Whatever is worth doing should be done well.—A. PETTIGREW, *Bowdon, Cheshire.*

### THE LINCOLNSHIRE BEE-KEEPERS' ASSOCIATION SHOW.

THE Lincolnshire Bee-keepers' Association is one of twelve county societies formed for the promotion of bee-keeping. The Society is in a very flourishing condition, numbering some 260 members, and is affiliated to the British Bee-keepers' Association. It held its sixth annual Exhibition of bees, honey, hives, &c., together with very interesting bee manipulations, at Louth, on Thursday last, at The Cedars, the residence of Joseph Bennett, Esq., J.P. The exhibits were numerous, exceeding in number those of the British Bee-keepers' Association held recently at South Kensington, and were arranged in three commodious tents. Bees were not very largely exhibited. The class for Ligurians contained four entries, and the first prize was secured by Dr. Carline of Lincoln. In the class for British bees there were six entries, the first prize being awarded to Mr. H. Maples of Spalding. For any other than the preceding two varieties there were only two entries, Mr. T. Sells of Uffington securing the first position.

There were eleven classes for honey. The entries numbered altogether some 130, one class alone—that for the best glass of extracted or run honey of not less than 5 lbs. weight—mustering thirty-five entries. The first prize in this class was won by Mr. H. O. Smith of Louth. Quality was to be the chief point of excellence. Mr. W. Forman of Louth won the silver cup of the Association for the largest quantity of honey taken without destroying the bees. In these classes also the British Bee-keepers' Association offered a silver medal, a bronze medal, and a certificate, which were won by Dr. Russell of Lincoln, the Rev. W. V. Turner, Vicar of Bardney, and Mr. G. Bywater of Louth respectively. In hives and appliances there was an extensive and interesting exhibition, some very capital specimens of hives on many different principles, honey extractors, &c., being shown to the public. There was also a very interesting class for the best and largest collection of honey-and-pollen-producing plants to be shown either dried or otherwise. Here Mr. Godfrey of Grantham, the indefatigable and enthusiastic Honorary Secretary of the Society, carried off the laurels. Perhaps the most interesting part of the whole Exhibition was the bee-driving competition. This took place in a tent constructed for the purpose. The centre of this tent, where the hives of bees and the manipulators were, was open to the air, and the outside of the tent being closed in by the canvas sides and the inside protected by fine network from the intrusion of the bees, and it was very interesting to the public to see how thoroughly at home the various manipulators were with the bees.

On the evening preceding the Show a conversazione was held in the Town Hall, Louth, the Rector, Canon Wilde, presiding. Speeches were made or papers read on subjects interesting to apianians by the following gentlemen—J. G. Desborough, Esq., Stamford; T. W. Cowan, Esq., Horsham, Chairman of the British Bee-keepers' Association; W. Carr, Esq.; the Rev. J. L. Sisson of Edingthorpe, Norfolk; and the Rev. D. W. Pennell of Swansea.

We would suggest to the Committee that in future it would be very much better in an exhibition of this magnitude to issue a catalogue. The prize cards did not even mention the name of the successful competitors.

#### TRADE CATALOGUES RECEIVED.

Osborn & Sons, Fulham.—*Catalogue of Fruit Trees and Grape Vines.*

Geo. Cooling & Son, Bath.—*Catalogue of Bulbs.*

Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Catalogue of Bulbs (Illustrated).*

Samuel May, Leeds.—*Catalogue of Bulbs.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**The Canary Creeper** (*A. J. S.*).—The *Tropæolum* ordinarily designated by the above popular name is *Tropæolum peregrinum*, and there is not, as you suppose, a species correctly named *T. canariense*, which is a popular but erroneous title for the plant you have. If you have access to a library containing the "Botanical Magazine" you will find the plant figured on plate 1351.

**Portland Cement for Hot-water Pipes** (*Eighteen-years Subscriber*).—We know by experience that Portland cement makes sound and lasting joints. It is well to first press in a little packing firmly, then apply the cement carefully and smoothly; if a leakage occurs—and we have seen more than one—it is solely in consequence of a want of care on the part of the workman who used the cement. It is worth remembering, however, that it is almost impossible to remove pipes from the sockets that are jointed with cement, and we do not advise its use unless the heating arrangements are intended to be permanent.

**Bouquets** (*H. S.*).—There is no standard size for bouquets. The question is determined by taste and the custom of localities. In some districts it is the fashion to have hand bouquets much larger than in others, as may be seen by the competition at local shows. You cannot do better than note the sizes of the prize bouquets at the best shows in your district. Generally speaking, however, the choice of flowers and the free and tasteful method in which they are arranged are of far more importance than an inch more or less in the diameter of the bouquets.

**Peach Tree for Wall** (*T. S.*).—If Peach trees usually succeed in gardens in your district you might try the experiment of planting a Royal George, but whether it will ripen its wood and fruit well will depend entirely on the weather. We should not expect that a tree in such a position would have given satisfaction during the past four or five years. A Victoria Plum would be more certain to produce good crops of fruit, or a Williams' Bon Chrétien Pear. Strawberries are placed in houses from November to March, the time depending entirely on the character of the houses and the period when ripe fruit is required. On these points you afford us no data whatever for enabling us to answer your letter more explicitly.

**Garden Management** (*E. D., Wicklow*).—We are obliged by your letter, which shall have attention. The subjects to which you refer are so important that, although some of them have been prominently treated in our columns, they may be advantageously referred to again for the benefit of new readers and of those older subscribers who find the necessity of further advice that will tend to the better management of gardens.

**Mildew on Rose** (*A. A. M.*).—The leaf of the *Maréchal Niel* is attacked by mildew. Dissolve 2 or 3 ozs. of soft soap in a gallon of water, and with this syringe the plant, then dust the affected parts whilst wet with flowers of sulphur. The leaf you have sent is of an *Abutilon*, possibly *A. vexillarium*. It is suitable for training up a rafter in the greenhouse, where its pendant flowers can be seen to advantage.

**Golden Pyrethrum** (*L. S.*).—The leaves were very much crushed, owing to having been sent in a letter instead of in a small box, and were not in condition to enable us to judge of the merits of the variety. So far as we can judge it appears to be a lacinated form of the old favourite, but the leaves are not so finely divided as the variety sent out by Messrs. Osborn & Sons under the name of *Pyrethrum aureum laciniatum*; it may still, however, be a useful variety.

**Flavour of Fruits** (*Inquirer*).—This is entirely a matter of taste, but the Black Jamaica is one of the richest flavoured Pine Apples in cultivation. The Muscat of Alexandria is not a red Grape but amber-coloured when in good condition, and its flavour is not surpassed by any other Muscat variety. We are unable to answer your third question as the names were not published. In regard to your last inquiry you had better apply to Mr. Casella, meteorological instrument maker, High Holborn, London, who will supply you with the information you require.

**Heating Greenhouse** (*Amateur*).—Small portable boilers and pipes have been frequently advertised in our columns that would be suitable for your house; but, as we have many times stated, it is impossible that we can recommend dealers in any garden requisite. No doubt small portable boilers will be advertised again now that the period of the year has arrived when inquiries are frequent for them. We have not tried the fertiliser you mention, but it is no doubt suitable for plants in pots, and must be used according to the instructions that accompany it. Your last question is very vague, and we can only say that the majority of greenhouse plants will be safe during the winter if the night temperature is kept between 40° and 45°, the day temperature by fire heat alone being about 5° higher.

**Various** (*K. D.*).—If the Arums are strong we think they would succeed if planted now, but should prefer planting in early summer towards the end of May or in June. All kinds of insects should be kept off Chrysanthemums by syringing the plants occasionally with weak tobacco water or any approved insecticide. *Tropæolum speciosum* cannot be readily transplanted, and we should only attempt the removal of a portion of the plants, doing the work quickly yet carefully immediately the growths appear in spring. *Cerastium tomentosum* would form a suitable silvery carpet for your bed, small portions being dibbed in an inch or two apart now or in March. Any permanent covering would exhaust the soil more or less, but whether to the extent of injuring the Clematises no one can tell without knowing the condition of the plants. Consult with a good practical gardener on the spot. The *Imantophyllums* are too much shaded. If you stand the plants in a warm position out of doors in July, and let them remain so long as the weather is warm, they will probably bloom if they are strong and healthy and the pots well filled with roots. Your *Luculia* will probably not recover unless you can plant it out in a light position in the house. It cannot be successfully grown under Vines, and is seldom seen in good condition when attempts are made to cultivate it in pots by amateurs.

**Mildew on Peach Trees** (*Roby*).—Mildew is much more prevalent during some seasons than others, and its spread is much accelerated by dryness at the roots and a close moist atmosphere. You had better cleanse the house thoroughly after the leaves have fallen from the trees, and then paint the branches with a composition of sulphur and clay, a little of the latter being added to make the former adhere. The border if inside the house should also be examined, as it may be dry where the roots are, and a portion of the top soil removed and fresh compost added. Immediately mildew appears in the spring dust the affected parts with sulphur. Mr. Bardey prevents mildew attacking Peach trees and Roses by syringing with a solution of soft soap made as follows: A lump of soft soap (about 2 lbs. or so) is placed in a saucepan and boiled for twenty minutes; this is placed in a large pot and mixed with five or six gallons of water. About half a pint of this solution is placed in an ordinary large watering can full of water, and used every time the trees and Roses are syringed. Not a vestige of mildew is seen on the foliage, and the water does not injure the petals of the Roses.

**Figs Unsatisfactory** (*J. E.*).—Your former letter did not reach us. The cause of the fruits dropping is either the result of the wood not having been matured, or imperfect fertilisation, or both. You can scarcely expect satisfactory crops if the trees are closely crowded against evergreens. Light and air are essential for maturing the wood, and unless this is accomplished the attention you give to the roots will be of little avail. Cannot you remove the evergreens or shorten their growth? Thin out the growths of the Figs, too, during the summer, retaining those that are short-jointed, and exposing the foliage to the full action of the light and air. You do not state whether the trees ever have ripened good crops; if they have not, possibly the position is not suitable nor the variety the best for outdoor culture. Overluxuriance caused by too rich soil, and overcrowding of the trees, are common causes of failure in Fig culture in the open air.

**Mildew on Grapes** (*G. M.*).—Only a portion of your letter can be read in consequence of its having been placed with the fruit that was much injured in transit, and the juice extracting the writing. So far as we can gather your management as regards temperature has been correct. Your Vines no doubt received a check, either by the inclemency of the weather in the spring, or by being too dry at the roots. Had you applied sulphur to the berries immediately the mildew appeared and repeated the application as needed they would not have been in the condition they are now. See what we have said in reply to another correspondent, "*Roby*," and read also an article on page 256 of our issue of September 15th, 1880; if you attend to the instructions referred to you may expect better results next year. If you do not possess the number we have mentioned it may be had from the publisher in return for 3½d. in postage stamps, with a request that he send you No. 12 of the third series.

**The Cucumber Disease** (*W. Turner*).—The form of disease that has ruined your crops is, we regret to say, incurable, at least it has baffled the efforts of the most skilled gardeners and best Cucumber growers who have attempted its extermination. You appear to have done all in your power to save your plants and crops, and we can only suggest that you cease attempting to grow Cucumbers in the house for two years, and endeavour to produce a supply in frames or hotbeds. We have known cases where it was impossible to grow Cucumbers in a disease-stricken house while the plants in frames flourished, but this is not always the case. The only practical mode of maintaining a supply of fruit where the disease exists is to keep on constantly raising young plants, and let each, if they will, bear two or three fruits before the disease develops into a virulent form. If you would like to read much that has been published on this form of disease you will find it in vol. xx. of the Journal; if you do not possess this volume the following numbers, which can be had from the publisher in return for 3½d. each, will answer your requirements—524, 526, 529, 530, 532, 534, and 536. No. 720 contains illustrations of the Cucumber root disease, which will afford you instruction.

**Hedge for Kitchen Garden Boundary** (*Ignoramus*).—Privet would grow the most quickly, and though forming a good screen is not strong enough to resist cattle. A mixture of Privet alternating with Quicks makes a somewhat stouter hedge, but the Privet outgrows and smothers the Quicks, and though a screen is thereby quickly formed it is not equal to one formed of Quicks alone, which we should have. The ground should be well trenched and manured so as to encourage a good growth of the Thorns. The trenching should be done with as little delay as possible, to admit of the plants being planted as soon as it is safe to move them, or when the leaves have fallen. Plant strong recently transplanted Quick, eight plants in a yard in a single row, and when the buds are swelling in spring cut the stems off about 4 inches from the ground. This will cause them to form a close bottom and make strong upright growth. Keep the ground clear of weeds through the summer, and in winter point over the soil on both sides so as to form a loose surface, and bury any weeds, but not so deep as to interfere with the roots. The fence may be trimmed in July with the shears, having the hedge about 9 inches in width at the base and slightly narrowing upwards. When about 36 inches in height it should be topped, and about 6 inches added to the height annually until the height required is attained. A double row of Quick makes a stouter fence, and a firmer and closer base is had by plashing—that is, letting the Thorns grow for a few years without topping, and then cutting and laying them down slantingly and keeping them in position with stakes. The fence must be protected from animals until it is established.

**Disbudding Chrysanthemums** (*F. W.*).—We are obliged by your letter, and have endeavoured to carry out your suggestion, but it was not practicable. The superfluous buds must be removed before they are developed so much as to show clear of the foliage; they, in fact, must often be searched for and carefully removed with a penknife when they are little larger than pins' heads. Mr. Moor-

man has explained in another column the difference between crown and terminal buds. Crown buds are never surrounded by other buds on the same stem, but by two or three young shoots; it is these growths that produce what are known as terminal buds, as no growth is made beyond them, but a cluster of other buds surround the one at the end of each shoot. A plant grown from a cutting and not stopped will, about the month of May, often cease to elongate for a few days, and will push forth two or three growths from near the apex. If the centre of these are examined a small bud will be found; this is what is called the "May bud," and is of no use, and the growths should be pushed on rapidly past it. In time, about July or early August, these, now primary growths, will each produce a crown bud, and two or three growths, not buds, around it. It is this bud, known as the "July bud," that usually produces the finest exhibition blooms; but it will not be of good form or substance unless the surrounding growths are removed immediately the crown bud can be discerned to be satisfactory. If this bud is not secured then only terminal buds can be relied on, and the side buds surrounding these must be picked out the moment the work can be safely done. More blooms are taken from terminal buds near London than around Liverpool, possibly because the crown buds of some of the varieties in the south might be too early if they were permitted to develop. This, however, is a question for the "fancy." We know that all of them do not admit the point, and we know also that it is only long experience and close observation that enables a grower to choose the buds of the different varieties that can be depended on to give the finest blooms. We hope the subject is now plainer to you than before.

**Crested Kale** (*G. O. S.*).—The leaves you send are curious, but they are not so crested as some that have been sent us of similar parentage. We have seen the peculiar curled or crested growth that is evenly spread over the surface of the leaf represented in various colours, consequently imparting a prettier appearance to it.

**Naming Fruits** (*To Correspondents*).—Several parcels of fruit have been received at this office during Dr. Hogg's absence from London. They will be preserved, and the names of such specimens as can be identified will be published in due time. It is necessary to state that the conditions attached to sending fruit for naming are that all specimens must be fair examples of their kind, and if the fruits differ in form on a given tree more than one specimen should be sent; that all dessert fruit must be ripe, or closely approaching ripeness, when it is sent; and culinary fruit be in its best state for use, and that no correspondent must send more than six varieties at once.

**Names of Plants** (*Hopville*).—*Pyrus spectabilis* fl.-pl. (*W. D. H.*).—*Neottia spiralis* (*Spiranthes autumnalis*). (*Rosa*).—The Orchids, which were packed in wool, were both dried and crushed. The leaves resemble those of *Mandevilla suaveolens*. (*W. E. B.*).—4, *Achillea Ptarmica*. The other specimens were quite insufficient for identification. (*R. P. O.*).—You are quite right, the Orchid is a fine variety of *Oncidium flexuosum*. (*H. S.*).—1, Apparently a *Bilbergia*, but so small a fragment cannot be determined with certainty; 2, not sufficient; 3, *Begonia Sutherlandii*; 4, *Farugium grande*; 5, *Gymnogramma chrysophylla*; 6, *Begonia fuchsoides*. (*F. P.*).—Very much withered, but apparently *Pyrus spectabilis* fl.-pl. (*J. W.*).—*Antennaria tomentosa*, a hardy alpine plant, useful for rockeries and carpet bedding. (*Hersham*).—*Cratægus latifolius*. (*Inquirer*).—*Oncidium Lancanum*.

**Artificial Comb Foundation** (*F. W. Pye*).—Mr. Raitt, Beecroft, Blairgowrie, made the foundations to which you refer. He makes two kinds—one for brood combs, and one for supers. The super foundations are made of whiter wax, and are lighter than the brood foundation.

**Feed Bees not Building out Foundation** (*Buzz*).—The difficulty you experience in getting your bees, even when fed, to build out foundation arises from two causes—First, the lateness of the season; and second, the presence of as much comb in the hive as the bees are able to fully cover. If you see any reason to induce them still to build out foundation you will succeed by removing three or four of their nine combs and putting foundation one sheet at a time in the centre. A few days since we removed all the combs from a stock and gave it six Woodbury sheets, which are all now quite finished combs, and yet a single frame of foundation added in the centre of their brood would probably have remained during the late cheerless weather almost untouched. It must not be forgotten that working out foundation is work, and that it consequently somewhat wears out the bees, reducing their change of living on to the spring; but of course if brood is being abundantly raised you will depend rather upon the yet unhatched bees than upon the little labourers you have determined to still keep at it.

COVENT GARDEN MARKET.—SEPTEMBER 14.

OUR market is now abundantly supplied with all kinds of produce in season, and prices are generally lower.

FRUIT.

POULTRY AND PIGEON CHRONICLE.

A WET HAYTIME AND HARVEST.

(Continued from page 234.)

REFERRING to the practice of Messrs. Neilson and Knowles, it will be noticed that they get rid of all the harassing difficulties, as well as the extra expenses attending haymaking, especially in an adverse and rainy time. They are, however, entitled to claim the making of hay of superior quality and feeding value, not only in seasons when the rainfall impedes the ordinary process of making hay, but also when the season is more favourable, reducing the risk by earthing the hay at the early period of only two days' exposure, the juices and feeding quality of the grass being then retained and concentrated in the hay, and any excess of heat and fermentation being removed by the exhaust system. Although we entirely agree with these gentlemen as regards their plan of securing the hay under iron-roofed sheds or barns, yet we have to consider how the same advantages can be secured when ricks are built in the field in which the grass was produced. If we sell the rick of hay for delivery off the farm, or if we cut it out as required for feeding sheep in the adjoining field, it appears practically objectionable to carry hay a considerable distance to be built into a stack at the homestead. We therefore suggest that the same advantages may be obtained by Mr. Knowles' plan of saving the hay when ricks are built in the field as when made under the fixed iron roofing of a hay barn, except that thatching would be required in the former case and dispensed with in the latter.

Instead of the exhaust pipe being a fixture made of drain or sewage pipes there may be placed for use an iron gas pipe, or stack pipe used for carrying off water from buildings, of the requisite capacity, say a bore of 4 or 5 inches, which may when making the stand or bottom for the rick be, as usual, made of bavins or bean haulm. The pipe being laid to reach the centre of the rick will then be available if the chimney in the stack is made to meet the end of the pipe, on the ground being a little raised in the middle of the stand, and secured in position by a few elods of earth. At the same time secure the pipe in connection with the chimney, in order that it may be made to a great extent an airtight pass for the heat of the rick when the exhaust fan is in operation.

We think this arrangement, which can be made with but little trouble, offers all the advantages of the system, and likewise the benefit to be derived from placing the ricks of hay in or near the fields where the crops were grown. There is a somewhat similar effect upon either green or damp hay between the system of securing it by Mr. Knowles' plan and that of Mr. Gibbs; but although the same object is attained—that of freeing the hay from sap and moisture, the latter is, however, done by drying it out by heat before carrying to stack. The former plan is to allow the stack to ferment and heat, and then exhaust the heat by mechanical means. We remained sceptical as to the alleged effect obtained from ventilating a solid haystack with a rather large-sized dressing machine fan until facts, relating to ten years of successful practice which cannot be overset, have induced us to give it prominent notice; and as the operation is attended with less cost, both in the machinery and the labour attending its operation as compared with Mr. Gibbs' system of drying, we can only conclude

that Mr. Knowles' plan is preferable as a farm practice. Our opinion, however, refers principally to the saving of hay, for we should prefer Mr. Gibbs' plan of drying before stacking for corn, simply because we cannot allow a corn stack to ferment and heat without deteriorating the grain more or less, whether of Wheat, Barley, Rye, or Oats for all useful purposes in consumption, as well as that of seeding the land for a future crop.

It is important to consider how often we have suffered seriously from the effects of wet seasons at haytime and harvest. In referring to the past we find it recorded that from the end of September, 1878, to the same date in 1879, which is the real agricultural year, we had no less than 44 inches of rain—about one-third over the average, and the excess was unfortunately received during the months of June, July, and August, in which we had an excess of rain in each month of more than double the average, 1 inch of rain meaning as nearly as possible 100 tons of water per acre. Thus it is we have to go back more than sixty years before we can find a parallel, or a year equally wet and disastrous. For although by the excess of wet injury was produced both in haying and harvest, yet by a very low temperature and deficient sunshine probably a still greater injury was inflicted upon the various agricultural products and operations. A wet harvest means a wet August, which we have experienced this year, and probably more injury or quite as much has been done by sprouting and staining the corn in the southern and midland counties than in 1879. We have no occupation at present so much concerned in the weather as agricultural pursuits. Formerly the working of mills depended very much upon water power and its supply in the summer months, before steam was introduced, particularly in the north of England. There were formerly a vast number of silk, cotton, and woollen manufactories carried on by water power, which depended on the rainfall, therefore any excess of rain at the haying and harvest periods now seriously affects agriculture more than any other pursuit. There are several important facts connected with the rainfall which it is important to point out. One reason why greater precautions are not taken to secure a better harvest both for hay and corn, especially in the southern and south-eastern counties, is the amount of uncertainty which prevails in regard to the weather; for if we could tell on the beginning of August what sort of weather would prevail during that month we could then tell what was the best system to pursue.

We have found that in the course of thirty-eight years, including 1879, we have had ten wet harvests—not all very wet, or sufficient to sprout the corn, but wet compared with harvests generally. This is one in about every four years, whereas we only find the corn sprouted or seriously deteriorated about once in eight years. These facts induce many farmers to become careless in regard to other years, relying on this calculation, although the excess of rainfall by no means occurs at any particular period, for they may appear as they have done lately within a few years, or be deferred to a period of ten years or more. Hence the peculiar and uncertain position of the home farmer, demanding of him not only great industry, but constant apprehension of coming events, to meet which no time should ever be lost to make hay while the sun shines, or stack the corn when in condition at the earliest opportunity. Delays in his calling are always dangerous; at the same time, to say when the hay or the corn is fit for stacking should not be a matter of guess, but be decided upon an amount of experience which young beginners cannot have, hence the necessity of attention to the writings and doings of those who have gone before them. As regards hay, we would rather have it under-made than over-dry; the same in cutting grass for hay, we would rather have it young and growing than approaching a seed stem. Again, with regard to corn, we would rather cut any kind of grain early so that the hardening process of the grain may be effected in the sheaf, or, what is better, in the stack, if we are satisfied that it will not heat in consequence of weeds, &c., contained in the bulk, for we have always obtained the best samples of grain when the ripening process was completed in the stack.

The next point deserving attention is how to proceed when corn has taken rain after being cut, and we can name two special instances, for in the years 1848 and 1852 we know that we had Wheat standing in stook which received a month of rainy weather, quite sufficient to prevent stacking, yet where farmers had patience a spell of fine weather came in both seasons, enabling them to rick the corn with the grain unsprouted and in sound heavy condition. We certainly advocate the erection on home farms of hay and corn barns, the roof and pillars of iron; not all exactly at the homestead, for we object to large quantities of produce of hay and corn standing contiguously in a rickyard; but they may be placed on convenient sites to be found upon every farm. We consider this more advisable than ever, for we cannot afford to wait the convenience of a professional thatcher without great risk, nor can we

now educate the labourers into thatchers as we have done for a great many years, for after having taught them their work they will leave work without notice, at great inconvenience to the farmer. Building ricks, both of hay and corn, is nothing like so neatly and economically done as formerly; still, as it must in many instances be done, it is a matter in which the roofing of them is of the greatest consequence, such as making the roof with the sheaf butts sloping like thatch. Lastly, we recommend, under difficulties which may occur sometimes, the plan of putting a portion of the crops into small temporary stacks in the field, both of hay and corn, as in Scotland, Wales, and the northern counties.

#### WORK ON THE HOME FARM.

*Horse Labour.*—When not engaged in harvest work horses should now be employed in seeding and working the land for Trifolium and Vetches. Many fields of young Clover will be found thin of plants in consequence of the dry summer; these may be resown with Trifolium and only harrowed in with two or three of the iron harrow tines and rolled down, because the few remaining plants of Clover and grass will be saved and grow together as a mixed crop for either hay or feeding. The autumn cultivation of stubbles should now be continued daily with steam power, and by using the cultivator about 8 inches in depth, or as deep as the previous ploughing was done, both longways and crossways, it will bring on the surface where couch grass is found a large portion of it in lumps and clods of various sizes, and thus enable the horses to follow up the work by using Howard's self-lifting drag and the two-horse roller by turns—about two draggings between each rolling. This work may be continued until all the couch is combed out and disposed of either by burning in the field or carting away to a heap to become decayed and mellow. We prefer the latter plan, for it can be done during all kinds of weather except excessive rains, and also save a portion of the work necessary to reduce the couch into a condition for burning. At intervals some horses may be employed in drawing dung from the homestead on to the Clover leas ready to be ploughed in for Wheat; and if it is properly spread the land may be ploughed and pressed by steam power, as the rains of August have reduced the land to a moist and favourable condition for ploughing. This may be deferred until the autumn tillage is nearly completed, for it may be done in rainy weather, whereas autumn tillage can only be done and should be continued as long as the weather is dry and the land free to work.

The home farmer will now require to look for seed Wheat, and decide upon the sorts best suited to his soil as dictated by his own experience. If he has but little experience to rely upon he will have noticed, or should have done so, those varieties which have succeeded best in the vicinity of the home farm, for there is always something to be learnt by an inquiring mind from looking over the hedge and observing what is being done by his neighbours. Upon light hill lands we find that those sorts of Wheat answer well which throw a good bulk of straw, such as the Champion White from Berkshire, Morton's Red Straw White from Gloucestershire, and the Golden Drop Red Wheat grown in many districts. Upon good loamy or mixed soils in high condition and likely to grow a bulky crop of straw in a favourable season, we recommend the Club-headed Rough Chaff from Essex, as it not only grows very short in the straw but also very thick on the ground, and is seldom laid by storms to injure the yield. At the same time the grain is of the finest quality for the miller. On cold strong lands we find Nursery, a red Wheat with white straw and chaff as grown in Sussex and Hampshire, a hardy sort, which will retain plant better under difficulties than any variety with which we are acquainted. It is also well adapted for hill lands where much exposed, and it also produces the finest quality of all the varieties of Red Wheat. We have called attention to the selection of sorts of Wheat, anticipating the seed time. It is, however, now full time to be sowing winter Oats, winter Barley, and Rye, and we prefer the Giant or St. John's Day Rye to the ordinary sort, especially in loamy and good soil; but on hill lands under exposure to bleak winds the ordinary kind is more reliable, it being hardier than the first-named sort.

*Hand Labour.*—There is still some Turnip-hoeing to be done, and the sooner it is completed the better. If, however, the plants are not likely to thrive well they may only be dragged, so that numbers may tell instead of large roots, especially when required to remain during the winter for spring feeding to be followed by a crop of Mangold, or when required to be ploughed in for manure. We find when passed through an old cutter, and ploughed in and spread evenly, and the land pressed, it is a good preparation for Lent corn, especially upon mixed soils which will not bear the sheep in a wet season. Hedge-trimming should now be finished. Thatching buildings may now be done with advantage while the straw is new and tough.

*Live Stock.*—Sheep may now be purchased, especially the lambs to be wintered and sold as mutton in the spring. The down ewes either from Wilts, Hants, Dorset, or Sussex intended for producing the early lambs at Easter may now have the rams removed from the flock, so that no lambs may fall later than the middle of February. We prefer to place all those ewes not in lamb upon root-feeding, cake, &c., to come out as early mutton instead of bringing a late lamb, that being against the successful feeding of ewes and lambs and selling them fat together. The long-woolled flocks will have the rams running with them for a month or six weeks longer yet, for in the grass

districts the lambs are not required to fall before the spring grass is ready for feeding. This observation applies chiefly to the midland, western, and northern counties. In south-western counties, where the horned Dorset and Somerset breeds are kept, these ewes are now for the most part forward in lamb, and will commence lambing in October—that is to say, those which are off-going stock and sold to the graziers in the home and southern counties for supplying the London and other markets with early lambs, commencing the sale of them about Christmas, and through January, February, and March. The breeding flocks, however, of these horned sheep are not often required to lamb much before December, and are mated with the rams accordingly. It is now a good time to look out for half-fat steers, just beneath the butcher's quality, for putting in the boxes for winter feeding; for these may often be made to come out during January and February, and can always be kept at a better profit than by taking up poor animals. All the stock of the farm may now be assisted with roots—working horses receiving Carrots, bullocks hybrid Turnips, young stock common Turnips, sheep early Turnips or Mangolds, for it is a plan now adopted to give wether sheep cut Mangolds in the field where they grew cut and mixed with bean or barley meal, or else decorticated cotton, or a mixture of all. The Mangold roots, however, we pull and stack between hurdles for ten days or a fortnight before being used. Dairy cows should now have Cabbages in the racks at milking time cut and mixed with meal or bran.

**CORN OR CATTLE.**

[Read at the British Association, York, September 1st, 1881, by William E. A. Axon, M.R.S.L., F.S.S.]

It is abundantly shown by statistics that the people of Great Britain are very largely dependant for their daily bread upon supplies from foreign sources, and that the proportion of imported over home-grown foods is steadily increasing. So marked, indeed, has this tendency become in late years that many appear to think our islands really incapable of feeding their inhabitants. Thus, an American publicist has roundly asserted that "if every acre of land in the British Isles were cultivated to its utmost capacity, the inhabitants could not raise food to supply the common necessities of life." It may not be without interest to test such statements as these, and it will easily be seen that they are very wide of the mark, and that under suitable conditions Britain is still able not only to maintain her present population but to find food for an enormous increase.

The agricultural returns show that the total acreage of the United Kingdom, including the Channel Islands and the Isle of Man, is 77,828,948, of which 47,586,700 are returned as under "crops, bare fallow, and grass." The corn crops cover 10,672,086 acres, the green crops 4,746,293. Clover and grass under rotation amount to 6,389,225 acres, and the permanent pasture, exclusive of heath or mountain land, is not less than 24,717,092 acres. Orchards have 180,000, and market gardens 44,000 acres. 2,409,000 acres are devoted to woods and plantations. In the ten years between 1870 and 1880 nearly 591,000 acres have ceased to be used for Wheat-growing. In the same period there has been an increase of nearly 2½ millions in permanent pasture.

The following table shows the land extent of crops, and gives an estimate of their average produce per annum. The calculation as to the amount raised from each acre is based upon the figures given by Mr. Robert Scott Burn (*Outlines of Modern Farming*. London, 1869. Vol. I. p. 22).

Estimate of the production of vegetable foods in the United Kingdom, including the Isle of Man and the Channel Islands, in 1880:—

	Acres.	Produce per acre.	Total produce.
WHEAT .....	3,065,895	{ 1680 lbs.....	5,150,703,600 lbs. grain.
		{ 2576 lbs.....	7,897,745,520 lbs. straw.
BARLEY .....	2,695,000	{ 1089 lbs.....	2,934,855,000 lbs. grain.
		{ 2016 lbs.....	5,433,120,000 lbs. straw.
OATS.....	4,191,716	{ 1360 lbs.....	5,700,733,760 lbs. grain.
		{ 2240 lbs.....	9,389,443,840 lbs. straw.
BEANS AND PEAS—			
Beans .....	436,361		
Peas .....	235,177		
	671,638	{ 1550 lbs.....	1,040,883,900 lbs. grain.
		{ 2240 lbs.....	1,504,245,120 lbs. straw.

The amount of land in the United Kingdom devoted to permanent pasture is 24,717,092 acres, calculated to produce at the rate of 50 lbs. of flesh meat per acre, 1,235,854,600 lbs., which at Mr. Greg's estimate of consumption of 3 lbs. per day, shows a sustaining power for 1,128,634 persons per annum.

The corn crops cover 10,672,086 acres, and the average yield of grain would be 17,929,104,480 lbs., which at 2 lbs. per head per day would feed 24,560,417 persons. Hence, without reckoning at all on the green crops, we have a sustaining power for 25½ millions of persons.

There have been various estimates as to the extent of English food production. Mr. Caird supplied figures from which, in 1877, Mr. S. Bourne calculated the average corn growth at 54,000,000 cwts.; but it is a gradually decreasing quantity. Mr. Bourne further reckons the growth of English flesh meat at 25½ million cwts., a much higher estimate than would follow from the basis adopted by Mr. Greg. It may be well then to say here, that Mr. Bourne counts the home produce of Wheat at 54 million cwts., the foreign supply at 53 million cwts., home-grown flesh meat at 26 million cwts., foreign supply at 5½ million cwts., home-made cheese and butter at three million cwts.,

foreign supply at three million cwts., home-grown Potatoes at nine million cwts., foreign supply at half a million. From a further calculation he came to the conclusion that in 1877, of the 33 million persons of the United Kingdom, 18 millions might be sustained on food grown at home, and 15 on that received from abroad. Whatever estimate be adopted, it would seem that the American criticism already quoted had some justification.

But let us suppose that the present process by which corn-growing districts have gradually been converted into grazing lands to continue until the entire available surface is devoted to cattle-raising.

The total of arable and pasture acreage of the United Kingdom in 1880 was 47,586,700, which, at a production of 50 lbs. weight of butchers' meat per annum, would give a nett result of 2,379,335,000 lbs., or an amount sufficient, at 3 lbs. per day, to feed 2,172,908 persons. If mankind were exclusively carnivorous, a much larger quantity would be required. The Canadian boatmen and the Esquimaux, when deprived of other food, consume from 6 lbs. to 8 lbs. daily.

If, however, instead of being devoted to cattle-raising, we suppose the same acreage to be under corn crops, and to produce on an average 1420 lbs. to the acre, we have an annual return of 67,673,114,000 lbs., or an amount sufficient, at 2 lbs. per day, to feed 92,702,896 persons. After leaving an ample margin for any diversity of opinion as to the bases of such calculations, it is clear that there is sufficient material in our own land for the food of its people. The real remedy for over-population is food reform. This assertion is corroborated by a careful estimate of Dr. C. D. Hunter, who argues that forty-four men could be supported on 100 acres devoted to sheep-raising; 53 on a dairy farm, 250 on Wheat, and 683 on Potatoes.

The British farmer, in face of the competition of cheap foreign-grown corn, has turned his attention more and more to cattle-raising, but there are not wanting signs that in the future he will encounter an equally keen rivalry in the production of flesh meat.

At the present moment we are spending enormous sums on needless luxuries. The self-imposed taxation in intoxicants and narcotics, including their direct and indirect consequences, would pay off the national debt in three or four years. The sewage, which should be returned to the land as a fertilising agent, is thrown away at an estimated waste of £30,000,000 per year. A similar evil tendency has been shown in the matter of food, in which the poor and dear has been selected, to the neglect of the cheaper and better. The ignorant have taken cost as a measure of value, and, aping the luxurious habits of their wealthier neighbours, the poor are spending upon beef and bacon the money which would be much better employed in the purchase of the kindly fruits of the earth. The diffusion of knowledge on the relative values of various kinds of food may be expected to correct some of the evils arising from the present vulgar delusions as to the necessity of a flesh diet, or its superiority over one derived from fruits or cereals.

The testimony of history is clear, that population and civilisation increase only when the nomadic hunters settle down as cultivators of the soil. The welfare of the nation is indissolubly connected with the economy of its food supply. The productiveness of the land might be improved by the removal of legislative hindrances to its free culture, and by returning to it the excreta of our teeming populations. The encouragement of fruit-growing is as legitimate an object of national concern as the development of fisheries. If such steps be taken we may hope to see England no longer dependant upon foreign nations for food supply, but able, by her green orchards and yellow corn fields, to find an ample and healthy support for her children and her children's children.

**A QUARTER OF A CENTURY AGO.**

It is interesting to compare the poultry fancy of to-day with that of some years ago. We are perhaps inclined to think it has meanwhile made more progress than it really has. Through the kindness of a fancier of very long standing—still a fancier we are glad to say, though no longer an exhibitor of Dorkings—we have been able to peruse a number of the "Poultry Chronicle" of 1854. The publication must now be very scarce indeed, so we are tempted to cull some notes and extracts from it. To begin with, in this number of December 6th, no less than nine large poultry shows are advertised as to be held in the month of December—viz, those of the Dublin Amateur Society; South Durham and North Riding of Yorkshire at Darlington; Nelson, Lancs.; Bath and West of England at Bath; the sixth Birmingham Show, Nottinghamshire Association at Southwell, Kendal, Essex Association at Colchester, and Manchester.

From an article on the then forthcoming Birmingham Show we gather the curious fact, that whereas hitherto an exhibitor had been allowed to show six pens, only four would that year be received from one exhibitor.

Some prize lists differ but little from those of the present day;

the classification is a little better, and separate classes for adults and chickens seem to have been almost universal.

In an article on "Poultry Judges and their Duties," the pros and cons are well weighed concerning the advisability of having many or few judges. The question, however, was a far different one to that of the present day, as it was taken for granted that the many judges would judge together as a board. Fortunately no one wishes now to revive the latter system; the experience of the Paris Exhibition alone would condemn it.

A letter headed "A Word to the Unwise" contains much advice which from experiment we are certain is most valuable. The writer says, "Many there are that still go on complaining that their poultry, and especially their chickens, keep dying off from catarrh or cold complaints. Let me, therefore, give one more very modern instance of the rapidly beneficial effect of artificial warmth in both arresting and curing bronchial and roup affections in several chickens, Bantams and Polish. On referring to the late edition of Mowbray it will be seen that not only a warm but an artificially warmed apartment is strongly recommended. Observing, therefore, ten days ago that four Bantams and three Polish chickens after exposure to wet without and accidental wet within their domicile, were affected, some with catarrh, others with the more advanced roup discharge from the nostrils, and others with the gapy rattling or bronchial irritation in the throat or chest, I forthwith removed them into a greenhouse warmed by fires. I was surprised to see that all my patients at once sought out the warmest—yes, I might say the hottest flags, and there nestled. So warm were these flags which they selected, that I question whether I could have retained my own hand upon them and called it a comfortable warmth. The result was that some of them in three or four, and all within ten days, were perfectly recovered, showing clearly the efficacy of the sound practical advice given in the late edition of Mowbray, that an artificially warmed apartment is most essential in the treatment of such complaints." A letter on "fraudulent practices" proves that even in those early days of the fancy many abuses had crept into exhibitions which of late years have caused so much bitter disappointment to honest fanciers. Borrowing, painting, falsification of ages are here alluded to as by no means unknown.

An extract from an American journal speaks of Dorkings imported from London as being "beautifully speckled, chocolate and white." These were subsequently crossed with Game to obtain more vigour of constitution. In the same article the Dominique is thus alluded to—"The Dominica hen, well selected and completely bred, is a fine useful bird. They are of no particular breed, only distinguished as Dominicas by their colour, which usually indicates hardness and fecundity. We have seldom known bad hens of this variety."

A report of the Reading Show is interesting. The entries of Dorkings seem to have been very numerous. In one class sixty pens competed for four prizes. There were no less than twenty trios of White Dorkings in two classes. We recognise the names of one or two fanciers of the present day as successful exhibitors. Among them Mr. Smith of Henley-in-Arden showed Coloured Dorkings, Mr. Clift of Dorking White Dorkings, Miss Julia Milward Turkeys.

In a report of the Derby Show we see that Dr. Hitchman, still a fancier and breeder of Dorkings, took first prize for Coloured Dorkings, and that his pen sold for fifteen guineas.

The advertisement columns of the "Poultry Chronicle" show that high prices were then asked for well-bred birds, and as much as two guineas a dozen for their eggs.—C.

#### SQUIRREL-TAILED FOWLS.

In farmyard fowls this is no blemish, but in show birds it is a great fault—so great, indeed, that no matter how good a fowl may be in all other points, if it has a squirrel tail it will never win in good company, and fowls of the kind should be avoided for breeding. Probably some may not know what a squirrel-tailed fowl is, but if they were breeding and showing such they would soon find out. A successful exhibitor of Grapes at the Manchester Show told me there, that he had the finest Scotch-Grey cock in the country, and being interested in the breed I thought I might be able to secure the bird, but further my informant told me that his tail was a most ornamental one, as it "came over his back and touched his head." After this I said no more on the matter, as that was a full indication of a squirrel-tailed fowl. When the tail bends sharply over the back and touches, or almost touches the head like that of a squirrel, it is considered a great fault, and probably it is so, as it certainly does not look so well as a tail as one further from the head and hanging more in whip fashion. There is another kind of tail which is equally or more faulty still,

and this is what is known as a wry tail. In this the tail is carried on one side and is more unsightly than when carried over the back. Wry tails often come from in-breeding, as many fowls so affected have humps or deformities on the back. There is no cure for either, and the only way to avoid them is to be particular in not breeding from any fowls the least inclined that way, as imperfect tails are a great blemish in show birds.—J. MUIR.

#### FORTHCOMING POULTRY SHOWS.

WE have before us a number of schedules of forthcoming poultry shows, some of them of considerable interest to fanciers. First on our list is the Exhibition of the Altrincham Society, to be held on the 19th inst. at Bowdon. There are forty-one classes for poultry with three prizes in each, of 30s., 15s., and 7s. 6d., and twenty-four classes for Pigeons, with prizes of 15s., 10s., and 5s. The Secretary is Mr. Alfred Wilde, 41, Church Street, Altrincham. On October 5th, 6th, and 7th, a Show will be held at Southampton. A series of good and admirably managed shows were formerly held there, but of late have been discontinued, owing, we believe, to the poor attendance of visitors at them. The schedule now before us is a good one, and the Secretary is Mr. G. Billett, well known as a good manager of shows. The list is somewhat peculiar from the fact that in the poultry department cocks or cockerels have many more classes than hens; thus there are separate classes for both varieties of Brahma cocks, while the hens compete together—two classes for Cochin cocks, three for Dorking cocks, three for Game, while the hens of each breed will compete together. The schedule is altogether a liberal one for poultry, Pigeons, and cage birds, and we advise exhibitors to send for it. On October 6th, 7th, and 8th a Show will be held at Nottingham under the rules of the Poultry Club. The Hon. Sec. is Mr. R. Hill, 92, Parliament Street, Nottingham. The classification of poultry, Pigeons, and Rabbits is fair, and a list of subscriptions to a guarantee fund is published. This is a good plan. On October 18th and 19th, also under the rules of the Poultry Club, a Show will be held at Leek. There are four prizes in each of the sixteen classes for poultry, and three in the Rabbit and Pigeon classes. There is also a Show of cage birds, with four prizes in each class. The Hon. Sec. is Mr. F. J. Milner. On November 3rd another Show will be held under the Poultry Club rules—viz., that at Doveridge in Derbyshire. It is solely for poultry, to which forty-six classes are given. On November 9th and 10th a Show with extensive classification will be held at Carlisle. Game have eight classes, Dorkings four, Brahmas four, Cochins four, Hamburgs ten, &c. The Secretary is Mr. George Coulthard.

#### OUR LETTER BOX.

**White Game Fowl (H. L. B.).**—These birds are but seldom seen in the show pen, partly because they are scarce, and partly because they are not usually so good in the general characteristics of the Game fowl as to compete successfully with the other varieties of the breed. They were at first neglected in consequence of their real or supposed delicacy and their want of success in the fighting pit, and having once fallen behind have never recovered their lost ground. They are only suitable for a grass run where they can have plenty of liberty. In such a situation they will look well, lay well, and if killed at three or four months old will make admirable table fowls.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

4th.—Fine day, bright in the afternoon and evening.  
5th.—Dull cloudy day, with heavy rain at night.  
6th.—Wild morning, bright with occasional short sharp showers; thunder at noon; bright afternoon; rain at night.  
7th.—Dull early; bright morning; very fine afternoon; fine evening.  
8th.—Dense fog early; bright morning; cloudy afternoon; rain in evening.  
9th.—Dull morning; bright afternoon and night.  
10th.—Dull, with one or two slight showers.  
The first part of the week was, on the whole, fine and pleasant, but with occasional showers; the latter part was dull and damp. Temperature average, and about 2° above that of the preceding week.—G. J. SYMONS.

28th	W	Sale of Bulbs at Mr. Stevens' Rooms, Covent Garden.

## FRUIT AT SAWBRIDGEWORTH.

**L**ESSONS worth learning can always be had at a great nursery, especially on that particular branch of practice for which it may be famed. Sawbridgeworth, as all the gardening world knows, is famed for fruit, and as this is the period when results can be seen—the harvest—an opportunity is afforded for spending an hour in Mr. Rivers' establishment interestingly, and a record of the information there gathered may not be unprofitable to some readers of the Journal on the eve of the planting season. It must be remembered that not only are all the most useful kinds of fruit grown in this nursery, and nearly all forms of culture adopted, but the best varieties of each kind are tested and new varieties proved; indeed, in not a few instances what the world calls "new," Mr. Rivers has good cause to almost regard as old friends, for he is in the habit of growing a new variety of fruit for a number of years and in large quantities before, to use a plain but well understood term, he "makes anything to do about it." This is the case especially with seedling Plums, Pears, Peaches, and Nectarines; and the observation applies with equal force to at least one Grape, for he grew the Gros Maroe for a generation before he exhibited it for a certificate and obtained one. The leading fruits of the nursery may be briefly alluded to under their respective heads.

## GRAPES.

Very extensive structures are devoted to these, not only for growing Vines in pots, of which there are thousands, but for establishing the Vines and fruiting them in the manner in which they are grown in private gardens. A great number of varieties are thus tested, about three Vines of each being fruited. As may be expected in mixed houses, where what may be described as Black Hamburgh treatment is given, all the sorts do not succeed equally well, yet the crops on the whole are so good as to render the structures highly imposing. The variety named, for instance, Gros Maroe, is grand, the bunches being numerous and good, the berries of great size, and the colour splendid—a rich blue-black powdery bloom that no one can fail to admire. This is a noble exhibition Grape, sprightly and refreshing in flavour. The Vine is a strong grower, and closely pruned not infrequently a little shy; but as managed "at home" it produces bunches in abundance. Experience has proved that the short-spur system of pruning is not suited for this Grape. First of all the laterals must be trained thinly—20 inches apart is not too great a distance—so that the wood is matured, then a few inches at

the base of each should be left, and the probability will be that the cultivator will have bunches to thin out. A better plan still is probably to make a choice of young wood, and lay it in after the manner of Peach wood, disbudding to prevent that great evil overcrowding, and bunches may be expected from every eye. This Grape is not remarkable for large bunches, those on the Vines in question ranging from 1 lb. to 2½ lbs. In appearance this is the finest Grape in the whole collection, and its quality is decidedly good, the fruit possessing a good deal of the Black Hamburgh property of not cloying the palate.

The Gros Colman, the largest of all black Grapes, is bearing with almost equal freedom, but the berries are not quite finished, and it is a question if they will ever be of superior quality, for the simple reason that this variety requires more heat. This Grape has caused disappointment in many places, not because it is bad as a variety, but because it has not had a fair chance to develop its flavour. It is not a cool-house Grape, and the fact may well be remembered by those who contemplate adding it to their collections. Start the Vines early, give what is known as Muscat treatment, and under good culture Gros Colman will produce fine bunches and noble berries of satisfactory quality. Black Alicante is bearing prodigiously, 2 to 3 lbs. to each lineal foot of rod, showing that it is the heaviest cropper in cultivation, and being of excellent appearance it proves a profitable market Grape. Madresfield Court is in excellent condition, and apparently the older the Vines become, and the better crops they bear, the less do the berries crack. It succeeds well under Black Hamburgh treatment, and is undoubtedly one of the finest and richest of autumn Grapes. Mrs. Pince's Muscat is much finer than usual, and is colouring well. When in good condition this is a superior Grape, but it is too capricious to be relied on for planting in small collections, where the failure of any one rod is often a matter of great inconvenience. Even more capricious is the noble Duke of Buccleuch, yet it has produced several good bunches and fine berries with little or no spot.

Foster's Seedling is yet, perhaps, the most reliable white companion to the Black Hamburgh. Buckland Sweetwater is often seen finer and tasted better, but it is not so certain as Foster's. Neither of these Grapes give full and general satisfaction, and Ollerhead's White will possibly supplant them both. Certain it is that the two rods at Wimbledon House grow as strongly and fruit as freely as any rods need do, quite equalling Foster's in this respect, also in setting, while the fruit is as large or larger, a little deeper amber in colour, with a thicker skin, firmer flesh, and better flavour, the bunches being in size and shape all that can be desired. It is not, however, a Muscat Grape, and should not be injured by being overpraised, which is the unfortunate fate of many varieties when they are first seen. It may be fairly said it is an improved Foster's Seedling, and that is quite sufficient to stamp it as a variety giving promise of substantial merit and great usefulness. This is a digression, yet allowable, in a little discussion on Grapes. To return to Sawbridgeworth. The Black Muscat or Muscat Hamburgh is a comparative failure, so also is Waltham Cross; and these are not the only examples that denote the unsuitability, because of their uncertainty, of these varieties for small collections. Dr. Hogg is fruiting freely, bunches good, fruit small to medium, flavour a mixture

of Muscat and Frontignan, both moderately pronounced, and, perhaps, a trace of the peculiar aroma of the Strawberry Grape. Other ordinary varieties do not call for notice. The Ryton Muscat is esteemed as the best of the type, but the differences between the old Muscat of Alexandria, Bowood Muscat, Tynningham Muscat, and Tottenham Muscat are, generally speaking, more fanciful than real; but, however that may be, they are not all propagated from the same stock in this nursery.

*Vines in Pots.*—These demand attention. No one can see the thousands of fine "fruiters" and "planters" without wondering from whence comes the demand for them; but if the demand was not equal to the supply it is certain they would not be provided, and so even are they that there is little, if any, advantage to be had by picking and choosing. It is instructive to observe, too, how unnecessary is the practice of drying the roots for ripening the canes. The wood is as hard and brown as possible, yet the foliage is perfectly fresh, and so it will remain for some time—a sure indication of soundness and health. Two of the Vines of last year, a Muscat and Alwick Seedling, are fruiting in their pots plunged in little beds of soil supported with bricks. The roots have taken possession of the soil, and are fed with liquid manure. The Muscat has ripened twenty-three bunches of good Grapes, or say 12 lbs., certainly worth from 3s. 6d. to 4s. per lb., so that this mode of culture is profitable. The Alwick Seedling is ripening fifteen full and good bunches that will average nearly or quite a pound each. Several varieties of Frontignans are fruiting. It is surprising that these delicious Grapes are not more extensively grown. They are small, it is true, but for quality there is none to equal them, while they bear most freely and are early. Very good were the Early Saumur and Early Silver Frontignans, but others of the race are equal to them. They are not market Grapes, but are worthy of the attention of those who regard superior quality of greater importance than size of fruit.

#### PEACHES.

The crops of fruit of these have never been finer, and the large, cheaply built, span-roofed orchard houses must have been very profitable. The trees are grown in much the same manner as standard Apples in the garden, and receive little or no more attention than Apple trees do in pruning. These houses are not heated, but in northern and cold localities artificial heat is essential for insuring crops; indeed it adds to the value of Peach houses anywhere, and the returns justify the little extra outlay involved. Trees on trellises in other houses are also bearing splendid crops, one row of 4-inch pipes being arranged round the structures. Air is admitted by short lengths of earthenware pipes laid on the ground at intervals, one end in the house, the other outside, the ventilation being governed by moveable plugs. This plan is very simple and efficient.

The varieties of Peaches are so numerous that it is no easy matter to make a selection for securing a succession of fruit of good quality. The American variety Alexander must now be placed at the head of the early kinds. It is as early if not earlier than Early Beatrice, and is large in size, rich in colour, and of excellent flavour. Early Louise follows, a rather small but good Peach, and may be dispensed with in small collections. Early Rivers, larger and a finely flavoured fruit, and is succeeded by Hale's Early, a well-known and approved variety. To this Rivers' Early York, a most excellent Peach, affords a good succession. Then come the Early Grosse Mignonne, very good; A Bec; Magdala, fine and distinct in flavour; Dr. Hogg, rich in colour, and is proving a profitable market fruit; Alexandra, a splendid Peach; Grosse Mignonne, old and excellent; Bellegarde, a well-known good variety; Royal George; Noblesse; Gladstone, a great bearer and a valuable Peach; Albatross; Princess of Wales, very large and good; the Nectarine Peach, and Dese Tardive. These are only a few out of a long list of excellent varieties, but sufficient have probably been named for the majority of cultivators.

#### NECTARINES.

There has been, and indeed is yet, a grand harvest of these, and the fruit of some of the newer varieties is remarkable by its size and excellence. Indeed Nectarines have been revolutionised at Sawbridgeworth and are yearly increasing in popularity, although the demand for them in the markets is not nearly so great as for Peaches. The best of them have a richness, fulness, and wine-like flavour which Peaches lack, while they keep better—qualities that are becoming more and more appreciated. The earliest Nectarine is Advance. It is large and rich if not gathered until it shows signs of shrivelling. Lord Napier follows. It was raised by the present Mr. Rivers, and it is certainly not surpassed for a combination of good properties, if equalled, by any other variety. Humboldt is large and rich, and the Improved Downton and

Stanwick Elruge are varieties of great merit. Then follows Albert Victor, one of the largest of all. A fruit casually gathered was 9½ inches in circumference and weighed 8 ozs., quality excellent; it will be largely cultivated as it becomes better known. Spencer is a large and excellent fruit worthy of notice. Then comes the better known and valuable Pine Apple, followed by Victoria, the best of all the late varieties, and, grown under glass especially, is very superior, and the fruit is very large. A new variety, Dryden, will probably take a prominent position when it becomes known on account of its full, very distinct, and rich flavour; it is also a large and fine fruit. The older varieties are not specially attended to, not because some of them, such as Balgowan, Violette Hative, Hardwicke, and others are not good, but because they are sufficiently well known; but they are not in all points equal to the newer introductions.

#### PLUMS.

Many new varieties of these have been raised, several of which have not been named. There are large plantations of the best old and new sorts, and many trees trained to wire as diagonal cordons are very attractive, convenient, and decidedly profitable. The Early Prolific has again been very lucrative, 16s. per bushel having been obtained for the crop. The Czar is proving valuable for succeeding it, and the best testimony of its merits is the great demand that exists for trees for the Kentish orchards. The Sultan, too, is a fine Plum, and the Purple Gage is very useful. Large crops were being gathered of that very fine Plum Pond's Seedling, which is larger than Victoria and succeeds it, but is not quite such a great cropper. Early Transparent Gage and Oullins Golden Gage are meritorious, the last making splendid standards. Of the late sorts we have Grand Duke, a valuable acquisition, and there is quite a plantation in full bearing of another fine late variety not yet named; it will perhaps be the Grand Duchess, as it will assuredly be a worthy companion to the Duke. The fruit is large, crop full, and although the fruit was quite hard it was richly coloured, being covered with a thick powdery violet-blue bloom that gives it a beautiful appearance. It is singular that, although this appears to be of the Diamond type, it was raised from Reine Claude de Bayar. It is a variety of great promise, as indeed other seedlings are that, however, have not been so fully proved as this.

#### CHERRIES.

Of these the most noteworthy trees are in pots in a house with boarded sides and a glass roof, from which a regular supply of superior fruit has been maintained since June, and there are varieties not yet ripe. Who with the means for growing the trees would be without a supply of this delicious fruit, since it can be had so easily, certainly, and inexpensively, and preserved so well? The following is a small and good selection for this purpose—Bigarreau Jaboulay, Early Rivers, Governor Wood, Bigarreau Noir de Schmidt, Late Black Bigarreau, Monstrueux de Mezel, and two valuable late varieties not yet ripe—Emperor Francis and Guigne de Winchel.

#### PEARS.

Only a few of the newer varieties can be referred to and brief reference made to the trees in pots. They are laden with fruit, far finer than that on the ordinary outdoor trees: indeed, with one striking exception, which will be noticed, it may be said that except on the trees in pots the Pear crop is a failure. There was an abundance of blossom, but it failed to set outdoors. The pot trees have the shelter of glass until the fruit commences swelling, and are then plunged in the open air to mature the crops, and the results show the advantages of the system. The trees, 3 to 4 feet high, are in 9 and 10-inch pots, and as they are plunged closely together they occupy little space. The few new Pears that demand attention are Autocrat, a very large Pear, ripening at the end of October. It was raised from Beuré de Capiaumont, and is very hardy, robust and free, and is quite distinct in growth and fruit. Princess, raised from Louise Bonne de Jersey, the excellent flavour of which it inherits, but the fruit is half as large again and ripens at Christmas. But the most striking Pear in the nursery is Fertility, not because it is large, nor that the fruit is of the highest quality, but because of the abundant crop. There is a far greater weight of fruit in a small plantation of Fertility than on the trees of all other varieties combined, which can only be accounted for by the great hardiness of the blossom of the Pear under notice. Judging by the remarkable appearance of the trees Fertility will become of great service for orchard culture and for producing a large supply of fruit for market purposes. Among the older Pears that have resisted successfully the frosts of spring is Marie Louise d'Uccle—an excellent variety that Mr. Witherspoon has found of special value in the north of England. Of the Pears now in use, or just

over, Beurré de l'Assomption is by far the finest, and is of superior quality.

#### APPLES.

Very briefly must these be referred to. Cox's Orange Pippin is far ahead of all other dessert varieties in the abundance of its crop, the trees being laden with highly coloured fruits. Among culinary Apples Lord Grosvenor commands attention by its extreme productiveness. It is of the Lord Suffield type, but the fruit is more dense and heavy--no small advantage. Stirling Castle is similarly productive and the fruit splendid. This is probably the finest and most useful late autumn and early winter kitchen Apple in cultivation, and trees should be freely planted; nor must the good and serviceable Ecklinville Seedling and the productive old variety Dumelow's Seedling be forgotten by those who intend planting. The new American Apple Benoni is fruiting, and justifies all that has been said of its symmetry and beauty.

The fruit trees of all kinds in pots are remarkable by their numbers and quality, trained Peaches in pots meeting with great approval, and this method of preparing them will have to be extended. The best varieties of American Strawberries have been tried in the nursery, but they have not equalled expectations, the climate not being suitable for fully developing their qualities. Thus not only what to plant but what to avoid planting may be learned in the practical and experimental fruit grounds and houses at Sawbridgeworth, and this record of a visit may not be without a measure of usefulness to some readers.—EXPERIENTIA DOCET.

#### RAISING HARDY PLANTS FROM SEED.

"J. W.'s" remarks on raising Carnations from seed reminds me of some plants of the variety "Grenadin," raised from seed sown last year, which have bloomed finely this season. The plants are dwarf, very free flowering, early, coming into flower a fortnight before any other. The flowers are brilliant scarlet and deliciously Clove-scented. Out of a number of seedlings a large per-centage have double flowers. Like all the Cloves, propagation is readily effected by pipings inserted under handlights in sandy soil, kept moist, close, and shaded till rooted.

I agree with "SINGLE-HANDED" respecting raising plants from seed to secure a profusion of flowers, as they afford a far more pleasing display than florists' varieties, needing no cultured taste to appreciate them, and where display is a chief object the result is very satisfactory. It is, however, of primary importance that the seed be of a good strain, saved from the finest varieties only, and then the result with ordinary care will please all.

No enthusiast, or grower of Pansies, Pinks, Carnations, or Auriculas looks forward with greater interest to the blooming of the named varieties than to that of the many seedlings which he calculates will enable him to add one or more varieties superior in some respect to his other beauties. There is no raiser of plants from seed but will sooner or later come to making comparisons, and in the end selections, discarding the small ill-shaped flower for that most in accord with advancing taste regarding excellence of form, purity, distinctness, and brilliancy of colour and substance. The liking for Dog Roses will result in beds of glowing Hybrid Perpetuals and lovely Tea Roses; the beautiful wild Heartsease will be supplanted by superb Pansies, and the modest Violets give place to enlarged forms of improved fragrance.

"SINGLE-HANDED'S" meaning, I think, has been and still is misunderstood. His object was to show that it is practically impossible to follow the florists and have a display of flowers gratifying those uneducated in the florist's art. Those with an ardent love for flowers, and desiring them in variable profusion, would not seek for varieties that are notable only on the exhibition stand, where everybody admires them, when a much less expenditure in less refined plants would give them an abundance of flowers that would make their gardens gay and useful. There is no comparison of a garden Rose with an exhibition one; they are viewed from two different standpoints. Blooms of an Austrian Briar placed in comparison with Maréchal Niel would be ludicrous, and such, I must confess, are some of the inferences drawn by "SINGLE HANDED" from comparisons of single with double flowers. Single flowers as a rule are of brief duration, double flowers on the other hand are much more durable.

There is one thing that says much for single flowers—viz., they are just now fashionable. Yet, however much we may and do admire them, there is no need to imitate Nature in gardens other than to bring together such of her best and varied forms as will render them interesting and enjoyable to all beholders. A garden of double flowers would not please even a florist, much less a lover of flowers. There would be too much similarity. No

one has a keener perception for the beautiful than the florist, and he holds to his particular fancy uninfluenced by the search for novelty, which mostly constitutes fashion and commands popularity. Wherever there is beauty that can be rendered permanent by careful selection, and judicious crossing or breeding result in improvement, no pains or sacrifice are considered too great to secure the object in view. If the florist has spoiled any flower—I know not any—it certainly has not been in making a Daisy double or in giving a Chrysanthemum its incurved petals. The florist must have beauty up to or approaching some standard, transforming anthers into petals, giving fulness in place of sparseness, beauty instead of deformity. It is just the same with cultivators: whatever is grown is desired to be of the best, and every effort is put forth to improve the plant and flower. Some seek it by beginning with florists' varieties, and fail because they have not counted on such needing particular care and special treatment. Yet some enthusiast will take to the higher forms at once and prove successful, because failure only spurs him on to greater efforts. Violent contrast and glaring flower beds are all that are needed to satisfy some; heterogeneous masses, lavish in their floral wealth, gratify others; whilst a few go in for a little of everything, and have nothing at all from a cultural point of view.—G. ABBEY.

#### THE BEST TOMATOES.

AS soon as any plant, fruit, or vegetable becomes popular we have numbers of what are termed new and improved varieties of them. Sometimes there are good grounds for claims of the kind, but quite as often there are none. Many examples could be given to prove the truth of this, and amongst others the Tomato. The varieties of this we now possess are astonishing, their names might be given by the score, and those who desire only to grow the best must have much difficulty in making their choice. Nearly every year we take some popular class in hand to try for our own guidance and satisfaction, and this season we selected Tomatoes for trial.

Seed was obtained under thirty-six different names. Some of these which we knew to be good were grown as an early batch against the back wall of a lean-to vinery, a Pine stove, and in a Cucumber house; they were planted side by side in good loam mixed with cow dung. The plants were raised at the same time, and they were all planted out together and given the same chance in every way. Amongst them were many American varieties and some new sorts which were said to be distinct crosses. From these seedlings we expected much and obtained least, as not one of them really combined the qualities of both parents. Selected sorts are mostly the best, and the American kinds, although numerous, are certainly very diverse.

In making our selection we had two or three points prominently in view. The chief of these are productiveness, size, shape, and early maturity. Some varieties began to bloom and form fruit before they were many inches high, others extended considerably, and one named the French Free never had any fruit. Another one from America named Grape Shot turned out to be the Cape Gooseberry, and this was an agreeable substitute for the small Tomato we expected to see.

Amongst others, we had one from Mr. D. Thomson of Drumlanrig, and this we consider the best of all. It is very early, very fruitful, of fine size, and extra flavour. It somewhat resembles Stamfordian, but is far more fruitful than that variety. In weight it varies from 10 ozs. to 1 lb. It is a very robust grower and fruits at every joint, and it succeeds almost as well in a pot as planted out. When better known this variety will be sure to be much grown. Mr. Thomson does not call it a hybrid of his own, but a selection from Exeelsior, and it is much superior to that variety.

Next to the Drumlanrig Tomato we prefer Crossling's Glamorgan, which is a most abundant bearer of finely coloured well-flavoured fruit. It is more ribbed than the former and flatter in shape, and as a kind to grow for market it has much to recommend it. Another from Mr. Coleman of Eastnor bears a strong likeness to the Glamorgan in every way. Canadian Victor is a smooth red we are well pleased with. Acme is also a pretty fruiter, but it lacks flavour as most of its colour do, such as Vick's Criterion, Fiji Island, and others. Trophy is fairly good, much in the Glamorgan style, but not to be compared with it. Essex Hybrid is prolific, but is not a large fruiter.

Amongst the small ornamental kinds Carter's Red Currant is attractive. Its berries are about the size of large green peas, and fifty or sixty of these are produced on each bunch. For pots this variety would be most ornamental. Yellow Plum is another prolific ornamental variety. Its fruits are about the size of pigeons' eggs, and are produced in bunches of about a dozen

close together on the stem. These, too, among the small forms are what we have selected for future culture, and the Drumlanrig and Glamorgan are our large kinds. So decidedly superior are these four to the others that we do not consider the remainder worth further trial; but apart from usefulness, some growers attach considerable importance to variety in form and colour, and as a yellow Tomato Carter's Green Gage is noteworthy. This is a prolific high-flavoured variety, and may be added as a fifth to those we have chosen. Yellow Trophy of the same colour is much inferior, and Yellow Cherry is not so good as Yellow Plum. General Grant has been poor with us, and it appears to be small. Stamfordian fruits too sparingly to please us, and many of the fruit have holes in the centre. This is great blemish in any Tomato fruit, and should always be avoided in selecting fruit from which to save seed.

Few seeds are more easily saved than that of the Tomato, as it is quite ripe as soon as the fruit is ready for eating, and can easily be removed before cooking. Perhaps it may be as well to remark, that most of the kinds we have grown under glass have also been planted against the wall in the open air, and the results corresponded with those under glass.—J. MUIR, *Margam*.

#### ANTHURIUM SCHERTZERIANUM.

UNLESS potted in much too close and heavy soil this popular stove plant thrives fairly well; but we think even the orthodox mixture of fibry peat and charcoal too close for first-class results. To be sure, if the peat be fibry enough, and plenty of charcoal or crocks be added, and the plant is not overpotted and is carefully watered, very satisfactory success will attend the cultivator if the other necessary conditions—heat and cleanliness—be ensured. But we would recommend a mixture of sphagnum and charcoal alone. It is perfectly evident that in its native home it does not bury its roots in soil, but is a true epiphyte, the roots of which delight in moist air such as exists among growing mosses. It is, in fact, very much of the nature of an epiphytal Orchid, the roots of which will thrive and find sustenance enough in air alone if moist. Such conditions may not be very easily imitated, but a porous potful of clean fresh sphagnum and charcoal alone offers a medium in which Anthuriums thrive surprisingly.

Half filling the pots with crocks we consider a mistake. Ample drainage is decidedly necessary, for stagnant water is sure to cause the roots to decay, and then sickly plants must result. At the same time we recommend filling the pot with moss and charcoal from the bottom, with the exception of a concave crock over the drainage hole. When the pots are half, or even one-fourth, filled with crocks the best roots are starved, for to the bottoms of the pots the best roots go, and when they are there they should find something to live on. I can fancy some one exclaiming that there cannot be much in sphagnum, and perhaps there is not; but quite as much in fibry peat, so long as it remains fibry, and when it ceases to be so it is worse than useless.

A more generous diet assists them, however, as we have proved. This should not be in a substantial form, such as loam or other soil, but should be conveyed to the roots of the plants by means of water. We are learning now that a soil for plants in pots if mechanically right is very easily made chemically right, and that soil in pots, however generous to begin with, speedily has its good qualities exhausted by the plants or washed out by repeated waterings, and needs continual replacement by means of water. We like pots well filled with roots, for then we can keep the pots always moist with water tainted, and no more, with manure. We are never sure of not doing mischief with watering when small plants are in large pots, but it is quite different with large plants in small pots. When our Anthuriums fill their pots with roots we do not shift the plants, as some do, unless that be an absolute necessity; but we taint the water with sewage, which is as good and cheaper than guano, and we find the result to be a magnificent growth such as the plants never attained under the orthodox treatment. This being so, we certainly advise your readers to try the system here indicated. If the result sets neighbours asking questions a service will be done them if they are referred to this number of the Journal. We may add that the new Anthurium Andreanum will grow in a stove under the above treatment. We have seen several such plants under "Orchid Culture."—SINGLE-HANDED.

MUSTARD V. THE TURNIP FLY.—In many gardens, and still more farms this year, I noticed a second sowing had to be made owing to the ravages of the Turnip fly (*Haltica nemorum*, or more properly *Phyllotreta nemorum*), and this applies to the whole Cruciferæ family, entailing loss of time, money and crops.

The usual remedy is dusting with slaked lime, sulphur, or both; road dust, soot, or drawing a tarred or oiled cloth over the plants to catch the ravenous black larvæ when they leap upwards. I noticed in a market garden to-day what was to me a novel remedy, though it may not be new to all your readers—a central line of Mustard, with seedling Cabbages, Cauliflowers, and Broccoli on one side, and various Turnips on the other, all without a leaf touched. I understand this is a perfect remedy.—W. J. M., *Clonmel*.

#### CHOICE PEACHES AND NECTARINES.

NEARLY all those who grow Peaches and Nectarines are anxious to know what are the best early varieties. Ours are grown in pots in a good orchard house, and they have succeeded remarkably well this year. Alexander is certainly the best early Peach; next to it is Amsden June—both American-raised varieties. Alexander is the better of the two. The fruit is larger and quite of as good quality as that of Amsden June. They ripened together in the same position. They both produce better fruit than Early Beatrice, and were a few days earlier; but I ought to say that the tree of Early Beatrice did not occupy quite such a good position. Goshawk (Rivers) is a very good late Peach, bearing some resemblance to Barrington, but earlier; the fruit is of large size and excellent quality. Lord Napier is the best early Nectarine—no other ought to be named beside it. The fruit is of the largest size, the best quality, and is the earliest good Nectarine. Stanwick Elruge is also a splendid, richly flavoured, highly coloured variety, ripening before Violette Hâtive or Elruge. It should be grown in the most select collections.—J. DOUGLAS.

#### THE PROPAGATION OF CONIFERS.

(Continued from page 216.)

IN addition to the large number of Conifers raised by cuttings thousands are annually propagated by means of grafting. The extent to which this operation is carried out in large nurseries where Conifers are a speciality would surprise those who have no knowledge of such work; but the most surprising part of all, when the work is judiciously performed, is the small number of deaths that follow. Successful results mainly depend upon proper accommodation for treating the plants after they are grafted and after they leave the propagating house. The Conifers grafted are principally new and choice varieties. Whether they succeed better on their own roots or when grafted it is not the object of these notes to consider; but one thing is certain, that delicate-growing kinds are considerably improved when worked on strong-growing stocks. By grafting, a stock of young plants can be raised more quickly than by cuttings, for if propagation by cuttings only were adopted a considerable time would elapse before plants are sufficiently developed to give many cuttings. The portions of growth employed for scions can be much smaller, and in consequence a good stock is raised in less time.

Before the operation of grafting is performed considerable labour is entailed in preparing the stocks. Generally they are established in 3 or 4-inch pots. The stocks are potted any time during the winter and spring as opportunities present themselves—for instance, during wet or bad weather, when it is impossible to proceed with outdoor work. The plants selected for the stocks are not the most handsome specimens, because those generally are selected that are not likely to become symmetrical plants; but they must be free and healthy. One or two crocks are placed at the bottom of each pot, and the stocks are potted in a soil consisting of good loam, a portion of decayed manure, and a little red or river sand. As the stocks are potted they are placed outside and plunged, covering the pots with soil, or they are placed on hard beds and the spaces filled in between and over the top of the pots with spent tan, ashes, or any material that may be at hand. They remain in this position through the summer until required about this season of the year for grafting. The only attention they need is to give them plenty of water, the object in plunging being only to save labour in this respect.

The stock usually employed is *Cupressus Lawsoniana* for *C. L. lutea*, and *lutea aurea*, *C. pyramidalis alba*, *p. argentea*, *p. sulphurea*, and other choice kinds. Choice Junipers, such as *J. chinensis aurea*, *J. japonica albo-variegata*, *J. japonica aurea*, and others are worked on the common *J. chinensis*. Many of the Golden and choice Yews are worked on the common English Yew, *Taxus baccata*. The choice and Golden Thujas are worked on *Thuia occidentalis*, others on *T. gigantea* and *T. orientalis*. *Thuiaopsis borcalis* is used for *T. b. aurea*, *T. argentea variegata*, and the variegated form of *T. dolabrata*. The common and strong-growing *Retinosporas* serve for the rare and more beautiful varieties.

*Wellingtonia gigantea*, which is raised in quantity from seed, is used for *W. pendula* and the variegated form of *W. gigantea*. The same system is carried out with other classes not mentioned, but an idea may be formed of the variety of stocks employed.

When the grafting time arrives the stocks are carried into the Coniferæ house to be worked, and as soon as the operation is completed the plants are placed in the frame and kept close for a time. Before grafting and as the work proceeds the stocks are trimmed clean at the bottom and the tops are frequently cut off; the side branches of the Yews are also well shortened to allow the plants to stand close together after they are grafted. The mode of grafting adopted is that known as side-grafting. The cut on the stock is made in a downward direction to the pot about three-quarters of an inch in length, leaving in removing this portion a small ledge or angle for the base of the scion to rest in. The scion must be cut clean so as to fit well the cut on the stock, and be made secure by means of worsted, no clay nor wax being necessary. The size of the scion employed greatly depends upon circumstances. If the stock of plants is limited very small pieces are generally used. Although the large scions when established make finer plants by planting-out time it would be unwise to have the scions too large, and as a rule they never exceed if equal those used for cuttings. Any of the side growths are suitable for scions providing they have every appearance of afterwards becoming good plants. The treatment of these plants while in the propagating frame consists of watering and dewing them frequently with the syringe. After the frames are kept close for a time the lights are lifted at night and replaced in the morning. This treatment is continued until the stock and scion are united when the lights have been finally removed, and if favourable a little air is given to prepare the plants for removal.

The time of removing the plants very much depends upon what is required to take their place in the propagating house. If wanted for starting any other plants the Conifers are removed directly the stock and scion are thoroughly united and the plants have been prepared for their new quarters. I have seen thousands removed and die by scores afterwards; no fault could be attached either to the grafter or to those in whose charge they were placed. The question may reasonably be asked, What was the cause of death? The answer is, The want of proper accommodation and convenience to give the plants the attention they needed. In a large Coniferæ-growing establishment I have seen hundreds of plants die through being placed in low cold pits instead of having a little heat and encouraged until the severe weather was past. A number of low span-roofed houses were afterwards built with a bed on each side 3 to 4 feet wide, and a narrow path down the centre with a flow and return 3-inch hot-water pipe. These were capital houses, and could not have been better adapted to the convenience of the plants. The rate of deaths decreased considerably when a little heat was given. A temperature of 40° to 45° when the plants are first removed from the propagating house is suitable, and afterwards only sufficient to exclude frost. After the month of March artificial heat is unnecessary.—W. BARDNEY.

(To be continued.)

#### A COTTAGERS' HORTICULTURAL SOCIETY.

PROBABLY in but few districts do the cottagers receive greater encouragement to cultivate vegetables, fruits, and flowers than do those in the district round Mells, near Frome, Somerset. This is mainly due to the exertions of the Rev. G. W. Horner and Dr. Terry, the latter acting in the capacity of Secretary. The village on the annual exhibition day assumes a gay holiday appearance, and the large rectory barn where the Show is held is invariably thronged with appreciative visitors. As a consequence of this encouragement the cottagers are becoming quite proficient in vegetable and flower culture, and grow varieties of known excellence—in marked contrast to those in other districts where no similar stimulants to exertions are given. A collection of six varieties of vegetables, staged by James Daniels, consisting of Ne Plus Ultra Peas, Veitch's Autumn Giant Cauliflowers, Suttons' Reading Onions, Snowball Turnips, James' Intermediate Carrots and Parsnips, would have made its mark at the great Manchester Show. Better Parsnips were never shown. Other exhibitors also staged capital vegetables. Next in importance to the classes for collections were those for Potatoes, and here the awards of competent judges on previous occasions have resulted in the gradual extinction of such uncertain varieties as Early Rose, Climax, Prolifics and Flukes, and the widespread cultivation of such superior varieties as Myatt's Ashleaf, Schoolmaster, and Magnum Bonum. There were abundant specimens of these staged equal to any we have seen elsewhere. Onions, Cabbages, Parsnips, Turnips, Beet, Marrows, Pumpkins, and Beans were all well represented. A few very good dishes of Apples and Plums were staged, and nosegays of garden and wild flowers were exhibited extensively, and in a few instances were tastefully arranged.

In addition to the cottagers' plants a large group of flowering and

fine-foliage plants was tastefully arranged by Mr. Tickle, gardener to the Rev. G. W. Horner, and the same exhibitor also filled a table with a generally good collection of vegetables. Mr. T. Wheeler, gardener to G. Walters, Esq., Wadbury, brought a basket of well-grown Muscat of Alexandria and Black Hamburgh Grapes, and a dish of highly coloured Peaches. At the conclusion of their labours the Judges were requested to write in a book their opinions upon the various exhibits, and to make suggestions for the guidance of the Secretary and exhibitors, this being read to the latter the next evening when the prizes were presented. This is decidedly worthy of imitation by other societies.—W. I.

#### CLETHRA ALNIFOLIA.

WHEN this dwarf hardy summer-flowering shrub is blooming freely, as it was seen in Mr. Van Geert's collection in August, it is extremely attractive. Spikes of flowers, many of them much larger than those shown in the engraving, are produced from every axil; indeed so freely were the flowers produced that the low bushes bristled with them. They are creamy white in colour,

Fig. 44.—*Clethra alnifolia*.

delicately fragrant, and, associated with the fresh-looking light green foliage, are admirably adapted for vase decoration. Being a native of the swamps of Virginia it requires moist, deep, and tolerably rich soil. The soil in which it was succeeding so well was a light, free-working, and rather sandy loam. It is worthy of a suitable position in the front of shrubberies, or even in large borders of herbaceous plants that are grown for affording flowers for cutting. It is deciduous, quite hardy, and was introduced in 1731. It is of close and rather compact habit, and grows about 3 feet high.

#### LATE VEGETABLE MARROWS.

PLANTS of these which have been fruiting for some months are now becoming exhausted. The fruit which formed early is

fully grown, and more than likely too old for use, and so long as these are on the plants few young fruits will ever swell to a useful size after this time. For some years past we have cut every old fruit from our Vegetable Marrow plants about the middle of September, and after that they appear to take fresh life, as they bloom freely and form many fruit, which can be had in the most delicate state during October and sometimes in November. At the present time we have a stock of young Vegetable Marrows coming on our plants, as if it was the month of July, and all we do to secure them is, as we have said, removing all old fruits. Those who have not tried this plan should do so at once, and they will be more than satisfied with the result before many weeks are past.—J. MUIR.

### A WEEK IN BELGIUM.

[THE SECOND DAY.]

THIS was the Show day at Antwerp, or rather the day of preparations, for all great events open on Sundays in Belgium. We shall never have time in England for preparing so deliberately for a show as they do "over the water." With us all is hurry, rush, and work; with them it is steady yet thorough enjoyment. This is in brief the routine: We first sip wine for two hours until the jurymen are ready, or the plants are ready for examination; then we work for two hours very pleasantly, then engage in luncheon for two or three hours more, and afterwards—but this unofficially—retire to the outside of a café and drink coffee from glasses. This latter practice is quite an institution, and originated with a detachment of the French army which found itself in a position where coffee was plentiful but cups scarce; glasses were, however, within reach, and the coffee was so much enjoyed in them that the custom became established. By the way, I could not help fancying that had we so fixed ourselves in London and all the foot passengers had to step into the road to pass on their way, that some officious personage might have considered we were obstructing the footpath. But they are not so particular in Antwerp, at least in some parts of it where the streets are wide; and as for the cafés, they appear to be under much less restrictions than our taverns, for they can keep open for a week if they like, and gentle and simple mix together in them, classism being decidedly less pronounced there than here. After the show comes the banquet, at which there is a pleasant gathering of horticulturists, and laudatory speeches elicit responsive "bravos," which are at least as euphonious as our jerky English "hear hears," especially when they degenerate into "yaw yaws," as they do in some assemblies. Such is a slight sketch of the proceedings in connection with a Belgian show, and if those Britishers who are there are not happy it is certainly not the fault of their hospitable hosts and ever-courteous friends.

It has been said that the work in show preparation is more deliberate in Belgium than here, yet undoubtedly someone must labour diligently; this is generally the secretary, and in connection with the Exhibition in question Mr. Van der Linden, who occupied that position, worked so assiduously that the result was utter prostration on a bed of sickness. The labour and the worry of the working officials of shows generally are greater than the outside public have any idea of, as many a secretary and manager in this country knows to his cost, the last being Mr. Bruce Findlay. Let, therefore, no one be unduly severe in their criticism of these public servants if every detail is not perfect, but rather let them be judged by the general results and on a broad and liberal basis. In Belgium military aid is rendered at the horticultural exhibitions. A detachment from the army is placed at the disposal of the "architect" who arranges the plants, and the soldiers, trained to obedience, are found very tractable and useful helpers. Soldiers, too, guard all the doors, and generally perform the duties that policemen do with us, these being mostly, and happily, of an ornamental character.

"Are the shows crowded with visitors?" is a question that has been frequently asked of me. I must answer in the negative, subject to one important qualification. If the Royal Family visit a show in England the public flock there, and it is the same in Belgium, only there Royal patronage is more readily granted than it is here. If the exhibitions are not attended by Royalty there is abundance of room for the plants to be examined without the crowding that is seen at a national Rose show or at a Manchester Whitsuntide fête. The continental societies are, however, pretty well independent of "gate money," and the chief object of the exhibitions appear to be to afford means for the intercommunion of friends and the advancement of commercial horticulture, which is such an important industry of the nation.

We now take a stroll through the town and suburbs—not, however, this time entering either the churches, many of which are so

beautiful, the celebrated cathedral, or the museum, which contain the masterpieces of Rubens and others of the celebrated old Flemish painters—but to look at the trees, shrubs, and flowers. The winters in Belgium during the past three years have been very intense—quite as severe as with us, judging by results, for many of the Planes in the boulevards have been injured, while all the Hollies and nearly all the Rhododendrons in gardens and nurseries have been killed to the ground. One of the finest specimens in Europe of the Umbrella Pine (*Sciadopitys verticillata*) in the Zoological Gardens was unfortunately destroyed last winter, though it is gratifying to notice that Japanese shrubs and Conifers have generally passed through the winter with impunity. The Golden Catalpa is freely employed in ornamental planting and is highly effective, the trees being pollarded annually like Willows; the result is round-headed trees with fine golden leaves. This is the best plan also of treating the Golden Elder, and also, as will be hereafter shown, of managing that grand shrubby ornament *Hydrangea paniculata grandiflora*. Carpet bedding is extending, and some of it is good; but there is a lack of that high finish that is apparent in the London parks. The *Alternantheras*, however, were brilliant in colour; and the Golden *Spergula* (*S. pilifera aurca*) formed a more close and satisfactory bright golden carpet than can be produced either by the Golden Feather or Golden Chickweed, and carpet-bedders might well try this plant in England. It was introduced by Mr. Charles Van Geert, and has been exhibited by Messrs. Veitch; but a few plants in pots afford slight index of its appearance as seen established in lines and panels.

Now a glance at domestic floriculture. Famous as Belgium is for its nurseries, and great as is the horticultural industry of the kingdom, the Belgians as a body do not appear to be a flower-loving people to anything like the extent the English are. There is none of that beautiful window-sill gardening in Antwerp that is growing so rapidly with us, and that forms such an attractive feature in many suburban thoroughfares and country homes; while window plants there, which are almost exclusively Palms, are only seen in hotels and the homes of the well-to-do classes, the working population not indulging in the luxury of plants nearly to the same extent that is apparent in England. The plants offered in the markets, too, are immeasurably inferior to those splendid examples of culture that are provided in millions for the adornment of British homes. The purchasing power of the operative classes in Belgium is much less than in England, and there is possibly nothing left for luxuries, or if there is it is certainly not expended in plants and flowers. As a rule the ordinary workers in nurseries and gardens receive about two francs (1s. 8d.) a day from 6 A.M. to 8 P.M., the women earning about a penny an hour. Mr. Van Geert, however, has long tried the experiment of having no fixed scale in his nurseries, but payment is governed by results; his men are thus encouraged to make their services as valuable as possible, knowing they will receive a just reward. It is gratifying to learn that this plan answers admirably and proves mutually advantageous.

As the "second day" was brought to a close in the establishment just alluded to it may be appropriately, if briefly, described. It is not a large nursery—not indeed so large as formerly, but a visit under the guidance of the experienced proprietor and his skilled son and coadjutor is both pleasant and instructive. It was once outside the fortifications, but is now within those formidable lines, and the pressure of builders has been irresistible—hence the reduction of this and the establishment of a country nursery. It is as much like a trial ground or a small botanical garden as a nursery, the owner having for his own pleasure collections of various plants, and has spent a long life in conducting experiments in culture and instituting comparisons and making selections of various plants; for instance, all the *Ceanothuses* he could obtain have been recently tried, and now all are discarded but three—namely, *Gloire de Versailles*, blue; *Marie Simon*, pink; and *Nivens*, white. These having been proved to be of sterling worth are propagated largely, and beautiful they are for beds, borders, or walls. The former is better known in England than the two latter, which are particularly chaste, their elegant clusters of flowers being admirably adapted for vase decoration. Many beautiful variegated trees and shrubs, also ornamental Japanese plants, are grown. An Elm (*Ulmus media alba-marginata*) is as striking in the distance as the Variegated Maple, the white so greatly predominating and so pure. The tree is of free growth, with large leaves, and cannot fail to form a conspicuous object in shrubberies and ornamental plantations. Variegated *Weigelas* form bright fringes to larger trees, and *Philadelphus coronarius variegatus* is very clearly margined with white, and would have a fine effect in shrubberies. The Golden Box, for edgings and as dwarf plants for balconies or the margin of shrubberies, is not

only very bright but has, somewhat unexpectedly, been less injured by the extreme frost than any other variety. Hardy Ericas, a fine collection; the best varieties of hardy Azaleas, rare and choice shrubs and Conifers, Clematises, and aquatics, are all represented here.

Very striking are some ornamental Japanese plants that, since their hardiness has been proved, will impart a fine feature to shrubberies. Among them are *Rhus Osbecki*, a native of China and also of Japan. It flowered here last year as a small tree, about 7 feet high; the flowers were produced at the top of the stem in the middle of a crown of foliage, and looked like an immense bouquet of *Spiraea arifolia* 2 to 3 feet diameter. Such a mass of white feathery plumes in contrast with the grand foliage must have had a fine effect, but even when not in flower the plants are highly ornamental. *Rhus juglandifolia* is perhaps still more striking in growth and foliage. The leaves are of great size, somewhat resembling those of the Walnut, as the name implies, but far larger and finer. It was received as a new introduction from Japan, and is certainly of noble appearance, and is a plant or tree of great promise. *Phellodendron amurense* is also of remarkable appearance. It is described by Ruprecht in Koch's "Dendrologie" as a native of Amur in North Asia. In leaves and growth it has some resemblance to *Rhus juglandifolia*, although it belongs to another family—*Rutaceae*. Of its flowers and height Mr. Van Geert knows nothing, but its foliage is certainly magnificent. *Aralia Maximowiczii* is distinct and fine, the leaves being large, deeply lobed, and of a reddish-brown hue changing to dark red, and will be valuable for many decorative purposes. It is new, and I understand it was first sent by Maximowicz from Amur to Dr. Regel of St. Petersburg. When it is remembered that these plants were uninjured last winter where all the Hollies surrounding them were killed their value is enhanced, and they must be regarded as valuable acquisitions highly worthy of the notice of cultivators. Two dwarf flowering shrubs also deserve notice—*Clethra alnifolia* and *Hydrangea involucrata vera*, sprays of which are figured in another column. Both were very attractive, the latter being highly distinct and seldom seen.

Hardy Hibiscuses appear popular, and certainly few if any summer and autumn-flowering shrubs can equal them. A blue, *H. syriacus cœlestis*, is now added to the red, rose, and white varieties, and is an acquisition; but all the colours are beautiful, and the shrubs under favourable conditions flower in quite a small state. Belgium is not a Grape-growing country, yet there is a fine collection of Vines in this nursery. They are not grown in pots but planted out, some in baskets to facilitate removal, and the splendid canes indicate how well the soil is adapted for Vines, and if the same attention and skill were devoted to their culture under glass as in England superior produce could not fail to be obtained. Possibly Mr. Van Geert is working on the principle that supply creates a demand, for certainly he has an extensive collection of Vines carefully selected and well cultivated.

The glass structures and pits are tolerably extensive. A fine curvilinear house about 120 feet long by 20 feet wide has been recently completed, and is wholly occupied with Palms. Grand specimens of *Corypha australis* and *Latania borbonica* occupy the centre, and small healthy portable specimens of all the more useful kinds are represented in thousands. As much care is taken in sponging the plants and keeping them clean and healthy as is devoted to choice Orchids in this country. Other houses of the same length are filled with Camellias, and brick pits are devoted to these plants, many of which are planted out. These pits are not heated, but the glass is covered with protecting material in the winter. Pits of a similar character are devoted to the raising of Conifers and choice evergreens, for which this nursery has long been famed.

Large numbers of Camellias in bud are arranged under and amongst Lombardy Poplars, and so have the shade that is found essential for producing rich green foliage; and a very enjoyable arcade of Hornbeam accommodates groups of plants ready for export to England and other countries. This arbour is about 100 yards long and nearly 3 wide. The trees have been planted 6 feet apart, three branches trained from each tree, the spring of the arch being about 9 feet from the ground, and the apex 3 to 4 feet higher. There are side openings between the trees 3 feet wide, and the whole is ornamental, useful, and enjoyable. The branches, it should be said, have been trained with great precision and regularity, indicating that much care has been exercised in completing the work.

A great number of handsome Bays in tubs break the level appearance of the nursery, and colour is imparted by Clematises and Liliams. The "best of everything" is evidently the motto of the establishment, and is even carried out in the Willows grown for securing packages, for all the best were tried, and *Salix*

*uralensis* showed its decided superiority, and is now exclusively cultivated; it produces annual growths 10 feet in length, slender, and extremely tough and pliable. It is so manifestly good and useful that it is named here for the benefit of those who employ Willows largely during the planting season.

The whole establishment is clean and orderly, but it is in a great measure only the propagating ground of Mr. Van Geert's much larger nursery at Calmpthout, at which a day was spent profitably and pleasurably.—J. WRIGHT.

### PRODUCE OF POTATOES.

I HAVE much pleasure in forwarding you the enclosed, and if it is likely to be of sufficient interest to any of the readers of your excellent Journal it is at your service. I have still twenty-two sets to lift, but they will not be fit for a month or five weeks.—A. TITE, *The Vicarage, Thornton Steward*.

POTATOES PLANTED MARCH 30TH, 1881, LIFTED SEPTEMBER 8TH, 1881.

### BRIGHTON HORTICULTURAL SOCIETY.

THERE was not a large number of plants at the Exhibition held on the 14th and 15th inst., and without some of the leading local nurserymen both the competition and the display would have been poor. As regards quality, however, most of the collections were very satisfactory. Fruit we have also seen more largely represented there at previous shows; and though some of the black Grapes were good, of fair size, and well finished, there were no examples of special merit. Peaches, Nectarines, Apples, and Pears were numerous, and in several cases very creditable to their exhibitors.

*Plants*.—Some groups and collections were staged in the handsome apartments of the Pavilion, but the majority was arranged in a long marquee in the grounds. One of the chief classes was that for a group of plants arranged for effect in a space not exceeding 150 square feet. Two competitors appeared—namely, Mr. W. Balchin, Western Road, Brighton, and Mr. W. Miles, Cliftonville, the former being successful in securing the leading prize, the Ashbury cup, valued six and a half guineas, which was offered by James Ashbury, Esq. This group consisted chiefly of neat specimen fine-foliage plants, including Palms, Ferns, Crotons, Dracænas, and Coleuses, several well-grown examples of Liliams contributing to the brightness of the collection with other flowering plants, edged with Selaginellas and Adiantums. Mr. Miles was placed second with a group arranged in a very similar manner—in fact there was little difference in the relative merits of the two collections. In the Sussex amateurs' and gardeners' division of the schedule a similar class was provided, the first prize in that also being a silver cup value five guineas. Three groups were staged, the chief honours being secured by Mr. Meachen, gardener to C. Armstrong, Esq., Withdeane, who had a neat arrangement of Crotons, Lilies, Ixoras, Marantas, Pelargoniums, Ferns, and Coleuses, a fine specimen *Yucca aloifolia variegata* at the back being noticeable, and near the fore part of the group was a plant of the pretty Orchid *Vanda cœrulea*, bearing over a dozen large and delicately tinted flowers. Mr. Turner, gardener to Major Wray, followed very closely with a pretty group, in which double Tuberoses were freely employed and with excellent effect. Mr. Howick, gardener to A. Granville Uttermare, Esq., Withdeane House, took the third position with a bright arrangement, but a little too flat.

For eight stove and greenhouse plants in the open class Mr. Balchin carried off the chief prize, having amongst others good specimens of *Erica cerinthoides carinata* and *Statice imbricata*, the latter being extremely fine with abundance of flowers. Mr. Huggett, gardener to D. Jeffery, Esq., Eastbourne, followed, his most noteworthy plant

being a specimen of *Swainsonia galegifolia alba* flowering excellently. In the class for four stove or greenhouse plants Mr. Gilbert of Hastings was worthily adjudged the leading position for admirably grown plants in first-rate condition. *Vallota purpurea* with over a dozen trusses of flowers was particularly fine, and was greatly admired. Another notable plant was *Erica turgida* with abundance of its long tubular flowers. Mr. Miles and Mr. Townshend, gardener to Capt. Thompson, Withdeane, carried off the other prizes in the class, both showing fairly well.

Fine-foliage plants were well represented in the open class for eight varieties, J. Warren, Esq., Handcross Park, Sussex, being the most successful exhibitor, taking the premier position with handsome specimens of *Cycas revoluta*, *Croton Hendersonii*, *C. undulatus*, *C. interruptus*, *Encephalartos villosus*, several *Gleichenias*, and a grand example of *Dicksonia squarrosa*, which was tilted sufficiently to show the magnificent crown of fronds to the best advantage. Mr. Balchin was a good second, his most remarkable plant being a *Musa Ensete* 12 or 14 feet high. Mr. Miles secured the third position with fine specimens of *Chamædorea elegans* and *Encephalartos villosus* amongst others. In the Sussex classes for fine-foliage plants Messrs. Meachen, Howick, and Townshend carried off the chief prizes with healthy well-grown specimens. In the long marquee other noticeable exhibits were the *Pelargoniums* and *Fuchsias*, the former being fairly bright, but neither call for special comment.

Cut flowers were numerous, the Dahlias forming the chief feature in the display. The principal exhibitors were Messrs. Keynes & Co. of Salisbury, who held the leading positions in all the classes they entered. The blooms were of excellent form and the colours clear and bright, a large number of the best Show and Fancy varieties being represented. Mr. W. Seale of Sevenoaks followed in most of the classes, showing blooms of great size and fine colours. Roses were contributed by Messrs. Paul & Son, Cheshunt; Mitchell & Son, Piltown, Uckfield; A. Slaughter, Steyning; and Seale, who exhibited very creditable blooms for such a late period of the season. Asters were similarly well represented by collections from Mr. Allfrey, gardener to Miss Nevill, and Mr. Morgan, gardener to Major Scott, Reigate, who secured the chief prizes. Bouquets, wreaths, and table decorations occupied considerable space in one of the Pavilion apartments. Messrs. Miles, Balchin, W. Brown of Richmond, Surrey, and Seale being the principal prizetakers.

*Fruit*.—The most important class in the open section was that for a collection of twelve dishes of fruits, the prizes being the Ashbury silver cup, £2 10s., and £1 10s. The cup was well won by Mr. Rutland, gardener to the Duke of Richmond and Gordon, Goodwood, who had neat bunches of Black Alicante Grapes well coloured, *Violette Hâtive* Peaches very fine, Worcester Pearmain Apples fine colour, Dr. Hogg Melon good, Washington Plums well ripened, and Williams' Bon Chrétien Pears good, amongst several other satisfactory dishes. The second position was accorded to Mr. Fennell, gardener to E. Cazalet, Esq., Tonbridge, for a good Black Jamaica Pine Apple, Madresfield Court Grapes, fine; Jefferson Plums, Bellegarde Peaches, and Brunswick Figs also being of good quality. Mr. Goldsmith, gardener to Mrs. Lambert, Bletchingley, was third; and Mr. W. Johnston, gardener to the Marchioness of Camden, Bayham Abbey, was awarded an extra prize for a good collection. Black Grapes were fairly represented; Messrs. Johnston, Goldsmith; Osborn, Kay's nursery, Finchley; Mr. Bashford, gardener to Mrs. Douglas, Tunbridge Wells; and Mr. A. S. Hart, Dyke Road, were the prizetakers.

Peaches were well shown by Mr. Balchin, who had some good examples of Barrington; Mr. Duncan, of Warnham, and Mr. Fowler, gardener to Lady Willoughby, both staging fruits of the same variety very little inferior to the first. Fine Pears were contributed by Messrs. Rutland and Townshend, who carried off the chief prizes in the classes for culinary and dessert varieties. Among those from the former were some fine examples of Callebasse Grosse. Mr. Rutland also staged some of the best Apples.

Miscellaneous exhibits were contributed by several firms, especially by Messrs. Balchin and Miles. One of the best groups from the former was a number of plants of his new *Mignonette*, *Reseda odorata proliifera alba*, in first-rate condition; while from Mr. Miles a bright group of *Pelargonium West Brighton Gem* was very attractive. Messrs. Cheal & Son of Crawley had a number of new Melons, with boxes of cut flowers. Mr. J. Cattell, Westerham, Kent, staged a large collection of ornamental Gourds; and Messrs. Keynes & Co. staged several boxes of Dahlia blooms, including some fine new varieties, of which several were certificated, together with the following.

*Pelargonium West Brighton Gem* (Miles).—A variety which has been frequently referred to and described in these columns. On this occasion it was shown in excellent condition, the floriferousness of the plants and the brilliancy of the flowers being remarkable.

*Aquilegia formosa variegata* (Cattell).—A pretty form of Columbine with neat leaves blotched and splashed with yellow on green, and sometimes having a purplish shade. It has also been certificated at Sevenoaks this year, and is to be sent out next spring. In the specimens shown the variegation was clearly and brightly marked.

*Dahlia Florence Brown* (Keynes).—A Fancy variety with very symmetrical flowers of good depth. The ground colour is a peculiar buff shade, and is streaked with deep crimson.

*Dahlia Joseph B. Service* (Keynes).—A rich bright yellow self, of very good form and substance, but especially noteworthy the colour.

*Dahlia Miss Batchelor* (Keynes).—The bright scarlet Show variety

recently certificated at Kensington, and which was so much admired for its neatness and excellent form.

*Melons Shepherd's Perfection and Crawley Paragon* (Cheal & Son).—Two new Melons from Crawley, which have been recently shown at Kensington. The first is a large fruit with green, nearly white, flesh; the other is a scarlet-flesh variety that appears to net well.

As usual the Exhibition was held in the Pavilion and grounds, the attendance of visitors on the first day being very good, the Exhibition remaining open till a late hour, the rooms being lighted with gas and the marquee with Chinese lanterns, which produced a very beautiful effect.

WE have received from Mr. OLLERHEAD, gardener to Sir Henry Peek, Bart., a few berries of a NEW GRAPE, which bids well to supply the desideratum so long wanted of a white companion to the Black Hamburgh. The two white Grapes upon which we have relied hitherto are Buekland Sweetwater and Foster's Seedling. The former is what may be called an early variety, and does not improve by hanging; the latter, though it hangs longer, is not remarkable for excellence of flavour. Mr. Ollerhead's seedling is rich in flavour, superior to Foster's Seedling, and judging from the toughness of the skin has all the character of a good keeping Grape.

— THE remarkably handsome specimen of *VALLOTA PURPUREA*, shown at the Brighton Exhibition last week by Mr. Gilbert, well indicated the decorative value of this fine old plant when in its best condition. The four dozen trusses each included from four to six fully expanded brightly coloured flowers, and there appeared to be many other trusses coming forward. The specimen was certainly the most attractive flowering plant in the Exhibition, and was very creditable to the grower.

— MR. L. MITCHAM sends us a dish of CANADIAN WONDER BEAN GROWN IN LONDON, as his employer thinks they are worthy of notice. They are not only "worthy of notice," but of high commendation, as the pods are from 8 to 9 inches long, fleshy and crisp, and they show how admirably adapted Kidney Beans are for cultivating in town gardens.

— A CORRESPONDENT of "Vick's Illustrated Magazine" contributes the following upon COLOURING WHITE FLOWERS, which we give without comment—"A very pretty experiment is performed by putting the stem of a freshly cut Tuberose, or other white flower, into diluted scarlet ink for a short time. The liquid will be drawn up into the veins, colouring them in a very pleasant manner. It is also instructive, showing whether a plant is net-veined or paralleled-veined. A Tuberose coloured not too highly makes a very pretty novelty."

— MR. GOODACRE of Elvaston Castle has sent us a remarkably fine bunch of *VENN'S BLACK MUSCAT GRAPE*. It is large, full, and of excellent form. Berries large, uniform, highly finished, and of superior flavour. We congratulate the cultivator on his success in growing this highly flavoured Grape, which is somewhat capricious, and not often seen in such good condition as in the example now before us.

— MR. BROWN of Birkwood Gardens, N.B., sends us the following account of a large Cockseomb—"At the annual Show of the Upperward of Lanarkshire Horticultural Society, held on August 29th, Mr. Henry Syme, gardener, Ridgepark, Lanark, staged two Cockseombs for competition, the largest measuring 45 inches from tip to tip, and 16 inches over the crown, its companion being only some 2 inches less. At the same Show he ex-

hibited six plants all measuring over 40 inches. The Cockscomb is of the "Empress" strain, sent out by the Messrs. Carter & Co."

— "It is surprising," writes "W. J. M." "in how many ways VALLOTAS can be utilised for decorative purposes, and how beautiful they are when well and generously cultivated. Two-year-old bulbs," our correspondent goes on to say, "are now producing four spikes, each bearing that number of flowers. The plants are in 4½-inch pots, and placed in vases for room decoration at Summerhill. Thus grown there is no better window plant than the Vallota."

— THE September number of the American "Gardeners' Monthly" gives a woodcut illustration of a new Lily under the name of *LILIUM LONGIFLORUM FLORIBUNDUM*. It is said to have been introduced by Messrs. Kift & Sons, West Chester, and is thus described—"The flowers and foliage indicate that it has a close relationship to the form of *L. longiflorum*, recently named *L. Harrisii*. The difference is, that while that seems to produce flowers ranging from three to twelve on a stem, this one runs from that to fifty-two, the number on this one engraved. It is simply more floriferous than that one has been found to be. This arises of course from some fasciation of the stems, and its value will depend on the permanency of this fasciation. For our part we see no reason why such a character may not be permanent in plants raised from offsets, as Lilies are. If it prove so it will be an extremely valuable plant to the cut-flower grower."

— MR. WILLIAM FELL, of the firm of Messrs. W. Fell & Co., Hexham, states that he has lately seen at Hardreding, Haltwhistle, the seat of J. Armstrong, Esq., a SPIKE OF *LILIUM AURATUM* HAVING SEVENTY-FIVE FLOWERS. The stem is fasciated, and the flowers overlap each other and produce a singular effect. The gardener, Mr. Jackson, states the bulb has been in his possession for four years.

— MR. COWAN writes on POTATO CULTURE IN IRELAND:—"However small the Potato plots are, whether in fields or in vacant spots between the rocks on the mountain sides, the best is always made of the little patches. Cabbages are grown amongst the Potatoes at 15 to 20 feet from each other. These come in useful for the cows and do not interfere with the Potatoes in any way. Nearly all the Potatoes are grown on the 'lazy-bed' system, which is of great advantage in wet summers."

— IT is surprising that such an ornamental shrub as *EUONYMUS LATIFOLIUS*, which has been known in this country for about a century and a half, should have waited so many years to receive the honorary distinction of a certificate from the Royal Horticultural Society. Many must have been pleased with the recognition the shrub received on the occasion of the last meeting, when specimens were shown by the two firms—Messrs. Veitch, Chelsea, and W. Paul & Son of Waltham Cross. Nearly forty years ago Loudon wrote respecting it as follows—"In British gardens this form, much the handsomest species of the genus from its broad shining leaves and its large red pendulous fruits with orange-coloured seeds, which when the capsules open are suspended from the cells somewhat in the manner that the seeds of the Magnolias hang from their strobils. Even the wood of this species during winter is much handsomer than that of any other, the branches being regularly divaricate, with a clear bark of a reddish green, and with long pointed dark brown buds, by which alone this species may be distinguished from the others."

— A GUERNSEY correspondent sends us flower spikes of the peculiar little Orchid *PHOLIDOTA IMBRICATA*, which was described some time ago in this Journal as follows:—"The species is a native of various parts of India, in the same mountainous districts where *P. pallida* abounds—viz., Sylhet, Chittagong, &c.,

where it is found growing on the stems and branches of trees. The flowers are small, of a yellowish tinge, and are produced in dense, pendulous, slender flattened spikes, each flower being subtended by a small, brownish, acute bract, from which character the specific name is derived. The appearance of these spikes is suggestive of the *Dendrochilums*, but the flowers are devoid of the fragrance that distinguish those charming little plants. There has been some confusion in reference to *P. imbricata* and *P. pallida*, for the latter was figured and described as the former in vol. xxi. of the "Botanical Register," but the mistake was subsequently corrected, and the one originally described was named *P. pallida* from its flowers being whitish. There are also other differences between the species which are patent to the most cursory examination; for instance, the bracts in *P. pallida* are blunt, while they are acute in *P. imbricata*, and the spikes of the former are loose, whereas in the latter they are dense. The species under consideration has also the reputation of being more easily cultivated than the other."

— AT the annual Show of the Royal Manchester, Liverpool, and North Lancashire Agricultural Society, held at Blackburn last week, a silver medal was awarded to MR. J. MATTHEWS, of the Royal Pottery, Weston-super-Mare, for the best collection of vases. This is the third silver medal for his pottery Mr. Matthews has taken this year.

#### INTERNATIONAL POTATO EXHIBITION, CRYSTAL PALACE.—SEPT. 20TH AND 21ST.

IN the number and quality of the Potatoes shown the Exhibition of Tuesday and Wednesday last was unquestionably satisfactory, and though in scarcely any respect superior to that of last year, it was alike creditable to the exhibitors and the supporters of the Institution. Further, the occasion was rendered especially notable by the President, the Right Hon. the Lord Mayor of London, William McArthur, M.P., with the Sheriffs and several Aldermen, attending in state to open the Exhibition on Tuesday. His Lordship also subsequently presided at the luncheon held in the Marble Hall, when, in proposing the toast of success to the Potato Exhibition, he expressed high approval of the intentions of the promoters, and considered that the means they have adopted of encouraging Potato cultivation is likely to meet with much success.

Class A, for twenty-four varieties. Six prizes were offered, the first of ten guineas being given by Messrs. J. Carter & Co., High Holborn; the remaining five of seven guineas, five guineas, three guineas, two guineas, and one guinea, were given by the Crystal Palace Company. Thirteen collections were staged, all of good quality. The first prize was obtained by Mr. Ellington, West Row Gardens, Mildenhall, for a substantial collection of handsome even tubers, mostly of good size. The varieties were—Blanchard, Magnum Bonum, Rector of Woodstock, Bedford Prolific, Purple King, Bresee's Prolific, Trophy, Wiltshire Snowflake, Triumph, Schoolmaster, Beauty of Hebron, Covent Garden Perfection, Vicar of Laleham, Woodstock Kidney, Grampian, Mammoth Pearl, Beauty of Kent, Porter's Excelsior, Manhattan, Pride of America, Matchless, International Kidney, Early King, and Jackson's White Kidney. The second prize was obtained by Mr. W. Kerr, Dargavel, Dumfries, with clean satisfactory tubers, the following varieties being especially noteworthy—Matchless, International, Brownell's Beauty, St. Patrick, Climax, Silver Skin, Grampian, Excelsior, Triumph, Bresee's Prolific, Early Ohio, White Seedling Kidney, and Trophy. Mr. J. Lye, gardener to the Hon. Mrs. Hay, Market Lavington, was third with a very creditable collection, the tubers being chiefly of moderate size and very clean. Bountiful, White Emperor, Ruby, Matchless, Porter's Excelsior, and Breadfruit were well shown. Mr. W. Finlay, Wroxton Abbey Garden, Banbury, was fourth; Mr. J. Millen, Hamstead Park Gardens, Newbury, was fifth; and Mr. H. Gribble, gardener to the Right Hon. Sir Richard Malins, Maidenhead, was sixth.

Class B, for eighteen varieties. This class was open only to gentlemen's gardeners, the awards being made by gardeners who were not competitors; the six prizes, varying from seven to one guinea, being given by Messrs. Sutton & Sons, Reading. The premier award was secured by Mr. J. Matthews, gardener to E. Twopenny, Esq., Sittingbourne, for even and creditable samples of Vicar of Laleham, Early Goodrich, Magnum Bonum, Porter's Excelsior, Beauty of Hebron, Trophy, Reading Abbey, Woodstock Kidney, Schoolmaster, Manhattan, Holborn Favourite, Wiltshire Snowflake, Superior, Pride of America, Beauty of Kent, Pride of Ontario, Triumph, and Late

Rose. Mr. W. Crump, gardener to the Duke of Marlborough, Blenheim, was second with a collection very near the preceding in merit, his best dishes being King of Potatoes, Woodstock Kidney, Triumph, Webb's Surprise, Bedford Prolific, Edgcott Seedling, Garibaldi, and St. Patrick. Mr. J. Millen was third with neat even tubers, the best being Vicar of Laleham, Beauty of Kent, and Late Rose. Mr. James Lye secured the fourth position; Mr. W. Finlay, and Mr. J. Cooper, gardener to Col. Long, Saxmundham, being fifth and sixth.

Class C, for twelve dishes, distinct, English varieties. Six prizes were offered, the first of six guineas by Messrs. J. Carter & Co., the second of £4 10s. by Vice-President Mr. Alderman Hadley, the third of £3 10s. by Messrs. George Ure & Co., Bonnybridge, Scotland, and the fourth of £2 10s. by Messrs. Kerr & Fotheringham. The chief prize was secured by Mr. W. Ellington with a collection similar to that in class A, having good tubers of Beauty of Kent, Schoolmaster, Grampian, Vicar of Laleham, Magnum Bonum, Porter's Excelsior, Woodstock Kidney, Covent Garden Perfection, Model, Bedford Prolific, Blanchard, and Early King. Mr. W. Crump was second with fine tubers of Model, International, Radstock Beauty, Edgcott Seedling, and Porter's Excelsior. Mr. James Lye was third, Mr. John Reid fourth, Mr. James Matthews fifth, and Mr. W. Kerr sixth. There were eighteen collections, two being disqualified, one having nine American varieties.

Class D, for nine dishes of distinct American varieties. The first of the five prizes was offered by Messrs. B. R. Bliss & Sons, New York, the second by Vice-President James Abbiss, Esq., the third by Messrs. Barr & Sugden, Covent Garden, and the fourth by Mr. Ex-Sheriff Woolton, London. Mr. William Finlay easily secured the leading prize with clean handsome tubers of Trophy, Beauty of Hebron, Manhattan, Pride of Ontario, American Purple, Matchless, Superior, Early Rose, and Snowflake. Mr. William Kerr was second with tubers of moderate size. Messrs. Lott & Hart, Whitehill Nursery, Faversham, were third; Mr. W. Sedge, gardener to the Rev. J. W. Mellor, Sittingbourne, fourth; and Mr. John Reid fifth. Fourteen collections were staged, one being disqualified for containing some varieties that were not American.

Class E, for six dishes, distinct varieties. Five prizes were offered, the first by the Vice-President Peter McKinlay, Esq., the second by Vice-President L. Fawell, Esq., and the third by William Holloway, Esq., St. Paul's Churchyard. The chief position was secured by Mr. W. Finlay with very satisfactory dishes of Salmon Kidney, McKinlay's Pride, Ley's Favourite, Model, American Purple, and Edgcott Seedling. The second prize was awarded to Mr. L. Stanton, Maidford, Towcester, for very large specimens of Mammoth Pearl, Centennial, Snowflake, Trophy, Schoolmaster, and White Elephant. Mr. F. Miller was third with smaller but neater examples, his Yorkshire Hero and Vicar of Laleham being good. Mr. W. Crump was fourth, and Mr. G. Bloxham, gardener to Sir P. Duncombe, Bart., Bletchley, fifth. Thirty-one collections were staged.

Class F, for three dishes of distinct new varieties not in commerce before 1880, including one dish of Matchless. The four prizes were presented by Messrs. Hooper & Co., Covent Garden. Mr. Richard Dean, Ranelagh Road, Ealing, was first with fine examples of Mr. Bresee, Matchless, Reading Hero. Mr. William Kerr was second with Adirondack, Matchless, and Queen of the Valley. Mr. F. Miller, gardener to J. F. Friend, Esq., Margate, was third with Reading Hero, Matchless, and Beauty of Kent; and Mr. John Reid, Ayr, N.B., was fourth with Adirondack, Pride of America, and Matchless, all staging very neat examples. There were nine entries.

Class G, for three dishes of white round varieties. The first prize was given by George Wright, Esq., Falkirk, and the other three by the Amies Chemical Manure Co., 75, Mark Lane. Mr. W. Kerr was first with Climax, Schoolmaster, and an unnamed variety, all very even and of moderate size. Mr. J. Matthews was second with Porter's Excelsior, Early Goodrich, and Schoolmaster. Mr. F. Miller was third with Devonshire Plum, Silver Skin, and Schoolmaster; and Mr. W. Ellington was fourth. There were eighteen collections.

Class H, for three dishes of coloured round varieties. The first prize was offered by Mr. Richard Dean, Ealing. The chief position was obtained by Mr. W. Ellington with Vicar of Laleham, Blanchard, and Triumph. Mr. W. Kerr followed with Grampian in the place of Blanchard, the other varieties being the same. Mr. F. Miller was third with similar varieties; and the fourth prize was obtained by Mr. Gribble. Twenty dishes were staged.

Class I, for three dishes of white kidney varieties, to include a dish of Wiltshire Snowflake. Four prizes were offered by Messrs. Daniels Bros., Norwich. Mr. Richard Dean was adjudged the first position for good dishes of Advance, Pride of America, and Wiltshire Snowflake. Mr. F. Miller was second with Wiltshire Snowflake, Woodstock Kidney, and Yorkshire Hero. Mr. T. Pickworth, Loughborough, followed with Lady Gordon, Wiltshire Snowflake, and International. Mr. J. Wormleighton, Guilsborough, Northampton, took the fourth position with Daniels' Advance and Wormleighton's Seedling.

Class K, for three dishes of coloured kidney varieties, the first prize was given by Messrs. Harrison & Sons, Leicester. Mr. W. Kerr was first with Trophy, Brownell's Emperor, and an unnamed variety resembling American Purple; Mr. J. Matthews second with Beauty of Hebron, Trophy, and Superior; Mr. W. Ellington third with Purple King, Beauty of Hebron, and Trophy; and Mr. T. H. Hill, gardener to A. W. R. Brise, Esq., Witham, Essex, fourth with similar varieties. Fifteen entries.

Class L, for the best dish of Suttons' Magnum Bonum, in which growers for sale could not compete, Messrs. Sutton & Sons giving the four prizes. Mr. B. West, Nuneham, Oxford, was first; Mr. Charles Ross, gardener to C. Eyre, Esq., Newbury, second; Mr. S. Cornish, gardener to J. Abbiss, Esq., Enfield, third; and Mr. J. Millen fourth, all staging good samples of the variety. There were twenty-two dishes.

Class M, for the best dish of Schoolmaster, Messrs. Webb & Sons, Wordsley, Stourbridge, offering the four prizes, Messrs. G. Bloxham, L. Stanton, W. Ellington, and J. Millen were the prizetakers in that order. Thirty dishes were staged.

Class N, for the best dish of Suttons' Woodstock Kidney. In this and the two following classes Messrs. Sutton contributed all the prizes. Messrs. L. Stanton, F. Millen, C. W. Howard, Bridge, Canterbury, and W. Finlay secured the prizes in the order named, ten dishes being staged.

Class O, for the best dish of Reading Abbey, Messrs. J. Millen, W. Finlay, J. Matthews, and J. C. Ross were the prizetakers among fifteen exhibitors.

Class P, for the best dish of Reading Hero, Messrs. J. Millen, F. Miller; S. Haines, gardener to Earl Radnor, Highworth; and James Lye were the successful exhibitors in the order named, fifteen dishes being contributed.

Four classes were provided for nine varieties, a separate dish of each being required to permit the Judges testing the respective qualities of the varieties when cooked. Messrs. John Laing & Co., Forest Hill, and Messrs. Hooper & Co. conjointly offered a prize of £1 for the best dish or variety in each of the classes where a certificate had been awarded. A number of dishes were staged, but as the judging was deferred to a late hour on Wednesday we were unable to obtain the awards.

A novel feature of the Exhibition was the collection shown by Mr. Shirley Hibberd, comprising forty dishes, each dish representing the exact total produce of one root, save only that diseased tubers had been thrown out. These were grown on a loam of average quality without manure; they were planted April 22nd, and lifted (for the most part unripe) September 12th. The principal object in thus presenting them was to give practical illustrations of the relative productiveness of the several sorts:—Farren's Kidney, a white handsome variety of excellent quality; total weight of one root 6 lbs. Collins's Kidney, a white sort of moderate quality, 2 lbs. 3 ozs. Carters' Silver Skin, a neat white round of excellent quality, 6 lbs. Holborn Favourite, a handsome white round, 4 lbs. 2 ozs. American Purple, a smallish and a very pretty purple kidney, 2 lbs. 7 ozs. American Purple, a dish of the same consisting of the produce of three roots grown in pure coal ashes: an ugly sample, total weight of three roots, 2 lbs. 1 oz., or 11 ozs. each root. Fenn's Bountiful, a pretty red kidney of good quality, 2 lbs. 7 ozs. Suttons' Reading Hero, a white round of intermediate character, quality excellent, 3 lbs. Fenn's Seedling No. 1, a very neat white round; nice nutty flavour, 4 lbs. 2 ozs. The Queen, a neat smallish round white of fine quality, 4 lbs. 5 ozs. Woodstock Kidney, a white variety of the finest quality, requiring a lighter soil than this sample was grown in, 2 lbs. Fenn's No. 6, a handsome white round of the finest quality, 5 lbs. Fillbasket, a pretty white round, 3 lbs. 6 ozs. Rev. C. Radclyffe, a neat white round of fine quality, 2 lbs. 7 ozs. Sunrise, a neat white round, 3 lbs. White Elephant, large, long, coarse; better than Chardon for cattle feed, 9 lbs. 12 ozs. Extra Early Peach Blow, white round, with blush of pale pink, 4 lbs. 12 ozs. Masterpiece, white round, long and flat, 2 lbs. 2 ozs. Wiltshire Snowflake, a handsome white round, quality fine; too many chats, 3 lbs. 9 ozs. Mammoth Pearl, an ugly white round of poor quality, 3 lbs. 2 ozs. St. Patrick, a white kidney of good quality; the sample shown was finger-shaped and twisted, but very bright, 4 lbs. 8 ozs. Beauty of Norfolk, a very fine white kidney, 7 lbs. 5 ozs. White Star, a handsome kidney of fine quality and a good keeper; the sample shown was not first-rate. Mr. Hibberd reporting that it needs a lighter soil than it was grown in, 4 lbs. Armstrong's Prolific, an ugly white round, of no quality, 2 lbs. 12 ozs. Peerless Rose, a small red kidney suitable for exhibition, quality good, 3 lbs. Surrey Gate Post, a finger-shaped white kidney of good quality, 2 lbs. 6 ozs. Advancer, a pebble-shaped white of good quality, 4 lbs. 3 ozs. Pink Flounder, an ugly oblong root, of a pale pink colour, 7 lbs. Queen of the Valley, a coloured kidney of good quality, 5 lbs. 8 ozs. Queen of the Valley, another stool of the same, grown in lime rubbish, 4 lbs. 1 oz. Victoria Regent, a smallish round white, early and good, 2 lbs. 12 ozs. Pink Pyramid, an ugly oblong root of a pale pink colour, 3 lbs. 8 ozs. Pink Pointer, a neat elliptical kidney of a tawny pink colour, deep pink at nose end, 2 lbs. 14 ozs. Pink Domino, a pink kidney of good quality, 3 lbs. Daniels' Silver Skin, a neat white round, 4 lbs. 8 ozs. Handsome Round, a smallish white of fair quality, 2 lbs. 12 ozs. Wormleighton's Seedling has not made a good crop at Stoke Newington, and was lifted too early, 3 lbs. Improved Shaw, an early white round of good quality, but rather wanting in size, 3 lbs. 2 ozs. Johnston's Downshire has never been a good cropper at Stoke Newington; the sample shown was wanting in size, 2 lbs. 14 ozs.

The miscellaneous exhibits were very numerous, large collections of Potatoes being contributed by Messrs. Sutton & Sons of Reading; Carter & Co., High Holborn; Harrison & Son, Leicester; Webb and Son, Stourbridge; Lee & Son, Hammersmith; and Hooper & Co., Covent Garden, many varieties being represented by heaps of considerable dimensions. Mr. Robert Fenn of Sulhamstead sent about

thirty dishes of varieties raised by himself, several being entered in the classes for new varieties. A portion of the trial collection of Potatoes at the Royal Horticultural Society's Gardens, Chiswick, comprising 120 varieties, also formed a feature of much interest. Messrs. J. Veitch & Sons, Chelsea, staged about two hundred dishes of Apples and Pears, the former being remarkably fine. Messrs. W. Paul & Son, Waltham Cross, also had a similarly extensive collection of Apples and Pears, with six boxes of Rose blooms very fresh and bright. Mr. R. B. Cant of Colchester sent three boxes of Roses, and Messrs. H. Cannell & Son, Swanley, had several handsome collections of Dahlias and Verbenas, which brightened the appearance of the tables very pleasingly.

#### HONG KONG.

(Continued from page 182.)

OF that small portion of Victoria which stands on the limited strip of level soil between the spurs of the hills and the water.

Queen's Road is the main artery; it is, in fact, the longest and widest thoroughfare, extending from under the Peak almost to the Happy Valley, a distance of about three miles. It begins in the lower quarters of the town as Queen's Road East, and runs a somewhat winding course through the great business centre, where are the superior class of Chinese shops, the European stores, the courts, the clubs, the hotels, and the piazzas, till it reaches the City Hall and Beaconsfield Arcade. Here between the cricket and parade grounds, and directly under the cathedral, on a fresh morning in November or a moonlight night somewhat earlier in the season, Hong Kong appears to perhaps the greatest advantage. Glittering in the sunlight or gleaming softly in the moonlight are the elegant City Hall, Beaconsfield Arcade, and cathedral, toned down in a setting of the freshest sward and avenues of Banyan trees, between which on one side can be seen the rippling surface of the ship-studded harbour, while on the other towers up the heavy lowering mass of the sombre green Peak. The *Graphic*

Fig. 45.—VIEW IN THE GARDENS AT HONG KONG.

last January published some so-called illustrations of this, which give but a very poor idea of a scene that would have driven some of our poets who have raved about the beauties of the Italian cities into a state of absolute speechlessness could they have extended their experiences thus far.

But not less beautiful in their way, though more confined in their view, are the winding walks which conduct the visitor from the cathedral up the face of the hills to the more elevated roads of the town and to the ornamental grounds of the public gardens and Government House. These, like the Queen's Road west of the City Hall to the Happy Valley, are planted and overshadowed with well-grown specimens of the *Ficus retusa*, which has been found to be the tree that, while combining the joint qualities of quick growth with plentiful shade, thrives on the granitic soil of the roads in Victoria; also in places are to be seen specimens of the *Pinus sinensis*, a somewhat scraggy untidy tree of its class, but which has been found to take kindly to the soil of Hong Kong and helps to add to the garment of vegetation that is every year

creeping more thickly over the once bare face of the hills. The greatest efforts are being made by the Government to promote this object, and for that purpose it procured some nine years ago, on the advice of Sir Joseph Hooker, the services of Mr. Charles Ford, a Yorkshireman, who has since 1872 been installed at Hong Kong as curator of the gardens and manager of the department of afforestation. To this gentleman I must express my indebtedness for much information, and also for the remarks on the arboriculture and botany of Hong Kong. When Mr. Ford arrived there was everything to be done towards reclaiming the foot hills from their condition of bareness, and for some years progress was not so rapid as Mr. Ford could have wished, in consequence of some conflict of individual opinions in the matter. Until 1877 some sixty thousand saplings had only been planted, a large percentage of which died. Now, however, Mr. Ford finds himself with ten different nurseries in Hong Kong and Kowloon, occupying in all about twenty acres, from whence he last year drew 270,000 saplings, which he planted along the hills and in various parts of the

town, while this year he expects to follow with 250,000 more. The tree used for the foot hills is mainly *Pinus sinensis*, and *Ficus retusa* for the roads and streets. Among the latter, however, Mr. Ford has determined to introduce more variety, and has set out with others *Camphora officinarum*, *Swietenia Mahogani*, *Quercus Harlandii*, and *Ailantus nobilis*. He is also making free use of the different varieties of the Hong Kong Oak, the Tallow Tree, the *Eucalypti*, and *Pinus Massoniana*.

In approaching the gardens from any direction you cannot help being struck with the clean solid nature of the walks over which the flickering shadows of the Banyan leaves are playing. They are of concrete, with gutters on each side, and altogether form kind of watercourses along which the water after a swamping rain runs with almost as much ease and quickness as it does off a duck's back, away down into the harbour. The cleanliness and dryness of its roads is one of the remarkable features of Hong Kong. Within a quarter of an hour of a deluge ceasing you can walk out dry foot, and, looking up at the hills above your head, see little silvery streams tumbling down in all directions through the town, pursuing their appointed channels to the sea. It forms quite a strange blending of wild highland with the formal grandeur of urban scenery.

Just outside the eastern gate of the gardens a road, called Kennedy Road branches away to the left, winding round the spurs of the hills at a height of some 200 feet above the harbour, and continuing for a distance of about two miles. It is the favourite promenade of the Hong Kongers, and they may be seen there every afternoon—ladies with their chairs, and coolies following them; and gentlemen without these walking and talking, or else sitting enjoying the contemplation of the hospital three-deckers, the turret ships, the ironclads, the great ocean-going steamers, and the swarm of ships and junks, sampans, and rowing boats below.

The gardens are not so remarkable for their size as they are for their neatness and finish, and for the fact that they exist at all. On looking up from the harbour below, it seems hardly credible that there should be so much space devoted to ornamental grounds and winding promenades as there is both in and around Government House and the gardens above it. Altogether the ornamental grounds do not exceed twenty-four acres, some six of which lie around Government House. The remainder is divided into two portions, the larger being situated almost directly over Government House, and the other lying away a little to the west with the road to the Peak between. This latter is known as the Palm Garden, and differs from the eastern portion in being smaller and occupying one level. In it are planted varieties of the *Aralia*, *Coffea*, *Canna*, *Cycas*, *Calamus*, *Coccos*, *Areca*, *Seafortia*, and *Phoenix*, which, though many of them are still young, form as a whole a very pleasing, secluded, and romantic resort. This is particularly the case at the western corner, where there is an outlet by a balustraded path which debouches upon the ascent leading from the Caine Road to the highest residential road in Victoria, known as the Robinson Road. From the middle of this path you look down upon a mountain torrent's rocky bed spanned by a stone bridge, under which after rain the water will be foaming, while around you, behind, before, and to the left, are moss-encrusted rocks peeping through a curtain of dripping drooping foliage. Here you may sit so as to obtain a view into the Palm Garden, and there, in contemplation of that vista and lulled by the sound of rushing and dropping water, you may fancy yourself in that Elysium land so faintly foreshadowed by Lalla Rookh and the Koran.

The main portion of the Gardens is arranged in terraces with a broad walk running down the middle of them, from which smaller ones strike off in every direction. Conspicuous round its outskirts are specimens of *Cryptomeria japonica*, *Araucaria excelsa*, *Cupressus Lawsoniana*, Oaks, and Banyans. Here and there a somewhat indifferent-looking *Musa* rears its head, with *Thujas* and an occasional *Magnolia*. The flower beds are very neatly arranged in the ordinary ribbon-border style of gardening, the stock materials being apparently much the same as those employed at home. In one particular spot are confined some kangaroos, emus, and water birds, all of which afford considerable amusement to the wondering crowd of blue-robed pig-tailed Chinese and to the members of the convention of European children, who, with their ugly Chinese "amahs" or nurses, congregate here every afternoon when the intense heat and glare of the day have begun to decline. On Sundays the company of visitors is augmented by the presence of members of the Eurasian (or half-breed) *jeunesse dorée*. These combine as a rule much of the large frame, aquiline features, and independent bearing of their European fathers with the soft, suave, inscrutable impassiveness of their Chinese mothers. Many of them have quite an elegant bearing, and in their long

white tunics falling far below the knees have often a not unstriking resemblance to Roman youths.—A WANDERER.

(To be continued.)

### FRUIT NOTES.

THE fruit crop here is better than it was in the two preceding years. The supply of Apples is good. Most of the orchard as well as bush and pyramid-pruned trees have borne fruit abundantly. One of the best of Apples, Ribston Pippin, is bearing well, and an orchard tree of the Golden Pippin has a good crop of fruit. Wellington, Beauty of Kent, Cox's Orange Pippin, Norfolk Beefing, Striped Beefing, Dutch Codlin, Keswick Codlin, Alfriston, Holland Pippin, Lord Suffield, Hawthornden, King of the Pippins, Leydon Pippin, Nonsueh, Nonpareil, and Baldwin have all full crops. This last-named Apple has excellent keeping qualities, and it also forms plenty of fruit spurs. A large handsome culinary Apple not generally known is Pott's Seedling. This year it is particularly fine. A trained pyramid, 8 feet in height and the same in diameter at its base, is bearing a fine crop of large Apples. It is a vigorous grower, and is worth a trial.

The following Pears have full crops, the first to ripen being Doyenné d'Été, an excellent little Pear, and in season about three weeks if two gatherings are made. Then followed the Lammas, a medium-sized Pear, ripening about mid-August, but in quality it is not good. Jargonelle, ripening about the same time on a south wall, was of superior flavour. The next to ripen was Beurré Giffard, a small but delicious Pear. Williams' Bon Chrétien followed, and has fruited well, particularly against a south aspect. It, however, makes a good orchard tree, and, as is generally known, it is one of the best Pears in its season. Other varieties that have good crops are Louise Bonne of Jersey, Passe Colmar, Duchesse d'Angoulême, Beurré Bose, Autumn Bergamot, which makes a good orchard tree, and ripens in favourable seasons in October, Crasanne, Marie Louise, Beurré Diel, Beurré Rance, very full, Easter Beurré, and Catillae, the last-named being an excellent baking variety.

Plums are a very partial crop; Jefferson's, Kirke's, Green Gage, Pond's Seedling, Blue Impératrice, Coe's Golden Drop, Magnum Bonum, Yellow Orleans, Victoria, and Early Prolific being represented by few fruits, but Blue Orleans, Reine Claude Violette, and Washington are very full and heavy. The Prune Damson is also good, and should be more grown than it is. The fruit is longer and a different shape from the ordinary round Damson. It is also more constant in bearing.

Bush fruits of all kinds have been good, Strawberries and Raspberries plentiful, and Nut trees are bearing well. Cherries have not been good, except the Morello, and that has borne heavily. Apricots have been a fair average, the large Early Peach, Roman, and Moor Park being good. Breda had a good crop, but the fruit is so small that it is hardly worth growing. Peaches and Nectarines have a very fair crop, but the severe winters and cold springs of the last few years, together with the wet dull summers, have so crippled the trees that a large crop cannot be expected, and the damp sunless weather of the last few weeks is not favourable for their ripening, the flavour being deficient. The soil all the above are growing in is a deep loam resting on gravel.—A. HARDING, *Orton Hall*.

### THE ARRANGEMENT OF CUT FLOWERS.

(Continued from page 238.)

IN all large establishments where floral decoration is valued there should be a "flower room" especially devoted to the work. It should contain a table close to the window, another large table or two, a sink with a water tap, a large lofty cupboard with plenty of broad shelves, and a broad shelf or two along any convenient part of the walls. The window table should have a drawer for scissors, knives, wire, string, dusters, cotton wool, a packet of gum arabic, and a bundle of flower sticks. Some white sand, ehareoal, and moss should also be kept in boxes under one of the tables, care being taken to pass the sand through a fine sieve before it is put in the box, and there should be a large iron spoon for placing the sand into the flower stands. A small piece of ehareoal is placed in every vase to keep the water sweet. A single drop of gum dissolved in water and allowed to fall carefully in the centre of a flower prevents its shedding its petals; it is not often that this has to be done, but it is worth knowing when flowers become scarce. A set of water jugs, a very small waterpot with a finely perforated rose for moistening sand, a sponge and set of brushes for cleaning vases, and a clock, renders our list of the flower-room furniture complete.

Flower stands, vases, and china flower pots are kept in the

cupboard and upon the wall shelves. Perhaps there are few things more difficult than the selection of these indispensable adjuncts to floral decoration by the uninitiated; so varied are the forms and so charming the colours set forth in tempting array at the china shop, that even experienced hands are not unfrequently led to purchase articles that prove unsuitable for a given purpose. Coloured flower stands should if possible always be avoided, for if they are used flowers must be chosen to harmonise with them, and so our selection would always be unduly restricted. White stands are of course admissible; but the most useful are undoubtedly those of transparent glass, which, although colourless, yet when filled with clear water impart an air of brightness that mingles most pleasantly with the varied charms of the flowers. Of all forms fish globes are the most useful for the dinner table, and the flower-room cupboard should contain a complete set of them, consisting of a dozen of each of the larger sizes and five or six dozen of each of the smaller ones downward to those that will not contain more water than a teacup. A single globe of the largest size answers admirably for the centre of a circular table, just as three or more do for a long table. The smaller sizes all prove useful in turn, being used either singly in circles around the large ones, or in groups in a variety of ways. My meaning will perhaps be most readily understood by those whose resources are frequently severely taxed to impart a distinct character to a series of consecutive table decorations. A considerable number of circular wooden blocks of various thicknesses and diameters to suit the different globes, all of them covered with dark crimson plush, are used to elevate the globes above the tablecloth, salvers of glass mirrors set in silver being sometimes used for the large central globes.

Of other table stands what are known as Marsh stands are still used in the plain forms in which they were originally brought before the public. Various modifications have found favour according to the promptings of individual taste or fancy; a favourite one of medium size, consisting of a bottom saucer for sand, from the centre of which springs a single water vase, is very useful. Glass baskets are also useful; so, too, are the small slender glass vases suitable for a single Rose, or two or three trusses of smaller flowers, of which mention was made on page 237. They are very elegant and are usually frosted. Iridescent and crackled glass vases are very beautiful—so beautiful that they are usually found in sitting-rooms, but there should be one or two sets for dinner-table work, and they are not expensive. For corridors, vestibules, landings of wide roomy stairs, and various nooks and corners, gigantic china vases 2 or 3 feet high are best for standing upon the floor; but if there are tables or brackets, then there is nothing better than large china bowls filled if possible with fragrant flowers. What is more liked than a bowl of Sweet Pea blossom, or Mignonne, Honeysuckle, Lily of the Valley, Harebell, Roses, Violets, or Primroses? All are welcomed in their seasons. Depend upon it, it is not the costly Orchid or other rare flowers requiring expensive glass structures for their culture that are most often in favour even in a palace. There is a craving for the "old-fashioned flowers" of our childhood, and only a selection of those of the most easy culture are needful to carry on the work of decoration well. Of Roses we cannot have too many, especially of Moss Roses, Damask, Cabbage, Gloire de Dijon, and Maréchal Niel. Let there be plenty of Sweet Peas—not small clumps, but long rows in succession throughout summer and autumn. I have now two rows, one on each side of a path some 200 feet long, just bursting into bloom, forming an avenue of sweetness and affording a bountiful supply of cut flowers. Anemones, Zinnias, Asters, Scabious, pink and white Mallow, Love-in-a-Mist, pink and white Canterbury Bells, Columbines, Cornflowers, Larkspurs, Lupins, Pinks, Carnations, Picotees, Myosotis are all highly valued for the rich supply of cut flowers which they afford, every one of which can be turned to account for decorative purposes.—EDWARD LUCKHURST.

THIS is a subject I have long been interested in as concerns gardeners. I believe it is a fact that a large number have little taste, because taste is not cultivated. I have often had flowers provided me by gardeners who have ample resources, and have often received only such that could be bought for a trifle in the market. This is what I entirely object to. If, for instance, I send flowers to a friend I want a selection chiefly of those not to be obtained by that friend as he goes along the street. All these flowers are no doubt beautiful in themselves, and I merely wish to instance the limitation of taste. The flowers are often acceptable enough; but what disappoints me so much is, that some of the best kinds for the purpose are entirely omitted, and the duty of supply is considered accomplished if the selection is limited to a few bright colours with a few sprays of *Adiantum cuneatum*, as if there were no other pretty foliage in existence. Again, if

you have flowers sent in at intervals the very same kinds are sent in over and over again, while there are hosts of others to provide a change—perhaps something particularly good; but all these are passed over, apparently because they do not belong to a regular set. To receive anything in season outside the houses or flower garden is too often out of the question.

My opinion is that many gardeners have no proper knowledge of the floral wealth of this country. They do not, for instance, as a rule acquaint themselves with herbaceous plants. Lately these hardy flowers have received a slight from someone actually condemning them on the strength—rather weak, I imagine—of some seen where they have no reputation for cultivating them. I say cultivating them, because while common they are very rarely cultivated, and less often perhaps intelligently selected. The expression "herbaceous plants" might well be given up, because it has become like a red rag to one sex of a bovine species, and often appears to prevent interest in the class, which has got a bad name and is hung without trial. We often find that those who strongly condemn herbaceous plants do actually cultivate a number of them under some other head, quite forgetting what they are. By the expression is too often understood only the bad and useless.

If I am asked why there is so little taste among gardeners, I answer that few have any artistic education. Some are of course endowed with natural taste, but others can acquire taste in no other way than by systematic study. How few there are who undertake this! It is, indeed, extremely important, because the class whom gardeners serve have of late years greatly grown in taste, and if gardeners are to interest their employers they must be able to show the beauties of their outdoor establishments. I have met with many well able to appreciate what they cannot obtain, except by asking, from the average gardener of the present day. Turning to Mr. Luckhurst's article which has excited these remarks I find that he has treated well of floral arrangement, but how can anyone arrange tastefully without an appreciation of the materials at command?—R. I. L.

#### A WEEK IN LONDON.

TRAVELLING through the country I found little to interest me until I reached Derbyshire, when I was much pleased with the grand scenery in that county. I have never travelled before on the midland route from Manchester to London, and I never before found so much of Nature's handiwork to interest and render a weary railway journey attractive. This county was beautiful, with frequent fields of grain, and large towering hills rising to a great height, and the sides covered with Firs. The county of Derby appears from what I saw of it to be a fine field in which the landscape gardener may study Nature. After leaving this county I found but little of interest further on the journey until the great metropolis was reached. It was then night, and dark, and when passing over Blackfriars Bridge the Thames Embankment was pointed out to me, and so beautiful it looked, illuminated with the electric light, that I was tempted to go and see it again. The young trees are doing well, and a good authority informed me that these trees retain their foliage longer than any other trees in London. I have certainly never seen anything to equal the Embankment in any provincial town. London is much different from what many expect to find it, and I must say I was rather surprised to see the thousands of trees, young and old, growing in the streets. At every turn, in every street in the suburbs, trees abound. The Plane (*Platanus orientalis*) appears to thrive well, grows rapidly, and retains its fine bold green foliage until frosts occur. Limes are also largely planted, but the foliage was almost gone, and the trees presented quite an autumnal appearance. It would be interesting to know how the Plane would do in the northern counties. If it is sufficiently hardy it would prove a valuable tree for the neighbourhood of smoky towns. The Robinia also grows luxuriantly in the environs of London. The various roads and streets present quite a different appearance from those round any provincial town I have seen. What with the trees and the little garden in front of nearly every house, and the houses festooned and draped with Virginian Creepers, quite a lively and country-like appearance is produced, and never before have I seen this fine old creeper grown so largely and effectively. The enthusiasm that evidently prevails for flowers is very striking, and every small garden is decorated with flowering and other plants; this no doubt is due in a large measure to the flowers and flower-garden decorations in the parks. I wonder why provincial towns do not follow the example of London, and adorn their parks for the enjoyment of the public. I have visited many, and scarcely ever is a flower to be seen. A friend told me a short time ago he had been visiting Liverpool and one of its parks, which was one of

the most beautiful he had ever seen, but after walking through the principal parts could scarcely find any flowers.

The Scarlet Runner Bean attracted my attention. Every occupant of the houses evidently devotes a portion of their small garden to the growth of these Beans. They really look grand as you travel by rail through the suburbs. Not only are they ornamental but useful, and the plants are carrying a heavy crop of beans this season. I have just noted two or three things that attracted most attention, but intend giving a few notes of the parks and places of horticultural interest. The first being the

#### CRYSTAL PALACE.

I must admit I went with some curiosity to see this renowned place. I had formed some gigantic idea that it would be superb, far surpassing anything I had ever seen in the horticultural world. These ideas were grounded in my imagination from the glowing descriptions given from time to time in the gardening journals. The remarks of your correspondent Mr. Wm. Taylor, which were given in the Journal after a visit there, caused me to doubt whether my idea formed of the place would be realised. I thought his statement rather bold and sweeping, especially after the bestowal of so much praise; but according to my judgment it was the best and most correct description of the gardening at the Crystal Palace I have ever read. Certainly I saw a few good Tree Ferns and the fine old *Ruscus androgynus* growing luxuriantly. I was rather late in the season, for the bedding and the flowering plants had been much injured with the wet weather. The most showy beds in the grounds were composed of mixed double Zinnias, and they were very fine. Beds of *Phlox Drummondii* and mixed Verbenas were also showy. I thought of finding some fine carpet beds, but was disappointed. The carpet beds contained two or three neat designs; but in some beds too much *Alternanthera* was used, in others the *Iresine* and *Tagetes*, which were employed in the centre and for lines, had been too severely pinched to keep them in due bounds, and in consequence spoiled what would have otherwise been pretty beds. Viewing the bare terraces from the grounds they are in my opinion most unsightly. Would they not be better covered with Ivy or some other neat-growing climber? The next establishment visited was

#### HYDE PARK.

Numbers of young trees have been planted there of late years, and will, in a few more years, make a grand improvement to the Park. Being interested a little about herbaceous plants, since so much has been written in their favour lately, I watched eagerly the mixed borders for any especially good plant, but found nothing of any moment except *Anemone japonica* and *A. j. alba*, the next best plant being *Hydrangea paniculata*, a really grand plant, which should be grown in all gardens. The bedding had undoubtedly been very fine, but the flowering plants, especially the Pelargoniums, were much spoiled by the wet weather. The four most simple beds (circular) and yet the most conspicuous of all, were composed of *Gazania splendens* and *Iresine brilliantissima* mixed. The yellow flowers of the former contrasted admirably with the bright foliage of the latter. No doubt the old *Gazania*, which is seldom seen now, will become popular again for mixed beds. Another pretty mixed bed was composed of Pelargonium Verona, a fine gold-leaved variety with pink flowers, and *Iresine Lindenii*, edged with Cliveden Purple Pansies. Some beds composed of Pelargonium Ariosto, a variegated Ivy-leaf, and *Viola Blue Bell* were very attractive. Amongst the beds of Pelargoniums the two varieties that appeared to have stood the wet best were Mrs. Holden and Lady Emily, which were very fine. The subtropical beds looked well, and are far superior to the beds of flowering plants for late summer decoration. Two beds were filled with Cannas in variety, with a variegated *Abutilon*, probably *A. nœvium maculatum*, with a few plants of *A. Boule de Neige* flowering very well, a row of *Centaurea candidissima* all round, next to this a row of *Lobelia*, and edged with *Echeveria secunda glauca*. Two other beds very similar were equal in point of merit, and only differed from the others in having a row of *Dracæna rutilans* and *Grevillea robusta* planted alternately and arranged between the Cannas and the *Centaureas*. It is not surprising that these subtropical beds are so much admired by the public.

Of carpet beds, one noticeable bed had for the centre *Echeveria metallica* surrounded with *Alternanthera magnifica*, which was raised above the rest of the bed, the edge of the raised portion being formed with a close even row of *Echeveria secunda glauca*, then a band of *Mentha Pulegium gibraltaria* with another row of *Echeverias*, then the golden *Alternanthera paronychyoides aurea* dotted with *Pachyphytum bracteosum* and edged with *Echeverias* mixed with a little *Sedum glaucum*. Another bed which was very attractive had for a centre a single plant of *Echeveria metallica*

surrounded with *Alternanthera* and *Sedum acre elegans*, the lines being formed of *Echeverias*, and the remaining portion of the groundwork with *Mentha*, small patches of *Alternanthera*, and succulents. The next noticeable bed had a centre plant of *Centaurea candidissima*, the groundwork in the inner portion of the design being *Herniaria glabra*, a close-growing green plant. *Alternantheras* filled four small circles in this groundwork, which was edged with Golden Feather and a band of *Alternanthera*, the remaining groundwork being composed of *Cerastium tomentosum* with small triangular pieces of a small *Saxifraga* with single specimens of *Echeveria metallica* dotted in suitable positions.

The introduction of a number of succulents in the carpet beds was quite a noticeable feature, and considerably improved the beds, which otherwise would have presented a rather flat appearance. The carpet beds were by far the most attractive, and the beds of Pelargoniums had no chance of competing with them either for neatness, brightness, or beauty.—A COUNTRYMAN.

(To be continued.)

#### PLANTS FOR WINTER AND SPRING.

GROWING plants for winter and spring flowering, planted out either in pits or the open garden, is one of the simplest and most efficient modes of cultivating these throughout the summer. I have grown many plants thus for a number of years past, and always successfully. At the present time the plants should be lifted and potted. I place our stock, without exception as to kind, into as small pots as the roots can be forced into, the soil used being rich in manure. When potted the plants are all placed in a position out of doors, where they are perfectly shaded from the sun. They require very little water, no syringing, and do not lose a leaf. A month, or perhaps three weeks, after lifting the plants are housed; they are by that time slightly at home in the soil they are potted in, and can be subjected to heat as they may require it. If kept growing and forming roots we give them liquid manure about once in every ten days, but when kept cool for spring flowering they do not require it nearly so often.

*Bouvardias*, *Cyclamens*, *Begonias*, *Eupatorium Weinmannianum* are grown in frames during summer; *Deutzia gracilis*, *Solanum Capsicastrum*, *Calla æthiopica*, *Hoteia japonica* are grown in kitchen-garden borders; *Chrysanthemums* are also grown largely for transplanting into cool-house borders to afford flowers for cutting. Lily of the Valley, Azaleas of the mollis type, *Rhododendrons*, *Schizostylis coccinea*, Zonal Pelargoniums, and, in fact, almost all kinds of easy-grown plants, may be thus grown with little trouble and certain success.—R. P. BROTHERSTON.

#### PREPARING FOR WINTER.

(Continued from page 171.)

EARTHING-UP AND PROTECTING CELERY.—The former operation is undoubtedly one of the most important to be performed in the kitchen garden at this time of the year. Celery may be well grown—and there appears to be much that is very strong and very clean in the gardens of amateurs and cottagers this season—and yet be partially spoilt in the blanching. Some err in leaving their plants too long before commencing to earth them up; others go to the other extreme, and complete the operation before the plants are either strong enough or forward enough for the operation. In the first case a difficulty is often experienced in protecting the heart; and the leafstalks, owing to long exposure, become tough and strong-flavoured, and consequently but little besides the heart is really eatable. On the other hand, if earthed-up prematurely the growth is arrested, and the produce is of an inferior description accordingly.

I take special pains with the rows of Celery. It is my pride to see it turned out clean, straight, and solid, and it would be particularly annoying if the reverse should be the case simply because sufficient attention had not been paid to the earthing. Some urge, and to a certain extent rightly, that large heads of Celery should not be grown, simply because the hearts only are sent into the dining room; but, according to my experience, the stronger the plant the better will be the heart both in size and quality. Besides, few employers, I trust, expect their gardeners to grow Celery for their use only, and if some of the outer leaves are solid and well blanched they are eatable. At any rate, the owners of small gardens do not waste the greater part of well-grown Celery; and these I strongly advise not to smother up their rows of comparatively weakly plants from a desire to secure early produce. Of course in the majority of moderate-sized or large gardens Celery is now being lifted in good condition, and more is being gradually earthed-up in order to maintain the supply. Those in charge of these doubtless know as much about

Celery as I do; but there are others of lesser pretensions who do not, and for whose benefit I will briefly detail our mode of operations.

It must be borne in mind that the Celery is not erect-growing, as if left to itself in the open the outer leaves will gradually open out and assume a horizontal position, and will split or crack off when an attempt is made to bring them up to the position in which they are required to protect the heart. When, therefore, the plants are growing strongly, whether intended for early or late supplies, all suckers and the very smallest outer leaves are pulled off cleanly, and the first earth worked in around them to a depth of about 3 inches. This is either performed a few hours after a heavy rain, or, in the case of dry weather prevailing, after a heavy watering has been given. Where but little manure was dug into the trenches liquid manure should be freely used, or a good dressing of soot and lime, with a small portion of salt added, dusted along the rows prior to watering both at the first and second earthing. This mixture acts as a fertiliser, and also to a certain extent as a preventive of slugs and worms, which in most cases do much damage to the Celery. In about fourteen days another light earthing is given, care being taken not to be in advance of the inner leaves, and also not to unduly press in the outer stalks about them. Yet another earthing is performed, completing finally about three weeks before the Celery is required for use, or, in the case of the later supplies, whenever frost is imminent.

At the third earthing the soil is worked rather more closely and firmly about the leafstalks, which at the final operation are brought closely together and the soil worked round tightly with the hand, the ridge being rounded off so as to throw off the rains. It is not advisable to bury much of the foliage, and in order to preserve the heart from the soil it is a good practice to tie up the leafstalks with strips of matting slightly above the soil line, untying immediately after the earth has been applied. This I find preferable to holding by the hand. After the two first earthings especially, the drier and lighter the soil employed is the better, and for this reason dry weather should always be selected for the operation; and where the soil is naturally very stiff either lighter soil, sand, or coal ashes should be worked around the Celery, enclosing this with the stiffer soil. It is a difficult matter to protect the plants from slugs and snails. We are using soot and lime freely, but another season I hope to be able to thoroughly dress the ground with quicklime some time prior to digging the trenches.

Celery, as many of us know to our cost, is far from being hardy, and if the foliage is destroyed by frost the stalks soon decay. Various methods of protecting are resorted to, the simplest and best probably being two broad boards nailed together in the form of the letter V and inverted over the tops, removing them during favourable weather. Dry fern or bracken will here be used when required, and much may be done with rough litter and branches of evergreens.—W. IGGULDEN, *Marston*.

#### CLERODENDRON FRAGRANS.

THERE is no sweeter-scented, more floriferous, or more ornamental Clerodendron in our gardens than this. It is rarely the name is to be found in nurserymen's lists, nor do we see the plant often in gardens; and all this is very surprising, as it is one of the easiest plants to grow anyone could possess. In shape its leaves are not unlike those of the Vine, but they are rougher and thicker. In habit it is dwarf and branching, and the flowers are produced in Ixora-like clusters at the end of every shoot. It grows quickly and bears stopping well—so well, indeed, that it is a great advantage to stop it frequently, as the shoots which this readily produces soon bloom. One plant which we have been trying is now bearing its third crop of bloom since March last. This has been secured by cutting off the preceding blooms as soon as they were opened, and thereby causing the back buds to produce flowering shoots.

A rich compost is needed, and the temperature I have found best suited for it is that of a stove, but in summer I should think it would do well in any conservatory. As yet the flowers are each about the size of a sixpence, quite double, with very thick wax-like petals, pale pink in colour, and as strongly scented as a Gardenia, only their fragrance is suggestive of almonds. It is most easily increased by cuttings, which will root freely in a little bottom heat at any time of the year. Plants in flower may be had in any size pot. Handsome plants can be grown in 8-inch pots, and specimens fit for showing may be had in a few sizes larger.—M. M.

#### HYDRANGEA INVOLUCRATA VERA.

LIKE the Clethra referred to in another column, this plant was flowering freely in the Antwerp nursery. It is totally distinct

from all others of the genus, and is decidedly ornamental both in foliage and flowers. The prevailing colour of the trusses is blue, but the expanded flowers are brighter. The plant is a native of Japan, and was introduced, named, and described by Siebold some years ago, but has for some reason or other remained scarce, and is seldom seen in gardens. The protecting involucreted bud is very remarkable, in this respect being totally dissimilar from all other Hydrangeas. The hardiness of this plant has also been established, as it has endured without the slightest injury the extreme severity of the last three winters, and has flowered freely

Fig. 46.—*Hydrangea involucrata vera*.

every year. It is of low and rather close growth, rarely exceeding 2 feet in height. A flower truss is produced by every growth, and is suitable for the margins of shrubberies or borders of hardy flowers.

#### LESSONS OF LIFE FOR YOUNG GARDENERS.

HAVING given the readers of the *Journal of Horticulture* a brief narrative of my life, I now come to notice some of the lessons learned by the way. This will be done with a view to guide and encourage young gardeners and others anxious to progress.

The occupation of gardening is honourable and respectable: to men of energy who have sympathy for what is natural and beautiful it is pleasurable and exalting. The pleasures derived from well-kept gardens and gardening pursuits are second to none, except those of religion and social life. Some young men have no tastes—no talents for gardening. Their natural instincts and desires tend in other directions. There is no accounting for the differences of taste and inclination. Circumstances and associations lead some young men to commence gardening who have no real love for it. A life of service and activity does not suit their notions of independence and self-gratification. Such men have a very hard and uphill battle to fight through life, for unless a love

for gardening be begotten in them in early life it will be hard work for them ever to advance on the high road to mediocrity.

It is quite otherwise with young men of energy who love gardening, and who are bent on their own advancement and elevation. All that such men need is a little encouragement and guidance. In our time we have known many young men of this kind who succeeded in raising themselves to positions of distinction, and some of them still rank among the aristocracy of their profession. With a view to encourage and assist the young readers of this Journal I ask the Editor to let me now call some of them to my side, so that I can talk to them in a semi-conversational style.

Young men, you have now commenced the battle of life, and you well know that you are surrounded by a world of busy activities—a world of buyers and sellers—a world of vice and virtue—a world in which the race is to the swift and the battle to the strong. In gardening, as in most occupations, it holds that "whatsoever a man soweth, that shall he also reap." This is a lesson of prime importance, and has a wide and general application. Young men like you have it in your power now to shape your own future to a very great extent—in other words, to act so that you can look hopefully forward to a happy and successful life. In all your efforts to advance remember that first-class men are scarce, second-rate men are plentiful, and that third and fourth-grade men are more plentiful still. There is now, and there has been for forty years, greater difficulty in finding first-class gardeners than there is in finding first-rate situations for such. Capable and accomplished gardeners, like good fruit, are in demand and seldom remain long in the market. Now look for a moment at the comforts of a gardener in a good situation. His wages are constant and certain; he has a free house, coals, milk, fruit, vegetables. In one of the situations I held I was allowed butter and game. At the age of twenty-seven I entered on my first head place, wages £70 a year; in my second place I had £80, third £84, and last one £90, and of course the usual perquisites; and though the places I filled were not the highest, their material comforts were great and satisfactory. And since I left service twenty-two years ago the wages of gardeners, both masters and journeymen, have risen considerably. These things are now mentioned for your encouragement and to stimulate you in aiming at excellence and success.

In coming to the question of education let me say that young gardeners cannot be too well educated, for education proper is uplifting in every sense—tending to make them more intelligent and better servants, fitting them for higher positions, giving them more self-respect with a distinct power to command the respect of both rich and poor around them. Gardeners have to meet and converse with the highest classes of society. Even the Queen herself has said that she prefers gardeners who can talk to her in a becoming manner. Those who have commenced a career of gardening with defective education should begin at once to improve themselves in this respect. To all such I would say. Do not delay, and never despair. A strong resolve followed by effort will overcome every difficulty and do the work.

"An egg before an eagle, a thought before a thing."

During the winter months gardeners have much time for reading and improvement, and if this time is not properly spent it will be worse than lost—worse than wasted. If the soil of our gardens be not properly cultivated and cropped we are certain to have a splendid crop of weeds.

As bread is the first consideration of man, the means by which it is to be earned should never be forgotten. A man's own business or profession should be his chief study. Young men, let nothing else go before gardening science and practice. But as all streets and byways of a city are in some way connected to the main or central thoroughfare, so all branches of science and scientific pursuits run into one another, and therefore you can never gain too much scientific knowledge, which expands the mind and gives to man a firmer grasp of his own business—a deeper penetration into and a greater power to explain the works of Nature around.

Perhaps you are aware that some people say there is a difference between "a thinking man" and "a man thinking," and they hold up "the man thinking" as the better of the two. You will likely enough do the same by-and-by. Two apprentice gardeners without instructions or experience were told to tie up some beds of Pinks. They obtained sticks and matting, and they had knives. The elder of them began finishing every plant as he went on. The other apprentice looked at his companion for a moment, using first a stick, then the matting, then the knife. He would not be fettered and embarrassed by a bundle of sticks; he stuck them all in the beds before he tied a plant, then obtained a piece of matting and finished his work before the other had done one-half of his.

On finding himself so far behind he said, "I see your way is the best." This simple story is representative of a thousand instances of men working without thinking. A young gardener "thinking" seeks and finds the easiest and speediest way of doing work; notices all that is being done around him, even from the erection of a pigstye to the erection of a mansion; and he desires to know the reason for everything done and the way of doing it. Young men of this stamp acting to the best of their ability speedily rise into distinction, commanding the respect of masters, overseers, and companions in toil. Men thinking and acting are men that can be safely entrusted with work and the superintendence of other men. Men thinking and energetic soon become men of independent thought, who stamp their own individuality on all they undertake, able to meet difficulties and pass through emergencies without fear; whereas men of slow thought and action are somewhat like sheep, which follow one another in tracks up the mountain side.

On going to a new place let your motto be "Full and Faithful Service." In serving your master well you serve yourself better: merits and meritorious conduct never remain secrets, and seldom go unrewarded. On visiting Chatsworth Gardens two years ago I took leave to ask Mr. Speed how he obtained his present situation. Mr. Speed replied by stating that his first head place was a small one in Nottinghamshire where he had twelve men under him, affording ample help to keep the place well. "I resolved to do everything well, and thus rear a mound of excellent gardening on which I could stand and be seen. The family here heard about me and engaged me to manage Chatsworth Gardens." I commend to your notice the example of Mr. Speed as one worth being imitated by all young gardeners. Gentlemen and ladies want their gardens well kept; they freely and ungrudgingly spend money to have them well kept and managed; if they are not well kept who is to be blamed? If gardens are not well managed they are a source of disappointment and annoyance to the employers. We all know this, and therefore nothing more need be said about it. For your own comfort and satisfaction, as well as for the pleasure and gratification of your employers, do your very best to have everything under your care in the highest state of health and best possible keeping. If you have not assistance enough to do everything well, respectfully tell your employer, and tell him at the best time and in a manner to make him see that you are intensely anxious to meet his wishes and have the gardens in good condition. All through life I have been often applied to for gardeners, and consulted by gentlemen about their gardeners, and almost always found them very reasonable, willing to encourage their servants, and very unwilling to part with good men.

Finding I have much to say yet I must make my remarks brief and pointed. While young men are journeymen they should guard themselves against the dangers of courting, for when young men begin to keep company with the opposite sex their books become less attractive, they come to a standstill in gardening and make no progress. In our time we have known very many young men who have made a good beginning and who had good prospects completely blighted for life by early courtship. How foolish it is for anybody to seek a bird before he has a cage ready for it! Head gardeners should never be on intimate terms with house servants, male or female, should know no secrets, and hear no whispering from anybody. The great business of life is to do right, to deal with everybody and everything honestly—never to battle against conscience. The man that goes wrong and wittingly does wrong lives in a wood full of shadows. In a verse of poetry which will close this letter young men will find a condensed encyclopædia of precautions against the mistakes and dangers of life.

"O mortal man, in every act beware,  
For one false step may cause an age of care;  
Ever thy credit keep, 'tis quickly gone;  
Though gained by many actions, lost by one."

—A. PETTIGREW, *Bowdon.*

#### HARDY FRUIT GARDEN.

WHERE it is contemplated to plant new trees against walls or renew worn-out trees the borders should be made soon, to allow of their getting settled and the soil ameliorated before the time for

planting arrives. Under ordinary circumstances it is not necessary to do more than trench the ground—not, however, bringing up much bad soil, but stirring it so as to allow the water to pass through it freely and be conducted away by the drains, which must not be more distant than 15 feet apart, and should not be less than 3 feet deep, as it is not the water near the surface that wants carrying off, but that which, without the drains, would lodge in the subsoil. Light soils should have a liberal addition of strong fibrous loam, whilst those that are very stiff will be improved by adding an eighth part of old mortar rubbish. Such a course of preparation is mostly sufficient to secure success with bush, pyramid, espalier, and cordon trees, no manure being mixed with the soil but placed on the surface after the trees are planted. Ground intended for bush fruit, such as Gooseberries, Currants, Raspberries, &c., should, on the other hand, have a free application of manure, as there is little danger of their growing too freely to fruit satisfactorily. In forming borders for trees to be trained to walls it will be necessary, unless the soil is of a texture that cannot well be improved, to form proper borders, so as to secure the best results, and to not only form them, but to keep them exclusively for the trees. More than half the ills attending fruit trees against walls result from the cropping of the borders, and the consequent mutilation of and deep spread of the roots; the heavy manuring for the vegetable crops also induces luxuriant growth of the trees, which is unfavourable to fertility.

Half the height of a wall affords ample breadth of border for any fruit tree. It is not necessary to restrict the roots to that extent, but have a low 4½-inch wall at that distance from the main wall, and pigeon-holed so as to allow of the roots passing outside if requisite. Any tendency to over-luxuriance is readily stayed by annually or biennially taking out a trench and cutting the roots close to the low border wall, and this without interfering with the principal roots, or giving so great a check as often results from lifting. The soil where it is unsuitable for forming borders should be taken out to a depth of 3 feet, the base sloping from the wall outward not less than 1 inch in 12. About 3 inches of rubble should be spread in, and covered with a mixture of two parts of coarse sand or fine gravel to one of lime, thoroughly incorporated and brought to the consistency of thin mortar. This with a proper inclination will form a good bottom, being, in fact, a capital concrete. Allow it to harden, then place a drain longitudinally in the border and two-thirds its width from the wall, erecting the dwarf wall on the concrete. Put in 6 inches of rubble, coarsest at bottom, cover with a layer of turves grass side downwards, and fill-in with compost 9 inches higher than the intended level to allow for settling, the material being put on if possible somewhat dry and tolerably firm. The top 3 or 4 inches of a pasture where the soil is a medium-textured loam, inclined to be strong rather than light, adding a tenth of old mortar rubbish, or in lieu thereof chalk in pieces up to the size of an egg, with a fortieth part of half-inch bones, and if the loam be deficient of grit add a tenth of road scrapings, the whole to be thoroughly incorporated, will suit every description of fruit tree, and with proper surface dressing will endure indefinitely. With such borders the trees are under control, and need less of those after-manipulations that as often result in sterility as in fruitfulness.

#### FRUIT HOUSES.

*Melons.*—Considerable attention is needed at this season to prevent canker at the collar and in the old growths, the only remedy for which is to apply freshly slaked lime on the first appearance of the disease, repeating the application as necessary. To lessen the tendency to canker and the fruit cracking reduce the supply of water both at the roots and in the atmosphere; indeed, the syringe must now only be used on very bright days, damping the house morning and afternoon while the fruit is swelling. The hot-water pipes may be lightly coated with sulphur to prevent the increase of red spider. Give a good watering to the last batch of plants directly the fruits begin swelling, earthing up the roots, and making the soil moderately firm. A temperature of 70° to 75° must be secured by day, with 5° less at night, allowing an advance from sun heat to 85° or 90°, ventilation being afforded carefully and moderately. In pits and frames water overhead must be avoided, and be very sparingly employed at

the roots. Renovate the linings when the heat is found declining, and employ a covering over the lights on cold nights. Keep all laterals in check by frequent stopping, affording as much light as possible to the principal foliage.

*Cucumbers.*—The prolonged dull wet weather has necessitated the employment of fires to secure a temperature of 65° to 70° at night and 70° to 75° by day. Syringe only on bright fine days and early in the afternoon, so as to have the foliage dry before night. The plants for autumn fruiting must have liberal attention to secure a strong growth, as much of the after success depends on this; therefore remove all tendrils and staminate blossoms, cropping but lightly, and do not allow the fruit to hang too long on the vines. Pinch out the growing points every eight or ten days; continue earthing up the roots as they protrude through the sides of the ridges and hillocks, and encourage surface roots by additions of fresh lumpy soil. The plants for winter fruiting have been potted off, and are growing in a genial temperature of 70° to 75°, with 10° to 15° more when the weather is favourable. Keep them near to the glass, and spare no pains to ensure a sturdy growth. Complete at once preparing the fermenting materials, if such are employed for bottom heat, a temperature of 90° being suitable, as the heat will decline; but where the bottom heat is furnished by hot water 80° is sufficient. Hillocks or ridges should be formed about 10 inches in depth and a foot over the top, employing turfy loam, and when the soil becomes warmed through the plants may be placed out, making the soil moderately firm. Pinch out all laterals up to the bottom of the trellis as soon as they become visible, and guard against slugs by drawing a circle round each plant with soot or quicklime a short distance from the stem. Maintain the heat in frames and pits by renovating the linings as necessary, and cover at night. Be careful in supplying water, and keep the growths fairly thin, stopping them a joint or two beyond the fruit, and removing bad leaves.

#### MUSHROOM HOUSE.

Preparation of material for forming successional Mushroom beds will need to be made, and it must be commenced with as little delay as possible to secure a supply when it is most appreciated—i.e., during the winter months. In the preparation of the materials the necessary dryness should be secured with as little fermentation as possible, as that induces a state of decay which is not favourable to the spread of the spawn and the growth of the Mushrooms. In open dry sheds there is no difficulty in securing the proper drying of the materials, especially if it be spread out thinly. Be careful not to have the material too dry, as after the beds are made much moisture will be evaporated, and the chances are that the heat will become exhausted for the want of sufficient moisture to continue the fermentation. Crude horse droppings are considered alone available for Mushroom-growing; but this is a mistake, as more enduring beds, as well as those producing the best quality Mushrooms, are those made of about three parts horse droppings to one of stable litter or sweepings formed of straw, chaff, sawdust, or hay. The material having been properly prepared and laid in the chambers or bins heat will soon be produced, and the beds should then be trodden well down or beaten with a mallet as firmly as possible. If the heat rise unduly beat the bed well down again, as it will settle down more closely as the fermentation progresses. When the heat in the body of the material is not over 90° nor less than 85° make holes in the bed about 2 inches deep, or so as to admit the pieces of spawn, which should be about half an inch beneath the surface of the bed. The holes may be 6 to 9 inches apart every way, and in each place a piece of spawn about a couple of inches square, pressing the material firmly around them with a thin layer over them, and then beat down as firmly as possible. In a week or ten days the bed should be earthed with a couple of inches depth of good yellow turfy loam, which can be beaten down to about an inch in thickness, making it smooth with the back of the spade. A covering of dry hay or soft straw will ensure greater uniformity of heat and moisture in the bed, but it must only remain on until the Mushrooms commence showing. Earlier-formed beds will shortly commence bearing, and should have the surface kept regularly moist by damping with tepid water, and the temperature kept steady at 55°. Avoid a too moist condition of the beds and atmosphere.

## PLANT HOUSES.

*Dutch Bulbs.*—The first batch of Early White Roman Hyacinths, also Blue Roman, with Double Roman and Paper White Narcissus potted some time ago, have rooted and should be removed from the plunging material, and be placed in the shade for a few days until any growth they have made becomes green, when they can be arranged on shelves near the glass, and not subjected to a higher temperature than 50° until the spikes are a good size, after which the flowering may be accelerated by a slight increase of heat. Another batch of bulbs should now be potted and treated similarly to the first batch—*i.e.*, plunged in ashes in a frame to protect them from heavy rains. Hyacinths, Narcissuses, Tulips, Crocuses, &c., intended for early flowering should be potted at once, plunging them in ashes near a wall, or where they can be protected from heavy rains and frost. When sufficiently rooted they can be transferred to a light position in a house where they will be kept slowly growing, and thence to the forcing pit as required.

*Chrysanthemums.*—Attend to staking and training these—the upright bush fashion is the best for general purposes—using no more sticks than are necessary to keep the plants in shape. Thin the flower buds in good time, as where good flowers are wanted all the side laterals should be removed from the principal shoots, and the buds thinned to one to each shoot as soon as discernible. Plants that have all the strong shoots retained should also have but one flower allowed to each. The small varieties must be moderately thinned, so as to enhance the size of the flowers. Afford liquid manure abundantly, and syringe in the afternoon of dry days, and if aphides appear promptly subdue them with an insecticide or tobacco water.

*Pelargoniums.*—Plants of Show, Fancy, Spotted, and Regal varieties that were shaken out, repotted, and placed in pits or frames should be housed at once, assigning them light positions, where they will not be more distant from the glass than a couple of feet. Afford water very sparingly at present and for some time to come, giving only sufficient to keep the plants in progressive growth, as a too moist condition of the soil is not favourable to root-formation, and induces too much leaf growth. Zonals being prepared for winter flowering should be placed under glass at once in a dry pit where ventilation can be freely given, and when required to bloom they should be placed in a temperature of not less than 50° at night.

Heliotropes, Salvias, Solanums, Mignonette, Tree Carnations, &c., grown for winter flowering should be at once taken under cover, as the first frost will do the two former serious injury. The situation for these plants cannot be too light, and to flower freely all but the Solanums (which are of course grown for their berries, and these to be durable must not have more heat than an ordinary greenhouse) must have a temperature of 50° secured to them.

*Schizostylis coccinea* and *Anemone japonica alba* grown in pots specially for indoor decoration must now be moved indoors, and in a greenhouse or conservatory they will make a fine autumn display. Plants also of dwarf Scabious grown in pots should be moved indoors and given weak liquid manure; they will continue flowering for a long time, and are very useful for cutting.

## REFLECTIONS ON THE SEASON.

WHATEVER may have been the case in England, we bee-keepers of Scotland have nothing to boast of as the result of the season's work. In spite of a terribly severe winter stocks were both numerous and strong in spring, and, though later than usual, swarmed with uncommon pertinacity. There, however, our record of success closes. Speaking generally, honey we have none. Most of us will have to winter entirely on sugar. Even the few who have taken any honey will have to replace it in quantity, if not in value, with syrup.

When we inquire into the causes of such a failure we have no hesitation in acquitting both bees and bee-keepers. The former have done their very best; the latter we know have in most cases

done the same. Never before, we honestly believe, were such skilful preparations made and such unrelenting attention bestowed with a view to surplus honey, and never before were such attentions so hopelessly baffled. The causes, speaking generally, were entirely beyond human or apian control. The three great sources of surplus—fruit blossoms, Clover, and Heather—were all there, but the first alone seemed to yield more than a hand-to-mouth living. Clover bloomed as richly as ever was seen, and the hills are still aglow with the purple Heather bloom, but neither Clover nor Heather seemed to offer much attraction to the bees. The real fact is, we in Scotland have spent the summer under a belt of clouds, which only cleared away at times to allow the earth to radiate its little heat into the higher regions of the atmosphere. The clear nights have, therefore, as a rule, been frosty, and it is matter of observation that, however fine may be the succeeding day, the honey secretion will be almost nil. During the whole season from about June 7th these frosts, combined with northerly winds and absence of sunshine, have thwarted every effort to obtain honey in any quantity.

As a rule, early swarms are now the best supplied stocks, as many of them had the chance of a few good days for storage before there was brood in the hive to attend to; yet 20 lbs of honey is the most I have taken from my best, and even that has to be replaced by sugar. Stocks worked on the non-swarving system, besides having been the source of unusual trouble during the swarming mania, have done no better than early swarms; indeed, as a rule, they have yielded less surplus, and their vast populations have already all but consumed their summer's store. This is another link in the evidence in favour of the limited swarming system.

As a result of the peculiar season, favourable enough for breeding, but deficient in surplus honey, supers have been bred-in to an unusual extent. In some cases brood was found in each of two or three tiers of supers. Though I have not had any trouble from this cause, I have seen so much of it in other apiaries that I venture to note two undoubted sources of the evil that lie within the control of the bee-keeper. The first is the habit so generally followed of placing the second tier of supers below the first. I have generally followed this system, mainly with a view to preserving the first tier from the discoloration caused by the traffic of the bees through it towards the highest tiers, and the ease with which it may subsequently be removed. In favourable seasons I have never had any cause to regret this practice; but in such a season as the past it has frequently happened, unknown to the bee-keeper, that eggs were deposited in the first tier before being raised by another. This afforded the best possible inducement for the queen to fill the intermediate supers with brood, and suggests the advisability of altering our practice on this point, though it may involve some extra inconvenience. The second source of the trouble has been in the more general use of drone foundation in the supers. Experiments conducted in my own and others' apiaries are conclusive in favour of worker foundation at any time. Bees preparing to swarm, as those in hives heavily supered frequently are, are too fond of raising drones to make it good policy to tempt them into supers by means of drone foundation. They will work on it readily enough, but mainly for a purpose, and that the raising of drones. This evil is all the more felt where worker foundation is largely used in the stock hive. I have found, on the other hand, that hives not intending to swarm, such as those with queens of the present season, will finish six sections with worker guides before they will "put a tooth" on the seventh one of drone foundation.

While on the matter of foundation it may be remarked that its use during the season has been corroborative of its value. As a rule, swarms left to build their own combs have failed to more than half fill their hives, while even late August swarms on foundation are as good stocks as any. The owners of dome-shaped skeps thus find themselves in a very unenviable position. Last week I drove the bees from four such skeps standing beside each other, all swarms of the present year, and found that I could not fill more than three Woodbury frames with the transferred combs from all the four. I added three sheets of foundation, but found the united swarms all too small to make one good wintering stock, and the honey in the four did not average 2 lbs. to each.—WILLIAM RAITT, *Blairgowrie*.

## TRADE CATALOGUES RECEIVED.

- James Yates, Stockport.—*Catalogue of Bulbs.*  
 W. Paul & Son, Waltham Cross, Herts.—*Catalogue of Roses, Fruit Trees, and Evergreens.*  
 Isaac Davies, Brook Lane, Ormskirk, Lancashire.—*Select Rhododendrons and Azaleas.*  
 George Cooling & Son, Bath.—*Catalogue of Bulbs.*  
 Harrison & Sons, Leicester.—*List of Bulbs.*  
 Sherratt & Pointon, Biddulph near Congleton.—*Catalogue of Bulbs.*  
 J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees, Shrubs, Bulbs, and Seeds.*

**Books (A.).**—The "Cottage Gardener's Dictionary" is not published at this office, and we are unable to say when the next edition will be ready.

**Peaches Decaying (D. East).**—If you will send fresh fruits wrapped in smooth paper they shall be carefully examined; the cotton wool adhered so closely to them that it could not be separated without tearing the skin. They appear to be infested with a fungus.

**Amaranthus salicifolius (A. A. M.).**—Seeds of this plant can be had from any seedsmen who advertise in our columns, and the produce will no doubt be as good as from seed obtained from Queensland. We have seen much better examples of the plant than those you have sent grown from seed raised in this country. We do not understand what you mean by asking if the plant is a Coleus after you have correctly described it as an Amaranthus.

**Gloxinias Starting into Growth (Idem).**—You have given the plants too much water after they ceased flowering. If you have a stove in which a temperature of 65° can be maintained in the winter you may remove the corns and pot them in fresh soil, and grow them on a shelf near the glass; if you have not such convenience, all you can do is to gradually diminish the supply of water and permit the growths to wither and the corns to rest until the spring. They are almost certain to contain some buds still in a dormant state, and they should be kept dormant.

**Insects on Cucumbers (Hortus).**—It is impossible for anyone to say with accuracy what the insects are without seeing them. You cannot do better than fumigate the house lightly on a few consecutive nights; strong fumigation would injure the plants. If this fails syringe the plants with an insecticide, or, what would perhaps be better, apply it with a vaporiser such as was advertised in our columns a few weeks ago.

**Writings on Strawberries (J. E.).**—In reply to your question, "What do you think of my compilation of matter from the writings of Messrs. Gloede, Thompson, Luckhurst, Douglas, and others, with additions and modifications?" we reply candidly that we think very little of it; and we have an opinion that at least some of the writers whose excellent work has been "modified" will not be flattered by having their names so prominently associated with what you have produced. We hope you have sent each of them a copy. You do not adopt the usual course of stating whence you obtained the writings; and we presume, therefore, that you did not obtain the permission of the authors for thus treating their work.

**Peas (F. Heav).**—The same Pea was sent to us last year from the north of England. It appears to be distinct. Although the pods are short they are remarkably well filled, and as you say it is very prolific it is no doubt a useful variety; but in appearance the pods are much inferior to those of the leading varieties in commerce. The Peas you have sent were much too old to enable us to judge of their quality. If you have reason to think the variety possesses special merit you should endeavour to have it tried at Chiswick. If you write to Mr. Barron he will inform you if he is able to test it with other varieties.

**Insects on Plum Trees (F. J.).**—The under sides of the leaves have been much infested with aphides, of which there are many on those you have sent, and the exudations falling on the upper surfaces of the leaves have formed a suitable nidus for fungus, hence the present unsightly state of the leaves. The trees ought to have been well and timely syringed with an insecticide, and the evil would have been averted. As the trees, however, appear vigorous they will not probably be materially injured, but you had better prevent similar attacks in the future. It is impossible to name small, imperfect and unripe Pears, but it is not at all improbable that your tree is correctly named, and you would have had better specimens with better treatment.

**Cissus discolor (S. J.).**—No stove plant is of easier culture than this. Raise young plants in the spring; pot them in a mixture of equal parts of peat, loam, and leaf soil, and place them in a moist partially shaded position in a well-heated stove. The plants do not grow freely nor the leaves colour well under intense light and in a dry atmosphere. We have seen the plant luxuriate in tropical ferneries where the air was almost saturated with moisture and the shade dense, and we have known an unsightly plant removed from a dry stage and placed under it, then commence growing freely.

**Pitmaston Orange Nectarine (W. J.).**—The fruit you have sent resembles a very small specimen of this good Nectarine. Your trees have possibly been overcropped, or are otherwise not in satisfactory condition. Fruit of the first size and quality is produced in unheated houses; but to ensure full flavour it should hang until it shows signs of shrivelling. Perhaps you gather it too soon and before the flavour is developed. The Fern frouds are shrivelled, and we cannot determine the names.

**Grapes Shankng (Paddle).**—Wet soil is not the sole cause of Grapes shanking. Overcropping is a very prominent cause; extreme dryness of the soil will also cause shanking, as will a sharp cold current of air acting on the laterals in their early stages of growth. The only means of ascertaining whether a border is too wet is to examine it by digging down to the concrete; we have known some inches of water accumulate on the concrete in consequence of the "fall" not being sufficient, or the outlet of the drains having been neglected. We suspect your Vines have been overcropped—that is, the laterals where the shanking occurs are too weak and the foliage insufficient for the local demands of the Vine and fruit. You afford us no data whereon to found anything but a general reply, which, however, may lead you to find out the cause of the evil, and this being ascertained the remedy in most cases naturally suggests itself. The fruit to which you allude is probably the Loquat (*Eriobotrya japonica*), of which you will find a figure and full description on pages 292 and 293 of our last volume, the issue of April 4th of the present year. If you have not preserved the number it can be had in return for 3½d. in postage stamps sent to the publisher.

**The Artillery Plant (Idem).**—It is quite true that the "explosions" of this plant can be heard, but they are very faint, and it is only by placing the ear near the plant that any sound can be heard at all, but the "smoke"—that is, the puffs of the escaping pollen, is plainly visible. The plant must be grown in a light position on the shelf of a stove, or greenhouse in summer, so that it flowers freely. If when the buds are ready for expansion the plant is

sprinkle with water, or dipped, and the superfluous water then shaken off, the anthers, owing to the great sensibility of the filaments, suddenly expand, and the pollen is forcibly dispersed.

**Pyrus (Cydonia) japonica Fruiting (Killie).**—It is not at all unusual for fruit to be produced by this ornamental shrub when it is grown in a favourable position and the branches secured to a wall. We have seen fruits very much larger than those you describe. The fruit can be preserved and eaten safely by those who like it, but we do not remember having met with anyone who said he enjoyed it. If any of our readers have a different estimate of the fruit we shall be glad to know how it was prepared to render it acceptable.

**Fig for the Open Air (J. E.).**—You cannot have a more suitable variety than the Brown Turkey. You may proceed as you propose with your tree; remove also the luxuriant growths, and admit the sun and air to the shorter-jointed growths remaining.

**Lily of the Valley (P., Mitcham).**—You may either sow the seed now in pots and plunge them in frames, or sow in spring in gentle heat. The seed is quite ready for gathering; but we think you have made a mistake in allowing it to mature, as the crowns must necessarily be weakened, and the plants are more conveniently raised by division than from seed.

**Judging Potatoes and Peas (R. A.).**—Unless separate classes are provided for round and kidney varieties, which ought always to be the case, dissatisfaction is sure to be given, for, as you state, one judge may prefer round and another kidney-shaped tubers. Such occurrences as the one to which you direct our attention is the result of the system more than the fault of the men. As to a certain judge having "a particular fancy for a certain variety of Pea, and always giving it the prize," we presume he does not judge alone but has a coadjutor, and both agree that a given dish is best. It is not at all unusual for a certain variety of Pea and Potato to win several prizes. It is of the first importance that the judges selected be competent, and it is desirable in the case of provincial shows they should be strangers to the district. The publication of your letter, as you have stated the case, would be of no service, and would provoke unpleasant replies. If you were to give more thought to the subject and treat it on a broad and general basis you might contribute a letter that would be useful.

**Insects Destroying Willow Leaves (W. Harrison).**—The flies sent belong to the genus *Anthomyia*. The determination of the species in this genus is difficult without a "series" of the insects can be examined. We note your remark that the larva are apparently confined to the species of *Salix*, leaves of which are enclosed—*S. Russelliana*, we conclude. An important question is, How the flies could be prevented from depositing their eggs? for little can be done when the larva have hatched out. In plantations of Willow perhaps the flies might, many of them, be smoked out of existence if weeds, &c., were made into bonfires at the period they are first noticed on the wing; or you might try the effect of saturating some pieces of flannel or other old material with paraffin and hanging them in one of the bushes immediately the insects are seen flying about the trees in spring. If you try this experiment, keeping the flannel moist for a time by renewed applications of paraffin, you will oblige by communicating the result to the Editor. The plan has been proved of value in preventing attacks of the Celery fly in gardens.

**Wintering Bedding Plants (G. P.).**—*Alternantheras* and *Coleuses* are stove plants, and cannot be safely wintered in the structure in which the temperature falls frequently below 55°, and a minimum temperature of 60° is better. *Mesembryanthemum cordifolium variegatum* (No. 1), may be preserved on the shelf of a warm greenhouse where the temperature does not frequently fall below 45°; it is equally safe in a higher temperature, and will exist in a lower if the soil and atmosphere are not too moist. The plant No. 2 is *Mesembryanthemum tenuifolium*, and No. 3 *Sedum Sieboldi*, both of which will be safe in an ordinary greenhouse temperature, or any house from which the frost is excluded, the soil being kept comparatively dry during the winter, but not dust dry. *Sedum glaucum* is quite hardy, and will pass the winter safely in well-drained soil from which the rain passes freely, excessive wet being sometimes injurious. We cannot advise you on the *Saxifraga* without knowing the species. We do not name varieties of *Pelargoniums* nor any other florists' flowers, which are far too numerous, and many of them too much alike to be determined except by actual comparison with others in a large collection. We will readily attend to your questions and aid you so far as we can if you state your wants fully and clearly, yet as concisely as possible.

**Scale on Pear Tree (Idem).**—The scale insect on your Pear tree is *Aspidiotus ostreaformis*. If you dissolve 3 or 4 ozs. of soft soap in a gallon of water, and add thereto half a pint of paraffin, and apply to the branches, not the buds, scrubbing them thoroughly, you will soon reduce the numbers of the insects.

**Datura Stramonium (F. A., Lichfield).**—The above is the name of the plant you have sent, and on which you require information. It is commonly called the Thorn Apple or Stramonium. It is an acrid narcotic, belonging to the family of Nightshades. It is found wild in Britain, having escaped from the gardens, and its habitat is generally among rubbish and on dung-hills. It is easily known by its large oval seed vessels, thickly covered with stout sharp spines. The whole plant has a disagreeable, nauseous, and heavy odour, particularly when bruised, and an acrid bitter taste. It loses much of its odour by drying, but retains its properties. When taken internally in moderate doses it causes numbness, vertigo, dimness of vision, dilation of the pupils, produces a slight delirium, intoxication, and forgetfulness, and these effects pass off in five or six hours; but if the quantity taken be large, then all the symptoms of poisoning are presented, as heartburn, intense thirst, a feeling of strangulation, delirium, madness, convulsive movements, and paralysis; congestion of the brain ensues, symptoms of inflammation are manifested, and death follows in twelve or fifteen hours. M. Orfila states that Stramonium acts with more force on the brain than *Belladonna*, and produces more furious delirium. Stramonium smoked like tobacco is a popular remedy for the cure of asthma. Its use in this way has been derived from the East Indies, where other species are used for this purpose. It is the root and lower parts of the stem which are so employed, and the smoke excites a sense of heat in the chest, followed by copious expectoration, and sometimes attended with temporary vertigo and drowsiness. The seeds have the same nauseous bitter taste as the leaves, and in them Braude discovered an alkaline principle called *Datura*, combined with an excess of malic acid. It is in the form of colourless crystals, inodorous, and when first applied to the tongue is bitterish, but afterwards of the taste of tobacco; its action is poisonous.

**Selection of Fruits (R. F.).**—The following varieties will be suitable for your purpose. Peaches: Hale's Early, Rivers' Early York, A Bee, Dr. Hogg, Royal George, and Grosse Mignonne. Nectarines: Lord Napier, Stauwick Elruge, Improved Downton, and Pine Apple. We doubt if you can plant any

more profitable Plums either against walls or as standards than Rivers' Prolific, The Czar, Purple Gage, and Victoria. If you only want a few trees we should select the first and last-named, as it is a mistake to have very small quantities of several sorts for market purposes.

**Planting Vines in Autumn (W. B.).**—Provided you plant the Vines now or later on, they must not be kept growing through the winter, but should be cut back to the bottom of the rafters or trellis when the leaves have fallen, and be given a season of rest. They will not require a higher temperature than 40° to 45° by artificial means through the winter, allowing them to start naturally in spring, and when growth is fairly started encourage it as much as possible. Autumn planting is not advisable. The best time to plant Vines is spring, when the shoots are an inch or two long, and if well attended to they will make strong canes, and should be cut in early winter to within three eyes from the bottom of the trellis. Vines propagated from eyes in February, grown and planted out early in June, will make strong canes by autumn, probably better than those planted the autumn previous; but we should plant in spring, as cut-backs are easily managed and have roots and stored-up sap calculated to insure a good and well-ripened growth. Grapes that are the best for bottling are also the best for keeping on the Vines, but your query is so indefinite as to preclude our giving a satisfactory reply. State your requirements explicitly, and we shall be glad to help you.

**Constructing a Vinery (F. J.).**—We should have the house 16 feet in width instead of 12 feet, as there is much to be said in favour of a good breadth of trellis for Vines. The height at the back will need to be 15 feet for a house 16 feet in width, reckoning from the under side of the rafters, the house being a lean-to; and where there is a wall available and the aspect south, a half-span is not advisable, besides it is more costly. In front you will need brickwork from the bottom of the border about 3 feet 6 inches high, to allow for drainage and compost; and if the border is partly within and part outside, the front wall should have 9-inch pillars 2 feet between the openings, and arched over to admit of the roots passing from the inside to the outside border, and the top of the opening should be a little below the intended surface level. Above ground we should have about 18 inches of brickwork in front, and 2 feet 6 inches of wood-work and glass, or a 2-inch wall plate the width of the wall (9 inches), top plate 2½ inches, and 9 inches wide, the lights being made to open the full length of the house. By having the pathway about 3 feet from the back wall there will be plenty of head room. In addition to the ventilators in front we should have top lights 2 feet wide, to open the full length of the house, the front lights opening from the bottom outward being hinged to the wall plate at the top, the upper lights being opened by crank and lever movement as desired. We should have the rafters 2 feet 6 inches distance apart, these being 9 inches by 2½ inches, and between these midway have bars 4 inches by 1½ inch, these being fixed with the upper surface level, and each rebated half an inch wide and three-quarters of an inch deep for the glass, taking off the upper edge of the rebate with a plane, as we should glaze without top putty, only bedding the glass with putty and secure it in position with copper tacks. An iron cross-bar will be needed between the rafters to keep the wood sash at a proper level and width, otherwise it would warp or sink with the weight of the glass. The front lights should have 2-inch bars and be sashed to correspond with the roof. The glass should be 21 oz. thirds, and in squares double in length that of the width, or as near thereto as possible. At page 462, vol. i., third series, November 18th, 1880, is a plan of a lean-to vinery suitable for amateurs, which may probably help you. If you have not the number it may be obtained if you enclose 3½d. in stamps with address to the publisher at this office, stating the number of the Journal—viz., No. 21, vol. i., third series.

**Naming Fruits (Leon).**—The carriage of all parcels of fruit sent to be named must be paid by the sender; each specimen must be numbered and the name of the sender enclosed in the parcel, whether a special letter is sent by post or not. Only six specimens can be named at one time, and a portion of young growth should be sent with Plums. Your other question will be answered next week.

**Names of Fruits (J. H. Goodacre).**—1 and 2, We cannot name these; 3, Boston Russet; 4, Tower of Glamis; 5, Bedfordshire Foundling; 6, Minchall Crab; 7, Sturmer Pippin; 8, Federal Pearmain. (*Somerset*).—Pond's Seedling. (*W. R.*).—1, Sturmer Pippin; 2, Manks Codlin; 3, Not known, but not Red Astrachan. No growths nor foliage accompanied the Plums and they cannot be named. (*R. Veitch*).—American Mother. (*S.*).—1, Beauty of Kent; 2, Selwood's Reinette; 5, Claygate Pearmain; 6, Jersey Gratioli; 12, Purple Gage. (*C. H. Prinsop*).—Souvenir du Congrès. (*G. Hillier*).—1 and 2 not known; 3, Williams' Bon Chrétien. (*G. G.*).—Early Harvest and Red Astrachan. (*F. R.*).—Cellini. (*W. Bishop*).—2, Northern Greening; 3 and 5, Golden Nonpareil; 6, Dumelow's Seedling; 10, Ribston Pippin; 11, Domino. (*R. P. O.*).—The conical fruit is French Codlin, the other Reinette Van Mons. The Apple is Beadnell's Seedling. The Plums are—1, Coc's Golden Drop; 2, Jefferson's; 3, not known, no growth accompanied it. (*Mrs. Henniker*).—Leicester Burton Pippin, a popular market Apple in the midland counties. (*R. P. Williams*).—Cellini.

**Names of Plants (A. Boyle).**—*Nephrolepis tuberosa*. (*Douglas*).—1, Resembles *Oncidium lanceanum*; 2, *Oncidium splendidum*; 3, *Oncidium wentworthianum*. (*Rosa*).—The Orchid with brownish flowers is *Pholidota imbricata*, a native of several mountainous districts in India. For description and particulars concerning it see page 267 of the present issue. The other is apparently an *Epidendrum*, but was too withered to be determined. (*F. L.*).—*Chenopodium rubrum*. (*J. C.*).—*Phytolacca decandra*. (*S.*).—*Cotoneaster rigida*.

**Queen Fertilisation (A.).**—The facts you bring before us are of abounding interest. The small whitish mass is what you suppose it to be, but whether in a complete form or not we cannot yet determine. As soon as we received it on Saturday we examined it under the microscope, and the two hoods at once determined what it was. We then with a small quantity of water under cover placed it on what is known to histologists as the "warm stage," by which the object is kept up to a desired temperature, and very quickly the well-known movements of the spermatozoa commenced, or rather re-commenced. The whole mass of fluid driven out by pressure is still (Tuesday morning, ten o'clock) in rapid movement. An eighth objective and a deep eyepiece magnifying about 1200 diameters shows it to be full of countless millions of nucleated cells, which cannot be more than the thirty-thousandth of an inch in diameter. Each one of these has an irregular, vibrating, and dancing movement, which keeps the fluid in constant agitation. We intend after watching these phenomena to separate from the rest, when we will report further to you on the matter. —F. C.

## POULTRY AND PIGEON CHRONICLE.

## CONTINUOUS CORN-GROWING AND CLAY FARMING.

HAVING incidentally and briefly alluded to this subject we will now refer to the subject more fully. The scientific experiments of Messrs. Lawes and Gilbert at Rothampstead upon continuous corn-growing having proved not only interesting but successful, have induced a general change of opinion amongst the most intelligent and far-seeing agriculturists, a large number of whom formerly denied that such a system on any soil could be maintained under any circumstances with profit. But the experiments at Rothampstead teach us the fallacy of supposing that the benefit to be derived from artificial manures is fleeting and unstable. For upwards of thirty years phosphates and nitrate of soda applied upon heavy clay land at a cost of about 60s. per acre have maintained it in a most fertile condition, producing corn crops continuously, and returning on an average of years close upon thirty-six bushels of Wheat, and during a period of about twenty-eight years nearly fifty bushels of Barley per acre. We also notice that during the latter portion of these years it gave a better average produce than those obtained previously, thus justifying the conclusion that no retrogression had occurred, and that the same management which had so economically secured this high fertility can also maintain it.

Regarding this question of manuring there are some important facts, which demonstrate that on heavy land the greatest return both of Wheat and Barley have been reached with portable manures, and that upon an average of twenty-five years dissolved bones and nitrate of soda, at a cost of about 60s. per acre, produced several bushels of corn more than an annual dressing of fourteen tons of good farmyard manure. This is shown in a statement of Messrs. Lawes and Gilbert in the "Journal of the Royal Agricultural Society," vol. xxv., and vol. ix. second series. There is one result in the crops obtained in these experiments that ought not to be lost sight of, that the maximum crops were obtained in the most favourable seasons and *vice versa*, the year 1879 being the lowest of a long series of years, and practically exhibiting the

fact that we are more dependant upon seasons than upon any system of manuring. It must be remembered, however, that a dry climate like that of the eastern and south-eastern counties is also an all-important condition for successful continuous corn-growing. Amidst the frequent mists and rains of the extreme western counties of England or Ireland, or in various parts of the counties of Cumberland and Westmoreland, with a rainfall of 60 or 70 inches, it would be quite out of the question to extend corn-growing, or diminish the area of the roots and grass crops which in moist districts will prove advantageous, especially on home farms heavily stocked with cattle and sheep.

We will now refer to those who have in consequence been induced to carry out a system of continuous corn-growing and artificial manuring. The first and great pioneer in this matter whom we shall introduce to our readers is Mr. John Prout, who has published a pamphlet with the title of "Profitable Clay Farming under a Just System of Tenant Right." It will at once be seen that any question of tenant right does not apply on the home farm, or farms in hand and unlet, which at the present time of agricultural depression unfortunately prevails upon various estates throughout the kingdom, because under these circumstances the home farmer has nothing to prevent him from adopting a course of cropping and general management which may be considered best suited to the soil and situation of the farm, and most likely to yield a profitable return for the capital invested in the cultivation. The practical system adopted by Mr. Prout at Sawbridgeworth, Herts, should be understood by every home farmer or manager entrusted with the conducting and tillage of farms, and in order to obtain this object we recommend his pamphlet for their consideration. The system may be briefly described as perpetual corn-growing on heavy land, by means of deep and cheap steam tillage and liberal applications of artificial manure. Mr. Prout states, "The indispensable preparatory requisites are—1, effectual subsoil drainage, and 2, fields of considerable dimensions; to which may be added, 3, straight and neat fences; 4, sound headland roads; and 5, convenient field water supply." To this we may add as a necessary precaution in continuous corn-growing, that no wide hedgerows, or spreading timber trees, or woodlands should be allowed to exist which would injure the growth of cereal crops or prove damaging at harvest time. At this particular time there are probably large numbers of heavy clay land farms in almost every county being given up by the tenants. In various instances it is with great difficulty they can be let to tenants of experience and possessing sufficient capital, except at such a sacrifice as few proprietors are prepared to accept as occupiers, but preferring to take the land into their own hands for several reasons, especially where the land is foul and out of condition, or, as in many cases, being still very wet and requiring drainage, or the buildings and farmsteadings may be out of repair or require additions. All these are matters which will frequently induce the landowner to have carried out under the directions of his farm steward or agent. This was precisely the state of things which prevailed upon the Blount's Farm and Sweet Dews' Farm (which are now thrown into one), situated near Sawbridgeworth, at the time of Mr. Prout's purchase of these farms in 1861, and probably, as regards the state of the land, very similar to many farms which are now continually coming to hand in various districts. It perhaps will be best to let Mr. Prout speak for himself as to the manner and system he adopted to bring them into the highly profitable state and condition in which they now are.

"I began at once with permanent improvements; not, however, in building, for the two sets of farm premises with little addition were ample for my purpose. The land, consisting of clay and strong loam lying upon a subsoil of drift clay and cretaceous gravel, was in a wet condition. Here, therefore, as will be the case upon millions of acres still lying unimproved, the first and

fundamental process of amelioration was to drain the whole effectually with pipe tiles. The land lay tolerably well for draining, and the first thing was to ascertain, by test holes dug in the different fields, what would be the best depth at which to lay the tiles. The average depth chosen was  $3\frac{1}{2}$  feet, the distance apart 33 feet; the 2-inch pipes of these parallel drains empty into 4-inch and 6-inch mains, discharging, in most cases, into an open drain or ditch of 5 or 6 feet in depth, these mains intersecting or dividing the fields, and conducting the surplus water into a stream which is a tributary of the river Lea. The work was completed in four years, at a cost of £6 per acre. The rainfall at Sawbridgeworth, I believe, averages about 23 or 24 inches per annum, which is moderate in quantity compared with the fall in the west of England; but I cannot assign too much importance to the work of draining well. Indeed, the transformation effected in the very texture of the soil, as well as in its temperature and in the climate of the farm (to which I shall refer), are results following from this efficient drainage and from the steam tillage which was rendered possible by the drying of the land." We have quoted from Mr. Prout's pamphlet, seeing how aptly his proceedings may be applied in certain districts upon land coming to hand, and for the present unlet, which upon strong soils at the present is the only possible way of making them profitable in occupation either as arable or pasture land, although the cost will amount, in some cases, to one-third or one-fourth of the purchase value. We propose next week to make further quotations, making also our own comments, showing how far they may be worth following on a home farm or land in hand.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Horses are still engaged in the work of autumn cultivation by following the steam cultivator, which will have been passed through the soil both lengthways and crossways by harrowing with Howard's self-lifting drag, followed by the two-horse roller, until the harrowings and rollings have been repeated enough to bring all couch and weeds to the surface, and carted away to a heap, and not regarding a little earth attached, or so free from it as is required for burning in small heaps in the field in dry weather. This is the surest way to clear the surface of any rubbish, and preparing it in readiness for a deep winter fallow ploughing after the Wheat-sowing is concluded. Some farmers burn these clods of couch and earth in large fires to obtain ashes for the purpose of drilling with future crops, which is not a bad plan; other farmers use the ashes for dressing the meadows or parkland, but we prefer to lay out the couch lumps with earth attached on to grass land without burning, for we have seen it laid out fresh from the field, and do more good on the grass land and more lasting in its effects than a good dressing of farm-yard dung. Some horses will be engaged drawing out dung from the heap or yard, as the case may be, on to the Clover leas; and here we must refer to the effect of the dung-spreading machine, which when attached to the dung-cart will spread the manure of any condition or state, whether decayed or otherwise, as fast as it can be hauled from the cart into the machine, which work is also done better and quicker than by the ordinary hand labour. Upon the hill farms and the dry friable soils where Wheat is commonly sown after Clover the ploughing and pressing may now succeed the dunging as fast as spread, as early-ploughed Clover lea is best when allowed to get settled and stale before being sown or drilled. If the work on the home farm should be in arrear from any cause this ploughing and pressing work can be done simultaneously by the steam plough turning four or five furrows at one operation, and in this way will fetch up any lost time which may have occurred. We wish here to state that on light land after Clover we consider that the Wheat is much surer to retain plant when sown broadcast, or, what is better, by pressing and drilling at one operation, whereby the seed is made to fall into the groove caused by the ring of the presser than when worked down and drilled in the ordinary way, because the seed is seldom buried deep enough to feel the solid ground and obtain a firm hold early enough to stand the effects of winter weather, and then the plants become a prey to insects, such as wireworm, slugs, &c., and is more likely also to be lifted out by frost when the ground shrinks after a thaw. In the event of applying guano or any artificial manures at the time of sowing, it is always more effective and acts better on the plant when buried deep in the press grooves than when applied by the drill, even though the drill may be made to deposit the manure deeper than the seed. Again, we like the plan of ploughing, pressing, and seeding light land after Turnips or other root crops better than by drilling the seed, the saving of a regular plant being much more certain. It is none too soon to drill or sow Wheat upon the hilly and exposed districts on the chalk or limestone soils, for the young plants on such land ought to obtain a good hold upon the subsoil before Christmas.

*Hand Labour.*—Hedging and ditching may now be done with advantage, particularly upon the strong flat-lying land with high banks and deep dykes, and especially upon farms where there is much underground draining done, which finds an outlet in the ordinary ditches of the farm, for the outfalls can then be found and cleared so as to work freely during the winter. It is, however, the

best plan to have a map of the draining done in every field, not only showing the number and direction of the drains, but the outfalls also; for unless this is done and kept with attention it is not only difficult to keep open the outfalls, but in the event of a stoppage the repairs may be effected without much trouble or expense, when, by referring to the map, we can find all the drains. We have done this mapping of the drain work on various estates on which we have directed the drainage, and it has given great satisfaction to the proprietor, and especially after a few years when the bailiff and labourers have been changed.

**Live Stock.**—Autumn grass is now in most cases quite plentiful, and well suited for dairy cows, which are now holding out the milking period better than usual. It is a good time to buy in young cattle, both yearlings and yearlings off. Those brought over from Ireland which are now offering in the markets, are of an improved breed and character compared with the importations of a few years ago. We have lately had the opportunity of buying this young stock, both steers and heifers, at a moderate price. As, however, these Irish importations are mostly reared from cows of various characters, but begotten by a good shorthorn bull, they have good long and thick coats, designating their parentage, but the best only should be selected for keeping; and it is in this selection where the judgment and experience are required, because those accustomed to this business can pick out nearly every animal that comes from the best cows, and this is especially desirable both in steers for fattening and heifers for breeding, but particularly in the latter; for we find the kindly-looking stock best for the dairy, but for steers to go into the boxes for winter feeding we prefer the heavy-fleshed thick-coated animals, which make beef quickest and the heaviest weights when sold. The season is now arrived for buying in the early-lambing horned Dorset and Somerset ewes to go into the home and southern counties where the early lambs are principally reared for the London market. The first and principal fair for the purchase of these ewes is held at Appleshaw in the north of Hampshire the first week in October, at which time many flocks will be just beginning to drop their lambs, and these ewes are now for the most part sent up out of Dorset and Somersetshire by rail, whereas they formerly used to travel to the fair, leaving their native pastures and reaching the fair ground at the end of a week's travelling. Still the ewes when forward in lamb do not suffer so much from travelling as they do by the treatment they get on the railway. Some farmers even now go down and buy the stock at their home, and drive them long distances instead of moving them by railway.

## POULTRY AND PIGEONS

### SILVER-GREY DORKINGS.

I HAVE been requested by the managers of the Crystal Palace Show to collect for a cup for Silver-Grey Dorkings. I have always thought that shows should be self-supporting; but as I am informed that the last Palace Show was not financially a success, and it is a show exceptionally interesting and enjoyable to all fanciers, I cannot refuse once more to appeal to Dorking breeders through your columns. The cup is to be of the value of four guineas for the best adult Silver-Grey Dorking cock or hen. Intending subscribers will save me much trouble by kindly sending their contributions direct to myself.

While writing of the Crystal Palace Show it may not be out of place to state that last year I was a witness of the repacking and departure of the birds at the close of the Show. The care, order, and rapidity with which this operation was carried out (a point at which arrangements break down at many shows) was most praiseworthy, and would, I am sure, have re-assured those most diffident of trusting their pets at public exhibitions.—O. ERNEST CRESSWELL, *Morney Cross, near Hereford.*

### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at Charing Cross Hotel on the 19th inst. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Rev. E. H. Morgan, and Messrs. A. Comyns, H. R. Dugmore, J. C. Fraser, and S. Lucas.

**NEW MEMBERS.**—The following new Member was elected: John Westacott, 5, Trumpington Street, Cambridge. The following new Associate Members were elected: Harry Greenwood, Northoline, Gainsborough; John C. Parker, 2, Beech Villas, The Lound, Kendal.

**ELECTION OF COMMITTEEMAN.**—Mr. George Vigers, Horsham, Waiton-on-Thames, being the only candidate nominated to the vacancy on the Committee, was declared duly elected.

**OWNERS BIDDING FOR AND BUYING-IN THEIR EXHIBITS.**—The opinions (copies of which are annexed hereto) of Mr. H. H. Cozens-Hardy of the Equity Bar, and Mr. John Anstie of the Common Law

Bar, which had been taken by the direction of the Committee, were considered, and in view of these opinions it was resolved that—

“The resolution passed at the meeting of the Committee held on the 28th March last, condemning the practice of owners *being permitted* by poultry show committees to bid for and buy-in their own exhibits, be rescinded.”

**CLUB SHOW.**—The resolution, of which notice had been given at the last meeting, was proposed and seconded, and after some discussion passed in the following amended form—

“That the Poultry Club do (if satisfactory arrangements with that object can be made) guarantee the expenses of, and give prizes at a Show to be held during this season, and do forthwith open negotiations with the Committee of the Cambridge Ornithological Society, with a view to holding such Show in conjunction with them about the beginning of January, 1882.”

The following gentlemen were appointed as a sub-committee to carry out the above resolution: The Rev. E. H. Morgan, and Messrs. S. Lucas, and L. C. C. R. Norris.

**RETURN CARRIAGE FROM RAMSGATE SHOW.**—Complaints from several quarters having reached the Secretary that, although it was stated in the schedule to the recent Ramsgate Show that arrangements had been made with the South-Eastern Railway Company that all exhibits should be returned from the Show carriage free, yet payment of the full carriage had been in all cases exacted by the railway company, it was resolved—

“That the Secretary be directed to write to the Secretary of the Ramsgate Show asking what arrangements (if any) had been made by the Show authorities with the South-Eastern Railway Company as to the carriage of exhibits returned from the Show.”

**SHOWS TO BE HELD UNDER POULTRY CLUB RULES.**—An application that a special prize of £1 1s. should be granted to the Show of the “Nottingham Amalgamated Poultry, Rabbit, and Pigeon Society,” to be held in October under Poultry Club rules, was considered and acceded to. The Secretary reported that Leek Show was also to be held under Club rules.

**NEXT MEETING OF COMMITTEE.**—The next meeting was fixed for October 26th at Oxford.—ALEX. COMYNS, *Hon. Sec., 47, Chancery Lane, Sept. 20th, 1881.*

[We are unfortunately prevented by pressure upon our space from publishing the opinions above referred to. The general effect of them, however, appears to be as follows: That a condition of sale authorising owners to bid is perfectly legal; that even in the absence of such a condition an owner may bid for and buy-in his exhibits either in the open or selling classes unless the sale is declared to be “without reserve;” that an owner may claim his own birds in either class at the sales office; and that he may withdraw his birds from sale at any time upon payment of the commission upon the catalogue price. There is only one point upon which there appears to be any difference between the two opinions. Mr. Cozens-Hardy's opinion is, that it being lawful for the owner to bid for and buy-in his birds, a purchaser at a price run up by such bidding would have no legal remedy; while in Mr. Anstie's view, although an owner may bid for and buy-in his exhibits, yet he might, in the event of first bidding and then allowing the bird to go to a purchaser at a price raised by his bidding, be liable to have the sale avoided or have an action of damages brought against him, unless the purchaser had notice or knew that the owner was bidding. The case laid before counsel was based upon and contained a full statement of the rules and conditions of the Crystal Palace and Birmingham Shows.]

### REMARKS.

11th.—Dull damp day, with occasional slight showers.  
 12th.—Dull and drizzly all day.  
 13th.—Fine pleasant day, but not very bright.  
 14th.—Beautifully fine, bright, and warm.  
 15th.—Foggy morning with slight showers; fine bright afternoon.  
 16th.—Dense fog all the morning; fine afternoon, slightly foggy.  
 17th.—Fog early; fine bright day; cloudy evening.

A variable week, some days very pleasant, others the reverse, on the whole fine but not bright. Temperature rather lower than that of the preceding week, and almost exactly the average.—G. J. SYMONS.

### BOILERS VERSUS WATER.

**N**OW frequently we are asked, "What sort of boiler do you use?" but who ever heard the question asked, "What sort of water do you use in the boiler?" Yet the latter is in my estimation the more important of the two questions, sediment being deposited and corrosion formed in proportion to the amount of chalk and iron in the water. This sediment, or furring, ultimately chokes up the boiler, which is followed by bursting, repair, and too frequently removal before the apparatus is half worn out, the latter involving a serious expenditure.

During the severe weather we experienced last winter one of our 8-foot Trentham boilers showed signs of giving way, which gradually increased until April, when the water issued from the cracks to such an extent that the fire was completely useless, and had we experienced rough weather something must have been done, but the sun coming to our aid rendered the question of repair or removal quite optional for a time.

I consulted one of the principal hot-water engineers in London as to what we could do. The reply was, "You will never do any good with the boiler, you will have to put in a new one. How long has this one been in?" "Nine years, two of them heating over two miles of piping when required." "Ah! it is full of sediment from end to end. I know you will never get it out to do any good. We have tried to clean out boilers, but it was no use," &c. With this I resolved to see what could be done, and took the earliest opportunity of taking the matter in hand. I commenced by taking out the furnace doors, bars, and bridge of boiler; then drilled holes and punched old rivets in the middle of the boiler along the side of the crack 18 inches long. I then set back 7 inches to clear the bulge caused by the deposit, and removed the whole piece 18 inches by 7, behind which I found the deposit concreted as hard as an iron wall, which I had to remove with hammer and chisel. The next question was how to remove the sediment from the bottom of the boiler, as the plug hole was too small; consequently I cut a hand-hole  $7\frac{1}{2}$  inches by  $4\frac{1}{2}$ . I then succeeded in removing the deposit off the bolt-heads, and with chisels and bent irons worked it down the sides of the boiler and so cleared the whole of one side. I then turned my attention to the other side, and in the same way cut out the piece 8 inches by 5 inches wide, where there was a split 8 inches long. I found this side of boiler exactly in the same state as the other. I chiselled out the deposit, and then by means of bent rods dislodged the lumps on the top of

the boiler immediately over the fire, and gradually cleaned and washed the whole boiler from end to end.

The next thing was how to put on the plates. We first drilled the bolt holes, then with a piece of perforated zinc cut to the shape of the boiler and size of the necessary patch, and punched holes along sides to correspond with the bolt holes. We had thus a proper index to work from. We then cut plates of the proper sizes, the largest being 25 inches long by 12 inches wide, drilled holes in them for the bolts, and proceeded to fix the plates on the boiler with three-quarter-inch bolts, and set screws alternately, the bolt-heads being placed inside the boiler and the nuts in the fire-way. These were screwed up as tightly as possible, and then the holes for the set screws were tapped through both plates, and the screws tightly fixed in, so that when finished both plates were as close together as if forced by hydraulic pressure, the small portion of red lead used being forced out all round, there being little or nothing required between the plates. In this way the whole was fitted together, the bridge, bars, and face of boiler put in, the water turned on, and the fire started on August the 13th. As a test we turned out the other fire, and the patched boiler has since been doing the necessary work without the slightest signs of leakage or fracture of the joints from fire or pressure, and I feel quite convinced the patches will stand as long as any other portion of the boiler. The great point in patching boilers is to cut the injured piece clean out, so that the water comes in direct contact with the new patch, and not on the injured edges of the fracture.

It might naturally be supposed by some that the boiler had been neglected and never cleaned out; but this was not so. It has been the practice to run the water out of the boilers four or five times a year. The sediment was deposited on the bolts along the sides of the fire, and gradually extended across the boiler, forming a shelf or receiver for falling sediment from the top of the boiler. This was the chief seat of the evil. The sides were so thoroughly choked up that no water could pass through, while the passage from the return pipes along the bottom of the boiler and up the end to the flow pipe was perfectly clear—*i.e.*, where the least amount of heat acted on the water.

The state of this boiler led to a thorough investigation of all the others, and we found more or less corrosion in all of them. One of Gray's tubular boilers was nearly choked in the same way. This was taken to pieces, and the bottom bars and ring were nearly full of sediment, which was at once cleaned out, the parts put together again, and the boiler refixed.

The question arises, How are we to prevent the furring of boilers? My employer (Sir Henry Peek, Bt.) suggested putting in Potatoes. This may answer in a small way, but I am of opinion that something different from Potatoes is required for an apparatus with two miles of piping. If the Trentham boilers were provided with four plug holes at intervals around the end, and a hand hole in the bottom, they might be easily raked out, the deposit dislodged and cleared away at any time. I should be glad to have the experience of others on the important question of the furring of boilers and means of preventing it.

The lumps of deposit removed with my own hands from the boiler in question were submitted to the Fruit Committee of

the Royal Horticultural Society. They filled five large boxes and weighed when dried within a few pounds of 5 cwt. I have been requested to submit them to the Scientific Committee, and intend doing so.

The water we are supplied with is from the Southwark and Vauxhall Water Company.—J. OLLERHEAD, *Wimbledon House*.

[This is a question of very great importance, and suggests that full provision should be made for cleansing boilers from the deposit that may accumulate. Defective circulation in boilers is no doubt often the result of furring, and few gardeners could have worked for eight days in a cylinder 2 feet 10 inches in diameter, and have done the cleansing and patching above narrated. We have inspected the work, and must say it was a wonderful performance; the deposit we have also seen, and some of it is an inch in thickness and as hard as flint. The boiler thus saved cost £160. But such a waste of fuel as furring involves, besides the risk of fracture, ought never to be incurred, and need not be if provision were made for supplying boilers with rain water, which should be collected in tanks for the purpose, where the ordinary spring or river water is unsuitable.—ED.]

#### HARDY PERENNIALS.

WHATEVER may have been the case elsewhere, the arrangements of ordinary flowering bedding plants about this neighbourhood may be pronounced a failure this season. They grew well and flowered well to the end of July, when the petals of Pelargoniums fell with the falling rain, and the colours of the Verbenas were washed out, leaving us rather too much of one thing. True, the lost colours are brightening up now with the returning sunshine, but the thermometer at the freezing point bids us remember that they must be short-lived. Amongst hardy perennials the case has been different. These have grown as well as ever, and the rain has only had the effect of making them last longer in beauty.

I will name a few of the best of those in flower now, and add that all may be relied on as perfectly hardy, they having passed through the trying ordeal of the last two winters unprotected.

*Coreopsis præcox* is 4 feet high, of a bright but peculiarly soft yellow colour, flowers abundantly for three months, and stands a long time when cut, for which it is very suitable. This is, perhaps, the easiest to grow of all the herbaceous species of this genus. *C. lanceolata*, which was figured in the Journal a few weeks back, is perhaps more beautiful in its individual flowers, but its season is not so prolonged as the first named. *C. auriculata*, nearly out of flower now, is also good and distinct.

*Monarda didyma* is 3 feet high, its flowers and leaves being Bergamot-scented, but it is past its best, though the colour of its scarlet flowers appears to have been caught by the edges of its leaves, and consequently it is not altogether without beauty as well as perfume. *M. mollis*, taller, with lilac-coloured flowers, is rather later and is still beautiful. Another variety which I have under the name of *M. purpurea* (this and *Vallota purpurea* were presumably named by some botanist afflicted with colour blindness) is nearly pink and is still in flower.

*Centrocarrha grandiflora*, syn. *Rudbeckia fulgida*, is a beautiful plant which flowers all through the summer and is useful for a variety of purposes. I have it in circular masses of 5 feet diameter on the grass, in smaller patches dotted amongst Purple King Verbenas, a patch here and there at the edges of shrubberies, besides being freely intermixed in the herbaceous borders. It looks well in each of these places, and I have never heard anyone say there is too much of it. Its flower stalks grow about 18 inches to 2 feet high, while its foliage forms a dense carpet close to the ground. Its flowers are  $2\frac{1}{2}$  to 3 inches across, the centre of which is raised in a half-globular form, is dark brown, and forms a perfect contrast with its bright yellow petals, which are not set close enough to please a florist, but are perfection in the eye of an artist. It is not too much to say that in beauty this plant is equal to the Japan Anemones, while its season is three times as long.

Amongst Asters or Michaelmas Daisies there are a great many weeds which, by some unaccountable stretch of the imagination, some people will persist in calling beautiful, but which find no home amongst my selection. There are, on the other hand, amongst them some of the most telling border plants we have, and I think at the present time there is nothing more beautiful than *Aster pendula*, which I have also received under the name of *A. patens*. This grows 4 feet high, has bright lavender-coloured star-shaped flowers, produced in such abundance as to completely cover the foliage on the upper part of its stems. The petals turn down-

wards after they have been expanded a day or two. *A. longifolius formosus* is a dwarf plant about 2 feet high, just showing its beautiful rosy lilac flowers, which will continue till the frost cuts them off. *A. Amellus*, almost a bright blue and only 18 inches high, is probably the flower amongst Asters which most people would select as the best; it is indeed very pretty, requires little or no support, and is useful for both borders and late autumn beds. Another variety called *A. Amellus bessarabicus* has larger flowers with more purple in them. *A. amelloides* closely resembles the last-named, and is not required where the two others are grown. *A. rosmarinifolius*, 1 foot high and lilac-coloured, is useful because of its dwarf and rigid habit, as is also *A. hyssopifolius*, which is about the same height, nearly the same colour, but distinct in growth, having a light airiness about it such as few dwarf plants possess. *A. ericoides* is scarcely in flower yet; it grows 4 feet high, has small white flowers produced in great abundance, which are useful for cutting for the purpose of lighting up heavier-looking flowers. *A. dumosus* is a dwarf-growing variety, about 2 feet, with similar flowers to the preceding and a spreading habit. These are the best of the Asters in my possession which are flowering now; other good forms, amongst which is *A. grandiflora*, are too late to be of much service.

Of Achilleas, the best, *A. Ptarmica flore-pleno*, a small double white one 2 feet high and invaluable for cutting, is almost over, but *A. ageratoides*, 3 feet high, also white but single, and with handsome serrated foliage, is not an unworthy successor. *A. Eupatorium*, 4 feet high, with Artemisia-like foliage and Golden Cauliflower-like heads of bloom 4 inches across, is very distinct and good; while *A. egyptiaca*, as well as having similar heads to the preceding, has a base of silvery foliage which forms a most pleasing contrast to the flowers. This plant is dwarf, scarcely exceeding a foot in height.

Most Veronicas are over, but here are two which are pretty in the background. *V. exaltata* is rather too exalted perhaps for a small garden, being 7 feet high, but the blue spikes are very conspicuous behind other plants and about 9 feet from the walk. *V. virginica* is not quite so tall, has white flowers, and is a good companion to the former.

*Physostegia speciosa* is even taller than the Veronicas, and has pink Salvia-like flowers, which are pretty in a suitable position.

Further back than the last-named plant, not because it is taller, but because it is more massive, is *Polygonum Sieboldii*, with its white feathery-like flowers and handsome foliage. This plant is scarcely suited for an herbaceous border of limited extent, as it requires much room, and notwithstanding its beauty it becomes a troublesome weed if not closely looked after. It is suitable for a semi-wild shrubbery or to plant by itself on the grass. We have here broken the line of shrubs by making a special recess for it, and the result is satisfactory. *P. Brunonis* is a very different plant, growing close to the ground and producing pink spikes of flower 9 inches high. *P. viviparum*, another dwarf species, though not particularly beautiful, is interesting from the fact of its seeds vegetating on the plant.

Colchicums are now fine. *C. byzantinum* is particularly showy, and *C. speciosum* has beautiful flowers as large as a Tulip. Other good sorts are *C. autumnale album*, *C. autumnale plenum*, *C. autumnale album plenum*, *C. autumnale striatum*, and *C. autumnale variegatum*. The blue Eryngos are still good, *Eryngium amethystinum* being the showiest; but *E. falcatum* and *E. Bourgati* are both worth growing. *Sylphium trifoliatum* is a very handsome yellow Sunflower-like plant about 6 feet high, and *S. laciniatum* has reached an altitude of 12 feet, but is by no means so handsome as the first-named species.

Other good plants in flower are *Chrysocoma Linosyris*, 3 feet, yellow; *Sedum Fabaria*, 18 inches, opening pink and getting darker afterwards; *Tradescantia*, 2 feet, in variety blue, purple, and white; *Lobelia siphilitica* and *S. siphilitica alba*, 2 feet; *Chelone obliqua*, or "Turtle Head," lately figured in the Journal, and its white variety *C. obliqua alba*, both about 3 feet; Japan Anemones, three varieties, too well known to need description; *Pyrethrum uliginosum*, a 6-foot Marguerite of great beauty; *Solidago* in variety; *Harpalium rigidum*, 4 feet, yellow; *Gaillardia hybrida*, 3 feet, yellow and brown; and *Origanum sipyleum*, the pretty little Hop plant with pink flowers.

Only a single spike of *Crocus aurea* is visible; the root producing this was possibly planted deeper than the rest and thus escaped the frost. A tall variety of *Eupatorium purpureum* annually rises to the height of 12 or 14 feet, and is handsome in the background. *Hyacinthus candicans* withstood the frost and has flowered well, being nearly over now. *Aconitum autumnale* is later than usual and scarcely showing colour yet, and *Phygelius capensis* was so hard cut back by the frost that it has not flowered much.

In addition to the above and some others of minor importance we have a variety of Phloxes and Pentstemons which, taken altogether, make a very interesting collection of hardy autumn flowers.—WILLIAM TAYLOR.

#### STRAWBERRY-GROWING IN COLD AND NORTHERN LOCALITIES.

It were well if cultivators who give their experience to the public by means of the press would indicate what climate and in what latitude they practise; for it often happens that those who imitate the published practice of others fail, not because the teaching has been wrong, but because of altered conditions demanding different courses to ensure success. We garden far north, where the "mists" occasionally cause the rain-gauges to indicate a rainfall of more than an inch a day, and where people boast of an early harvest when the corn is in the stack-yard by September. Here Spinach must be sown by the beginning of August, and Onions at the end of July, in order to have them strong enough to winter well; and Gooseberries, in seasons like this, are plentiful at the middle of September. To be sure, this has been a particularly cold and sunless season, but even in the best of seasons things here are in their prime after those in more favoured localities are over. The consequence of all this is, that we are obliged to adopt modes of culture which in more favoured positions might not only be unnecessary but unsuitable.

Like most gardeners we are ambitious to have everything in the best condition possible; but to succeed we have had to "invent" new modes of cultivation, and having departed from ordinary cultivation, and thereby succeeded more than is usual in the cultivation of Strawberries, we think not a few of your readers may find something to interest them, and possibly something profitable, in the following mode of growing Strawberries in cold and northern localities.

We ought to premise that our soil is poor and thin. Now soil poor and thin is not the best soil for Strawberry-growing; therefore in preparing our soil we do something towards deepening and enriching it. Most of it is now two spades deep: when we first dug it, it was only one. In preparing it, we trench it to the bottom and place a liberal allowance of manure between the layers of earth. The last layer of earth is the shovellings from the bottom of the trench, and is new soil manufactured as stated below, but as it is rather poor we put a good layer of manure under it. It is trenched in autumn, and during hard frost we spread another layer of old hotbed manure over the surface, and with a fork incorporate the new soil and new manure, for nothing we find surpasses new soil and new manure for Strawberries and Potatoes. We say, "and Potatoes," for such soil has to be prepared further than merely trenching, manuring, and forking it. Such soil if planted with Strawberries in autumn is too loose to hold the plants properly, and also too rich where the sun so seldom shines, but where the rain keeps everything cold and damp. Spring planting we consider a waste of time and ground, and here it is not at all suitable, as plants put out in spring do not fruit, but on properly prepared soil grow too strongly to be fruitful. Autumn planting, on soil prepared by trenching and cropping with early Potatoes, we find very successful as far as the Strawberries are concerned, and the Potatoes are always a large crop when plenty of room is given them.

Now is the time to prepare the soil, for it must be firm. More failures, we believe, arise from planting Strawberries in newly dug-up soil than from any other cause. Those who intend making new plantations next year, but who trench and plant at once, we advise to try our plan and prepare now.

In manufacturing new soil, as hinted at above, a few inches depth is pecked up—it is very hard and rusty—and a layer of manure is placed over it loosely. Out of the soil the rain washes the rust, and into it the manure, and when thrown by-and-by to the top, manured, forked, and exposed, it makes grand soil for Potatoes, and the Potatoes prepare it for Strawberries. After the Potatoes are lifted the ground is merely pointed over with a fork and cleaned, and is then ready for the new plants. So much for the preparation of the soil—an important matter; now for a word on the preparation of the plants.

Autumn—that is, September—planting for newly detached runners which have been trodden on and pulled about in the gathering of the fruit on the parent plants, and which are nearly rootless, will not do. Plants starved and stunted, turned out of 3-inch pots with their roots coiled and wiry, will not do; at any rate, such are not the best by a long way. We prepare ours partly on a shady border, partly in frames, when such can be spared, which too often they cannot. However, a shady border and rich soil (half soil, half decayed manure) give excellent results.

Runners obtained from the earliest plants, before trampling begins, and just as they push roots, dibbled rather closely into this, sprinkled with water and shaded if need be, make fine plants by September that can be lifted with balls of roots as big as 6-inch pots if need be, and with uncramped roots, strong leathery leaves, and fine plump crowns, which are considerably superior to the 3-inch-pot nurslings.

The slight check they receive in lifting does them good. It stops them, hardens them, and makes them extremely fruitful. When the Potatoes are off soon enough—say in July—the trouble of the second planting may be saved, especially if showery weather prevail. That cannot be ensured though, and so, all things considered, we find plants prepared as we have advised best.

We plant them a foot apart in the rows, and 18 inches between the rows. This is twice as thick as they are ultimately thinned to; but by so planting them a full crop of large fruit is had the first season, and when this is gathered every alternate row is hoed out. After the frosts of winter come we mulch the ground with manure. The rains wash in the strength of this and render the supply of liquid manure unnecessary. In the sunny south it may do good: here it only causes sterility by inducing overluxuriance.

We allow the runners to grow. Our permanent rows are 3 feet apart, and the second year we allow young plants to root and develop themselves among the decaying mulch, for young plants produce the finest fruit. We dig between the rows, and do not find that the roots are injured; but we find it much easier than hoeing, and raking, as is frequently done, half destroying those that remain in the process. We have also tried keeping the first plants isolated, as is often recommended, but do not find it worth the trouble—the encouragement of young plants giving better results.

The second year's crop is generally very large, and, on our soil, is the best the plantation yields. There is not room the second year for further extension of the rows in breadth, but by that time the food supply is beginning to fail; the flush of their growth is past; they grow moderately, and so on the old plants set hard buds freely. In winter we top-dress the whole by riddling fine decayed manure over them, and this enables them to perfect another good crop, when down they go.—A NORTH BRITON.

#### SEASONABLE NOTES.

DRYING ONIONS.—"A KITCHEN GARDENER," at page 238, gives some seasonable remarks on the harvesting of Onions, which no doubt will suit numbers of your readers who are similarly situated to your correspondent. However, there are doubtless others who, like myself, would never save an Onion by the process named. In our district the ground is generally saturated by September, and we think it early when our Onions are fit to pull them. The bulbs are spread out in a Melon pit when the soil is dry, and through which the wind is allowed to whistle. When the air is saturated a little heat is kept in the pipes. A viney from which the fruit is cut is also a good place. Coolness and dryness are essential, and if the Onions are spread in a close and warm structure they will be spoiled.

DIANTHUS NAPOLEON III.—We notice some writers who recommend this very useful plant state that it is not easily kept through the winter. One says that in order to keep it he lifts and places the plants in a frame. Striking cuttings, which become plentiful in autumn, and keeping them as ordinary Pinks are kept, we consider a better plan, as young plants give much better results than an old one. Ours propagated thus, and planted out in April in liberally manured soil, are still (Sept. 20th) blooming. We know of no other plant that will give such a number of flowers from the same space and over such a period as will this. It ought to be of extreme value for market purposes.

PROPAGATING VIOLAS.—Violas are in a large number of cases, perhaps in the majority, very badly treated. They are generally propagated too early and in much too sandy and poor soil, and unsuitable cuttings are employed. If growers would have a little patience until the cool moist nights come, and then pull off the springing shoots when they are about 2 or 3 inches long and have small roots at their base, and then plant them in frames (or boxes to be afterwards placed in frames), employing rich soil, instead of taking rootless cuttings and planting them in poor sandy soil, they would be astonished at the results. Dividing the old plants in spring we only mention to condemn. Violas in frames should not be coddled, it weakens them. The lights should only be used during hard frost, and to keep off rains. They should be planted out on thoroughly dug and enriched soil not later than

April even in the far north, and earlier south. Planting them along with the rest of the bedding plants in May means failure even where *Violas* are at home. In dry warm districts it effectually deprives the plants of the last chance of thriving.—  
PRACTITIONER.

#### MRS. PINCE'S BLACK MUSCAT GRAPE.

WE have this Grape here in a cool greenhouse growing side by side with the Black Hamburg and other sorts. It keeps good time in the ripening process with the Black Hamburg, and its flavour is little short (even at this early period) if not equal to that of the Muscat of Alexandria. I would strongly advise intending planters when the season for that operation comes round—say the month of April; I have planted successfully as late as the 15th of May—not to omit this excellent Grape in their collection, however small, or for whatever purpose the Grapes may be intended. I have an opinion that this variety will some time or other supersede the not unfrequently much-overrated Black Hamburg, more especially if required for a late purpose and the season happens to be wet and very cloudy.

I trust your correspondents will not be behind in recording their experiences regarding suitable varieties of Apples, Pears, &c., in the Journal during the next few weeks, for the planting season is fast approaching, and many sorts have been well tested this season, it being a more fruitful one than the past two or three years, at least in this part of the country.—W. H. C., *Tunbridge*.

#### LESSONS OF LIFE FOR YOUNG GARDENERS.

MR. PETTIGREW in his remarks on this subject makes use of the following:—"There is now, and there has been for forty years, greater difficulty in finding first-class gardeners than there is in finding first-rate places for such." If that is the case how does he account for the great number of really good gardeners who are at all times seeking situations? I am aware that some are successful in obtaining good situations, but I am inclined to believe that more places are secured through influence than from real merit. We need only to look at our nurseries to see the number of men out of employment, and surely they are not all second and third-rate men. I am sure Mr. Pettigrew could find many first-class men in the various nurseries who would be truly grateful to him if he could assist them in their efforts to obtain a good situation, and men who would give him no cause to regret having recommended them.

Another point I notice is the encouragement held out to young gardeners. Mr. Pettigrew asks us to look for a moment at "the comforts of a gardener in a good situation." I willingly admit that a gardener in a good situation has, as our American cousins would say, "a good time;" but what about the unfortunate gardener in an indifferent situation? what are his comforts? Comforts they are, if comforts consist in an unwearied endeavour to keep the place neat and clean with about half the strength that is necessary, and endeavouring to make the garden pay by what he can dispose of after the house is served. Ladies and gentlemen wish their gardens well kept; but I unhesitatingly assert that they do not in many cases spend their money in the free and ungrudging manner described by Mr. Pettigrew. The gardener has greater responsibilities than any other servant, and, as a rule, he is the worst paid. Let ladies and gentlemen pay their gardeners a fair wage, and they will have no cause to complain of their gardeners' abilities. Again, let the gardener without influence to back him up lose his situation; he will find, as many know to their cost, what an uphill battle he has to fight before he can again obtain a really good situation—perhaps many months, and sometimes years, in a nursery before he can succeed in securing what he wishes. I think it only fair that young gardeners commencing life should see the dark side of a gardener's life as well as the rosy prospect held out to them by Mr. Pettigrew. I believe it would induce many in their first, and what perhaps is a comfortable situation, not to give it up because something goes wrong and they fancy their employers are unjust to them. Many do this, and live to regret it afterwards.—CANTAB.

BEGONIAS FOR BEDDING.—No bedding plants survived the rough weather we have been having lately better than the tuberous-rooted Begonias, and as some gardeners may benefit by my experience with them I will state it briefly. About the end of September I take up the plants and place them in a cool airy shed after the tops have withered. Most of the soil is removed, and they are placed close together in boxes and kept in a cool dry place free from frost for the winter. About the end of March

remove the old soil from the tubers and place them in fresh soil about 4 inches apart in the boxes; transfer them to a cool frame, and when the shoots appear through the soil ventilate freely, removing the lights, but afford protection from frost and cold rain. Planting can be done about the 1st of June. The most suitable edging for the beds is *Polemonium cœruleum variegatum*.—  
A. R. T.

#### SCRAPS ABOUT FRUIT.

I HAVE often thought if amateurs and gardeners throughout the country were to send you scraps of matter relating to fruits, that much interesting and useful information would be collected. There are a number of cultivators who, because they cannot send an exhaustive article on a given subject, do not send at all. But do not they pass by matters and incidents that, although they appear small in themselves, may, if recorded, be productive of good results? I think this must be the case, and that a great mistake is made by many persons in not giving sufficient attention to what they deem trifles, or small isolated facts. The other day, for instance, I went into a large garden and was pointed out the difference between the flavour of a Pine-Apple Nectarine that was gathered as soon as it was ripe, and another that was showing signs of shrivelling. The gardener, a most competent man, said—"As a rule Nectarines are gathered too early." "Why, then," I replied, "do you not tell the world so through the Journal?" (which I saw in the fruit-room). "Oh," was his response, "they all know that." Now here, I think, is a great mistake. It is assumed that "we all know that" as regards the points, peculiarities, and adaptabilities of all kinds of fruit, and hence nothing is told, when at the same time a thousand people would accept with gladness a hint or a little scrap of information that could be so easily imparted.

Then we came to some trees of Small's Admirable Apple laden with fine fruit. "This Apple," said my friend casually, "always bears best from the ends of the shoots, and those who shorten them much are not likely to have much fruit." My prompt and unrestrained expression was—"There you are again! This is another of the 'all knows,' when, I believe, not half of the amateurs in the country have the fact impressed on their minds. Why don't you write about it?" "Write about it!" he slowly remarked, evidently pitying my simplicity; "I should not like to put my name to a common matter of that kind." "Well," I replied, "never mind your name, send the facts with your name privately, and leave the rest to the Editor. We want your experience and will do without your name, good as it is; and if you can now and then send scraps, simple items in your estimation, they would be of much service to others." He promised to "see about it," and I think this means he will comply with my request. But as a rule I confess I do not like "see abouts," but I *should* like to see some common scraps of fruit lore in the columns of the Journal. I have a collection of trees just coming into bearing, and may help a little if only as a slight return for the trouble that has been taken on my behalf in the naming of fruits that I have occasionally sent to the office, and herewith send six more.

If you think, Mr. Editor, there is anything in my suggestion pray print the letter; if not, burn it without compunction; you know best. I am not thin-skinned, or I should never do for—  
A COUNTRY SURGEON.

[We are not likely to burn such a letter as this, and the best assurance we can give that "scraps" of experience are acceptable is by publishing some that we have received this week in this column, instead of inserting them as we intended in "Notes and Gleanings." We think there is something "in" our friend's suggestion, and shall be glad to see what comes out of it.—ED.]

FORMAN'S EXCELSIOR STRAWBERRY.—"AMATEUR" wishes to have the opinion of one who has tried this Strawberry. I have grown it for a few years, and can speak with confidence respecting it. It has bright green foliage, is of dwarf habit, and retains its greenness through the most severe weather. The fruit is oval-shaped, of large size, pink throughout: flavour excellent, and for a dessert berry is unrivalled. It thrives well in poor soil. For further opinion see Mr. William Boyce on Strawberry culture in "Cassell's Family Magazine" for September, 1881.—GEORGE KENDALL, *Louth*.

I NOTICED in your number of September 15th an inquiry by one of your correspondents as to the merits of Forman's Excelsior Strawberry. As the fruit is a "native of Louth" I may be likely to know a little of its worth. The fruit is very large, often measuring 9 to 11 inches in circumference; fine, dark, rich colour, good flavour, and, taking it altogether, very captivating. The

plant is very hardy and prolific. My friend Mr. Forman is justly proud of his offspring, which gained the first prize at the Nottingham Show, and also a first-class certificate as a new variety.—HENRY BOOTHBY, *Louth.*

**STIRLING CASTLE APPLE.**—It is stated on page 261 that “this is probably the finest and most useful late autumn and early winter kitchen Apple in cultivation.” This is high praise, and probably not a few readers would like the soundness of it tested. It appears to me the best way of doing this would be for those who consider they have a more valuable culinary Apple in use, say from October to Christmas, to name it, and point out its superiority. If after this test the claims of Stirling Castle predominate, it then follows that everybody must plant it. Will those of your readers who have fruited Cox’s Pomona kindly give their opinions respecting it?—F. D.

**JERSEY GRATIOLI PEAR.**—This variety is not often recommended to the notice of cultivators, yet I find it a distinct and excellent October Pear. The fruit is roundish, of good size, very juicy and melting, and delicately perfumed; it, however, does not keep long after it is ripe, especially where there are children about, as in my case. I think one tree at least should be included in all collections, particularly as it grows well and bears freely. What can be the origin of the peculiar alliance of “home and foreign” names of this Pear? This always strikes me as being singular.—A KENTISH CURATE.

#### INTERNATIONAL POTATO EXHIBITION.

IN consequence of the large amount of work on the opening day of the International Potato Exhibition it was found impossible to give proper attention to the seedlings submitted for certificates and prizes; but the matter was taken in hand immediately afterwards, and is still in progress. As about one hundred sorts were entered in the four classes for seedlings, a certain length of time must elapse ere they can be reported on. However, as regards Classes Q, for white kidney, and S, for white round, the following awards have been made, of which Mr. Shirley Hibberd obligingly sends the appended descriptions:—

**Magnet.**—A very handsome narrow white kidney, of exquisite texture and flavour, presenting a most elegant appearance on the table. Sent by Mr. Charles Ross of Newbury. First prize in Class 2 and first-class certificate.

**Kentish Invicta.**—A handsome broad white kidney, resembling (as shown) the best type of Magnum Bonum. It is, however, far superior in quality to that variety; the texture fine, the flavour full but delicate, and the appearance on the table elegant. Sent by Messrs. Lott and Hart, of Faversham. First-class certificate.

**Lady Truscott.**—A neat white smallish round, spherical, much netted; flesh white, fine in texture; the flavour delicate, buttery, gratifying; the appearance on the table all that can be desired. First-class certificate.

**Fenn’s No. 3 Early White Round.**—A very neat and handsome round of fair size, pebble-shaped; eyes few and even with the surface; flesh white and fine in texture; flavour remarkably good. First prize in Class S, and first-class certificate.

#### HOW TO KILL THE PEAR SCALE.

WILL you kindly republish a paragraph that appeared in the *Cottage Gardener* fourteen years ago on this subject, and ask your readers for any experience they may have had with boiled linseed oil for this purpose? A friend tells me he has used it for scale on a Peach tree and on a Stephanotis with good results, but I have no personal experience in the matter.—WM. TAYLOR.

[The following is the paragraph referred to—

“What could induce you to publish that tremendous receipt for killing, not the scale only, but gardeners also? Picture to yourself the gardener’s face growing longer and longer as he reads that ‘he is to unvail the scale-infested tree, scrub it all over two or three times, next wash it with a solution of soft soap, then dress it all over with a nasty composition, working it into every hole, angle, or crevice.’ None but a man in command of an army of painters as well as sub-gardeners could attempt to execute such a formidable receipt.

“Try the following plan—Paint the tree all over with pure boiled linseed oil in January or February; avoid oiling the bloom buds if you can—it is, however, of no great moment. This is a thoroughly efficient measure, and comparatively easy of execution. No erratic scale will crawl upon the polished branches. My gardener had seen this method employed years ago with great success, and he persuaded me to allow him to make a trial of it. I said the oil would smother the tree. He said the tree would rather like it than otherwise. Two upright-trained Pear trees on the Quince stock were operated on in February last. One tree had only the lower portion of the cordons oiled, the upper part being coated with the usual horrid composition; the other tree was oiled all over. When I saw it shining like polished mahogany I thought it was indeed all over

with it. At this moment both the trees thus operated upon are in better health than they have shown for years. One is bearing an excellent crop of fruit, the other is more luxuriant than is consistent with fruitfulness; but it is ‘all over’ with the scale.”

We shall be glad to have the experience of any of our readers who have tried the above remedy.]

#### DAHLIA GLABRATA.

VERY different from the Show and Fancy types of Dahlias is this graceful species, which with other single forms is now rapidly rising in general favour as a pretty garden plant, and one which affords a bountiful supply of flowers suitable for cutting. The brightness and elegance of these render them very useful for

Fig. 47.—*Dahlia glabrata.*

decorative purposes at this season of the year and until the frost affects the plants. The colour, too, a light mauve tint, is very delicate, and with the exercise of taste some very pleasing combinations may be arranged for vases and other table ornaments.

*Dahlia glabrata* requires similar treatment to the other forms of the genus—taking the slender tubers up in late autumn and storing them in a dry cool position secure from frost. Light rich soil is required, and few stakes to keep the plant neat and compact is almost all the attention specially needed.

**EARWIGS AND PEACHES.**—Earwigs are destroying many hundreds of Peaches here on trees against walls. The means we

employ to destroy these pests is placing Broad Bean stalks between the branches and the wall, about a dozen in a tree, searching them every morning. These insects are easily dislodged from the Bean stalks by blowing them into a bottle half filled with water.—G., Kent.

## A WEEK IN LONDON.

### HAMPTON COURT.

THIS was the next place visited, and a truly grand place it is. The Palace alone is worth a long journey to see, and thousands do not know that this magnificent pile stands on eight acres of ground, having six acres of foundations and ten of roofing, six being covered with lead and four with tiles. But it is not my intention in these notes to deal with the Palace or any of its many historic associations, but of the bedding and other subjects of horticultural interest. The famous old Vine is again bearing a heavy crop of fruit, but showing signs of exhaustion, and one of the uppermost branches will in all probability die this year. It is a pity this interesting old Vine should be so confined for room. Carrying a heavy crop every year with a very restricted growth is sufficient to exhaust it. I do not think the roots of this Vine can reach the Thames, as has been frequently stated. I am given to understand the greater quantity of the roots must be in the border at the front of the house, as when this border is watered during dry weather the effect is soon discernible on the foliage of the Vine. Outside the vinery is a grand old plant of *Wistaria sinensis*, covering a wall 130 feet long and 25 high, but, like the Vine, is restricted, or would undoubtedly have travelled a very long distance.

Leaving the vinery I visited the promenade in front of the Palace, which is fully three-quarters of a mile in length and broad in proportion. A finer walk is seldom seen. From this promenade is viewed a long subtropical border on the side of the Palace more than half a mile in length, and admirably suited to the position. On the opposite side, and running the whole length of the promenade, is the bedding for which Mr. Graham has become so noted of late years. From this point there is a grand view of the three avenues of Elms, which have been planted in double rows on each side. The centre one is most commanding, with the stately trees and canal of water passing down the centre, which is 41 yards wide, and terminates with a fine view of Surbiton. The grounds contain some fine old Yews, which form avenues, and to some might present a gloomy appearance, but they look grand and contrast well with the brilliant colours of the Pelargonium beds.

The bedding this year is all that can be desired—in fact the carpet beds are not surpassed in neatness and beauty by any I have seen. I had concluded that carpet beds were rather unpopular after reading so much against the system, but let the lovers of hardy flowers go and see for themselves. They should watch the herbaceous border or any of the other beds as well as the carpet beds, and see which the people flock round and admire. I am fully convinced that the carpet beds are the most popular. In spite of this Mr. Graham adopts a wise course, and varies the style of bedding as much as possible, and therefore gratifies a great number of tastes. Those for whom the carpet beds have no charm can turn to the beds of fine-foliage plants or to the mixed beds. One of the most striking of the latter contained *Abutilon naevium maculatum*, *Verbena venosa*, and *Iresine Lindenii* intermixed and edged with a broad band of the latter. This was a simple but an imposing bed which must retain its beauty until late in autumn. Violas are largely used mixed with gold and silver tricolor and bicolor Pelargoniums, and produce from a distance a very pleasing effect. In nearly every case the Pelargoniums are planted thickly, so that if a dry season follows and the Violas fail early there is no blank in the beds. If, on the other hand, the season is moist and they grow luxuriantly, then they can be kept in due bounds with the knife. A silver-leaved Pelargonium with *Viola Blue Bell* and edged with *Cannell's dwarf Ageratum*, formed an effective bed in this style. The *Ageratum* is a fine bedding plant, not growing more than 2 to 3 inches high, and is covered with bloom. To keep it neat the strong growths from the collar must be removed as they appear. One bed has a centre of Mrs. Pollock and *Sophie Dumaresque* Pelargoniums, carpeted with the *Viola Favourite* and edged with *Iresine Lindenii* and *Euonymus radicans variegatus*. Another example included a scarlet seedling *Verbena*, a fine flower and a bold eye, very much like *Crimson King*; *Alyssum maritimum variegatum*, *Cineraria maritima*, and *Viola Blue Bell*, with a few plants of *Viola Tory*, and edged with the dwarf *Ageratum*. This bed was very striking from a distance, and presented a very peculiar and yet pleasing shade of colour. Other mixed beds were formed of different

Roses; for example, *Souvenir de la Malmaison* with scarlet *Verbenas*, with a band of *Pelargonium Vesuvius* and edged with *Artemisia gracilis*. It would occupy too much space to enumerate all the beds, and I shall only mention one more before passing to the carpet beds. This was composed of *Pelargonium Henry Jacoby* edged with a band of *Black Douglas* and *Alyssum saxatile variegatum*. The *Pelargonium* is a very fine bedding variety, having large dark crimson trusses of bloom, which rendered it the most conspicuous in the grounds.

The most attractive carpet bed was an oblong with three raised figures in the centre. The centre figure was an oval of *Pachyphyton bracteosum*, the lines being marked with *Echeveria secunda glauca*, having between the two a narrow band of *Alternanthera*. At each end were two small figures of *Leucophyton Brownii*, and then follow the other two raised portions, one at each end, of *Sempervivum montanum*. On each side of the central figures are two others formed of *Alternanthera magnifica*, with another band on each side exactly opposite of *Leucophyton Brownii*. The corner figures, four in number, were filled with *Abutilon vexillarium variegatum* in splendid condition. Between these a small circle at each end was filled with *Alternanthera versicolor grandis*. A narrow band of *Mesembryanthemum cordifolium variegatum* running through the whole of the figures described completes the design, except the edging of *Echeveria secunda glauca* and *Sedum glaucum* intermixed. This was a very beautiful bed, the design being excellent, and the colours most tastefully blended. There were other large oblong carpet beds with various designs, and differing widely from the one described both in appearance and the plants employed. In some cases the groundwork was formed with *Mentha* and in others of *Herniaria glabra*, a close-growing green plant much neater than the *Mentha*. This is without doubt the finest green plant used for carpet bedding, and it is perfectly hardy. *Alternanthera paronychioides aurea* is a great acquisition in this class of plants, and it was used in several designs with great taste and judgment. Some circular beds were really splendid, one forming a double Grecian cross with a circle in the centre of *Pachyphyton bracteosum*, the cross of *Alternanthera paronychioides major*, the remaining portion of the bed being *Mesembryanthemum*. Another circular bed in close proximity to the above had figures somewhat in the shape of anchors formed with *Abutilon vexillarium variegatum*, the groundwork being of *Alternanthera* with four raised mounds of *Echeveria Peacockii*, a very striking species. Mr. Graham values this very highly, and is increasing his stock as much as possible. No doubt this will when it becomes plentiful take the place of the popular *E. secunda glauca*.

I shall leave the bedding at this well-kept place without further reference to any of the many attractive beds, but before doing so must thank Mr. Graham for his kindness and courtesy to me, at the same time congratulate him on his success in flower-garden decoration, and I consider he well deserves the high compliments which have been paid him from time to time.

Before leaving the grounds I inspected the fine avenue of Horse Chestnuts in Bushy Park; they are grand trees, and must present a beautiful picture when in flower. This avenue is a mile long, and the Chestnuts are the finest I have seen. This day horticulturally was brought to a close by inspecting the old

### KITCHEN GARDEN.

This is managed for Messrs. T. Jackson & Son, Kingston-on-Thames, by Mr. Latham. The garden is very extensive, and contains a good quantity of glass; in fact some twenty men are employed in these gardens. The ground was well cropped with the best of vegetables, and large squares were devoted to *Seakale*, *Asparagus*, and *Strawberries*. I noticed on a border in front of one of the houses some *Tomatoes* planted out and trained upright to stakes; the plants were bearing a large crop, the bunches of fruit hanging like ropes of *Onions*. At a rough calculation I should say there was fully a ton of fruit, all the chief large-fruited varieties being grown; one called *Large Red* was carrying the heaviest crop. The walls are covered with old fruit trees, which had formerly the spurs a great distance from the wall; they have now been well cut back, and good crops of fine fruit are produced close to the wall. The vinerics are rather numerous, and some of the Vines are very old, but were carrying heavy crops of good average fruit. In one house some young Vines planted three years were fruiting well and growing luxuriantly. Hundreds of young Vines in pots were growing in a span-roofed house, the canes being good and the eyes plump. Several houses are devoted to *Peach* and *Nectarine* trees, which are planted across the house about 2 yards apart and trained fan-shaped to upright wires. More fruit is obtained by this method than by planting at the front of the house as is general. The only doubt I entertained was

about the fruit colouring, but was informed that it had been quite satisfactory in that respect. Melons are largely and well grown in pots, the only artificial heat the plants have being that from the bed of leaves on which they are planted.

The produce of two varieties of Potatoes that had just been dug is noteworthy—namely, Mammoth Pearl 438 lbs., and Matchless only a few pounds less; the former is a large and somewhat irregular tuber, the latter more symmetrical, being of the shape of Paterson's Victoria: 14 lbs. of each were planted, and grown in the ordinary way. Both these Potatoes are of excellent quality.

Abundance of produce is secured from this garden, and the various departments reflect the highest credit upon the manager.—A COUNTRYMAN.

(To be continued.)

#### TOMATOES AT THE MANCHESTER EXHIBITION.

I HAVE been very interested in the full report of the above Show. It was not my fortune to see what must have been a grand exhibition; and I do not wish to find fault with my award, but I think for the guidance of exhibitors the awards should be explained. Good medium-sized, but perfect specimens, of the three kinds of Tomatoes were sent, and I gather from various sources mine were considered the best. I could have sent fruit double the size or even larger, as I had at that time fruit up to a pound in weight, but they were imperfect in form. I am informed that the fruits in the first and second prize collections were very ugly and much cracked.

At the Alexandra Palace last year I took the precaution to stage one dish of large but irregular-shaped fruit, which were passed over, and I obtained the first prize for a smaller but better shaped medium-sized fruit. This I take for granted is as it should be, as I should always suppose, unless otherwise stated, that beauty would stand before size. I expected there would be good competition at Manchester, but did not think even in the Tomato class that any dish would be overlooked; yet the awards surprised a few, and they were certainly misleading.

I see by the published official catalogue there were twenty-one entries in Class 58, of which I believe most staged; at least there were eighteen dishes staged, showing that the competition was good, yet in some of the gardening periodicals not the slightest notice has been taken of this class.

I am writing at a disadvantage, as I did not see what was exhibited, but hope these remarks will be received as written—not in a carping or grumbling spirit, but simply to elicit further information to guide myself and others in staging Tomatoes for competition.

Before I finish I ought to say, that although some weeks we cut over 1 cwt. of Tomatoes, yet I know how difficult it is to find a good dozen, so that great credit is due to the Manchester exhibitors.—STEPHEN CASTLE, *Manager, The Vineyard, West Lynn, Norfolk.*

#### AUTUMN PROPAGATION OF BEDDING PLANTS.

ON page 171 I wrote at some length upon the propagation of such plants as Pelargoniums, Iresines, Coleuses, Verbenas, and Heliotropes; and in continuation of those remarks I propose to offer a few hints upon hardier kinds, such as shrubby Calceolarias, Violas, and Echeverias.

*Calceolarias.*—These are not so extensively grown as of old, owing to their fickleness—many plants frequently inexplicably dying some time after being planted, especially should hot dry weather prevail, this giving the beds an objectionable appearance. Where, however, they do succeed they are very effective, and as they are easily propagated and wintered they should be grown in quantity. The cuttings may be taken any time during October, or even in November, but it is not advisable to delay propagating till very late in the season, as the young growth—which must be selected—is liable to be injured by early frosts. Owing to the long-continued showery weather cuttings are very abundant, and also rather too succulent. The preference should be given to flowerless shoots well exposed and of medium size, and these may be cut below the third joint, or if extra sturdy at the fourth joint, and one or two pair of leaves may be trimmed off, the cuttings being inserted up to the second pair of leaves. Two or more handlights, or a single-light or double-light frame according to the number of plants required, may be utilised, and are most suitable for them, a dry heat being especially injurious to Calceolarias. No bottom heat is required, but it is advisable to form a shallow bed—say 18 inches deep at the back with a slope to the front, with any half-decayed material, such as the linings of old hotbeds, on which to place the frames or handlights. In the case of deep frames more light rough material should be thrown in, the object

being to bring the cuttings near to the glass. Over this a thin layer of common soil may be spread, next about 3 inches of finely sifted light sandy soil, finishing with a thin layer of sand, and beating down firmly with the back of a spade. The handlights to be placed on after the bed is prepared. The cuttings should not be crowded, or those that are sappy especially are liable to damp off. They may be disposed from 2 to 3 inches apart, and the base of each should always touch the bottom of the hole made by a slightly blunt dibble. They should be watered-in, and kept close and shaded from bright sunshine till rooted, which in the case of those inserted early in October would be effected by the end of November; afterwards on favourable occasions, both by night and day, ventilate freely to prevent active growth at an unfavourable time. They will be unaffected by a slight frost, and should not be protected other than by the lights, unless severe frost is imminent, when in addition to mats or pieces of old carpets and similar protecting material, the whole bed and lights should be heavily covered with loose dry litter. If the plants be found to be frozen at any time sprinkle them with cold water, gradually exposing them to light when completely thawed.

*Violas.*—Unlike the preceding these are rapidly increasing in popularity, the yellow varieties indeed being excellent substitutes for Calceolarias. They are hardy, but to have them in perfection during the summer months it is advisable to strike and winter them in handglasses or in cold frames prepared as recommended for the Calceolarias. In most cases a number of short flowerless shoots springing from the base, and about 2 inches long, will be found, and these should at once be taken and dibbled in about 2 inches apart, and otherwise treated similarly to the Calceolarias. They will form roots readily during the winter, and become neat little plants fit for transplanting in April. Old plants are easily divided in the spring, but if allowed to remain in their present quarters will greatly impoverish the soil; and although plants obtained by division are the first to be effective they are the first to fail, especially during a dry season.

*Echeveria secunda glauca.*—These plants have long been extensively grown in large gardens, but I find amateurs do not understand their treatment, and this season several have asked for information on the subject. For "facing" the margins of beds filled with carpeting plants or otherwise they are as much in demand as ever, surplus plants being in great request. During a comparatively mild winter they will survive unprotected, especially if the position be a dry one; it is safest, however, to lift and store them away closely in cold frames or in shallow boxes and placed in a light dry position. The stock is generally increased by division; and at lifting time all the side shoots should be pulled off and dibbled in boxes or frames. Any light soil will suit them, and they should not be coddled—only protected from severe frosts, snow, and drip. Small pieces taken off this autumn will not grow to a sufficient size to be employed with the old plants next season, but may be planted in an inner line or a separate bed.

*Various Plants.*—*Sedum glaucum* is much admired when forming a groundwork in a carpet bed; it is hardy, and may be increased to a remarkable extent in the spring. *Mentha Pulegium gibraltarica* is not perfectly hardy, but a small quantity disposed in thin patches in cold frames, ventilated on all favourable occasions, and protected from very severe frosts, may be increased to any extent in the spring. Close thick patches are liable to damp off. *Gnaphalium lanatum* is now not much used. Cuttings may be struck and wintered in cold frames or handlights. *Stachys lanata* is a much more effective silvery-foliaged plant, is quite hardy, and easily propagated by division either in the autumn or spring. The old *Gazania splendens* is still worthy of cultivation. It is remarkably effective planted with *Iresine Lindenii*. Cuttings of young growth may now be taken, treating them in every respect similar to the shrubby Calceolarias; they will also strike in the spring with the assistance of a mild heat. I have omitted mention of the good old *Verbena venosa*. When the beds are broken up save a number of these with their roots entire; reduce the tops considerably, pack the plants away closely in shallow boxes, and place them in a cold frame. Give sufficient water to keep the long thick roots plump, as these if cut into lengths an inch long, dibbled in thickly in boxes, and placed in heat, will each form a strong plant by the time required.—W. I. M.

**THE ONION AND CARROT MAGGOT.**—The maggot in Onions and Carrots have been more abundant than usual this season. In this neighbourhood whole breadths have been entirely destroyed. The means I have taken to prevent it is when digging to give a good dressing of soot and lime if the ground has been trenched; lightly fork it in afterwards. When the season arrives for sowing

give a good dressing of soot and wood ashes, and with a wooden rake well work it in. After its being trodden and the drills drawn give another dressing, then sow the seed. I find wood ashes an excellent preventive against grubs of all kinds, as well as being a valuable manure.—H. L.

#### PEACH TRAINING.

SOME friends have been good enough to forward me copies of a paper containing further criticisms on my writings, and one of them in a note advises me "not to take too much notice of a critic, who is apparently more indebted than any writer of the day to the works of others;" and adds significantly that "if the said critic was confined to his own practice probably he would write much less voluminously, and I hope more usefully. It is pretty well understood amongst gardeners that those who are driven for subjects to the works of others have very little of their own worth writing about."

I would not trouble you again on this subject, but my critic, finding the system I recommended is not to be condemned, takes a fresh tack and accuses me of borrowing it from Thompson's "Gardeners' Assistant." Well, drowning men, we know, will catch at straws; but there is no straw here to catch at, for it so happens that Mr. Thompson recommends quite the opposite system—*i.e.*, fan-training. So much for fast writing without thinking.

As I had the advantage of learning something about training from Mr. Thompson personally, and on his own favourite trees, my "ignorance" of the subject must arise from insurmountable natural causes, and not from the fact of having had no opportunities.

I do not wish to take up any more of your space with personal matters which are of no use to gardeners, therefore I will thank my friends to spare themselves the trouble of sending me any more papers in which I may have the honour to be noticed.—WM. TAYLOR.

#### NOTES ON CIRCUIT.—No. 3.

THERE is one great advantage that I have gained in my wanderings as a judge, that I come to know those with whom I have been long acquainted by their writings, and concerning whom I have often conjectured what manner of persons they were in the flesh. Amongst those writers of the Journal whose communications are always full of sound teaching and practical common sense are Mr. Pettigrew the gardener at Cardiff Castle and Mr. Muir the gardener at Margam Park. My visit to Cardiff to judge at their first Rose Show, of which I have already given some account, gave me the opportunity of making their acquaintance and of finding that I had not misjudged the writers. The cordiality with which I was welcomed by Mr. Pettigrew made my visit most agreeable, and when under his guidance I went through the grounds of Cardiff Castle I had a time of much enjoyment.

Cardiff Castle is well known as one of the seats of the Marquis of Bute, and who also owns the rapidly increasing town which has sprung into such importance in South Wales as the port from whence so much of the coal found in this portion of the United Kingdom is exported. The Castle is quite close upon the streets of the town, as in so many of our large feudal properties; and the grounds which surround it tend to take off the idea of dreariness which a town, however bustling it may be, must have whose chief export is coal. The Castle itself is a fine building, and large sums of money have been spent upon it by the present owner. Interiors have little interest for me, and I was therefore more concerned with the surroundings. The pleasure grounds are tastefully laid out; and on the Castle walls facing the south Vines have been trained up to a great height, and in this mild climate their crops ripen well. It is well known that the outdoor cultivation of the Grape has been specially tried by the Marquis of Bute, but as the vineyards are some three miles away I was not able to see them. The Sophia Gardens, comprising eleven acres, have been given as a recreation ground to the inhabitants and are well kept. The kitchen gardens comprise about eight acres, and I need not say with so experienced a gardener as Mr. Pettigrew are in excellent order. The amount of glass, however, is by no means commensurate with the requirements of such a house, and the houses are fewer in number and smaller than I have seen in places at all equal to it in importance. There are four vineries not large, a Peach house, a greenhouse, a plant stove, Pine stove, and eight Pine pits. There was a fine crop of Eastnor Castle Melon in one of the houses, and of the many candidates for favour in this fruit there are few which can claim superiority to this. It is an abundant cropper, and the fruit of first-rate quality. There,

too, was to be seen in great perfection the Cucumber of which notice has been taken in the gardening papers lately—one of Mr. Pettigrew's own raising—Cardiff Castle, and a most valuable variety it is, producing large quantities of fairly sized fruit, well shaped and of good quality. What a great mistake it is to grow huge Cucumbers! When people tell you that they have Cucumbers 2½ feet long one can only express regret that they should think so much of size. Few persons want a Cucumber to be put on a table in its natural state, and even if they did it would be no advantage to have one stretching over any dish you might put it upon. But as they are nearly always cut up before being served the point to aim at is simply quality and not size, and this quality Cardiff Castle most thoroughly possesses. I saw here a plan which I have not noticed anywhere else. Round the collar of the plants of Melons there was placed what seemed to me, and I believe was, about 3 inches of the rim of a large pot, making a circular protection to it; and the reason of this was in watering to prevent any water falling on the neck of the plant, which Mr. Pettigrew considered the cause of much of the canker and decay that take place in Melons, and for the same reason a pane of glass was placed against the stem of the Cucumber plants. They received abundance of moisture, but not on the collar of the plant, and nothing could exceed their vigour and health. In the Peach house I also noticed what was to me a novel plan. The front lights of the house were hung on pivots, so that the upper surface of the leaves of the Peach trees which were trained on the trellises might be syringed as well as the under surface, and thus the attacks of red spider be prevented. No trace of that pest was anywhere to be seen.

The Vines were in the most luxuriant health, and of course (for do we not find it so everywhere?) the staple varieties were Black Hamburgh for black Grapes and Muscat of Alexandria for white. Notwithstanding the numerous claimants to public favour that have appeared of late years these two favourites hold their own against all comers. Dukes, and Champions, and Doctors, and ladies even, may for a brief season jostle them out; but after all the gardener knows that these are dependable and relies on them chiefly. Alicante and Gros Colman were also grown on account of their keeping qualities, and in every large establishment some of the newer kinds are sure to be grown; but where the number of varieties is necessarily limited these two old favourites will afford the chief supply. By-the-by, in my little house I have been greatly annoyed by mice eating the Grapes. I have invited them to eat toasted cheese served up in a neat little apparatus, but they decline it, and seem to be vegetarians, for the Grapes are nibbled and eaten and the cheese left. The Pines exhibited the same high state of culture as the rest of the fruit, and were perfectly free from any insect pest.

The plant houses were full of well-grown plants, such as are usually to be found in such establishments—*Eucharis amazonica* in large numbers and fine plants; Azaleas; Coleus, some grand plants prepared for exhibition, but nothing unusual. In the grounds the Roses on Manetti stocks were very fine, and had the weather been more favourable Mr. Pettigrew would have been able to exhibit blooms equal to those shown at our large exhibitions. At the Exhibition there the Marquis of Bute gave a prize for the best twelve blooms of the York-and-Lancaster Rose. Several boxes were exhibited, and the prize was won by Mr. Pettigrew. But great was my surprise on visiting the Oxford Botanic Gardens next day, under the guidance of Mr. Baxter, to be told that the Rose so generally grown and known under that title was really not it, but one called *Rosa Mundi*; the true York-and-Lancaster being an entirely different flower, not so flat, and often coming with one-half of the Rose white and the other red, not striped as in the flower ordinarily called by the name.

It was a matter of great regret to me that I could not remain any longer in Cardiff, or pay a visit I had hoped to have done to my excellent friend Mr. Llewelyn at Penllergare near Swansea; but exhibitors came crowding thick upon one another, and so I was obliged to leave; but it was a most pleasant visit, and I shall not soon forget the courtesy and kindness shown to me by Mr. Pettigrew; and of one thing I felt more than ever assured, that now that I had seen and talked with him I could the more readily assent to any teachings which he may hereafter favour us with in the pages of the Journal.—D., Deal.

SHADING CAMELLIAS.—I do not think it is wise to plant Camellias against hedges or walls, nor yet within a dozen feet of them, because I have always noticed (in Cornwall at all events) that when they are so grown they do not produce flowers except on one side. I have always seen the best Camellias grown fully exposed to the sun, but protected by tall-growing trees

200 or 300 yards off. In fact, several specimen Camellia trees are so grown in Cornish gardens; but it must be remembered, however, that in Cornwall the sun is not nearly so powerful as in some other districts of the country.—W. ROBERTS.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 29.  
NEW SERIES.

SOME years ago the present writer contributed to the pages of a scientific journal an article upon "Darkling Spiders," which led to a lively discussion upon the habits of one group of these creatures. In this article an account was given of the curious and sometimes large webs that are to be found in dark closets or cupboards, or in similar places where it is exceedingly unlikely that spiders could capture any quantity of flying insects; and it was suggested that these webs, seemingly the work of several spiders, must be designed for retreats merely. From the information then elicited it appears that the number of flies and other winged insects that enter closets, sheds, &c., where there is little light is greater than might be supposed; also in such places these webs may be designed to entrap crawling insects and mites which are sure to frequent them. But, as a general rule, webs are spread by spiders with the object of catching winged insects, though a variety of insects in different stages tumble into the snares. Caterpillars are often found in spiders' webs, and to some species of these the occupiers of the webs manifest great dislike, ejecting them as speedily as possible. Should one of the leaf-rolling caterpillars fall into a web the result is usually a prolonged struggle between it and the spider; its dexterity enables it to slip out of the coils of silk thrown round the body, and only after it has received several bites does the caterpillar succumb.

Those spiders which do not construct webs secure their prey either by their wonderful agility, or by placing themselves in ambush to spring out upon their victims as they incautiously approach, and the species that are simply hunters manage to secure both winged and wingless insects. Subsistence is a precarious thing with most of the spiders. The web-makers in exposed situations are liable to have their webs destroyed, or a spell of wet weather may prevent their taking flying insects, and the wanderers of the race run many risks; hence it is found that all spiders are able to endure prolonged fasts, though when they have an abundance of food within reach they show themselves exceedingly voracious. Some of the species have an ingenious way of keeping their captives alive, having evidently a dislike to insects that are not fresh killed. They do nothing to these prisoners they wish to preserve, except to fix them firmly by silken cords in a safe position upon the web, where they may struggle ineffectually for several days, until the spider thinks fit to wound them with its fangs and bear them off to its retreat. Now and then these escape from durance, and there are of course insects often entangled in webs which the spiders find it necessary to settle at once—the stinging Hymenoptera, for instance. Wasps and spiders have at times desperate conflicts, the result being occasionally the death of both combatants. It seems, we may note here, to be a fact that when very few insects are obtainable, as during some of the winter months, spiders will bite up and devour fragments of their own webs.

Cannibalism is excessively common amongst spiders, and a couple are seldom to be observed approaching each other without suspicious caution; yet there are some small species that find sufficient food by wandering about the webs of the larger *Epeiræ*

or garden spiders, taking their minor captures. Possibly they also spin little but compact webs amongst the broad circles made by their kin. And at the period of their first appearance in the world young spiders of many species keep in company; an example familiar to most gardeners is that of a common *Epeira*, the juveniles of which are pale yellow with one black spot, noticeable in clusters upon walls and palings during the month of May. Until they have passed one or more moults they live together amicably, forming a web which supplies food and a home. A naturalist saw one of these, newly hatched, eject a line a hundred times its own length and attach this to a distant point, when, the rest of the brood assisting, a broad band of silk was soon constructed. The parent spiders have only now and then been observed in the act of feeding their progeny, but the jealous affection with which they guard their bag of eggs is apparent. They will bear this about from one spot to another, and fight for it to the death.

The spiders (fig. 48) belonging to the family *Drassidæ* are generally of a dull brown or grey colour, though one of our British species

Fig. 48.—Water Spiders.

—*D. micans*—displays a metallic brilliancy on the abdomen. They are of moderate size, having slim bodies, and live upon walls or under stones, also upon trees with decaying bark, and occasionally amongst low plants. Each makes for itself a habitation in the form of a silken tribe, which is usually open at each end, though not always. They obtain their food by hunting. Formerly the water spider, *Argyroneta aquatica*, was placed in this family; but Mr. Cambridge removed it to the *Agelenidæ*, since it is a web-producer. This spider is still in request as an adornment for the aqua-vivarium, and it is sometimes introduced into ponds on lawns if to an extent it has been eclipsed by newer favourites. Its habits are particularly interesting, for this species constructs a dome-like cell or chamber, which is fastened to the stem of some aquatic plant, and to which a supply of air in globules is carried down by the spider. The hairs that clothe the body completely secure it from getting wet, and by manœuvring the bubble of air, which is always borne about under the water, the spider is as much at home under water as upon land. Its researches for food

are not confined to the fluid element, but anything captured on the bank is carried down to the cell to be devoured. The eggs are deposited and hatched also in a submerged cocoon.

In the genus *Cinifo* we find webs that are constructed in an irregular manner, and made of a flocculent, sticky silk, which soon becomes discoloured or dirty. These spiders have an additional pair of spinnerets, which are covered with flat plates; each of these contains about two thousand minute holes. *Agelena labyrinthica* is the spider which we so often perceive along the hedges, or on the clumps of bushes upon heaths. The exterior of the web is a mass of white and stout silk, spreading out for some distance, having lines leading to a tube or tunnel, at the bottom of which the spider lurks. The spiders of the genus *Tegenaria* occur in passages, rooms, and outhouses, their webs being sheet-like and rather angular, having a nest or hiding place in one corner below. These spiders are brownish, with a double row of markings along the abdomen, and long stout legs, often hairy. Some of the species, such as *T. domestica*, seem to subsist chiefly upon house flies, and they have the peculiarity of thickening their webs from time to time until they appear almost papery. In winter they are active, except during extremely cold weather, when they may be so far tamed as to take insects from the hand. *T. atrica*, which makes a large web of dark silk, endeavours to place its web across a gap or opening, by which flying insects are likely to try to pass. In damp rooms woodlice have been seen crawling in or near the webs of these house spiders, but they are not interfered with. Though apt to engage in combat I once observed one of them run from its own web into that of a neighbour's who had a boisterous fly, and the two having mastered it feasted upon it amicably.—J. R. S. C.

SIR TREVOR LAWRENCE, BART., writes respecting the PRESENTATION TO MR. J. DOMINY as follows:—"Will you kindly make known the result of our endeavour to raise a small fund as a recognition of the services to horticulture and the personal worth of Mr. John Dominy on his retirement from the service of Messrs. Veitch & Sons? I have received £262 10s. 6d. from 114 subscribers. After paying for advertisements, £13 4s., and a few other small expenses, I shall have £250 to present to Mr. Dominy. I should mention that many of the subscriptions were accompanied by letters which showed that the writers had a great regard for Mr. Dominy. Indeed, the testimony to his personal qualities and to his skill as a raiser and grower of Orchids has been most emphatic. With the consent of the Council of the Royal Horticultural Society I propose to present the fund to Mr. Dominy after the meeting of the Council on October 11th, at 3 P.M. I beg to thank the subscribers for the liberality and ready kindness with which they have contributed."

— WE are informed that Messrs. J. Veitch & Sons, Chelsea, had a handsome COLLECTION OF NEPENTHES at the HAMBURGH EXHIBITION on the 14th to 18th inst., when the grand gold medal and the States medal were awarded to them. The collection was greatly admired, and included a number of the most attractive forms in cultivation.

— IN reference to FLOWERS AT GENERAL GARFIELD'S FUNERAL the following cablegram has been received from America—"The floral ornamentation is most lavish. Indeed such enormous quantities of flowers have kept pouring in from all quarters that those in charge of the arrangements are in a difficulty as to how they shall dispose of them. They have come by trains in great bulk, as if they were the commonest merchandise. Yet in spite of all this profuse floral tribute there rests on the coffin lid but one floral decoration. It is the exquisitely lovely wreath sent by the Queen of England." This wreath, we are informed, was composed of white Roses, Stephanotis, and Smilax leaves.

— MESSRS. W. HENDER & SON, Plymouth, send us examples of their DOUBLE-FLORET DAHLIA, with the statement that it has been twice certificated, the Judges "considering it to be probably a forerunner of a new race of Dahlias, as the inner florets may become elongated and so alter the present appearance of the Dahlia considerably." The variety is certainly a remarkable one, and is really entitled to the designation "double," for most of the florets include two and some three smaller florets. This gives the head a peculiar appearance, especially as the larger florets are somewhat quilled. In general form the bloom is globular and solid, the colour being a bright shade of scarlet.

— WE regret to have to refer to two ACCIDENTS TO GARDENERS that have recently occurred. Mr. Wildsmith of Heckfield sustained serious injuries by having been thrown out of a trap last week, but he is now, we are glad to learn, progressing favourably; and we are also pleased to hear that Mr. Simpson of Wortley, who recently broke his leg, is now so far recovered as to move with the aid of a crutch. We hope to hear of the speedy and complete recovery of these well-known gardeners.

— A CORRESPONDENT observes—"AMARANTHUS MELANCHOLICUS RUBER has this season been admired by numerous visitors, as it is more showy than such plants as *Coleus Verschaffelti*, *Iresine Lindenii*, and Dell's Beet growing near it. It is superior to the three above mentioned; it is more compact in growth, brighter in colour, and bears pinching well. The unusually hot summer undoubtedly was very favourable to it. Where it succeeds well it is a great acquisition among bedding plants."

— "D. C." writes—"TROPÆOLUM SPECIOSUM is singularly capricious. I had a plant which, till a good situation was found, was placed against a kitchen garden wall facing nearly south and apparently a dry situation. By accident it was left there, and having been covered with flowers this summer I have desired the gardener to leave it permanently. In the hot weather it was a little scorched, but I had tried it before in north and appropriate situations with no good results, so I conclude it to be a capricious plant. It is most beautiful even in the extreme north of Scotland, and all points to a damp and cool aspect as the most likely, though I have seen it fail to flower in a damp Yorkshire dale this autumn."

— "W. K." sends the following note—"On visiting Kew a few days ago my attention was attracted by some trees of *PYRUS BACCATA*, which are planted freely in the shrubbery borders with excellent effect. These trees are of double value for shrubbery work. In the spring they bear abundance of snowy-white flowers, and in autumn they look equally handsome laden with their rosy fruits. These fruits could be used in a variety of ways for decorative purposes with admirable results, arranged in vases associated with flowers and Grasses."

— THE same correspondent observes that "In the Orchid house at the above-named establishment may now be seen in flower a fine plant of *DENDROBIUM AUREUM* VAR. *PHILIPPINENSE*. The flowers are similar to the typical form, but larger and of a lighter colour. The pseudo-bulbs are very different from the species, being about 4 feet in length. The plant is flowering profusely from the old stems, producing four and five flowers from most of the joints. When the variety becomes better known it cannot but find favour with most Orchid-growers. It is at present comparatively new, having been introduced to this country about twelve months ago. Mr. Low, at Clapton we believe, first introduced it. *Dendrobium formosum* var. *giganteum* is another valuable Orchid, and is also in flower in the same house. The flowers are pure white with a broad band of bright orange at the base of the labellum; they are produced from the extremity

of the young matured growths. These two Dendrobies should certainly find a place in every Orchid collection."

— SOME pods of Carter's CHAMPION RUNNER BEAN have been sent to us, grown by Mr. E. K. Piper of Oxford, and who states he has taken the prize offered at the Woodstock Show for nine years in succession with this variety. The pods are 9 inches in length, and are very fleshy and fine.

— BLOOMS of the new DAHLIA GEORGE RAWLINGS, which was certificated at the last meeting of the Royal Horticultural Society, have been sent us by the raiser, Mr. G. Rawlings of Romford. They are of great substance, close and firm, symmetrical in build, and of considerable depth. The florets are a rich dark maroon, shading to deep but rich crimson at the margin, which has a very pleasing effect in a good light. The variety is certainly a handsome one, and the specimens we have seen indicate that it well merits the honour bestowed upon it by the Floral Committee.

— THE EPPING FOREST AND COUNTY OF ESSEX NATURALISTS' FIELD CLUB will hold their annual Cryptogamic Meeting on Saturday, October 1st, 1881, in the northern section of Epping Forest (High Beach, Monks Woods, Theydon Woods, &c.). The Council announce that the following well-known botanists have kindly promised their valuable aid as referees and conductors at the Meeting:—For Fungi: Dr. M. C. Cooke, M.A., F.L.S.; Mr. Worthington Smith, F.L.S.; Dr. H. T. Wharton, M.A., F.L.S.; Mr. James English. For Mosses, Lichens, and Phanerogams: Dr. Braithwaite, F.L.S.; Mr. E. M. Holmes, F.L.S.

— IN a brief descriptive note of GLYN-Y-MEL, FISHGUARD, PEMBROKESHIRE, the romantically situated seat of J. Worthington, Esq., a correspondent, "W. T. R.," states that a wall of Bourjasotte Figs is very fine, the fruits measuring from 10 to 10½ inches in circumference, but we are not informed whether it is the White, Black, or Grizzly Bourjasotte. *Lilium auratum* is also said to be very fine, the stems bearing from twenty-four to twenty-eight flowers each. Azaleas and Camellias also succeed well in the open air, *A. indica* being a "perfect sight" in May. The fruit crops are described as good, and Mistletoe plentiful, which is "a rare circumstance in Wales." The gardens are under the competent management of Mr. F. Pratt.

— MESSRS. H. CANNELL & SON of Swanley send us blooms of an extremely beautiful TUBEROUS BEGONIA named MADAME DUMAS. The flowers are double, very full, the petals disposed symmetrically, and, being of great substance, are suggestive of Camellias. The colour is a delicate blush, nearly white, the pink tint being very faint but pretty. The chief quality of the flower is, however, its surprising fulness and regularity of form, which we have not seen surpassed by any other double variety. Blooms of the large-flowering single variety Countess of Kingston were also sent, and are noteworthy for their size, in some instances exceeding 5 inches in diameter, and for the brightness of the scarlet hue.

— "ALL lovers of horticulture," says a Manchester paper, "will be pleased to learn that the initial steps have been taken—under such auspices as guarantee a successful issue of the undertaking—to recognise in a substantial and practical manner the eminent services which MR. BRUCE FINDLAY has rendered to these kindred arts. Mr. Findlay has occupied the position of Curator to the Manchester Botanical Society for nearly a quarter of a century; he has been actively concerned in all the great national and international exhibitions promoted by that Society, and, indeed, is entitled to the credit of whatever success has been attained by these shows. A number of gentlemen assembled at a private meeting at the Town Hall a few days ago, under the presidency of the Mayor (Mr. Alderman Baker), unanimously resolved to advocate a substantial presentation to Mr. Findlay in

recognition of his services, and an Executive Committee was appointed to carry out the resolution. The following gentlemen compose the Committee—Mr. C. S. Agnew, Mr. Joseph Broome, Mr. S. Barlow, Mr. G. Benton, Mr. John Galloway, jun., Mr. John Grantham, Mr. Richard Hardwick, Mr. Robert Tait, and Dr. John Watts—Mr. Broome taking the office of Chairman, Mr. Barlow the functions of Treasurer, and Mr. Tait the duties of Hon. Secretary. Subscriptions amounting to over £250 were entered at the meeting."

— WILSON'S STYLUS PEN.—Messrs. Letts & Son (Limited) have introduced a new stylographic pen at a small cost compared with that at which the original article of that name was sold for. This possesses all the merits of the other, and is one of the most convenient of caligraphic arrangements we have seen; for not only is it furnished with an abundant supply of ink always ready for use, but the article itself is so portable it can be carried conveniently in the waistcoat pocket, where it takes up no more space than an ordinary pencil-case.

— WE are informed that the WIMBLEDON ROYAL HORTICULTURAL SOCIETY will hold an Exhibition of Chrysanthemums in the Lecture Hall, Wimbledon, on Wednesday, November 23rd. Mr. H. A. Rolt is the Secretary.

— "AN OLD SUBSCRIBER" writes—"Can any of your correspondents inform me if there is any use to which the STEMS OR LEAVES OF JERUSALEM ARTICHOKE can be applied? I am under the impression that it has been stated that the stems could be manufactured into an article resembling hemp. If there is any useful purpose to which the stems or leaves can be devoted I should be glad to know the process of preparation needed."

— WE observe that an American nurseryman announces a NEW WEeping DOGWOOD for distribution shortly. He describes it as "a variety of the Great Dogwood, *Cornus florida*, which is itself known as one of the most beautiful of ornamental plants, being admired especially for its large white floral bracts, which are succeeded by red berries as brilliant as the Holly, while in the fall the deep red foliage is one of the chief elements in our scenery. A weeping variety of such a plant would alone be a welcome addition to our lists, even though it had to be grafted on tall stems, as other weeping plants are. But this beautiful plant has one advantage in which it is alone among weeping trees; while every branch is heavily pendulous, the leader ascends straight as an arrow, and makes a specimen which charms everyone by its regular beauty, so unusual in weeping trees."

— WE are requested to state that the WOOLHOPE NATURALISTS' FIELD CLUB will hold the last field meeting of the year at Hereford on Thursday, October 6th, for a foray among the Funguses, when many distinguished mycologists will be present. There will be an exhibition of Funguses in the Museum room at the Free Library, and an evening meeting will be held there on Wednesday evening, October 5th, at 8 P.M., to name and study them. The Foray will be made in Stoke Edith park and grounds, by the kind permission of Lady Emily Foley. The dinner will take place at the Green Dragon Hotel at 4.30 P.M., when some edible Funguses will be served, cooked from the Club receipts. A soirée will be held at the house of Thos. Cam, Esq., at 8 P.M., to which he kindly invites all who may be present at the meeting. After dinner, or at the evening meetings, papers will be read on the following subjects—"The Progress of Mycology," by Dr. Bull; "Fungus Mimics," by M. C. Cooke, M.A., LL.D., &c., &c. "The Herefordshire Carices," by the President of the Club; "The Fungi of the Dolomites," by Thos. Howse, Esq., F.L.S., &c. "The Fungi which Attack the Wheat," by the Rev. John E. Vize, M.A.; "The Germination of the Uredines, and the Relationship of *Æcidium Berberidis* to *Puccinia Graminis*," by C. B.

Plowright, Esq. ; "Protococcus," by the Rev. John E. Vize, M.A. ; "Monstrosities in [Fungi," by W. Phillips, Esq., F.L.S., and a curious and abnormal cellar Polypus will be shown by Mr. Phillips ; "Two Tomato Diseases," by C. B. Plowright, Esq. Gentlemen intending to be present are requested to send their names to the Secretary, Mr. Theophilus Lane, Broomy Hill, Hereford, on or before Monday, October 3rd, that all proper arrangements may be made for their comfort. The Pomona Committee of the Club have decided to hold an exhibition of Apples and Pears on Wednesday and Thursday, October 26th and 27th, and request the favour of the personal interest of the Members in support of it. Donations in aid of the prize fund are much needed.

— A LADY correspondent writing to us from the neighbourhood of Lago Maggiore, Italy, observes—"One of the most attractive and fragrant shrubs here is *OLEA FRAGRANS*. The perfume makes itself felt in the gardens ; and if the plant grows freely in the open air here, where snow falls during winter, it might succeed in England, and prove attractive in a cool conservatory on account of the remarkably powerful perfume of its flowers." Most English gardeners know this plant very well, for it has now been in cultivation here for more than a century, and is a welcome addition to any greenhouse or conservatory.

— "WITHIN a day's march of MESHED," writes the correspondent of a daily contemporary, "the cornfields begin to give place to vast expanses of Melon and Cucumber cultivation, of which enormous quantities are consumed during the hot weather. Here and there the tendrils of the plants are trained over slight frameworks, so that the great broad leaves form arbours to protect the watchmen from the sun. Nothing could be prettier than the appearance of these fresh green bowers with their great broad staring yellow flowers, after the dusty plain and scorched stubble-fields. At intervals, too, are orchards. Peaches, Plums, Apricots, and Grapes, all of delicious quality, are brought to market in great quantities. The dark purple Plums are very remarkable, some being as large as good-sized Peaches. The ground is everywhere inundated with pools of water, and irrigation trenches cross and recross each other in a complex maze. This surface water is, I should think, mostly derived from the Keshef Rood, the river which formerly watered Toos, the ancient capital. Besides this surface water there is also a large subterranean amount being conveyed in underground channels to more distant fields situated at a lower level."

— A GERMAN paper, referring to the TAXATION OF TOBACCO, relates an example of remarkably sharp practice which has given rise to much comment. It appears that two revenue officers in the execution of their duties visited the Königsberg Botanical Gardens, and having ascertained that a number of Tobacco plants was grown there for scientific purposes, they considered it necessary these should be taxed. The Director refused to pay the tax, and in consequence the plants were uprooted.

— PROFESSOR DAWSON, of the Dominion Geological Survey, reports that the FORESTS OF BRITISH COLUMBIA are of vast importance. Many first-class mills have been established in various parts of the country, and the total annual product is stated to be about two hundred million feet, of which twenty-five million feet is exported to other countries, twenty-five million feet used at home, and one hundred and fifty million feet sent to California. Professor Dawson estimates that one hundred and ten million acres (or two-thirds of the whole province) are covered with timber. The Douglas Fir or Oregon Pine is the most valuable commercial tree. It frequently exceeds 8 feet in diameter, and rises to a height of from 200 to 300 feet, forming great and dark forests. The Western Hemlock and the Red Cedar are the other important trees of the province, both of which, the latter especi-

ally, grow to a great size. When the great plains of Canada become populous the mines and forests of British Columbia are likely to be of great importance.

#### SOUND POTATOES AND THEIR CULTIVATION.

My Potatoes have again turned out a fine crop. Myatt's Prolific and Rivers' Royal Ashleaf were dug up in July quite sound, the former by far the heavier crop. The late variety, Suttons' Magnum Bonum, was harvested at the beginning of this month perfectly sound and free from disease, the yield averaging over five sacks to each bushel of seed planted. My gardener called my attention to the first three roots he had lifted, and we counted their produce to be sixty-four good-sized tubers. He is always careful to select ground for Potatoes on which ordinary green crops have been grown the previous year. The soil is well trenched during the winter, and in early spring liberally dressed with leaf soil only. He plants as early in March as the season will permit, and is thereby enabled to secure the crop before the autumn rains commence. Last year's Magnum Bonums remained in good condition to the middle of the following July.—W. G., *Elmdale, Sutton, Surrey.*

#### DIMORPHOUS FLOWERS.

THAT portion of Sir John Lubbock's presidential address before the British Association which points out that pollen from long-stamened flowers of Primroses, if applied to the stigmas of long-styled forms and *vice versa*, produces a much greater percentage of seeds than when the flowers are fertilised with their own or even other pollen from a similar flower, may, we fear, be read in many instances without the reader learning the lesson which it contains. This fact induces us to say a few words on the fertilisation of Primrose flowers. The way usual among gardeners, and we fear among those which grow seed for sale, is to pull the corolla of pin-eyed (long-styled) flowers with the stamens, which are halfway down the tube, out of its socket and over the pistil. This operation causes a few grains of pollen to settle on the stigma, and the formation of, in comparatively rare instances, a few seeds. The cross-fertilisation of different forms, if done under favourable conditions, will, on the other hand, result in every flower setting and every seed-pod filling with a full complement of good seed. This is not all. It has again and again been proved, and now no longer admits of any doubt, that in-and-in bred seed becomes more or less rapidly weak in vitality, and the resulting plants are in proportion weak ; indeed, eventually the race becomes weak. It is quite different when different strains are crossed, and it is quite necessary that the different forms of dimorphous and trimorphous plants be crossed. The crossing of species does not invariably produce greater vigour in the offspring, but the crossing of different races of the same species almost invariably produces that result.

This much by the way, although what we have said is worth remembering. What we want to consider just now is Sir John Lubbock's reference to dimorphous flowers repeated in another form. Instead of leaving Chinese Primulas (for to these we more particularly refer) to set themselves, or even to fertilise either of the two forms with pollen from another plant belonging to the same form, we advise all who wish to save their own Primula seed to choose pin-eyed flowers for seed-bearers, and thrum-eyed forms to furnish the pollen. The fertilisation of thrum-eyed flowers by pollen from pin-eyed flowers will have precisely the same effect, but it is much easier to perform the operation on pin-eyed flowers. Of course we expect everyone will be alive to the advantages to be derived from selecting the best and most vigorous examples from which to raise seed. Advantage, also, will arise from the crossing of strains ; and as a few flowers will afford pollen sufficient to fertilise a large number if the pollen is used economically, flowers may be procured, if thought desirable, even by post from friends.

It is of little use applying pollen to stigmas in November, December, or January. Sunny weather is necessary to secure the best results ; therefore it is soon enough to begin by February. The selected plants should be stood on a sunny shelf and fed with weak liquid manure rich in phosphates and potash, such as is furnished by any good guano water or weak sewage. If this precaution is taken, more seeds, and seeds of a better quality, will follow. We have experimented and proved it. The pollen should be applied with a camel-hair pencil, and the best time to do it is about mid-day. If your aim be to secure the strongest plumpest seed for your own use, do not be greedy, but be content with from one to two dozen pods from each plant according to its size and strength. Ripen the seeds in a sunny position under

glass, but do not let impatience cause you to submit the plants to a high temperature, for that weakens them. Flowers fertilised in February will, in a warm greenhouse, ripen their seed in good time for furnishing plants for spring use the year following. They will scarcely do for very early plants, though.

Raising Primula seed is by many gardeners regarded as a secret. If it has been so it is one no longer, and we hope everybody will be better by knowing it. Let all who practise it make careful

selection, and take care to begin with the best strain procurable, and seize on every improvement.—A SCOTCHMAN.

#### ROSA RUGOSA.

FOR several seasons one of the most noteworthy features in Mr. T. Ware's nursery, Tottenham, has been the fine clumps of the handsome Japanese Rose named above, which form such con-

Fig. 49.—ROSA RUGOSA.

spicuous objects upon the rockery there. Defying all severity of weather and the low temperatures such as have been experienced in the last two or three winters, the plants grow vigorously, and every summer flower profusely, the flowers being followed by handsome clusters of bright red coral-like fruits. Few ornamental flowering shrubs possess so many valuable qualities. Perfect hardiness, free growth, compact habit, pretty and abundant white or crimson flowers, and bright-coloured fruits constitute an assemblage of attractions which in these utilitarian days cannot be long disregarded. Such a plant deserves popularity, and this it will undoubtedly obtain, for all who have tried it recommend it to their friends most cordially.

True, this Rosa has one unpleasant character. The thorny accompaniments which an old adage teaches us always to expect with Roses are unusually abundant in the case of *Rosa rugosa*, the stems being so thickly clothed with spines of various sizes that they present quite a formidable appearance. However, this interferes but little with the real utility of the plant, as the flowers and fruit are seen to the best advantage when growing, and are not so well adapted for cutting as some others. The foliage, too, is beautiful, of a fine green tint, the leaves neatly pinnate, each leaflet being wrinkled or rugose upon the upper surface.

The species is a native of China and Japan, where it is said to be found growing wild in sandy soil, and it has been also culti-

vated there during a long period. Several varieties are obtained from seed, varying from rich crimson through lighter shades to pure white; but all are beautiful, especially the extremes of the series.

The woodcut (fig. 49), shows both flowers and fruit, and was prepared from a specimen furnished by Mr. T. Ware.

### WASPS.

LAST year, through July, August, September, and even later, I had to contend with the wasps for all my garden fruit. I took with a most seductive beverage for them—skilfully compounded of beer, sugar, water, and quassia chips—about one pint of wasps daily for several weeks, and wondered where they all came from. This year during April and May qucen wasps were most extraordinarily abundant. I killed on several days six, seven, and even ten. Now not a wasp is to be seen. I dare venture to give a shilling for a wasp caught within a mile of my house. We have been able to gather a most abundant crop of Currants, Raspberries, and Gooseberries without being annoyed by these insects. What has become of them? I think that one of our late frosts must have destroyed all the young broods in the nests. How are they in other parts of the island?—G. O. S.

### AN ESTIMATE OF GRAPES.

AN English gardener who has an intimate knowledge of Grapes having been requested by a Belgian gentleman to furnish him with a descriptive list of the Grapes that are most approved in England, and their adaptability for cool or warm houses, also for affording a supply at different periods—has submitted the following paper to us for perusal, and for publication if we think it worthy of a place in the Journal. As we think our correspondent has made a judicious selection, and has described the varieties with considerable accuracy, his estimate can scarcely fail being useful, while the varieties named will be sufficient for most cultivators who require a good and serviceable collection of Grapes.

#### THE BEST BLACK GRAPES (EARLY).

BLACK HAMBURGH is the most useful Grape in existence. Free grower; fine bearer, and quality. *Early*, and well managed keeps until January. In England it is in use from May till the end of the year. Victoria and Frankenthal (Pope's Hamburg) are fine forms of it, and in some soils differ very slightly, if at all, from the type. Mill Hill Hamburg is a more delicate grower, but fruit fine. Dutch Hamburg, larger but coarser. More Vines of the Black Hamburg are sold and grown in England than of all the other varieties combined. You may confidently recommend it as the *BEST early Black* and general purposes Grape. Warm or cool house. A bunch of Black Hamburg has been grown by Mr. Hunter of Lambton Castle (Earl of Durham's) weighing 21 lbs. 12 ozs.

MADRESFIELD COURT.—A splendid Grape for early autumn. Sometimes the berries crack when the Vines are strong and crop light. Large bunches, noble berries, rich quality. Will not force so early as the Black Hamburg. Warm or cool house.

BLACK CHAMPION.—A little earlier than Black Hamburg. Berries rather oval, and colour well; bunches short, and not shouldered. Not much grown nor wanted except for variety.

MUSCAT CHAMPION or CHAMPION HAMBURGH. MUSCAT.—Fine bunches and berries, splendid quality; colour grizzly, seldom if ever black, and on this account not much grown in England. Early autumn. Warm or cool vinery.

BLACK FRONTIGNAN.—Although the bunches are not large, and the berries only medium-sized, yet the flavour is very rich, and as the Vine bears well in a warm or cool house it is worth growing.

MEURTHE FRONTIGNAN.—Has larger berries than the preceding, and is in other respects equally good. One of the best of its type. Both these ought to be more grown in England for their fine flavour—Frontignan and Muscat mixed, the latter preponderating; but English gardeners must have *size* as well as quality.

#### LATER, BUT NOT VERY LATE, KEEPING (BLACK) VARIETIES.

VENN'S BLACK MUSCAT.—When in good condition fine in every respect—size, colour, quality; but—and a very important "but" it is—the berries do not always set and stone well, and they sometimes "shank," decay at the footstalks, and turn like bags of vinegar (acetic acid).

BLACK MUSCAT OF ALEXANDRIA.—Precisely the same remarks apply here, indeed about half the number of English gardeners consider the two varieties identical. If there is a difference between them it appears to be very slight. Only skilled cultivators can grow these Grapes well. This is also known as Muscat Hamburg and Snow's Black Muscat.

BLACK PRINCE.—Pretty tapering bunches, seldom shouldered; good-sized oval berries, bluish black, and of excellent quality. Good grower, bearer, and setter, ripening well in a cool house. Totally distinct from Mill Hill Hamburg. As you ask this question I may

say there is as much difference between them as between a dray horse and an Arab in appearance.

WEST'S ST. PETER'S.—Fine bunches, and good-sized roundish oval berries, very black, almost purple; juicy, sweet, and refreshing. It requires a warm house, and keeps well until February. A very good Grape.

ROYAL ASCOT.—Rather small bunches, but good berries, crackling and refreshing; one Vine, however, is sufficient in most gardens, and it can easily be dispensed with.

TRENTHAM BLACK.—Large, tapering, and well-shouldered bunches, and medium-sized oval berries, very black, and of a rich vinous flavour. It ripens about the same time as the Black Hamburg, but keeps better, continuing the supply until the very late Grapes are ready for use. A good Grape, and succeeds well either in a cool or warm house.

#### THE BEST KEEPING (BLACK) GRAPES.

LADY DOWNE'S.—Although not the finest in appearance, this is perhaps the best of all late Grapes. The Vine is a good grower and excellent bearer; bunches long, slightly shouldered; berries roundish oval, above medium size, good in colour when well ripened, and of superior quality, having a faint trace of Muscat flavour. Will hang fresh till March, sometimes later. Must have a warm house.

ALICANTE.—A handsome and useful late Grape, though not of the highest quality. The Vine is a free grower, great bearer, and sets its fruit freely; bunches large, and broad across the shoulders; berries large, oval, and jet black; juicy, and much of the Hamburg quality. Will ripen its fruit in a moderately cool vinery, but the quality is much improved when the Vines are grown in a high temperature and the fruit is ripened early. Much grown for the market.

MRS. PINCE'S BLACK MUSCAT.—A good keeping Grape of the highest quality; rich Muscat flavour. A free grower and good bearer; bunches large, tapering, and shouldered; berries of good size and perfectly oval, but do not usually colour well. The want of colour generally is the fault of this Grape, and to aid the colouring process the Vine should be allowed to carry more foliage than other varieties. It is best grown in a warm house.

GROS GUILLAUME.—Incorrectly sold under the name of Barbarossa, which is a red Grape and seldom seen. Gros Guillaume produces the largest bunches of all black Grapes, with berries of good size and nearly round; juicy, sweet, and approaching the Black Hamburg quality. Pruned on the short-spur system the Vine is often a shy bearer. Young canes should be retained when pruning, and these strong and well ripened usually produce fine bunches freely. Bunches are grown from 18 lbs. to 25 lbs. It requires a warm house, and keeps late.

GROS COLMAN.—Vine a very strong grower; bunches good; berries of great size and round—the largest of all black Grapes. Ripened in a cool house the flavour is poor, but in brisk heat is fairly good. A most imposing Grape and a good keeper. Is rising in repute as a market Grape.

ALNWICK SEEDLING.—In appearance and general character much resembles the Alicante, but is of better quality. It does not, however, set its berries so well, and to ensure full bunches the flowers should be artificially fertilised by lightly drawing a rabbit's tail or a bunch of Feather Grass over them; and if pollen can be supplied from other free-setting varieties so much the better. Has had a first-class certificate from the Royal Horticultural Society. A good keeper.

GROS MAROC.—A strong grower like Gros Colman, but in other respects quite distinct. Bunches of good size, tapering, and handsome; berries oval, and of a splendid blue-black colour; quality refreshing, something of the Black Hamburg quality. It was introduced from France by the late Mr. Rivers, and was awarded a first-class certificate in 1880 by the Fruit Committee of the Royal Horticultural Society. Skin tough but not thick. It will probably prove a good if not a very late keeper; it should be grown in a warm house to ensure the best quality.

*Note.*—Many people think that to have Grapes *late* in the spring they should be ripened *late* in the previous autumn. This is a great mistake. If they are not ripened well they will not keep well, and it is impossible for their quality to develop in dull, cool, autumn (October) weather to anything like the same extent as when aided by the sun in August and early September; therefore Grapes that are intended to keep late must be ripened early. The bunches should also be thinned much more freely than those of summer and autumn Grapes, for crowded bunches will not keep long.

#### THE BEST WHITE GRAPES (EARLY).

The earliest white Grapes belong to the Sweetwater and Muscadine sections. Of the former *Early White Malvasia* is one of the earliest, and good; bunches medium, thin, tapering; berries medium to small, juicy, rich, and sweet. Cool house or wall.

FOSTER'S SEEDLING.—Considered the best of the Sweetwater class. A good grower and great bearer, with fine bunches of medium-sized berries of good quality. The most useful white Grape for forcing early with the Black Hamburg. For this purpose it is more largely grown in England than all other white (not Muscat) Grapes combined.

BUCKLAND SWEETWATER.—Also a very popular, freely grown, and good Grape. The berries are larger than Foster's and of equally good if not better quality; but the Vine is not such a constant bearer, and the berries are rather liable to shank; skin very thin. A very

good Grape for growing with the Black Hamburg, and few vineries should be without at least one rod of it.

Of the white Frontignans *Early Saumur Frontignan*, *Chasselas Musqué de Sillery* (*Salamon's Frontignan*), *Early Auvergne Frontignan*, *Troveren Frontignan*, *Josling's St. Albans* (*Chasselas Musqué*) are all early, with rather small tapering bunches, and small to medium berries of rich flavour; not much grown in England—too small generally—but occasionally fruited in pots. The best in this section, but a little later, are Dr. Hogg (the best of all), and Duchess of Buccleuch, both of which have much larger bunches than those named above, and of excellent flavour. The Frontignans first named are as early as the Sweetwaters—earlier than the two popular varieties last named in that section, and are useful for pot culture.

#### LARGER EARLY WHITE GRAPES.

**GOLDEN HAMBURGH.**—Bunches of good size, loose; berries large, oval; skin thin, pale amber; juicy, sugary, and vinous. Rather delicate, and must not hang long. Cool house.

**GOLDEN CHAMPION.**—Bunches good; berries very large, oval; skin thin, pale amber; very fleshy and juicy, with Hamburg flavour. A shy bearer, but when well grown a remarkably fine Grape. First-class certificate by the Royal Horticultural Society. One Vine should be grown in the Black Hamburg house for trial.

**DUKE OF BUCCLEUCH.**—This is the finest and at the same time most capricious white Grape in England. In some places it grows well, producing its good bunches and magnificent berries freely; in other places it will not grow and fruit at all. Under the charge of the brothers Messrs. William Thomson (the raiser) of the Tweed Vineyard, and David Thomson, gardener to the Duke of Buccleuch, it grows luxuriantly, and fruit is produced by the ton. The berries are round, of enormous size, and thin skin, amber; quality delicious, like a sweetmeat, very juicy, and of a rich Hamburg flavour. The Duke of Buccleuch will not eat any other white early Grape. It ripens before the Black Hamburg in the same house. The Vine is of a succulent nature, hence requires plenty of water; and then the wood must be well ripened and not pruned too closely.

**MRS. PEARSON.**—It has large bunches—indeed very fine—and large, nearly round, clear amber berries, sometimes with a faint tinge of pink when in the best condition. The fruit is fleshy, juicy, with a rich sprightly flavour. The Vine is a very good grower and bearer. Hamburg treatment. Certificated. *Golden Queen* of the same raiser is neither reliable in appearance nor quality, and is only very rarely seen in excellent condition.

#### WINTER GRAPES (MUSCATS).

**MUSCAT OF ALEXANDRIA.**—This is unquestionably the prince of white Grapes for winter. It is not necessary to describe it. There is no real difference between this and the Bowood and Tynningham Muscat. The distinction is a "fancy" one, and all are often propagated from the same stocks and labelled according to the orders received by nurserymen. I do not know that there is anything wrong in this, as purchasers get a good Grape whatever name is written on the label. The alleged differences are wholly due to soil and culture, as they do not exist when all the Vines are grown in the same house and border. The *Canon Hall Muscat* is quite distinct, having larger berries, but not of such high quality; it is also a very bad setter, and requires the treatment suggested for Ahwick Seedling. These Muscats must have a high temperature.

*Note.*—Will you accept a hint? If you have any Vines (varieties) that do not grow freely, graft them on Muscat of Alexandria stocks. This is, generally speaking, the best stock that can be had, and there are few varieties that do not thrive on it.

#### LATEST WHITE GRAPES (NOT MUSCATS).

**SYRIAN.**—Very large bunches, fine berries, and when grown in heat of good quality; grown in a cool house inferior; a very strong grower, and fairly good keeper. Largest bunch exhibited, 25 lbs. 15 ozs.

**RAISIN DE CALABRE** (CALABRIAN RAISIN).—Very large bunches, and fair-sized roundish berries. Vine a good grower and bearer; fruit not rich, but juicy and pleasant. A good keeper and useful. Largest bunch 26 lbs. 4 ozs.

**TREBBIANO.**—Bunches large and well shouldered; berries of good size and nearly oval generally, but in this respect variable; colour greenish white; fruit fleshy, juicy, and refreshing, but not rich. A good keeper and serviceable. Growth free, and bears well.

**WHITE TOKAY.**—Bunches of good size and well shouldered; berries large, nearly oval; skin rather thin, pale amber; quality good, juicy, refreshing, and sometimes rich. A good grower, bearer, and keeper. One of the best late Grapes.

**WHITE LADY DOWNE'S.**—A good Grape when well grown, which is not often, as it is delicate and shy, and in no respect by any means equal to the typical black variety; indeed white late Grapes are inferior in keeping properties and general usefulness to the black varieties. A reliable and really good late-keeping white Grape is yet a desideratum.

#### WHEN TO PLANT STRAWBERRIES.

SOME gardeners say now is the time to plant Strawberries, but according to my experience it is too late. We have planted Strawberries from June until October, and the time we like best

is about the end of July. At that time this year we planted out many hundreds of runners, and they are now most promising. If planted now little or no growth would be made this season, and would have little fruit next year; but as it is they are thoroughly established plants, with plenty of healthy leaves and stout crowns which will stand the winter well. Judging from others we have had before, a full crop of fruit will be obtained from our young plants before they have been planted out a year.—J. MUIR, *Marjam*.

#### PORTRAITS OF NEW AND NOTABLE PLANTS.

**BOLBOPHYLLUM BECCARII.** (*Nat. ord.*, Orchideæ).—"This is in many respects one of the most gigantic of Orchids; none is known with so stout a rhizome, so large a leaf, or such massive inflorescence. On the other hand, specimens of various species of Vanilla are far more bulky; and it has been credibly stated a single plant of *Vanda teres* in Birma is a sufficient load for an elephant! In one character *B. Beccarii* transcends all other Orchids, if not all other vegetables, and that is in the fact of its flowers, which is loathsome beyond description; of the same nature as that of *Amorphophallus* and of other Aroids (that of putrid fish), but more widely diffused, penetrating, and enduring. This most singular plant was discovered in 1853 by Thomas Lobb, when collecting for Messrs. Veitch, in the Island of Borneo, and leaves collected by him are preserved in the Lindley Herbarium of Orchids, now at Kew; but it was the celebrated traveller and botanist, Odoardo Beccari, who first obtained flowering specimens, which led to the determination of its genus, and to its being described by Reichenbach. It is singular that the Malayan Islands should present three of the largest-flowered and most foetid plants in the world—this, the *Raffaria* of Sumatra, and the wonderful *Amorphophallus Titanum*, discovered in this last-named island by M. Beccari."—(*Bot. Mag.*, t. 6567.)

**GEUM ELATUM.** (*Nat. ord.*, Rosaceæ).—"This belongs to a small section of *Geum*, separated from it by Willdenow as the genus *Sieversia*, the species of which differ from their congeners in the style, which elongates as the achene ripens, but does not become suddenly bent or twisted above the middle; as, however, all its other characters are those of *Geum*, which the species altogether resemble in habit, *Sieversia* has been reduced to a section of that genus. It includes about a dozen species, natives of mountainous districts in Europe, northern Asia, and N. America, where one, *S. Rossii*, is a native of high arctic regions. *Geum elatum* inhabits the whole length of the Himalaya. In its typical form, as figured here, it ranges from Kashmir to Kumaon, at elevations of 9000 to 12,000 feet; further eastwards, in Nipal and Sikkim, it is replaced by a subalpine form, var. *humile*; *Royle* (*Geum adnatum*, *Wall.*), a small plant, with usually a one-flowered scape, which inhabits elevations of 12,000 to 15,000 feet."—(*Ibid.*, t. 6568.)

**KNIPHOFIA COMOSA.** (*Nat. ord.*, Liliaceæ).—"The genus *Kniphofia* is interesting geographically because like *Gladiolus*, *Aloe*, *Philippia*, *Aristea*, *Geissorhiza*, *Moræa*, and many others, it has its head quarters at the Cape, and is represented in Abyssinia and other mountainous regions of tropical Africa by outlying representatives. Two of the Abyssinian species have lately been brought into cultivation—the present plant and *K. Quartiniana*, *A. Rich.*, which was figured lately in Regel's 'Gartenflora' (Tab. 907). *K. comosa* is much dwarfer in habit than the well-known *K. Uvaria* of the Cape, with narrower leaves and smaller flowers, with the stamens and style very much exerted from the perianth. Of the smaller Cape species it approaches closely *K. pumila*, *Kunth*, a figure of which, under the name *Tritoma pumila*, will be found at Tab. 764 of the 'Botanical Magazine.'—(*Ibid.*, t. 6569.)

**CRINUM BALFOURII.** (*Nat. ord.*, Amaryllidaceæ).—"This is a well-marked new species of *Crinum*, discovered by Dr. Isaac B. Balfour in his recent exploration of the Island of Socotra. Its nearest alliance is with two Himalayan species, *C. amœnum* and *longifolium* of Roxburgh; but all the three sub-genera of *Crinum*, *Stenaster*, *Platyaster*, and *Codonocrinum* are represented in each of the three tropical continents, and also in Australia. The flowers are pure white and very fragrant, and the bulb and leaves are much smaller than those of the ordinarily cultivated kinds, so that it will be a decided acquisition from a horticultural point of view; and it is to be hoped, as Dr. Balfour secured a good supply of bulbs, that it will be permanently established as a memorial in our conservatories of his adventurous and successful expedition, in which about a hundred new species and twenty new genera of plants were discovered."—(*Ibid.*, t. 6570.)

**HOMALONEMA WALLISII.** (*Nat. ord.*, Aroideæ).—"H. *Wallisii* was discovered by the collector whose name it bears in the Andes of Columbia when travelling for Mr. Bull, to whom the Royal

Gardens are indebted for the plant which flowered at Kew in October, 1878. Mr. Brown states there are two forms of the species—one with narrower leaves that have very indistinct cartilaginous margins."—(*Ibid.*, t. 6571.)

#### CHILIAN BEET.

FEW plants are more useful or easier to grow than Chilian Beet. In the subtropical garden it contrasts well with the various shades of green. In lines or masses it also has a charming effect. If taken up and potted the plants are valuable for decoration in the houses. In potting them it is necessary to be careful in keeping the leaves from drooping, from which I have found they seldom recover satisfactorily. To avoid this they should be placed in a cool frame and kept quite close for about a fortnight, damping them twice a day and shading. Pots 6 inches in diameter are large enough. The compost should be chiefly of well-decomposed manure and loam, supplying liquid manure frequently, as the pots are soon filled with roots, which require plenty of nourishment to keep the fleshy leaves in a healthy condition. In about three weeks after potting they may be safely removed to the greenhouse or conservatory. For decoration in the drawing-room and dinner table they are also invaluable, having a charming effect by artificial light.—A YOUNG GARDENER.

#### KITCHEN GARDEN.

WHERE advantage has been taken of the recent fair weather, the crops of Onions and Potatoes have been lifted and stored. The ground that has been occupied with Onions will be suitable for Cabbage, plants of which from the August sowing should be placed out as soon as ready, allowing them a distance of 18 inches every way, but if large heads are required 2 feet distance is not too much. Those for planting in spring or to fill-up vacancies through the winter should be pricked-out into beds about 3 inches apart. Where the demand for young Cabbages in spring is considerable, plant them a foot distance apart on warm borders.

*Lettuce.*—Plants from the August sowing which are to afford the spring and early summer supply should now be planted, and may be taken on a warm south border in the intervening spaces between where the early Peas will presently be sown at 4 feet apart, placing a row of Cos in the centre, and a row of a Cabbage variety on each side, and this will leave a space of 2 feet for the Peas. Stanstead Winter Cabbage and the old Black-seeded Brown Cos are unsurpassed. Other borders may be planted so as to continue the succession; and where there are borders available at the base of east or west walls they may also be occupied with Cos or Cabbage varieties, or both according to the demand, a distance of a foot being allowed from the wall, placing two rows 9 inches apart with the plants a foot asunder. After planting the main crop is completed, a quantity of the Cos should be pricked out on a sheltered border where protection can be given should the winter prove severe, and reserve some of the Cabbage varieties to fill up any vacancies that may occur, dusting the plants with quicklime to destroy slugs. Lettuces that are to occupy cold frames through the winter and afford an early spring supply should at once be planted, employing those from seed sown in late July of Early Paris Market, All the Year Round, and Sugar-loaf Bath Cos. Plant in alternate rows the Cabbage and Cos at 9 inches distance apart, the Cabbage sorts being 6 inches apart in the rows to allow of every alternate one being cut early, and the Cos 9 inches apart. The soil should be rich and moderately firm. Due attention must be paid to watering, and precautions should be taken to guard against the depredations of slugs, not placing the lights on the frames until frost occurs or when heavy rains prevail, ventilating freely when the temperature outside exceeds 35°. It will also be necessary to provide accommodation for the Lettuce and Endive, which are to be lifted from the open ground to give a continuous supply when that outside is injured or destroyed by frost. It will be an advantage to lift the plants now that are sufficiently advanced in

growth for the purpose, and they will withstand damp much better than those lifted after they have become saturated with the autumn rains. Where large supplies of Lettuce and Endive are needed shallow pits with moveable lights should be provided, and sufficient means of affording artificial heat to exclude frost. Endive may yet be planted at the foot of walls or in other warm situations to give a supply in spring. The best for planting now are Green Curled and Picpus, with the Close-hearted or Round-leaved Batavian.

Parsley which is sown in pits should be well thinned, and when the nights become frosty the lights may be placed on and removed during the day. If it was inconvenient to sow in the pits, spring-sown plants may be carefully lifted and planted in pits, or where these are not at command plant in deep boxes or pots, and place them in an orchard house or vinery where the fruit has been cut. Where Chervil is in regular demand it may be treated in a similar manner.

*Radishes.*—Make a sowing in a frame filled to within 9 inches of the glass with rich light soil, keeping the lights on until the seed has germinated, when they must be removed except when frost prevails. The best varieties for this purpose are Early Forcing Red and White Turnip, Wood's Frame, and French Breakfast.

*Cauliflowers.*—Prick out the best of the plants from the August sowing into handlights, having eleven plants in a 2-foot-square light, and proportionately less in those of smaller dimensions, every alternate plant being lifted spring so that five remain to give heads in May or June; south or at least a warm situation should be chosen for these. Supply water if necessary, and dress with lime, wood ashes, or soot to destroy slugs. The lights must be kept off until frost so as to induce a hardy sturdy habit. Prick off into frames a requisite number of the others for spring planting, employing good loam, as they grow much more sturdily in strong than in loose light soil. To insure an early supply promising plants from the August sowing of Veitch's Early Forcing may be placed in 3-inch pots and plunged in ashes in a frame, exposing them fully until winter, and then employ the lights only during frost, ventilating freely on all favourable occasions. When the pots are filled with roots transfer the plants to others a couple of inches larger, keeping them about an inch lower in the pots, and in December place them in a Peach or other cool house; there they will make steady progress, and may be shifted into 7-inch pots when the others are filled with roots, supplying liquid manure. In February or March transfer the plants to any available deep pits, the heads being about a foot from the glass, and there with protection over the lights on frosty nights, plenty of air when the weather is favourable, and liberal supplies of liquid manure, heads for cutting will be obtained a fortnight or three weeks in advance of those from handlights.

Let no opportunity pass in favourable weather without attending to earthing up Celery requiring it, and in tying up Cos Lettuces and Endive. Be prepared in case of sudden frost to cover French Beans, and to take up and protect Cauliflowers which are fit for use. A few of the outer leaves turned inwards over the heads will mostly be sufficient to protect them from frost for some time yet. Clear off exhausted crops of Peas, Beans, and Cauliflowers, and have all in readiness for digging and trenching, the latter being attended to as early as convenient while there is yet warmth in the soil, as trenching in cold weather is only turning under cold soil and retarding the growth of the crops in spring correspondingly.

#### FRUIT HOUSES.

*Vines.*—Where it is intended to have ripe Grapes by the end of April or beginning of May the Vines must be pruned at once, as the house will need to be closed by the middle of November, and forcing must be commenced early in December. The glass should be thoroughly cleaned, and the woodwork be washed with soap and water, and if necessary painted. The loose bark may be removed from the Vines, and then thoroughly wash them with tepid soap and water. If red spider has been present a dressing with an insecticide will be beneficial. Remove the old mulching and surface soil, supplying a few inches depth of fibrous loam with which has been incorporated about a twenty-fifth part of bone manure. The outside border

should be protected from heavy rains. Free ventilation is necessary, closing the houses only to exclude frost or when heavy rains prevail. Midseason houses will soon be cleared of fruit, and if the wood of the Vines is not thoroughly brown and hard apply fire heat in the daytime, turning it off at night, and keep lateral growths in check by stopping them. Young Vines and those newly planted which have been allowed to ramble should now have some of the shoots cut off, being careful not to injure the leaves on the main rods, and maintain a warm well-ventilated atmosphere till the wood is matured. Late Grapes of all kinds ought now to be fully ripe; if, however, there is any doubt as to their maturity, apply fire heat with a circulation of air constantly till all uncertainty is past. Late Hamburgs and other thin-skinned Grapes should have a little assistance from fire heat if necessary with adequate ventilation to ripen them; but after the Grapes are ripe a temperature of 50° is ample. Examine ripe Grapes frequently for decayed berries, expelling damp, and preventing it as much as possible by occasional fire heat in the daytime with free ventilation; night firing should be avoided as far as possible.

*Peaches and Nectarines.*—The earliest trees are now entirely denuded of foliage, and should, if the branches have not already been loosened from the trellis, be at once attended to, the trees being entirely loosened from the trellis, and the woodwork thoroughly cleaned with soap and water, and the glass both inside and out washed with water only; the trellis should be thoroughly cleaned and the walls limewashed. If painting be necessary it should be done to allow of its hardening before the house is closed. The trees likewise should be washed with tepid water, or they may be syringed with water at 140° to 160°. If there be any scale, or the trees were infested with aphides or red spider, dress them with an insecticide. The main branches of the trees should first be secured in position, spreading them evenly over the trellis, and they may be secured with small tarred string, allowing sufficient space in the ties for the swelling of the branches. The distance between the branches on a properly trained tree will range from 12 to 18 inches, and the bearing wood should be evenly distributed between those, and trained about one-third across the space between the branch it originates from and the one adjoining; this will allow space for the wood another season. No pruning will be necessary, as shoots of 5 or 6 feet length will be ripened to their points, and have fruit buds the whole length, and may be allowed to carry a fruit to every 12 or 15 inches of wood. It will therefore only be necessary to cut out superfluous or weakly shoots. The inside border should have the surface soil and old mulching removed, supplying fresh loam, to which has been added some bone meal, mulching the surface with 2 or 3 inches of short manure. A good watering should be given to the inside border if there be the least indication of dryness. The house should be kept open to the fullest extent, only closing it during the prevalence of frost.

As cold rains may be expected soon the outside border should be protected with litter, or, what is better, tarpaulin or wooden shutters. The trees which ripened the fruit in June are nearly devoid of foliage, and may be treated similarly to the earliest, which ripened the fruit early in May onwards; or if the lights have been removed they may remain off until the early part of November, when they should be replaced. Houses of later trees must have full ventilation, and any trees in late houses not ripening the wood well should be assisted with a little warmth, and will be advantageous likewise to later sorts ripening their crops. An occasional forcible syringing will be necessary to free the foliage from red spider. On no account must the trees lack moisture at the roots when ripening the wood, and any weakly trees should be afforded liquid manure. Any renovation of the borders or lifting of the trees must be attended to when the wood is mature and whilst bearing the foliage.

*Figs.*—Figs in pots intended for early forcing must at once have attention; and as it is not advisable to shift the trees into larger pots a few inches of soil should be removed from the base of the balls, cutting back the roots, and making the drainage good, supplying fibrous loam, to which has been added a sixth of road scrapings and a twentieth of crushed bones. The loose surface soil also must be removed, and from the roots at the sides of the pot, not disturbing

them too much. The materials can hardly be rammed too firmly. Water thoroughly, and place the plants in a house where they can have plenty of air. Fig trees planted out should be kept drier at the roots, but avoid extreme dryness. When the second crop is gathered keep the house cool and dry, ventilating fully except when frost prevails. Root-pruning or partial lifting being required it should be attended to as soon as the leaves give signs of maturity and whilst yet upon the trees.

#### PLANT HOUSES.

*Azaleas.*—Plants that were forced into flower by the new year and afterwards at once started into growth had the growth completed in good time, and have been moved to a cool house or given a sheltered situation outdoors. If these are required to flower again by Christmas they must not be kept too long in cool quarters, but should have a house with a temperature of 45° to 50°, so as not to necessitate so much heat later on. Such varieties as *A. Borsig* and *Narcissiflora* flower early naturally, and are very desirable. *A. alba*, *Fielder's White*, and *vittata elegans* also force readily. They do not require much training or tying. If any fixed shading has been used it should now be removed, so as to give the plants all the light possible for maturing the wood and buds, as without this it is useless expecting fine trusses of large flowers. The later-flowering plants should at once be tied into the required form, as if done before growth is quite complete the points of the shoots will assume their natural upright position.

*Camellias.*—Plants that flowered about this time last year, and were encouraged with heat and moisture to make and complete an early growth, have their bloom buds now swelling, and should be given a temperature slightly warmer than an ordinary greenhouse, or about 50°, in which the flowers will expand freely. Plants not likely to come into flower by the time they are required from the buds being in a backward condition, should be kept in a similar temperature to those being brought into flower, with a little moisture in the atmosphere; but there must not be any attempt at forcing, or the plants will start into growth and the flower buds will fall. Where these plants have been placed out of doors after their buds were set they should be taken in before there is danger from frost or heavy rains; the latter, from causing the loss of the roots, will induce the buds to fall. Thoroughly cleanse the foliage of any dirt that may have accumulated from insects or other cause.

*Hardwooded Plants.*—These must at once be placed in their winter quarters, and after such a season as the present should be in fine condition, and from the well-matured wood be better able to resist attacks of mildew. See that every plant as it is taken in is free from this pest. Any plants infested should be laid on their sides and thoroughly syringed with sulphur water, which can be made by putting water in a tub with 3 ozs. of flowers of sulphur to every gallon of water, stirring well every day for four days, employing the clear liquid, and being careful to keep it from the roots of the plants, or it will do serious injury. The lightest positions should be given such plants as *Boronias*, *Gompholobiums*, *Phoenocomas*, *Pimeleas*, and *Tremandras*, elevating them near the glass, and do not crowd them, or the plants will lose their lower leaves or be very much weakened. *Epacris* and *Eriostemons* will bear a lower temperature than most others, but they should have a temperature of 40° to 45°, and for *Leschenaultias* the temperature must not often fall below 45°, whilst for the general stock 36° to 40° artificially is suitable. Heaths should, if no separate structure exist for them, be placed at the coolest end or where more air can be given, but a separate house is much the best. The present is a good time for potting any Heaths that require increased root space, being careful to have the soil of the old ball thoroughly moistened through before moving, ramming the new soil quite as firmly as the old. No shading will be needed at this season, and no side air should be given for two or three weeks. Water will hardly be necessary for a few days after potting.

*Cyclamens.*—Encourage free growth by a genial atmosphere and temperature of 50° to 55°. Keep the plants near the glass, and supply clear weak liquid manure. The present is a good time to sow seed in pots or pans of good turfy loam with about a fifth of leaf soil and a free admixture of sand. The young plants obtained should

be grown on in a stove temperature, potted off singly when showing the second leaf, and as the pots are filled with roots transfer to a larger size, but avoid overpotting, and if well attended to the plants will flower the winter following, being very effective in 5-inch pots for decorative purposes. Plants from seed sown in spring are now neat little specimens in 3-inch pots, and should be transferred to 5-inch pots when they have filled the smaller size with roots, providing good drainage, and place them near the light in a house where growth will be encouraged.

## THE BEE-KEEPER.

### PREPARATIONS FOR WINTER.

"YOUR bees have butchered all the bees of one of my stocks and have taken all its honey," recently said one of our Bowdon bee-keepers to another. This is not a very common occurrence, but it occasionally happens. The bees of weak hives are sometimes over-mastered and killed by robbers more bent on plunder than war. September is a month of fighting and robbing amongst bees. The weather during this month is generally warm enough to induce them to fly abroad; and, as flowers so late in the season do not yield much honey, bees will have it elsewhere if they can obtain it. Hence their constant attempts to rob other hives, and to enter those not well defended. The fine weather of September, it may be safely said, is spent by bees in seeking and defending hoarded wealth. In this work there is a great loss of hives. Hives are often greatly reduced in strength, and the slain may be seen in heaps near the doors of hives which have been persistently attacked. Artificial feeding is the cause of many destructive battles, and therefore the administration of syrup in mild weather is not unattended with risk. Whatever feeding is necessary in September should be given as speedily as possible in order that it may be stored up and the bees settle down into the quiet of winter life. Continuous feeding now would keep the bees in a constant state of excitement, and cause them to eat the food given to them instead of storing it up. During the last six or eight weeks bees here have gathered no honey, and have had to live on what was stored up in July. During this time there has been an enormous consumption of honey. Hives that were well filled with honey and heavy at the beginning of August had lost much of their weight by the beginning of September, and during the last two or three weeks the consumption of honey has been great.

An examination of hives, minute and thorough, was suggested in a late issue of this Journal. Those who have not examined their hives should do so as soon as they conveniently can, and see that the hives are clean and cosy, also well stored with bees and honey. Many bee-keepers in the spring months of the present year found great difficulty in inducing their bees to leave their nests to take artificial food. Both top and bottom feeding failed to entice the bees to leave their combs, the weather was so cold. Proper attention to hives now would prevent the necessity of untimely feeding in spring, and keep the minds of apiarians at rest about their bees during the winter and early spring months. The various modes of feeding are understood and all are very good. We have boards with tin troughs in them sufficiently large to hold 3 quarts or 6 lbs. of syrup in each, which we use for rapid feeding in autumn. Such troughs, filled with good syrup and placed under strong hives, are emptied in two and three hours; and they are so constructed with tubes and funnels that they can be filled and refilled from the outside without disturbing the bees or uncovering the hives. The tin troughs in our feeding boards are 11 inches wide and 1½ inch deep. For the purpose of storing syrup rapidly large pie dishes and dripping tins with chips of wood in them can be used in hives not full of combs; and hives full of combs can be raised by ekes to admit the dishes and dripping tins between combs and boards. By-and-by the weather will be too cold for feeding bees—too cold for them to elaborate and store away food for winter and spring use, too cold for them to nurse brood if breeding commence.

As soon as feeding is completed the boards of hives should be well scraped and cleaned. If wet they should be dried or changed. If their doors are not already contracted, they should be for two purposes—viz., first to keep mice out, and secondly to prevent unnecessary loss of heat. If mice find access to hives in winter they are very destructive. The bodies of bees are not eaten, but after all are beheaded the mice eat the honey. As

bees like to close themselves cosily up in their winter quarters, and keep the cold out by using propolis in small cavities and crevices and in cementing the hives to the boards, we approve of the use of mortar for the latter purpose, for it tends to drive the rain that may fall on the boards off and outward.

The covering and protection of hives on the approach of winter is of more importance than many bee-keepers seem to believe. Protection from both rain and severe frost should be aimed at. Nothing answers better for an inner covering of hives than a good thickness of soft dry hay placed over and around them and pressed close. For an outer covering wheat straw well drawn out and combed with the fingers and neatly tied answers and looks well; indeed, no other kind of covering on hives looks so well. Straw covers are cheap, characteristic, and if well made and put on are ornamental. Roofing felt and other kinds of materials are used for covering hives. In large apiaries substitutes of all kinds are used as covers.

The distance for hives to be placed above the ground is a question of great importance. Our hives in summer are about 4 inches above the ground; in winter we like to have them about 8 inches above the level. Snow seldom is more than 8 inches deep. Hives should be above the snow line in winter in order to be kept dry, for wet boards in frosty weather may become too cold for the bees standing on them. Even if the moisture of boards do not become frozen, it will cause the combs to decay. After hives are covered and secured for winter very little, if any, attention will be required in the apiary till about the middle of February.—A. PETTIGREW, *Bowdon*.

### FEEDING BEES.

"LEON" wishes to know if it will be necessary to feed a driven stock "all through the winter." As there seems to be a very general misconception in regard to winter feeding, I shall answer his query in a more general way. And first of all let me say that winter is the period when bees ought to be allowed perfect quiet and rest. Anything that disturbs them then inevitably causes a loss that cannot be repaired. Of all disturbing causes feeding is probably the most general. It is quite usual to find old-fashioned bee-keepers going round their hives in the dead of winter pouring in syrup at the crown hole or pushing in a wooden trough at the doorway. In either case the bees are tempted to leave the cluster probably never to return; robbers are invited to share the oozing spoil, mould and dysentery generally result, and spring finds the stock reduced to a handful if not dead.

"LEON'S" query admits of but one answer at this season—viz., feed at once, as rapidly as possible, all the stores the stock is likely to require till spring, say 15 to 20 lbs. of syrup; thereafter tuck up warmly and leave all quiet till spring.

Autumn feeding is, I think, a necessary evil. While it goes on the bees are kept in an unnatural state of excitement that results in reduced numbers. The little brood then raised cannot make up for the loss of the thousands that perish. The brood itself, if raised late, is frequently the cause of dysentery during the winter, since the young bees emerge from their cells with bodies distended with fœces, and if they do not get a cleansing flight soon the combs are soiled and the air poisoned, resulting in a general attack of dysentery. This leads us to the conclusion that necessary feeding should in autumn be completed as rapidly and as early as possible. Unsealed stores are also well known as a cause of great mortality in winter. The honey or syrup in open cells readily absorbs the vapours of the hive, swells in bulk, oozes out of the cells, rendering the whole hive damp, and finally poisons the bees. The end of September is late enough to feed any bees, but the earlier before then the better. As a matter of fact, I may add that all of my bees that have required feeding this autumn have dwindled to less than half their strength. Those not fed at all still cover all their combs. The latter, however, are not fully provided, but what they have will be all at once by filling their empty combs from a watering can.

Slow autumn feeding has sometimes another evil—it causes the queen to exhaust herself, laying at a time when the bees cannot raise brood. I have several hives in which eggs are always plentiful, but I never see a larva or a sealed brood cell; this is owing to the absence of pollen, which has been very scarce with us, what is in the hive being already so covered with honey or syrup that the bees themselves do not know where to find it.

The above remarks apply, of course, to syrup feeding, and are only partially true of candy-feeding. The latter may be safely practised all through the winter, but only in cases of necessity, as it still causes some excitement, and if flour is used will cause breeding at an untimely season. The time is now at hand when I propose to pack my stocks for the winter, leaving to

each only as many combs of sealed food as the bees can cover. According to my usual custom I shall place a cake of bee candy across the frames under the quilt, partly as a further supply, but chiefly as an excellent means of providing a winter passage over the frames where it is warmest. Over all and on either side of division boards I shall pour loose chaff, see that roofs are water-tight but well ventilated, close the doorways to within an inch or two, and bid defiance to a zero temperature. — WILLIAM RAITT, *Blairgowrie.*

#### TRADE CATALOGUES RECEIVED.

R. H. Vertegans, Edgbaston, Birmingham.—*Catalogue of Bulbs.*  
Wm. Rumsey, Waltham Cross.—*Catalogue of Roses and Trees.*  
Joseph Schwartz, Lyon, France.—*Catalogue of Roses.*  
Thomas Meehan, Germantown, Philadelphia.—*Catalogue of Plants.*

\* \* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Work on Orchids** (*A Constant Reader*).—The price of the last edition of Mr. B. S. Williams' "Orchid-Growers' Manual" is 7s. 6d., post free 8s., and not 6s. 6d., as was stated on page 232.

**Beetle** (*Inquirer*).—The insect forwarded is one of the Sexton or Burying Beetles (*Necrophorus Vespillo*), a widely distributed species, and of some utility, as the beetles seek out and bury dead grubs, &c., in which the eggs are laid and the larvæ afterwards feed.

**Heating by Gas** (*A. G.*).—Heating by gas is not much employed, or only on a small scale; but you would probably obtain the information you require from Mr. Clarke, Vinery House, Allerton, Liverpool.

**Grecian Agriculture** (*R. B.*).—You had better consult Jebb's "Modern Greece." You will find that the cultivation of its soil is profitable and progressive. The culture since 1830 has increased of Olives, threefold; of Figs, sixfold; of Currants, fifteenfold. The last-named occupy nearly forty thousand acres.

**Indexes** (*M. H.*).—Your suggestion is an excellent one, and we only refrain from publishing it on the ground that disappointment would be caused by many who would find it impossible to carry out the project, as the necessary materials are not obtainable.

**Violets Unhealthy** (*A Gloucestershire Subscriber*).—Your plants have been much infested with red spider, these insects having attacked the under sides of the leaves and extracted the juices from them. Violets should be grown in a partially shaded place in the summer, such as the north side of a hedge or wall, but not under trees. You had better remove the runners, together with the worst of the leaves. The insects will do little if any more injury at this late season, and the leaves that will be produced will be green and healthy.

**Vine Leaves Discoloured** (*Idem*).—There is nothing to be alarmed at about the Vines; but no doubt it would be advisable to remove a little of the surface soil from the border, so that fresh loam can be placed in contact with the roots, and over the loam a layer of rich manure 3 or 4 inches in thickness, where it should remain to decay. This will induce the increase of feeding roots, and the Vines will be invigorated.

**Caterpillars** (*Idem*).—You can only eradicate those on the Savoys by hand-picking, but they might in a great measure have been prevented by frequent dustings of soot when the plants were young. If you dust them now it will not be easily washed off those parts required for cooking. The best means of preventing the recurrence of an attack on your Gooseberry and Currant trees is to remove 2 or 3 inches of the surface soil as soon as all the leaves have fallen, and add fresh soil, manure, or tan. You may dress the surface of the ground under the trees with soot and gas lime in the spring, a small handful of the latter being quite sufficient for each square yard of soil. Cyclamens need more heat than a cold frame affords to induce free growth and early flowers.

**Growing Rhododendrons in Sawdust** (*A. G.*).—Rhododendrons succeed well in sawdust, but it must be mixed with soil, and from its slow decomposition it supplies material similar to that obtained from peat beds. It will not be necessary to give water in winter, as the rainfall will be sufficient to keep the soil in a thoroughly moist condition, but in an unusually dry period in summer applications of water will be beneficial.

**Suckers from Standard Roses for Stocks** (*Young Gardener*).—If the suckers are taken up with a portion of root in early December and planted in rows in good soil they would grow, and after a year's growth they would be of sufficient strength for budding; but they send up suckers so freely as to be inferior as stocks either to the Manetti or seedling Briar. The name of the wild flower is *Scrophularia aquatica*.

**Staging for Greenhouse** (*Chas. Diamond*).—We are left to guess at an important element in your case—namely, the height of the stage No. 3 from the glass. If it is not above 3 or 4 feet probably the plants may succeed, especially as some of them may be tall; if not, they can be raised on inverted flower pots at the back of the stage. It is impossible, however, for us to give a satisfactory reply without knowing more particulars both of the house and plants. No one can give you a precise answer to your other question except Messrs. Messenger and Co. of Loughborough, who will readily give you the information you require in reply to a letter addressed to them.

**Nectarines Cracking** (*E. D. C.*).—The stone of the fruit you sent was very imperfect, the result either of defective fertilisation of the blossoms or a deficiency of calcareous matter in the soil; and when the stones are imperfect the fruit often shrinks and cracks. When your tree is flowering gather pollen from a free-setting variety of either Peach or Nectarine and apply it to the flowers; it can be easily done with a camel's-hair brush; or a rabbit's tail or a dried plume of the Pampas Grass brushed lightly over the flowers at noon on two or three consecutive fine days would probably be beneficial.

**Lifting Peach Trees** (*Durham*).—If the buds are prominent we should lift the trees now, shading them for an hour or two occasionally if bright weather should prevail, and sprinkling the foliage if needed to maintain its freshness. The trees would then produce fresh roots before winter, and would grow and fruit next year as if they had not been removed, except we should expect the growth to be better and the fruit finer, assuming that at present the soil is not satisfactory and the root-action defective. If the buds are not prominent we should allow the trees to remain ten days longer before lifting them. You give us no information relative to the age and condition of the trees, or our reply might have been more explicit and possibly more useful.

**Caterpillars on Viburnum** (*W. J. E.*).—Pour boiling water on 2 or 3 ozs. of hellebore powder and stir well, then add sufficient water to make a gallon of the insecticide. With this syringe the bush, and if the water is applied as hot as the hand can be borne in it, it will be the more effectual. Four ounces of quassia chips boiled for half an hour in a gallon of water, 2 ozs. of soft soap being dissolved in it at the same time, would probably be equally effectual if similarly applied. As soon as the leaves have fallen not only remove them but 3 or 4 inches of soil for a considerable distance round the shrub, and add fresh compost. If you adopt these measures you will not have so many caterpillars another year.

**Fruit Trees for Espaliers** (*W. M.*).—At 12½ feet distance apart you will have space for twenty-four trees. Of Cherries:—Empress Eugénie, May Duke, and Archduke may be selected, they being had on the Mahaleb stock. Apples on the English Paradise stock:—Mr. Gladstone, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Reinette du Canada, Dutch Mignonette, Cockle Pippin, and Sturmer Pippin are suitable varieties; they are named in the order of ripening. Pears on Quince stocks:—Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Comte de Lamy, Doyenné du Comice, Marie Louise, and Benrre Bachelier will form a good collection. Plums:—Early Prolific, Mitchelson's, and Victoria for culinary purposes; for dessert, July Green Gage, Green Gage, and Kirke's.

**Wintering Lothian Stocks** (*W. Wallace*).—We should pot them at once and place them in a shaded place out of doors until the occurrence of frost, then winter them in frames. They will endure several degrees of frost, especially if they are not too wet; indeed they should be kept rather dry during the severe weather of winter. Pentstemons may also be wintered in frames, protection being afforded when needed to exclude frost or nearly so. The pots will be better plunged in ashes or cocoa-nut refuse, and all decayed leaves must be promptly removed from the plants. These remarks apply equally to the Stocks. Two useful Apples are Stirling Castle and Dumelow's Seedling, both culinary varieties.

**Hardships of Gardeners** (*A. T.*).—We well know, and regret it, that not a few gardeners are expected to make bricks without straw, so unreasonably exacting are some employers. You are, however, adopting a wise course by making the utmost of the means at your disposal. A perseverance in this course will in time command approbation, and if your work gives evidence of superior ability it will sooner or later attract the notice of someone, and will eventually prove of advantage to you. Hasty changes, at the present time especially, are very unsafe, as every gentleman wanting a gardener has the choice of ten men. Under these circumstances it is only those men who can adduce the best evidence of ability who can hope to be appointed, and a man who is always moving is seldom able to produce such evidence. We could name men who were once not better, if as well, situated as yourself, who by following the course we have suggested—working assiduously in their calling and their own self-improvement, waiting patiently and moving judiciously, who now occupy leading positions in the gardening world.

**Storing Fruit** (*F. J.*).—We presume you cannot place a small stove in your fruit room in very severe weather. We should place the fruit on a thick layer of clean straw, and for a time at least ventilate the room freely; eventually after the fruit has dried ventilation becomes of less importance, and the room should be kept dark or nearly so, opening the door or windows occasionally to maintain a sweet atmosphere. During severe frost you might cover the fruit thickly with dry chaff, which is sweeter and better than cocoa-nut fibre refuse or sawdust, especially that from trees which contain turpentine. When fruit is spread on bare shelves it is often frozen through the boards on which it rests, however thickly it is covered. If you cannot preserve the fruit in the manner suggested, you may on the approach of severe frost pack it in large boxes with clean dry silver sand or chaff, and place the boxes out of the reach of frost. We have not, however, found this necessary, having had plenty of protecting material and used it.

**Climbers for House Walls** (*S. M. G.*).—For the west aspect:—*Aristolochia Siphon*, *Lonicera flava*, *L. odoratissima*, *L. Periclymenum*, and *L. sempervirens* var. *Browni*, *floribunda* and *Youngi*; *Clematis aznrea grandiflora*, *C. montana major*, *C. Viticella rubra grandiflora*, *C. Lucie Lemoine*, *C. Mrs. Hope*, *C. Vesta*, *C. purpurea elegans*, *C. Henryi*, *C. Jackmanni*, *Bignonia radicans*, *Cydonia japonica* and var. *alba*, *Jasminum officinale grandiflorum*, and *Roses Rêve d'Or*, *Bonquet d'Or*, *Anna Ollivier*, *Cheshunt Hybrid*, *Climbing Devoniensis*, *Gloire de Dijon*, *Marcelin Rhoda*, and *Perle de Lyon*. South:—*Jasminum revolutum*, *Wistaria sinensis* and var. *alba*, *Berberidopsis corallina*, *Ceanothus azureus*, *Gloire de Versailles*, *C. integerrimus*, *C. floribundus*, *Escallonia macrantha*, *Magnolia grandiflora floribunda*, *Chimonanthus fragrans*, *Garrya elliptica*, *Lardizabala biternata*, *Passiflora cærulea*, and *Roses Maréchal Niel*, *Sombreuil*, *Perle des Jardins*, and *Innocente Pirola*. North:—*Ampelopsis hederacea*, *Clematis Vitalba*, *Hedera (Ivy) canariensis*, *H. palmata*, *H. Ragneriana*, *Cratægus pyracantha*, *Forsythia suspensa*, *Tropæolum speciosum*, and *Jasminum nudiflorum*.

**Ventilating a Vinery** (*F. Walker*).—When Grapes are grown in an unheated vinery beyond doubt it is advisable to close as early in the afternoon as possible during the growing season. No stated time can be determined for opening and closing a vinery, this not being a question of clockwork at all but solely one of temperature. Assuming that the thermometer in the house registers 60° before the sun reaches the structure in the morning we should, when the heat reaches 65°, open the top lights slightly, but not sufficient to cause the mercury to fall to 59°. We should open the lights still wider at 70°, and again at 75°; but in neither case sufficiently so to cause the temperature to fall. At 80° we should give a little front air, and if the heat still increased should open both front and top ventilators, and allow the maximum temperature to remain as near 85° as possible, the thermometer being perfectly shaded. Early in the afternoon as soon as the heat commenced declining we should first reduce the front ventilation, then the top, with the object of maintaining the heat at 85° as long as possible, and close the house when we were certain that temperature would not be exceeded afterwards. At night we should open the top lights slightly and leave them open, as we do not approve of a perfectly close vinery in the summer. As there is Peaches in the house it will be necessary to keep the house as cool as possible during the winter to retard the starting of the trees in spring, and possibly, having regard to the position and state of the trees, we should open the front ventilators sooner; but, having regard to the vines alone—and it is only in respect of these that you ask information—we have described what we consider the proper method of ventilation. The moisture, as a rule, should be governed by the temperature.

**Trees and Shrubs as a Screen for Building** (*S. M. G.*).—The quickest-growing deciduous tree is Lombardy Poplar, and in evergreens Corsican Pine, but it is not so dense in growth as the Austrian Pine. Other deciduous trees are Acer platanoides, Aesculus Hippocastanum, Betula alba, Platanus occidentalis, Tilia europæa, Ulmus montana, Quercus rubra, Acer Pseudo-platanus, A. rubrum, Fagus sylvatica, and F. purpurea. The following deciduous shrubs or small trees are suitable for planting—Amelanchier arbutifolia floribunda, Cerasus Padus, Cytisus Laburum alpinum, Deutzia crenata flore-pleno, Philadelphus coronarius, Pyrus Aucuparia, P. Aria, P. prunifolia, Rhus glabra, Crataegus Oxyacantha var. coccinea plena, multplex, rosea; Spiræa arifolia, S. prunifolia flore-pleno, S. callosa superba, Syringa vulgaris and alba, Viburnum opulus, and Weigela rosea. Of evergreen shrubs—Aucuba japonica, Berberis Darwinii, common and Portugal Laurel, Hollies in variety, and Viburnum Tinus. We should plant the deciduous trees at the back, and with Yew and Holly, so as ultimately to form a good undergrowth of evergreens, as those thrive well under deciduous trees provided the latter are thinned in due time. The lesser trees and shrubs we should dispose in front so as to form an ornamental shrubbery, having a good breadth of Rhododendrons on the outside. If you employ Conifers they must not be mixed with deciduous trees if they are to remain permanently, though you may have Lombardy Poplars at the back and Austrian Pines in front.

**Peach Trees Unhealthy** (*F. C.*).—The fact that the tree planted out produces fine green leaves while those in pots have small yellow foliage suggests that the latter do not obtain the nutriment they require. Some mistake may have been made in watering, either by saturating the soil before the roots were in an active state or, on the other hand, permitting the soil to be too dry as the trees advanced in growth. If the pots are very full of roots the latter is probably the case, and top-dressings of manure would also have been beneficial. Have you Mr. Rivers' work on the orchard house? If you have, you cannot do better than follow the instructions it contains. If you do not possess the work you had better obtain it; it is published by Longmans, and can be had through a bookseller. As your young trees are so liable to injury by frost we should certainly pot them as you propose. Loosening the ligatures would be safer than removing them at once, but the condition of the stems and buds must guide you in this matter. The most complete work on practical gardening is McIntosh's "Book of the Garden," published by Blackwood & Sons, London and Edinburgh. Your other questions shall be answered next week.

**Plants for Shaded Borders** (*S. M. G.*).—The following selection includes such plants as you require—Aeonitum pyrenaicum, Ajuga reptans, Allium victorale, Anemone apennina, A. nemorosa plena, Aroniceum glaciæle, Aubrieta graeca, Arabis albida, Caltha palustris plena, Campanula aggregata, Colchicum autumnale var., C. speciosum, Convallaria majalis, C. polygonatum, Cyclamen hederifolium, Epigaea repens, Snowdrops, Daffodils, Winter Aconite, Helleborus niger maximus, H. orientalis, Hepatica angulosa, H. triloba vars., Mimulus vars., Omphalodes verna, Peonia vars., Primula acaulis vars., Ranunculus aconitifolius plenus, Rhododendron hirsutum, Scilla siberica, Hypericum calycinum, Synphytum album, S. orientale, Trollius europæus, T. napellifolius, and Violets.

**Names of Fruits** (*M. D.*).—1, Cellini; 2, Dumelow's Seedling; 3, Ecklinville Seedling; 4, Cox's Orange Pippin; 5, Beauty of Kent; 6, Court Pendu Plat. (*G. Wells*).—1, Cockpit; 2, Norfolk Stone Pippin; 3, Red Autumn Calville. The Pear is probably Suzette de Bavay. (*H. C. P.*)—14, Grosse Calebasse; 35, Fondante d'Automne. We cannot identify the others from the specimens sent. (*H. G. M.*).—1, De Neige; 2, Lord Lennox; 3, Red Ingestrie; 4, Beurré Capiaumont; 5, Swan's Egg. (*A Subscriber*).—We cannot identify the sorts from such poor specimens. (*R. P. Williams*).—The Apple you have sent this week is undoubtedly Cellini, and if the one sent last week is not the same variety produced by a different stock it is the Nonsuch. There are such variations in fruits that it is often impossible to determine the name of a variety from a solitary specimen. (*J. M. Hopkins*).—The seedling Apple does not appear to be of any special merit; but a single specimen is not sufficient whereon to found an estimate. (*G. F. W.*).—It appears to be a highly coloured example of Grauestein. It is said to have originated in the garden of the Duke of Augustenberg at the castle of Grafenstein.

**Names of Plants** (*F. W.*).—Peganum Harmala. (*P. H.*).—A variety of Stapelia Bufonia. (*Inquirer*).—1, Adiantum venustum; 2, A. Capillus-Veneris variety; 3, Selaginella cuspidata; 4, Polypodium vulgare var. caubricum; 5, Specimen not sufficient to determine the species; it is one of the Aspidiums; 6, Nephrolepis cordifolia. (*F. T. Arnold*).—The Begonia with narrow leaves is B. angularis; the other is B. Sambo. (*H. C. T.*).—1, Chrysocoma Linosyris; 2, Helianthus multiflorus. (*M. H. M.*).—The plant with broad leaves is Olea fragrans, and has been grown in England for more than a hundred years. The plant with small Orange-like fruits is Aegle sepiaria, occasionally seen under the name of Citrus trifolium. It is included in the Orange family, and is closely allied to the genus Citrus. Both the Aegle and the Olea are natives of Japan. (*T. W. G.*).—Francoa ramosa. (*J. C.*).—Trachelium coreuleum. (*G. W. C.*).—The specimen is insufficient for satisfactory determination, but it resembles Solidago Virgaurea.

**Hives Deserted** (*Subscriber*).—The hives with many drones which you lately found cleared of bees was lost through robbery, invited by its undoubted

queenlessness. We presume it was not a moveable-comb hive, else its state would surely have been discovered in time to prevent its ruin. The brown colour of the combs we take to evidence their having been used at one time for breeding purposes. The crumbs at the entrance are the *débris* of cells and cappings torn down by the robbers. The other stock found deserted and in similar condition had probably suffered from the same cause. The remedy in such cases is to make sure that all parent stocks and after-swarms are provided with laying queens within three weeks from swarming.

COVENT GARDEN MARKET.—SEPTEMBER 28.

WE have nothing new to quote this week beyond a better demand for good Peaches and Pines.

POULTRY AND PIGEON CHRONICLE.

CONTINUOUS CORN-CROPPING AND CLAY FARMING.

(Continued from page 279.)

HAVING previously quoted from Mr. Prout's pamphlet the account and method of draining his purchased estate at Sawbridgeworth, we will now make a further quotation referring to its original state and condition, and the means adopted to bring the land and fields into a state fit for steam culture. He states, "The two farms enclosed within one ring fence I found subdivided into fifty-one enclosures, averaging under 9 acres each. Straggling internal fences, encumbered with brushwood, pollard trees, and other inferior timber wasted a great proportion of the ground, hindered the proper expedition of tillage operations, harboured weeds, birds, insects, and vermin, injuriously shaded both land and crops, and would have been of great expense to reduce into neat form and to keep trimmed and in repair. In four years I grubbed up nearly six and a half miles of ancient hedgerow, removed crooked banks, and filled-in the ditches alongside; the whole area of the two farms into nine principal fields of nearly 50 acres each, arranged generally in quadrilateral figure."

We have copied this statement, as it shows how the face of these farms, together measuring 450 acres, was relaid out and made available for steam cultivation. These farms in their former state represent the condition of hundreds of farms at present existing in different counties, many of which under existing circumstances of agricultural depression will come into the owners' hand to be remodelled or let to great disadvantage. Mr. Prout's outlay and expenditure and system of laying-out will prove to some extent the best policy of proceeding to improve the occupying and letting value of clay land farms, especially if

used as arable land, and to some considerable extent if laid into pasture. The total cost of drainage, outfalls, wells, reservoirs, alteration of buildings, clearing of hedges and trees, levelling, reclaiming, and remodelling the plan of the farm, amounted to about £4500, or £10 per acre. He, however, as owner, gained 18½ acres of land, while the rental of the farm was largely increased; also from being, as in its former state, quite uninviting to an occupier, would in the future be sure to command a tenant of capital and experience.

It will be well to examine whether this farm and the system of cropping adopted can advantageously be compared with the ordinary systems of management commonly practised upon such land in various districts of the kingdom. As a landlord's question it is important to understand the benefit of the estate improvements, and also original cost thereof. It appears that the first cost of the 450 acres of land in the year 1861, then in two farms, amounted to the sum of £15,000. The purchase also of corners to straighten the boundaries, together with legal expenses, came to about £1000, thus making the total purchase money £16,000, or £35 per acre; but adding £4500, the cost of improvements up to the year 1865, made the cost to stand at £20,500, or £45 per acre, and making the improved rent 35s. per acre. In the year 1875, or ten years after the above estimate was formed, the estate was valued by a well-known and competent surveyor at 45s. per acre, and fixing the value of the fee-simple at £31,000, or £69 per acre; a considerable portion of this augmented value no doubt being due to the system pursued by the occupier.

We must now look to the other side of the picture, for without doubt the unfortunate agricultural depression which has prevailed since 1875 has caused a serious diminution in the value of this estate, notwithstanding the large outlay in stocking and tillage, and the intelligent and practical management of the farm under a new and peculiar system. The history of the tillage upon Mr. Prout's farm is well worth the study of the home farmer as well as the proprietor of the land. The cost of steam tillage and extra labour of various kinds was great, especially in the first four years, yet no amount of horse labour would have accomplished the operations in the same time so as not to miss seasons, and without injury to the land by the trampling of horses. We must further point out that much encouragement for improvers is to be derived in Mr. Prout's statement from the progressive diminution of steam tillage expenses on this farm, the average of thirteen years having been 429 acres, and for the last four years 301 acres. In like manner the cost of manual labour, the average for thirteen years, having been £509, whereas the average of the last four years was only £455. These economical results are evidently due to the greater friability of the soil, gradually effected by the action of thorough drainage, and the influence of deep as well as mechanically efficient culture by steam power. Again, rotation of cropping, the basis of ordinary arable husbandry, is unknown upon this farm. On looking at the tabular synopsis of cropping it will be found that of late years, since a rotation has become possible, about six-sevenths of the whole area have been always under corn, while the acreage of roots has been little. For the five years ending 1874 the bare fallow was nil, the breadth of roots reduced to a plot of a few acres, the average extent of corn 360 acres, and the average crop of hay made from artificial grasses 71 acres, while latterly the cropping has been about six-sevenths of the farm with cereal crops, and the remaining seventh hay, all sold off. During the first nine years no Red Clover was sown, the land being Clover-sick, since then about 50 acres of Clover have been grown annually—in other words, 348 acres of Clover have been sold for £4520, equal to £12 19s. 9d. per acre during the seven years from 1872 to 1878. The proportion of Wheat grown in the years 1872-74 was increased, because it was found that whatever might be the yield or the market price of Barley or of Oats, the Wheat crops made from £2 to £3 more money. Since then, however, and until last year (1880) more Barley has been grown, and in 1878 and 1879 the breadth of Barley approached to double that of Wheat.

Having no order or exact rotation of crops a major portion of the Wheat follows Wheat; some is sown after Barley, some after Oats, and a part after Clover. To enable such a succession of crops to be taken with advantage we must have a soil which shows by analysis that its contents possess the requisite amount of plant food. In Mr. Prout's case he very judiciously obtained the valuable advice of Dr. Voëlcker, in order that theory and practice might be made to agree upon the best-known terms. According to a careful analysis of the soil of three fields, which it was assumed represented the average of the farm, and by confining attention to the more important soil constituents, the three fields contained per acre in a depth of only 6 inches, and in a readily available form (without giving minute details, for which we cannot here find

space), we find according to the given data that 6 inches of soil from one of these fields called "Broadfield" contain as much phosphoric acid as 118 good crops of Wheat of 40 bushels, and 2 tons of straw; as much potash as 212 crops, and as much sulphuric acid as 215 crops of Wheat; and that 2256 crops of Wheat contain no more lime, 1120 crops no more magnesia than is found in 6 inches of this soil. In the case of a field called Blackacre was found in 6 inches of soil as much phosphoric acid as in 171 crops of Wheat. Of potash 272 crops of Wheat, of lime 5176 crops, and of magnesia as in 391 crops of Wheat. The same calculations have been carried out applying to crops of Barley, and they afford clear evidence of the enormous quantities of plant food which lie buried in only 6 inches of an acre of clay land; 2 or 3 feet of such land, practically speaking, contain almost unlimited stores of mineral plant food. Now, although it seems almost incredible that clay soils should possess such extraordinary powers of production, yet it is almost equally incredible that the resources of the soil are not more drawn upon in our systems of cropping and better understood as to the tillage required to obtain such advantages. These statements are full of truth and of practical knowledge, because no man is better able to elucidate these scientific results than Dr. Voëlcker; and as he has been Mr. Prout's adviser from first to last in the conducting of his farming business, it confers equal credit on Mr. Prout as having acted under the directions of Dr. Voëlcker, and on Dr. Voëlcker for having contributed by his scientific knowledge and research so great a boon to the agriculturists of our country. At the present time of agricultural depression, when the idea that the growth of corn is unprofitable, and that strong heavy lands should be laid into permanent pasture is very general, not only amongst tenant farmers, but also amongst the owners of estates and the home farmers also, it will be our endeavour to advise the home farmer upon the subject.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Both horses and oxen are fully employed. There are still farmers to be found who persist in the use of oxen, and we approve of them in the absence of steam power, because they can when purchased or taken into work about the middle of July be made to render good service at any labour on the land from that time through the harvest and Wheat-sowing until all the land intended for roots or Barley has been fallow-ploughed. We know farmers now who prefer ox labour as a supplement to horse power instead of resorting to steam power; and this may answer upon light hill land, and thus reduce the number of horses, which grow out of value, whilst oxen improve when well kept during the working period, and are ready at any customary period to go into the boxes and be fattened for the shambles. Sowing Rye, winter Barley, winter Vetches, winter Beans, also sowing Trifolium where it may have failed; for we have sown it as late as November with success, but not without using an extra quantity of seed, say 30 lbs. per acre. Lifting Potatoes may still be continued by using the lifting frame attached to an ordinary plough minus the turn furrow, and where plenty of hand labour can be obtained a large area may be lifted in little time. The land after Potatoes, if fairly cultivated, will be clean and fit for seeding with Wheat if the soil is loamy and adapted for that crop; but in case of light land, either sand, gravel, or limestone, the land may stand over for Barley in the spring, which may be sown early. Clover seldom injures or delays the harvesting of Wheat as it does Barley; besides, Wheat when seeded to Clover should be cut higher, leaving the Clover plants entire, which we have found produce a good cutting for horses and cattle until November, when the frost comes. The only green fodder to cut at present is obtained on the Clover lea where the first and second cutting were delayed for the purpose of insuring a succession, or in seeds saved in the Wheat. The cultivation of corn stubbles should now be continued until the autumn rains set in, because there is plenty of time on the mixed soiled farms for ploughing and seeding for Wheat when the land has become too heavy for the continuation of autumn fallowing and cleaning. These observations, however, apply only to farms of mixed soils only, for on the hill farms there is plenty of work for ploughing and preparing and manuring for Wheat-seeding. In the same way the season for sowing Wheat cannot with safety be deferred on the clay land farms, especially where it is sown after fallow preparation or fallow crops, such as Tares and Mustard.

*Hand Labour.*—Men, women, and boys are employed in picking up Potatoes as fast as they are lifted or ploughed out. Stubble Turnips should now be finished hoeing as soon as possible. Upon some flat land the Mangold crop may now be pulled, carted, and stored at the homestead or in some field where they may be required for feeding sheep next spring or summer. If the crop is left too long on the land the carting of the crop may prove injurious to the land for a succeeding crop.

*Live Stock.*—The fattening bullocks on the pastures which are fit for sale should now be disposed of, retaining those in lower condition to be finished off in the boxes by root and cake feeding. Many farmers are afraid to commence the use of Mangolds for feeding the fattening

cattle at this period, but we have never hesitated in doing so in the month of September, the safeguard being pulling a week or ten days before using and feeding with a diminished quantity, together with barley or bean meal, instead of cake, or mixed with it. Many half-fat bullocks not good enough for the butcher will now be offered in the markets for sale, and these are the best to buy and put into the boxes for winter fattening, for they will make more profit than poor animals, however cheaply they may be purchased. The dairy cows have lately done well owing to the flush of grass produced by the heavy rains in August. The rainfall of that month, we understand, amounted to 7 inches. All these may do fairly for some time yet without supplementary food, but they should be carefully watched as to the milk they yield, for if it diminishes much the cows should have Cabbage, cotton cake, or meal, in order to lengthen the milking period. As soon, however, as they go dry they should be moderately fed without allowing them to gain flesh; it is from this cause that so many fine well-doing animals come to grief at calving time; for when they lay on fat internally during pregnancy they are more likely to suffer seriously either before or just after dropping their calves. All the young cattle, both yearlings and two years off, have done well lately. The only fear is that they may be attacked with quarter-ill, for although there is no remedy for this complaint it may often be prevented by allowing the animals a dry pasture as a night lair. The down ewes of every sort, which are now seasoned in lamb, should be kept with great regularity and moderately, for it is in the early stages of pregnancy that irregular or over-feeding is likely to produce abortion. This, however, is not so likely to occur with the long-wooled ewes which are fed chiefly on grass at this time of year. The horned Dorset and Somerset ewes are now near their lambing time—at least, those kept entirely for the production of the earliest lambs; still they should be only moderately fed until after weaning time.

#### VARIETIES.

WE are desired to state that the next Tredegar Show will be held on Tuesday and Wednesday the 22nd and 23rd November next, the entries closing on Monday, October 31st, 1881.

— THE poultry and Pigeon fancy seems to be extending to the Cape Colony. Possibly the presence there of General Hassard may have had something to do with this. Not long ago we heard of a show being held, and we now learn that ten White Fantails from the lofts of Mr. O. E. Cresswell have lately started for the Cape.

— WE have the schedule of the Oxford Show, to be held on October 26th and 27th, differing little from that of last year. Ducks are well treated with six classes; Dragoons have sixteen classes, Antwerps nine, Homers four, Turbits nine, &c.

— AMERICAN WHEAT.—It may now be accepted as certain that the quantity of Wheat available for export from the United States during the present season will fall far short of the exports for last year. The crop of 1880 amounted to 480,000,000 bushels; the crop of the present year is put at 355,000,000 bushels. Assuming that the reserve of seven million quarters left from former crops is drawn upon to some extent, and making allowance for the greater economy begotten of high prices, it is possible that, as in previous years, a third of the total yield may be available for export, but even then there would be a falling-off of very nearly 120,000,000 bushels. The crop, too, has not been secured in good condition. It is expected in America that the value of Wheat during the next six months will be 20 per cent. higher than during the corresponding period of last year.

— AGRICULTURAL STATISTICS OF IRELAND FOR 1881.—The Registrar-General has just issued his annual general abstracts of the agricultural statistics of Ireland for the current year. "These abstracts," says the *Irish Farmers' Gazette*, "reveal a more satisfactory state of matters than many would expect to find in Ireland at the present moment. They show that in spite of all the so-called distress and the terrible agitation which we have heard so much about, the actual condition of the country in a purely agricultural sense has within the past twelve months made some actual progress. Compared with last year the area under Wheat shows an increase of 5301 acres; Oats an increase of 10,437 acres; Bere and Rye an increase of 789 acres; Beans and Peas an increase of 1737 acres; and Barley a decrease of 7864 acres. There is thus in cereal crops a net increase of 10,400 acres. Green crops show a still larger increase—namely, 21,755 acres; but this is wholly due to a very large increase

in the area under Potatoes, which is stated to be 33,643 acres more than in 1880. The larger breadth under Potatoes this year is perhaps mainly due to the plentiful supply of first-rate seed which the excellent crop of last year left in the country, and the renewed confidence which the great success of imported seed had imparted. The area under Mangold Wurtzel and Beet shows an increase of 3347 acres, and Vetches and Rape an increase of 839 acres; while in Turnips there is a decrease of no less than 7460 acres. In Cabbage there is a decrease of 7868 acres, and in other green crops a decrease of 756 acres. The decline shown in the Flax crop will to many be the most surprising feature of the abstracts. The area under Flax this last year is given at 147,085 acres, or no fewer than 10,455 acres less than in 1880. Total increase in the total extent of land under crops in 1881, 110,277 acres. It is exceedingly satisfactory to find in the stock of cattle an increase amounting to 32,962. In pigs there is an increase of 237,772; but in sheep there is a decrease of no fewer than 303,880—a circumstance that must be attributed almost entirely to the terrible prevalence of rot and other diseases."

— IRISH BUTTER AT THE DAIRY SHOW.—The following letter appeared in the *Times* of September 17th from Messrs. James Hudson and James Carter, the Judges of Irish butters at the Agricultural Hall last week:—"That there should be, in addition to the four prizes, fifteen exhibits very highly commended, thirty-one highly commended, and ten commended (and each one worthy of a prize) out of 141 entries, is a significant proof that Irish dairymen have not been slow to avail themselves of the opportunities afforded them by the instructions practically placed at their disposal by their agricultural society and by the teaching of such men as Canon Bagot and Mr. Robertson. In our experience we have never before seen such a fine display of Irish butter as the class referred to, nor one more likely to stimulate the consumption in this metropolis and its surroundings. There are a few specimens without any salt at all; but, with one exception, they are not good, which only confirms the experience of years that Irish butter of fine quality needs from one per cent. (or 1 oz. to 7 lbs.) of salt (not more) to preserve it, as Irish grass is weak owing to so much moisture. Our Irish friends are doubtless now convinced that, by indiscriminate use of salt, want of care in churning, indifference to scrupulous cleanliness, and not adopting packages to meet the requirements of the day, they have encouraged a prejudice which they now have the opportunity of altogether eradicating; and it is our firm opinion that if the result of this Show is only an earnest of what is likely to follow, there will be such an extended field for dairy operations in the sister country as will open up for it a most glorious future."

— AMERICAN MEAT IN LONDON.—"It would be interesting," says the *Daily News*, "to be informed what has become of the American meat sold out of the Central Market since the trade began in 1876. How much of it has been retailed as English meat at English prices? Our readers may be surprised to hear that up to the end of last month there has passed through the Central Market a grand total of 108,025 tons of American meat, as certified by Superintendent Stephens. Every year the American imports have increased with a steady strong stride. In 1876 there were received 5513 tons; in 1877, 14,641 tons; in 1878, 19,370 tons; in 1879, 20,751 tons; in 1880, 25,836 tons. During the present year the increase has been still going on, so that, though there has been a temporary relaxation of imports during the past few weeks, there have, from January to August inclusive, been received 21,914 tons, being 3163 tons more than during the corresponding period of last year. These figures, it should be remembered, refer only to dead meat, and there remains to be added the live stock slaughtered at Deptford. The increase in this direction is as remarkable as the other. In 1879, for example, there were killed at Deptford 28,615 American beasts and 10,457 sheep; last year the numbers were 63,704 beeves and 21,703 muttons. It would be a boon to the general public if the Markets Committee, who will be asked to inquire into the question of wilful obstruction, would, while they are about it, try and discover to what extent the ordinary consumer has benefited by this enormous importation of cheap beef and mutton during the past five years, if indeed he has benefited at all."

## POULTRY AND PIGEONS

### POULTRY NOTES.

AT the Dairy Show we had many opportunities of learning what success poultry breeders in general have had this year. We think it may be taken to have been on the whole a fair average season. Some have had good hatches all through, but most people had many failures in February and March. Those who were fortunate enough to have eggs to set in December had good hatching results from these, but had some difficulty in getting the chickens through the severe weather in the early part of the year, and the size of the January-hatched birds is consequently below the average. At the end of March things mended with most fanciers, and there are plenty of April-hatched birds in all quarters. These have done better than usual this year, doubtless because there were few early chickens to soil the runs and absorb an unfair share of care and food to the detriment of the late-comers. We therefore expect that the later shows will not suffer much, if at all, from the partial failure of the hatching season. A point in their favour will be that the unusually early moult which we hear of from many quarters will undoubtedly lead to the old classes being amply filled. We anticipate a successful year for the Crystal Palace and all the later shows.

THE Islington Show being a month earlier than usual could not be expected to be up to the average. In many classes the birds were so raw and unformed that passing judgment upon them must have been a somewhat difficult task. A judge can only take the birds as he finds them and place them according to their present merits; but to a judge who is also a breeder, and who sees indications of latent excellences in the youngsters with half-grown hackles and invisible tails, it must often be a hard struggle to follow out this rule. Exhibitors, too, are sometimes inclined to be over-exacting, and expect the judge to place their exhibits not according to their visible points but according to his estimation of what they will be later on. The exhibitor knows what his birds will in all probability grow into; his acquaintance with the strain enables him to see much more in the youngsters than the judge can see: the exhibitor can predict with reasonable certainty where the judge can only see promise which may never reach fulfilment. The advantage of having a judge who has himself been a breeder is that he knows which points are of most importance in the breeding yard, and also knows what changes and improvements time is certain to effect. Taking the birds as they are, reasonable allowance may be made for such matters; and it is here that the judge who has actually kept the variety he is adjudicating upon has the advantage over the man who has merely picked up his knowledge in the show yard and from books; but a prudent judge will rather err on the side of allowing too little than too much for such changes.

A GOOD example of what we mean may be found in the Light Brahma classes. Here chickens are constantly exhibited with young feathers, which show a decided yellow or buff tinge. The owner, probably, is certain that this is merely the sap in the young feathers, which have only just grown or are still growing, and that another week or two will clear all this away and leave the feathers of the much-desired pure white. The judge who has been a breeder of Light Brahmas knows the parts of the plumage likely to be affected by any real impurity of colour, as also the indications which prove that what seems to be foul colour is merely sap. He can therefore make allowance for this seeming defect in cases where he is certain that it will not be permanent, while he makes no allowance for it in cases where he is uncertain as to whether it is or is not a real impurity of colour. The judge without practical experience must either exclude all birds which apparently are affected by the fault, and thus, perhaps, withhold a prize from the best bird in the class, or run the risk of admitting really foul-coloured birds to honours to which they have no claim. In some strains certain parts of the plumage grow full of sap and then clear off; in others these parts are liable to be permanently defective in colour. No judge should make any allowance for such doubtful matters. The defect being there, and there being an uncertainty as to its permanence, he is bound to count it as a defect. This may seem hard to the owner, who knows that in his strain such colour always disappears with the maturity of the feather, but it is the only basis upon which a fair decision can be arrived at.

TWO matters in connection with the Show at the Agricultural

Hall seem to call for a special word of censure. There was much to praise. The awards were made known with commendable rapidity, the birds were well cared for in the matter of food, and the general arrangements were excellent, but upon some of the days of the Show the heat in the gallery was almost unendurable. A six-days show is bad enough at any time, but six days of such an atmosphere as the birds experienced on the Monday would have killed many of them. As it was we could almost see the combs of some of the cockerels growing, so much were they drawn up by the heat, while hundreds of the poor birds were to be seen gasping for breath. If there are means of ventilation in the Hall they should have been made use of, and if there are no such means they should certainly be provided by another year. That is one matter; the other relates to the judging of the class for table poultry. The prizes were liberal in this class and the entries were numerous, no less than twenty-eight pairs of chickens coming forward. They were judged by a poulterer, who in the first place ignored the conditions of the schedule by giving first prize to a pair of cockerels undescribed in the catalogue, while the class was for a "cockerel and pullet" or "pair of pullets," and the rules required the parentage to be stated; and in the next place, as we are credibly informed, made his awards without handling a single bird. How even a poulterer could tell the table qualities of a bird by merely looking at it in its pen passes our comprehension. The Judge seems to have acted on the principle, so far as he had any principle in his judging, that Dorkings were the best table fowls, and that large Dorkings were better than small Dorkings. We had no opportunity of handling the exhibits, but so far as appearances went we thought many of the other birds better than some of the winners. There were some good Houdans and also some meaty-looking cross-bred birds. These may or may not have been really better than the winners, but in any case they should have been handled and the quality of their flesh ascertained before any awards were made. The judging here was universally condemned, and we trust that by another year the Committee will find some means of having this class properly adjudicated upon.

### CHICKENS IN AUTUMN.

AUTUMN is upon us; it is time, therefore, to give some hints on the management of chickens in autumn. If weather be only fairly favourable it is not a season in which we find it difficult to keep our poultry, the young birds especially, in good health. This, we well know, is not the opinion of all fanciers, but for our part we have always found it more difficult to manage chickens through the hottest months of summer than through the autumn. Much, however, depends upon whether our advice has been taken and a judicious system of thinning-out has been constantly kept up; if so, the good results therefrom are sure now to be visible. Wherever the fewest chickens have been reared these are the finest. Those which have suffered from summer catarrhs should now be outgrowing them, and all should be getting on apace. Cockerels in particular advance with amazing strides through September and October. Cold nights, combined with hot and sunny days such as we have lately been enjoying, seem to brace and stimulate them. It is perfectly wonderful what a fine month about this time of year will do for April and May-hatched cockerels in bringing them on. We have often, notably last year, quite despaired at Michaelmas of our cockerels, from their lateness, ever cutting a respectable figure at the great autumn shows, and then, so quick has been the progress of some, that by the time of the Crystal Palace Show cups have fallen to their lot.

As in summer heat and want of ventilation in the poultry houses are the chief difficulties against which we have to contend, so in autumn damp, both in the soil and in the houses, is the great enemy of poultry. First, then, as to the houses. We would rather keep poultry in the most tumble-down old cart-shed, provided it were really dry, than in the most elaborate house with damp flooring or an imperfect roof. Fortunately damp in houses is almost always remediable. If the roof is bad a new one must be put on such as we have often described. Patching is seldom satisfactory. If the floor is damp it must be excavated a foot, dry rubbish put in, and a floor of dry earth, raised somewhat above the surrounding ground, rammed down on the top of it.

Damp in the soil is a far more difficult evil to deal with, yet according to our experience far from an insuperable one. When poultry have complete liberty they will always find out dry corners in wet weather under some densely Ivy-clad stem, or slanting tree, or leaning wall. In bright frosty mornings they will escape the chilling exhalations of the ground by mounting some bough or fence.

It is a peculiar pleasure to us to watch our birds through the dim

autumn mists catching the first rays of the sun on railings which divide some low lying riverside paddocks. Where fowls are confined like protections and places of escape from cold and damp must be provided. A perch in the middle of a yard, after the fashion of a common tressle perch in houses, is a good adjunct to a run, and an old door leant against the corner of a paling will afford much comfort. In spite, however, of these and similar common-sense arrangements, if densely foggy mornings follow cold nights in autumn cold and roup will sometimes prevail, and then some nourishing stimulant, such as our old friend Spratt's food, should at once be administered.

Cockerels and pullets, as we have frequently observed, require somewhat different treatment. The former, when properly separated both from pullets and from the general stock of adult poultry, may without harm be brought on a little with special feeding; this, however, we should reserve for some time when they seem to flag a little or cease growing, unless they are particularly required for exhibition. Pullets, on the other hand, very seldom require such forcing. Now and then the fancier who is particularly desirous of winning some prize must resort to it. It is much to be able to show a pullet exactly at her best time. There is a particular nick of time just before she lays when a good bird of any breed looks handsome. Her comb sprouts and is rosy, and in a few days her size almost doubles. When she has laid six or eight eggs this beauty goes off again, her form seems to shrink; and if she is allowed to lay in one place till she becomes at all broody an early pullet will probably go into a deep moult, and not be again in show condition this year; therefore some experience in bringing on young birds is of much value. Till a pullet has begun to show rosiness of comb she may be retarded in doing so and in coming on to lay by being moved from her accustomed run to a strange one. Young birds are for the most part exhibited singly in these days; this much simplifies the management of exhibition chickens. When, however, a pair are required it is best to decide upon them some time beforehand, and let them run quietly together. If a cockerel and pullet be suddenly put together in the basket or pen a skirmish is sure to follow, and damage will be done. Those who breed solely for the table will, of course, be killing off, or have killed off, all their chickens as fast as they come on; we now write therefore chiefly for those who exhibit their picked birds, or who at least keep them for pleasure and ornament. A practical eye, or indeed that of any intelligent person, will soon distinguish those birds which are growing faster than their companions; if such be good all round, inferior ones should now give way to them. Many breeders of profitable poultry are now glad to purchase at moderate prices early chickens which fail a little in show qualities. Continue to weed out to the last, and there is every chance of the small and select residue distinguishing themselves at the Crystal Palace and Birmingham.—C.

#### OSTRICH FARMING IN SOUTH AFRICA.\*

THIS work contains a great deal of useful practical information as to the management of an Ostrich farm in most of its details, and as to the kindred subjects of which it is desirable for the South African farmer to have a knowledge. With these matters we have, however, little concern, and we took up the book chiefly in the hope of finding something new or instructive upon the subject of artificial incubation, which is largely practised upon the South African farms. We must confess that our expectations were not realised. There is a chapter upon artificial hatching, but it is short and chiefly devoted to the ancient history of incubation. Mr. Douglass, it seems, is the patentee of an Ostrich incubator, and there is in his work an illustration of the "Heather-ton Incubating Room." An account of his incubator and of the method of heating used would have been especially interesting. Mr. Douglass is, however, silent upon these matters, and we can merely infer from some passages in which he characterises the allegation "that the smell of paraffin is injurious to the eggs and chicks" as "utter rubbish," and alleges that "if anything, the smell is good for them, acting as a disinfectant," that Mr. Douglass's machine is heated by lamp. From the way in which the author insists upon the necessity of giving the heat only to the germ floating at the top of the egg, keeping the bottom of the egg cool, and avoiding almost entirely any evaporation from the egg, it would also seem that his incubator is constructed upon the top-contact principle. The incubators are, we are told, so constructed that the eggs can be put in daily as laid; and Mr. Douglass truly asserts that the best proof of the perfection to which artificial hatching has been brought is to be found in the fact that from

80 to 90 per cent. of hardy chicks have been hatched from large numbers of eggs taken when fresh laid and incubated. All this renders us the more anxious for detailed information, but the author has doubtless good reasons for his reticence.

From the chapter on natural hatching we learn that the birds vary very much in their habits of sitting, some sitting so closely that the eggs are never cold, while others are constantly off for an hour or more at a time, and yet bring out nearly every egg. Nests are sometimes abandoned before all the chicks are hatched, and even though the eggs have thus grown quite cold the author advises the application of artificial heat, which will most likely cause them to recover and hatch out. The parents assist the young chicks, which "they know by instinct are fast in the shell," by breaking the shell with their breast bone, and "sometimes they will even take the chick by the head and shake it clean out of the shell." Neither of these processes would be much approved amongst fanciers of smaller birds, but we presume the young Ostrich is able to endure them without injury, as they seem to be expected from good hatchers.

The chief evil to which the young Ostriches are subject is one which has only developed of late years, and which is known as yellow liver. Mr. Douglass is inclined to attribute this disease to continued high feeding for the purpose of increasing the egg-production. He thinks this may have "gradually affected the stamina of nearly all our domesticated Ostriches, causing the progeny to be weakly and easily affected by change of weather or other unfavourable circumstances." From this the home-fancier of the large breeds of poultry, who is constantly feeding highly to produce size, may with advantage take a hint. As recently noted in a contemporary, it is an undoubted fact that liver disease has been far too prevalent of late years, amongst Asiatics especially. Here, perhaps, we have the key to the mystery.

#### OUR LETTER BOX.

**Management of Poultry (J. B.).**—Allow the hen to remain with the chickens as long as she is willing to do so. Feed them four times a day; oatmeal or barley meal and middlings will be best for the first and third meals; bread and ale for the second meal will help them to fledge, and by the time they have produced feathers the bread and ale may be left out and the chickens fed only three times. The last meal at night should be groats now; later on change for sound oats, barley, or wheat. Feed your hens in the morning with soft food, and give grain at night. Feed the grain separately and change it now and then. Mix your soft food so that it will crumble when thrown down and not be sloppy. Only give as much food as your hens will eat with avidity, and never leave any lying about. A constant supply of clean water and green food is most important. We published not long since a complete table giving the constituents of the different sorts of grain, &c. Spanish-Brahmas are a cross between the two breeds, and the prize-winning of the parents hardly adds to the value of the chickens. You had better procure some book upon poultry matters. We publish a small one, "The Poultry Book for the Many," sent post free for 6½d.

**Peacomb (H., Essex).**—A peacomb should not be high nor coarse, 1½ or 2 inches is quite high enough. It should be thick at the base, and fixed firmly on the head. The centre should have some blunt serrations. On either side, halfway between the base of the comb and its top, should be the distinct impression of another comb, similar to the centre, projecting merely, but in no way detached.

#### REMARKS.

18th.—Fine bright warm day, a little lightning in N.N.W. at 10.15 P.M.  
 19th.—Fine pleasant day, but not very bright.  
 20th.—Fine bright day; rain at night.  
 21st.—Very heavy rain, and thunder and lightning about 2 A.M.; dull damp morning; fair afternoon.  
 22nd.—Dull day; wet evening and night.  
 23rd.—Morning dull; fair afternoon.  
 24th.—Dull day; wet evening and night.

Rather a dull week, with much rain, but the greater part of it falling at night. Temperature about 3° above the average.—G. J. SYMONS.

### THE ROSE ELECTION.

**T**HE results of the polling which I am now about to lay before the readers of our Journal, if proving nought else, decidedly affirm an increase in the lovers of exhibition varieties of the queen of flowers. In former elections the number of voters has never reached fifty, whilst now with a more restricted franchise no less than sixty-seven have sent replies, which are tabulated. If, as the wise man said, "In the multitude of counsellors there is safety," surely the present election should produce more useful as well as more reliable results. Some old names will be missed from the lists, but, on the other hand, we have replies from over twenty nurserymen, many of them very extensive growers, having a world-wide reputation, which must make the tabulated results valuable as a guide to those who need guidance; and I cannot help thinking, that while they are helping those with less experience to form their opinions, they are also doing themselves some benefit amongst buyers of Roses. I trust it is so.

Not only is this the heaviest poll "on record," but when forty-eight varieties have been asked for, it is the largest number of varieties that have been tabulated—very nearly one hundred Roses—all, in fact, are tabulated that reached double figures, and we may safely affirm that in the list published the best exhibition Roses are to be found. Yet at the outset, I am again struck by one extraordinary result I have noticed in previous elections—how few, how very few, Roses are considered by all the electors worthy of a position, not amongst the first twelve, but in the first forty-eight. Surely most of us would have said that at least a dozen Roses must be named by every elector, and yet the tabulated result shows us that only three are thus favoured. From this I think we may learn one thing at least—that peculiarities of soil, climate, and situation affect the character of the varieties and render some, most valuable to others, useless here and there. This, at least, is a reason for giving each elector his due, and acknowledging what each one of us know by practical experience, that the omission of a name or names in the forty-eight may mean, not ignorance, but an inability from some of these circumstances over which we have little or no control to bring out in anything like their proper character certain varieties, and hence their exclusion.

Again, we do know that certain years favour the perfection of certain varieties, and *vice versa*, and the varying position of some is thus accounted for—notably, for instance, François Michelin has not been seen so generally good for two, if not

three seasons, and as a result he has lost a place in the first twelve, and Etienne Levet has also narrowly escaped joining him. There are some other terrible lowerings of position, especially Victor Verdier, in 1877 No. 29, now 55; Emilie Hausberg, No. 23, now as low as 51. Of the latter I have only had a single bloom this year, and it might have been anything but its real self, so utterly worthless; but perhaps the most wonderful change is that of Edouard Morren, No. 19 in 1877, now No. 73! Equally extraordinary are the shifts upwards of some, especially E. Y. Teas, now No. 13, then No. 35; Comtesse de Srenye, No. 24, as against 45 in 1877. Here I would just note that the nurserymen with their large stocks are almost unanimous in naming her ladyship, whilst probably not a few amateurs had with their past experience tried and discarded her. Those, who like myself, have retained one or two plants have been agreeably surprised this year by seeing how beautiful she is when in her glory—every inch a queen! But what is the rise of these two Roses compared to that of A. K. Williams, now No. 11, and Madame Gabriel Luizet, now No. 22, both of which were only introduced in 1877? There are other contrasts which may be made between the two elections; and to facilitate "comparisons," which Mrs. Partington says "are odorous," hence fitted to Roses, I have added another column—the position of each Rose in election of 1877.

I am bound to state that some electors seem to have considered that Teas were omitted, whilst others have purposely omitted them. Some feel that Hybrid Perpetuals and Teas cannot be compared together, and it appears to me that the number of electors feeling this is on the increase; nor is this feeling one to be passed by unnoticed, especially when it is mentioned by such Rose lovers as Rev. C. H. Bulmer and Messrs. G. Baker and Whitwell. The position, therefore, of the Teas is, perhaps, rather lower than it should be, and it has somewhat altered the condition of the poll. Possibly another year I may be able to meet the wishes of these electors by a general election with Teas excluded, but in a separate table.

Two or three voting papers with only twenty-four names have not been tabulated. Two or three electors also inadvertently named the same Rose twice, thus losing one vote; but one elector named the same Rose as A1 and as A3. This seemed to me inexplicable—how anyone could consider a Rose as in the best twelve, and second twenty-four. So I wrote requesting an explanation. To my greater surprise the voting paper was returned with the name scratched out of the best twelve, and a Rose named that had not been previously mentioned even in the forty-eight! This, it appeared to me, showed an amount of carelessness sufficient to make the return of no value. As one such return, though not absolutely destroying the value of the table for general purposes, does undoubtedly affect it, I felt myself compelled to reject the enigmatical return in question.

The schedule is familiar now to many readers of our Journal, but still I must again explain. The first column is the position of each Rose in the last general election, next the position in the present, then the name, date of introduction, and raiser of the Rose. Then A, B, C represent the first, second, and third-class votes of the amateurs, and the same letters with an asterisk the same votes of the nurserymen, and it will be noticed that the amateurs are for practical purposes as two to one, and now the list may tell its own tale.

## RESULTS OF THE POLLING.

Position in General Election 1877.	No.	Name of Rose.	Class.	Age.	Raiser's Name.	Amateurs.			Total.	Nurse-rymen.			Total.	Grand Total.

Marie Baumann is again the leading Rose, and few of us will grudge her the position which most of us consider she deserves. She is easily A1 tested by first-class votes, as she has sixty-six first-class votes out of the sixty-seven voters. Indeed the position of the Roses is curiously altered if tested by first-class votes only, as shown by this table of the first twenty-four—

Marie Baumann	66
Alfred Colomb	58
Charles Lefebvre	57
A. K. Williams	57
Maréchal Niel	56
La France	55
Baronne de Rothschild	50
Louis V. Houtte	33
Marie Rady	27
Etienne Levet	27
Marquise de Castellane	25
Duke of Edinburgh	22
E. Y. Teas	17
Mad. V. Verdier	17
François Michelon	16
Horace Vernet	15
Catherine Mermet	15
Dr. Andry	11
Capitaine Christy	9
Mad. Gab. Luizet	9
Comtesse de Serenye	9
Senateur de Vaisse	6
Dupuy Jamain	4
Comtesse d'Oxford	2

This is a very rapid falling-off. It is curious that with positions altered the first twelve are still "all there," a statement that could not be made of the second twelve.

In this election no note has been made of similar, or, as Mr. G. Paul well puts it, "too much alike" Roses. I think in future elections this should be done. It has been acted on by a few of the electors; and as connected with this subject I print Rev. C. H. Bulmer's list, the vote in each of the synonyms being given to the first-named.

## REV. C. H. BULMER'S SELECTION.

1. Alfred Colomb	23. Monsieur Noman
2. La France	24. Horace Vernet
3. Marie Baumann	
4. Charles Lefebvre, syn.	25. Lord Macaulay
Marguerite Brassac	26. E. Y. Teas
5. Brune, de Rothschild	27. Capitaine Christy, syn.
6. Etienne Levet	Jules Finger
7. A. K. Williams	28. Duchesse de Vallambrosa
8. Comtesse d'Oxford,	29. Comtesse de Serenye
syn. Hippolyte Jamain.	30. Reynolds Hole, syn.
9. Marquise de Castellane	Sultan of Zanzibar
10. Louis Van Houtte	31. Senateur Vaisse
11. Dupuy Jamain	32. Elie Morel
12. Mdlle. Eugénie Verdier, syn. Marie Finger	33. Annie Laxton
	34. Marquise de Gibot
	35. Fisher Holmes
	36. Madame Victor Verdier
13. Duchess of Bedford	
14. François Michelon	
15. Marie Rady	
16. Dr. Andry	
17. Xavier Olibo	
18. Abel Grand, syns.	
Marguerite de St. Amand, Princess Mary of Cambridge	
19. Duke of Edinburgh	
20. Duc de Wellington	
21. Edouard Morren	
22. Exposition de Brie, syns. Mauriee Bernardin, Ferdinand de Lesseps, Sir Gar-net Wolseley	
	37. Le Havre
	38. Prince Camille de Rohan
	39. Pierre Notting
	40. Mad. Gabriel Luizet
	41. John Hopper
	42. Mrs. Baker
	43. Victor Verdier
	44. Duchesse de Morny
	45. Star of Waltham
	46. Mrs. Laxton
	47. Countess of Rosebery
	48. Earl of Beaconsfield

Tea Roses in this election are omitted as exhibition varieties, not because the best and finest grown are not worthy of a place, but because so few exhibit them, while the comparative merits of Teas and H.P.'s stand on such different ground. Many varieties (H.P.'s) would have higher places, only I have given superior rank to those more generally exhibited, more constant in flowering, and robust in constitution.—C. H. B.

It is curious to note that two of these poll the same number of votes—viz., Eugénie Verdier and Marie Finger; and that the latter, which I for one consider the more robust, is steadily ousting its more aged rival, as may be seen by reference to their relative positions in 1877.

\* All these Roses marked with an asterisk were not tabulated in the Election of 1877; they may have received a few votes, but not more than nine—the lowest number allowed.

The number of Roscs named by all the electors is 223, and of these as many as fifty-eight varieties had only a solitary vote.

The electors to whom we are all indebted for their returned voting papers are as follows—*Amateurs*: Miss Bulmer, Hereford; Miss Penrice, Norwich; the Revs. C. H. Bulmer, Hereford; A. Cheales, Brockham; H. H. D'Ombraim, Ashford; J. M. Fuller, Bexley; W. H. Jackson, Bedford; J. H. Pemberton, Havering-atte-Bower; E. N. Pochin, Leicester; J. P. Tomlinson, Torquay; J. A. Williams, Yardley Wood; G. H. W. Watson, Coventry. Messrs. G. Baker, Reigate; H. B. Biron, Canterbury; James Brown, Heaton Mersey; J. Burrell, Heighington; F. Burnside, Farningham; John Choyce, Atherstone; A. Evans, Marston; G. H. Fewkes, Erdington; F. H. Gale, Hitchin; W. J. Grant, Ledbury; T. Gravely, Cowfold; A. K. Griffith, Edgbaston; P. Grubb, Warminster; T. B. Hall, Rock Ferry; T. B. Haywood, Reigate; J. Hinton, Warminster; G. Humphries, Chippenham; T. Jaxton, Bedford; E. Mawley, Croydon; J. Mayo, Oxford; E. Mitchell, Romford; G. Mount, Canterbury; F. C. Pawle, Reigate; Alfred Slaughter, Steyning; J. Sargant, Reigate; J. Sladden, Evesham; Joseph Smith, Warminster; A. G. Soames, Grimshy; J. Tranter; Upper Assenden; A. J. Waterlow, Reigate; W. H. Wakeley, Rainham; Ernest Wilkins, Sutton, Surrey; E. R. Whitwell, near Darlington. *Nurserymen*: Messrs. Bunyard & Co., Maidstone; B. R. Cant, Colchester; Cooling & Son, Bath; Cranston, Hereford; H. Curtis, Torquay; Davison & Co., Hereford; Dickson & Sons, Chester; Durhin & Co., Englishcombe near Bath; Farren, Cambridge; Francis & Co., Hertford; Frettingham, Beeston near Nottingham; Jefferies & Sons, Cirencester; Keynes & Co., Salisbury; Laing & Co., Forest Hill, Kent; Mack & Son, Catterick Bridge, York; J. Mattock, New Headington, Oxford; Merryweather, Southwell, Notts; Mitchell & Sons, Piltown, Uckfield; G. W. Piper, Uckfield; George Prince, Oxford; W. Rumsey, Waltham Cross; Stephen Treseder, Cardiff.

And now, a word of thanks to all who have helped. It is no formal word. I gratefully acknowledge the help and assistance I have received from both classes of voters, and the many kind letters which have accompanied the returns from persons whom I know only through the medium of our Journal, and whom I am never likely to meet and to give the warm hearty grip of hand which I would now do through its columns. We have a common bond of union in our love for the beautiful flower that gives happiness and hope to so many of the weary, careworn, and suffering in this life, and that adds a zest and pleasure to health and success—one and all, I thank most heartily.—JOSEPH HINTON, Warminster.

#### AUTUMN IN THE KITCHEN GARDEN.

To manage a kitchen garden properly daily attention is needed, and in autumn the work is almost as pressing as in spring. In spring a good supply of vegetables for the summer is the object in view; in autumn attention should be directed in the same way towards the winter supplies. True, not much cultivation can be begun at this time, but everything partly grown can be assisted, and that matured can be preserved.

Cleanliness is a great matter in the kitchen garden in autumn. Many take great interest in making neat beds in spring and dressing and keeping everything clean at that time, but in autumn it is allowed to become a forest of overgrown vegetables and weeds. "It does not matter," some may say, "as the ground will soon be all cleared, and then everything will be right;" and this may seem so, but what prospects to look forward to next spring, and what lots of weeds will appear amongst the young seedlings! Indeed one season's neglect, or what is supposed to be the saving of a few days' labour in hoeing or weeding in autumn, will cause weeks of work in the following season. Many may not be able to find much time to rake and sweep in the kitchen garden in autumn, but hoeing should never be neglected, and they must be busy and short-handed who cannot take a few hours weekly at this operation. Asparagus beds and bush-fruit quarters are always inclined to become weedy, and very dirty they may often be seen in autumn; but all who value a clean easily-kept garden will never allow this to happen. According to our experience it is surprising how easily a garden is kept clean if weeds are never allowed to make any progress.

The present is a good time to note down the merits of any particular vegetable or fruit in the kitchen garden, and any that has not proved satisfactory should be either thrown away or marked for removal afterwards. When any plant is in leaf and fruit it is much easier to form a just estimate of it than trying to remember it at midwinter. Now is also a good time to note the time each vegetable takes to gain maturity after sowing or planting. To crop a kitchen garden after the best system all crops should be

arranged for the following year before those of the preceding season are cleared off the ground. Next year our kitchen garden crops will not be planted at random; they are all allotted now, not only in memory, but also on a label placed on each space. It is surprising the help this is in a busy spring.

Many kinds of summer vegetables will now be over. Peas are mostly past, and Kidney Beans always go with the first frost. There is nothing gained by leaving these dry on the ground; but if they are collected into a heap, mixed with the sweepings of lawns and old soil, manure will be formed by spring good enough for the best of vegetables. In heaps of this kind weeds should never be placed, but decayed leaves of every kind may be used.

Those who delight in good vegetables generally try to save seeds of their favourite sorts, and this can now be seen to; the earlier in autumn the seeds can be ripened and saved the better. In very few cases is seed-saving attended to in a proper way, as few grow crops purposely to gather all the produce for seed. As a rule it is only what becomes too old before it can be used that is gathered for seed, and this is frequently too late in the season to give it justice. Last spring we exercised a little more forethought in this matter, as we sowed rows of several varieties purposely for seed, and we find the yield from these much better.

The experience of the past two or three winters should make us all prepare for another, and well it will repay anyone to make provision before the autumn is too far gone. Superfluous growth should not be allowed to remain, as it all impedes hardy development, and this is much wanted in winter. All kinds of Cabbage, Savoys, &c., which have made enormous side leaves might have most of them removed at once, as they only make the centres more tender, and they will die away in severe weather. Brussels Sprouts, too, generally lose their leaves in winter, and as these protect the sprouts they miss their protection more than they would do if they were taken off in autumn and allowed to grow exposed. The protection of roots will very soon demand attention. It is a bad plan to trust them all under one condition, the best way being to have some in the ground and some out of it, some at hand for use and others as a reserve.

Autumn-planted Cabbage should now be starting into growth freely, but slugs are often as troublesome now as any time in all the year, and the young plants must be carefully watched. It is a great matter to have them well established before the weather becomes severe, as they do not grow much afterwards, and when very small at such a time they are liable to die. Those who wish to be well provided for severe weather in winter will not allow the autumn to pass too far before being well supplied with protectors. Mats and canvas are too expensive to employ for everything in the kitchen garden, but a good rick of dried fern or bracken will be found of the utmost service.—M. M.

#### THE ARRANGEMENT OF CUT FLOWERS.

MR. LUCKHURST's articles are at all times instructive and profitable, but none, we venture to state, could be read with greater interest or profit than his recent contributions on the arrangement of cut flowers. He undoubtedly possesses great taste both in floral decoration and landscape gardening, therefore much weight may be attached to his teachings in this difficult branch of the gardener's profession. He has in the present instance turned his knowledge and experience to good account in explaining those principles which should guide every gardener in the selection and arrangement of cut flowers.

That there is, as a rule, an absence of taste among the majority of gardeners we cannot deny, since we have ample evidence to adduce in support of the truth of this assertion. And why is it so? Simply because in nine-tenths of such cases gardeners do not take the trouble to cultivate taste for artistic gardening. True, everyone is not in possession of this natural gift; but much bad taste might be avoided if gardeners were to strive to acquire an artistic knowledge of this branch of their profession by a systematic course of study. The arrangement of cut flowers tastefully is at all times a beautiful, instructive, and profitable study, and should receive greater attention from gardeners generally than it now does.

Unfortunately, to most gardeners the operation of arranging cut flowers is a mere mechanical one. No attempt whatever is made on their part to arrange the flowers with harmony or taste. So long as a few glaring masses of colour are huddled together in various receptacles, their ideas of taste are accomplished. We have frequently seen examples of very bad taste in this direction on the part of men holding good positions as gardeners, and from whom we should naturally expect totally different results. We will give one instance to support the foregoing remarks. This was the decoration of a dinner table, the colours selected being

of the most glaring type—yellow, scarlet, orange, and a smattering of pink; these were massed together in a large centrepiece, no attempt being made to relieve the mass of colour with a due proportion of greenery, or give it the least appearance of lightness, but having that flat heavy appearance which we need not describe. In the smaller glasses, too, the same style prevailed, masses of yellow being highly conspicuous in the shape of yellow Dahlias and other kindred flowers. This gardener, in response to a question as to the propriety of employing such glaring flowers for table decoration, informed us that there was “nothing like having large masses of yellow and scarlet for decorative purposes; it shows up well.” Here then, we think, was ample need for a knowledge of the rudiments of taste.

Again, with regard to bouquets. How many gardeners are there who can make a really tasteful bouquet? Their numbers are not legion, at least judging from the samples which we meet with at flower shows. Instead of a bouquet distinguished by lightness, absence of crowding in arrangement, soft and pleasing to the eye, we find them crowded and glaring, and altogether unworthy of the name.

Every young gardener who aspires to become a master of his profession should not neglect to cultivate a taste for the arrangement of cut flowers. He will not only find it useful to him in his profession. Depend upon it the services of a man holding this qualification are, and will be, much more valued by his employer, in addition to the greater amount of pleasure which a man derives from a systematic study of the laws of taste.—HORTUS.

#### PLUMS.

THESE have borne abundantly, but have not been similarly productive in all positions. Kirke's had a heavy crop against walls, but failed completely as pyramids and standards. Jefferson was equally fruitful both as wall trees and standards; indeed the latter gave much the finer fruit, probably owing to the standards not being so much affected by the drought as the wall trees. Green Gage has been much finer from trees on a south aspect wall than those of trees on an east aspect, and preceded the latter by ten days. The finest of dessert Plums, July Green Gage, shows a disposition to cast its fruit just before ripening, and, this having been its prevailing characteristic for some years, it has been discarded. Boddaerts Green Gage is very much larger than the old Green Gage, and is very fine; indeed, it is one of the very best, ripening in advance of Green Gage. De Montfort, although but of medium size, is of a fine deep purple colour with good bloom, and is first-rate, coming in by the middle of August. Jefferson invariably bears well, and in early and middle September is what Coe's Golden Drop is at the end of September and early October—indispensable from their surpassing richness. Kirke's has borne abundantly as usual, the fruit being large, roundish oval, deep purple, with splendid bloom, and in quality unsurpassed by any. Belgian Purple is unquestionably a fine Plum when it comes to perfection, but it does not succeed with me on a south aspect, the fruit gumming. Denniston's Superb bears freely as a standard, but if the weather be at all wet when the fruit is approaching ripening it cracks very much. Against a wall it thrives better, but to have Plums ripen perfectly when the season is wet, glass copings would pay the cost almost the first season by saving the crop; indeed, all stone fruits need to have water or rain kept from them after they commence ripening. The very finest of the Gages, Transparent Gage, has not borne freely; in fact it never does, and the least moisture causes the fruit to crack. The trees thrive best when allowed to extend freely, training in plenty of young wood even if the old wood has to be removed to admit it. Purple Gage, one of the richest of Plums, fruits indifferently when closely spurred, but treated similarly to Transparent it is free, the quality being unrivalled by any, Green Gage not excepted. Golden Gage is another kind that does not bear freely when the growth is restricted much, and being very hardy succeeds admirably as a standard or pyramid. Ickworth Impératrice if allowed to hang until it shrivels is richly flavoured, or if gathered when ripe and kept in a light airy fruit room, is, after a time, first-rate, and should be grown where late Plums are desired. It bears abundantly against a wall.

Does anyone know an early Plum named Mother; pale yellow streaked or spotted with red, with a white bloom? It was grown in some gardens over thirty years ago against south walls as an early Plum, and ripened early in August. It was larger than Mirabelle, and of fair quality. Is it synonymous with Drap d'Or? I will refer to the culinary Plums in a future issue.—G. ABBEY.

LILY OF THE VALLEY.—The delicate and fragrant flowers of these plants are always acceptable, and any means should be

adopted to prolong the supply. My plants were started early in the year, were continued under glass in a good light position, and assisted with liquid manure to make a strong growth; then, being placed outdoors in June, the growth was completed early, and the crowns are well developed. Such plants will force readily in gentle bottom heat and with a temperature of 60° to 65°. Those I have now introduced will flower by the middle of November. Imported or home-grown single crowns or clumps started before January need bottom heat to encourage growth before they are exposed to light, which should be done gradually. The bottom heat I find most suitable is about 90°, and top heat 60° to 65° to 75°.—X.

#### THE GLADIOLUS.

THE Gladiolus has not yet attained to the position occupied by many florist flowers, the cultivation of which has been reduced to the certainty of a science. The Gladiolus is still the subject of much diversity of opinion as regards what are essential points in its cultivation. If we visit a garden where a certain flower has been made a speciality we may expect to find the same flower better represented after the lapse of five or ten years. It is altogether different with the Gladiolus. The garden which half a dozen summers back could boast of corms by the hundred or thousand, may be at this date destitute of one representative corm derived from those. We have all our pet systems of cultivation, which all seem to fail under particular conditions. Several years ago, when on a gardening tour, I saw a splendid collection in a baronet's garden under the care of a shrewd gardener, who was a formidable competitor at the local flower show. The great secret in the cultivation of the Gladiolus, according to his opinion, was to be found in the mode of planting the corms. However, Gladioluses have ceased to be a feature in that garden long ago. The various theories regarding the deterioration of the Gladiolus and its dying-out in collections have been from time to time under discussion in this Journal, but so far I am afraid without any certain means of keeping the stock healthy having been broached. I have an amateur friend who buys corms every year, as he does his Hyacinths, and I had a friend in a large garden who worked on the same principle; but it is comparatively few, either gardeners or amateurs, who have money to spare for this purpose.

Since I have made a point of lifting late-flowering plants, which up to the beginning of October had not finished growth, and allowed them to “finish up” under glass, I have found a great improvement. There is no difficulty with early-flowering varieties, as in most seasons they make enormous corms. I have had a corm of Shakespeare, one of four from one root, which was over a foot in circumference; but the late variety, Meyerbeer, I never find complete its growth here without being lifted, and, of course, the corms are very small, though they flower freely. To ascertain the truth with regard to bought roots being superior to home-grown ones, I last spring bought, amongst others, duplicates of some of the newer leading varieties, and found on comparing these with our home-grown corms that in no single instance were the bought roots larger, but, on the contrary, some of ours were three times larger. Fourteen of the purchased corms did not grow, and in every case where they have grown the home plants are stronger.

What I consider the main points to be acted on in order to secure healthy growth are these: Not to plant too early; to have rich well-prepared soil; and, in seasons like those we have experienced of late years, to lift all plants which have not finished growth, and allow them to do so under glass. To explain these points more in detail, I find that nothing is gained in earliness by planting at an early date, when both soil and atmosphere are cold. Here planting is not performed till April, nor later than the middle of the month, though in more backward districts it might be done later than that time. I have always found that the warmer the soil was before planting the stronger and quicker has been the growth of the plant and the longer the spikes of bloom. Early varieties come in at their usual time, and late varieties do not hasten, so that practically there is nothing gained by planting one batch earlier than another. Last year, from corms planted on the same day, we had blooms from the middle of July until the stock was lifted in the middle of October, and from some of these lifted plants we furnished vases with spikes until late in November. But in order that the most may be made of the genial weather from the beginning, a rich soil is an equal necessity. Our ground is trenched two spades in depth, the loose soil is shovelled out, and the bottom of the trench forked-up, manure being worked in at the same time and as the work goes on. The manure we use is half from the cow houses, with the remainder old hotbed manure. Watering has

not been required as part of their routine cultivation for some years until last season, when the beds had one good soaking to carry them through the flowering season and to render the corms plump.

The third point I have noted as essential is lifting the late plants in order to finish growth under glass. Those who have only a small stock may lift each plant and pot it. This can be performed at the bed as the plants are lifted, the ordinary soil of the bed being good enough for this purpose. Place the plants in an airy house and keep them watered until the foliage has ripened. Our plan now is to lift and carry at once to the border of a late Peach house, where they stand with good balls of soil attached until ripened. In a year like the present where the bloom is late—at least thus far north it is—our whole stock will be lifted and ripened under glass. I think such a beautiful plant as the *Gladiolus* is quite worth all the trouble.

In planting we draw a deep drill with a hoe, place some coarse sand under and over the corms, label as planting goes on, and level the soil. In our case 5 inches is about the average depth we plant the corms. When I had only a few dozen corms they were planted in clumps in the flower borders, a hole being made and a couple of shovelfuls of a rich prepared compost placed in and mixed with the soil of the border. Five or six corms were planted in one clump.

The routine summer work consists in hoeing the beds once a fortnight, and when the spikes appear they need support. I have discontinued giving each plant a stake, but insert stout stakes at equal distances in each row; run a strong string along, twisting it round each stake, and to this string the spikes are tied. The stakes need not be more than from 2 to 2½ feet out of the ground. This plan succeeds admirably in our windy garden. I consider it a great improvement, as the flowers can be seen without a lot of sticks appearing at the same time. When a few spikes are wanted for exhibiting it is necessary to shade them from the time the first flower opens. A newspaper supported by three sticks answers the purpose well. If the weather is very hot and the under flowers in any of the spikes likely to wither, cut these spikes and place them in a bottle of water in a cool room or cellar. In dull weather again a spike may be forwarded by placing it in a cool stove. Remove all spikes that have flowered. When the corms are lifted I always allow the soil to remain attached to the roots, and allow all green leaves to turn yellow before removing them. The soil need not be removed from the corms till spring, as it serves to protect the small corms, which cluster in numbers round the base of the large one. I have never made much of these small corms. When planted in the open garden large numbers never grow, and when placed in pots they have often failed because sufficient attention could not be given them. However, they are worth looking after as a means of increasing stock. I think of setting a frame apart for these, allowing them to remain until they have finished their growth. If especially fine spikes are required try a little guano or potassic nitrate strewn on the surface of the bed just as the spikes are showing.—R. P. BROTHERSTON.

#### AMERICAN BLACKBERRIES.

To all who care for preserved Blackberries, either in the form of jelly or jam, I would say, Plant the American varieties. A single row across a quarter of the kitchen garden has afforded bushels of fruit this year, from four to five gallons being picked each time that successive batches have become ripe enough for gathering. A rude fence of poles was made 6 feet high, and the long unpruned growth tied upon it soon grew into one of the most ornamental hedges conceivable.—EDWARD LUCKHURST.

I HAVE forwarded a few bunches of the Parsley-leaved Bramble. Two years ago I had some planted against a rough wall, which is now covered, and the plants loaded with fruit similar to those sent you; they look ornamental, and the fruit is fine for either tarts or jam. We have not had two fine days consecutively for several weeks, so that the flavour is not nearly so good as usual; they were very wet when gathered this morning.—JAMES CARTER, *Keighley*.

[The specimens sent indicate the great productiveness of this Blackberry, and for covering fences and forming arches over walks it is admirably adapted. As thus grown it is highly ornamental, and the fruit is useful.—ED.]

CASSIA CORYMBOSA.—As an autumn-flowering plant I find this very useful, the abundant bright yellow flowers being pleasing at this season. Any plants that have still a number of flowers to

open will do so more freely if placed in a light position in a house a few degrees warmer than an ordinary greenhouse, and thus a prolonged supply of flowers will be obtained. Plants that have flowered should at once be cut back, and may be placed at the warmest part of the greenhouse, where they will soon commence growth, and will continue growing slowly through the winter. If not cut back closely after flowering it soon becomes straggling in growth.—A. G. A.

#### CHRYSOCOMA LINOSYRIS.

GOLDILOCKS is probably known to many of our readers as a really valuable border plant for autumn flowering, but there are still some who have yet to make its acquaintance. To these the figure will convey an idea of the close-branching habit distinguishing the plant, the small linear pointed leaves, and tuft-like flowerheads; but the chief attraction of Goldilocks is, as is quaintly indicated in the popular name, the bright yellow colour of the

Fig. 50.—*Chrysocoma Linosyris*.

very abundant blooms. In Mr. Parker's nursery a week since it was most attractive, long lines forming compact hedges so densely covered with the flowerheads that scarcely any foliage was visible. At a short distance these had a remarkable effect, even on a dull showery day, and when the sun is shining they contrast grandly with the similar lines of Dahlias, Asters, and other plants which render the Tooting Nursery so attractive and interesting at this time of year.

#### SELECT VARIETIES OF FRUIT.

THE following fruits are recommended after a somewhat lengthened experience with them. Doubtless many are omitted which are as good as some of those named, but I have endeavoured to give a succession in each class which I believe may be fairly depended on.

*Dessert Apples*.—Margaret, Juneating, Irish Peach, Devonshire Quarrenden, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, and Dutch Mignonne. *Kitchen Apples*.—Keswick Codlin, Golden Noble, Waltham Abbey Seedling (this requires no sugar), Blenheim Pippin (also a good dessert Apple), Dumclow's Seedling, and Northern Greening.

*Pears for Standards, Walls, Pyramids, or Bushes*.—Doyen d'

d'Été, Jargonelle, Williams' Bon Chrétien, Beurrié d'Amanlis, Fondante d'Automne, Beurrié Hardy, Comte de Lamy, Louise Bonne of Jersey, Marie Louise, and Josephine de Malines. The following varieties will require a wall in most parts of the country and are worth it—Beurrié Superfin, Doyenné du Comice, Thompson's, Van Mons Leon Leclerc, Glou Moigéau, Bergamotte Esperen, Easter Beurrié, and Ne Plus Meuris. Marie Louise is also generally improved by being grown against a wall.

*Plums for Walls and Standards.*—*For Walls*—Early Rivers, Jefferson, Washington, Green Gage, Kirke's, White Magnum Bonum, Golden Drop, and Ickworth Impératrice. *For Standards*—Early Rivers, Washington, Victoria, and Winesour for every use to which the Damson is applied.

*Peaches.*—Early Louise, Hale's Early, Grosse Mignonne, Bellegarde, Barrington, and Walburton Admirable.

*Nectarines.*—Lord Napier, Violette Hâtive, and Rivers' Orange. Order early, and plant if possible not later than the last week in November.—WM. TAYLOR.

### TUBEROUS BEGONIAS.

PROBABLY in no class of plants grown indoors or out has the same improvement been made within the last few years as has been effected with Tuberos Begonias. When they first reached this locality they were then generally grown in heat, and in a few instances in the stove. They were next found to do well in the greenhouse, and ultimately to make most accommodating bedding plants, growing fairly well on hillside or valley, partially shaded, in rich loam, loam and peat, light soil, and even in poor soil. I have seen them under all those circumstances and grown them under some of them, and am therefore justified in not only describing them as accommodating, but the leading flowers of the future. These reflections were partially suggested by seeing some very superior specimens, distinct advances on anything that had hitherto come under my notice, in the collection at W. A. Riall's, Esq., Amer Ville House, near Clonmel. Much depends on having a good strain, and then judgment in hybridising and raising seedlings and growing them freely. Where there are thousands of seedlings raised it is not necessary to name them for bedding purposes: naming them here has been given up. Messrs. Sutton and Sons announced this long since; and I believe Messrs. Laing, Forest Hill, and H. Cannell, Swanley, only name very distinct seedlings. Begonias are the only speciality at Mr. Riall's, and though the houses are crowded there are numbers of seedlings planted out in beds. Many are now blooming without any special care, and are undoubtedly of superior merit. Hundreds have not yet bloomed, but those I noticed were chiefly single. They varied principally from pure white to yellow, rose, crimson, and bright orange, with all the delicate shaded tints between these.

Although the beauty of many was on the wane, at the time of my visit enough remained to show the superiority of the strain and the culture adopted. The size of the flowers exceeded my expectations, and the shape even more so. Except the older drooping kinds the vast majority were round, and many fully 5 inches in diameter. Other peculiar features were serrated or fringed edges to the petals, principally on those fine robust specimens grown upright. And here I may remark that to my mind those with drooping and pendulous flowers were inferior and not so showy as those stout, firm, upright flowers. Another point, too, is that many of the flowers had five petals, making the circular disc more perfect; and this, too, should be perpetuated. Gardeners are as a rule unselfish, and Mr. Maher made no secret of how he grew such fine specimens. The chief facts are a compost of loam, leaf soil, and well-decayed manure; storing the plants in a temperature not much under 50° in winter, allowing them to start naturally, repotting and slight forcing to give them a start in early spring, shifting them into larger-sized pots for large specimens, and after a vigorous start into growth cool treatment throughout afterwards. One of the elements of success I must notice was the constant use of weak guano water during the season of growth.—W. J. M., *Clonmel*.

### SCRAPS ABOUT FRUIT.

I THANK you for publishing my letter last week and receiving my suggestion so favourably. I am certain if cultivators would contribute notes on different varieties of fruits much valuable information would be gathered. Especially would I ask them to notice the failings of any sorts that have not answered their expectations. There are numbers of readers who may not have much to say, but if each would tell the little he knows the aggregate of fragments would amount to a great store of knowledge that ought not to be lost to the host of learners, new with every

year, who are thirsting for information. By a record of facts bearing on fruit-culture as much may be learned in a month as a cultivator could learn from his own experience in five years. In asking for the aid that others can give I make, I trust, no great nor unreasonable request, as I only ask for the atoms.—A COUNTRY SURGEON.

ALTHOUGH I cannot resist "A COUNTRY SURGEON'S" request to send a few "simple items," I fear that what I send will be too "simple" for publication; they are mere jottings of passing experience. The best culinary Apple I find for this season of the year is Ecklinville Seedling. It is of large size, excellent quality, and is a very free bearer even on the Crab stock, which I find is the best stock for it, and on which it seldom fails to have a heavy crop.

ALBERT VICTOR NECTARINE.—This is one of the finest Nectarines grown. The fruit is very large and the quality excellent, but I find the flavour is better after the fruit has been gathered a few days. I think it may be called the best moderately late Nectarine.

THREE GOOD PEARS.—Amateurs with not much wall room at disposal will find the following three Pears all that can be desired for giving a supply, early and late, of superior quality:—Beurrié Superfin, Marie Louise, and Josephine de Malines. The first and last do best on the Quince stock, Marie Louise on the Pear. They are best trained to a south wall, and are worthy of it.

SOME people say, "Plant fruit trees in this generation to benefit the next;" but if you plant good trees of Apples on the Paradise, and Pears on the Quince, you may gather fruit two years after planting.

WORMSLEY PIPPIN APPLE.—Although this Apple is not very largely grown it should be included in all collections on account of its good quality, very free bearing, and good keeping properties. It would be a capital market sort.

BLENHHEIM AND RIBSTON PIPPINS.—Are these planted as largely as formerly? I think not; but are there two better Apples grown considering all their good qualities? It is only in old orchards that good established trees are found, and young ones are not extensively planted—in some orchards not at all. What shall we do when the old trees are worn out? But I suspect we shall then feel the force of the old saying, "We never miss our friends till they are gone."—THE DOCTOR'S FRIEND, *Worcestershire*.

THE DOMINO APPLE.—I see that scraps on fruit are invited; I therefore send one, and may perhaps send others. Although this Apple is grown in the midland counties and much valued there, in Nottinghamshire especially, it does not appear to be generally known, or at least it is absent from many collections in the south. It is considered by those who grow it well to be an improvement on the Keswick Codlin, to which it bears some resemblance, yet it is quite distinct from that old favourite by its darker green fruit, and the tree also appears to be of less pendulous habit. Domino is a heavy bearer, the branches being often wreathed with fruit like ropes of Onions. It is fully as early as the Keswick, and the fruit is not blown off the trees so readily as that of Lord Suffield. Can anyone give the origin of the Domino Apple? and will those who have grown it state their opinions on its merits? I have not grown it, but have seen it frequently and heard it praised.—A TRAVELLER.

THE DYMOND PEACH.—"A COUNTRY SURGEON" wishes for information on fruits. So do I. A gentleman visiting me in September said, on noticing a barren Peach tree, "You should grow the Dymond, it is so hardy." I asked no particulars respecting it, presuming I should find it in the catalogues; but it is not included in any of those before me, neither is it described in my edition of the "Fruit Manual." I wrote to my friend asking if he was correct about the name, or whether his Peach had any other names, also where he obtained the tree. His reply is as follows—"All I know about the Peach is that it grows well, bears regularly, and is good. I cannot say where the tree came from, as the gardener who planted it left me two years ago, and I do not know where he is now or I would write to him; but as you take in a gardening paper, which is more than I do, you ought, I should think, easily get the information you want." I now ask if there is such a Peach as this? if so, what is it like, and where a tree can be obtained? I shall be thankful for any particulars

that can be published on the, to me, invisible "Dymond" Peach.—A HAMPSHIRE CLERGYMAN.

FORMAN'S EXCELSIOR STRAWBERRY.—One can always depend upon what Mr. Henry Boothby says, but the statement in your last week's number that the fruit of this Strawberry is "9 to 11 inches in circumference" surprises me. May I ask how the measurement was taken, whether the fruit is deeply corrugated, and if the line of corrugation was followed to make up the measurement? I have just passed a tape round an ordinary wine bottle, and find that is only 10½ inches in circumference; and if this Strawberry is larger than the diameter of a wine bottle it must be a monster, and suggest more bites than are usually found in Cherries or Strawberries either.—B. L. S.

FRUIT TREES IN HEDGES.—Attention was recently called in the pages of a contemporary to planting fruit trees in hedges as a novel idea worthy of attention. The plan is a very old one in Sussex, especially as regards Damsons, Bullaces, Plums, Cherries, and Apples, all which answer well as standards in this position. This is probably owing chiefly to the local custom of planting hedges on broad raised banks formed of sods or soil thrown up on each hand, so as to make a ditch on each side of the hedge. This method affords the trees an unusual amount of good soil, and at the same time renders them safe from an accumulation of stagnant water. Certainly it has the merit of economy of space to recommend it, and excellent crops of fruit may often be seen upon the trees. I may add that I obtained my entire supply of Damsons from hedge trees this year.—EDWARD LUCKHURST.

WARNER'S KING APPLE.—What an appropriate name! It is, indeed, king of culinary Apples in its season, and its noble fruit surpasses all other in size. The trees, too, are admirably in keeping, with their large stems and sturdy branches, like Keswick Codlin always bearing an annual supply of fruit. This year the crop is not only unusually abundant, but is especially remarkable for the large size of the fruit. "Ah!" said I, when gathering some very fine Tower of Glamis, "King is beaten this year." But when we came to the King it was found that his majesty admirably holds his own.—A KENTISH GROWER.

BELLE DE SEPTEMBRE AND THE CZAR PLUMS.—If the following remarks are of any value to your readers I send them for what they are worth. I planted a small orchard two years ago of standard trees, and among them are a row of The Czar Plum and one of Belle de Septembre. While there has been more or less fruit on all the other varieties, the two I have mentioned have borne such abundant crops that I have been obliged to support the trees. In one instance where my man neglected to do this effectually a tree of The Czar was so heavily laden that one morning I found the stem snapped in the middle. Belle de Septembre bears out its name, for during the whole of last month it has been like a burning bush all aglow.—H. HEYWOOD.

JERSEY GRATIOLI PEAR.—In reply to "A KENTISH CURATE," who inquires as to the origin of this Pear, permit me to inform him and the readers of the Journal that the peculiar alliance of "home and foreign" in its composition arose from a desire to correct erroneous nomenclature. When this Pear was first imported from Jersey to the Horticultural Society it was received under the name of "Gratioli" only; but as this is the name by which the Italians designate the Summer Bon Chrétien, the Chiswick authorities of that day added the specific distinction of Jersey to prevent the confusion which was inevitable between the two fruits if Gratioli had stood alone.—E. J., *Wells, Somerset*.

COX'S POMONA APPLE.—I suspect I am very much like the gardener whom a "A COUNTRY SURGEON" has immortalised in your pages as "THEY-ALL-KNOW-THAT." I have lived too long under the veil of "they all know that," and conscience tells me that there are many things that other people may think worth knowing which I selfishly keep to myself. I feel "A COUNTRY SURGEON'S" reproof, and I hope will profit by it; and not I only, but many who are Journal readers. I would like everybody to know what a splendid Apple Cox's Pomona is. I have five trees, which are perfect pictures as I look at them from the window of the room where I am writing. They are about twelve years old, and form handsome umbrella-shaped trees of about 8 feet high, and each tree carries over a bushel of the gorgeously painted fruit. I would advise everybody who is planting this season

not to forget a tree or two of Cox's Pomona.—W. BALCHIN *Somerford*.

I HAVE several young trees of Cox's Pomona, and am increasing the number. I would not, however, advise its being grown in a small collection in the north. It is a sort which will pay for pinching in early August as a means of increasing its fruitfulness. R. P. B.

BARONNE DE MELLO PEAR.—In response to "COUNTRY SURGEON'S" suggestion in your last week's issue of the Journal, allow me to draw your readers' attention to the merit of this most excellent Pear, which, as far as my observation goes, is but seldom met with. It is one of the most valuable dessert Pears I know of, with a most distinct appearance, being of a light russety brown colour, flesh quite white, flavour of the first order, with a pleasant aroma. It must be grown against a wall. With us it is trained in upright cordons. It never fails to produce a heavy crop, and in favourable seasons the fruit requires thinning severely.—DRUID, *Staffordshire*.

STIRLING CASTLE APPLE.—I have planted Stirling Castle Apple largely, and have budded twenty more stocks with it this autumn. I find it one of the freest bearers, though the fruit does not grow to a large size here. The trees grow very slowly. It is in use here up to the middle and the end of December. Lord Suffield continues into October with us, and is followed by Keswick Codlin and Ecklinville Seedling, all three of which are worthy of growing alongside Stirling Castle, and following them is Manks Codlin—another never-failing sort. The estimate of Stirling Castle as given at page 261 is very near the mark, but I do not know whether this variety or Manks Codlin is "the finest and most useful late autumn and early winter kitchen Apple in cultivation."—R. P. B., *East Lothian*.

OLD GOLDEN PIPPIN.—An orchard tree of this pretty little Apple is bearing abundantly with me this season. For the last two years it has fruited very sparingly, which no doubt has contributed to increasing vigour, as, although an old tree, its foliage is as green and healthy as any in the garden. It is about 15 feet in height, and about five bushels of fruit have just been gathered from it. I never noticed before what may perhaps be termed a monstrosity, a few twin-fruited specimens—that is, two Apples joined together with only one stalk, but two eyes, or calyces, and two ovaries. This variety is said to be excellent for Apple jam, a preserve much relished by some people.

SIBERIAN CRABS.—This is evidently a year for these. They are good for planting in mixed shrubberies or for single specimens on lawns, and when in bloom will vie with the Apple or Pear for beauty. There is a double-blossomed variety that blooms the end of May or first half of June (according to season), very similar in colour to the majority of Apple blossom, but being double it travels well, and is useful as an auxiliary in cut-flower furnishing. It has a good crop of fruit this year as well, but small—not much larger than Hawthorn berries. The scarlet Cherry-fruited kind (*Pyrus cerasifera*) is very ornamental, and is highly prized by some as a preserve. But the most ornamental to my knowledge of all, in my estimation, is a yellow-fruited kind, sent on Saturday with Golden Pippin, with long stalks, hanging on the tree in bunches, and singly. The fruit is as large as the Golden Pippin, but of a very bright yellow. This variety, I think, is not very common, and I should like to know the name of it. I find from an old work a variety mentioned as Knight's Yellow, would it be that?—A. HARDING, *Northamptonshire*.

[The Apple is the Twin or Cluster Golden Pippin, and not the true old Golden Pippin. The Crab is the large yellow-fruited Siberian, and is highly ornamental.—ED.]

#### ADVICE TO YOUNG GARDENERS.

WILL you kindly grant a small space in your valuable Journal that I may offer my thanks to Mr. Pettigrew for his much-valued advice to young gardeners? I am a young gardener, and trust you will print this, my first attempt at writing, to show Mr. Pettigrew our appreciation of his efforts to help and guide us upon our way through life. We young gardeners require an occasional reminder of our failings, and a few words encouraging us to perform our duties faithfully. Such advice as that of Mr. Pettigrew's is both wholesome and stimulating; it stirs us up to renewed efforts, and makes us more determined than ever to continue and not weary in well-doing. We hope some more suc-

cessful veterans in life will see their way to place their experience before the readers of this Journal, that young gardeners may be profited by it, and that they themselves may have the satisfaction of knowing that they have contributed something to the advancement of the rising generation.—R. M.

#### SENECIO PULCHER.

THE woodcut (fig. 51) represents a flowerhead and portion of a leaf of the attractive Groundsel, *Senecio pulcher*, from a plant in Mr. Parker's nursery at Tooting, where this, among many other handsome plants, receives special attention. The care bestowed upon it seems to be well repaid, for though the habit is not quite so compact as might be desirable, the flowerheads are of unusual

Fig. 51.—*Senecio pulcher*.

size and remarkably bright in colour. As regards the designation of the particular tint some varying opinions are expressed, but light magenta seems to express it as nearly as possible. It is a most pleasing shade, and when the other flowers are judiciously and tastefully selected blooms of this *Senecio* may be employed to excellent advantage in many floral arrangements.

The great desideratum, too, in border plants—hardiness, is provided in the one under consideration, and a border can be made really attractive late in summer and early in autumn by freely planting the best forms of Michaelmas Daisies, *Anemone japonica*, and this *Senecio* in clumps.

One other mode of culture—namely, in pots, well deserves the attention of gardeners; for though the plants are rather too tall for the side shelves of greenhouses or conservatories, they are well suited for the central beds, where they produce an excellent effect.

**WINTER-FLOWERING BEGONIAS.**—Where collections of these useful plants are grown they will repay the cultivator for the attention they require. The plants should now be exposed to all

the light possible to induce them to flower strongly. Those that have filled the pots with roots now require liquid manure, and in a cool stove they will afford more enduring flowers for cutting than those flowered in a warmer and closer atmosphere.—W.

#### APPLES AND PEARS.

As the planting season will soon arrive I will give a few hints to those who have not had much experience with hardy fruit trees. I shall only describe those varieties that I have found succeed best either as standard, pyramid, espalier, cordon, or wall trees.

**APPLES.**—To succeed, Apple trees require a good deep loam, but with extra attention they can be grown well in almost any soil. If the ground be poor top-dress with some rich farmyard manure, and if procurable add some good loam when digging. Some gardeners will not dig the soil nearer than 6 or 7 feet from the tree, but I find that where the soil is well loosened the trees produce the finest fruit. Apples, however, much dislike badly drained ground. The difference may be seen in many orchards this season; those on high well-drained soil being far the best, whilst those on low wet ground are denuded of fruit and foliage. Some recommend drainage to be placed under each tree, but except for Peaches or Nectarines I do not see the advantage of this. If the garden is wet it should be drained. The ground ought to be prepared for the trees by deep trenching. No manure will be required unless the soil is very hungry, as that applied by top-dressing is the best. I have some good turfy loam ready to place round the roots, as they spread into that very freely. Procure the trees from a nurseryman who makes a speciality of fruit trees, and then no disappointment will be caused by incorrect naming. Order early, and have the trees as clean as possible.

As regards the best stocks for Apples, I find for orchards it is best to have them grafted on the Crab, either standards or pyramids, and in gardens also where there is room, as the trees last longer in bearing, but do not commence bearing so soon as those grafted on the Paradise. Apples on the latter stock should be planted between the permanent trees, when they will commence bearing the second year after planting. For small gardens the Paradise stock is best suited. Two years after planting the trees on the Crab take them up and replant them, as this will be of great benefit, inducing them to bear much sooner than if left undisturbed.

Planting may be commenced early in November. Be careful not to plant too deeply. Pyramids or bushes may have the soil up to the graft; for standards 2 inches depth of soil above the top roots is sufficient. Cut off all bruised roots, place some of the turfy loam at the bottom, sprinkle some fine soil about the roots, well shake it in, but do not tread it; place some of the roughest on that, and fill up with the ordinary soil. Place some short litter round each tree to protect the roots from frost and drought. Standard trees will require a good stake to prevent them being injured by wind. Some gardeners do not prune at all the first season, but I find it is best to do so early in March.

**Culinary Apples.**—The following are some of the best varieties for succession:—Lord Suffield, fruit very large, abundant bearer and of good quality; succeeds well on the Crab. Ecklinville Seedling, a sure and prolific bearer, fruit of good quality; it is best grown as a pyramid, as the fruit is liable to be blown off standard trees. Emperor Alexander, fruit very large and handsome either on the Paradise or Crab stocks. Cellini, large and handsome, tree a prolific bearer; succeeds admirably as a pyramid. Stirling Castle, a splendid fruit, and tree a great bearer. Gloria Mundi or Belle Dubois, fruit large on the Paradise stock. Warner's King, fruit very large; it is a prolific pyramid or orchard tree on the Crab or Paradise stock. Gravenstein, good for kitchen or dessert; espalier. Mère de Ménage, fruit large and handsome; makes a good orchard tree. Cox's Pomona, fruit very handsome and prolific; a fine orchard tree. Beauty of Kent, well suited for orchards. Blenheim Orange, too well known to need description. Dumelow's Seedling, a prolific bearer, fruit of good quality; a useful late orchard tree. Bedfordshire Foundling, large; good orchard tree. Alfriston, very large on the Paradise, and prolific.

**Dessert Apples.**—These may be grown as espaliers, pyramids, and horizontal cordons. They all succeed best on the Paradise stock, although pyramids may be grown on the Crab, but the fruit on the Paradise is much finer and of better colour. The following I have found a good selection to give a succession:—Irish Peach, medium size; fruit of good flavour. Kerry Pippin, fruit small but of excellent flavour. Cox's Orange Pippin, very prolific; considered by some the best Apple in cultivation. Ribston Pippin, well known. King of the Pippins, fruit handsome; a prolific orchard tree. Ashmead's Kernel, good flavour. Brownlee's Russet; Scarlet Nonpareil, fine late Apple. Duke of Devon-

shire, prolific; late. Northern Spy, fruit of pleasant flavour; succeeds best on the Paradise stock. Adams' Pearmain, fruit of good flavour and handsome. Sturmer Pippin, a useful late Apple; a prolific bearer. Court-Pendu-Plat, a late but sure bearer; it makes a fine pyramid. Melon Apple, splendid flavour; succeeds best trained to a wall. The notes on Pears must form another chapter.—FRUIT-GROWER.

MR. T. LAXTON writes to us as follows on a WHITE BEAUTY OF HEBRON POTATO—"This variety, like others of the coloured American sorts, seems prone to give off white tubers—the origin, doubtless, of some others of the transatlantic varieties which have reached us recently. The freak has occurred with Beauty of Hebron both in the Experimental Garden and also in the hands of a neighbour. In all other respects except colour White Beauty of Hebron seems a parallel of its parent, and must be a decided acquisition, as the great objection hitherto to the old variety and to others of the 'Rose' type is the colour, which depreciates their value for market purposes."

— A KENTISH gardener states that he recently observed in Maidstone Cemetery a LARGE BED OF TUBEROUS BEGONIAS. The bed contained about three hundred plants in fine condition, the flowers being of various shades of colour, all the plants flowering profusely, proving their usefulness for bedding-out, especially in the southern counties.

— "SCIENTIA" writes, "Amongst a number of varieties of CEANOTHUS planted out in a bed at Chiswick, one named GLOIRE DE VAITE (Lemoine, 1879), was most conspicuous. It is a good grower and profuse flowerer, having large trusses of a light blue colour. It is admirably adapted for walls or planting in beds as practised at Chiswick. A large bed filled with this variety would be very striking at this season of the year."

— A NORTHERN correspondent says, "POLYGONUM BRUNONIS is one of the prettiest plants flowering at the present time. It is well suited for the rockery, being very showy with its spike of pink or rose-coloured flowers, which rise about 9 inches high. It is a plant that should have a position on all rockeries, as they are comparatively dull at this season."

— "LANCASTRIAN" finds VERONICA LONGIFOLIA SUBSESSILE one of the best of the genus, deserving a place amongst the most select herbaceous plants. It produces a bold well-filled spike of blue flowers about 2 feet in length during August and September.

— "L. D. W." observes "that the OLD WHITE MULE PINK is not only valuable for the borders but for growing in pots. Gardeners and amateurs would find it useful, and it is surprising it is not more generally employed for indoor decorative purposes."

— "W. B." considers "that EUPATORIUM AGERATOIDES is a grand hardy plant too seldom seen in collections. It grows from 3 to 4 feet high, and is suitable for the back row of a border or for planting amongst shrubs. It is doubly welcome, as it is flowering profusely now, and a few plants when well established would afford abundance of flowers for cutting."

— LET me caution your readers against a kind of Beet which I was tempted to try from the favourable report I received of it. It is called by the French BETTERAVE CRAPAUDINE, and has recently been introduced to this country. I have a long row of it, and its foliage and roots stand quite 2 feet out of the ground.

Were it not for the colour it would pass for a coarse growth of Mangold Wurtzel. Instead of the small delicate top which characterises a fine stock of Beet, this has six or seven tops all larger than a single one ought to be. The root is large and coarse, and has as many prongs as tops. Such is my experience of Betterave crapaudine.—J. JACKSON,

— ONE of the finest STANDARD ROSES I have ever seen is one in the garden of Henry Webb, Esq., Redstone Manor House, Redhill. Its stem is 3 inches in diameter, and its branches, some of which droop to the ground while others grow upwards from a thicket of luxuriant growth, 7 to 8 feet high. The tree when in bloom is a mass of colour interspersed with a plentiful accompaniment of greenery. What is the cause of this extraordinary growth? Is it the variety which thus affects the stock? or is the stock some particular form of the wild Rose, which expands its growth more freely than the Dog Rose usually does? This is a subject I should like much to have discussed, as it is an important one to all rosarians.—H.

— THE DAHLIA GROUND AT SWANLEY has lately been the most striking feature, the plants being grown by the acre and include all sections—Show, Fancy, Bouquet, and single, the most approved varieties of each being represented. The blooms of the larger kinds are very fine, and of the smaller most profuse. The richest of the singles is Paragon, except, perhaps, some seedlings, among which are several new colours. The old single white variety Alba is strikingly attractive, and should be grown in every garden. Whether there are more distinct single white Dahlias is perhaps a moot question, but none at present, it may safely be said, surpasses the one in question. The dwarf single scarlet and dwarf single yellows are brilliant by their numerous flowers, but for richness of effect all—both singles and doubles—are eclipsed by half a dozen plants of an unnamed variety that for decorative purposes will probably find its way into all gardens and pleasure grounds where Dahlias are grown. The flowers are small, double, but not formal and symmetrical, brilliant scarlet, and produced so freely that each plant is like a bouquet. Such a rich glow of colour is seldom seen as these plants afford, and Mr. Cannell must give the variety a good name and propagate it largely.

— THE appearance of the masses of flowers in the Pansy ground in the same establishment shows that as a TRIO OF BEDDING VIOLAS the following are not surpassed for continuity of flowering—Blue Bell, Yellow Boy, and Vestal, the last-named being white. Some newer varieties may possibly excel them, but not yet grown in sufficient quantity to judge of their effect in the same manner as those named, which should be obtained by those who do not possess them, and propagated by those who do for lines and masses, the present being the best time for inserting slips and cuttings. They strike readily under handlights, or in gritty soil in an open border, inserting them deeply. The old Magpie Pansy is flowering freely now; it is a quaint and distinct variety, the flowers being admirably adapted for vase decoration.

— OF CHRYSANTHEMUMS there will be a great display shortly, a plant of each of the 149 varieties being grown for testing the truthfulness of the stock. Young plants of these are grown in small pots, the stock of each variety being plunged in separate beds, having 2 or 3 feet of space between them, with the object of keeping them distinct and reducing mistakes to a minimum. The beds are arranged in the order of the catalogue, and the great extent of space the plants occupy afford practical testimony of the popularity of this fine autumn flower.

— MANY other things are noteworthy in the nursery, both under glass and out of doors, but only the PRIMULAS can be referred to. These include all the strains in cultivation, and so numerous are the plants that they occupy a length of 800 feet

of staging 4 feet wide. They are in the best of health, and are just commencing to flower. Eventually the display will be remarkable both by its extent and the great variety of colours that must necessarily be represented.

— THE following GARDENING APPOINTMENTS have been recently made:—Mr. Wm. Cruickshank, late gardener to R. E. Warburton, Esq., Arley Hall, Northwich, has been appointed gardener to the Hon. Jas. Saumarez, Saumarez Park, Guernsey; Mr. Jas. Fletcher, late foreman at Frogmore, succeeds Mr. Cavanagh as gardener to J. E. Taylor, Esq., Coppins, Iver; and Mr. Alfred Waters, late foreman at Norris Green, Liverpool, succeeds Mr. McKellar as gardener to C. Magniac, Esq., M.P., Colworth Hall, Sharnbrook, Beds.

— WE agree with the *Journal of Forestry* that the GENERAL CULTIVATION OF FRUIT TREES has never been practised by the rural population in this country with the same intelligence and industry which we see so common in fruit-growing countries on the continent, where neither soil nor climate are in any way superior to our own. Throughout most of central Europe fruit trees are planted by the farmers and cottagers with judicious care and discrimination in their fields and gardens. In an ordinary season they gather abundance of luscious fruit—not only enough to supply their domestic wants, but also to send large quantities to market, from which they realise an acceptable addition to their income. This is all done without losing a square yard of ground that could be profitably devoted to any other food crop. The trees are planted along roadsides, on the margins of the fields, in the hedgerows, and in other odd places and corners, where they occupy ground that cannot be conveniently or profitably cultivated.

— “P. T.” writes, “PYRETHRUM ULIGINOSUM is a telling object in the flower garden at this season. Perhaps it is better suited for the shrubbery, as its tall and rather coarse habit is more adapted for such a position. The flowers are large, very showy, and of pure whiteness. It is what some people would call an ‘effective’ plant.”

— THE Jamaica Government are offering great advantages to those who are inclined to embark in the CULTIVATION OF CINCHONA. Suitable land is offered at a very low rate, and it seems to us that, with proper methods and selection of the right kind of plants, there is room in Jamaica for a limited number of plantations of this kind. In connection with this, Mr. D. Morris has issued a valuable series of “Hints and Suggestions for Raising Cinchona Plants from Seeds, and Establishing Cinchona Plantations.”—(*Nature*.)

— A RECENT visitor to SANDLEA HOUSE, DATCHET, observes that “There are few small gardens more charmingly situated, as it is close to historic Windsor, a portion of the home park with its magnificent trees facing it, and the Thames running by the side of the well-kept and tastefully laid-out pleasure grounds. It is in the possession of Mrs. Fowler, and was laid out some years since by Mr. George Eyles. The gardens and houses are kept in admirable condition under the superintendence of Mr. Thomas Fraser, the head gardener, who has been for some years in his present position with credit to himself and his employer.” The same correspondent remarks that “Carpet bedding on the WINDSOR CASTLE SLOPES is very beautiful, and well worth the attention even of those who decry this system of gardening.”

— FROM every part of the country we hear of the abundance of the CROP OF WILD FRUITS. Crab Apples appear to be a heavier crop than has been seen for many years, and Sloes are fully as abundant. The Mountain Ash is loaded with “Rowans,” and the thrifty housewife is rejoicing at the prospect of the dozens of wine she can make from the abundant supply of Elder berries. The Yew is thickly sprinkled with its juicy scarlet berries, on

which thrushes and blackbirds, besides smaller fry, are enjoying a rare feast. When these fail them Haws and Holly berries, which are enormous crops, will keep up the supply of food for the woodland songsters till the return of spring. The store of such food has not been so large for a good many years, but we hope that the abundance of these wild fruits does not presage the approach of another severe winter, in accordance with the popular belief.—(*Journal of Forestry*.)

— SPECIAL articles on popular subjects that appear from time to time in the daily papers usually bear the impress of ability on the part of the contributors and sound judgment on the part of the editors; but we are unable to congratulate either the editor of the *Standard* or his contributor on an article on TREES NEAR TOWNS that found its way into print on the 28th ult. That the writer has little knowledge of the subject on which he was permitted to instruct others is apparent and perhaps excusable; but he might have taken the trouble to have referred to some books before preparing his wordy yet empty and inaccurate lecture. He refers to Araucarias as “Monkey-puzzlers,” but we have not to read far before finding that there are man-puzzling trees as well. He falls very foul of the Plane tree, because, like some others, it is not English “in any sense,” although it has been with us for more than three centuries; and if trees “of its class” must be had we are to plant Sycamores, “as they have in a measure become acclimatised.” In what “measure” a native tree has become acclimatised it would be interesting to know, but it is amusing to be told it is in the same “class” as the Plane. In his zeal for English and his contempt for exotic trees the specialist goes into ecstasies over the Horse Chestnut among others, in blissful ignorance that, like the Plane, it can hardly be English “in any sense,” seeing that it is an exotic of much more recent introduction than the Plane. In one place we are told if a young Oak springs up in a garden it is cut off at once, as “it would spoil the Laurels,” and in another place “the cold-blooded Laurels kill everything else.” We ought to have had Oaks, Elms, and Beeches on the Thames Embankment, then rooks would have come to the Oaks and woodpeckers to the Beeches, the “sound of one of these birds being worth ten thousand Laurels;” and if a Hawthorn is planted “almost every bird will come to it, from the wood pigeon down to the wren,” and “Ash attracts turtle doves,” and so on with similar nonsense. The Lime, it is stated, will run a race with any tree; but he forgets one, and an English tree, that will leave it far behind. But, seriously, our author does not appear to know that the trees he urges for towns have been tried and failed. Does he not know of thousands of Elms near London that are mutilated because of the liability of the tree to cast its limbs in storm and calm? This is a grand but dangerous tree, and people are warned not to go under the majestic specimens at Windsor. He seems to forget, too, that before the woodpecker comes to the Beeches they must be old and decayed; and before huge Oaks and Beeches are flourishing on the Thames Embankment the celebrated New Zealander will be pointing out the site once occupied by the great metropolis, and the weary pedestrian in the post-railway period will be resting his weary limbs under the Wayfaring Tree, which we learn for the first time is the Barberry! Our author then soars amongst the stars and plays with Sirius, Arcturus, and the Pleiades, and there we leave him to find his level; but in the meantime, if our important contemporary desires to maintain its reputation as a standard authority on the subjects on which it treats, its specialists must show that they have at least a fair amount of practical knowledge of those subjects on which they are encouraged to write. Perhaps, however, the article was only intended for a burlesque!

A SELECTION OF APPLES AND PEARS.—The following varieties, ripening or being fit for use in the order named, are suitable for

a small garden :— Of culinary Apples Carlisle Codlin, Cellini, Stirling Castle, Blenheim Pippin, Dumelow's Seedling, and Hanwell Souring ; and of dessert Apples Devonshire Quarrenden, King of the Pippins, Blenheim Orange, Cox's Orange Pippin, Margil, and Golden Reinette. Good and profitable Pears are Jargonelle, Williams' Bon Chrétien, Beurré Superfin. Louise Bonne of Jersey, Marie Louise, Pitmaston Duchess, Beurré Diel, Haeon's Incomparable, Beurré d'Aremberg, Glou Morceau, Bergamotte Esperen, and Beurré Rance. All of these, with the exception of Jargonelle and Glou Morceau, will succeed as pyramids or espaliers ; but all are improved by being trained to walls.— W. IGGULDEN, *Wiltshire*.

### HONG KONG.

(Continued from page 270.)

THE true nature of the Chinaman is quite a mystery to the European. Probably when the latter fancies he knows the China-

man best he is still only acquainted with the outside of him. The true reason of this is no doubt due to the fact that the Chinaman has the religious, intellectual, and æsthetic part of his nature developed so slightly as not to afford a sufficient opportunity to the European of meeting him on some of the many common topics which neutralise the banefully narrowing and self-seeking effects of a spirit of unmitigated trading. Chinese religion is yet sunk in a superstition dark as that of the European middle ages. Chinese science, like a puppy, has hardly emerged from the period of its post-natal blindness. Chinese history of the world is the history of China, while Chinese art has not yet mastered the idea of perspective. The only common standing ground in the æsthetic province which the Chinese have with Europeans is in music (*sic*). Helmholtz has identified the Scotch musical scale with that of the Chinese ; but before I read this fact I was struck with the remarkable similarity of character in the airs played on the tibia : Chinese religious processions with those rendered on the bagpipes in Scotland. They are both high-pitched, harsh, imperfectly phrased, and set in the minor key. As a proof of this I may state

Fig. 52.—BROAD WALK IN THE GARDENS AT HONG KONG.

that while I was in Hong Kong a Scotchman in the place went about during several evenings "skirling" on his pipes, and the Chinese, who listen with the most perfect apathy to music on the piano and organ, were delighted beyond measure. The only subject on which the Chinaman brings all his faculties to bear, and in which he consequently succeeds, is trade and money-grubbing. He will resort to all sorts of devices, undergo any privations, submit to every kind of rebuff with what one might almost call an insolence of meekness, exhibit the most inexhaustible patience, and toil as unweariedly as a piece of mechanism to amass money. He undercuts everybody everywhere, whether as a coolie in the guano islands of Peru and the sugar plantations of Queensland, as a domestic servant and petty artisan in San Francisco, or as a wholesale or retail dealer in the Chinese treaty ports and the Straits. He is slowly but surely ousting the European merchants, as he now deals directly with the European manufactures instead

of, as formerly, invoking their assistance to procure the goods he requires ; and when he has obtained these at ordinary trade or wholesale prices, he can then retail them at a cheaper rate than a European tradesman, as his home is on the spot, and he has no desire to make a fortune speedily in order that he may be able to hurry away to a more congenial clime where he may end his days. There is a wonderful difference in appearance between the paunchy, oily, monkish-looking, well-to-do Chinese merchant or shop-keeper, and the poor, wiry, worn-looking chair coolie or working coolie. But they are alike in this particular, that they will do a job for a small sum rather than lose the chance of making money altogether ; and when they have the money they take care by very frugal living that it shall not be all consumed in self-indulgence and on thoughtless enjoyment of the present. In organising trade the Chinaman is unexcelled ; but unless something else is added unto this, unless he learns to open his mind

with the gradual extension of his operations, he will become a horrible incubus to other nations which in their desperation they will at all hazards throw off.

In a previous communication I made reference to the gardens of Hong Kong, and sent a view showing their attractiveness in connection with the surrounding scenery. As representing the diversified character of those gardens I now send a view of the Broad Walk, which with its terraces, trees, and magnificent background is extremely imposing, and shows that when Art and Nature are appropriately blended how satisfactory are the effects produced. These gardens are a credit to those who designed them, and they are a pleasant adjunct of the busy town. I enclose also an account of the botany of Hong Kong, which will form a future article.—A WANDERER.

(To be continued.)

#### CURRENTS.

FEW fruits are more useful or more generally cultivated than the Currant. It is scarcely possible to find a garden of any moderate size without a few Currant bushes. In many instances they are looked upon as capable of growing anywhere, and certainly they are so hardy and vigorous that it is difficult to prevent them producing fruit. We frequently see them planted under the spreading branches of trees, and, even in that position they produce fruit. In these days, however, most of us endeavour to produce large fine fruit, and to accomplish that end we must go the proper way to work. Currants flourish in a good rich loam, with plenty of room to allow a proper circulation of air about them and sun to ripen their fruit. Red Currants should not be pruned too hard. Some of my bushes suffered from excessive pruning two years in succession, and did not produce above half the quantity of fruit of others more tenderly cut. We gathered splendid Red Currants as late as the 21st September, the bushes having been protected by tiffany as soon as the fruit became red. Black Currant bushes grow very vigorously here, and annually throw up strong young shoots from the roots. In September we cut out all the old wood, and leave the young wood only for the next year. When I first requested my man to do this he looked astonished, and told me I should have no fruit the following year. He has, however, quite altered his opinion, and only last week I saw him very busy clearing out the old wood. My Currants never fail to produce a large crop of fine fruit. They have a dressing of leaf soil every spring.—W. G., *Elmdale, Surrey*.

#### NOTES ON ROSES.

A WORSE autumnal bloom I do not remember, and yet the past few fine days have brought from their hiding places dear friends in all their old fulness, freshness, and brightness. To-day, the last of September, I have gathered really grand blooms of Marie Baumann, Alfred Colomb, Ferdinand de Lesseps, Louis Doré, La France, &c., and, strange to say, the only really good and typical representative I have seen of H.P. Jules Finger. I have been sorely disappointed up to now with this Rose, but three blooms cut this morning from one maiden standard have quite satisfied me. Let me recommend as very good autumnals Olga Marix and Acidalie. Both are most useful as to colour, and most accommodating as to freedom of blooming. Ferdinand de Lesseps is usually bracketed with Exposition de Brie and Maurice Bernardin, but with me is more satisfactory in every respect than the two latter. It is one of the most useful dark Roses we have, and thrives well on the Manetti. Is Madame Hippolyte Jamain a H.P.? I may be unfortunate, but have never yet seen on my few plants of this variety a second bloom. How different is her Tea sister in this respect!

Writing of Teas, I find Madame Lambard and Innocente Pirola both excellent in quality and quantity of bloom at this season of the year. Madame Angele Jacquier I have not sufficiently tried to speak positively as to her merits apart from her prettiness and distinctness.

How many of your readers are able to induce Reine du Portugal to open? I can see in my mind's eye now the glorious treble of this Tea Rose as shown by Messrs. Robert Mack & Son at the Sutton Coldfield Rose Show this year. I forgot to ask this firm's representative whether the blooms were shown under glass or in the open. Certainly their box of eight trebles at this Show was the finest stand of Teas exhibited during the present season.

Going back to H.P.'s, will your correspondents give me their ideas as to Paul Jamain? With me it is another Charles Lefebvre; perhaps a trifle "rounder" in shape, but not sufficiently distinct for me to keep.

Duchess of Bedford is, I think, the best novelty since A. K.

Williams. It is a grand Rose, too, for pots when grown in cold frame. I am glad to find that sport of our old friend Madame C. Joigneaux keeps to its first character. I refer to William Warden. The colour is quite charming, and as it makes less wood than "Madame" so it gives many more flowers; at least, this I find to be the case at Yardley Wood.—J. A. W.

#### GRAPES AT THE EDINBURGH FRUIT SHOW.

YOUR reporter, in his account of the Edinburgh Show in September, states, in regard to an exhibit of Grapes sent by me, that "apart from being badly packed and considerably rubbed they were not in good condition." In this description your correspondent has not given you a faithful account of what he saw. It is not true that the fruit was not in good condition. In view of what has been written lately the fruit was sent as examples that had set in a low temperature, all particulars of which were given on the card attached, besides particulars that were furnished to the Secretary and those who set them up for me, fully explaining that though mostly well coloured they were not quite ripe, that not being considered essential, the object being to show that the berries had set and swelled well. Had the reporter understood his duty and wished to perform it in a fair and impartial manner he could have given his opinion on the merits of the case, and stated whether the berries were set imperfectly or otherwise, &c.; but he only indulges in vague insinuations as to the quality of the fruit, without having the courage to say what was amiss with it. I was too unwell at the time either to pack the Grapes myself or go with them, and they were packed and sent to the Secretary in the ordinary way. That they were rubbed in the bloom I am aware, but not in a way to interfere with the purpose of the exhibit, which I trusted was sufficiently understood by gardeners, although I was well aware at the time that I was sending them "into the camp of the Philistines."

I have not been able to write you on the subject till now; and just to show how far your reporter's estimate of the Grapes I sent to the Show is just and true, I beg herewith to send you samples of the several kinds from the same Vines, and I am content to let you pronounce a verdict upon them as to the way the berries have set and their condition generally. They are not our largest bunches, nor are they so fine as those sent to the Show, but they are fair examples of crops in more than 200 feet of vineries here. They are, of course, a little riper than those at Edinburgh, but not better coloured, and are not yet perhaps quite ripe in all cases as regards flavour. As to gardeners not being "impressed with the economy of the system," I have only to state that if the letters which I have received from both gentlemen and their gardeners desirous of adopting the said system through "having seen" our Grapes at the Show be any evidence of the impression produced, I would be well justified in saying your reporter had failed to catch the drift of opinion regarding them. I enclose privately an example of the communications I have had in the shape of a letter from a gentleman in Scotland who, although his Vines "have borne very good Grapes" hitherto, is induced to adopt my practice through "having seen my exhibit of Grapes grown in cool night temperatures," and asks for instructions how to proceed.

It is a curious commentary on the reporter's verdict that a man who already grows good Grapes should be induced to adopt another plan which, according to your reporter, produces Grapes that are "not in good condition." Another letter, from a Scotch gentleman at a certain castle (whose name I give you), states that he planted his Vines and treated them according to the advice of one of the Judges at the late Edinburgh Show, giving his Muscats a night temperature of 75° min. when in flower, with the result that he has never had a satisfactory crop, the fruit neither setting well nor finishing satisfactorily, while the foliage after the setting period has been always severely injured by red spider, adding that neither he nor his gardener can account for their failure unless it be the high temperature, as nothing else they can discover appears to be amiss with the Vines, which generally start well and do well till the high-temperature stage is reached. This passage describes so accurately the results of the excessively high temperature system that I am induced to reproduce it here.—J. SIMPSON, *Wortley, Sheffield*.

P.S.—In addition to what is stated above I may mention that two bunches of Alnwick Seedling were awarded the first prize for black Grapes at the Handsworth (Sheffield) Show a few days before the Edinburgh Exhibition, and they were from the same Vine.—J. S.

[As "examples of setting" the bunches sent are highly satisfactory; indeed they are quite full, and all the berries are good, some being very fine, especially those of Gros Guillaume and Alnwick

Seedling; and although the last-named Grape does not always set freely, the bunch before us is perfect in that respect. The long tapering bunch of Museat is similarly full and has swelled every berry to the point; and the Black Hamburgh, Lady Downe's, and Alicante are also good and full bunches. The Grapes are far above the average as grown for home use, but all of them are not perfectly ripe; and as they were necessarily less ripe at Edinburgh it is not surprising that they were not criticised exclusively as "examples of setting," but their general appearance was taken into account. Our reporter may, of course, have "failed to catch the drift of opinion" respecting them; but we have to say that he is perfectly competent to judge Grapes, and is in the habit of sending produce to his employer's table at least equal to the examples now before us, admirably as the bunches are set, and good and regular as are the berries.—ED.]

#### LINSEED OIL v. PEAR SCALE.

ON opening the *Journal of Horticulture* this morning I was surprised to see an old letter of mine again appearing in print. The two upright Pear trees alluded to in my letter were not injured in the slightest degree by the painting of boiled linseed oil which my gardener gave them, but it was "all over" with the scale, and the trees were not infested with that pest again.

Three years ago an upright-trained Apple tree was painted with this oil: care, however, was taken not to touch the flower buds or the leading shoots of the year. This tree is now in good healthy fruit-bearing condition, and is quite free from scale. My gardener has also painted a Peach tree. The last year's growth and the spurs were not painted, and the result was most satisfactory. Care must be taken to obtain pure linseed oil, as much inferior oil is now sold under the name of boiled linseed oil.

I feel I am so much indebted to Mr. Wm. Taylor for his admirable communications to our Journal, that I shall be most willing to answer any further questions he may think proper to ask on this subject.—C. M.

[A letter will be published next week from a gardener of great experience, who has found linseed oil dangerous, and he does not advise its use as an insecticide. If in the meantime anyone applies the oil to fruit trees it is important that the above injunction be borne in mind, and the oil be obtained pure.—ED.]

#### PLANTING STRAWBERRIES ON LIGHT SOIL.

THE soil in the garden under my charge is one of the poorest anyone can have to deal with for Strawberry-growing, the surface in some parts being little more than sand about the depth of the spade, and overlying red sandstone rock. But though the soil is unsuitable my employers expect good Strawberries, and what they require it is only right that we should strive our best to provide. I tried various plans and placed plants out at various times and ways before I tried my present method, which has answered very well so far, for this year the crop was very heavy and fine. Having selected the ground as early in the winter as convenient I dig it as deeply as I can without bringing up the sand, and give a good dressing of cow manure (this year I have given also a dressing of marl), mixing the manure and soil well together. In March I spread over the surface  $1\frac{1}{2}$  inch in depth a dressing of wood ashes, soot, and decayed manure from an old hotbed (manure and leaves). This I fork very lightly in and tread the ground firm. Drills are then drawn a foot apart and Onion seed is sown. Throughout the season the bed is hoed and weeded. About the end of July, as early as rooted runners can be obtained, I take the best and plant them in every alternate space between the rows of Onions 18 inches apart. Showery weather is chosen for the planting time, and the afternoon is preferred. I give a thorough supply of water, and more is seldom required afterwards, as the Onion tops shade the plants a little. When the plants are growing freely and the Onion tops are in the way, we turn these over each way from the Strawberries; this also acts beneficially to the Onions, checking the formation of thick necks. As soon as the Onions are ripe they are removed and the ground is hoed and raked. The Strawberry plants make fine crowns and produce a very good crop of fruit the first year, the fruit being fine, but the crop is not quite so heavy as in the following year. As soon as the fruit is gathered the second year I plant Broccoli between the rows, and when I have obtained what Strawberry plants are required I rake the bed clean. The Broccoli make very good firm growth in the hard ground.

A surface-dressing of half-decayed littery manure is given in April, which the rain washes clean by the time the fruit is ripe, and we are not troubled by thunder showers splashing the soil on

the fruit. In this way I prepare the ground for three crops at one time (Onions, Strawberries, and Broccoli), have a solid and fairly rich ground for planting, and available to plant early, at a minimum expense for labour.—SPADE.

#### AN AMATEUR'S GARDEN.

HAVING had the pleasure of visiting the garden of a well-known amateur exhibitor—viz., that of Mr. Richard Mann, Howden Dyke, Howden, East Yorkshire, I feel confident that a brief description of what I saw and learnt will interest some of the readers of this Journal. Mr. Mann is a chemical manure maker, and devotes the whole of his leisure to the improvement and cultivation of florists' flowers. I was shown a fine display of African Marigolds, a strain entirely of his own production, and the result of nearly twenty years' careful cultivation. I was told that they have carried off first honours wherever exhibited, including the first prize at the "International" Show of the present year at Manchester. There is a splendid collection of Hollyhocks, many of them great improvements on the older and still existing varieties. For these a plot of land is set apart and specially made up of a strong mixture of clay and sand. Carnations and Picotees seem to be a speciality, and above eight hundred plants in full bloom formed a display I shall not easily forget. Grown on clay soil they seem to flourish, and produce rich colours. Mr. Mann has taken prizes for them at all the chief Yorkshire shows for many years. Phloxes are well grown, and the collection comprises about fifty varieties, including the following, which are very fine. Auguste Rivière, Bellini, Clara, Cameron, Deliverance, Le Lion, Lothair, Madame Domage, Mrs. Laing, Mrs. Grundy, and Roi des Roses. A magnificent bed of Show and Fancy Pansies attracted my notice, the most conspicuous of which were, Rob, Cowan, Thalia, Buttereup, Miss Darling, Marjory, Mrs. Birkmire, Mrs. E. H. Wood, Robt. Burns, De Foe, Dr. Livingstone, Dean Ramsay, John Rowatt, Mrs. Horsburgh, Rev. D. Taylor, Janet Lees, and George Fisher.

I should take up too much of your valuable space were I to refer at length to the beds of Asters, Zinnias, Dahlias, and Roses; but I may remark that whatever Mr. Mann takes in hand he devotes that care and persevering energy to it that has marked his career of twenty-five years as a successful amateur exhibitor. He told me that he had taken above one thousand prizes since 1875 (excluding the present year), for flowers alone.

I am a lover of flowers, and take a great interest in their cultivation, and as a constant reader of your valuable paper I should like to see other notes on "amateurs' " gardens.—HOMO.

#### THE USE OF FIRE HEAT FOR GRAPES.

THE subject of night temperatures for Grapes has been much discussed within the last few years, and since the re-opening of the subject through Mr. Simpson's staging examples grown under his system the weary round is to be trod once more—at least, so it seems. Still the subject is an important one, and if it could be unprejudicially discussed might be not altogether unprofitable. In order to do so, facts must be dealt with and considered and mere assumption left out. For instance, it does harm and not good to assume, as appears to have been too generally done, from what has appeared in the *Scotsman*, as elsewhere, that every bunch of Grapes that gained prizes at Edinburgh were grown on the high-night temperature system. To do so is begging the question entirely, when, for all the public knows, they may have been grown under the cool system. Indeed, we know that some of the very best were. This being the fact, what reliance are we to put on the judgment of one who selects not very good samples of Grapes which are stated to have been grown under the low-night temperature system and compares them with others grown under the same system, but which are very fine, and takes the good samples as proof that high-night temperatures are best? Simply this, such hasty judgment is worth nothing. Nothing but carefully considered and carefully carried out experiments will ever settle the question. Bad Grapes may be seen at any time grown under orthodox conditions so far as temperatures are concerned; but we are not, therefore, to condemn a system whereby many have succeeded. We presume nobody will dissent from this. All we ask is, that the rule be applied in the other case. This is just what has not been done.

It must not be supposed that we are concerned about the defence of Mr. Simpson, for we are not; he is quite qualified enough to do that for himself. But we do say that justice has not been done him in regard to his Edinburgh exhibit. It would be too much to say that the bunches were perfect in regard to setting, but very few growers can show better set bunches. We were visiting some

rather famous Grape-growing establishments just at the time of the Edinburgh Show, and not many of them could have shown much better set bunches: indeed, most were not so good. As some of the growers at these places have, at one time or other, advocated the high-night temperature system, we presume they practise what they preach. If so, the results do not seem to an ordinary observer to be so much better, if indeed so good, as that attained under the system they have condemned. So far in the discussion in the *Scotsman*, few or none of the famous growers have deigned to say a word. Why? Simply this: systems must be judged by the results, and few could show better or even as good results, so far as setting is concerned, as shown by the bunches from Wortley.

The fact is, and we have proved it, that Grapes may be set under very varying night temperatures if other conditions are right. One of these conditions we hold to be thoroughly ripened wood, and this cannot be done so well in October as in August. The application of fire heat at night to the extent it is usually done is, without any doubt, weakening in its results, and Vines under such treatment cannot perfect the same amount of fruit as they could under more natural conditions. The question is, as we look at it, not so much the amount of coal necessary for a given extent of vinery, but when to apply it. I think we are pretty generally agreed that unless Grapes and wood are ripe by the middle of September they are never properly ripened at all, at least in the northern counties of England and in Scotland. Grapes which are green at the beginning of September must, if they are to be ripened at all, be subjected to a regular course of fire heat at a time of the year when coal is least profitably used to assist Vines. We think few will think otherwise; indeed, this part of Grape-growing is a settled one among all good growers. This being so, it will be conceded that unripe Grapes in September are a mistake. There are two ways of having Grapes ripe by the end of August or beginning of September. One way is to allow the Vine to start "naturally," as it is called, and then to keep them going smartly by means of high temperatures night and day.

This system we think wrong and wasteful—wasteful, not so much of coal, as of the energy of the Vines. The amount of coal necessary under the different systems we do not consider varies much, but the results are not equal, and we are sure, for ourselves at least, that the most economical way is to assist the Vines to start early, so that wood and fruit may be ripened while the day is long and the sun bright. While Vine leaves and shoots are young they may be forwarded with fire heat nearly as rapidly as with sun heat, but they cannot be ripened to perfection so late as the end of September or October. Vines started in February may be allowed to proceed leisurely through the summer, and will benefit greatly by being treated to a refreshing coolness at night; but if they are allowed to start late in spring there is nothing for it but high temperature night and day, especially in such seasons as the present has been in the north, if we are not to be caught with green Grapes in September. When this is the case fires must be kept on then, and not to the best purpose.

Judging from the examples staged at Edinburgh this is Mr. Simpson's position. His Grapes were green. How does Mr. Simpson ripen them? He must burn coal, in no stinted quantities either, for weeks after other peoples' fires are out. The majority burn their coal at night, and so have their crop ripe early. Mr. Simpson, in order to have his ripe, burns the coal late in autumn. Neither system we consider right. Low night temperatures we decidedly favour, but when this system is to be followed early starting is necessary to ensure the best results. We know some have tried low night temperatures and have ultimately abandoned them for the reasons we have given. To all such, and to others who may wish to give the system a fair trial, we say, Start Vines early; at least, not later than the beginning of March, and never fail to maintain good day temperatures,

especially with bright sunshine. Do not imagine you are going to save coal, though. Saving a ton or two in spring or summer, to be compelled to burn as much or more to little purpose late in autumn, is not saving coal but wasting it, and spoiling the Grapes beside. It is well if such a system does not eventually end in having the Vines also spoilt, for ill-ripened Vines not only do not fruit freely, they are extremely liable to fail altogether, and that prematurely.—SINGLE-HANDED.

#### TREE-LIFTING IN SUSSEX.

As the season for transplanting trees and shrubs is approaching it becomes important to gather experience on the subject, with the object of ascertaining the safest and most expeditious methods of doing the work. As I was aware that some tree-lifting implements had been added to other important inventions of an occasional correspondent of the Journal, "PHILODENDRON," and learning that these implements could be seen in use in Dr. Newington's garden near Ticehurst, I recently visited the garden in question; and now, having had the opportunity of inspecting the working of the method, I unhesitatingly pronounce it excellent. The combined strong curved prongs, tubular lever, and fulcrum represented in the annexed engraving, constitute a garden appliance of substantial utility. Shrubs, Conifers, fruit and forest trees that have attained a considerable size can be lifted far more quickly and satisfactorily than by digging them up in the ordinary manner; indeed, it is placing a moderate estimate on the capacity of the implements by stating that the three

Fig. 53.—Tree-lifting Implements.

men who were working them could do more work in a day than it would be possible for them to accomplish in a week with spades and ordinary digging forks, and the great extent of roots secured by the new system fully accounts for the remarkable growth of the specimens that have been removed. Spruces 10 feet high have received no check whatever. In a large plantation of Larches there were only two failures; and the trees forming a Holly hedge, more than fifty years old, removed last year, are now quite established and growing in their new position. The prongs are made in different sizes for lifting moderate and large trees, and two or three of them can be inserted round a specimen 10 or 12 feet high and the tree be raised out of the ground in two minutes, the maximum quantity of roots being drawn out and soil retained, as the curved prongs meet under the ball and lift it out as if it had been cast in a mould. This new tree-lifting apparatus cannot fail to be of great service on private estates and in public plantations in this and other countries where the work of tree-lifting involves such a large annual expenditure.

The following instructions for using the implements, prepared by the inventor, will render the subject plain to all.

Place the fork c at from 2 to 3 or 4 feet from the trunk of the tree, take the handle in the hands and move it from side to side, and backwards and forwards: this movement will cause the curved tines to penetrate under the trunk of the tree; now slip on the

tubular lever D, and if the tines have not penetrated deeply enough, put the foot on the treadle and move the fork again as before. A spit of earth is to be removed from the back of the fork. The fulcrum A B is now to be placed on the earth near the shoulders of the fork; the upper bar of the fulcrum is to be thrown back so as to allow the handle of the fork to rest upon the lower bar. Now weigh down the lever so as to displace the roots of the tree, then lift up the lever, shut the upper bar of the fulcrum, and weigh the lever on this upper bar, when the ball of earth, the roots, and the tree will be suspended high enough to allow of an iron plate, or trolley, being drawn under the ball. It is a good plan to place sand or fine mould round the fibres of the roots when planting.

Two tree-lifters may be used with great advantage when the trees are large. Three have been used for balls 7 feet in diameter. The spoon expansion, made of Whitworth steel, is affixed on the large prong F E for lifting large specimens.

Further particulars in reference to the invention, which is patented, will be supplied by Dr. Newington, Ticehurst, Sussex.—J. WRIGHT.

#### REVIEW OF BOOK.

*Garden Pests and their Eradication.* L. Upcott Gill,  
170, Strand, W.C.

THIS little work is more pretentious than another recent work upon the subject of injurious insects, since it attempts to embrace the species that are hurtful in the flower garden as well as those that attack vegetables, fruit, and timber. Owing to this it is to some extent meagre, and an alphabetical arrangement is carried out that is insufficiently clear, because in some cases the insect appears under its familiar name and in others it is placed under the plant it mostly frequents. Thus, under the heading of "Rose Grubs and Sawflies" a variety of insects are briefly mentioned; and the familiar ground weevil (*Otiorhynchus sulcatus*) is entered as a "Pot Maggot," and other points of the arrangement are peculiar. We think that the better plan in such a handbook is to take the insects with the names of the plants they frequent as headings, adding, perhaps, in a separate arrangement the species that are general feeders. The entomological information is on the whole correct; and the illustrations, though of a popular nature, are sufficiently recognisable with a few exceptions. In one or two figures the artist seems to have given the insects an attitude somewhat comical, as in the representation of a crane-fly (*Tipula oleracea*). It would have been an advantage if the author had noted throughout the times of appearance in the larva and imago states. A list of remedies in the way of preventive applications and destroyers has been compiled from various sources and is a useful feature in the book: but some of them have claims which are not sustained in practice, and others of real service are omitted. We thought the idea that wireworms would eat oilcake until they burst had been long ago exploded; and although it is stated that sulphuring the pipes in houses and heating them will kill thrips, it is not stated that the fumes will often first kill the foliage of the Vines and plants. Yet if nothing new in the way of remedies is advanced—and it does not appear to be sufficiently explained that dilute sulphuric acid is only to be used where nothing grows which it is wished to preserve—still no gardener will regret the trifle laid out upon this helpful volume.

#### THE PROPAGATION OF CONIFERS.

(Continued from page 263.)

GRAFTED plants require much attention after the scions are thoroughly united to the stock. They all need examining during March, and the upper portion of the stock must be cut off close to where the scion was affixed. Small stakes about 9 inches or a foot in length should be in readiness, and great care must be taken not to injure the young plant when removing the useless portion of the stock. As the work proceeds each young plant will require a stake, which should be made secure to the stock by means of bast matting below the place where worked, with another tie round the union to prevent the scion being broken off. The growth must be tied upright if it does not assume that position. This is rather a tedious operation, but when completed the only attention needed is an abundant supply of water as the soil becomes dry. Ventilate when the weather is favourable, increasing the ventilation considerably as the spring advances until the plants are thoroughly hardened.

The time of planting varies considerably both with the grafted plants and those raised from cuttings which have been wintered outside. As a general rule the spring is a busy time in all nurseries, and much work has to be done about the time these should be planted out. After the season for sending out Conifers

those remaining unsold are lifted and replanted, so that no ground will be wasted. In some instances they are all removed, in others a portion from one end only are lifted to fill up the blank spaces. In well-managed nurseries the latter is only done when the remaining plants had been transplanted the previous year. After the shifting is done there is generally plenty of vacant ground. In most instances this is the time when the young stock is planted out. The ground is well dug, and the plants are placed 9 inches apart in rows a foot asunder. The plants are turned out of the pots without disturbing the roots. A little soil is placed to each and pressed firmly round the ball with the foot, then a little manure is placed along the row and finally finished off with soil. The manure is not dug into the ground as is generally practised in private establishments, but it is placed close to the roots of the plants, so that when they commence rooting they quickly reach it. These plants are only removed when they require more room (which is in two years) and when sold.

Many Abies, Pines, and Piceas, as well as *Cedrus* and *Araucaria imbricata*, are raised from seed annually. The common kinds are sown outside in beds during the spring months at the same time as the Larch seed is sown. Before sowing the seed the whole is soaked in a large tank or other suitable place. The choice kinds are sown in pans or in a frame prepared for them, where they can remain until large enough for potting or planting out. The choicest kinds are often potted, by which means they can be planted out afterwards when convenient. This is not the case when planting from the seed bed, as the operation must be performed in the season. Some few Abies, such as *A. Englemanni glauca* and other beautiful varieties, are increased by grafting, employing some of the common kinds as a stock; but there appears to be more difficulty in successfully grafting Abies or Pines than the majority of Conifers, as they do not take readily to the stock.—WM. BARDNEY.

#### HARDY FRUIT GARDEN.

LATE Plums have not ripened well owing to the continued rains. Many fruits have cracked, and some are falling from the trees, the footstalks having shanked. Those valuable kinds, Coe's Golden Drop and Ickworth Impératrice, will be in condition some time yet, and they will hang for a considerable time on the trees if the weather prove favourable and means are taken to exclude wasps and flies, but any fruits quite ripe will also keep good if gathered and placed singly upon shelves in a light airy fruit-room. Continue gathering Apples and Pears as they become ripe, placing the choicest singly upon shelves in the fruit-room, which ought to be thoroughly cleaned. The room must also be kept dry and cool. Filberts and other Nuts should be gathered and spread out thinly in an airy room, but should not be divested of the husks.

Where root-pruning is deemed necessary to check over-luxuriance of growth, and to induce the formation of fruit-spurs or shorter-jointed fruitful wood, it should be attended to as soon as the growth is complete and the wood somewhat hardened, and may safely be performed between now and the early part of November. When the growth is very gross and the wood comparatively soft, root-pruning must not be performed until the leaves are falling; as, if done too early, the sappy growths will, if the autumn be bright and dry, shrivel and die back. This particularly applies to Peaches and Nectarines, and to trees generally that have made young shoots of some length in the current season. It is difficult to give any precise directions for root-pruning, much depending on the vigour and size as well as age of the trees; but as a general rule a trench should be formed at a distance from the stem equal to about one-third the height of the trees. If the roots are thick only those should be cut or some of them, leaving the small roots intact. From the trench towards the stem the loose surface soil should be removed, and the soil removed from amongst the roots without injuring or disturbing them too much, and they may, especially if deep, be lifted, laying them in fresh compost, and making the soil firm around them. A mulching

of short litter will make all safe for the winter, and encourage root-formation. At the time of root-pruning any useless shoots may be removed from the trees, so as to admit abundance of air and light in order to thoroughly ripen the bearing wood or spurs for next season.

Intending planters should visit a nursery in good time and select their trees, and arrange for their being carefully lifted and packed with as little exposure of the roots as possible. A short list of reliable kinds may not be unacceptable to inexperienced fruit-growers. South walls are suitable for Peaches, Nectarines, Apricots, and Figs, and generally a tree or two of some early or desirable kind of Plum and Cherry. *Peaches*.—Alexander, Hale's Early, Dr. Hogg, Grosse Mignonne, Royal George, Noblesse, Dymond, Barrington, Stirling Castle, and Lord Palmerston. *Nectarines*.—Lord Napier, Rivers' Early Orange, Violette Hâtive, and Pine Apple. *Apricots*.—Kaisha, St. Ambroise, and Moor Park, with Shipley's for preserving. In some localities Apricots succeed on east walls. *Cherries*.—Belle d'Orleans, Empress Eugénie, and May Duke. *Plums*.—Early Favourite, July Green Gage, and Green Gage. Where Peaches do not succeed against walls those with a south aspect may profitably be occupied with Plums of the choicer kinds, such as Green Gage, Jefferson, Kirke's, Transparent Gage, and Coe's Golden Drop. *Figs*.—Brown Turkey, White Marseilles, and where there is plenty of space Brunswick. East walls are suitable for Cherries and Plums. *Cherries*.—May Duke, Bigarreau Napoleon, Governor Wood, and Nouvelle Royale. *Plums, Dessert*.—July Green Gage, Green Gage, De Montfort, Denniston's Superb, Kirke's, Jefferson, Transparent Gage, Purple Gage, Guthrie's Late Green, Coe's Golden Drop, and Ickworth Impératrice. *Culinary Plums*.—Early Prolific, Czar, Prince Englebert, Pond's Seedling, Prince of Wales, and White Magnum Bonum. *Pears* are suitable for west walls, also east; some of the most suitable are Jargonelle, Beurré d'Amanlis, Gratioli of Jersey, Beurré Superfin, Louise Bonne of Jersey, Marie Louise d'Uccle, Durondeau, Doyenné du Comice, Maréchal de Cour, Marie Louise, Beurré Diel, Van Mons Leon Lelerc, Passe Colmar, Beurré d'Aremberg, Glou Morceau, Winter Nelis, Josephine de Malines, Bergamotte Esperen, and Ne Plus Meuris. North walls are most suitable for Morello Cherries, but such Pears as Jargonelle, Williams' Bon Chrétien, and Comte de Lamy succeed fairly, and some of the free-bearing kinds of Plums—Early Prolific, Victoria, Mitchelson's, and Prince Englebert, with Belle de Septembre. Cherries of the Duke and Kentish class also succeed, Currants being grown in such positions for late use. Apples are seldom given a place against walls, but the fruit is much finer so grown than in the open. Some worth a place are Cobham, King of the Pippins, Melon, Dutch Mignonne, Northern Spy, Ribston Pippin, Cox's Orange Pippin, Adams' Pearmain, and Reinette du Canada.

#### FRUIT HOUSES.

*Vines*.—Late Grapes that were judiciously assisted by fire heat in spring have crops of fine well-coloured fruit, calculated to winter much better than such as still require heat. Liberal ventilation will be required on all favourable occasions, and as the foliage ripens the temperature may be allowed to fall to a minimum of 50°. Ripe Grapes of the thin-skinned varieties, such as Hamburgs, should be examined twice weekly, removing decayed berries, stopping lateral growths, the houses being dry and cool, employing fire at night only to maintain a minimum temperature of 45° to 50°, and avoid sweeping, or dust will accumulate on the bunches. In order to secure the ripening of the wood of young Vines maintain a high and dry atmosphere by day, shutting off the heat and ventilating freely at night. To check growth the laterals should be moderately stopped; but not so much as to give a sudden check or cause the starting of the principal buds. If former directions have been followed the earliest Vines have been pruned, and a good supply of fermenting materials should be prepared for making a bed inside the house, and for covering the outside border at least a fortnight before fire heat is commenced. A mixture of about two parts leaves with one of stable litter is suitable, giving a milder and more lasting heat than if composed of litter alone. If materials of this description are not obtainable a covering of litter, or better of bracken, should at once be placed on the border. For covering the borders of late houses a supply of this material should be procured, or failing this dry litter

or straw should be employed, as an equable temperature at the roots is essential to keep Grapes in good condition.

*Pines*.—Young growing plants must at this season be so arranged as to obtain the fullest benefit of sun heat, and as this is diminishing the temperature at night should also be reduced, maintaining it at 55° to 60°, and 65° in the daytime by artificial means. Ventilate freely whenever the weather is favourable. Particular attention must be given to watering, examining the plants at least once a week, and whenever water is needed supply it liberally. Plants in shallow beds of plunging material heated by hot-water pipes require water more frequently than those in beds of fermenting material. Fruiting plants, with the fruit in an advanced stage, must not be overwatered, as when this occurs and the temperature is not high the fruit sometimes turns black at the centre during the winter and early spring months. The temperature should be maintained at 70° at night, ranging the temperature from 75° to 90° in the daytime, closing at 85°, sprinkling the pathways when they become dry, and occasionally syringe the plants on sunny afternoons, keeping the bottom heat regular at 85° to 90°.

*Cucumbers*.—The plants for winter fruiting must be planted out not later than the middle of the month to ensure a good supply of fruit by midwinter. Hot-water pipes are unquestionably the best means of affording bottom heat, but where fermenting materials are employed they should be had in a sweet condition. Be careful not to overcrop the autumn-fruiting plants, striving to maintain a healthy growth, which can only be secured by close and regular attention. Maintain a night temperature of 65° to 70°, 75° in the daytime, and ventilate moderately whenever the weather is favourable. Syringe lightly on bright afternoons, gradually reducing the supply of moisture as the days shorten. Place a little fresh compost to the autumn-fruiting plants about every ten days, affording weak tepid liquid manure twice a week, and fumigate moderately but repeatedly if aphides are observed.

*Melons*.—Water should only be given to prevent the foliage flagging. Keep the foliage thinned so as to admit light freely. The last batch of plants have their fruits swelling, which must be supported by tables, securing a temperature of 70° at night and 75° in the daytime, or more from sun heat. Fruits ripening need a dry warm atmosphere and a little air constantly; those swelling require moderate atmospheric moisture, syringing lightly on bright afternoons. In dung-heated pits and frames the heat must be maintained by linings, not giving any water at the roots after this. Ventilate freely whenever opportunity offers. Any fruits swelled to a good size and not likely to ripen in the frames for want of heat may be cut with a portion of stem, and placed in a sunny position in the Melon house or other warm structure.

#### FLOWER GARDEN.

Plants required to be saved from the frost must without further delay be taken up and placed under shelter. Tricolor, bronze, and any Pelargoniums of slow growth need not be cut back much, merely removing any crowded branches, leaving the other shoots their full length to afford a supply of cuttings in spring. The green-leaved varieties, being hardier, are not injured so readily as the ornamental-leaved varieties. Old plants, from the freedom with which they bloom, are preferable to those from cuttings struck either in autumn or spring, and where room is available these should be preserved, cutting back the tops and roots, and pot in as small pots as practicable, or they may be packed closely in boxes. The tender succulents, such as *Echeveria metallica*, *Pachyphytums*, *Kleinias*, and *Sempervivum tabulæforme*, should be taken up or protected from frost, for if in the least injured they are difficult to winter. Those recently propagated, also *Coleuses*, *Iresines*, indeed all plants that are tender and likely to be wanted for propagating purposes, should be housed at once.

Herbaceous plants need attention, removing decayed leaves and flower stems. *Anemone japonica* and its variety *alba* has abundance of flowers. *Aster Amellus*, *A. Amellus majus*, *A. coccineus*, *A. dumosus*, *A. grandiflorus*, *A. longifolius formosus*, *A. spectabilis*, *A. nova-belgi*, and *A. patens* are fine for autumn; *Tritomas* are grand, and so still are *Phloxes*. *Schizostylis* when the autumn is mild is

a fine border plant, and so are Tritonias for late summer. Statice latifolia, Zephyranthes candidus, Sternbergia lutea, Colchicum autumnale vars., C. speciosum; Crocus nudiflorum, C. sativus, C. Sieberi, and C. speciosus; Cyclamen hederæfolium, Hypericum calycinum, Fuchsia corallina, F. globosa, F. Riccartoni, and F. gracilis; Plumbago Larpentæ, Polygonum vacciniifolium, and Sedum spectabile, are fine for late summer and autumn. Hollyhocks as they cease flowering should have the stems cut away, which will assist the production of shoots for cuttings, and if those are taken off with a heel they will root in a close frame with a little heat. Seed may yet be sown, and young plants should be pricked out or potted off, and if protected in cold frames they will bloom finely next year. Any gaps should be filled with Brompton Stocks, Wallflowers, and other gay spring-flowering plants. Seedling perennials, also biennials, should now be planted where they are to bloom. Chrysanthemums must have supports, and should have liquid manure water liberally. Hyacinths, Narcissuses, and Tulips intended for mixed borders can be planted at once. Anemones for early bloom should be planted. The French double Chrysanthemum-flowered varieties are very fine and very useful for cutting. A. fulgens is very bright in colour and valuable for cutting. Irises, both English and Spanish, should be planted, also the early-flowering Gladioli, such as ramosus, floribundus, Queen Victoria, cardinalis, and byzantinus. Complete planting layers of Carnations, potting choice kinds and placing them in frames. Choice Pansies may be potted, also rooted cuttings, placing them in cold frames. Beds of common varieties and seedlings should be formed, and the plants will bloom finely early next season. Prick off choice seedlings in frames. Pinks and Clove Carnations may also be planted. Ranunculuses for cutting are unsurpassed and should be planted now for early blooming, the double French being very free and effective. Where there is a great demand for cut flowers in spring Narcissus biflorus, N. Poeticus and its vars., N. angustifolius, N. ornatus, and flore-pleno should be grown in quantity.

#### PLANT HOUSES.

*Greenhouse.*—Neriums are not so much grown as they deserve to be. The flowers are very useful, and small well-flowered plants are very effective. Cuttings taken of shoots that have ripened the wood and set their flower buds may be struck in brisk heat, and make useful decorative plants in 6-inch pots. Any old plants that have a number of flower buds partially expanded will open them better in an intermediate temperature than in a greenhouse or conservatory. Large plants that made their growth early in the season and were turned out in a sunny position to ripen, should not have more water than is needed to keep the foliage in good condition; and when the flowers are showing the plants may be moved to a light position in a house where a temperature of 55° artificially is maintained, if it is wished to accelerate the flowering.

Whilst the weather continues mild admit plenty of air both night and day, which will ripen the growth of the plants. Give sufficient but not too much water; do not allow the soil to become too dry before applying it. Late Fuchsias should have encouragement to continue flowering, applying weak liquid manure, also keep the seed pods removed as soon as the flowers have fallen.

A few of the most forward plants of Daphne indica may be placed in a temperature of 50° artificially, which will cause them to flower earlier, and they bear more cutting than is the case with later plants, as they will make more roots and corresponding growth in spring.

*Orchids.*—Plants that have completed growth must have a moderate supply of water, being careful not to wet the crown of the plants. Those on blocks still growing require their roots well moistened every morning either by syringing or dipping, and those that have completed their growth need damping every two or three days; but the grower must be guided by the condition of the atmosphere in which the plants are grown. Many Orchids naturally grow now, and should occupy the most favourable part of the house. Regulate the moisture according to character of the plants; those growing must have a moist atmosphere, those that have finished growth need a drier atmosphere and more air. Ventilation must be regulated by the weather. Phalænopsids must be very carefully supplied with moisture, as, should the leaves be overcharged with moisture, they

are likely to decay. Encourage Calanthes with heat and moisture, keeping the leaves clean by frequent sponging. Many showy Orchids will yet be blooming, and the practice of moving them into a drier atmosphere may be continued, the temperature being kept at 50° to 55°, in which they will last longer and be more enjoyable. A decline must now be made in the temperature. For the East India house allow a mean of 70° by day and 60° at night; Cattleya house, 65° by day and 55° at night; and Odontoglossum house, 55° by day and 45° at night. Let the woodwork and glass, both inside and out, be thoroughly cleansed. Take advantage of wet weather to give the plants a thorough cleaning. Keep a sharp look-out for slugs, searching for them at night with a lamp.

#### CONTRACTING SPACE OF HIVES.

THE practice of contracting the space of hives probably originated in the Stewarton system. This hive in the height of summer has three workshops or breeding boxes 6 inches deep, and some supers 4 inches deep, all 14 inches wide. The supers are removed at the end of the honey season, and when the bees begin to sit in less compass one or two of the breeding boxes are removed. In this way the bees have less space to keep warm. Some of the most advanced men of the bar-frame school have, since they adopted larger hives, followed the practice of making their hives less before winter sets in. Some frames are removed, and the partition frames or walls are so placed that the bees are confined to six or eight combs during the winter. The combs removed are kept in a dry place for future use.

The question I wish to see discussed is this: Is this practice healthful and helpful? If it is good for bees and advantageous to bee-keepers, in what sense is it so? I shall be glad if our friends who have used contracted hives in winter will favour the readers of the Journal with their experience and opinions. The question is both interesting and important, and therefore should be well understood.

Though our hives are not capable of contraction, and my experience on this question may not be deemed of great value, the question has been before me all my life. My father thought that hives not filled with combs, and hives eked or enlarged, kept their bees through winter better than hives without any empty space in them kept theirs. My experience forbids me to fear losing bees through having much empty space in stock hives in winter. For many reasons we like the stocks to be full or nearly full of combs in autumn. But many times have we known large hives not half filled with combs kept for stock come safely through winters of severity and succeed well; indeed I do not remember an instance of a hive suffering loss of population owing to its size or to unoccupied space in it. At the present time we have some hives very strong in bees but not filled with combs. The question then arises: If the empty space were cut off by some contrivance, would the bees be healthier or live longer? Would the hives be stronger in spring? This is the question now offered for discussion. It is a wider question than appears at first sight, for the removal of combs and the contraction of hives in winter may be more advantageous in some apiaries than in others. It is known, of course, that where hives are not filled with combs in autumn the bees have to spend both time and honey in the manufacture of combs in spring, and therefore do not swarm so early as those quite filled with combs, all other things being equal; but this does not touch the question of the health of bees in small houses or quarters in winter. On the question thus mooted let us have a full expression of opinion.—A. PETTIGREW, *Bowdon.*

#### SUGAR AND SUGAR-BOILING.

“ONE of the Great Unwashed,” who seems to be little the wiser for Mr. Cheshire’s excellent article on sugar, wishes to be informed, through the Journal, what sort of sugar for bee-food he is to ask from his merchant, whether loaf or soft sugar, whether white or brown, whether with large or small crystals, and whether bect sugar is as wholesome as cane sugar, &c.

In this country sugar sold for domestic purposes is now rarely if ever adulterated. The use of sand and starch for this purpose has been long abandoned as being so easy of detection, and grape sugar manufactured from corn starch, though said to be used in

New York for purposes of adulteration, is by its nature precluded from being mixed with any good granulated cane or beet sugar. The main difference between the various grades of domestic sugar is thus not so much a question of adulteration as of their degree of refinement. Whether the source of the saccharine matter be sugarcane or beetroot, the resulting sugar *in its purity* is chemically and in appearance the same, and known as cane sugar. But grades vary according to the amount of organic matter; uncrystallisable grape sugar, mineral salts, and water remaining as a result of imperfect refinement, and in some cases of the lime used in one stage of the process but not thoroughly removed. There can be no doubt, therefore, that the more highly refined sugars, white, dry, crystalline, and giving a perfectly clear solution, though costing a little more, are the best and cheapest in the end. Among these grades I find that known as "Dutch crushed" to be generally the best value for the money, and I am strengthened in this conclusion by finding it most generally preferred by our large confectioners and preserve-makers. The lower the grade of sugar the more water and organic matter must be paid for, until we reach a grade containing so much molasses as to be positively destructive to the bees.

Having selected our sugar we come to the method of preparing it for the food of bees. Given in its dry state, bees will readily take it if water be supplied by its side; but this method of feeding has three disadvantages—the bees are very apt to waste it by carrying the dry grains outside the hive; the process is slow and necessitates a long-continued agitation among the bees; and there is frequently a loss from the solution afterwards crystallising in the cells. Boiling is therefore resorted to as a means of reducing the sugar as near as may be to the nature and consistency of natural honey. A few facts and figures relative to sugar-boiling may not, therefore, be out of place.

By placing a quantity of crushed sugar with a little water in a brass or tinned kettle over a brisk fire we note the following distinctive changes which the application of heat will cause it to assume. First, the lumps break up and dissolve, forming a *simple syrup*. By increasing the heat till the syrup boils the liquid of course becomes more and more dense, until it reaches a point where not enough water remains to hold the sugar in perfect solution. If it be now set aside and allowed to cool gradually, the excess of sugar will deposit itself in clear crystals on the sides and bottom of the vessel, and we shall have what is usually known as *rock candy*. If, instead of setting it aside, we continue the boiling, nearly all the water will soon evaporate, and the sugar will manifest a tendency to assume a granular condition, especially upon the sides of the vessel. A few degrees of heat beyond this point, and we have the sugar in a melted form of a thick pasty consistency, but clear and transparent still. A spoon dipped into the mass will leave a thread behind it on its withdrawal, and if the portion removed be plunged into cold water it will at once become hard and brittle as a pipe stem. It has now reached that condition where the confectioner, by a few simple manipulations, can produce very many changes in its appearance, and it is from sugar in this state that the greater number of our rocks and candies are produced. Very little more heat will burn the mass, resulting in the formation of caramel, which is little better than poison to bees. This takes place at a heat of about 260°.

If bee candy is wanted the vessel is removed from the fire when the liquid on trial on a spoon in cold water is viscid enough to leave a thread on the finger. Stirring is continued till the mass begins to set, when it is poured into paper moulds laid in plates or trays. For liquid food it must not be allowed to boil so long, else it will granulate on cooling. Three pounds of sugar will make five pounds of syrup as thick as it is possible to make it, and prevent crystallisation. But if cream of tartar or vinegar be added while the syrup is on the fire it will so hasten the change into uncrystallisable sugar that even a greater consistency may be attained. There is, however, no need for supplying bees with syrup thicker than newly gathered honey. I therefore prepare my syrup as follows for winter food. To 15 lbs. of white crushed sugar I add 6 lbs. of water and half a teaspoonful cream of tartar, or a wineglass of vinegar, boil briskly for five minutes or till the whole loses 1 lb. by evaporation, and use when nearly cold. The syrup is then as nearly as possible like newly gathered honey, and is very quickly sealed over by the bees.—WILLIAM RAITT, *Blairgowrie*.

#### TRADE CATALOGUES RECEIVED.

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees and Shrubs*.  
Francis & Arthur Dickson & Sons, The Upton Nurseries, Chester.—*Catalogue of Select Roses*.  
Cranston Nursery & Seed Company, Hereford.—*Catalogue of Roses*.

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Azaleas, Camellias, and Rhododendrons*.

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Address (G. S.).**—If you write to Mr. W. Lovel, Weaverthorpe, York, he will, we think, give you the information you require.

**Books (R. Reid).**—There is no work arranged in the manner you refer to in your letter, nor would such a work give general satisfaction. You will find more practical information on gardening generally, including annual, perennial, and florists' flowers, in our "Garden Manual" than could be given in any such catalogue you suggest. The "Garden Manual" can be had from this office in return for 1s. 9d. in postage stamps.

**Heating by Gas (A. G.).**—You have sent a letter to the address we gave you to which you have omitted to attach your name. If you make good the deficiency your letter will be attended to.

**Late Roses (R. C.).**—As your trees are so few you might easily protect them by making a rough framework and covering with canvas or some other material during inclement weather and frosty nights, the framework being sufficiently high to prevent the canvas resting on the blooms or buds.

**Continental Nurserymen (A Market Gardener).**—You will find the addresses of all the leading continental nurserymen in the "Horticultural Directory" that will shortly be published. When you are established as a nurseryman your own name and address can be added if you send us the necessary information; in all probability, however, this will not be in time for the next edition unless you become established quickly.

**Gros Colman Grape (T. C.).**—Gros Colman is the name by which it was introduced, and it is under that name that it first appeared in M. A. Leroy's catalogue of 1860. It seems to have travelled westward from the East, for in the catalogue of Jacquemet-Bonnefont of Aunonay for 1858 it is mentioned by the name of Gros Colmar. In that of De Baray in 1852 it is called Gros Colmar, and this is the earliest record we can find of it in nurserymen's lists. The rule is to regard the first names of fruits as correct, and if the name of Gros Colmar can be found recorded previously to 1852 that name may then be regarded as the correct one.

**Figs Not Ripening (R. G.).**—The trees are overburdened with fruit, and the temperature is not sufficient to ripen the crop. Twelve-inch pots are a suitable size for trees in pots, but if more root space is required we should pot the trees as soon as the second crop is ripe. The fruits will certainly not ripen in a house having no artificial heat, but will probably fall, and would be better removed at once, as they only weaken the trees and prevent the ripening of the wood, upon which a full first crop mainly depends. If the trees were placed in a house with a temperature of 60° to 65° artificially and air admitted constantly they would probably ripen the second crop.

**Heating Fernery (J. W.).**—As no pipes for heating can be admitted into the house you will derive more satisfaction by growing hardy Ferns, of which there are so many attractive forms, than attempting the culture of tender species. The dry heat of a stove would injure the slender fronds of these, and render the plants unsightly. We are unable to recommend any stove that would answer your expectations, but if any of our readers have found a stove satisfactory for heating a fernery we shall be glad to hear from them.

**Potato Awards (C. M.).**—We are obliged by your letter. As was stated in our report of the Potato Show the new varieties were not adjudicated upon on the day of the Show, and if you refer to page 235 of our last issue you will find the reason of the necessary delay in publishing the awards. Four varieties are there named as having been tested and certificated by the Judges.

**Grapes for Christmas (Inquirer).**—Lady Downe's is the best-flavoured late Grape, and started early is in good condition at Christmas. Gros Colman is also good at the same time grown in heat. The Vine is a strong grower, and one taking up less room, and good is West's St. Peter's. The best white Grape is the Muscat of Alexandria. Trebbiano and White Tokay are also late Grapes of fair quality. So far as we can understand your wants we think they would be best met by growing fewer varieties, say Lady Downe's and Muscat of Alexandria; but on this question you must judge for yourself.

**Nurserymen's Yearly Tenancy (An Anxious One).**—Your question is not sufficiently clear for the case to be understood. If there is no special agreement to the contrary a nurseryman, like any other tenant, must have a written notice of six months to give up possession of his holding, the six months terminating at the time at which he took possession. Thus, if he took possession at Michaelmas, and did not receive notice to quit until June, he could not be disturbed until Michaelmas in the following year; but if, on the contrary, he received a proper notice fully six months before Michaelmas he would have to leave at the time stated in that notice.

**Paint for Greenhouse (F. C.).**—For the inside of the house there is certainly no better paint than that made of the best whitelead, and we doubt if any paint can surpass it for outside work, though some prefer the anti-corrosion

paints; for the inside of houses they leave the surfaces too rough, and the painted work cannot be easily washed clean when washing is needed. The question of its application depends obviously on the manipulative skill of the amateur. Some amateurs are excellent painters, and others the reverse.

**Staging for Greenhouse** (*Chas. Diamond*).—The plants you name can be grown successfully on a stage 4 feet from the glass by elevating such plants as need it on inverted flower pots. You would also find a broad shelf along the back of the house and about 18 inches from the glass of great value for nearly all plants in a young state; in fact we advise you to affix a shelf broad or narrow wherever you find it convenient for doing so, and your greenhouse will be doubly useful.

**Tuberous Begonias** (*H. W.*).—You will find a method of wintering these described on page 284 of our last week's issue. The note was communicated by the manager of one of the finest flower gardens in the kingdom in which Begonias are grown extensively and successfully. The present is the time for taking up the plants, and you can, of course, place them in pots if you prefer instead of storing them in boxes. Not much soil is removed when the plants are first taken up, but it is only reduced after the tops are withered if the corms are stored thickly in boxes.

**Rust on Grapes** (*J. C.*).—The Grape sent resembles Mrs. Pearson. There are many causes of rust, but the most common is the admission of a strong current of air after the sun has raised the temperature of the house rapidly, thus inducing the deposition of moisture on the comparatively cold surface of the Grapes; the air then admitted causes rapid evaporation, and rust ensues. Rust is often a consequence of sprinkling highly heated pipes with water, the vapour produced being rapidly condensed on the skin of the berries, and then air is admitted to allow of the moisture passing off. Rust may also be caused by syringing with water impregnated with chalk or iron, and in the early stages of growth by fumes arising from sulphured hot-water pipes.

**Vine in Orchard House** (*F. C.*).—If the growth of the Vine inside the house is healthy and covers the roof, or promises to do so, we fail to see what you would gain by having the whole length of the stem inside. The best part of the Vine is the top, not the lower portion of the stem. We certainly do not advise you to carry out your project of covering the stem near the house with soil, and then cutting off the Vine there. Nor do we, so far as we understand your case, advise you to remove the Vine, as you might then have more growth in the house from the 8 or 9 feet of stem than could have the necessary light and air for rendering it fruitful. If the growths are removed from the stem outside and it is wrapped with haybands the Vine will flourish, provided the soil is suitable and proper treatment is given to the growths inside the house. If the Vine is unhealthy we should plant a young one in good soil and a suitable position, and gradually remove the old as space was required for the new Vine. We do not comprehend the condition of the bunch of which you complain; perhaps the injury resulted from a sharp current of air when the fruit was swelling.

**Pelargonium v. Geranium** (*Idem*).—The plants grown in gardens for bedding or decorative purposes under the names of Show, Fancy, or Zonal Geraniums are all Pelargoniums, the true Geraniums being hardy plants, several forming common English weeds. The true Pelargoniums are mostly natives of the Cape of Good Hope, and from the species originally introduced thence the varieties now in cultivation have been obtained, either as sports or seedling variations produced by crossing and hybridising. The chief botanical characters that distinguish Pelargoniums from Geraniums are that the former have flowers in the majority of cases slightly irregular—that is, the petals are not all of equal size, though this is not so observable in the modern type of Zonal varieties. The stamens in the Pelargoniums vary from four to seven, while in the Geraniums they are exactly double the number of petals—namely, ten, or the same number—viz., five. The Pelargoniums, too, have a nectary closely united to the flower-stalk, which is one distinctive character, easily observed by cutting the stalk across just beneath the flower. The so-called Geraniums with scented leaves are all true Pelargoniums.

**Covert for Game** (*Col. A. B.*).—Your land is probably stiff and good, hence Gorse or Whin does not succeed, as it makes growth in summer which does not ripen well, and is consequently injured or killed in severe winters. The best covert that has come under our notice was formed of small trees or shrubs with clumps of evergreen trees, chiefly Norway Spruce, for the roosting of pheasants. Some Oak trees and Hollies were carefully preserved, and the ground planted near them with Blackthorn and Privet, a few English Yews being interspersed. The Oaks and Hollies were soon taken possession of by the pheasants as roosts, the rank growth of Blackthorn and Privet being such that poachers did not care to penetrate, and was not liked by heathers, but very much praised by the keepers as a preserve. Plants were placed 4½ feet asunder, and in rows the same distance apart. The Spruces and Hollies were introduced 18 feet apart. Between the Spruces and Hollies in their respective lines the central plant was English Yew, the other plants being Privet and Blackthorn, the covert generally being formed of Blackthorn and Privet, grouped so as to have a pleasing appearance, as it was the home covert, and desired to be as picturesque as possible. There were separate clumps of Blackthorn and Privet, also mixed clumps of Spruce, Holly, Yew, Blackthorn, Hazel interspersed with wild Pear, Crahs, Spurge Laurel, Ivy, Elder, and Dog Roses, the hedges of the latter having a fine effect in autumn. Advantage was taken of hollow wet ground to introduce Birch, Alder, Dogwood, Bitter Willow, and Snowberry. On the margin were planted *Rhododendron ponticum*, *Berberis aquifolium*, and *B. Darwini* in clumps, the *Rhododendrons* forming capital nesting places for the pheasants. White Thorns, Mountain Ash, Barberry, and Bramble also were introduced to form a covert of an ornamental character with as much berry food for the pheasants as practicable. In March Broom seed was sown, about 8 lbs. per acre; Wood Millet Grass, 4 lbs.; and a similar quantity of coarse tufted Grasses. This covert is only 13 statute acres in extent, but adjoins a large wood, and there is always abundant exercise for the sportsman. Blackthorn alone makes a capital covert; plants 2 to 2½ feet high transplanted are the most suitable. Hazel also should be planted, and Privet, of which by far the best is the strong-growing evergreen *Ligustrum ovalifolium*. Plant them 4½ feet apart.

**Specimens for Naming** (*W. H. Panty*).—We have received no question relative to the *Stephanotis* nor flowers for naming to which your signature was attached. We have named some plants to "W. H. W.," whose writing resembles your own, but they can scarcely be from you, as we suppose you would not adopt two signatures. The names of the senders of flowers or fruit should always accompany the specimens, whether separate letters referring to them are sent through the post or not. We often receive three or four parcels with no names in them, and as many letters by post stating that specimens have been sent for naming, and if we cannot decipher the stamp of the post office how are we to know to which parcels the different letters refer?

**Names of Fruit** (*G. B.*).—We have attended to all the fruit that has been received except a parcel from Hereford, and some others that neither contained the names nor initials of the senders. (*J. E.*).—The name of the Pear is Brougham, a seedling of Mr. T. A. Knight, raised from the Swan's Egg. (*Leon*).—1, Flower of Kent; 2, not known; 3, Cox's Orange Pippin; 4, French Codlin; 5, Old Golden Pippin; 6, Kerry Pippin. Your suggestion cannot be carried out, and only six varieties should be sent at the same time. (*H. C. Bingley*).—2, Thompson's; 3, Beurré Lefèvre; 5, 7, and 9, Duchesse d'Angoulême; 6, Beurré Diel; 10, Beurré Clairgeau; 12, Catillac. We cannot name the others. (*Dr. Francis*).—1, Pitmaston Nonpareil; 2, Ord's Apple; 3, Holbert's Victoria; 4 and 5, Not known; 6, Royal Pearmain. (*D. Brown*).—1, Fondante d'Automne. The others are not in condition for naming, not even approaching ripeness. (*J. E.*).—1, Round Winter Nonesuch; 2, Duchess of Oldenburg; 3, Lady's Finger of Lincolnshire; 4, Margil; 5, Sam Young; 7, Grey Leadington; 8, Golden Reinette. (*W. Marshall*).—1, Royal Russet; 2, Cellini; 4, Golden Winter Pearmain; 5, Beauty of Kent; 7, Sops in Wine; 9, Ribston Pippin. Sorry we cannot name the others.

**Names of Plants** (*G. D.*).—*Menziesia polifolia alba*. (*H. J.*).—*Ceanothus azureus*. (*W. H. W.*).—1, *Eupatorium riparium*; 2, Too withered to be identified; 3, *Panicum variegatum*; 4, *Selaginella Wildenovii*. (*T. O. G.*).—*Bartsia odoutites*; it has no marked qualities, either beneficial or injurious. (*F. R.*).—*Amygdalus communis amara*, the Bitter Almond; its fruiting is not an uncommon occurrence in this country. (*J. T.*).—1, *Cratægus orientalis*, the Eastern Thorn; 2, *Cratægus Aronia*, the Aronia Thorn; 3, *Cratægus punctata*, the Dotted-fruited Thorn; 4, *Cratægus coccinea*, the Scarlet-fruited Thorn; 5, *Pyrus Aria*, the White Beam; 6, *Viburnum Lantana*, the Wayfaring Tree. (*P. N. P., of York*).—The tree is an *Amelanchier*, and probably *A. sanguinea*, but it is impossible to determine with accuracy from such a fragmentary specimen.

**Bees** (*Puddle*).—You had better procure our "Bee-keeping for the Many," which you can have in return for 4½d. in postage stamps sent to the publisher. Mr. Pettigrew's "Handy Book on Bees" would probably be useful to you. It is published by Blackwoods, and can be had through a bookseller.

**Making Syrup for Bees** (*H. M.*).—You will find the particulars you require in an article in our present issue. You cannot do better than follow the instructions on feeding that have recently appeared. The white substance which your bees are collecting is pollen.

COVENT GARDEN MARKET.—OCTOBER 5.

OUR market is now assuming a steadier aspect, consignments falling off, and prices are likely to be harder. Pines in good demand.

POULTRY AND PIGEON CHRONICLE.

CONTINUOUS CORN-GROWING AND CLAY FARMING.

(Continued from page 301.)

IN continuation of the narrative of Mr. Prout's proceedings in reference to this subject we find various matters of great practical importance to the home farmer will appear. To show how these matters have been estimated by the agricultural community we remember that another gentleman, Mr. Middleditch, decided upon farming pursuits in the year 1866, who after several years of commercial pursuits in India was struck with the accounts of Mr.

Prout's agricultural successes. A survey of the clean and beautiful crops at Sawbridgeworth made him an enthusiastic disciple, and he determined to prosecute the system at Blunsden, near Swindon, in North Wiltshire, where he had acquired a farm of 160 acres of heavy clay loam. But this small holding affording inadequate scope he purchased several other farms, making an aggregate of about 600 acres arable and 100 acres of pasture. The Council of the Royal Agricultural Society of England also, being desirous that the striking results of the farming by these two gentlemen should be investigated and made public, instructed Mr. Finlay Dun, of Weston Park, Warwickshire, to prepare a report of these two interesting farms for publication in the Society's Journal, which was published in 1875, 2nd series, vol. xi., part i., No. xxi. We commend this interesting and valuable report to the notice of home farmers generally, but especially to young men, who will find a fund of information narrated in a thoroughly intelligent and practical manner.

As we have previously given Dr. Voelcker's statement of the capability of Mr. Prout's farm, ascertained by analysis of the soil, we will now quote his observations as to the future ability of the land to produce valuable crops upon his present system of farming. He states, "No fear need be entertained that under this system of cultivation and manuring the land will be impoverished, for after twelve or fourteen years, during which I have watched Mr. Prout's farming operations, I can perceive no indications of incipient exhaustion, but, on the contrary, clear evidence of the great improvement which has been effected in once unproductive clay land; nor can I recognise any theoretical grounds for doubting the wonderful improvement which Mr. Prout has achieved in his land at Sawbridgeworth will be a less success in years to come than it has been in the past. I can see no reason why this system of manuring, and an occasional dead summer fallow, in order to give a thorough cleaning to the land, Mr. Prout should not be able to grow Wheat or Barley profitably for an indefinite number of years without injury to the land." This theoretical opinion must be accepted as correct, because it is justified by the practical results of Mr. Prout's management and the profits resulting therefrom; we therefore quote from a tabular statement of profits and prices, which shows "That the yearly profit of £1142 for eleven years, 1868 to 1878, has accrued under a general imperial average for July, August, and September, of 54s. 2d. for Wheat, 36s. 8d. for Barley, and 27s. 5d. for Oats. Prices were for the first seven years of the series, but the profit was less—namely, £1074 per acre; and for the last four years prices were lower, but the profit greater—namely, £1262 per year. The truth is that yield and expenditure have a greater influence upon profit than the price of corn has." This is very necessary to be remembered, especially in times of depression, when it is averred by many that corn will not yield a profit, but that instead of farming arable land their chief attention should be turned towards pasture and grazing land.

It is also important to know by statements up to last year from impartial judges the actual condition of Mr. Prout's farm in the year 1880. On the 23rd of August Mr. Finlay Dun reported as follows in the "Chamber of Agriculture Journal:"—"Notwithstanding the limited opportunity for keeping down rubbish this farm is cleaner than most in the neighbourhood, or indeed most elsewhere. Black Grass and wild Oats are the chief weeds; there is very little Twitch, and not any Docks or Thistles. Notwithstanding the scourging corn cultivation, the crops are anything but feeble, knee-broken, or otherwise indicative of exhaustion. I went over Mr. Prout's farm this week. His 436 acres are in a very satisfactory state. His crops are uniformly good. He has 158 acres of Wheat, in about equal proportions of Square-head (a useful, strong-strawed, white-chaffed red Wheat), and of Rivett's Bearded Wheat. Barley reaches 132 acres; as elsewhere, will

probably pay better than Wheat. The dripping season has suited the Black Tartarian Oats, which are a beautiful crop—strong, thick, and well corned, extending to 86 acres, some of the best pieces promising a yield of eight quarters; 16 acres were in tares, partly used green, the remainder yielding about 2 tons an acre of hay, which will be used for the horses cut into chaff, and given with a portion of the 4 acres of Mangolds. Giant Saintfoin in its second year in the worst field of the farm had done remarkably well; machine-cut, and luckily well made, about eighty horse-loads were five weeks ago cleared off 40 acres, and put into two ricks, for which £350 had been bid. Forced along by the summer rains a second cutting has since been well saved, and must be worth £150. Considering that the Saintfoin has had no manure this year, £12 an acre must be regarded as a very satisfactory return."

We have made this quotation as given by an independent observer, because it illustrates that in the nineteenth year of Mr. Prout's farming, while not his best because of the very moderate season of 1880, yet it is not an unfavourable member of the series, its produce not being forced by extra manure, and still betrays no decrease in the long-taxed fertility of the soil; nor is it easy to see anything likely to prevent the continuous corn-cropping under the same rate of manurial dressing, and the same complete and perfect mechanical tillage. Most practical farmers will note that anything like 50s. per acre as an annual dressing, which is necessary to the continuance of the system, is a serious item in the accounts; at the same time, however, it must not be forgotten that the produce of straw per acre when sold is worth this amount in nearly every district in the kingdom, and in some counties considerably more. The home farmer must also remember that he can do what he thinks advisable with his produce, not being hampered with the conditions of a lease, like most of the tenantry in England.

The steam tillage must now be referred to, as it is the most important factor in the system of cultivation both on Mr. Prout's and Mr. Middleditch's farms, for we find that steam has greatly contributed to the success on both these farms, at Sawbridgeworth and Blunsden. It has also enabled the work to be done thoroughly and economically, the land ploughed up early and whilst it was dry, and the seed put in seasonably. The steam tackle which has been used is a pair of Messrs. Fowler & Co.'s fourteen-horse-power engines, with ploughs and cultivator. The perfecting of the steam drill will considerably expedite and economise autumn labour, and render some of the various operations on the farms comparatively independent of horse labour, for it must be remembered that upon farms in general not only much costly labour incurred in root-cultivation and provision for sheep and cattle is entirely absent and comparatively unknown in the system upon which these farms under continuous corn-growing is carried on. With the steam drill which is necessary, made in two sections, each 10 feet wide, capable of sowing 40 acres a day, with both seed and manure, and with drags attached before and behind, the steam cultivator may be considered comparatively perfect. One of the greatest advantages attending the continuous growth of corn must not be overlooked, for under a close system of cropping, whether of corn or other crops, there is no time for Couch and weeds to accumulate in the land. This we have found in our own farming for many years past, although worked out only by horse power; yet we found that under a careful mode of forking-out Couch between the sowings of various crops the land became extremely clean, although we farmed on mixed soils, some of which being sandy loam very quickly would become foul and weedy under any of the ordinary systems of culture without the aid of steam power and autumn cultivation.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—The horse labour on the farm is now so pressing that it is rather difficult to say which should be done first. In case the most desirable work should be hindered by a spell of wet days the lea ground after Clover will always be fit for ploughing and pressing. We suggest that sowing Trifolium, Rye, Vetches, winter Oats, and Beans be finished as soon as possible. The best seedtime for Wheat on the hill farms and heavy tillage farms has now arrived, but upon the mixed soils and vale farms the best time will be between the 20th of October and the 14th of November. Autumn fallowing has been better done in most cases than in some previous seasons, and where the tillage has brought the couch and rubbish to the surface, and the weather unfavourable for burning, we recommend that it should be carted away to a heap to become fit for earthing the cattle boxes or for laying out upon pasture land as a dressing in lieu of dung. It often proves equally valuable for such a purpose as dung itself, partly on account of the earthy materials contained in it as well as for the vegetable substances in decay. We prefer sowing Wheat after the presser, or otherwise employing a

drill-presser whereby the seed falls into the press grooves, instead of drilling the seed, especially upon lea ground; for where the ground is properly pressed and seeded it can be horse-hoed or hand-hoed in the spring. The question of distance between the rows in drilling is important, and we prefer under ordinary cultivation the 10-inch space; but on good land in high condition we think 12 inches the best distance, as the straw will generally grow stiffer and not be so likely to go down before harvest. Besides, on some heavy soils, if the season should be adverse and the Wheat plant in the spring becomes weak and the land weedy, the horse hoe can be applied and worked at a depth which will move the soil well between the rows. This matter is often the only way to rally and improve the growth of the plant, a horse-hoeing being frequently equal in effect to a dressing of 1 cwt. of nitrate of soda per acre.

**Hand Labour.**—Spreading and filling dung will be going on, also hedge-trimming, and upon the flat-lying strong soils the water-furrowing after the Wheat is sown is a very important matter, taking care that they be made out several inches deeper than the land furrows; this is essential, even after the land is perfectly pipe-drained, in order that the surface may be freed of superfluous water as quickly as possible. Upon the home farm the underwood in the coppices and hedgerows should now be cut and made into hurdles both for use and for sale, as they are much sought for by flockmasters for folding their sheep. In case of land coming to hand on the estate which requires draining it is now a good time to commence the work, as the autumn rains will soon show the wettest parts of the land; but in any case test holes should be dug to ascertain the nature and variations of the subsoil before commencing the work.

**Live Stock.**—The purchase of sheep for the winter feeding of roots still continues. The great fair for the sale of Hampshire and Wiltshire down sheep will be held at Weyhill in North Hants on the 10th inst. The great fair for the sale of the horned Dorset and Somerset will be held at Appleshaw near Weyhill a few days previously—namely, from the 7th to the 9th inst. This is called a show fair, the animals being exhibited in the grass plots instead of being penned close within hurdles, as usual at other fairs, and the cws being forward in lamb it is better for them. Much business is, however, done on the farms where these horned sheep are reared in the counties of Dorset and Somerset, the animals being purchased at home and driven direct from their native pastures to the home and southern counties, where they are kept in large numbers and furnish early lambs for the London market. It is now a good time to purchase bullocks for box-feeding, as the Cabbage and early roots and Carrots are now ready for use; but instead of buying cattle only in store condition we prefer to take up animals about half fat, or just beneath the butcher's quality. Such stock bought now and well fed, with a moderate allowance of cut roots mixed with cake and bean meal, will pay better and be ready sooner in the spring than poor stock when bought in. In the southern and eastern counties Devon and Hereford cattle are preferred; in the northern and midland districts Aberdeens and Shorthorns prevail. All of these, especially if pure-bred, yield a fair profit for about twenty weeks' feeding. It is, however, preferred by some farmers, and we also approve it, to buy in good short-horned cows with calf at foot, and feed—instead of fattening bullocks—and either sell the milk or rear the calves for veal. In either case if the cows are kept at the same cost as a fattening bullock the well-bred stock of Shorthorns will fatten well during the milking period, and whether milk is sold or veal made it matters not—the important point is good feeding and careful management. All the young cattle, both calves and yearlings, should now as the nights get longer be accommodated with a dry pasture or paddock at night time, where they may also receive their allowance of cotton cake and meal in troughs mixed with cut roots or Cabbage. This will keep them in condition and probably avoid the disease called quarter-ill. Farm horses will in many instances be foddered with young Clover cut up, for we find both young and old Clover grown fit for mowing since the late rains in various localities.

#### VARIETIES.

**CANARIES BECOMING BLIND.**—I have four Canaries each blind with one eye, none of them very old, and one this year's bird. The eye appears slowly to shrink away. I am afraid there is no cure after they have become blind, but I should be glad to know the reason, and if I can do anything to prevent it. I feed my birds on Canary seed, rape, millet, broken groats, and a little hemp. One bird I have given away is blind with both eyes. These birds do not all belong to the same family.—E. M. S.

— **FARM PRODUCE IN 1800.**—The following note extracted from a "Whittlesey Farmer's Diary" has been sent to us by a correspondent—"1800, July 7th, Wheat was £7 7s. per quarter, beef 9s. 6d. per stone, mutton 8d. per lb., pork 9s. 4d. per stone, Barley £4 4s. per quarter, flour 5s. per stone. 1802, July 15th, a frost—ice as thick as a shilling."

— "ELECTRICITY," says a daily paper, "is gradually finding its

way, in some shape or other, into nearly all the chief industries, its latest utilisation being in the production of cheap alcohol from Beetroot. The current is passed through the crude spirit obtained by the distillation of the Beets, and the result is the dispersion of water by the liberation of hydrogen in electrolysis. Probably some of the spirit thus procured will be used for fortifying wines and adulterating brandies; but alcohol is now used to such an extent in the arts that the process will probably be developed extensively, and its discovery may lead to the extended cultivation of the Beetroot for other purposes than cattle-feeding, sugar-making, and dye-stuffs. The cultivation pays well in Germany and France, and it might possibly be found profitable in this country."

— **THE HARVEST IN MANITOBA.**—The correspondent of the *Daily News* sent the following cablegram from Montreal last Friday—"The harvest in Manitoba is very abundant. The average yield of grain is extraordinarily high. The average of Wheat per acre is twenty-eight bushels, or ten bushels higher than the highest average ever reached in Minnesota, which is the best Wheat-growing State."

— **AMERICAN FARMS.**—In an interesting work on American farming recently published, the author, Mr. Finlay Dun, directs attention to the diminishing size of the farms in the United States, the official returns showing that while in 1860 the farms averaged 190 acres only, the average fell in 1870 to 153 acres, and it is still diminishing. The farms in the New England States are, it appears, under 100 acres. The largest holdings are in California.

— **FARMING IN NEW ZEALAND.**—A correspondent writes from Nelson to a contemporary as follows:—"Most of the pamphlets written to promote emigration dwell largely upon the productiveness of the soil, but what is the use of large crops if there is either no market for them or the price offered is less than their cost? I know a farmer who grew some excellent Barley this year, and he cannot get 3s. a bushel for it. The same farmer sold fifty fat sheep for £20. Where is the profit to come from? In the Nelson Auction Rooms last Saturday I saw good cheese sold for 3d. to 4d. per lb. Who would make it for the money? A good fat bullock will fetch from £7 to £8. Thousands of bushels of Oats have changed hands for from 1s. to 1s. 6d. a bushel, though the price is now somewhat better when the unfortunate producer has none to sell. Farming, as a rule, does not pay in New Zealand any better than at home, and with my enlarged experience I would now earnestly recommend a considerable pause before any distressed English agriculturist resolves on the transference of his capital and energy from the English shires to these New Zealand solitudes. I know a good deal of English farmers, having been amongst them all my life, and I know a little about New Zealand farmers, and I have no hesitation in saying which I deem the better off. Only let men at home resolve on doing what they must do here in order to live—put their own shoulders to the wheel somewhat more, and put the drag on their household expenditure a good deal more—and a measure of calm enjoyment of life largely exceeding that to be secured either in Australia or Canada will be ensured."

— **LARGE CARGO OF AUSTRALIAN MEAT.**—About 150 tons of frozen meat, consisting of the cargo cases of more than three thousand sheep, arrived from Australia on Monday at Plymouth in the *Orient*. This was the full quantity that the vessel could accommodate. The meat was preserved by the refrigerating machinery patented by Mr. Haslam of Derby, and it is stated that the system has proved very successful.

#### ENTRIES AND PRIZE MONEY.

VARIOUS methods have from time to time been tried by the committees of poultry shows to meet cases where the entries in a class are too few to pay the prize money. Some schedules announce that if there are less than a certain number of entries the first prize will be withheld, others that in the like event first

prize only will be awarded. The Committee of the Hemel-Hempstead Show, which was held last week, adopted the somewhat sweeping rule, that if in any class there are less than ten entries that class shall be expunged from the list and the entry fees returned.

We think any rule of this kind objectionable, and that adopted at Hemel-Hempstead will probably be found to be detrimental to the long-run to the interests of the Show. An exhibitor who has once had his entry returned is not likely to enter again at that show. He will rather choose some other where he is certain of having his birds exhibited in any event. Accidental circumstances may one season lead to a want of entries in a generally well-filled class, and the fact of the disappointed exhibitors declining to come forward the next season will again cause a dearth of entries.

The rule in question bears hardly also upon visitors to the Show coming from a distance and finding that their favourite breed has been altogether or in part removed from the list. The Dark Brahma fanciers, for instance, who found that there were no cockerels exhibited in consequence of there having been only five entries, must have had a feeling that the inspection of even five cockerels would have given them a better idea as to how the youngsters were likely to turn out this year than the perusal of the statement in the catalogue, "Five entries—removed from list."

The general question is a difficult one to deal with, but upon the whole we think committees would find it to their advantage to omit any rule of this sort, and, framing their classification upon their past experience, rely upon the excess of entries in one class making up for the deficiency in another. This would generally be found to be so. Take the Brahmas at Hemel-Hempstead as an example. There were in the three classes which remained forty-four entries. If to these we add the five returned entries in the dark cockerel class we get a total of forty-nine entries, or an average of twelve and a quarter over the four classes. If we extend the average system to the thirty-six poultry classes, we find that there were 364 entries catalogued, which with thirty returned entries—representing seven expunged classes—gives a total of 394 entries, or an average of almost eleven entries per class. It is true that the return of those thirty entries enabled the Committee to effect a saving in prize money and pen hire of about £15, but, if our view be correct, such a saving is dearly bought.

If it be absolutely necessary to introduce such a rule into a schedule, we think the form which provides for only first prize being awarded is the least objectionable of those which we have seen. The withholding of first prize, except for want of merit, is a course which has the practical effect of much lessening the honour of winning. The fact that most exhibitors think more of the honour of winning a prize than of the amount of the prize money, leads us to suggest that a rule might with advantage be adopted, that if there were less than a certain number of entries in any class the prizes would be only one-half the amount stated in the schedule. This would still leave to the exhibitors the honour of winning and a fair proportion of the prize money, and would relieve the committee from a part of the burden of finding prize money.

What may be termed the co-operative principle has in some few cases been adopted. By this plan the entry fees, or a part of them in each class, are offered in certain proportions as prizes in that class. We do not know what amount of success has attended this experiment, but we hardly think it likely to succeed generally. It has too much of the gambling character about it to be acceptable to most fanciers. A rule such as we have suggested would, we think, effect all that is desired by exhibitors and committee men, and still leave sufficient certainty as to the amount of the prizes.

#### POULTRY NOTES.

A MOST successful show of poultry and Pigeons was held on Thursday in last week at Newnham in Gloucestershire. About 120 pens of poultry appeared, and nearly 300 of Pigeons—a wonderful entry considering the moderate prizes offered. The Jacobin, Turbit, Tumbler, and Dragoon classes were specially strong. Mr. O. E. Cresswell was the Judge.

THE uncertainty of English law is proverbial; still we were a little surprised at the legal opinions lately obtained by the Poultry Club concerning owners bidding for their own birds at exhibition auctions. It seems in the opinion of two eminent counsel that unless an auction sale is advertised as "without reserve" owners can bid for and buy-in their own birds equally in open and in selling classes. This opinion is contrary to more than one County Court decision. So much corruption has at various shows been

the result of this buying-in of selling-class birds by their owners, that should this opinion prove to be really the law we trust that selling classes will promptly be abolished at all well-managed shows, or that at least a carefully worded rule will be introduced into schedules to prevent such buying-in. To owners openly bidding for their own birds in open classes we never could see any objection, but the Poultry Club will do good service to the cause of honesty if it withholds its support from all shows where it is possible for dishonourable traffic to be carried on through selling classes.

THE same opinion raises a somewhat awkward question as to whether it may not legally be in the power of exhibitors to withdraw their birds from sale during a show.

WE have seen late broods of Turkeys suffering much from rheumatism of the hock joints. Some of our own (cooped too long on grass we believe) suffered to such an extent that their legs became completely bowed and distorted, and they could hardly walk. On removal to a dry house where all can perch they have completely recovered, and their legs are again perfectly strong and straight. This may be a hint to breeders of late Turkeys. It is only another instance of a fact upon which we have often remarked, that with young Turkeys as long as there is breath there is hope, not only of their living, but of their turning out fine and healthy birds.

WE remarked some weeks ago that our ducklings, and those of neighbours too, were suffering from leg-weakness and apparent convulsions, from which many died. We have since discovered that the leg-weakness was the sole malady, and is easily curable. The convulsions were only the ineffectual efforts of the poor little things to get upon their legs again, and their repeated struggles exhausted and killed them. We shut our own up in small dry pens on straw where they had little room to roll about, and in a week all the survivors were completely cured. Those which thus suffered in our flock were all Pekins.

SPEAKING of Pekins we cannot but remark that they are most disappointing birds on the table. As layers they are certainly unrivalled, but their size is more apparent than real, as the scales soon show, and for table Ducks we intend to return to old-fashioned Rouens and Aylesburys.—C.

#### OUR LETTER BOX.

**Pekin Ducks (Woolhampton).**—You will find an article on this breed in our number for March 4th, 1880 (vol. xxxviii., page 188), and some further notes in the number for July 8th of the same year (vol. i., new series, page 40). See also the above note. They are useful birds for laying.

**Ring Doves (N. C.).**—The Ring Dove is the Wood Pigeon or Cushat, and is perfectly hardy. Perhaps your question refers to the African Ring Dove (*Columba risorius*), which is somewhat like a Turtle Dove, and is not perfectly hardy in this climate. It must not be kept too warm in winter, but merely sheltered, as if in a shed or dovecote.

**Silver-Grey Rabbits (N. C.).**—You do not say where the Rabbits have been kept. If they are in a damp place where there is not an abundance of fresh air this will account for their dying. A cool orchard house will suit them very well. They require to be kept in a dry airy place.

#### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

#### REMARKS.

25th.—Wet early; fine, bright, warm day.  
 26th.—Fine bright day, but with one or two very slight showers in morning.  
 27th.—Dull cloudy day.  
 28th.—Fine, bright, and pleasant.  
 29th.—Fine but rather hazy; dense fog early.  
 30th.—Dense fog early; fine bright day.  
 1st.—Fine bright day, with cold easterly wind.  
 A fine bright week with no measurable quantity of rain, two dense fogs, and some cold easterly wind at the close. Temperature a little above the average, but nearly 5° below that of the preceding week.—G. J. SYMONS.

### PEARS FOR WALLS.

**N**OW that the period of the year is approaching for the planting of fruit trees, and as Pears will naturally receive their fair share of attention, it will not, perhaps, be wasting the space of the Journal by inviting those who are interested in producing fine walls of Pear trees to consider, if the force of modern ideas will permit them to do so, the possible advantages of the old system of culture that our grandfathers adopted with such marked success.

Without finding any serious fault with the fashion of the times, which impels almost everybody to plant trees on precocious stocks with the object of securing quick returns, it is yet worthy of some thought whether it is altogether wise to ignore the advantages of trees on the Pear stock for covering walls. For certain purposes the Quince is undoubtedly a valuable stock for a great number of Pears, but not for all, and in light and moist soils it is, perhaps, especially suitable; it is not surprising that it is used, yet in good sound soil it is not possible that such grand trees can be produced on it as on the Pear stock.

"Once upon a time," say a generation or two ago, the pride and glory of many a fine garden consisted in the splendid and splendidly trained specimens of trees on walls. Many gentlemen and gardeners who have passed the meridian of life will readily call to their recollections walls covered from base to summit with grand trees having branches equidistant from each other and as straight as gun rods, with strips of wall just visible, but not obtrusive between, the said branches being from 30 to 40 feet long and wreathed with fruit from end to end, the produce of each tree being computed by bushels and not by dozens, as is the fashion now-a-days.

Some such trees as those referred to are to be found now, but they are few and far between, and about equally seldom do we find a steady endeavour made to produce such samples of skilful culture and training as were produced by the gardeners of the past. Walls which in those days were furnished so completely and faultlessly, are now in too many instances mere examples of pomological patchwork formed by trees of all forms, half of them worked to death by too early and too heavy cropping, and the remainder miserable apologies for trees as regarded from the standard of the old masters of the ante-bedding and Coleus-growing period that has for the last few years appropriated the intellects and absorbed the "skill" of young men of the present day, and the culture of hardy fruits and outdoor gardening generally appears to have been proportionally neglected.

Puny pyramids on the Quince stock, pinched and root-pruned to accelerate their cropping and shorten their lives, are adapted for certain positions, and under some circumstances may be of temporary service. French cordons at different angles, and in grotesque shapes, may please the novelty-seeker, and some trees of the modern type well grown may be and are useful; but that they should drive the true old English-trained trees from English gardens is at least undesirable. While it would be obviously unwise to refuse to adopt a new system possessing some points of excellence, it does not follow that it should be carried out to the extent of annihilating what is good of older methods.

No one having experience on the subject can say that garden walls are, as a rule, covered as well in 1881 as they were in 1841. "The seasons have altered," some may say, "and Peach trees must have glass now." Granting even all that, which is, perhaps, granting too much, the objection has no force as applied to Pear trees; yet Pear walls are certainly not what they once were, and is not the great or initial cause of this the custom that has become established of planting trees on Quince stocks almost exclusively? If not, what is the cause?

Partly in consequence of much that has been written in the press, and one writer parodying another, and partly from taking catalogue guidance, which is necessarily brief even if some of it is good, it would almost seem as if the majority of young gardeners had forgotten, if they ever knew, that Pear trees will thrive on Pear stocks! Let me remind them that they will do so, and let me also say that on no other stock can such grand trees be grown and walls satisfactorily furnished.

Let gentlemen and gardeners who have new and lofty walls to cover with Pears, seriously consider the advisability of planting healthy trees on the Pear stock 24 or 30 feet apart according to the nature of the soil, and devote to these trees the attention that is requisite for producing superior specimens, and they will have fine fruits in a few years, and will leave evidence of their skill and abundance of fruit for future generations. In the meantime the spaces can be occupied with subsidiary cordon trees on the Quince, that will give immediate produce and wear out their little lives before the true old English trees have arrived at maturity. A wall of diagonal cordons, it is true, is attractive, but it appears to me that the great mistake that is made generally is planting one tree each of as many "cordons" as the wall will accommodate, and the results are, so far as I have seen, much too little fruit of the really first-class Pears, and too much of varieties of less dessert merit. With fine trees of the standard varieties on Pear stocks there is an abundance of fruit for use, and a surplus for friends or the market. These remarks are not so much directed to amateur fruit-fanciers as to those whose chief duty it is to maintain a large and long supply of excellent produce, and at the same time restore what is almost a lost feature of many fine gardens—noble wall trees.

The tendency to Frenchify English gardens is rather too pronounced, and especially as the result in nine cases out of ten is not good French but bad. Instead of bad French, then, I plead for a return to good old English in the culture and training of Pear trees on walls. Are there not readers who share in this desire, and who at the same time are

able and willing to say how the work should be done?—  
JOHN BULL.

#### PRIMROSES FROM SEED—PRIMULA CAPITATA.

THE same class of plants requires different treatment in different soils, and I find that in strong retentive soil nearly all the Primrose tribe succeed best when treated as biennials. In such soils the rootstocks and crowns become clubbed together in such a compact mass that successful division is hardly possible. When seed of the previous year is sown in early spring good flowering plants are ready for the next spring and are at their best in their second spring, after which they die off or flower badly, and are not worth the room they take. Some of them, however, grow so coarse as to be almost past flowering at two years old, and a better plan is to sow the seed in June as soon as ripe. These plants will be rather small in their first spring, but in the second year will be better than older plants.

What I have said applies not only to the coloured varieties of *Primula acaulis* and *Primula elatior*, the old garden Primrose and *Polyanthus*, but also to the Alpine Auricula and to most of the stronger species of Alpine, Himalayan, and Japanese Primrose. *Primula cortusoides* and *P. involucrata* and some others succeed well when divided, so does *P. farinosa* if care is taken to plant it deep in the soil, otherwise it invariably pushes itself out of the ground and so perishes. In its native place the plant seems to die from this cause at the age of two or three years.

Amongst the Primroses which do well the first and second years from seed, but deteriorate after division, I may mention *P. denticulata*, *P. cashmeriana*, *P. rosea*, and *P. capitata*. With the last-named, which is a comparatively recent introduction, I have been so successful that a description of my treatment may be interesting to those who wish to grow it. Early in the spring of 1880 I obtained three or four plants, probably seedlings raised in 1879. These began to flower about the end of May, and in a month there was ripe seed. I sowed some at once in a shallow seed pan, which I put into a cold frame to protect it from the splashing of heavy rain, and in a week the soil was covered with young plants. Their growth was very slow at first, but I transplanted them into shallow pans as soon as they were large enough to handle, and again as often as their growth required it. They were wintered in cold frames or a cool greenhouse, and grown on without ever losing their leaves, requiring no attention but transplanting when they became crowded.

At the end of March I had upwards of a thousand healthy little plants, measuring from 1 inch to 2 inches across. From this time they grew rapidly. Many were planted out in different situations and aspects; and I find that, whilst they do best in moist soil and an open situation on rockeries, they fail nowhere. They began to flower about the end of June, when just a year old, and have continued to grow and flower ever since. Some of them have now five or six umbels of flowers and as many separate crowns. Others, perhaps one-fifth of the whole, have perished in the effort of multiplying their crowns, the crowns and rootstock having clubbed together in a hard lump.

A second sowing from the same seed made in March this year came up slowly and sparingly; but some of the plants are already flowering. These will give me more trouble to winter than smaller plants would do, but will probably flower all through the spring. Of the original plants, three in number, I divided one which had four crowns into four plants, which I potted singly. All of these died but one, and that never made a good plant. The other two old plants I left out on my rockery; they lived through the winter and tried to keep their leaves, but the collar of the plants decayed in early spring and they were lost. I may say, in conclusion, that though my garden is well stocked with hardy plants of all kinds, nothing attracts more admiration than my border edgings of *Primula capitata*, which now, on the 3rd of October, are still fresh and gay. The colour of the flowers varies from lavender to dark violet. Before the last flowers on the umbel are open the seed on the earliest flowers of it is ripe; but owing to the ungenial August seed has not been produced very freely this year.—C. WOLLEY DOD.

#### THE USE OF FIRE HEAT FOR GRAPES.

I AM much obliged to your correspondent "SINGLE-HANDED" for his perfectly disinterested remarks in my favour, for I have not the least idea who he is; but he will excuse me saying that he is hardly correct in his surmises that I rob Peter to pay Paul by burning coal in autumn to make up for lost time by low temperatures in spring. I think I had better state the dates of the starting and finishing of some of our crops that afford a fair criterion in

the matter, and then your readers can judge for themselves whether or not the crops are longer in ripening than those which are treated to high temperatures. I cut the remainder of our late Grapes about the end of February for storage in the fruit-room, and started the Vines at the beginning of April, but the buds were swelling for two weeks previously. They grew quickly and were in flower the first week in May, when the nights were cold and frosty, so that the temperature fell low at nights, the fire being allowed to die out in the afternoons. The day heat rarely exceeded 80° or 85° maximum during the summer, and the Grapes were nearly all coloured black at the time of the Edinburgh Show, as my exhibit showed, but they were not ripe enough to eat. By the end of September, however, they were ripe generally, and since that period have been kept cool and dry. The Hamburgs—a late house—were allowed to come on about the same time; and as the crop is used in October when company is at the Hall and at the pheasant-shooting in November, fire is rarely employed at all during the season, and they are ripe at the beginning of October. We have been cutting them for a week. The Muscats were started at the middle of February, and are quite ripe now (October 6th), but earlier bunches were cut ripe some weeks ago. A second Hamburg house started at the 1st of January produced ripe fruit the first week in July at the warmest end of the house, and at the coolest end two weeks later. The spring was very cold and unfavourable, and during the early stages of growth the night temperature was often very low, and continually so when the Vines were in flower—frequently below 50°.

I treat Peaches just the same as Vines, subjecting them to a proportionately low temperature, that in early houses frequently falling to 35° when the trees are in flower, and no attempt being made to keep them above 40°. From a Royal George Peach started last January 1st two and a half dozen ripe Peaches were gathered and sent to London on June 13th; and from a Victoria Nectarine at the far end of the house, where there is a coil of hot-water pipes less, the first dish was gathered July 16th. The Victoria is a late kind. These trees were not hurried in the least, and these two trees bore sixty dozen fruits together. Black Prince Strawberries introduced into heat the second week in December produced ripe fruit the first week of March, and the fruit was ripe in quantity by the middle of that month. Madame Hericart de Thury was about ten days later. There was no hurrying here either. My theory is that low night temperatures in the early stages of growth do not retard maturity, or at least very little. I make the most of the daylight and the sunshine, but I do not practise higher day temperatures than other people. With regard to the statement that Grapes cannot be ripened to perfection "so late as the end of September or October," how about Grapes ripened at the new year? I have never tried to ripen our late Grapes before October, and they always finish well and keep well, and when I have had any surplus fruit to dispose of I could always obtain the highest price for it. My neighbour, Mr. Batley of Wentworth Castle, ripens his Alicantes later than we do, and his crop never fails to ripen or to keep. In April one year he was awarded the Royal Horticultural Society's first-class certificate for his Grapes, and he afterwards sold the same bunches for 20s. per pound in Covent Garden! He is the best grower and keeper of late Grapes I know. It is not so long since he received 15s. per pound for his Alicantes some time after the new year, and I have received nearly as much frequently. Mr. Batley's Grapes have been fruited for some dozen years or thereabout and have not yet missed a crop, and I never remember them being ripe at the end of September in any season.—J. SIMPSON, *Wortley*.

P.S.—I find on comparing notes with the foreman that I am slightly in error about the Peach house, which was closed on the 14th of December and began to be fired during the day in January. The other dates are correct. I may also add that I advocate low temperatures both on the score of economy of fuel, which in my case at least is no fiction, and the health of the Vines. I may say that we rarely ever find a shanked berry in any of our vineries. I never scrape, paint, nor wash the Vines, and I do not think anyone could show a cleaner bill of health. Spider and thrips will never be troublesome under low temperatures. May I ask your correspondents if they can point to any spot in the world where Vines thrive well naturally where the mean night temperatures approach those recommended under glass in this country by the advocates of high temperatures?—J. S.

VIOLETS.—How well the London, Russian Suprb, and Floribunda Violets are blooming this autumn! Victoria Regina, on the other hand, only produces very few blooms; indeed I am afraid that this fine Violet cannot be classed amongst the autumnal bloomers, at least this I yearly find to be its character here. It is,

however, splendid in spring. The new double De Parme has not bloomed this autumn as yet.—GEO. W. BOOTHBY.

#### STANDARD ROSES.

ONE of your correspondents, "H.," in last week's issue mentions a fine standard Rose at Redhill, and asks some questions as to stocks and other matters. I hardly dare reply on such a point, and can only say that if you receive replies from a source better qualified, commit mine to that sanctum of an editor, "the bourne from which no" manuscript "returns." The size of standard Rose trees depends on several matters, and, as I think, grand growth of standards is only obtained when there is perfect accord between stock, scion, situation, and soil. When these all agree it is quite possible to have such a tree as your correspondent describes, and, when obtained, I grant its beauty; but in an ordinary way and in certain localities I have hardly a word to say in favour of the mops.

What, then, are the conditions that go to make a grand standard Rose tree? First, the situation must not be too exposed to rough winds, and the soil must be good—these apply perhaps to all Roses—then a good straight and thick stock must be selected; it should have plenty of small fibrous roots, and the Dog Rose from which it is taken should be free in growth. I do not believe in small stocks for standards. But now comes the question, What Roses budded on this stock will so progress as to furnish a good head and merit the name of tree? Some certainly amongst our best Hybrid Perpetuals will flourish on it, though possibly not so grandly as that mentioned by "H.;" but Charles Lefebvre, Pierre Notting, Abel Grand, John Hopper, Madame C. Joigneaux, will certainly make good trees, and often Marie Baumann, Duke of Edinburgh, La France, and a few others will form very respectable heads. Many of the Teas will also succeed well and be masses of bloom, small, perhaps, but lovely. Gloire de Dijon, however, if allowed, will surely be found grand. But it strikes me that the Rose tree mentioned belongs to neither of these varieties. There is one other kind that seems to me *par excellence* the scion that will furnish on standard Briar such a tree as that which charmed your correspondent, and that kind is the summer Rose. Charles Lawson and Coupe d'Hébé will both make fine heads, and I should never be surprised at seeing trees such as "H." describes when a good Briar is budded with a summer Rose. It has always appeared to me that between the summer Roses and the Briar there is a perfect understanding—"you do your part, I'll do mine" sort of contract, which results in success. The main point, as I believe, for growth, is that there should be this thorough agreement between stock and scion—a suitability for each other—which after they have taken each other "for better, for worse," leaves no room for fallings-out. Often have I seen these Roses a mass of bloom, for the summer Roses are truly floriferous, making up for the non-continuance of bloom by its abundance during a short period.

At the present time I have a Charles Lawson standard that disdains any support, standing erect and displaying wondrous beauty until last winter's frost injured its proportions. Its stem must rival in diameter that mentioned by "H.," and the top of the head must be 8 feet from the ground. It is certainly sixteen or seventeen years old, and a hundred blooms must have been cut from it in some seasons. When I came to my present abode some fourteen years ago I found a standard at the top of a bank. I do not know the Rose. For exhibition purposes it is valueless, but I have allowed this tree to grow as it pleased. The head must be 6 or 7 feet through, and it is very beautiful from the quantity of flowers produced. It also is a summer Rose.

To obtain any sort of Rose in perfection the stock must suit the scion, and the latter the stock; and further, the stock must suit the soil. In hungry soil the Manetti and the seedling Briar will make a head, where the standard Briar, not seedling, quickly pines away. Some people say, "I have tried Roses and they never succeed here;" but it is unfair to say this until they have tried the various stocks. A few Roses on their own roots produce better results than on any stock. Some years ago I recollect there was a "stock" election, and if I am right the result was a qualified one depending on the soil, but Manetti obtained the greatest number of votes.

Perhaps now "H." has referred to this matter he will kindly take the trouble to enlighten us a little further, and let us know, if possible, the stock, the name of the scion, and something of the soil. It will interest some of your readers.—Y. B. A. Z.

#### BOILERS v. WATER.

IN his interesting article "Boilers v. Water," Mr. J. Ollerhead asks the question "How are we to prevent the furring of boilers?"

This is a serious consideration, and of great importance to all who are interested in heating glass structures; and I hope those who have had this difficulty to contend with will be able to recommend some remedy, as, doubtless, many who are situated in districts where the water is hard have found it necessary to try various methods to prevent furring. When the water used is hard the sides and top of the boiler soon become incrustated with a hard substance that accumulates until it seriously interferes with its heating capabilities. This, when possible, should be chipped off at regular intervals. With most boilers used for horticultural purposes this is impracticable. The furring may, however, be greatly checked, and in some cases prevented, by the regular use of common soda crystals. I have frequently recommended them to be dissolved in the water for feeding large boilers used for driving machinery, and in the last case the person in charge of two large ones informed me recently that he was now using soda to prevent incrustation, and found it very beneficial.—J. H. S.

#### DRACOCEPHALUM SPECIOSUM.

A PRETTY hardy plant, which in the southern counties prolongs its flowering period into October, is *Dracocephalum speciosum*, and as flowers become scarcer in the borders every occupant that

Fig. 54.—*Dracocephalum speciosum*.

continues in any degree bright and attractive seems invested with far more interest than it would earlier in the year. In late September, and October too, there is such a preponderance of the Compositæ that any distinct variation from the uniform floral characters marking that great family is especially welcome. This plant is really no trouble to grow, succeeding in ordinary border soil provided there be not too much stagnant moisture about its roots. The colour of the flowers is bright rosy purple, and stems are usually about 2 feet high, closely set with blooms upon the upper portion.

The woodcut (fig. 54) showing a spike of flowers and the upper

narrow leaves, was prepared from a specimen furnished by Mr. Parker of Tooting, where *D. speciosum* and several other species thrive particularly well.

#### RAITT'S STRAWBERRY BOXES.

By the courtesy of Mr. Raitt, who wrote those admirable articles in the Journal on Strawberry culture, I have received a sample box such as he packs his fruit in, and it is evident, as he says, that the fruit will travel hundreds of miles in such carefully contrived packages. However, the weight of woodwork is a little over a quarter of a hundredweight, and the nett weight of fruit it will contain only about a half hundredweight; the tare is therefore about 33 per cent. of the gross weight. This is a drawback where horse carriage is concerned, although only a matter of a few shillings per ton by rail. The "crate" is 26 inches long, 17 inches wide, and 12 inches deep. It holds three layers of little quart boxes without lids, the layers being separated by trays. It appears to be neat, compact, and admirable, not much more expensive than our punnet system, and certainly less likely to bruise the fruits. Has anyone else seen a better plan?—FRAGARIA.

#### HARDY PLANTS—PREPARING THE BORDERS.

BORDERS of mixed hardy flowers are now becoming fashionable, and there is much anxiety to obtain that practical knowledge which is so essential to successful cultivation. I have made these borders and plants a part of ordinary garden work for several years back, and I think that the details of the management may be useful to many readers who may wish to grow the best hardy flowers. Be it understood, however, that I am not a very great admirer of this style of flower gardening. I occupy the position of a gardener whose aim it is to make the most of the gardens I have under my charge, and therefore try my utmost, as far as means permit, to make the gardens interesting, varied, and enjoyable.

It used to be the invariable practice of gardening writers when treating on the culture of a plant to begin by detailing its history from its selection as a cutting, the potsherds, washing the pots, the mode of using the potsherds as drainage, how to procure and prepare the soil, how to fill the pot with soil, and the exact depth, how to insert the cutting, and so on through every item of detail in the history of the plant. It was a good old system, and I will follow it in the present case, and tell in the first place about the border and how to prepare it, and on the foundation thus laid give as much practical information as I can.

A truism in the pursuit of horticulture in all its branches is the impossibility of doing anything too well, provided the work is followed intelligently. This is as true in reference to the preparation of borders for the growth of these plants as to anything else. Therefore, if I had a border of bad soil, subsoil especially, to deal with, and could obtain means of doing so, I should remove much or all of what was really bad, and introduce good soil in its place. In the majority of cases such a proceeding would be impossible. A new Vine border is a difficult operation with many of us, and new flower borders are not to be thought of. I remember once commencing to renovate a border on which Cabbages would not thrive. Within easy wheeling distance was a large heap of decayed rubbish, quite beneath everyday attention. The border was trenched deeply, some of the worst of the soil removed, and the heap of rubbish made to fill the vacancy, where it proved of no slight benefit. Without the application of any manure *Gladiolus* attained to the height of 6 feet, while *Delphiniums* became giants—over 9 feet high.

Such measures, however, are not required everywhere. In ordinarily well-cultivated soils nothing more is necessary than a thick dressing of manure, 6 inches in thickness at least, then trenching the ground 2 feet deep. If the subsoil has not been cultivated do not turn it up to the surface, but mix manure with it and loosen the bottom. Many hardy plants, often the most effective, root deeply. The stronger growth of these will well repay the extra work. The manure I prefer is a mixture of material from the cowhouses and old hotbed manure. If possible have this work done in October. In spring, as soon as the ground is dry enough, spread 2 or 3 inches depth of light manure over the entire surface of the border, and point it in from 6 to 9 inches in depth. Any particular flowers, such as Phloxes, Dahlias, Hollyhocks, or Carnations, which I like to specially encourage, have in addition a compost of loam and manure, sometimes with chemical manure added, prepared for them. A spadeful of this compost is mixed in the border and the plants placed out in the position thus prepared. A border like the above I find suits plants very well for three years, at which time the whole border should be

emptied and retrenched in the same manner as at first. Many plants require lifting every year, and some become too large if left over two years. The proper way to treat all such is to give them some fresh compost, as I have recommended for Phloxes, and replant the divided pieces in what is virtually fresh soil. If by any means the border cannot be retrenched at the time recommended, fresh soil will be required as a surfacing to at least the front of the border in order to keep the border up to the proper level, and also to keep the plants in robust health. But surface dressings are not so good as periodically trenching and manuring the ground. Annually pointing the soil is not good policy.—R. P. BROTHERSTON.

#### SCRAPS ABOUT FRUIT.

WHEN I penned my last letter on this subject I never anticipated such a general response. The letters published last week show in a marked manner how much latent practical knowledge there is on the subject of fruit, and not less clearly do they show that there is a generous disposition to advance what may be useful when it is known that a record of simple facts is acceptable. Is it possible that any one man could have written a page and a half on fruit, and embodied so much varied and practical information as is contained in the isolated scraps that appeared in your last issue? Several hints there recorded are of great value to me, as I doubt not they are to many others, and I shall look with interest for other odds and ends of fruit experiences that I am sure are too good to be lost. I intend ordering The Czar Plum, Cox's Pomona, Ecklinville Seedling, and Wormsley Pippin Apples, and Baronne de Mello Pear.—A COUNTRY SURGEON.

JEFFERSON PLUM.—This Plum is known to a great number of people, but those that do not know it should plant it, and they will not be disappointed. The fruit is fine and of splendid quality.

WORCESTER PEARMAIN APPLE.—This will prove a good market variety, more particularly on account of its colour, as that is everything almost in a market fruit. I know growers planting it by the thousand, which is the best test of its value.

THREE GOOD DESSERT APPLES.—An amateur requiring only three varieties of dessert Apples should grow the following, all of them being heavy bearers and of good quality—Cox's Orange Pippin, King of the Pippins, and Sturmer Pippin, the latter keeping until June.

GRAVENSTEIN APPLE.—Gardeners and amateurs who do not grow Gravenstein Apple should procure it this season. It is a splendid culinary Apple, and useful for dessert, the flavour being excellent. Its colour also is very telling on an exhibition table, and the tree is a good grower and bearer.—THE DOCTOR'S FRIEND.

KING OF THE PIPPINS APPLE.—As this is the time when many fruits may be gathered and tested and new kinds planted, I think your "Scraps" on fruits most valuable morsels, and they cannot fail to be highly instructive at the present time. To those in want of a good Apple I would like to recommend them King of the Pippins. Our varieties of Apples here are numerous, but we have none to equal this. I am not meaning this season alone, but am considering its conduct year after year. In the first place it never fails to bear a crop; the fruit are always of a good size, very clean, and as a rule very beautiful. They may be gathered about this time, when they may be used in the kitchen or for dessert, and in any ordinary fruit-room they will remain sound and well flavoured for six months or so.—J. MUIR.

ONE of the most useful Apples is King of the Pippins Apple, the above. It is a certain cropper, but requires liberal treatment to bring the fruits to a good size and form strong wood for the succeeding year's crop. It is useful both for dessert and kitchen use.—B.

WARNER'S KING.—As a midwinter kind nothing need be desired better than this. All our trees are young. Some planted as maidens in the spring of 1880 are bearing a few fruits this year, and there is every promise of the whole of these trees bearing a small crop next year. We shall grow forty trees of this variety for affording the main winter supply of fruit. All the pruning it requires is to stop the ends of the main shoots in August and keep the side growths pinched in.—R. P. B.

MARIE LOUISE PEAR.—I can confirm what your Worcester-shire correspondent says on the subject of stocks for this Pear. Twelve years ago I planted three trees of Marie Louise, two on the Quince and one on the Crab. For the first five years the trees on the Quince gave the most fruit, but they did not grow so healthily as I wished, the ends of the shoots turning black and dying. One of these trees has died and the other is not satisfactory; but the one on the Pear stock is in the best of health, and I am sure has given five times more fruit than the other two on the Quince.—J. E. BELL, *Clifton*.

COX'S POMONA APPLE.—Having seen the inquiry of "F. D.," on page 285 of your Journal, I write to say that I have tested Cox's Pomona carefully as a kitchen Apple in the last fortnight against Small's Admirable, Hawthornden, and other varieties. The verdict is that Pomona is inferior in flavour, although lovely in appearance on the tree.—A KENTISH VICAR.

KESWICK CODLIN APPLE.—Always plant one or more trees of this according to the quantity of early fruit you require. When once the trees commence bearing they never fail to produce a fair crop of fruit. The growth is vigorous and sturdy, and the tree continues healthy and prolific for many years. Preference is sometimes given to Lord Suffield; but excellent as "my Lord" undoubtedly is, he has succumbed to canker, two trees of it being almost dead, while another pair of Keswick Codlin growing close by in the same kind of soil are "pictures of health."—E. LUCKHURST.

FORMAN'S EXCELSIOR STRAWBERRY.—I have had this Strawberry on trial at the Girtford Experimental Garden for three years, and every year has tended to increase my estimate of its value as one of our very finest modern Strawberries. The plant is hardy and a vigorous grower; fruit large and nearly globular, and of a bright scarlet colour; flesh firm. It ripened here this season on the 15th June, about two days later than Keens' Seedling. I shall try "Excelsior" again, and would recommend its being tried under glass.—T. LAXTON, *Bedford*.

It will be well if this variety does not come to be known as the "Winebottle Strawberry." "B. L. S." has certainly put the subject of big fruits in a strong light, and Mr. Boothby's reply will be awaited with interest. Would it not be well if the weight of the fruit could be named? Surely a fruit larger round than a wine bottle would be placed in the scales and a record kept of the result. Strawberry-measuring is not always satisfactory. I measured a fruit of James Veitch last year that girthed 9 inches round the edge, as if measuring a Cockscomb, but when tested with the scales it only weighed  $1\frac{1}{2}$  oz., as it was a thin fan-shaped fruit. Let us have the weight, then, of the specimen above referred to.—D. T.

I THANK your correspondent for his remarks last week questioning the accuracy of my statement the previous week, that this Strawberry has measured as much as 11 inches in circumference! I wrote from memory, and fully believed in the truthfulness of what I wrote. Both fruit and plant are everything that could be desired, but the maximum measurement ought to have been given as 9 inches. I think I ought to add that what has been achieved in the past might be accomplished even now. In the "Gardeners' Magazine" for July, 1863, I notice the following description of Strawberry "Refresher"—"Several of the berries weighed  $1\frac{1}{2}$  oz. each, and many are 8, 9, and 10 inches in circumference, and one 11 inches."—HENRY BOOTHBY, *Louth, Lincolnshire*.

DYMOND PEACH.—In answer to "A HAMPSHIRE CLERGYMAN" in your Journal of October 6th, page 311, I may say Dymond Peach is a fine variety, said to have been introduced by the late Mr. Veitch of Exeter, and may be had of Messrs. Lucombe, Pince, & Co., Exeter.—J. SEARLE, *Crediton*.

NEWTON'S SEEDLING STRAWBERRY.—My experience of the above variety, which I have grown for several years, and which has invariably produced very plentiful supplies of fruit of good quality, prompts me to offer a few remarks, as I feel convinced that if more generally known it would be much more extensively cultivated than it is at present. This is a very distinct variety both as regards fruit and foliage, is very hardy, and for preserving purposes is not surpassed, if equalled, by any Strawberry that I am acquainted with. As a market gardener's variety I cannot

conceive anything to surpass it, as, owing to the firmness of the fruit, they are not so liable to injury whilst in transit as most sorts are. Another point in favour of this variety is its stout fruitstalks, which, in many instances, hold up the fruit well clear of the ground. It is a medium-sized Strawberry, and does not aspire to the "from 9 to 11 inch in circumference" sorts. I can with confidence recommend it as one of the most serviceable and reliable.—W. W.

USEFUL APPLES.—We have here an orchard tree of King of the Pippins, which for the past seven years has borne full crops of very fine fruit. Another variety which never seems tired of bearing is Dutch Mignonne. The above are both useful, and may be used for the dessert as well as for kitchen purposes. Lord Lennox is also a very reliable variety, and is an excellent market and attractive dessert fruit. Court Pendu Plat, the last of all Apples to blossom, generally produces a fair crop. Cox's Orange Pippin and Ribston—two grand Apples, the former the most to be trusted for a crop—are well worthy of cultivation. Cellini bears heavily here every other year, and is a fairly good Apple. We have here a fine specimen orchard tree of Bess Pool, which is bearing an immense crop of splendid fruit; this is an excellent Apple, but I fancy not one that bears freely until the tree attains a good age.—MID-LINCOLN.

RED WARRINGTON GOOSEBERRY.—Such a valuable bush fruit as this is should always be planted extensively in every garden. It is valued here most of all for its delicious ripe fruit, much of which is made into jam, and still more is eaten fresh picked from the bushes at almost every meal during the long time it continues good after it is ripe. Its robust growth is somewhat drooping, but by judicious pruning the bushes become sufficiently erect to keep the fruit from contact with the ground, and they soon become handsome in form, and so large that a single bush yields no inconsiderable quantity of fruit. Plant two or three rows of them side by side, so that the fruit may easily be protected from the ravages of birds, and you will have an abundant supply of late summer fruit that is as much in demand as Strawberries are in their season.—E. L. O.

PEARSON'S PROLIFIC NUT.—I do like a name that means something as this does, for never was the term "prolific" more justly applied to fruit or vegetable than it is to this capital Nut. It forms a handsome tree quickly, its branches are very robust, the foliage large and stout, and the nuts cluster thickly all over the branches every summer, which shows, I think, that its blossom is exceptionally hardy. A neighbour has not more than a quart of Red Filberts off the whole of his trees this year. I have not many more, but then I have bushels of Prolific, and sent a basketful the other day, which ought to induce him to plant some of it; but he is somewhat stubborn, and says he does not think much of those writing fellows.—SUSSEX.

THE DAINTY APPLE.—Can any of your readers give me particulars as to the correct name of the above or the characters of the variety? The fruit is described to me as very beautiful, of moderate size, and regularly streaked with crimson from the eye to the base. It is said to be a culinary variety of fair quality, and ready for use during the present and following month.—X., *Surrey*.

I OBSERVE in your Journal that one of your correspondents regrets Blenheim Orange and Ribston Apples are not now much planted. Another justly recommends Pomona. The demand here is about in proportion as the names are given—Cox's Orange Pippin, Blenheim Orange, Wellington (Dumelow's Seedling), Cox's Pomona, Ribston Pippin, and Warner's King—for the above half-dozen kinds.—C. T., *Slough*.

#### ROCHEA FALCATA.

ALTHOUGH an old inhabitant of our gardens, and of easy cultivation, yet we seldom meet with this plant in good condition. Why it receives so little attention it is hard to understand, since it is in every way a most useful plant when under proper cultivation. We confidently assert that few plants will more amply repay the gardener for the time and skill bestowed upon it than the one now under notice. It is most useful as a decorative plant during the months of July, August, and September, when its fine large trusses of scarlet blooms, combined with the grey hue of its leaves, render it highly attractive amongst other flowering plants in the cool greenhouse or conservatory.

It is readily propagated by cuttings or leaves at almost any

season of the year. Cuttings may be taken now as follows:—Take the points of the shoots with three or four leaves attached, carefully remove the two lower ones, then cut the base of the cutting cleanly through the lower joint. Procure a number of 2-inch or thumb pots, fill one-third of their depth with broken potsherds, then fill the pots with a compost consisting of two-thirds of pounded brick or potsherds and one-third coarse sand. This being done, place a cutting firmly in the centre of each pot, afterwards giving a good watering, then place them on a shelf near the glass in a cool house. The cuttings must not be shaded, but fully exposed to the sun. Water must also be applied sparingly; indeed, we seldom give any after the first application till they are rooted.

The leaves taken off should be fully exposed to the sun in order to evaporate as much of the superfluous sap as possible. After a few days' exposure they should be laid on the surface of shallow pans previously filled with potsherds and coarse sand, and then placed on a shelf as advised for the cuttings. No water should be given unless they exhibit signs of shrivelling until they are rooted. As soon as the cuttings and leaves are rooted shift them on into 4 and 5-inch pots, in a soil composed of one-third turfy loam and remainder old mortar, brick rubbish, and sand. Give a good watering, and place them on a shelf or stage near the glass, where they may remain till they flower. Like most succulent plants they require but little water, even during active growth, therefore a little discrimination should be exercised in its application. Care should also be taken not to overpot the plants at any period of their growth, otherwise they will not flower satisfactorily.—A SOUTHERN GARDENER.

#### FRUIT TREES CANKERING AND BEARING.

PERMIT me to call the attention of some of the able and experienced fruit-growers, who help to make "our Journal" such instructive and pleasant reading, that what is most needed to be told to fruit-planters is caution as to sorts of Apples and Pears that canker, and next to this the relative time required to bring the sorts into bearing after planting. Very much loss and discouragement ensues through ignorance on these points. We have abundance of sound guidance as to the qualities of these fruits, but next to nothing on these two subjects of cankering, and a long or short time of coming into bearing after planting.

Irrespective of the cause of canker, of which much may be said of an instructive character, the fact that under precisely the same conditions of climate, soil, and aspect some very fine sorts canker to death, whilst others do not canker at all, speaks eloquently of the need of guidance to new planters. Again, whilst some Apples and Pears come to bearing freely in two, three, four, or five years, others do not do so for many years; and as I have said above, there is little or no guidance to be had in books or otherwise on these important points.

Meantime, let me caution intending planters who have heavy loam or clayey loam soil having a tendency to hold water near the surface, though they may have heavy crops and very large fruit of some sorts, as I have during the last three years; yet let them not plant such otherwise excellent fruits as Louise Bonne or Marie Louise Pears as pyramids, nor Cox's Orange Pippin, Lord Burghley, or Ribston Pippin Apples, for canker will destroy them.—S. S.

#### FLORISTS' FLOWERS—OCTOBER.

THE present month is one in which all growers of florists' flowers are preparing for the on-coming winter; for although the objects of their care are hardy that does not imply that they can stand any kind of treatment, and the fact of their being grown in pots takes away somewhat of that capability of standing all weathers which some of them possess. The Picotee, which will brave our hardest winters, as a bed of mine did that of 1880-81, when wintered in pots requires to be carefully watched lest what is called "spot" makes its appearance amongst the collection.

There is one enemy which is more injurious to all florists' flowers than anything else, and that is damp, whether arising from defective drainage, the use of bad soil, or a damp atmosphere in the frame or pit where plants are wintered. We are subject to such vicissitudes of climate in the winter months that sometimes there is a tendency to excite plants into growth, which damp encourages; and then frost or cold winds do the more damage. Moreover, an overdamp soil rots the roots, and of course deprives the plant of its sources of strength. Therefore I would say to all growers of florists' flowers, Above all things take care to guard against damp.

AURICULAS.—These may now be removed into their winter

quarters—*i.e.*, the frames are to be stood facing south instead, as they have been during the summer, facing north. Watering will have to be done more sparingly; and where, as in several collections in the north, glazed pots are used, they have the advantage of keeping the soil somewhat more moist, and thus of preventing the necessity of frequent waterings. The large outer leaves will gradually decay and should be taken off; and by the time that top-dressing is needed (January) there ought to remain just simply a stout heart instead of the large plant there was in the summer. Slugs should be watched for and destroyed, ventilate as much as possible, and avoid coddling. As the nights become colder mats should be in readiness to place over the frames. The plants will stand much frost without injury, but later on it injures the bloom.

CARNATIONS AND PICOTEES.—Layers ought now to be taken off and potted. It is best to put them singly into small pots. The soil should be a light loam without any mixture of manure, as it is not well for them to be excited into growth, all that is required being that they should be kept in a healthy condition and fill the pots with roots. They should be kept close for a few days and then placed in a similar position to the Auriculas; air to be admitted freely at all times when the weather is fine. Dead leaves should be taken off; and if green fly makes its appearance, as it is apt to do, they should be either brushed off or the frames must be fumigated. Where they are grown in beds, the plants may be placed out and secured by small sticks, as they are apt to be blown about by the winds and loosened. Wet then penetrates the collar of the plant and does considerable damage.

PANSIES.—The same treatment applies to these. If grown in pots they should be wintered in small pots in a light but not too rich soil. Unlike the Carnation and Auricula, they are not at rest during the winter months, and their tender foliage is very enticing to slugs, which should be carefully guarded against, as should also the attacks of green fly. When grown in beds they should be secured by small sticks, and kept clear of weeds.

GLADIOLI.—The smaller roots of these (seedlings and young corms of the named sorts) may now be lifted; and as there is little chance of seed this year the flowering stems of the larger corms may be cut off, as it will hasten the ripening of the corms. The small bulbules, as the French call them, may be kept when sufficiently dry in paper bags with a little dry sand. Towards the end of the month many of the corms which flowered early will be sufficiently ripened to take up. They may be laid out to dry in a cool and airy situation, but not exposed to frost. When dry enough the spawn may be taken off and the roots dried and stored away. There is nothing better than the frame of which I gave a sketch in a former volume of the Journal. The names may be written on the corm, and thus all fear of wrong naming be avoided.

DAHLIAS.—Towards the end of the month it will probably be necessary to lift the roots; but it will depend much on the weather, for if hard frost does not occur they will go on maturing in the ground. When lifted they should be dried off carefully, if possible in a cool vinery, and then stowed away in a dry place free from frost. Single Dahlias, which are now so popular, may be treated in the same way. The recommendation to grow them from seed in the spring is desirable enough for large gardens; but where space is a matter of moment it is better to grow a few named sorts, such as Paragon, Cervantesii, coccinea, &c., and start them again in the spring.

CHRYSANTHEMUMS.—These will now be coming on rapidly: the buds seem to be swelling fast and promise well. Where large flowers are desired disbudding has taken place, but where a goodly number of flowers is desired that may be dispensed with. A spoonful of Clay's fertiliser on the surface of each pot will materially help them now. The plants may now be safely placed under shelter, and will cheer their cultivator during the otherwise (floriculturally) dreary month of November.—D. Deal.

#### NEW STRAWBERRIES.

THE following amongst the recently introduced Strawberries tried at the Experimental Garden on fairly strong Strawberry soil have proved the most satisfactory—*viz.*, Crown Prince of Germany (Goethe), ripe June 21st; Forman's Excelsior (raised by Mr. Forman of Louth), and Seth Baydon (American), from Messrs. Ellwanger & Barry, both ripe on the 15th June. These are all good growers, and produce fine handsome fruit of rich flavour and first-rate quality. Keens' Seedling ripened on the 13th June. McMahon is a free-bearing Strawberry of good size and high quality. Duncan (American), a useful early sort.

Sharpless (also American), and Dr. Roden's Fair Lady promise well, but were planted too late for a satisfactory test. The best variegated-leaved Strawberry is "Variegated Enchantress" (Dr. Roden), which comes more constantly variegated and with better fruit than the other variegated Strawberries with which I am acquainted.—T. LAXTON, *Bedford*.

#### THE ROSE ELECTION.

THE thanks of all true rosarians are due to Mr. Hinton for his courteous labours, and I for one congratulate him on their successful results.

The position, however, of a few Roses is rather surprising, notably that of Comtesse de Serenye. Where is that elegance of form and delicacy of complexion which charmed us so much when she made her *débüt*? The loveliness of the girl has developed into the too great inclination to *embonpoint* (dare I say coarseness?) in the woman, and rarely now is to be seen that "maiden's blush" on her cheeks which was one of the most charming features of her first appearance.

Am I wrong, do you think, in suggesting yearly budding to reproduce her pristine charms? I think not, if we take the character of the votes into consideration. Twenty-four amateurs out of forty-five give her their votes, but of these sixteen seem to mark only fond memories of the past, while of nurserymen twenty-one out of twenty-two vote for her, fourteen placing her in the first twenty-four. Now as nurserymen chiefly look on maiden blooms and amateurs on cut-backs, I fancy there is some reason in what I say, and that Comtesse de Serenye grows somewhat coarse under good feeding. If, then, we are to see her again in the beauty of her girlhood, we must either put the Comtesse upon Banting diet or trust only to maiden blooms.

I wish with Mr. Hinton that positive notice had been taken of "too much alike Roses," for to see forty votes accorded to Ferdinand de Lesseps, while Exposition de Brie numbers only fifteen, speaks of some such unaccountable change of opinion as characterised the political election of 1880. Again, that Prince Camille de Rohan should stand forty-ninth on the list, while La Rosière occupies the undignified position of "wooden spoon," must have disturbed the equanimity of others besides myself.

I wonder, too, what offence poor Xavier Olibo has committed. Try him on the seedling Briar, ye who doubt his excellence; and if you have my experience you will find a Rose vigorous as Dupuy Jamain with the blooming properties of Marie Van Houtte.

I merely write this hoping to see further letters from some far more competent to write on the matter than I am.—H. B. B.

#### A WEEK IN BELGIUM.

[THE THIRD DAY.]

THIS may be described as a day in the country, and a most pleasant one it proved; profitable, too, it certainly ought to have been, as it was spent with one of the most experienced men in Europe in the particular branch of horticulture with which he is specially identified.

As has been stated, Mr. Van Geert's nursery at Antwerp has diminished in size owing to the steady growth of the town; but as this was foreseen some years ago ample provision was made to meet the anticipated change, and a country nursery was established in what is undoubtedly one of the healthiest parts of the kingdom, the land being well drained, the soil sandy yet good, and the air pure.

Calmpthout was not only judiciously selected on account of its natural advantages and ready access by rail—the station being within three minutes' walk from the nursery—but the ground was so disposed that utility and convenience were combined with artistic effect, and the nursery is of its kind a model one. It has been previously described in this Journal, but a second visit to a place which the first did not render quite familiar is often needed, always enjoyable, and seldom fails to be instructive where there is anything to be learned, as there is at the establishment in question. There is no glass, except in the windows of the villa. This building was commenced for a small office. Madame thought it would be more useful if a cooking kitchen was attached, the family thought it would be still further improved if an additional room were added, and then it was considered a pity that the walls should not be taken high enough for bedrooms; and so the place grew to its present dimensions, and it now forms the health sanatorium for family or friends who require a brief sojourn in a salubrious district. Perhaps the proprietor did not at the first see the necessity for such an erection, but the family instincts proved sound, and the only fault of the place now is that it is not large enough. The moral of this is, Do not despise the advice of a good

wife, nor treat with contumely the suggestions of the olive branches.

But my friend William Taylor, with his stern utilitarianism, will be reminding me that this is "not gardening." True, it is not, but it is in a rather more direct manner than I wish "leading up to it." I wanted a change *from* gardening when I left England, and I happened to suggest a few weeks ago that some of my readers have enough if not too much of it; hence I said as little about "gardening" as possible, and I have had more than sufficient testimony that the change of subject I ventured to introduce was specially acceptable. I am, however, driven to one phase of gardening now, but it is at any rate a change from clipping *Mentha* and plucking Golden Feather, or trying to prove whether single or double flowers are the more beautiful, or whether wild or exotic plants possess the greater charms. From these very abstruse and intellect-taxing—and I had almost said temper-trying—subjects I am happily free, and free also from fruit perplexities, for my "third day" was spent among trees, shrubs, and Conifers, and a reference to them will at least not be unseasonable on the eve of planting time.

The principal nursery—for there are two enclosures—is a parallelogram about a quarter of a mile long and perhaps 100 yards wide. It is divided into compartments longitudinally by hedges of Conifers about a foot wide, close and dense, and over 6 feet high. A walk runs down the centre of each compartment, and at intervals of 15 or 20 yards are cross hedges, some of them forming a segment of a circle, the top limb commencing at the top of the main hedge, the bottom resting as it were on the walk. Others are carried across the borders without any reduction of height, and meet each other over the walk, forming arches. Some of the hedges are Spruce, others Thuias; *T. gigantea*, or, as it is commonly called, *T. Lobbi*, making a beautiful hedge. Others are formed of *Abies excelsa*, *Picea Pinsapo*, &c., the latter being injured by the frost. As all these hedges are kept in perfect order the effect is quite unique; while, as will be readily understood, they afford valuable shelter, and at the same time nothing in the squares can be passed without being seen. Again, every avenue is distinguished by a letter, and every compartment numbered, so that if anything is wanted to be removed from or inserted in a particular place it is only requisite to give the number and letter, and there is no time lost in searching, and even a labourer cannot easily make a mistake. These remarks apply to the side avenues, the central one being different—wider and more imposing. The boundary lines here are formed with Purple Beeches and *Acer Negundo* variegata alternately planted and pruned, not clipped, into the form of cones, each having a base of about 3 feet where the trees touch each other, the height of many being about 18 feet. The rows are somewhat broken in places, but the effect of the stately columns with their boldly contrasting foliage is very striking. The borders along this avenue are divided into squares (open next the walk) by hedges of *Thuia occidentalis* 2 feet high. These enclosures were formed so that each would accommodate a single specimen, with the object of testing its beauty, hardiness, and worth. A pair of each kind were planted opposite each other in these squares, of which there are, I think, 170, for writing from memory I cannot pretend to numerical exactitude. "But why not have taken notes?" Well, taking notes on a rainy day is a nuisance whether one has an umbrella or not, so much of that formality was dispensed with. The squares were planted in 1858, Mr. Van Geert having at that time received many new plants from his friend Siebold. These remained and were proved, such of them that flourished being fine specimens at the time of the coronation of His Majesty King Leopold, who purchased one of each for planting at Laeken; the remainder, having then served their purpose, were sent to the first Paris International Exhibition, and from thence were distributed. The squares were subsequently re-occupied, but in a less systematic manner, but the object remaining the same—namely, proving the characters of new introductions as they were received. In these trial squares are many specimens that merit notice now, especially as those that remain healthy after winters that have killed Pear trees are unquestionably hardy.

One of the first specimens that arrested attention was *Abies Alcoquiana*, or Sir Rutherford Alcock's Japanese Spruce, about 15 feet high. At this height the beauty of this fine Spruce can be seen, as the glaucous undersides of the leaves are apparent, and the colour of the tree is a singular mixture of silvery blue and green, which cannot be perceived in small trees. This very hardy and decidedly ornamental species was introduced by the late Mr. J. G. Veitch in 1861, and was named in honour of Sir Rutherford Alcock, who was then British Minister at Yeddo. It should be included in all collections of Conifers. Near it was *Larix Kämpferi*, the Golden Chinese Larch, but much larger and uninjured,

except its leader. It is a distinct and fine form, hardy and ornamental. *Abies Pattoniana*, a free and graceful form of the Hemlock Spruce, Cedar-like in growth and most elegant, was 9 feet high; the young leaves being glaucous and the old leaves green, gave to the specimen a singular appearance. *A. Douglasii glauca* and *A. Nordmanniana aurea*, distinct forms of these two noble Firs, were both fine, *Cupressus Lawsoniana intertexta* near them contrasting effectively by its distinct, weeping, and most elegant growth. We now come to *Abies concolor*, which is considered by some authorities to be synonymous with *A. lasiocarpa*, but Mr. Van Geert is not one of them. Although he speaks highly of Messrs. Veitch's new work on the Coniferæ he cannot ignore the testimony of his plants, and the stocks of both at Calmpthout are clearly enough distinct. The leaves of the former differ both in colour and arrangement from those of the other, being arranged all round the branches, and not pectinate as in *C. lasiocarpa*. Along every young growth of this a pencil could be laid without touching a leaf, but it was impossible to do anything of the kind with the plants of *A. concolor*. Both, however, are among the finest and hardiest of the North American Silver Firs, and form noble lawn ornaments. *Abies orientalis*, or, as known in this and many other nurseries as *A. Witmanniana*, 20 feet high. This is a very hardy and beautiful Spruce; its early growths are bright yellow, and as the colour changes slowly the tree has a distinct and attractive appearance for a long time. *Picea grandis* and *P. amabilis* have both been injured by the intensity of the frost. *P. sibirica*, 16 feet high, is attractive by its fine rich green, but this species produces its young growth so early that it is occasionally injured by frost. *P. Pinsapo glauca* is compact in habit and very beautiful. *Abies nigra pumila* is also very dense and very dark; but *A. Menziesii* is not proving satisfactory, as the trees after they attain a fair size lose so many leaves.

It is gratifying to notice how admirably the *Retinosporas* have endured the severity of the frost. Not a spray appears to have been injured, and henceforth these elegant Conifers may be planted without fear. There are thousands of plants in varied heights, a specimen 15 feet high of *R. plumosa* being very beautiful. *R. p. argentea*, 10 feet high, has a singular appearance, as the bottom of the specimen is of the normal form, only the upper portion being variegated, the growth being regular throughout. All the other sorts of *Retinosporas* are similarly fresh and healthy, and their ornamental character is well displayed. *Thuopsis borealis pendula* is one of the best varieties of the species, and *T. b. compressa* attracts notice, it being more dwarf and dense than the variety *compacta*. *T. dolabrata* is largely grown, and has received no injury. It is not generally known that this is one of the finest room and corridor plants in existence; but that it is I shall be able to adduce sufficient testimony, but not gathered in Belgium. *Thuias* have also passed the wintry ordeal well. All the popular forms are included in the collection, but none was more attractive than a grand specimen of *T. Wareana*, bearing thousands of small yellowish cones. Only one form of *Cryptomeria japonica* has escaped destruction—namely, the variety *compacta*, and it is fresh, green, and healthy, the specimen being 14 feet high. All the Hollies were cut to the ground, and most of the Yews were killed. One of them, however, *Taxus cuspidata*, the true Japanese Yew, as received direct from Siebold, has not had a leaf discoloured; the best specimen is 5 feet high, handsome in form, and as green as grass. Mr. Van Geert says the excellent habit of this Yew is only maintained by taking the graft from leaders; if side growths are used a spreading and less attractive habit is assumed by the shrubs. The distinct *T. Dovastoni* has only been slightly injured; and a number of plants grafted with the Golden form—a new variety not yet in commerce—have survived. When these are established the specimens will resemble golden umbrellas. *Torreya myristica* (the Californian Nutmeg) has proved quite hardy, and when well grown and covered with fruits it is very ornamental. Amongst the Junipers *J. procumbens* merits notice. It rarely exceeds 9 inches in height, and is grown for covering banks in hot sunny positions.

There are many more noteworthy Conifers, but one only can be alluded to—namely, the new variety exhibited this year for the first time by Mr. Van Geert, under the name of *Pinus commutata argentea*, and which secured the first prize at the Antwerp Exhibition in the class for new plants raised from seed. A similar award was also unanimously granted to it the week following at the Show of the Royal Linnean Society held in Brussels. The plants exhibited were like frosted silver with a bluish tint, and the stocks in the nursery had passed the winter scatheless. The demand for them, however, was great, and all the best are probably gone now. It is quite distinct from *P. Englemanni* as grown in this nursery, the latter having much longer and irregular leaves, and was, moreover, much injured by frost. This

new and decidedly attractive Silver Fir is a variety of great promise and an acquisition.

Too brief must be the reference to some other occupants of these nurseries. The different varieties of Tulip Trees demand attention. *Liriodendron tulipifera aurea marginata* has grand foliage, clearly margined with bright gold, producing a splendid effect. *L. t. integrifolia* has noble foliage, and the trees possess the valuable property of flowering when 4 or 5 feet high. *L. t. fastigiata* is remarkable in having the close upright growth of the Lombardy Poplar. These varieties were raised here, and have survived the winter with impunity. *Sambucus nigra punctata* is a small-leaved Elder, which seen at a distance resembles a mass of white flowers. The more the shoots are pinched the whiter are the succeeding growths, many of the tips being pure white. Large bushes kept in form by pinching have a remarkable effect, and would afford a striking contrast in public parks and private pleasure grounds with the surrounding greenery. *Cornus sibirica alba marginata* is undoubtedly one of the finest of variegated shrubs; the foliage is not burnt by the sun in summer, nor are the shrubs injured by the most severe frost. The Japanese Walnut, *Juglans japonica*, commands notice by its grand leaves; it is far more imposing than the English Walnut, but the trees have not yet fruited. Oaks with splendid foliage, such as *Quercus magnifica rubra*, *Q. macrocarpa*, and others; weeping trees of all kinds, and not a few rarities add to the beauty and diversified character of the grounds; but only one more plant can be particularised—not because it is rare, but because of its splendid condition. As seen grown in pots for balcony decoration and in shrubberies in England *Hydrangea paniculata grandiflora* is often fine, but as seen in this deep alluvial soil it was magnificent. A correspondent lately referred to the improved condition of plants that had been cut down by the frost. Those now under notice had been similarly cut down, and produced growths as thick as a man's finger, each terminating with a head of flowers as large as a moderate-sized bee hive, but more pointed. One plant had forty-three of these trusses and was grand. Let beds be made for this *Hydrangea* distant from large deciduous trees that deprive the soil of its fertility; let the ground be deeply trenched and well enriched, the plants cut down annually and the beds regularly dressed with manure, and a far different and far finer effect will be produced by this plant than many people dream of. If such results can be produced as those referred to my "day in the country" will not have been spent in vain, and this tedious description will be excusable.

I may add that the land in these nurseries is kept in a high state of fertility without the aid of farmyard manure. Every vestige of vegetation is saved, all the clippings of hedges, leaves, &c., being carefully collected. A covered tank is provided, and a shelf above for jars of chemicals. The natural components of the soil being ascertained, and elements necessary for the growth of the trees and Conifers understood, the necessary fertilisers are thrown in the tank, and in due time the contents are poured on the heaps periodically. The compost is not spread on the ground and dug-in, but is spread in every hole before a tree is planted. Nothing could be more satisfactory than the bushy fibres that are retained close to the stems, thus rendering transplanting as safe as possible, while the shrubs and trees are in the best health and colour. This "practice with science" routine has proved its value by many years of experience, and is not the least noteworthy feature of Calmpthout.—J. WRIGHT.

At a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Sir Trevor Lawrence, Bart., M.P., in the chair, the following candidates were duly elected Fellows of the Society—viz., James Alexander, William Armit, C. T. Buckland, Mrs. Cotton, D. Barri Crawshay, C. Herbert Curtis, Charles Digby Harron, A. A. James, E. R. Kesterton, Mrs. M. Macartney, Capt. F. L. Philp, Miss Russell, Mrs. Mayow Short, George Todd, Edmund Tonks.

— ON Tuesday last, after the meeting of the Royal Horticultural Society's Fruit and Floral Committees, Sir Trevor Law-

rence, Bart., in the presence of a large company, presented a TESTIMONIAL TO MR. DOMINY as a recognition of the valuable services he has rendered to horticulture, particularly in hybridising Orchids and Nepenthes. Subscriptions were received from over two hundred friends, a gold watch and two hundred guineas being the substantial form in which these were conveyed to Mr. Dominy. In the course of some remarks by Sir Trevor Lawrence he observed that the first hybrid Orchid was obtained by this hybridist in 1852—namely, *Cattleya Dominiana*; but his greatest triumph in this class of plants was *Cattleya exoniensis*. In 1864 the Devon and Exeter Horticultural Society presented Mr. Dominy with a piece of plate in recognition of his success as a hybridiser. Dr. Masters also testified to the value of the services which had been rendered to the horticultural world by the numerous beautiful Orchids raised by hybridising. In thanking his friends for their presentation Mr. Dominy stated that he owed his position and success to his great love for the profession of gardening, and his passport had been sobriety, patience, and perseverance.

— RELATIVE TO THE APPROACH OF WINTER, Mr. Hudson, The Gardens, Cragside, near Morpeth, informs us that the thermometer was 6° below freezing on the morning of the 9th inst.; and we learn from other districts that Dahlias, Kidney Beans, and similarly tender plants were cut down by frost last week.

— THE annual meeting of the NATIONAL AURICULA, CARNATION, AND PICOTEE SOCIETIES was held by permission of the Council of Royal Horticultural Society in the Council-room on the 11th inst. It was decided to hold the Auricula Exhibition on April 25th, and the Carnation and Picotee on July 25th, 1882, in the gardens of the Royal Horticultural Society. There are no alterations in the schedules, except that some restrictions are placed on the exhibitors of Show Auriculas in the interests of small growers. "Exhibitors showing in the classes for twelve and six will not be permitted to exhibit in Classes 4 and 2." The prizes for seedlings are to be continued as usual.

— MR. MOORMAN, gardener to the Misses Christy, Coombe Bank, Kingston, states that he has *CEANOTHUS GLOIRE DE VERSAILLES* still flowering freely in the garden, bearing large close trusses of blueish lilac flowers. It is unquestionably a fine variety; indeed, one of the best in cultivation.

— LAST week an EXHIBITION OF GOURDS was held at the ALEXANDRA PALACE, and, though the exhibits were not surprisingly abundant, the competition has the recommendation of novelty, at least so far as English shows are concerned. Two classes were provided, the first for the best collection of diverse Gourds, and the second for the heaviest Gourd of any kind. In both the prizes were liberal. Mr. J. Cattell of Westerham, Kent, had the best collection, comprising a great number of ornamental and peculiar forms, from the small but pretty Gooseberry Gourd to the enormous Pumpkins. The red-striped and strangely formed Turk's-cap Gourds, Custard Marrows, and many others were represented. Messrs. Biddles & Co., Loughborough; C. Osman, Sutton, Surrey; and W. Wiggins & Son, Tottenham, were the other contributors, taking the prizes in the order they are named with interesting but less varied collections than the first-named. One showed a number of green Tomatoes, apparently, under the impression that they were included in the appellation Gourds. The heaviest example was contributed by Mr. Gibbon, gardener to R. C. L. Bevan, Esq., Trent Park, East Barnet, and weighed 138½ lbs., being of globular form and quite 2½ feet in diameter. The next in weight was from Mr. J. Sheppard, The Gardens, Wolverstone, Ipswich, but that was 30 lbs. less than Mr. Gibbon's. Mr. J. Cattell held the third place with a fruit weighing 102½ lbs. In addition to these Messrs. W. Paul & Son, Waltham Cross, exhibited some large collections of Apples, Pears, and Roses, some

of the latter being very bright for such a late period of the season. Duchess of Bedford and Crown Prince were especially noteworthy. Numbers of Gladioli spikes were arranged upon tables, and served to brighten considerably Mr. J. F. Johnson's novel exhibition.

— MR. E. LUCKHURST sends the following remarks on TOMATO EARLY GEM:—"What is our standard of excellence for Tomatoes? Fine flavour, medium size, a smooth, rounded, handsome form free from ribs or indentions, an abundant crop, and early maturity. This is certainly not a description of the 'Giants' and 'Trophys,' but it faithfully portrays the chief points in Early Gem, which was, I believe, introduced a few years ago by Messrs. Veitch. The crop of its deliciously flavoured fruit is most abundant; and although all the huge clusters were left unthinned, yet some of the fruits weighed half a pound; but most of it is very little more than half that weight, very handsome, and of the best size for sending to table, where its remarkable flavour renders it a great favourite."

— IN connection with the coming CHRYSANTHEMUM EXHIBITION SEASON we are glad to observe that the majority of fixtures have been very carefully determined, so as to avoid clashing with other societies, especially those in neighbouring districts. In one important instance, however, the opposite is the case. Both the Kingston and the Westminster Aquarium Shows are noted for their extent and the quality of the exhibits, yet they are announced to be opened upon the same day, and consequently it will be strange if they do not both suffer by the absence of some exhibitors.

— IN the course of the address to the American Pomological Society at the eighteenth session held in Boston, September 14th to 16th, by the President, Marshall P. Wilder, Esq., occur the following remarks upon RAISING THE STANDARD OF MARKET FRUITS:—"Let us not forget the importance of maintaining a proper regard to the characteristics of a good fruit. So long as we raise fruit to eat we can have no hesitation in giving the first place to its eating qualities. Next in importance is durability, or keeping—that is, the property, whether early or late, of remaining sound after being gathered. The third requisite is size; but while we desire those of liberal size we should not forget that one of monstrous proportions is neither desirable for the market nor for table use. But, whether large or small, a variety should be uniform in size. Beauty, colour, and form will always be regarded as of great value. Brilliant colours will charm the eye although they may not gratify the taste, but a misshapen ugly form will never be tolerated by anyone of cultivated taste. I have dwelt upon this branch of our subject—and I would, if possible, enforce my views upon it still more strongly—not only because I desire to see the quality of our fruits raised, but to save the American Pomological Society from the reproach of recommending fruits, otherwise unworthy, because 'there is money in them.' I have spoken of the latter point with some reluctance, but from the belief that too much regard is being had to the size without regard to the form or beauty of fruit. If it be deemed advisable to give premiums to enlarge the size of products—as, for instance, the biggest Strawberry, Squash, or other monstrosity, let it be done for size without regard to form, colour, or quality, and not for the 'largest and best,' as is generally the custom. In considering perfection of form and quality before monstrous size the growers of vegetables are in advance of pomologists. It is our duty to correct public taste by our example, and not to encourage the growth of monstrosities or misshapen fruits which, if applied to the Apple, Pear, or even the Potato or Turnip, would not be worthy of cultivation."

— PRICE'S Patent Candle Company remind us of the approach of bad weather by sending us a parcel of GISHURSTINE. We have only to say that further experience justifies us in empha-

sising what we said of this preparation last year—that it is equally valuable for the boots of gardeners, farmers, and gamekeepers who wish to keep the leather soft and their feet dry.

#### AUTUMN-BLOOMING HERBACEOUS PLANTS.

THE many excellent engravings of hardy herbaceous plants published from time to time in the Journal, particularly those blooming during the autumn months, are a great acquisition, thereby diffusing useful knowledge to gardeners and the public who have to supply, or wish for a supply, of cut flowers when the beauty of summer may be said to have passed its zenith. I can speak much in praise of the two plants figured last week—*Chrysocoma Linosyris* and *Senecio pulcher*. Of the figure of the latter, the shape and size of the flower are excellent, but for the full value of the plants to be appreciated it is necessary to say that each stem carries from twelve to fifteen large and elegant flowers, several of them being open at the same time. Some of the Michaelmas Daisies are very beautiful just now, particularly *Aster crenatus*. Our borders are also gay with *Pyrethrum uliginosum* and *Chrysanthemum maximum*, these have been in flower some time, while the *Coreopsis linifolia* has been in bloom all the summer and is not done yet, also the *Rudbeckia Newmanii* is still gay with flowers. *Gaillardias* are now just over, but have bloomed profusely; but *Lobelia cardinalis* and *Anemones japonica*, *japonica alba*, and *hybrida* are as full of flower as they were a month ago. Had we never seen any but the pink *Anemone* we could but have said much in its praise, but the white is by far the most useful. Recently I had occasion to make several wreaths on the occasion of the loss of one of my respected employers, and the prettiest to my fancy of all the wreaths made was one composed solely of *Anemone japonica alba* and *Adiantum cuneatum*. These *Anemones* should be in every garden, as they bloom abundantly and are not particular as to soil.—J. W. MOORMAN.

#### FRUIT NOTES—APPLES AND PEARS.

No doubt brief remarks contributed from various parts of the country concerning the fruit crops are interesting; yet it is not enough to note which crops are above and which are below the average in certain gardens; it would be far more to the point to learn what varieties are found most profitable in the manner adopted by Mr. Harding on page 170. If something of this sort were not annually forthcoming, many intending planters would have to rely on their own selection from the trade catalogues, which, excellent as they may be, are, to say the least, very bewildering, seeing how many varieties of the respective fruits are catalogued. Or, again, if the selection is left to the vendors the result may not in the end prove satisfactory, as the experience of the foremen in the department does not often extend beyond the management of trees of a saleable size. The present is a good time to publish any hints on the subject, and those who intend planting ought to make their selections without much further delay and order early, the trade motto being "First come, first served," and that too with the best trees.

I am sorry to say our fruit crops, though in one or two instances better than usual, have still been somewhat disappointing. Apples of various kinds and in various positions all flowered profusely, but when fully expanded we experienced 10° of frost, which not only destroyed expanded blooms but also the majority of the later buds. What few blooms in many cases that did escape were very puny, and the fruits that followed are poor accordingly. The varieties the least affected by the frost, strange to say, are invariably good bearers, thus showing what a good constitution will do, even rendering them good frost-resisters. The crops of Keswick and Carlisle Codlins have been enormous. The next in point of productiveness are the trees of Hanwell Souring, and this is a valuable kitchen Apple, keeping till late in the spring. *Reinette du Canada* also cropped fairly, is a good keeper, and adapted for either culinary or dessert purposes. *Blenheim Pippin*, I am sorry to say, has cropped lightly, but the trees are in the lowest position in the garden, and consequently had not a fair chance. *Warner's King* and *Tower of Glammis* have borne fair crops, but the fruits are smaller than usual. They are profitable culinary kinds, and the same may be said of *Cellini*. Of dessert kinds we have fair crops of *Margil*, *Ribston Pippin*, *Court Pendu Plat*, *Cox's Orange Pippin*, and *Scarlet Nonpareil*, all of which may be considered profitable varieties and suitable for small gardens. To these may well be added the *Devonshire Quarrenden*. On higher ground near here the orchard trees are bearing very heavy crops of fruit, but I have not had an opportunity of learning the names of the varieties.

Pears generally have borne very good crops, especially those on

the walls, owing to their having set their fruit before the severe frosts were experienced. This was not the case, however, with a large standard tree of *Chaumontel* situated in the centre of the garden, and yet, in spite of the frost, there are several bushels of clean fair-sized fruit now hanging. We had abundance of *Doyenné d'Été*, but they were very small and much too dry to be of service. *Beurré Giffard* is somewhat later, but is a more valuable variety. *Jargonelles* were rather scarce; but of the delicious *Williams' Bon Chrétien* we had capital crops from trees trained to south, west, and east walls.

*Louise Bonne* of Jersey is a great favourite with me, being of good habit, productive, and the fruit handsome and good in quality. It succeeded here in south and east aspects on walls, and also as a pyramid. We ripened a few to follow the *Bon Chrétien*. *Beurré d'Amanlis* on a south wall cropped heavily, and the fruits are now remarkably good. On an east wall the fruit of this variety are very inferior in quality, whereas *Beurré Superfin*, which ripens about the same time, is most delicious, and this variety should receive the preference. Both succeed as standards or pyramids, but in this case the fruits are generally smaller. *Beurré Colman* on a south wall had heavy crops, and the fruits are now ripening. It is not generally a good bearer, and this season the fruits are below medium size. *Marie Louise* has done well this season, notably on an east wall, and, as is well known, is one of the best. *Gansel's Bergamot* does not succeed here, and the same may be said of *General Todleben*. I have never yet tasted a good fruit of the latter. *Beurré de Capiaumont* as usual has borne very heavy crops, but I have a poor opinion of its quality. *Duchesse d'Angoulême* is fairly cropped, but this, again, is generally too coarse in texture. *Glou Morceau*, I am sorry to say, is cracking badly on the south wall, but we have a fair crop of clean fruit on an east wall. *Huyshe's Victoria* is moderately prolific on south, west, and east walls, and is a very good late Pear. *Ne Plus Meuris* on an east wall is bearing a heavy crop of small fruit, which when ripe will consist of little beside core. *Autumn Crassane* and *Althorp Crassane* are bearing heavily on walls and standards. The latter is a profitable variety, but the former is generally very inferior in quality. *Beurré Diel* as usual is bearing good crops of fine fruit. *Beurré Clairgeau* on a west wall has cropped most heavily, and the fruit are large and clean, but those on south and east walls are very inferior. It is not a first-class variety at any time. *Beurré Rance* on an east wall is carrying a splendid crop of fine fruit, and these will be invaluable in the spring. The fruit of *Easter Beurré* have cracked badly and are worthless; and those of *Winter Nelis*, with the exception of those on an east wall, are much too small to be of service. When of good size it is most delicious. A pyramid of *Knight's Monarch* is bearing a good clean crop of fruit, which will be very acceptable in midwinter.

The soil of a garden is a deep strong loam on a clay subsoil, is well drained, and seems to suit Pears especially. Those Pears on the Quince stock were the first to be fruitful, but those on the Pear are now much more profitable.—W. IGGULDEN.

#### LINSEED OIL v. PEAR SCALE

UPWARDS of thirty years ago I had a Pear tree under my charge which was very much infested with scale. As only this tree was attacked, and to prevent the scale reaching the others, I gave orders for it to be taken out and burned. One of the men said, "Paint it all over with linseed oil except the buds, and that will clean it." I said it would kill the tree. He replied, "No, I have seen it done, and it was a complete cure." All the other men were of the same opinion as myself; and as the young man was rather of an inquiring turn of mind, and I had no reason to doubt the truth of what he said, and not caring much whether the tree was killed or not, I gave him permission to perform the operation as he had seen it done, and that if he killed the tree the consequences to him would be serious. The oil was applied in February; and at the usual time when the buds swelled they did so on the oiled tree, and he of course was sanguine and made the most of it, but it was only for a time. The leaves made no progress, a shoot was never produced, and when the hot weather came the leaves withered. In the autumn they made another attempt, but soon faded; and in the winter the tree was taken out, and when cut up it appeared as if the oil had penetrated into the heart of the wood. It was of a dark brown colour. The tree remained a curiosity the whole year, being very conspicuous standing on a wall among others with only a few small green leaves. It was the object of many inquiries, and was called *Adams' Tree*, the name of the experimenter. The poor fellow was tortured about it during the whole summer by the neighbours, and for certain he was glad when he had orders to take it out and cut it up.

Such is my experience with the linseed oil for killing scale on trees. No doubt but it will kill the scale, but what of the trees? In this case the operation was carefully performed, and no more oil was put on the tree than in my opinion was required to kill the scale—only a thin coating, and the buds not painted, so that the work was done according to the quotation from a former member of the *Cottage Gardener* fourteen years ago. When the idea of painting with oil occurred I am unable to say, or by whom; but it seems to have entered the minds of not a few, been

tried, and given up, and again revived as something new. As in the case of other ideas, my advice would be to all who may think of trying it is that given by *Punch* to those about to marry, "Don't."—ALEX. SHEARER.

TEN years ago I painted a large Marie Louise Pear tree with linseed oil procured from our painter's shop, rubbing it in well to the bark but avoiding the buds. It completely destroyed the scale and did not do the least harm to the tree, which is still in

Fig. 55.—CALCEOLARIA PAVONII.

fine health. Many years ago, when at Drumlanrig under Mr. McIntosh, I assisted to paint a wall of Pears and Plums with spirit of tar slightly diluted, painting buds as well as bark. It killed the scale effectually and every bud as well, and a good portion of the spurs; but the older wood broke freely at midsummer, and I never saw finer foliage on trees. They afterwards grew well.—J. SIMPSON, *Wortley*.

#### CALCEOLARIA PAVONII.

AS evidence of the value of this *Calceolaria* for the autumn decoration of the conservatory, we print the following extract

from a letter received from Messrs. James Dickson & Sons, Newton Nurseries, Chester:—"The enclosed flowers of *Calceolaria Pavonii* is a lateral spray, the main spikes being upwards of 2 feet long. The plant is now finely in flower, and will remain for some time. It is 7 feet high, 7 feet in diameter, and growing in a 12-inch pot. It is a grand plant for conservatory decoration. The small flower sent is *Calceolaria bicolor*, a fine species for autumn blooming in the conservatory."

Such a plant as the one referred to is seldom seen, and must indeed be "grand." The flowers are large, smooth, round, and of a clear yet soft yellow colour that is highly pleasing. The leaves are also very distinct by their broad winged petioles;

they are large, perfoliate, toothed, with a wrinkled surface and more or less hairy. *Calceolaria Pavonii* is described in the "Botanical Magazine," where it is figured (tab. 4525, 1850), as a rare and remarkably fine species figured by Ruiz and Pavon as the *C. perfoliata* of Linnæus, from the original plant detected by them at Chuicao and Muña in the Andes of Peru. The figure truthfully represents the spray that has been sent to us, and in some degree indicates how imposing a plant must be that is 7 feet high and through, and with flower spikes 2 feet long. A plant so fine and of easy culture merits attention.

### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 11TH.

THE monthly meetings are always very attractive and well attended, and this one was no exception to the rule. The Council-room was quite crowded with exhibits of flowers, plants, and fruit, while Apples and Pears formed an extensive and beautiful display in the vestibule. For October Orchids were remarkably well represented, and imparted much brightness to the meeting. A large number of members of both Committees attended. After the meeting Mr. Dominy was presented with a testimonial, particulars of which are given on another page.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. Mr. Thomas Coomber, gardener to J. I. Rolls, Esq., Hendre Park, Monmouth, sent a Smooth Cayenne Pine, which received a cultural commendation. Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, South Molton, sent a Smooth Cayenne Pine weighing 8 lbs. 2 ozs., which received a cultural commendation. Mr. E. J. Atherton of Chatteris sent two dishes of seedling Apples, which were passed as being of no merit. Mr. Edward Holmes, Whittington Nursery, Lichfield, sent a seedling Crab, in shape like a long Siberian Crab. Col. R. Trevor Clarke, Welton Place, Daventry, sent a seedling Pear raised from Marie Louise, which received a first-class certificate. A pretty German Apple called Landsberger Reinette was exhibited from the garden at Chiswick, and was found to be of superior flavour. Mr. Woodbridge sent a bunch of Foster's Seedling, which received a vote of thanks. Messrs. Lane & Son of Berkhamstead exhibited eight baskets of Grapes in a high state of cultivation; a silver Knightian medal was awarded. Mr. Roberts, The Gardens, Gunnersbury, sent two Queen Pines, one weighing 5 lbs. and the other 5 lbs. 12 ozs.; a cultural commendation was awarded. Mr. Dell, Stoke Rochford, Grantham, sent a seedling Apple which was passed. Mr. C. Haycock sent a dish of Peach Sanguine Grosse. The Committee were of opinion that it is an American seedling from the old Sanguinole; the quality was inferior. A vote of thanks was awarded. He also sent two branches of a late Plum, name unknown; the Committee identified it as Cheshire Damson. Mr. Mundell, gardener to Lord Ebury, Moorpark, sent an Apple called Moorpark Pippin. It was considered the same as an Apple grown in Kent under the name of Langby. It was considered a good kitchen Apple, but not worthy of a certificate. He also sent four handsome Queen Pines, to which a cultural commendation was awarded. Messrs. Veitch & Sons sent an Apple called Barker's Seedling, a large handsome fruit, some of which were as large as Warner's King; and Gloria Mundi—a very handsome Apple, but not superior to others already in cultivation. Mr. D. Lumsden, The Gardens, Bloxholm, sent a seedling Apple raised from Kerry Pippin crossed by London Pippin, but it was not considered of sufficient merit to receive any award. Mr. E. Gandy of Boughton Monchelsea sent fruit of Loddington Seedling Apple, large and handsome. Mr. Haywood, Woodhatch Lodge, Reigate, sent fruit of Melon Apple, for which a letter of thanks was awarded. Mr. O. F. Wainright, Rushton Hall, Kettering, sent a dish of Lemons, to which a cultural commendation was awarded. Messrs. Carter & Co., Holborn, sent the new Tennisball Onion and the new straw-coloured Giant Rocca, new varieties from the South of Europe; a letter of thanks was awarded. Messrs. Veitch staged a collection of nineteen varieties Kale. Mr. T. Laxton, Bedford, sent a dish of The Czar Runner Bean, which was passed as being too coarse. The General Horticultural Company exhibited two boxes, one containing Apples and the other Tomatoes from America, to show the safe manner in which they had travelled so far, and the system was highly commended.

In the vestibule, Apples, Pears, Potatoes, and Kales constituted an extensive and interesting display. Messrs. J. Veitch & Sons' collection of 164 varieties of Apples received especial attention, not only on account of the large number of varieties shown, but because the fruits were, in the majority of cases, very fine. It is worthy of notice also that all the fruit was gathered from the trees in Messrs. Veitch's Fulham nursery, scarcely out of the London smoke, and yet the examples contributed would have been creditable to any grower in the most favoured position. It is unnecessary to give the names of the varieties, indeed a selection of the best would alone occupy considerable space; suffice it that all the really good Apples in cultivation were represented, and the silver Knightian medal awarded was well merited. A number of Kales was also shown by the same firm, Dwarf Green Curled, Ragged Jack, Dwarf Purple Curled, Laciniata, and the Palm Tree form being noteworthy.

Messrs. H. Lane & Son, Great Berkhamstead, also had a large collection of Apples, comprising about a hundred varieties, some of

the fruits being very fine, especially Mère de Ménage, Scarlet Admirable, Emperor Alexander, Warner's King, and New Hawthornden. A collection of Cob Nuts and Filberts was also staged, including the Kentish, Gosford, and Daviana Cobs, with the open and close Filberts. A silver Knightian medal was awarded for the collection. Mr. R. Dean, Ealing, was awarded a bronze Banksian medal for a collection of hardy fruits, comprising some good Apples and Pears. Mr. Steggles, gardener to A. W. Green, Esq., Faulkners House, Tonbridge, also sent thirty-two dishes of Pears, some of very fine size. Doyenné Boussoch, Catillac, Beurré Diel, and Beurré Superfin were very fine. From the Society's Chiswick Garden two creditable collections were sent—namely, 192 dishes of Apples and 114 dishes of Potatoes. The majority of the Apples were excellent samples of their respective varieties.

There were only two competitors for Messrs. Hooper & Co.'s prizes for four dishes of Potatoes of the varieties Hooper's Round White, Covent Garden Perfection, Pride of America, and Beauty of Kent. Mr. C. W. Howard of Canterbury was accorded the first prize for clean even tubers, and Mr. G. Steggles followed with similar specimens.

**FLORAL COMMITTEE.**—James McIntosh, Esq., in the chair. Messrs. J. Veitch & Sons, Chelsea, had an interesting group of new and choice plants, many of which were certificated. One very noticeable portion of the collection were the *Cypripediums*, including good examples of the hybrids *C. euryandum* (*C. barbatum* × *C. Sedeni*), *C. porphyreum* (*C. Roezlii* × *C. Schlimii*), *C. vexillarium* (*C. Fairrieanum* × *C. barbatum*), *C. Ashburtonianum* (*C. barbatum* × *C. insigne*), *C. œnanthum* (*C. insigne* Maulei × *C. Harrisianum*), *C. Arthurianum* (*C. insigne* × *C. Fairrieanum*), and *C. calurum* (*C. longifolium* × *C. Sedeni*). Among several other noteworthy plants were a Japanese plant named *Caryopteris mastacantha* (or *incana*), a semi-shrubby plant with narrow obtusely serrated leaves and clusters of pale lilac flowers. Mr. W. Bull, Chelsea, exhibited several new plants and Orchids, among which a variety of *Odontoglossum vexillarium* named *rubellum* was noteworthy. It was shown as "a new autumn-flowered variety." The flowers are of moderate size and good colour, and the variety is said to prolong the blooming season till the end of the year. *Lælia autumnalis atro-rubens*, a variety with very rich dark purple flowers, was also very fine. A cultural commendation was awarded for *Oncidium incurvum*, with three fine panicles each a yard in length of its peculiar purple-spotted flowers. A vote of thanks was accorded for a small but handsome specimen of *Oncidium varicosum*, the bright yellow labellum of this species being of great size, and the compact panicle has a very bright effect.

Mr. B. S. Williams, Upper Holloway, contributed a pretty group of Orchids, including some handsome specimens. *Cælogyne Massangeana* had two racemes of its peculiar buff-coloured flowers. *Oncidium chrysothyrsus* was notable for the brilliant yellow colour of its large flowers. *Oncidium ornithorhynchum* had eight fine panicles. Very noticeable also was *Odontoglossum grande* with half a dozen large handsome richly coloured flowers. *Oncidium Forbesii* bore a fine close panicle of bright brown flowers veined with yellow at the margins of the sepals, petals, and lips. Messrs. Rawlings Bros., Romford, sent collections of Show, Fancy, and Pompon Dahlias, representing many fine varieties. Some of the best were in the Show varieties. Prince Bismarck, rich purple, good size; Harrison Weir, very neat, fine bright yellow; Thomas Goodwin, maroon; Joseph Green, scarlet; and Canary, clear yellow. Messrs. H. Cannell & Son, Swanley, exhibited a good collection of Dahlias; the single forms and the Cactus Dahlia, *D. Juarezii*, were especially well represented. Among the single forms *gracilis perfecta*, scarlet, broad florets; Yellow Dwarf, Paragon, and the pure white form named Alba, were particularly fine. A large number of flowers of a remarkably floriferous Dahlia, Glare of the Garden or Fire King, were shown. The flower heads are bright scarlet, and very effective. A box of Tuberosus Begonia blooms was also shown, including several handsome double varieties, notably the beautiful form recently described in these pages as Madame Dumas.

Mr. James, Castle Nursery, Norwood, contributed a group of Orchids, among which several examples of *Vanda cærulea* were very conspicuous and noteworthy. Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, exhibited a plant of a *Chrysanthemum* with white flowers, said to be a sport from James Salter, and named Lady Selborne. It may be remembered that this variety was shown at the Brixton *Cbrysanthemum* Show last year, and awarded a certificate as a distinct and meritorious sport from the well-known James Salter. The Floral Committee did not consider it worthy of a special award. A vote of thanks was accorded to Mr. J. T. Riches, Tooting, for flowers of Michaelmas Daisies, *Aster novæ-angliæ* and *A. ericoides* being notable. *Senecio pulcher* was also fine. A similar award was accorded to G. F. Wilson, Esq., Weybridge, for a fine panicle of *Oncidium unguiculatum*, a species with bright yellow labellum and narrow brownish petals and sepals.

Messrs. J. Carter, High Holborn, sent some fine blooms of African Marigolds, lemon and orange-coloured, one named Cloth of Gold being particularly handsome, very evenly striped with rich deep crimson and yellow. Mr. W. Baldwin, Hassock's Gate, Brighton, was accorded a vote of thanks for a plant of his Double White Mignonette in very good condition, the flowers possessing a surprisingly strong fragrance. Mr. C. Goldsmith, Sandhills, Betchingley, Surrey, sent a strange *Richardia* with a tripled spathe—that is, there were three large white spathes instead of one. Mr. George of Putney sent several seedling *Abutilons* of considerable merit. Brilliant was of a

good scarlet tint; King of Scarlets very dark in colour; and Striata, streaked with orange, were the most noteworthy, the flowers being well formed in each case.

A very interesting group of plants was contributed from the Society's garden at Chiswick, including Pelargoniums, Ferns, Begonias, Bouvardias, Solanums, and many other plants. One unnamed Solanum with spinose leaves and globular deep orange-coloured fruits about an inch in diameter, was observable in this group, and as the fruits appear to be produced freely it is probable the plant will prove useful for decorative purposes. Among the Bouvardias Maiden's Blush, of a pleasing rosy tint; elegans, scarlet; Hogarth, scarlet; and alba elegantissima, white, or faintly tinged with rose, were the best. In addition to the awards named above, votes of thanks were accorded to Messrs. Carter & Co. for their Marigolds; H. Cannell & Son for Single Dahlias; Rawlings Bros. for Dahlias; and James of Norwood for the group of Orchids.

*Nepenthes Rajah* (Veitch).—A very healthy specimen of this notable Nepenthes was exhibited, and though the pitchers were small they were of a very rich deep red colour. The pitchers of this species are reputed to be the largest of all other Nepenthes, and this is borne out by the dried specimen accompanying the plant, which was 9 or 10 inches in length and 4 to 6 in diameter. The plant shown was raised from seeds imported from Borneo, where it was found by Messrs. Peter Veitch and Burbidge upon Mount Kilu Balu.

*Nepenthes madagascarensis* (Veitch).—A pretty species, with neat very deep red pitchers. It is close and compact in habit, and seems to form pitchers freely in a young state.

*Adiantum cuneatum grandiceps* (Veitch).—A variety of this useful Fern with fronds or divided at the tips, after the style of so many British Ferns. It is graceful in habit, the heavy points of the fronds inducing a slight drooping appearance.

*Masdevallia velifera* (Veitch).—A peculiar species, with dull yellowish flowers of moderate size, and possessing a most offensive odour.

*Globba coccinea* (Veitch).—An extremely ornamental Zinziberaceous plant, with ovate dark green shining leaves, and terminal spikes of small scarlet strangely formed flowers and bracts. Very attractive, and easily grown in ordinary stove temperature.

*Davallia gibberosa* (Williams).—One of the most distinct forms of Davallias in cultivation, resembling in general appearance some of the Aspleniums of the *A. bulbiferum* type. The fronds are 2 or 2½ feet long, somewhat triangular in outline, and 1 foot broad at the widest portion. The frond is finely divided into linear dark green pinnules or segments, and has a very elegant appearance. The Fern will no doubt become a great favourite.

*Amaryllis Mrs. Garfield* (Williams).—This was stated to be a cross between *Defiance* and *reticulata*, and it evidently partook of the latter characters strongly. The flowers were not large but of moderately good form, very regularly streaked and netted with clear delicate rose upon a white ground. The softness of the tint and the evenness of the marking rendered the variety very pretty.

*Celogyne Massangeana* (Williams).—An attractive Orchid, the specimen shown having two long pendulous racemes of buff-coloured flowers.

*Adiantum Lathomi* (The General Horticultural Company).—This beautiful Fern, which is doubtless destined to take a high position in the favour of Fern-lovers, is another of Mr. Bause's raising, having been selected from a batch of *Adiantum scutum* which had been raised from spores. *A. Lathomi* closely resembles the above-named species in the form and size of the pinnules, but the habit is more compact, and the fronds, too, have their divisions more closely set, so that a fine head is formed, eminently suiting the plant for exhibition. The specimen shown was a handsome one in every way, several feet in diameter, and as healthy and fresh as could be desired.

*Dioon edule lanata* (Bull).—A neat and pretty variety, differing chiefly from the species in the slight woolly surface of the rigid fronds.

*Odontoglossum vexillarium rubellum* (Bull).—Many varieties of this fine *Odontoglossum* are now known; and though the one named above has not such large flowers as some others, it appears to possess other characters of considerable value. It was shown as an autumn-flowering variety, and is described as continuing in flower until the end of the year. Another distinctive mark is that the flowers on all the plants are exactly alike in shade—namely, a deep rose tint evenly spread over the flower.

*Coleus Ada Sentance*.—Another of the numerous handsome Coleuses that have been raised by Mr. King, gardener to G. Simpson, Esq., Wray Park, Reigate. The leaves are heart-shape, very neat in outline, rich rosy crimson in the centre, around which is a band of irregular maroon blotches, and a clearly defined margin of green and yellow. It is a very brightly coloured variety, and is quite equal to some other productions of this raiser. One shown on the same occasion, Mrs. Vogan, was, in the opinion of many, equally deserving of a certificate; the leaves were small, dark crimson, with a green margin, and being of excellent compact habit it would be especially useful for decorative purposes.

*Coleus Dolly Varden*.—Exhibited by Mr. R. Lloyd of Brookwood. It is a peculiar variety, the leaves being streaked with green, crimson, and maroon, the latter predominating.

*Dahlia Beauty* (Turner).—A Show variety, with large substantial flowers, bright clear yellow, the florets being tipped with pale pink.

### THE GLADIOLUS.

THERE are many interesting points in your correspondent's letter (R. P. Brotherton) which I may like to say something on a little later on; but there is one point at which I am very much surprised, where he says that "I have never made much of these small corms," alluding to the small bulbs which cluster round the large one. I may say that I have now a goodly number of flowering corms raised in this way, that my friend Mr. Banks raises a large number every year, and I have at this moment a row of eighteen *Horæe Vernet* flowering which I obtained two years as spawn on a large corm. If we want to keep up our collections we must depend on these, and therefore I would advise all Gladiolus growers when they are lifting their bulbs now to keep every one of them.—D., Deal.

### A WEEK IN LONDON.

#### BATTERSEA PARK.

THIS, without doubt, is the most attractive park in London. The formation is so varied that it shows to greater advantage the different styles of bedding employed than the others can, as they are mostly flat and have not suitable surroundings for subtropical bedding to produce the same imposing effect as at Battersea. The grounds have been admirably laid out, and are, independent of the bedding, a great attraction in themselves. In following one of the many winding walks we come to several nooks in which some style of bedding is displayed to the best advantage. No matter which way you turn there is some pleasing view—either the peculiar-shaped lake with its beautiful Water Lilies, or portions of the artificial rockwork overhung with *Cotoneaster*, *Vitis*, and other suitable plants.

In the borders numbers of herbaceous plants are employed, and thousands of *Anemone japonica alba* and *Anemone japonica* were flowering at the time of my visit. What an imposing appearance the former presents when grown in quantity near dark-leaved shrubs! In one nook there was quite a plantation of a very fine white Phlox named "The Queen," among stately plants of *Ricinus communis*; this arrangement was very imposing. Pentstemons, too, were freely employed. In addition to these I noticed beds of *Roses*, *Liliums*, *Delphiniums*, *Gladioli*, and many other beds of similar plants which were past their best, but must have been conspicuous in their season. Distinct from these were raised mounds and slopes covered with *Sedum*, *Saxifrages*, *Cerastium*, and many other plants. One plant employed in some of the subtropical beds was *Amaranthus caudatus*, and never have I seen it employed with so much taste. It was effectively employed in a circular bed, forming the groundwork for some large plants of *Dracæna lineata*. *Funkias* are largely planted in the borders and on the grass. Succulent beds also abound, and some of the occupants are very curious and command much attention from visitors. In addition to beds entirely composed of succulents, many are used in the carpet and other beds, as well as being planted on the grass. Palms and *Dracænas* are freely employed, some being very large and stately.

In some appropriate nooks were fine groups of *Eucalyptus globulus*, other groups being principally composed of *Brugmansias*, probably *B. Knightii*, producing their trumpet-shaped flowers freely; others of *Ricinus sanguineus* and *Solanum macrophyllum* with fine bold leaves. These more or less were mixed with *Lantanas*, *Verbena venosa*, variegated *Veronicas*, and other plants, being edged with *Salvia argentea* and *Chamæpeuce diacantha*. *Gazanias* and Zonal *Pelargoniums* contrasted well with the surrounding beds. Another handsome subtropical plant, *Polynnia grandis*, was most conspicuous with its large deeply cut leaves. It was very imposing, and scarcely surpassed by any other large-foliaged plant. Very graceful in some of the beds were the *Aralias*, *Acacia lophantha*, *Dracæna gracilis*, and *Grevilleas*. *Erythrina Crista-galli*, which was flowering profusely, was freely used in one of the borders with good effect. *Acer Negundo variegata* and the Golden Elder are also planted in some portions of the park, and contrast well with the green foliage surrounding them. One of the most natural pieces of grouping in the park was that portion devoted to the Ferns. They were grouped in a sheltered position under the shade of trees, and were growing and making new fronds freely, especially the *Cyatheas* and *Dicksonias*. The portion of ground in which they were arranged sloped somewhat on each side, and presented quite the appearance of a natural dell.

The carpet beds were not so numerous as in some of the other parks, but they were in excellent order, the designs neat and elegant, and the colours admirably blended. The soft silvery *Sedum*

acre elegans was freely used, as well as succulents, small *Dracænas*, and others. Some of the plants employed for the lines in these beds were allowed to rise a little higher than others, which added considerably to the beauty of the beds. This style breaks the flatness, and is a great improvement upon the even system that prevailed so long.

The *Pelargoniums* were much dashed with the previous wet weather, but from all appearance had been very brilliant. Henry Jacoby, dark scarlet; Mrs. Holden, pink; and the old *Manglesii* were still flowering with much freedom. In another portion of the park Dahlias were flowering freely in the borders. French Marigolds and mixed Zinnias were in full bloom and very attractive. Seedling *Verbenas* and *Mignonette* planted together constituted a beautiful border, with a few *Anemones* at the back row.

My hurried run through this beautiful park prevented me from taking notes of many features of interest, but I saw enough to convince me that Mr. Roger deserves to be congratulated on the admirable general condition of the park.—A COUNTRYMAN.

(To be continued.)

#### ECONOMICAL FLOWER GARDENING.

To those who have to produce a display of border flowers at a little cost and with few appliances, it may be of interest if I narrate my experience and success this year. My object was to raise a number of plants that would give me a good supply of cut flowers for various decorative purposes. In April I formed a good steady hotbed, and after covering it with a layer of soil 3 inches deep I placed over it a large two-light frame. When the temperature was at about 80° and falling, I sowed seeds of African and French Marigolds, *Zinnia elegans*, German Stocks, and *Pæony Perfection* Asters. As the time for sowing was carefully chosen the plants came up very well, and as soon as they could be handled they were pricked out in boxes and encouraged to grow in a little heat.

By the end of May the plants were all established in the borders, having been put out about the 20th. Since then they have needed little or no attention, and have flourished and produced basketfuls of flowers most useful for all kinds of decorative purposes. The African Marigolds were planted well back in the borders three in a clump. They are now 3 feet high, and are covered with their large orange-coloured flowers, and have been flowering for several weeks. They certainly rival the yellow Dahlias, for they are in flower for a much longer period and are very showy. The French Marigolds are not so tall, but produce a much greater variety of flowers, some of the light tinted buffs being very beautiful, while some are flaked after the manner of a *Carnation*. Zinnias are now produced much more double than they once were, and are valuable because of their unusual colours. The Stocks have produced a fine display, most of the flowers being double, and have proved most useful for cutting. There are better kinds of Asters for borders than the *Pæony Perfection*, but I grow that variety because the flowers are produced on good stalks, and are most useful in that form for my purposes. The frame in which the plants were sown was 8 feet long and 8 feet broad, and I suppose that 3s. or 4s. at the most would buy seed of the finest strains sufficient for a frame of that size. From such a frame I had hundreds of plants, and many were thrown away as I had not room for them in the borders.

Next season I intend to raise, in addition to the above, a number of *Phlox Drummondii*. The varieties are now so chaste and unique that they have become indispensable. In the same frame also I shall raise *Helichrysums*, for I see my friends have most beautiful displays, and were cutting quantities of flowers during a very wet cold August. I should also mention here that I have had a row of Sweet Peas staked and grown as ordinary Peas, and have had large quantities of their many-coloured fragrant flowers to help in vase and table decoration. If any of your readers wish to have an abundance of flowers for cutting at the lowest cost, from practical experience I can recommend the varieties mentioned above.—VINDEK.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 30. NEW SERIES.

A FAMILIAR nursery rhyme acquaints us with the retributive fate that befel "daddy longlegs" in consequence of his undevotional habits, and this name has been loosely applied by individuals, juvenile and adult, to various long-legged insects. It is frequently given to the craneflies (*Tipulæ*), still more often perhaps it is bestowed upon the spiders of the family *Pholcidae* that are seen perambulating walls or ceilings, and also at times lurking upon the shrubs of our gardens. I apprehend they feed more by night

than by day, as I have seldom seen one in the act of devouring anything; but, their bodies being slender, probably they require less food than some of their kin. Resting on the trunks of trees and upon palings they may resemble in colour with outstretched limbs, and the body kept flat, they are evidently in ambush for insects that may approach. These spiders do, however, construct slight webs, though they seem to be seldom "at home." *Pholcus phalangoides* is a common species with a light body darkly streaked.

The spiders of the family *Theridridæ* are of moderate size, some rather small; they are web-weavers, their webs being irregular in shape and composed of fine threads. They are not unusually found near each other, upon bushes or low plants; now and then they are spun in conservatories. The dark-bodied *T. tepidiarum* occurs only under glass, its partiality to warmth being supposed to indicate that it is an imported species. A notable peculiarity in the spiders of this family lies in the thorax, which is rather humped and projects over the thorax. Several of these species not only construct a web as a snare, but also make a nest of a tent-like form, and slightly thicker than the web, the outside of which the spiders stud over with small pebbles, bits of twig, or dry leaves. The eggs deposited in this nest are usually enclosed in one or more silken cocoons. The reddish brown black-spotted *Theridion riparium* has been seen feeding its young with ants some time after they had emerged from the egg, others in the group show a similar attention to their progeny. Many persons will have observed in gardens towards the end of the summer tiny pear-shaped objects of a greyish white dotted with a few points, occurring commonly in leaves partly folded. Some might fancy them of a vegetable nature, or large eggs of an insect; these are really the cocoons of *T. pallens*, a small light-coloured spider of this family, which seems to leave its eggs generally. Another small species allied to the preceding, *Lycosia montana*, abundant about hedges and masses of herbage, makes a web that is out of proportion to its own size, and crossed above by many silken cords which help to capture flying insects that may come near. The garden spiders of the family *Epeiridæ* have been conspicuous by their webs for several weeks past, nor do they withdraw from our view in autumn until the last of the moths, flies, and other insects that visit the Ivy bloom have died or become torpid. Those spiders that have in August spread their webs close to or on the ground (as some *Epeiræ* will) destroy a quantity of the injurious *Tipula oleracea*, and just now the webs placed in higher positions are covered with winged aphides. Undoubtedly helpful to horticulture as are these spiders, their webs, unless in nooks and corners, are seldom left undisturbed, but they show astonishing diligence both in repairing and reconstructing. It has been asserted that they go over the web at least once a day, even if it has not been injured, touching it up and strengthening. The *Epeiræ* commonly plant themselves boldly in the centre of this, but sometimes they prefer to secrete themselves under a leaf below their snare and close at hand.

It is not necessary to describe these well-known insects, but a few words must be devoted to their remarkable spinnerets. There are three pairs. The four larger ones are placed at angles to each other, as if to guard the third pair surrounded by them. Each pair has a number of spinning tubes, varying in their size and arrangement. From these spinnerets there is produced not only silk but a gummy secretion; the latter is believed to be developed specially by the inner and lesser pair. It had long been observed that the threads of the webs of the garden spider were more or less sticky, excepting the ends of those which met in the centre, and the old naturalists believed that the insects, having completed the geometric circle, went again over the threads to varnish them with this secretion. But Mr. Underhill gives it as the result of his observations, that the lines of an *Epeira's* web are made sticky while they are being drawn out by the action of the different pairs of spinnerets. Owing to this peculiarity in the web, the maker thereof cannot traverse it without breaking most of the threads, but a spider's strength of limb enables it to do so and avoid being entangled. It is noticeable, however, that one of the geometric spiders cannot traverse the web of a neighbour as easily as it can the web which has been constructed by itself; therefore, should a spider get into a strange web it is in some peril of being overtaken and seized by the rightful occupant. If closely pressed it will cut the threads at its rear and thus baffle pursuit. These spiders have an odd way of suddenly vibrating in the middle of their webs if alarmed, and not only then; hence some people have supposed they oscillate their webs in this way to free them from dust, or to test the strength of their threads. It has been stated that the *Epeiræ* and some other species occasionally make a ticking or snapping sound, but I have not been able to perceive this. Best known of all in this group is the common diadem spider,

E. diadema, with an abdomen of a brownish tint, upon which is mark that has been regarded as a diadem, and also as a cross. In France it is commonly called "Croix de St. Denis." The females are much larger than their male companions, and often prove to be parents of as many as seven hundred or eight hundred young spiders; but no doubt the greater number of these die immature, since the annual average of spiders we see remains much the same. Birds, though chary in touching adult spiders, clear off many of the small fry.

Poets and naturalists have repeatedly spoken of the beauty of the silvery gossamers, "that twinkle into green and gold." The word "gossamer" is, however, so applied to the webs that are produced by more than one species of spider, which webs, spread over bushes and trees, are shown up when the sun shines on a dewy autumn morning. But the proper gossamer spiders are those belonging to the genus *Xysticus*; they are able to rise in the air by means of the silken thread they throw out, and can travel for some distance with the wind. These spiders are so formed that they can move either forwards, backwards, or sideways, and they can run very rapidly though their legs are feeble, excepting the front pair. Some of them chase their prey, others hide to obtain it under leaves or in holes.

The wolf spiders (*Lycosidæ*) are numerous in Britain, about thirty species, large and small, being already reckoned up: this is the family to which the famous Italian spider, the Tarantula, belongs. *Dolomedes fimbriatus* is one of our largest British species, occurring in fenny and marshy districts, receiving from its semi-aquatic habits the name of the raft spider. It is brown in colour with an orange band and white spots, and its raft is contrived of twigs, leaves, or grass secured by silk. Upon this the spider sits. As it floats those aquatic insects that come to the surface are attainable, but it also plunges at times into shallow water and runs over the surface. Land insects are hunted when the spider is not inclined to be nautical. Upon nearly every lawn the grey wolf spider (*Lycosæ saccata*) glides about, the females dragging about their balls of eggs during the autumn. Lastly I mention the *Salticidæ*, so called from their leaping powers; they make no web, securing flies and other winged insects by springing upon them. They have an oblong thorax and small abdomen. The brown and white *S. scenicus* appears everywhere, and chases its prey with the greatest coolness, unawed by the presence of human beings.—J. R. S. C.

#### MR. SIMPSON'S GRAPES.

MR. SIMPSON is needlessly sensitive about his Grapes, and under the circumstances I should have imagined he would have let his Edinburgh exhibit pass quietly into oblivion. I was requested to furnish a moderately full report of the Edinburgh Show, and in doing so gave these Grapes quite as much attention as they merited. In the reports published by two of your contemporaries no mention is made of these Grapes. Why? For my own part I have not a word to withdraw from that furnished in the report. The Grapes had been badly packed, were badly rubbed, and were not in good condition. If Mr. Simpson has read "SINGLE-HANDED'S" communication on the next page to that in which his own appears he will find my report substantially borne out. He mentions them as "not very good samples."

My opinion of the Grapes is this—and if Mr. Simpson had not desired my opinion certainly I would not have troubled him with it—that at the Edinburgh Exhibition they were amongst the worst examples of Grape-growing staged. The bunches of Gros Guillaume and Raisin de Calabre were quite straggly, with those long stalks to the clusters of berries which tell so plainly of the previous year's wood having been unripened. At the same time the thinning had not only been badly done, but too many berries had been removed, and the marks of syringing were so patent that these alone would have prevented them, if in other respects good, from taking a place as first-rate examples of Grape culture. I cannot conceive how Grapes, which were so unripe in the second week of September as to set on edge the teeth of an inquisitive official of the Society, could be pronounced good examples.

As to gardeners "not being impressed with the economy of the system," I have only to say that I discussed the subject with a number of gardeners, several of whom have taken high positions in fruit shows. Nurserymen, amateur cultivators, and proprietors of gardens were like the gardeners in expressing their astonishment that such Grapes should have been sent to a high-class show. One gardener who grows his Vines on cool treatment, on reading on the ticket accompanying the Grapes that they had been produced at a great saving in fuel, made this remark—"The fuel has certainly been saved at the expense of the Grapes."

I am not much impressed with the letters Mr. Simpson has received. His correspondents appear to resemble those who are continually trying gardening theories and never succeed in carrying out any of them. I am afraid something else was wrong with the Muscats, which would not set in a temperature of 75°, than unsuitable temperature. Let us hear from a gardener who has proved to the world that he can grow Grapes that Muscats will not set at a temperature of 75°, and that red spider is sure to follow, and the letters of your correspondent will have due weight. The gentlemen whose Vines "have borne good crops of Grapes hitherto" I would not take in evidence either.

With regard to Alnwick Seedling, from the same Vine as that shown at Edinburgh, taking a first prize at Sheffield a few days previous to the former Show, I have only to say that to me it proves that the gardeners round Sheffield want to brush up a little in Grape-growing. But why, Mr. Simpson, did you not enter the lists at Edinburgh, and carry the war to some effect into the "camp of the Philistines?" And now let me say that all our Grapes are grown at low night temperatures in the earlier stages of their growth. I have to thank Mr. Simpson for the hint he gave us on the point several years ago. It was a step in the right direction, and if followed out in a sensible manner very good Grapes can be grown.—YOUR EDINBURGH REPORTER.

#### PLANTS IN POTS v. PLANTED OUT.

WHILE visiting some great gardens in the south of Scotland lately, and trying to gather hints of value, we were much struck with the difference between many plants in pots and others in borders. In the long corridor at Floors Castle we could not help remarking the magnificently healthy specimens of Camellias and numbers of other plants permanently planted out in prepared borders of loam. In one house there were some dozens of robust, healthy, and clean Gardenias, very superior to those generally seen in pots. At the same establishment Azaleas and other greenhouse and also stove plants in pots, although in some instances enjoying whole houses to each kind, were only very ordinary; thus showing the superiority of the system of planting-out. Bananas planted out and enjoying a whole house were very fine.

It is a curious fact that plants in pots in large gardens are not often seen in first-rate condition. There are more reasons than one for this, but probably the chief one is that much of the work has to be entrusted to young men who are inexperienced and perhaps careless; hence potting is carelessly done and watering is carelessly done, with the inevitable results. Carefulness in potting and in watering may not be very necessary in the case of plants which only exist a few months, although even with them the result depends very much on these operations. Many people fancy that Orchids, for instance, and Heaths are difficult plants to grow; but when these are properly potted and watered the supposed difficulties vanish. An overpotted Heath or Orchid is almost sure to suffer from overwatering if the supply is not regulated with an intelligent forethought not always possessed by young men. In the case of the Heath, dryness is extremely liable to cut short the existence of the plant if it is the least root-bound.

These facts have often exercised men at the head of large establishments. When gardens are so large that the gardener cannot possibly supervise everything personally, fine specimen Heaths and other hardwooded plants are seldom seen. In comparatively small gardens, when, perchance, all the potting and watering is done by the master himself, we seldom fail to find better results than in larger establishments. We have one such in our mind's eye at this moment. It is a single-handed place in Midlothian, famous for having produced the biggest bunch of Grapes on record, and famous for much more, as competitors at local shows well know. A year or two ago we visited Mr. Currer at Eskbank—for to him we refer—and after having seen the most famous gardens in the neighbourhood we were inclined to pronounce Mr. Currer the "best gardener in the county," as we were assured he was by the person who advised us not to miss Eskbank. The secret of the whole was simply this: Mr. Currer had to personally attend every plant himself. Others equally enthusiastic, equally skilful, fail to reach any high standard simply because important work, such as potting and watering, has to be relegated to others who do not fully understand it, and who do not always recognise their responsibility.

It is not always the gardener in charge who is to blame. Sometimes the difference of a couple of shillings a week determines whether a labourer shall or shall not take the place of a more skilful but perhaps less costly man. Not long ago we experienced a case of this kind. A more industrious labourer never worked in a garden; what he lacked was not zeal, but knowledge. In wash-

ing the pots in our Cattleya house he managed to break off several pounds' worth of young shoots in spite of all warning. The sacrifice was greater than the difference in wages for a year or two. It is the same when we have to engage a young or a not first-class workman, simply because the wages are serewed down to the last shilling.

This by the way, however. We were about to say something further upon potting. The subject has been discussed before, and we daresay most practitioners are agreed that the planting-out of a large number of plants, when that is practicable, secures better results than the pot system. It is, however, not practicable in small gardens, and neither is it so necessary; still, in these, pots are too much used for plants when they are in the juvenile stage. Striking cuttings in small pots and pricking out small seedlings into pots is, we consider, a mistake. For small plants and cuttings sandy soil is generally used. When this is placed in spoonfuls into small 60's it requires much mis-spent labour to prevent it becoming continually overdry, and much skill to keep it healthily moist. It is a thousand times better to place small plants the necessary distance apart in boxes. Calceolarias, Cinerarias, Primulas, Pelargoniums, Fuchsias, and all other soft and, in many instances, hardwooded plants, thrive much better treated thus, and if the soil be porous and flaky the plants may be lifted with fine balls of roots, and transferred at once to pots 6 inches wide. Young healthy plants will soon fill the pots with roots, and the plants will grow with a freedom never known by those nursed in thimblefuls of soil.

We think a large number of plants suffer from being overpotted. We are decidedly in favour of growing plants in the smallest pots possible, for we find it is easier to do so. Even many gross-feeding plants are spoilt by being overpotted. We do not advocate keeping plants rootbound, but decidedly prefer that evil to the opposite one. When a pot is only half filled with roots it needs some skill to keep the soil sweet, and sweet soil is necessary to health.

It is surprising how plants will thrive in small pots if care be taken that the soil be never dry. We have had plants of Fuchsias 6 to 7 feet high and 3 to 4 feet through at the base, which bloomed for six months in 10-inch pots. Rootbound they certainly were, but souring was impossible, and we had them growing robustly by keeping the soil continually moist with weak sewage water. To secure this bi-daily waterings were necessary, but the results justified the works. By the same means we have Petunias in 7-inch pots on trellises with 16 square feet of surface densely covered with flowers for months. Even such gross-rooting plants as Abutilons may be kept growing and flowering freely all summer in pots that were filled with roots in spring. Lapagerias, Camellias, Azaleas, Pelargoniums, Lilliums, Paneratiums, Eucharises—indeed almost every plant, derives benefit from such treatment. We grow some dozens of the varieties of Cedo Nulli Chrysanthemums in 6-inch pots, and astonishing plants they are. Our conservatory is so shaded that ordinary varieties in ordinary pots do no good; but the Cedo Nullis flower magnificently under the treatment described. It is not always that we dare use sewage water in the conservatory. It may be of some use to many readers similarly situated to say that sulphate of ammonia is found of great benefit. A pinch of it in a canful of water has a wonderful effect in exciting and maintaining vigour for a time. It should not, however, be relied upon to produce permanently good results with valuable plants that are to live for years.

Planting out Chrysanthemums, Solanums, Callas, and others for winter use saves considerable trouble when large quantities of plants are necessary. In small gardens it sometimes does not answer. We have given one reason why it does not succeed with us; but there is another. Planted-out Chrysanthemums make enormous roots, which must be accommodated with large pots, and these look very bad in small houses. For the sake of appearances we find it better to have neat little bushes and abundant flowers. However, this is a matter that each must suit himself in. There is one thing, however, certain—namely, that large conservatories and long corridors are better when furnished with plants growing in properly made borders. Well-made and drained borders are not easily soured, even by careless watering, and the consequence is that large numbers of plants so grown attain a condition far superior to those in pots.—SINGLE-HANDED.

VANDA TERES IN A TROPICAL CLIMATE.—A correspondent of the *Gardener* writes as follows concerning this Orchid:—"When I was in Singapore I found Vanda teres was brought down from Burmah in trading vessels and sold to the residents as a popular hardy flower for their gardens. I need scarcely say that Singapore possesses a tropical climate—a mean of 82°, I believe—

so that all our Crotons and Dracaenas and other stove shrubs from both hemispheres grow there in the open borders and beds just like Phloxes and Delphiniums here in England. I was in the Botanical Gardens out at Tanglin one day, and saw in the distance a mass of flowers dancing in the hot wind. Seeing numerous stakes to the plants, and their lilac flowers, they reminded me of a mass of Sweet Peas in a sheltered home garden. 'What is the pretty mass of Lilac yonder?' I asked. 'Oh,' replied the Curator, 'that is Vanda teres!' Planted out in the ordinary red loam of the island, it grew up the stout stakes, adhering by its numerous aerial roots as Sweet Peas or Vines cling by their tendrils: there it was in glorious flower, masses of it 7 feet in height and wide in proportion—a sight to delight anyone who only previously knew of Vanda teres as cramped in a pot, seorching and starved under a glaring roof of glass."

#### KITCHEN GARDEN.

CELERY should now be well earthed up, so that as little of the stems as possible will be exposed to the influence of frost. The stalks should be drawn together, and the soil made close about them with the hands, keeping the soil out of the centre of the plants. That ready for use will be more susceptible of injury, and if it suffer from frost will decay rapidly, hence the necessity of providing a good stock of dry litter or fern for protection when necessary, not only for this but also for Lettuces and Endive. Plant out Lettuce to stand the winter. Complete also pricking off Cauliflowers into handlights or frames, and guard against the depredations of slugs by dusting with quicklime, soot, or dry wood ashes. Plant the principal crop of Cabbages for spring or early summer use, encouraging the growth of these and winter Spinach by running the hoe between the rows. Cauliflowers and autumn Broccoli should be lifted and stored away, or the large outer leaves turned inwards over the heads will protect them from several moderate frosts.

The main crops of Beet, Carrots, Salsafy, and Scorzonera may now be lifted, being careful not to cut the tops too closely, and, after remaining a few days in an open shed to become moderately dry, store them in damp sand in a cool moist position. In lifting and trimming Beet it is necessary to avoid damage, otherwise the colour and quality will be injuriously affected. Keep Brussels Sprouts, Broccolis, and winter Greens free from decayed leaves, so as to expose and harden them as much as possible.

In the frame ground Cauliflowers and Lettuces should be kept exposed as long as the weather continues open, but all should be in readiness for protecting them in case of frost. These vegetables should have all the air possible whenever the weather is favourable from now up to transplanting in spring.

*Forcing Department.*—Tomatoes planted for winter and spring fruiting must have attention in thinning the shoots, stopping, and training. Avoid overcrowding, affording a temperature 55° to 60° at night. If grown in pots tepid liquid manure should be supplied copiously. Continue sowing French Beans in pots according to the accommodation and demand, keeping them near the glass, moderately ventilated, affording tepid liquid manure, and a night temperature of 60° to 65°. Pits or houses containing late crops of these will need a similar temperature, and a little ventilation constantly.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—The fruit is nearly all gathered in late houses. If there is any doubt about the ripeness of the wood fire heat should be given by day with a free ventilation, turning off the heat at night. Remove the bearing wood of the current year; and if the wood for another season be at all crowded it should be well thinned, leaving as much as will be required for next season's bearing, with full exposure for the foliage to light and air. Where young trees are growing luxuriantly and have shown a disposition not to set and stone well make a trench a few feet distance from the stem,

removing the soil down to the drainage, and cutting through all roots. Leave the soil out of the trench for about a fortnight, when it should be returned and well rammed down; this will encourage the ripening of the wood, and mostly result in the fruit setting and stoning satisfactorily the next season. Although a lessened supply of water will be needed now, the border inside must not be allowed to become dry, or the buds will be imperfectly formed and fall in quantity later on. Push forward the cleansing of the houses and trees, and where the roof lights are moveable it will be an advantage to expose the tree to the invigorating influences of the atmosphere during the autumn months, otherwise ventilate to the fullest extent, keeping them as cool as possible.

**Cherry House.**—Cherries are not nearly so much grown under glass as they should be early in the season for dessert when fresh ripe fruit is scarce, affording not only variety but a desirable addition during April, May, and early June. Cherries must have abundant ventilation, and the trees should be accommodated with a trellis about a foot distance from the glass. A house of about 12 feet width is ample, the back wall being also utilised, the front trellis not extending to the top of the house within 3 feet. The top and bottom lights must be made to open the full length of the house and upwards or outwards, so as to admit of air being given under any circumstances without admitting rain. A 6-foot width of border will suffice, and 4 feet for the back, which will leave 2 feet for pathway. Confine the roots of the trees to their respective borders, so as to allow of the lifting or root-pruning of individual trees as may be necessary. The border should be inside the house and the roots confined to it, as the trees have to make their growth when external conditions are not favourable. A 2½ feet depth of border is sufficient, having 9 inches of drainage, and drains to carry off superfluous water. Good turfy loam with the addition of a tenth of old mortar rubbish affords the most suitable compost, which should be made firm. The trees most suitable for planting are those that have been trained to a wall for three or four years. They may be lifted carefully and planted as soon as the leaves commence falling. Empress Eugénie, May Duke, Black Tartarian, Elton, and Governor Wood are good varieties, especially Black Tartarian. The roof lights of Cherry houses should be moveable. The lights removed from this structure must not be replaced for another month or six weeks. Trees in pots can now be examined, potting those that require it, and for the others surface-dressing the soil will be sufficient.

PLANT HOUSES.

**Stove.**—*Ipomœa Horsfalliæ* and other climbers that flower through the winter must not have much pruning; but other climbers, such as *Passifloras*, which flower in summer, should now be cut back freely, so as to admit light to the plants beneath them. Some *Passifloras*, however, are still flowering, notably *P. princeps*, *P. kermesina*, *P. Madonna*, and *P. calycina*, and too much of the growths must not be removed. *Allamandas* as roof climbers are flowering splendidly and will continue to do so until a late period, and are much appreciated at this advanced season, being duly supplied with tepid liquid manure. Plants intended for early flowering should have very little water, only affording a little when the leaves flag, keeping them near the glass in a warm well ventilated house, so as to ripen the growth. *Stephanotis* must not be pruned at this season, and should only have water to prevent the leaves becoming flaccid; trained on the roof the growth will mature perfectly. Any plants that have completed growth early and have been rested a time will, if encouraged by a brisk moist heat, start into growth; but to ensure flowering the shoots must be grown near the glass. *Gardenias* that have been forwarded early in the season will expand the buds freely in a rather moist heat of 65° at night and 70° to 75° by day. *Clerodendron Balfourianum* is one of the most accommodating plants in existence, and may be had in flower at any season by subjecting it to a system of alternate growth and resting. Plants that flowered in May or June, and have since completed their growth and been rested for a few weeks by keeping them drier, will, upon being placed in heat, again produce abundance of flowers. *Franciscea calycina* major when placed in heat grows and flowers freely, and is very acceptable as giving a shade of colour (violet) not common in flowers at this time of year, the only other plant of the colour flowering naturally

at this season being *Lasiandra macrantha*. *Pentas carnea* and *P. kermesina* are seldom out of flower, and young plants kept closely stopped so as to induce a bushy habit are useful for winter flowering.

THE BEE-KEEPER.

DEVELOPMENT OF QUEENS AND BEES.

“How long does it take to rear a queen from the egg—that is, till she is ready to fly? How long is it, after she emerges from the cell, before she will take her wedding flight?” The above questions are answered as follows in the *American Bee Journal*:—

Having passed three days in the egg and five in the larval state the workers close the cell, and the future queen commences to spin her cocoon, which occupies about a day. Then, apparently exhausted by her labours, for three days she obtains complete repose, and on the sixteenth day, as a perfect queen, she emerges from the cell. The strength of the colony and the character of the season may vary it a day or so.

Fig. 56. Larva of Bee.

When the embryo queen is nearly mature—within twelve to sixteen hours of emerging—the bees begin to demolish the exterior compartment, or extension of the top of the cell, reducing it to a level with the outer edge of the cap of the cell proper. The convex cap being then very prominent is very liable to be injured, and to protect it from injury

Fig. 57.—Finished Queen Cell, sealed over. a, convex cap; b, b, the extension of the cell.

Fig. 58.—Ripe Queen Cell, with the exterior compartment removed. a, the convex cap.

the bees coat it with a fresh layer of wax, making it nearly as thick as the walls of the cell.

The young queen pierces a hole through the edge of the cover with thr mandibles, and then makes a circular cut along its periphery. Being nearly detached from the cell walls the cap drops, opening a circular passage through which the young queen emerges.

From the egg to the queen emerging from the cell takes sixteen days. She is then a virgin queen, and for five or six days she moves around in much the same manner as a worker bee, helping herself to honey from uncapped cells.

About the fifth day, if the weather is pleasant, she may be seen crawling about the entrance of the hive, and if the next day is propitious she may try her wings some distance from the alighting board. She will appear somewhat excited, but after a while she will mount up and circle around, increasing the distance each time, to mark the hive, and insure a safe return from her wedding flight.

In the warmest part of the afternoon, when the drones are flying, she will spread her beautiful wings and soar into the air to mate with a drone. If successful she will bear the marks of it on her return; if not, she will, after a time on the same day, come out again and again until it is accomplished. She will then return, going quietly into the hive, and in a day or two she will commence to lay; so that generally, from eight to nine days after emerging from the cell, the queens are laying. Should the weather be unfavourable, and she fails to meet the drones within about twenty days, she will have failed in the object of her existence and become only a drone-producer.

The drone passes three days in the egg, about six and a half in the larval state, and changes into a perfect drone in twenty-four or twenty-five days, counting from the egg.

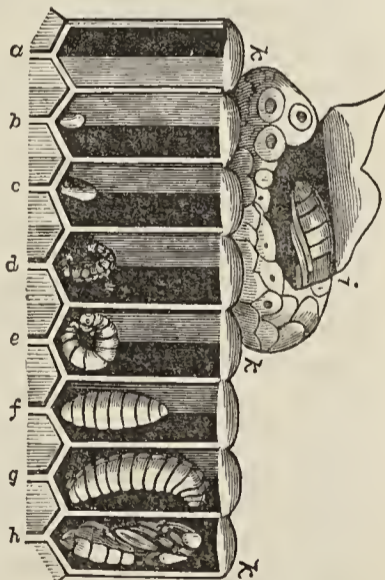

Fig. 59.—Eggs and Brood. a, Empty cell; b and c, eggs; d, e, f, and g, various stages of the larvæ; h, pupa; i, pupa or queen in queen cell; k, k, caps.

The worker, after passing about three days and a half in the egg, is hatched—a small white worm, grub, or maggot—and is called larva (a Latin word signifying a mask, for the bee is concealed or hidden in that state). It remains in this state about five days, and then the bees seal the cell over; the larva then spins around itself a silken covering, called a cocoon, which occupies about thirty-six hours. In this third stage it is called a nymphe, pupa, or chrysalis, in which state it remains until the twenty-first day, counting from the time the egg was laid, when it emerges from the cell a perfect working bee, and is called an imago.

The cocoon left behind forms a lining to the cell, and for this reason it is best not to use the same breeding comb too long, for each cocoon left behind imperceptibly, but not the less really, diminishes the size of the cell for its future occupant, and prevents the bees from attaining their full development of size.

When the weather is cool or the colony weak, the development is retarded to a greater or less extent—the heat should be above 70° Fahr. for the best results. Both the workers and the drones on emerging from the cells are rather helpless, and are soft, downy, and light in colour.

The workers and drones spin complete cocoons, enclosing themselves perfectly, but queens enclose only the head, thorax, and first ring of the abdomen—evidently to provide for the means of being destroyed by a rival queen before emerging from the cell, should it become desirable to do so.

In the contemplation of this exceedingly interesting subject is found much food for thought and meditation; and for instructive lessons none can rival the marvellous transformations that insect life undergoes in its processes of development! The repulsive maggot of to-day may to-morrow be the active little fly, visiting leaf and flower in merry and sportive mood! The repugnant caterpillar of to-day may to-morrow, as a chrysalis, be decked with green and gold, awaiting its speedy transformation to the butterfly, of brilliant tints and gorgeous beauty.

This is not a whit more wonderful than are the transformations from the egg to the tiny larva, from the larva to the pupa, and from the pupa to the fully developed honey bee, with its wondrous instincts and marvellous habits! The student never ceases to wonder and admire as he turns over leaf after leaf of the "book of Nature" devoted to this interesting insect. Indeed, there is a fascination about the apiary that is truly indescribable; but even that richly rewards the apiarist for all the time and labour bestowed upon it. Every scientific bee-keeper is an enthusiast. The wonderful economy of the bee hive, from its very nature, presents to the thoughtful student both admiration and delight at every step!

#### CRUDE HONEY AND OTHER QUESTIONS.

If there are still some people unconvinced that bees make honey from the crude material found in flowers, and would like to have the question (if it is a question) settled, I would feel obliged if they would state what evidence would be considered satisfactory. I have both crude and perfect honey taken from my own hives in the house at the present time, and everybody that examines them needs no more evidence. If any society of bee-keepers, or any three persons competent to know the difference between perfect and imperfect honey, would like to see them, I will send them by post if they request me to do so. Since the introduction and use of the "American Slinger" in taking honey from combs, the fact that crude honey is very imperfect and will not keep cannot be too widely known, for wherever the Slinger is used the imperfect honey is first cast out, being more watery. In other respects the question has been considered of little practical importance, and few bee-keepers care to know whether honey is swallowed once or twice before it is stored up by bees.

Another question of no great practical importance has, like that of crude honey, received little attention from bee-keepers—viz., the question of late breeding. If queens continue to lay for a month or two later in autumn than is usual, do they commence to lay in the following spring as early as the queens that had ceased to lay some weeks sooner? Is a certain amount of rest necessary? In July some seasons queens stop laying, or otherwise the bees decline to set their eggs. In other seasons bees continue to breed till September. This is easily understood and explained; but it is the length of the time of rest or cessation of egg-laying that is the question before us. It is a question difficult to solve satisfactorily.

Only one more question will be mooted now. In bee battles every bee stung speedily dies. Does the bee that gives the fatal probe die too? In stinging another bee does it lose its sting? Those who use microscopes in their investigation may soon settle this question. The sting of the honey bee is barbed, and, generally speaking, sticks when used in stinging animals, and carries with it the venom bag. I have thought that in bee battles and bee and drone massacres the conquering bees did not lose their stings, and this appeared to me to be a singular phenomenon and wise arrangement, but my convictions may have been formed on insufficient evidence. In the massacre of drones worker bees are not found

among the dead. Unsuccessful attempts have been often made to unite swarms of nearly equal strength, and the loss of whole swarms has resulted. In such unsuccessful attempts the loss of life has been enormous, but we have not noticed that the victorious bees suffered much from their victories.—A. PETTIGREW, *Bowdon, Cheshire.*

#### DRIVING AND UNITING BEES.

It is a long time ago I last wrote you accounts of my experience in bee-keeping. I have been a wanderer since I broke up my apiary in Hertfordshire, but I have now begun to get some stocks together again in this place. So much has been done of late years to disseminate the knowledge of scientific bee-keeping, and so many converts have been made, that any information on the subject is now sought out, and when found gratefully digested, by hundreds of readers who a few years ago had looked upon a bee as an interesting insect perhaps, but a creature to be kept away at as great a distance as possible.

This is a country with many bee-keepers—in fact, there are few cottagers scattered about the forests, which stretch away from Horsham to within a short distance of Tunbridge Wells, who do not keep bees; but they are nearly all kept on the old dome-shaped skep and brimstone-pit system. Here and there are intelligent men who are becoming alive to the errors of the old school, and have already begun to walk in the new road of success and profit; but they are only a very small minority, and any number of bees can be had for a trifling bribe and the trouble of driving. I have just rescued eight such stocks and united them in bar-frame hives. All but one skep were driven with the usual ease and success; and it is about this skep I wish to say a few words, as something may be gleaned from my remarks to assist others who may meet with a similar difficulty, and may explain to a novice what would surely puzzle him if he met with such a case at the outset of his attempts at driving.

The skep in question belonged to a friend's gardener. I had promised to drive out the bees and to put the owner into the way of feeding up the rescued swarm. It was a prime swarm of the current season and very heavy. I gave the usual puff of smoke, turned up the skep after a few minutes, and sprinkled well with thin syrup; after a short interval fixed the empty skep over the stock, which was stood in a zinc pail, and began to drive the bees out. From the first I noticed a reluctance to run, but after some amount of tapping I got a goodly number to go up; still, I could hear and see lots of bees far down in the dome among the combs, and I could not get nearly all to come up either by tapping, blowing, or by the use of smoke. I began to look for a reason, and on examining the combs found that there was only drone brood. A drone crawled out from its cell while I looked, and scattered here and there were other drone cells capped or with drone hatching. There was only one solution now of the difficulty—the hive was either queenless or about to become queenless; and I ventured the opinion to those looking on, my friend among the number, that the queen was still alive but too feeble to run up, and therefore a certain number of faithful subjects were braving smoke and what to them must have been like an earthquake rather than desert their dying queen. Robbers from the other hive were now becoming troublesome, and I advised the removal of the stock to a more secure spot. I placed the bees I had driven out on their stand and took the skep into a building. Near the window I cut out carefully comb after comb until I found, as I expected, the old queen and a bunch of bees in the centre of the hive top. She was so feeble that she could not turn herself up when on her back, nor could she crawl up the side of the hive. I therefore killed her, and in the evening joined the bees to the other stock. The bees were exceedingly quiet, and the spectators gained, as they said, more knowledge of bees through this little difficulty than they would have done otherwise. Should any of your readers meet with similar reluctance on the part of the bees to leave their skep when driving it may perhaps be similarly accounted for.—P. H. P., *Crowborough, Sussex.*

#### TRADE CATALOGUES RECEIVED.

- Boulton & Paul, Norwich.—*Illustrated List of Aviaries, Dog Kennels, &c.*  
 The Lawson Seed Nursery Company, Edinburgh and London.—*Catalogue of Trees and Shrubs.*  
 T. C. Schmidt, Erfurt.—*Catalogue of Immortelles, Dried Grasses, and Bouquet Papers.*  
 H. Cannell & Sons, Swanley, Kent.—*Catalogue of Winter-flowering Plants and Bulbs.*  
 Robert Mack & Son, Catterick Bridge, Yorkshire.—*Catalogues of General Nursery Stock and Roses.*

Cranston's Nursery and Seed Company, King's Acre, Hereford.—  
Catalogue of Fruit Trees.  
James Walters, Exeter.—Catalogue of Roses.

**Erratum.**—The name of Mr. G. Humphries, Kington Langley, Chippenham, as a voter in the Rose election, ought to have been placed in the nurserymen's instead of the amateurs' list, where it was inadvertently inserted last week.

**Potatoes (H. M.).**—Your crop is a good one if produced under the ordinary mode of culture, but is not extraordinary. We have known more than twice the yield when special attention has been given towards securing the best results.

**Oranges Splitting (W. M.).**—The trees have received a check of some kind during some period of the season, possibly during the hot weather of July, when the skin may have become firm and lost its elasticity, thereby being unable to expand, as the growth afterwards became more free. We are not sure, however, that we understand your letter, which is too brief to make the condition of the trees and the treatment they have received intelligible.

**Distinguishing Iris Roots (J. P.).**—The English and Spanish Irises can be readily separated from the German Irises, as the former have roundish bulbous roots, while the latter have rhizomes—that is, long, cylindrical, or irregularly formed brownish roots. You will not so readily separate the English from the Spanish, but the latter are generally the smaller, and are more slender in form.

**Bottling Grapes (George).**—The laterals on which the bunches are hanging are inserted in bottles of water, ordinary wine bottles being suitable, and placed in a slanting position so that the fruit hangs clear of the bottles. A room having a regular temperature of about 40° will do, but a few degrees more will do no harm, and a dark place is better than a light one. A very dry and too warm room conduces to the shrivelling of the berries; and on the other hand, if the temperature is very low, moisture is condensed on the fruit and its keeping property is impaired.

**Large or Small Garden (J. P. of York).**—We have not had the pleasure of inspecting the garden to which you refer, and are consequently unable to say whether we consider it a large or small one. The number of men employed is not always a criterion of the size of a garden. We know of gardens where a dozen men are kept not a quarter of the size of others where not half that number of men are employed. If you would like to write to Mr. Pettigrew, his address is Bowdon, Cheshire.

**Striking Roses (J. Wilton).**—You have been rightly informed; cuttings of nearly all Roses will strike if inserted in the open ground at the present time. Firm wood should be chosen, the portions that have borne flowers being usually suitable, and it is immaterial whether the cuttings are taken with a heel and cut smoothly across close under a joint. They may be about 9 inches long, two-thirds of the length in the soil, and one-third out. It is better to make trenches for them and then press the soil firmly round them; if thrust into the soil the ends are liable to injury by coming in contact with stones. If the soil is of a strong adhesive nature it will be an advantage if sand or gritty material is placed round the cuttings. The cuttings of last winter failed because they were inserted too late.

**Fuchsias and Pelargoniums (J. B.).**—You had better gradually reduce the supply of water to the Fuchsias so that the wood becomes firm and most of the leaves fall, then keep the plants in a cool temperature so as to give them a rest. About March place them in gentle heat after pruning them into the form required, and when they have fairly commenced growth turn them out of the pots, removing most of the old soil from the roots, and repot in fresh compost, then by syringing regularly in fine weather, and watering carefully, you may have them blooming freely by the time you name. If the Pelargoniums are Zonals you may keep them steadily growing in a light position in a temperature not exceeding 50° at night; if they have not a light position they will be kept drier and cooler, as growth made in the absence of light is always unsatisfactory. If your plants are show varieties they should be wintered on a shelf near the glass in a night temperature between 40° and 45°, watering the plants with great care.

**Ventilating Greenhouse (F. M.).**—Either of the modes of providing top ventilation will answer, and no one can so well tell you which method will be least expensive as the head carpenter you are employing. He will have no difficulty in giving you the close approximate cost of both methods. It is impossible for anyone to answer the question from your letter, as you do not even state whether you have rafters and framed lights or not. The old Vine is not likely to do much good; still, perhaps with the Deanery gardener's aid you may improve it. As a black Grape the Black Hamburg is the best, and Foster's Seedling is the most likely white variety to succeed in the house. You may grow stone fruits in the house if the trees are not shaded, also Cucumbers in summer, but some skill and much attention are requisite in succeeding with many crops in the same house. Many plants will grow in the shade, such as Ferns, ornamental-leaved Begonias, Camellias and Azaleas. Bulbs and all kinds of spring-flowering plants can also be grown before the Vines and trees shade the house too much. You had better obtain our "Garden Manual," post free, 1s. 9d., and our "Greenhouse for the Many," post free, 10d.

**Culture of Pentas carnea (K. D.).**—You will not find this plant difficult to grow successfully, provided the temperature of a stove or intermediate house can be secured. The compost should consist of light turfy loam, peat, and leaf soil in equal parts, with a plentiful admixture of sand. The pots must be thoroughly drained, as water should be freely supplied when the plants are growing. It is an old favourite in many gardens, owing to the flowers being produced in the dull season; though with judicious management the plants may be had in flower during the greater portion of the year. The specimen you send is a spray of *Sibthorpea europæa*, a hardy plant native of this country, and found in wet shady positions. A very pretty form with variegated foliage is in cultivation.

**Peaches and Nectarines (Tregning).**—The space being sufficient for six trees, four Peaches and two Nectarines, will perhaps suit you. Good Peaches

for your purpose are Hales' Early, Grosse Mignonne, Royal George, and Belle-garde; good Nectarines, Lord Napier and Violette Hâtive. If the soil is fertile and the water passes through it freely it will not be necessary to incur much expense in making a border; the site, however, must be well drained naturally or artificially. Order the trees now, and request that they be sent as soon as ready, and plant them as soon as they are received. The roots must be spread out quite straight, and covered about 3 inches deep with fresh loam, working it well amongst them, and on the surface of the soil over the roots, and a foot beyond them, spread a layer of half-decayed manure 4 inches thick to exclude frost and enrich the soil. This will be better than mixing manure with the soil. Do not secure the trees tightly to the trellis, as the border may settle somewhat, and the branches would then be injured; attach them loosely at first, then in the spring train them equidistant from each other, merely shortening any branches so as to secure well-balanced trees. Keep the house cool during the winter; even a little frost will not do harm to the trees, but must be excluded if you have plants in the house, and do not force to induce early growth in the spring, but let the trees start naturally. You had better cut off at once two-thirds of the growth from the top of the Vines to which you referred, and the lower growths, on which you must depend, will be benefited and form stronger eyes. We shall have pleasure in answering a letter at any time when you need information.

**The Mango (W. X. W.).**—The fruits which you state you have recently seen in Covent Garden Market are Mangoes, the produce of an East Indian tree allied to the *Rhus Cotinus*, so well known in English gardens. The tree is 50 feet high, with a spreading top, and when in flower is not unlike the Sweet Chestnut. The fruit, when fully ripe, is oval or somewhat kidney-shaped and flat, varying in size from that of a small Apple to a goose's egg; of a yellow or reddish colour, speckled with black, and filled with a fine agreeable juice. Some are full of fibres, and the juice runs out of these on cutting, or with a little handling; but those which have few or no fibres are much the finest; they eat like an Apple, but are more juicy, and have a rich sweet-perfumed flavour, accompanied with a grateful acidity. It is eaten without any preparation, except taking off the rind with the fingers or a knife, and is esteemed a very wholesome fruit, superior to the finest fruits of India, with the exception of the Mangosteen and some of the finest Pine Apples. Gentlemen within the tropics eat hardly any other fruit in the hot months; but if no wine be drunk with it the Mango is apt to produce boils, at least with new-comers, which are, however, conducive to health. Jellies, preserves, tarts, &c., are made from the unripe fruit in India. Preserved in sugar, it is not unfrequently served up at the tea-table. When unripe, it is very sour; and in this state boiled with sugar, butter, and eggs, it yields an acrid juice that tastes like boiled Apples or Gooseberries. The Javanese boil the unripe fruit in brine, which taste and are used as Olives; others boil them and steep them in vinegar and pepper to eat with meat like Cucumbers. Much of the unripe fruit comes to Europe in the form of a pickle. There are several other species of *Mangifera* which produce eatable fruit, but they are all inferior to even the worst of *M. indica*. *M. sylvatica*, besides being eaten, is dried by the natives of India and kept for medicinal purposes. The fruit of *M. oppositifolia* is the size of a small pullet's egg, and is universally eaten in Burmah.

**Names of Fruit (H. R. J.).**—We are only able to identify three of the Apples; 1, Round Winter Nonsuch; 4, probably Alfriston; 6, Ross Nonpareil. (S. B.).—1, Cellini; 2, Vineuse. (A. B.).—1, Fearn's Pippin. We cannot name the others from such unsatisfactory specimens. (H. H.).—1, not known; 2, Court of Wiek; 3, Birmingham Stone Pippin. (Reader).—1, The Apple is Kerry Pippin; the Pear is Flemish Beauty. (T. R.).—Pears: 1, Vernlam; 2, Ne Plus Meuris; 3, Beurré Mortefontaine; 4, Beurré Hardy; 5, Napoleon; 6, Nouveau Poiteau. The Apples next week. (C. E.).—Blenheim Pippin. (G. W. Y.).—1, Braddick's Nonpareil; 2, not known; 3, Reinette Diel; 4, Franklin's Golden Pippin; 5, Dumelow's Seedling; 6, Lord Lennox. (G. S. E.).—1, Cox's Orange Pippin; 2, Dumelow's Seedling; 3, not known; 4, Blenheim Pippin; 5, Blenheim Pippin; 6, Brownlee's Russet. (C. Wood).—Lewis's Incomparable. (Ramatho).—1, Pitmaston Pine Apple. We do not know Forfar Pippin, and therefore the name may be correct. You have an old edition of the "Fruit Manual," and the last is out of print. (Bickley).—Court Pendu Plat. (O. McA.).—Pears: 1, Jargonelle; 2, Marie Louise, both apparently from late blossoms; 3, Glou Morceau. Apples: 1, Winter Colman; 2, Probably Tower of Glamis; 3, Edinburgh Cluster. (Leon).—Berries, *Rhamnus catharticus* (purgative). Apples: 7, Alfriston; 8, Cellini; 9, Flower of Kent; 10, Forge; 15, Golden Winter Pearmain; 18, Beauty of Kent. (G. Y.).—Beurré Bose. (E. L., *Godalming*).—The wild fruit is *Pyrus torminalis*. Pears: 2, Chaumontel; 3, Beurré Rance. The other Pears are worthless, and must be wildings or Perry Pears. The Apple is Golden Reinette.

**Names of Plants (E. M. G.).**—1, *Taxodium sempervirens*; 2, *Libocedrus Doniana* (rather tender); 3, Too much withered to be determined, but it is probably a *Salvia*; 4, *Coronilla Emerus*; 5, *Crataegus orientalis*; 6, *Griselinia littoralis*. (G. P., *Ilfracombe*).—1, *Echeveria secunda glauca*; 2, *Cerastium tomentosum*; 3 and 4 were too shrivelled to be determined; 5, *Mentha Pulegium gibraltarium*; 6, *Sedum acre*; 7, *Diplacus glutinosus*. (W. R. N.).—1, *Hippophae rhamnoides*; 2, *Dracontopetalum Ruprechtii*; 3, *Senecio pulcher*; 4, *Bouvardia elegans*. (X. R. T.).—1, *Aralia Veitchii*; 2, *Crataegus orientalis*; 3, *Viburnum Lantana*; 4, *Calceolaria bicolor*; 5, *Asplenium bulbiferum*; 6, *Pteris argyrea*; 7, *Croton volutus*. (Inquirer).—*Colchicum autumnale*.

**Golden Syrup for Bees (H. M.).**—Golden syrup is obtained by clarifying the treacle which remains after repeated crystallisations of cane juice. It is therefore almost entirely destitute of crystallisable sugar, and necessarily contains considerable proportions of certain mineral salts, and of the re-actions produced by the agents employed in the various stages of refinement. Even in its purest forms it seems to be repugnant to the bees, as they can scarcely be prevailed on to take it; and even though they may be compelled to live on it, it would in all probability be a fruitful source of diarrhoea. But when we know that much so-called golden syrup is now produced from glucose, and consequently contains quantities of sulphate of iron, arsenic, dextrin, and other substances poisonous to bees, we can only advise you to the greatest caution in experimenting with it. Though apparently cheaper than syrup made from pure sugar, the latter undoubtedly contains so much more real bee-food that, even though there were no objectionable qualities in it, golden syrup will be found dearer in the end.

COVENT GARDEN MARKET.—OCTOBER 13.

THE supply and demand remain practically the same as last week, but prices are a little firmer.

## POULTRY AND PIGEON CHRONICLE.

## CONTINUOUS CORN-GROWING AND CLAY FARMING.

(Continued from page 324.)

ANOTHER gentleman of great experience in agriculture (Mr. Clare Sewell Read, of Honingham Thorpe, Norwich, Norfolk) gives the result of his experiment in continuous corn-growing in an article published in "The Squire," September, 1881. Mr. Read says, "For some years having successfully grown Barley after Wheat upon friable land, I thought I would try my hand at continuous corn-growing upon a clay soil in Norfolk. A compact little holding of 166 acres lay vacant within a mile or so of this farm, Honingham Thorpe. I hired it upon a long lease. It was about Christmas, 1873, that I entered on the farm. There were only 10 acres of Grass. About 40 acres of the arable land was good working soil; the rest was a very stiff loam resting upon a bed of impervious clay. I set to work at once. The stiff soil was all under-drained, generally 10 or 12 yards apart and 3 feet deep. The last draw from the bottom of the drain, being full of chalk nodules, was thrown on the surface. I thought that this stiff soil, with its calcareous clay subsoil, was just the soil for continuous corn-growing. I had often inspected and diligently studied the Rothamsted experiments, and I saw through them an endless vista of consecutive Barley crops on my new farm. By the advice of Dr. Voelcker the mineral phosphate was applied when the grain was sown, and the Wheat was top-dressed with nitrate of soda in the spring. The rest of the fallow land was sown with Barley, mineral superphosphate and nitrate of soda being harrowed-in with the seed. For two years the dressings answer well, but in the third they seem to lose their efficacy, and the land shows signs of being tired of corn-growing; but when the season has been favourable I find the land refuses to answer to the whip as it does at first. The corn not only grows weaker, but a great deal turns white before it ripens, and produces hardly any grain; while if the dressings are increased the straw is flaggy and weak, and is sure to lodge with the first pelting rain. After a long series of corn-growing the land appears very kind for Clover. In 1880, with one year's crop of Clover, I grew 5 quarters of Wheat, while

the other corn, after repeated cereals, was a most ordinary crop. I have attempted nothing new; I only tried to follow the teaching of others. With Mr. Lawes for my pattern and Dr. Voelcker for my guide I could not be far wrong; but the moral that I draw from my farm clay is (after confessing the fact that growing two white straw crops in succession is highly advantageous on many soils), that the extent of land adapted for continuous corn-growing by the aid of light manures is more limited than some recently published experiments would lead us to imagine."

This statement of Mr. Read's is not quite satisfactory; first because, taking Dr. Voelcker as his guide, we expected to have had an analysis of the soil. This, however, is shown to a certain extent by the fact that this impervious clay contained chalk nodules in the subsoil, and this may have induced the belief that they contained carbonate of lime to a great extent, but it is doubtful whether they contained but very little, if any, of the chalk constituents to an appreciable extent, having been from time immemorial drawn upon by the deep-rooting plants, cereals, and weeds, thereby reducing them to a mechanical manure only. We are therefore obliged to think that this soil was actually deficient in chalk, and that the crops spoken of as having turned white before ripening arose from this cause. In the absence, however, of any analysis these crops, which showed a weak and flaggy straw and yielding badly, were caused by the absence of the necessary plant food required to bring the crop to maturity; it may be therefore in consequence of the manures applied being deficient in some respects, and which would have been evident to a practical man if an analysis of soil has been afforded us. The fact that Clover lea produced a valuable crop of Wheat as compared with land sown after a succession of cereals goes far to prove that the decaying roots of the Clover contained manure sufficient, both in kind and quantity, but that the ordinary manuring for the cereals did not. We must therefore assume that Mr. Read's experiment was not carried out with the same prospect of success as those which were accomplished by Messrs. Prout and Middle-ditch, in consequence of potash and other essentials not being found or made available by tillage in the soil, or applied by hand manures in quantity sufficient to yield a full crop. We are induced to believe this because we had land upon our farm which had produced a succession of valuable crops of every kind for a period of sixty years without the application of any manure; but upon an analysis of the soil the whole matter was explained, because adjoining land of a similar appearance of the clay would not produce without the usual applications of farmyard manure, &c., the latter being deficient in potash chiefly, which was found in abundance in the former.

We must now endeavour to turn these experimental farms and their practices to the home farmer's benefit, and in doing this we will take as an example a farm of 300 acres to illustrate how far corn-growing can be carried out beyond the four-course rotation with advantage. On a home farm of this extent of arable, with some parkland and pasture, we shall require some roots for winter feeding and fattening of cattle and sheep, and the rotation we propose is that 100 acres be sown with Wheat, autumn-fallowed after harvest, and prepared by steam culture for Lent corn, either of Barley or Oats, according to circumstances of soil and season. Thus we dispose of two-thirds of the arable land; and as it is a three-course rotation we advocate the third course may be various, say 20 acres of Clover seeded in the early white Oats, Wheat, or Barley, 20 acres of Mangolds, 10 acres of Beans, 10 acres of Peas, 10 acres of Vetches, followed by Turnips or Rape; 10 acres of Cabbage of sorts, 10 of early Turnips and Swedes in equal portions, 10 acres of Carrots, White Belgian and Red Intermediate in equal quantities. This is a valuable rotation if rightly understood and carried out, the cereals and pulse to yield the chief profit of the farm by sale of the crops will extend over 220 acres; the other being fallow crops to the extent of 80 acres being composed of roots, &c., for stock-feeding. When properly prepared and cared for during growth these will leave the land clean, and thus lay the foundation for the two following cereal crops, the Wheat being seeded all out of fallow except the 20 acres following the Clover, which portion may easily be found clean and free from Couch may be autumn-fallowed, as before stated, for either Barley or Oats. The chief merit of a rotation of this kind is the extent and value of sale crops, and yet maintaining the land in a clean and productive state, the said crops to be manured by yard manure as far as it will go, but supplemented by artificial manures to the value and extent given in the account of Mr. Prout's farming, say 50s. per acre. This can be realised in most districts by the sale of straw, so that the cost of every acre for manure is furnished by the straw alone, except the portion required for litter of cattle pens and yards, in which case the manure arising from the straw and cattle feeding and fattening will prove a good change of

manures by varying the application of dung and hand manures alternately.

In practice we have found for many years that in a continuous and close system of cropping, owing to the frequent ploughing and opportunities afforded for forking-out any Couch, the land was kept perfectly clean by horse labour only, yet it is a matter of great importance that steam should be the chief power employed, and the horses reduced in number. It is not only the cost to be considered. The effect of steam culture, which can be effected within a limited time, and in some seasons in particular it is really the broad basis of profitable agriculture, enabling the home farmer to carry out any possible system and rotation of cropping, even with the hindrance of occasional untoward seasons such as have prevailed for several years, especially that of 1879.

These observations have been made as applicable to the home farm when it is connected with park and pasture land. We must now, however, refer to a system of sale crops entirely upon arable land alone, which may be practicable in many districts when applied to farms in hand other than the home farm, but especially where situated near to railway stations, provincial towns, and populous villages. A rotation may then be adopted as follows:— Upon farms of 300 acres (or farms of any other size in like proportion) say 100 acres of Wheat, for sale both of straw and corn; 100 acres of Lent corn, for sale both of straw and grain; also 100 acres consisting of root and pulse crops, including vegetables, sold green or saved for seed, such as Potatoes, Beans, Peas, Cabbage, Cauliflower, Broccoli, Carrots, and Mangold; also a portion of Clover, alternated in growth with Giant Saintfoin, to be cut for hay or saved for seed; say 10 acres early Potatoes, 10 acres late Potatoes, 20 acres Clover or Giant Saintfoin, 10 acres of Cabbage of sorts, 10 acres in Carrots of sorts, 10 acres Mangold, 10 acres of early or late Cauliflower or Broccoli, 10 acres of Beans, and 10 acres of Peas. In such a rotation we have the opportunity of alternation of any of these or other similar crops without disarranging the system. The constant tillage in connection with it will with ordinary care keep the land clean. With respect to manure we advise liberal dressings of artificial manures, varying in value from 50s. to 60s. per acre per annum, notwithstanding we are told by market gardeners and others that such cropping cannot be carried out without the use of town or stable dung. We, however, deny this *in toto*, as the result of our experience; but that artificial manures, including chalk or lime judiciously selected and applied, are equal to any system of cropping on loamy soils, however varied or complicated. In conclusion we ask the home farmer to consider that the cereals may be varied and taken in accordance with the circumstances by which he may be surrounded, for when the season may be adverse to the sowing of autumn Wheat some land may be left over for Lent corn, either Barley, Oats, or spring Wheat; in fact, the possible variations and alternations are almost endless without vitiating the system.

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will now consist of drilling Wheat upon the chalk hill farms in the most exposed situations first; on the strong flat-lying lands the seeding of Wheat should be done certainly not later than the 20th of October; on the mixed soils on the vale farms—such as gravel, sand, and dry loamy land—the sowing may be deferred until the last week of October and the first week in November, especially if it is Clover lea preparation, or early roots, or Rape fed off by sheep. On lea ground, or on any preparation where the land is clean, the usual distance between the rows of Wheat may be adopted; but on cold heavy land it should always be drilled at 10 or 12 inches apart, so that horse-hoeing in the spring may be effectually carried out. After a mild and wet winter the Wheat plant often looks weak and sickly, and weeds may threaten to injure the growth. Nothing, therefore, will be so likely to improve the crop as a horse-hoeing which will effectually break the surface. The quantity of seed per acre for Wheat is still a vexed question, and it is likely to remain so when we consider that the period of sowing, the soil and preparation, and climate must each have some influence on the question of the quantity of seed. The sorts of Wheat now in use are numerous, and the selection should depend upon the district in which the home farm is situated, and we also recommend the sowing of new and approved varieties, such as Hallett's Pedigree of sorts, Champion White from Reading, Berks; Rough Chaff from Essex, Nursery from Sussex and the fenlands of Cambridgeshire, Fenton White from the northern counties and the Lothians of Scotland, Morton's White from Gloucestershire, the Golden Drop Red Wheat from the chalk hills of Hants, Berks, and Oxon. These sorts offer a good opportunity for change from different districts. Some of them, however, are held for high prices, in which case it may be well to purchase only a few saeks, and use the increase in the future if found suitable for soil and climate. Very early sowing has been recommended by some farmers, sowing only a bushel per acre of seed, or less in the month of September, in order that it may tiller out and fill up a thick plant early in the spring. Upon many well-managed farms, however, early sow-

ing would be attended with various practical difficulties, much inconvenience, and derangement of the usual mode of culture and sheep-feeding. For instance, if all the Wheat on the home farm was to be sown, drilled, or planted in the month of September how could any autumn cultivation for future root and spring crops be effected? and how could the different crops preparatory for Wheat be cultivated following such crops as Potatoes, Turnips, and Rape, which will be in process of digging and feeding-off by sheep during the months of October and November upon dry soils on the vale farms? What is the advantage of saving a bushel of seed Wheat per acre compared with the benefit to be derived from various important items of tillage, sheep-feeding, &c., being done in due season?

*Hand Labour.*—Hedge-trimming should be finished, cutting wood and hushes in the woodlands or hedgerows may now be done, and making dead hedges commenced by using these materials. Men, women, and boys will be employed in gathering Potatoes behind the lifting plough and frame. The odd horse and man will be engaged in cutting up Clover and the grasses which have grown up in the Oat and Wheat stubbles, for since the rains in August the young Clovers in various instances have sprung up like magic, affording good green fodder for horses and other cattle, and as the season promises at present it may be continued as we have often done into the month of November.

*Live Stock.*—The wether sheep now eating-off early Turnips and Rape should be encouraged with an allowance of half a pound of oilcake per day, or 1 lb. of cotton cake, until the nights get longer, when they should receive hay or hay and straw chaff in addition. The leaves of Mangold will now be available for sheep and cattle, as it is now time to secure the crop, especially upon cold or strong land, in order that the carting may be done without injury to the land; in fact, it is a good plan to have them pitted in small heaps in the field, particularly if they will be required for feeding on the land in the spring. If, however, they are to be stored for preservation in the winter months at the home farm they may be covered with seaweed where it can be obtained, or with grass, &c., cut from the borders of fields or the plantations on the home farm, and after a month covered with earth to receive the frosts of winter. The dairy cows now demand attention, for after the middle of October the grass usually becomes short and stale and deficient in quality. We now begin to give them Cabbages strewed on the pastures, otherwise we give the Cabbage cut and mixed with sweet Oat straw chaff in the mangers at milking time night and morning, and we find them do well without decreasing their milk.

## POULTRY AND PIGEONS

#### POULTRY NOTES.

WE hear constant complaints of delay in the payment of poultry prizes. This is unwise on the part of committees and unjust. We believe that nothing has contributed more to the success of certain shows than the fact becoming known, as it is sure to be known, that the prize money is promptly paid, as it is from Oxford, Hemel Hempstead, and other well-managed exhibitions. We shall not at present name the places where such a procrastinating course is adopted, but committees may take warning and hasten to make up their accounts.

WE understand that a testimonial is being prepared for Mr. Fredk. Wragg, who for a long time has been the manager of Lady Gwydyr's poultry yards. We have more than once been most kindly shown over this beautiful establishment by Mr. Wragg, and are pleased to see this recognition of his civility to many visitors.

AT the meeting of the National Peristeronic Society last week an unusually good lot of young Pigeons were shown. Among the new members of the Society we observe the name of Lord St. Leonards, known chiefly hitherto as a fancier of Game fowls.

TWO or three months ago we received a circular about the formation of a club for the encouragement of the breeding of "German Toys." We fear the scheme is in abeyance, as we have heard no more about it, though we gave in our names as willing under certain conditions to become members.

WE have lately seen in a well-known western poultry yard some pure white Polish fowls with fine crests and well-bearded. We understand that they will not appear in public till the strain has been further perfected and established.

IN the aviaries of the same establishment we have seen a curious Archangel Pigeon, which has bright copper bars on its

black wings, of the same hue as the ordinary breast colour of the breed.

THE schedule of the Birmingham Show differs but little from last year. Plymouth Rocks and Aseels have classes, and the class for Silkies is restored. The classification of Ducks is very good, eight distinct varieties having classes to themselves. Birmingham has always been *the* Turkey Show, and still offers four classes for Turkeys, while at the Crystal Palace there is but one. In the Pigeon schedule we see no alterations. It is a pity that the vexatious Rule XIV. is adhered to. "Only one pen of poultry must be sent in each hamper, if otherwise packed they will be refused." We know of an instance in which several pens sent all the way from Montrose were refused in accordance with this troublesome regulation.

WE are glad to see that the Turbit Club has at last really good Turbit classification at one Show—viz., Carlisle. It is a pity, however, that this should be at a show held on November 9th and 10th, only two days before all exhibits have to be in the Crystal Palace.

THE schedule of the long-established Tredegar Show is published, drawn up much on the same lines as usual. The peculiar attraction of this Show is that the twelve extra prizes are given in addition to the liberal first prizes.

YEARS ago a Society was formed called "The National Ornithological Association." Its aims were too large and too indefinite, and it collapsed in consequence. We understand that a small balance from the small funds it possessed has long been a burden to the quondam treasurer, and that it is now proposed to hand over this sum to the Poultry Club, as doing the work which the Ornithological Association ought to have done. Whether the Poultry Club will accept it is another question.

WE have often wondered why someone expert in the treatment of the diseases of birds did not set up a hospital for them. Mr. Jenkinson of Sheffield has started such an establishment for poultry and Pigeons; if well managed it may prove a great boon to fanciers.—C.

#### THE CRYSTAL PALACE POULTRY AND PIGEON SHOW.

THE issue of the schedule for the Crystal Palace Show is always looked forward to with interest. We have just received a copy, and make a few notes thereon. The classification is as usual extended, and there are forty-eight cups offered for poultry and forty-two for Pigeons. Some of these are presented by exhibitors and some by the clubs representing the various breeds. Mr. Cresswell is responsible for the adult Silver Grey Dorking cup, Mr. Norris for the Dark Brahma cockerel cup, and Mr. Lucas for that for Light cockerels. The Langshans are this year wisely freed from the slight upon their pedigree implied in last year's classification. They have now a class to themselves, while the Black Cochins are relegated to the "Any other variety Cochin" class, where they will have to compete with Whites and mayhap Cuckoos. Leghorns have distinct classes for the Browns and Whites; Plymouth Rocks have separate classes for cock and hen, as also have Andalusians and Minorcas, which are rightly awarded distinct classes. We also note a class for Japanese Bantams, which, we trust, will be well filled.

The classification of the Ducks is somewhat singular. Aylesburys have only one class for drake and Duck; Rouens have the sexes separated, while Pekins have four classes in all, the sexes being separated, and there being also two classes for birds of 1881. There are also separate classes for drake and Duck other than Pekin hatched in 1881. The whole arrangement is somewhat complicated, and will, we fear, lead to mistakes in entering. The general heading is "Ducks (any age)," and under this heading are included the 1881 classes. The classes for table fowls are two, one for the absolutely heaviest pair, pure or cross-bred, the other for "couple of cockerels or couple of pullets cross-bred," to be judged for "fineness of quality, smallness of bone, absence of offal, and closeness of plumage." As the breed of each parent has to be stated, we presume the class is intended for first crosses only. By the way, it is curious that all the shows which give classes of this sort for table poultry word the condition as to parentage in the somewhat odd form, "sex and breed of parents must be stated." We suppose most exhibitors understand what is meant, but it might be more clearly expressed.

The Pigeon classes are 134 as against 149 for poultry. Carriers

and Dragoons have each a champion class for birds of any colour which have won more than two £1 prizes. Here again the arrangement is puzzling. The champion class 162 is for "Carrier cock any colour," while a small-print note in the next line informs us that "hens should be marked 162A." Would it not be much clearer to make the class for "cock or hen (sex to be stated)?" There are a good many other new classes, notably in the show Antwerp and Toy sections, but we have not space to refer to these in detail. In addition to the usual classes for Homing Antwerps there is one for birds which have competed in the races organised by the United Counties Flying Club. These must bear their identifying club marks. They will form an interesting addition to the homing classes, and will afford outsiders a good opportunity of seeing what the actual workers are like.

The names of the Judges are announced subject to additions to be made hereafter. We perceive with pleasure that the name of Mr. Lucas is included in the list. His experience as a breeder will doubtless enable him to make such awards as will satisfy the Light Brahma fanciers. Mr. G. Hall's name is also new to the Palace. He is, we believe, to take Game Bantam classes, a task for which his practical knowledge should amply qualify him. The other poultry Judges announced are the same as last year; while Captain Norman Hill and Messrs. Allsop, Charlton, Esquilant, Logan, Percival, and Tegetmeier are nominated for the Pigeon classes.

Curious and impracticable suggestions as to judging are by no means uncommon, but that made by the correspondent of a contemporary a week or two back carries off the palm so far. He wishes the Judge to affix a card to the pen of each prize bird, giving the reasons for his decisions and stating the points in which the winners are superior. There are many arguments which might be adduced against such a course as that suggested. One will suffice for our purpose, and that is the fact that no ordinary show would be long enough to enable a judge satisfactorily to carry out the suggestion. Imagine the labour which such a course would entail. Let the originator of the idea try it on a class or two. If judging by a numerical standard were introduced it might be practicable, but as things are it is a mere chimera. We do not suppose, by the way, that judging by a numerical standard would be acceptable in this country. We know that several leading fanciers declined at first to fill in the standard forms issued by the Poultry Club, on the ground that they did not approve of judging by a numerical standard. We believe, however, that there is no intention on the part of the Club to suggest the adoption of such a course. The standard being prepared is intended to be a guide as to the generally accepted views upon the points of the various breeds, and to be, to some extent, a check upon erroneous decisions, but not to be an arbitrary table of numerical values to be blindly followed in all cases by the judges. In America the judges, we believe, frequently "figure up" the birds after they have come to a decision as to the awards, as a check upon their general judgment. This is the furthest point to which the use of a numerical table of defects or merits can safely be extended, and it may be well that it should be generally known that the Poultry Club do not contemplate any more exact application of the standard by the Judges.

#### REMARKS.

2nd.—Fine and bright all day, with cold east wind.

3rd.—Fine and bright; very cold wind.

4th.—Fine and bright; cold wind.

5th.—Fine, overcast at times; misty evening. First frost on grass in morning.

6th.—Slight rain in morning; fine afternoon; moonlight evening.

7th.—Very fine bright morning, latter part of day cloudy.

8th.—Foggy dark morning, rain from 2 to 9 A.M. and from 0 to 8 P.M.

Considerably colder than any week since the spring. The mean maximum in shade is nearly 10° below the previous week, and grass frost occurred on two nights.—G. J. SYMONS.

20th	TH	Sale of Orchids from Madagascar at Mr. Stevens' Rooms, Covent [Garden.]
21st	F	
22nd	S	
23rd	SUN	19TH SUNDAY AFTER TRINITY.
24th	M	Apple and Pear Show at Hereford (two days).
25th	TU	
26th	W	

### A ROCKERY FOR ALPINE PLANTS.

HE cultivation of alpine plants is now attempted with more or less success in nearly every part of the kingdom. Visitors to my garden frequently tell me that they are going to make a rockery, and ask for advice; and though good advice on the subject, with full instructions for the work, has often been given in these pages, the last rockery I made has proved so successful that a description of it may furnish some useful hints to others; and as I helped to place every stone on it with my own hands, I am able to tell exactly how it was made.

The length of the rockery is about 30 yards, and its direction from north-east to south-west, so that it faces south-east and north-west. It runs along the side of a level carriage drive, and the situation is quite open and away from trees. I own that for choice I prefer the side of a steep bank, or a hill sloping at an angle of about 30°, and having a south-easterly aspect, on which to lay the stones for a rockery; but every garden has not this convenience, and a mound artificially raised answers very well, but requires more attention in watering during the summer.

The total width of the base is to be 8 feet; I therefore make a long mound of the native soil of the garden—stiff red clay, believing there is no better soil for a base. This is about 5 feet wide and from 2 to 3 feet high. Now it must be remembered that this may obstruct the surface water in heavy rain, especially on strong soils; I therefore lay a line of agricultural drain pipes along each side at a convenient depth, carrying them to the nearest drain or outfall.

The next consideration is the stone. Matlock tufa has the highest reputation in the neighbourhood of London as rockery stone, and is very expensive. Matlock is my native place, and I know the material well, and no doubt it is good; but I doubt whether it is better than the rough irregular blocks of limestone, full of cracks and holes, which lie about the surface in the mountain limestone districts of Lancashire and the West Riding of Yorkshire. I have heard gardeners who live in those parts say they wished they could get sandstone. My rockery is composed partly of the new red sandstone, which is quarried within a quarter of a mile, and partly of mountain limestone from Grange, in Lancashire. But everyone must use the stone he can most conveniently procure, preferring that which presents a rough cracked surface. I may remark that I do not attach great importance to the chemical composition either of stone or of soil, not because plants have no

preference, but because even if we know exactly the chemical conditions which suit each plant, it is so difficult to supply the materials in the right proportions and combinations. Mechanical conditions are at least equally important and far more easily proved. Ordinary coarse sand and broken stone, with loam and peat, and old dried mortar, as much from its mechanical as its chemical qualities, can be made to grow almost any alpine plant if climate and situation are suitable.

The more rough and shapeless the stones are the better. The largest I use are as much as two strong men can lift into their place. The lower part of my rockery is of sandstone, the blocks of which are larger and more regular, and the upper part of limestone. Along the base at each edge must be laid a foundation of stones of moderate size, at intervals of about their own width. Upon them must rest a row of larger stones tilted backwards, but after laying a few yards the rockery must be finished to the top before proceeding. This requires some skill in the selection of stones. The largest should be kept as keystones to lock together the smaller stones, but every stone should be so locked with its neighbours that a heavy man can step upon any of them without causing any displacement before a particle of soil is added to the original mound. This is a rule I invariably observe. Beware of trusting to soil to make the stones firm, if you do they will sooner or later give way; but do not be satisfied till the biggest labourer in your garden can step and jump upon every stone without moving it. Be careful also to have as many overhanging ledges as you can. You may then add the soil for the surface. Mind it is clear from grass roots and weeds, or you will have trouble. I use loam composed of the top spit of an old pasture, adding about one-fourth of coarse sand and leaf soil, and fill the stones till they stand from 1 foot to 3 inches above the soil, leaving as many level pockets as I can. How and with what I planted my rockery I will tell another time.—  
C. WOLLEY DOD, *Edge Hall*.

### FRUIT TREES CANKERING AND BEARING.

My pen, I fear has been idle of late. Alterations when extensive absorb, as most gardeners know, all a man's time. Working by day and planning at night leave little opportunities for press work, but the letter of "S. S." tempts me to send you a brief and hurried note.

First as to canker in fruit trees. I have seen more of this during the past two years than ever came under my notice before. When I say that frost is the immediate cause of canker, I do not expect everyone will believe me; but let those who doubt, and who live in districts where Apple trees have been injured, look at the tops of the trees for evidence.

During the winter of 1879 the late unripened growths of hundreds of Apple trees in the north were either killed or injured, and so far as I have seen not one out of a hundred of those frost-bitten growths escaped the canker. I can point to tops of trees that are full of it that were previously clean and healthy, and but for the frost there would have been few if any of the unsightly and injurious excrescences. We will now go a step further and see what is the predisposing cause of the injury, and we arrive at immature wood, and this is induced by low sites and wet soil. Low-lying positions should, then, as far as possible, be avoided in fruit-tree planting, and wet soils and subsoils should be drained. Calcareous matter should also be added to all soils that do not contain it.

This is all I can say at present on canker, its cause and prevention.

Now as to the relative earliness of bearing of fruit trees. In my experience varieties as a rule that mature fruit early bear early. There may be exceptions, but only, I think, sufficient to prove the rule. Let anyone plant rows of Apple trees of, say, Keswick Codlin, Lord Suffield, Duchess of Oldenburg, Stirling Castle, Cellini, and Hawthornden; and other rows, say, of Dumelow's Seedling, Winter Greening, Blenheim Pippin, Norfolk Beefing, Alfriston, and Boston Russet, and I think the first named six sorts will, during the first five years after planting, yield fully three times the bulk of fruit that the last six will. The varieties named are not "selections" of the best sorts to grow, but the names have been jotted down at random to illustrate what I believe is a principle—that early-ripening fruits are produced by early-bearing trees. I cannot go further into the subject now, and leave the idea for what it is worth, and I think it may possibly be worth something to those who wish to have a maximum quantity of fruit in a minimum amount of time after planting the trees. What do others say?—A NORTHERN GARDENER.

#### AUTUMN PROPAGATION OF ROSES.

DURING the summer a method for the propagation of unripe cuttings of Roses was described, and I have reason to believe that some readers have practised it successfully. It is, I think, the easiest and surest plan of propagation with which I am acquainted, but there is the difficulty of preserving the young plants through the following winter, which with some amateurs is a serious one. With winter propagation there need not be any difficulty in this way; the chief drawback is that some of the varieties do not ripen their wood sufficiently under ordinary outdoor culture to form cuttings such as we can warrant to strike. All those which are well ripened and are of moderate-sized growth may be counted on, and there is very little to do besides inserting them properly in the open ground and leaving them there. Such Roses as do not ripen their wood under ordinary culture will generally do so if grown in pots, when their shoots will be almost as sure to strike root as those of a Jules Margottin. Any of them, however, will strike in summer time under the treatment recommended for that season.

Although the plan of inserting Rose cuttings in autumn is probably the oldest plan for their propagation in existence, and it has been considerably revived during the past eighteen or twenty years, and received decided patronage from high quarters during the last four or five, it is not even now practised so often or so successfully as it ought to be, and the time may not be inopportune for once more reverting to the subject.

One common cause of failure is delaying the work too late. The last half of October and the first half of November is the time to insert the cuttings. If it is done later than November the chances are that the result will be a partial or total failure.

Another cause of failure is keeping the cuttings too long out of the ground. Perhaps there is a spell of bad weather, and on the score of economy an armful of cuttings are taken off in a hurry, carried to a warm dry shed, made leisurely there, and inserted at the first favourable opportunity. This plan will not do; it has been tried and failed. Although there may be no leaves on the cuttings, yet there is considerable evaporation from the bark, at any rate it soon begins to shrivel, though at first this is imperceptible, and cuttings which have been kept out of the ground forty-eight hours do not strike so freely as those which have been inserted immediately on severing them from the parent plant. If it is necessary for them to travel any distance they should be wrapped in something, such as damp moss, to prevent much evaporation.

A third cause of failure arises from the cuttings being heaved out of the ground by the frost. To prevent this it is a good plan to place 2 inches of coal ashes over the surface of the ground after the cuttings are inserted, and to tread along with one foot on each side close to the cuttings two or three times during winter after the frost is out of the ground. I also find it an advantage to make the cuttings longer than they are usually made—a foot is not too long—half of which should be in the ground. However, cuttings half that length will do where wood is scarce, but they must be looked to oftener during winter to see that the soil is properly close round them.

A fourth cause of failure which I have frequently met with arises from having the cuttings in what is called a sheltered place—against a wall or a hedge, where the soil is likely to be very poor and perhaps dry—and the plants, if plants are produced, do

not get sufficient air and light, but grow at unseasonable times and do not ripen, thus becoming an easy prey to mildew and other maladies, and are also difficult to remove. Let me remind your readers again that the Hybrid Perpetual Rose is not a tender plant unless it is made so by being coddled, that my cuttings are struck in the open garden along with the Gooseberries and Currants, and that the temperature at zero does them no harm, although I do not take the precaution to cover the surface with ashes or similar material as I am recommending others to do. "But," said a near and dear neighbour not unknown to your pages, "I covered my Rose roots with 6 inches of dung, and many of them are killed to the ground." "Possibly you did. Keep the dung away from them another season if they are on their own roots, or are dwarfs on Briars raised from seed or cuttings. Loosen the surface soil with a hoe now and then when it is dry, and you will succeed better."

Last year I went so far from previous practice as to leave a space of a foot from one cutting to another, and I may say that the experiment is satisfactory with most of the cuttings which were taken from plants in pots and some of those which were taken from plants growing in the open ground. Of the former, for instance, ten out of eleven Etienne Dupuy are now fine plants, one cutting having died. Of Madame Thérèse Levet, a most beautiful indoor Rose, fourteen cuttings all struck. Of La France, thirteen out of sixteen, and on one of the cuttings of the last-named variety during the summer I pointed out to a visitor three blooms as good as any I had seen at exhibitions this season. A row of Jules Margottin, perhaps 25 yards long (we cannot do without this old sort yet for cut flowers) taken from outdoor plants has nearly all struck and forms a nice little hedge. This has produced many very fair flowers for cutting.

I may here repeat that there is no better plan for inserting the cuttings than by making a trench box-edge fashion, placing the end of the cuttings firmly on the bottom, and then treading the soil in as hard as a turnpike road. Well-ripened wood is essential, but whether there is a heel or not is immaterial.—W. TAYLOR.

#### THE USE OF FIRE HEAT FOR GRAPES.

"SINGLE-HANDED'S" article on the application of fire heat to Grape Vines strikes to the point fair and forcibly. The cardinal point in the culture of all trees from which fruit is produced is to obtain ripe wood in autumn; the unfolding of the blossom and setting of the crops are then simple matters the following spring. Ripening the wood is the point from which we start, and in like manner we finish with ripening the wood again with its crop of fruit the following autumn. The conditions required for ripening both wood and fruit are identical—under natural conditions a warm sunny air, which we imitate by warm atmospheres artificially produced. Again and again the advantage of giving Vines a long season of growth has been pointed out in the Journal, though never perhaps more effectively than by "SINGLE-HANDED" on page 317. The middle of February is quite late enough in this district I find to start Grapes for winter keeping; indeed the beginning of the month is not too early.

I shall commence cropping some young Muscats next year, and shall start them, as I intend to keep them going, at the beginning of February. We can then allow the temperature to depend greatly on the weather, and grow the Vines slowly till the setting period in May, and thus have all the advantages of the summer and autumn sun for finishing the fruit, ripening the wood the meanwhile, and with the aid of a little fire heat can have the crops ripened thoroughly at a season when there is no difficulty in doing so. Black Hamburgs started in April ripen well with us and in good time.

The Grapes shown by Mr. Simpson at Edinburgh are the text on which your able correspondent founds his remarks. I quite agree with him as to the wastefulness apparent in the culture of these Grapes. It will take hard firing to have them well ripened, and it is impossible to impart to them the quality of Grapes ripened five weeks earlier. I can well imagine that gardeners who have tried Mr. Simpson's system in its integrity would be induced to give it up as a failure after seeing the Grapes in question.

When I thought the matter over before giving low temperatures an extended trial I put the *rationale* of the principle in this way. Early-forced Grapes are found to succeed in temperatures which are thought to be insufficient later on, though of course early-forced Vines have the advantage of hot weather to ripen in. For instance, Black Hamburgs to be ripe in early summer are in flower, say, in the beginning of February, and receive a temperature ranging between 70° and 75°. In a fortnight these temperatures are lowered to 65° to 70°, and in sunless weather may

be kept for weeks at that figure, and even in sunny weather from 80° to 85° are the highest temperatures reached for a few hours a day. Well, we start Vines in February to be ripe in autumn; we have them set in May, and there remains for them to finish their crop the best of the summer and autumn months. In warm weather you can indulge in afternoon temperatures with the house closed and a steaming atmosphere of 90° to 100°. I do not think these high moist temperatures of benefit to Vines, I rather prefer an afternoon temperature of 75° to 80° with ventilation as being more healthy. Of course in hot summer weather we have higher temperatures than these, but always with plenty of air; in fact I have had the ventilators of our vineries wide open at 10 P.M. and the temperature at 70°. In a season like that the necessity for fire heat was of the slightest, and in working with free ventilation we found that damping-down vineries was a part of the routine which could be abandoned without any ill effects.

All Grape-growers who employ fresh air as a factor in the production of good Grapes will find the necessity for employing water to cause atmospheric moisture to be less and less as they do with little fire heat and much air. Some of our best Grape-growers have almost dispensed with the "damping down" of their vineries altogether; but during sunless and cold summers, when Vines cannot obtain the amount of heat necessary, there is nothing for it but using the coal, and "SINGLE-HANDED'S" estimate of the time when coal is of the most benefit exactly fits the case.

Now as to the setting of Mr. Simpson's Grapes, I failed to see anything out of the common about them in that respect, but there were so many better Grapes beside them that perhaps it was somewhat difficult to form an unbiassed opinion on their merits. The setting of Grapes, in fact, does not depend entirely on temperatures. The best set Muscats of my experience were grown in a Pine stove, yet in the same garden in a well-appointed Muscat house under the usual 75° treatment the setting was not good. In a lower temperature here with old Vines we find the Muscats set ordinarily well, though great numbers of the berries which swell cannot be said to be properly set, as they are stoneless. I do not think a higher temperature would improve these, the fault is somewhere else. I should be pleased to know who are the Grape-growers "SINGLE-HANDED" refers to as showing some of the best Grapes at the past Edinburgh Show, and whether they were ripened in a low night temperature.—R. P. BROTHERSTON.

THAT a good practical knowledge of Grape-growing is necessary to every gardener no one will deny; therefore I do not consider that this subject is a wearying one. To those who have seen it discussed many times it may be so, but there are always young gardeners who are glad to improve their knowledge.

The coke bill is generally a serious item in the gardener's expenses, and any system that will assist him in reducing this will be acceptable. If good Grapes can be grown in a low night temperature, that will be one way of reducing the account. That such is the case I do not think it will be difficult to prove. During the past season we have heard many complain of the want of colour in their Grapes, and the difficulty of keeping red spider down. Some have attributed this to the excessive heat. That may be so; but I am inclined to believe that a high night temperature may also have something to do with it. In many places where the low night temperature system is adopted, the Grapes have been all that could be desired both in flavour and colour. In one of the vineries here Muscat of Alexandria and Black Alicante are planted, and during the flowering time the night temperature never exceeded 55°. Many assert that Muscats require a high night temperature to secure a good set. I have before me a table of the temperatures formerly kept in a large fruit-growing place in Lancashire. I find that 75° was the average night temperature for Muscats when in bloom, yet in a temperature 20° lower our Muscats set freely enough. The Grapes are well ripened, the colour is good, and we are free from red spider. I do not mean to say it is advisable to dispense with fire heat altogether, that depends upon the weather; we have found it an advantage to turn a little heat on at times, but we do without it as much as we possibly can.

In the Peach house we have had no fire heat beyond what was necessary to keep the frost out. We had an excellent crop, many of the Peaches weighing over 9 ozs., and measuring upwards of 10 inches in circumference. I should be glad to see what others have to say on this subject.—CANTAB.

#### FUCHSIA EDELWEISS.

WE have received sprays of this new Fuchsia from Messrs. Hender & Son, Plymouth, accompanied by the following letter

—"We send blooms of our seedling Fuchsia Edelweiss, which we hope to send out another spring. We have grown it beside some of the best varieties, such as Miss Lucy Finnis, Grand Duchess, Snowcloud, &c., and find it of better habit and a more profuse bloomer than any, having four to six blooms at a joint when growing strong. It is rather late now for good blooms; those sent are just as they come in ordinary cultivation. The white is very pure. If you think it worthy we should be glad of a line respecting it in the *Journal of Horticulture*."

We do think it worthy, and not overpraised in the above letter.

Fig. 60.—Fuchsia Edelweiss.

It is evidently a very profuse bloomer, and the flowers are of good form and very pure. They are reduced in size in the annexed engraving.

#### AUTUMN-PLANTED POTATOES.

LAST October I asked some questions about planting Potatoes, which were kindly answered in the *Journal*, and I was requested to send the results of the experiments that I was then about to try. The Potatoes were planted the first week in October about 6 inches deep, they were well covered with dry decayed manure, and the holes were then filled with soil. The tubers were not cut, and the variety was Early Rose. In due time the shoots appeared, and were much injured by the late frosts; the foliage never looked healthy after, and there was 10 per cent. blanks in the rows. The Potatoes were ready to lift the second week in July, but the crop was not heavy, many of the tubers being very small, most of the large tubers very ill-shaped, and when cooked they were close in substance, which I attributed to deep planting. So much for autumn-planted Potatoes. By way of test, at the end of March I planted one row of the same variety close to the others. The frost did not affect them, as they were not so forward, and it was surprising how they grew and took the lead. There was not a blank in the row, and they were ready to lift the first week in July, the crop being heavier, the tubers larger, with fewer

small ones amongst them than was the case with the autumn-planted Potatoes; they were well shaped, and when cooked were floury. The difference I attribute to late and shallow planting. They had no check, the tubers were just covered, and the sun ripened them.—WIMBLEDON.

#### ROSES—ARE WE PROGRESSING?

WHILE all Rose-growers must acknowledge with thanks our great indebtedness to Mr. Hinton for carrying out the wearisome task of tabulating his sixty-seven Rose returns, I fear that we must confess at the same time that we have no great cause for satisfaction at the result to which he has arrived, at least as far as the recent improvement of the exhibition Rose is concerned. We see that not very much has been done for it in the last ten years; perhaps it would be fairer to say eight, as the Roses of the last three years can hardly be said to have come into cultivation so generally as to take, for good or evil, the place to which they are justly entitled, though four of them have, I see, found their way into the list. On examination of the election we find, disappointingly I think, that all the first ten Roses are more than ten years old; that of the first fifty where dates are given, thirty-six are of similar date; that of the eleven Teas and Noisettes mentioned, nine date from 1838 to 1869; and that besides in the best of the old Roses there is, so to speak, a much greater individuality than in the new. It would be impossible to mistake the *Baronne*, *Maréchal*, or *La France* for any other Rose if we saw it across the room, and though cut blooms of the two first on the list are somewhat alike, the character of the plants is quite distinct. Of how many of the new Roses can it be said that we know at once what they are?

It would seem, then, that improvement in the present class of exhibition Rose has come nearly to a standstill. Every now and then, certainly, we get a Rose like *A. K. Williams*, absolutely new and surpassingly beautiful; but of the great majority, even of good Roses of the present day, we may almost say that we could have done very well without them.

Now, much as I admire our present exhibition Roses, I must confess that there is too much monotony of style and character about them. A dozen types are more than are to be found among them all. One tray in a show is much like another, somewhat better or somewhat worse, much the same coloured, much the same shaped flowers. Their owners are practically compelled to show only Roses of such a class and such a shape as is authorised by the fashion, and by adhering too rigidly to an artificial standard of excellence we lose much of beauty and variety. We must show Hybrid Perpetuals and Teas, and so have no chance of setting up flowers of any shade of colour not to be found in these two classes. We have no white Rose, for *Madame Lacharme* is not white and usually worthless, but we must not put in *Madame Plantier*; we have no brown crimson, but *Boule de Nantenil* is excluded as a summer Rose, and too flat besides; we have no slate colour with fiery eye, but there is no place for *Majolin*; no copper colour, but *Austrian Briar* would be a heresy; and the result is that outsiders say "when they have seen one tray they have seen all." And those exhibitors who value their Roses, and not merely, so to speak, as tools for their trade, grumble at the narrow scope allowed them by fashion in which to exercise their fancy.

Then, as we seem to have got nearly to the end of our present tether, is it impossible to strike out some variety in one style? It would be something if the National Rose Society would stir in this, giving prizes, say, for the twenty-four bunches of Roses best varied in colour and character irrespective of shape. Such a tray would contain a number of shades and tints never seen in shows now-a-days.

Again, has no one the courage to try his hand at raising unconventional seedlings, by hybridising or not as suits him? We cannot expect this of nurserymen, for they can only raise what will pay; but among amateurs. Yellow Perpetuals, or even Gallicas, striped, copper-colour, plenty wait to be raised. The drawback will be the difficulty of getting good seed; indeed this is the third year I have no ripe hews, and my seedlings of former years are becoming few in number as one after another is pulled and flung away; but a cheap orchard house well filled with varied Roses, or unoccupied portions of wall might help. Only there must be some appreciation of the fact that we are at a standstill at present, and that having excellence simple, we want variety of excellence.—DUCKWING.

#### LIQUID MANURE FOR FERNS.

As I do not remember seeing any mention of liquid manure being used for Ferns it tempted me some time ago to try its effects, as my plants are cut very much, and I could scarcely obtain

sufficient fronds to supply the house. Since using the liquid manure the plants look quite different and produce abundance of strong fronds, and though they have not been potted for three years, they grow as well as those which have been so treated each year. The liquid manure is obtained from a tank which comes from the stable, and is very strong, but it is only used weak, and given to the plants once a week in winter, and in summer when they require more water it is given twice a week. I would recommend Fern-growers to try this, but not to use it too strong at first, and take notice of the results. I have been benefited by many hints in the Journal, and hope the one I send may help others.—J. GILBERT.

#### SCRAPS ABOUT FRUIT.

APPLES—BAD AND GOOD BEARERS.—"A COUNTRY SURGEON" asks your readers to notice those Apples that have not answered their expectations. We have many sorts, and several of them bear only a few Apples, while others are always loaded with fruit. *Early Harvest* is a good Apple, but only bears a few every year—never a good crop. *Bess Pool* is no bearer with us, just producing a few fruits every year. *Blenheim Orange* is a very fine Apple and highly flavoured, but does not do very well; some of the trees bear a few fruits and others none. *Emperor Alexander* is very beautiful, of good flavour, but is a shy bearer, yet the tree does not grow luxuriantly. *Court Pendu Plat* is a first-rate dessert Apple but not a great bearer so far, but may improve as the tree gets older. I have kept fruit of it till the 1st of June. *Northern Spy* is a fine Apple and a good keeper, but seldom bears, yet the tree looks very healthy. The trees have all been root-pruned. There are only a few varieties that bear every year alike, and these we depend on for a supply. *Kerry Pippin* is one of the best dessert Apples we have; the tree is loaded with fruit every year. *Keswick Codlin*, an excellent bearer, and a capital kitchen Apple. *Lord Suffield*, one of the best early kitchen Apples, bears beautiful crops every year. *Warner's King*, very large, is covered with fruit every year, and is a first-rate kitchen Apple. *Scarlet Pearmain*, a good dessert Apple, bears a good crop every year. *Pearmain* is one of my favourites, the tree bearing heavily every year; I have kept the fruit till June. *Newtown Pippin*, a fine dessert Apple, as large as *Warner's King*; has a fair crop every year; is one of the best, also a good keeper.—F. WALKER, *Isle of Wight*.

STORING FRUIT.—A very important matter in connection with hardy fruits is that of storage. We are just finishing the storage of ours. What I want to note is this, that an unlimited supply of cool air is good for the fruit for a week or two after being stored, after that ventilate according to weather. It used to be thought that fruit kept best when in darkness. I think it doubtful if it does, and accordingly do not use shutters to the windows now unless in case of frost. These past severe winters, frost was kept from the fruit by keeping paraffin lamps constantly burning, and by covering the fruit with several layers of newspapers.

MANURING FRUIT TREES.—Very often fruit trees of all kinds are starved. How is it possible that fruit trees can produce crops year after year from practically exhausted ground? At present we are surfacing the ground amongst hardy fruits with a few inches in depth of manure. The soil is dug just so deep as to afford a covering to the manure.

STOCKS FOR APPLES.—Free-fruiting Apples like *Stirling Castle* and *Lord Suffield* have a tendency to make too little wood when worked on the *Paradise* stock, at least such is my experience. To get over this defect I bought a quantity of *Crab* stocks, and have budded them with the freest-bearing kinds. I now hope to have a strong healthy growth along with as heavy, or perhaps heavier, crops of fruit. It is a necessity, however, to transplant every two seasons for a few years in order to get the roots into a fibrous and stay-at-home condition.

DUTCH MIGNONNE.—I see this Apple is recommended as a free-bearing sort. So it is; but with us it has an unfortunate tendency to crack, which spoils it.

JEFFERSON AND VICTORIA PLUMS.—I can endorse what is said in favour of *Jefferson Plum*. It is the heaviest cropping dessert variety we have. The kitchen Plum which approaches most nearly to it in that desirable quality is *Victoria*. In recommending fruits the test point should always be that of fruitfulness.—R. P. B., *East Lothian*.

**WARNER'S KING APPLE.**—Permit me to advise "R. P. B." not to rely solely upon this Apple for a midwinter supply, but also to plant some other good sorts, such as Golden Noble, Tower of Glamis, and Hanwell Souring. The fine fruit of Warner's King is keeping badly this year—so badly that I cannot hope to have it really good after the present month. The trees of it here are correctly named, and the fruit usually keeps good much later in the year. Premature ripeness and decay will, I fear, be found prevalent among many other Apples this year. Is this a result of the extraordinary heat?—A KENTISH GROWER.

**GOOSEBERRIES.**—A desire to know all about Gooseberries induced me to supplement the rows of Warrington and such other sorts of proved excellence as Early Sulphur, Pitmaston Green Gage, Red Champagne, Lion's Provider, Green Overall, Dan's Mistake, Ironmonger, Whitesmith, Snowdrop, Rough Red, and Ploughboy, by making a mixed plantation of some eighty sorts, all of them quite unknown to me, but presumably good, as they were afforded a prominent place in the catalogue of a fruit-growing nurseryman of considerable note. Never was I more disappointed, for hardly any of them proved worthy of culture, and I turned the lesson to account by discarding the whole of the worthless sorts and adding to the number of those which I knew to be good.—E. L. O.

**BEURRÉ DE CAPIAUMONT PEAR.**—This is a variety that ought to be in every collection. Grown as a pyramid or standard it never fails to produce heavy crops of excellent fruit. When gathered about the middle of October it remains in good condition until Christmas. During the past unfavourable seasons which we have had this variety never failed to give a plentiful supply, and though the fruit was small it was of good quality.

**NAPOLEON PEAR.**—This is a large and fine variety I highly commend to be added to every collection. It has all the qualities of a good Pear, and the advantage over many by being a good keeper. We have it as an espalier, and find that it bears the close pinching process better than many varieties.

**BEURRE DE L'ASSOMPTION PEAR.**—I obtained a pyramid tree of this variety from a well-known nursery firm nearly four years ago, with it a very high character as to its free bearing, as well as other good qualities. I find it a very free bearer, but otherwise it is worthless as a pyramid. I am afraid I must have the wrong variety. Will any of your correspondents who may have given this Pear a trial kindly state their experience and oblige?—LEADENHAM, *Grantham*.

**PRUNING APPLE TREES.**—The Keswick Codlin and Dumelow's Seedling produce finer fruit on the young wood than when kept pruned-in on the spur system. There are many varieties of Apples from which the produce would be better, both in quality and quantity, if the knife were not used quite so freely. In the orchard Apple trees ought not to be pruned too hard. Finer fruit is gathered from trees which are occasionally thinned-out and kept within bounds than from trees which are annually cut-in as close as those which occupy a place in the kitchen garden. Some Apples bear the knife better than others; Blenheim Orange, Cockle Pippin, and King of the Pippins, all bear well when kept spurred-in. Would it not be an advantage if your correspondents were to state what soil their trees are growing in? Our soil is very poor and shallow, partly on chalk and partly on gravel. The varieties I have mentioned have borne excellent crops this season. Dumelow's Seedling ought to be in every collection.—CANTAB.

**NUTS.**—Cosford is very prolific; nut large, oblong, shell thin, large, well-flavoured kernel, and early, not keeping so well as those with thicker shells. Pearson's Prolific bears in a young state very freely, and is a dwarf grower; nut obtusely ovate, shell medium as to thickness, fine kernel, and excellent. Lambert's Filbert is the same as Kentish Cob (but is not a Cob, which are roundish and thick-shelled), very large, oblong, and compressed, kernel very full, and keeps well, not being fully flavoured until kept a time. Red Filbert, medium size ovate; kernel full with red skin, and very rich in flavour. It bears freely. White Filbert is similar to the Red, but with white skin, medium-sized nut, full kernel; quality excellent. Purple Filbert, ornamental foliage, and similar to Red Filbert as regards the nut, only the skin is deep purple; quality excellent. Frizzled Filbert, nut small, kernel full, shell thick. This is a late sort and a great bearer, producing the nuts in clusters. From its deeply frizzled

husk its appearance is unique. Cob, large nut and kernel, and capital for early use, but does not keep well; the tree is a great bearer. Merveille de Bolwyller, large and excellent in every respect, the tree being a great, constant, and early bearer. The three first-named are best; but all are good and desirable for variety.—G. ABBEY.

**GLASS COPING FOR APRICOTS.**—We have a considerable number of Apricot trees in the garden under my charge, in fact more than are wanted, simply because four large specimens protected by Rendle's glass coping yield extraordinary crops of fruit, quite sufficient for the demand. Owing to the Apricot's habit of early flowering, and the delicate nature of their blooms, extra precautions have to be taken to protect from frosts, and nothing I have tried equals the coping above referred to. The light yet warm nature of the blinds used in connection with the coping affords ample protection from both frosts and destructive easterly winds without unduly shading and weakening the blossoms. The crops are also forwarded considerably, and, what is of great importance, the growth ripens early, abundance of sound blossoms invariably resulting. The blinds during the summer are employed for shading purposes, and the glass is taken out and stowed in boxes till required again.—W. C. N.

**THREE EARLY-BEARING APPLES.**—Growers of fruit cannot always afford to wait many years for "returns," and for this reason varieties of Apples disposed to bear fruit when in a comparative young state are oftentimes selected. A friend of mine a few years since planted some hundreds of Apple trees, some of which bore freely during the third season, and carried excellent crops during the fourth season, without any apparent injury accruing to the trees. Cellini was one of the first to commence bearing, and Manks Codlin and Jolly Beggar also distinguished themselves. The two former are well known and appreciated; but the Jolly Beggar, according to my experience, is not so much planted by private growers as it deserves to be. It is a culinary Apple, of good size and flavour, in season from August to October.—ESSEX.

**APPLES FOR MARKET.**—Those who plant fruit trees with the intention of marketing the whole or part of the crops should first ascertain which are the most saleable culinary or dessert varieties. Those in the secret are well aware the former are invariably in much the greater demand, and of course plant accordingly. If varieties can be grown suitable for both purposes so much the better, and fair-sized bright-coloured fruit are generally preferred. These qualities are to be found in Blenheim Orange, King of the Pippins, Emperor Alexander, Fearn's Pippin, Cox's Pomona, and Gravenstein. Another lesson—market growers are not satisfied with selecting suitable varieties, but are very particular what soil they have them off, and also to have them perfectly free from American blight. What they prefer are trees that we should term "scraggy," well knowing that such, on their comparatively poor soils, are the first to form good trees. Vigorously grown trees are apt to "stand still" for years after removal, and those affected with American blight soon became cankered and worthless.—W. IGGULDEN.

#### A RUN TO THE WEST.

It is necessary to say at the outset that the starting point was London, the route the Great Western Railway, and the terminus Frome, so that the above heading may be intelligible, for obviously no place can be in the "west" to all the readers of this Journal. The question may now arise, What interest does Frome possess to the horticulturist? In itself it possesses little if any interest; but as it is the station for Marston House, the seat of the Earl of Cork and Orrery, whose garden is in charge of Mr. Iggulden, and as Longleat, the noble patrimony of the Marquis of Bath and the field of Mr. William Taylor's labours, is within easy distance of Marston, it will perhaps not be a matter of surprise that the busy Somersetshire town was so intimately connected with this run to the west.

The run was sharp and the stay brief, therefore no elaborate account will be given of the two gardens. Their salient features may, however, be noticed, and some impressions recorded that will not be unacceptable, and possibly may be useful. But last week, it may be premised, was not favourable for visiting gardens, so far, at least, as their attractiveness was concerned, for Dahlias and similarly tender flowers were killed by the frosts—"vrastzes," a native termed them—of a few days previous. Still, even "vrastzes" cannot demolish the interest of a garden nor obscure the work of good gardeners, and both outside and in there was

something worth seeing in the gardens and their surroundings that will now be referred to.

#### MARSTON HOUSE.

This is situated on the southern slope of a heavily wooded eminence about two miles and a half from Frome, and commands a view of great extent and beauty. The mansion is approached by a sunken carriage drive with bold shrub-clad lawns rising on either side. From the north side, or carriage entrance, a fine flight of steps flanked by vases leads up a series of five terraces to the higher ground, where noble trees, glades, and an enclosed flower garden are the principal features. On the opposite, or south, front is a fine terrace walk, from which an extensive lawn slopes to the park. There are no flower beds, and properly so, here; stately deciduous trees, a grand old Yew having a trunk nearly 30 feet in circumference, a fine Cedar, and Golden Wellingtonia being far more appropriate ornaments. It is from the terrace that the view is so fine, even magnificent—hill and dale, wood and water, rendering the scene as picturesque as it is extensive. The pleasure grounds are rich in trees, having an undergrowth of Laurels kept cut, and the park is heavily timbered, Elms, Beeches, and Chestnut attaining a great size, Thorn trees plentiful and all aglow with extraordinary crops of scarlet fruit. On the mansion are some of the finest Magnolias in the kingdom, and adjoining it a large conservatory kept gay with flowers, of which Lord Cork is a great admirer.

The gardens are on lower ground, about a quarter of a mile from the mansion, and separated from it by a portion of the park and a plantation of trees. About three acres are enclosed with walls, old, strong, and lofty; most of the trees are old too, yet some have fair crops of fruit. Bush fruit trees have been freely planted some years ago, but they are infested with the *Aphis lanigera*, and much labour will be necessary to cleanse them and render them satisfactory. There is a fine wall of cordon Pears too closely planted and trained, the branches being only 8 or 9 inches apart. By removing the worst of them and adding fresh soil and manure to the roots the trees may be renovated, and they are worth the effort that will be made to improve them. Glass copings over Apricot trees prove their value, the protected trees bearing twice the number of fruit that others do that have no protection. There are two vineries with exhausted Vines, so exhausted that there were only six bunches in the Muscat house. Most men would have uprooted them, made new borders, and planted young Vines, but Mr. Iggulden preferred to adopt a renovating process, and he will succeed. By heavy dressings of manure, which Vine roots cannot resist, he has already secured a mass of surface fibres and a fair extent of young wood. Fresh soil, wood ashes, &c., will do the rest, and he will have Grapes next year, and more the year following than he could have obtained from young Vines, besides saving much outlay. Such Vines as these can only be rendered healthy and fruitful by skill combined with persevering labour, and these they will have.

A Peach house some 200 feet long also needs renovation. The trees have the "yellows," and only fresh soil and surface roots can cure them. There are some half dozen span-roofed plant houses and ranges of pits of great service. These are being stocked with useful plants. In one house Tea Roses struck in the spring are in 11-inch pots and flowering freely. This is as quick and good work as can be wished, and Tree Carnations of the same age in 9-inch pots are in their way equally fine, and will give an abundance of flowers throughout the winter.

One house is brilliant with Zonal Pelargonium Guillon Mangilli, evidently most valuable for winter, and in striking contrast are a number of plants of *Begonia semperflorens grandiflora*. This *Begonia* should be grown in every stove or intermediate house in the kingdom where white flowers are required during autumn and winter, especially as the plants can be so easily raised and grown, those in question being the produce of seed sown in April of the present year. This is a new variety, and was exhibited before the Floral Committee of the Royal Horticultural Society last year, and only lost a certificate by one vote; but as the plants are now grown at Marston they represent a variety of decidedly greater merit and usefulness than some flowers that gain a mark of honour perhaps by one vote. This *Begonia* is much superior to the typical form, inasmuch as it is of much freer growth, has a branching habit, with larger trusses of finer pure white flowers. A great merit of the variety is that it comes quite true from seed, and a batch of plants must be at the least as valuable as a number of Primulas. All who see the plants in question admire them, and the sooner seed can be raised and distributed the better. In another house plants of the same variety are associated with a small unnamed scarlet *Begonia* of great decorative value, much resembling *B. Ingrami*, but superior to it, and it is not easy to imagine a more beautiful mixture. Both

the *Begonias* should be grown freely, and if grown as well as those at Marston they will not be likely to disappoint either employers or gardeners.

The usual kinds of decorative plants—Primulas, Cinerarias, Cyclamens, Bouvardias, and Violets—are grown in the manner that Mr. Iggulden has recommended in these columns, and their condition testifies to the soundness of his teachings. Strawberries in pots are excellent; indeed, everything that there has been time to do in the yet short term of service of the cultivator appears to have been done well.

It is not necessary to dwell on the kitchen gardening, as in this branch most of the best exhibitors of the day know of Mr. Iggulden's competence, and some of them would have been as well pleased at times if his productions had arrived too late. Lord Cork enjoys his garden and gives aid readily towards rendering it satisfactory, and there is not a doubt that his gardener will make the most of the means at his disposal. Marston taken in its entirety is a fine old country seat, and worthy of all the care that its noble owner exercises in its preservation and improvement. Notes on Longleat must be postponed.—J. W.

#### NOTES ON PEARS.

IN continuation of my article on page 312 as regards Pears, many people recommend strong loam for their successful growth. Although I know quite well it is the best, probably not two gardens in a score have that kind of soil, and my opinion is that with a little extra attention good Pears may be grown in almost any kind of soil. If the soil is light and poor place some good loam round the roots of the trees, and mulch heavily with farmyard manure during the summer months. The ground must be prepared by trenching, and have the loam ready by planting time for placing about the roots. It is certain that the fruit will not be so fine on pyramid and espalier trees as on trees against walls, although when grown as pyramids very creditable fruit may be obtained, especially if on the Quince stock. In many gardens there is little wall space; then the midseason and late kinds had better be grown as espaliers, as they come finer on that system than as pyramids. But where there is wall room it is best to devote them to the midseason and late kinds, and the early kinds as espaliers or pyramids. As regards the best stock for Pears that is a matter of opinion. If they are on the Pear or free stock they make trees much quicker, grow to a larger size, and are longer-lived than those on the Quince; but when on the latter stock the fruit is often finer, the trees are more prolific, and come into bearing much quicker. Consequently most people prefer the latter stock, although some kinds will not do on the Quince, such as Marie Louise, Winter Nelis, and Easter Beurré. Cordons are all best on the Quince. If large fruit are required for exhibition, cordons are the best; if principally for table use, the trees should be fan-shaped or horizontal-trained. When grown as cordons many varieties may be had in a small space, and every place of any extent should have some cordons, as they are very interesting, especially when many varieties are grown. The following I find the best varieties for succession:—Doyenné d'Été, Beurré Giffard, Williams' Bon Châtién, Beurré d'Amanlis, Louise Bonne of Jersey, Beurré Hardy, Beurré Superfin, Marie Louise, Pitmaston Duchess, Glou Morceau, Durondeau, Beurré d'Aremberg, Beurré Diel, Chaumontel, Josephine de Malines, Knight's Monarch, Bergamotte d'Espéren, Marie Benoît, and Olivier de Serres.—FRUIT-GROWER, *Worcestershire*.

#### NEPENTHES RAJAH AT HOME.

LAST week this remarkable *Nepenthes* was exhibited for the first time at South Kensington, and certificated by the Floral Committee of the Royal Horticultural Society. As was stated in our report the plant was found by Messrs. Peter Veitch and F. W. Burbidge upon Mount Kina Balu. The accompanying engraving is from a sketch by Mr. Burbidge, showing the mountain as seen towering through the valley mists of early morning, and illumined by the rising sun. We are further indebted to Mr. Burbidge for the following notes on *Nepenthes*, which will, we doubt not, be acceptable to our readers:—

"*Nepenthes*, or the true Pitcher Plants, are very plentiful in Borneo, many species growing in the lowlands near the sea, such as *N. Rafflesiana*, *N. Veitchii*, *N. bicalcarata*, *N. gracilis*, and its small variety *N. lævis*, *N. hirsuta*, and others; but it is on the Kina Balu or 'Chinese Widow' Mountain, which towers upwards into the clouds (about a hundred miles northwards of the British colony of Labuan), that the most wonderful species of the whole genus are to be found. The finest species already discovered on the rocky sides of Kina Balu are *N. Rajah*, so named by Sir

Joseph Dalton Hooker, K.C.S.I., the present Director of the Royal Gardens, Kew, in compliment to his friend Rajah Brooke, a man whose name is yet a "household word" throughout the length and breadth of Borneo, and among all the native races of the Malayan Archipelago. *N. Edwardsiana* is another fine species, having pitchers varying from 12 to 22 inches in length, and being of a soft vermilion red colour. *N. Lowii* is shaped like an old-fashioned wine flagon, and *N. villosa* true (not *N. Veitchii*, often misnamed *N. villosa*) is coloured like a well-ripened Peach of the Royal George race. Then *N. Boschiana* var. *Lowii* has long cylindrical green pitchers heavily blotched with dark purple; and *N. Burbidgei* has triangular stems, decurrent leaves, and bears pure white pitchers, something like the finest eggshell porcelain in texture, spotted with bright purplish red or crimson.

Of all these species *N. Rajah* is by far the most bold and distinct in habit of growth, and it bears pitchers of by far the largest size and capacity. The largest-sized pitchers borne by this species hold nearly four pints of water when full, and are capacious enough to drown a rat; indeed, Mr. Hugh Low actually did find a dead rat in one of the pitchers of this species, as related by Spencer St. John in his 'Life in the Forests of the Far East.' Mr. Low, although the original discoverer of all the above species, was singularly unfortunate in his attempts to introduce them alive into European gardens. So also Mr. Thos. Lobb, a most successful Eastern plant-hunter, failed even to reach their habitat, although he did penetrate

into the interior as far as Kina, the last village on the way to the great Pitcher Plant Mountain. The natives of Kina are a bold and independent people, and refused to allow Lobb to pass, but he ascended the small mountain of Labang Labang, to the right in our sketch, and there actually found *N. villosa*, although he failed to bring it home alive. Kina Balu is 13,700 feet high, and is five or six days' journey from the N.W. Bornean coast."

The following is an account of a journey to this mountain undertaken by Mr. Burbidge and Mr. Peter Veitch, as given in Mr. Burbidge's interesting work of travel, "The Gardens of the Sun\*."

"Returning to the Kina we engaged Boloung and Kurow, the acting head men of the village, and six of their followers, to take us up the great Kina Balu mountain on the morrow. 'Musa' and Pangeran Raman did most of the bargaining on our side, and at length concluded the matter by paying over the amount of cloth and brass wire as agreed. Next morning we selected sixteen of our men and started for the mountain. In a rich bit of shady forest on the other side of the Kina ridge we found the evergreen *Calanthe maculosa*, bearing spikes of white flowers much larger individually than those of *C. veratrifolia*. A foliage plant marked with silvery blotches above and crimson beneath was also collected. Our road was a rough and tiring one of sloping hillside paths very wet and slippery, and in places blocked by fallen trees. About one o'clock we reached a rushing stream, and our guides brought us to a large overhanging rock, where they said we must pass the night. It now began to rain heavily, so we at once told the men to cut sticks and Palm leaves

Fig. 61.—KINA BALU MOUNTAIN, N.W. BORNEO.

to lay on the ground where we were to sleep, and over which we could spread our waterproof sheets and rugs. This was soon done, and meanwhile our 'boys' prepared luncheon. We were disgusted at stopping thus early in the day, and wished our guides to proceed when the rain abated, which, however, they determinedly refused to do. To make the best of a bad bargain I and Mr. Veitch explored the forest above our camp, where we found a pretty Aroid with white blotched leaves, and another marbled with silvery grey; also a variegated plant resembling an *Anætochilus*, but which Professor Reichenbach tells me is the *Cystorchis variegata* of Blume. This plant I had previously gathered in another locality further south; indeed, it seems pretty generally distributed along the north-west coast. Specimens of two or three delicate Filmy Ferns were found near the stream; and at our camping place, which we named the 'Sleeping Rock,' the pretty little *Adiantum diaphanum* was plentiful, and living plants were brought to England from this habitat.

"About seven o'clock next morning we started on our upward journey. It was hot work at first, but we could feel it perceptibly get cooler after the first 2000 or 3000 feet. At about 4000 feet Mosses are very plentiful, the finest species gathered being *Dawsonia superba*, which fringed the path, but nowhere in great plenty. A new white-flowered species of *Burmannia* was also gathered, and small-flowered Orchids were seen. In one place a shower of small scarlet *Rhododendron* flowers covered the ground at our feet, the plant being epiphytal in the trees overhead. It was very misty, and the Moss which covered every rotten stick, and the vegetation generally, was dripping with moisture, and every sapling we grasped in climbing upwards was the means of shaking a shower-bath on us from the trees above. At about 5000 feet a dead and broken pitcher of

*Nepenthes Lowii* lying in the path led to the discovery of the plant itself scrambling among the mossy branches overhead, its singular flagon-shaped ascidia hanging from the point of every leaf. It is a vigorous-habited plant, with bright green leathery leaves, the petioles of which clasp the stem in a peculiar manner. The only plants we saw were epiphytal on mossy trunks and branches, and we searched for young plants diligently, but without success. All the pitchers hitherto seen are cauline ones, and as the plant has never yet been seen in a young state, it is an open question as to whether the radical pitchers differ in shape or size, as is the case with most other species. As we ascended higher, epiphytal Orchids, especially *Ericas*, *Dendrochilia*, and *Cœlogynes*, became more plentiful, and we came upon a large-flowered *Rhododendron*, bearing rich orange flowers 2 inches in diameter, and twenty flowers in a cluster! It grew on a dangerous declivity, and not one of our lazy men would venture to get it for us. Such a prize, however, was too lovely to forego, and after a wet scramble among the surrounding bushes I secured it in good condition. Two or three other species were seen in flower, but none equal to it in its golden beauty. Here also we found two of the most distinct of all *Rhododendrons*, *R. ericifolium* and *R. stenophyllum*. On open spaces among rocks and Sedges the giant *Nepenthes Rajah* began to appear, the plants being of all sizes, and in the most luxuriant health and beauty. The soil in which they grew was a stiff yellow loam, surfaced with sandstone grit, and around the larger plants a good deal of rich humus and leaf debris had collected. The long red-pitched *N. Edwardsiana* was seen in two places. This plant, like *N. Lowii*, is epiphytal in its perfect state, and is of a slender

\* London: John Murray, Albemarle Street.

rambling habit. Highest of all in the great *Nepenthes* zone came *N. villosa*, a beautiful plant, having rounded pitchers of the softest pink colour, with a crimson frilled orifice, similar to that of *N. Edwardsiana*. All thoughts of fatigue and discomfort vanished as we gazed on these living wonders of the Bornean Andes! Here, on this cloud-girt mountain side, were vegetable treasures which imperial Kew had longed for in vain. Discovered by Mr. Low in 1851, dried specimens had been transmitted by him to Europe, and Dr. (now Sir Joseph) Hooker had described and illustrated them in the Transactions of the Linnaean Society, but all attempts to introduce them alive into European gardens had failed. To see these plants in all their health and vigour was a sensation I shall never forget—one of those which we experience but rarely in a whole lifetime!

“Not being altogether satisfied with our trip to the mountain, we resolved to start off to it again, but this time to take another path so as to reach the ‘Marie Parie’ spur. We climbed up a rocky pathway, besides which we noticed fine plants of *Cypripedium Petreianum*, *Cystorchis variegata*, and a lovely yellow-flowered terrestrial Orchid belonging to the genus *Spathoglottis*, but quite distinct from *S. aurea*. As we descended, our path lay up through a belt of tall Bamboos, and here two species of *Nepenthes* were seen. One was the long green-pitched kind covered with purple blotches (*N. Boschiana* var. *Lowii*), and the other a tall-growing species, *N. Burbidgei*, bearing beautiful white pitchers, elegantly ever-shaped, diaphanous like ‘eggshell’ porcelain, and most daintily blotched with reddish crimson in a way quite unlike any other variety. This grew on both sides of the path, and climbed the trees to a height of 40 or 50 feet. We reached the crest of the ridge about three o’clock, in a heavy drenching shower, the climate being similar to that of a warm autumn evening in a Devonshire wood. We slept under some overhanging rocks at an elevation of about 4000 feet, having an understratum of sticks and brushwood to keep our waterproof sheets off the wet ground. The air, even at this low elevation, was chilly during the night, and we found a fire and blankets acceptable comforts. *Melastoma macrocarpa*, bearing its large rosy flowers, formed a large proportion of the brush around our camping ground. Here the large *Nepenthes* were very fine; and a beautiful white-flowered *Dendrobium* grows among the bushes. It belongs to the nigro-hirsute section, and has pseudo-bulbs 5 or 6 feet high. The blossoms are described by Mr. Low as being similar to those of *D. formosum giganteum*, but with a deep orange red blotch on the lip.

“Just above our camping ground, the long red-pitched *Nepenthes Edwardsiana* was very beautiful growing up through the low jungle, its pitchers contrasting with the tufts of rich green moss which draped trunks and branches everywhere. *N. Rajah* was also abundant; and we noticed some immense urns depending from its great broad leaves, far finer, indeed, than those found at 9000 feet elevation on the more southern spur.”

THE annual display of CHRYSANTHEMUMS AT FINSBURY PARK promises to be equal to last year, and will be opened to the public on and after Saturday, the 22nd inst.

— “A. B.” wishes to inform “D., Deal,” that the best way to manage the “spawn” of such GLADIOLI AS BRECHLEYENSIS is to plant it at once, 2 inches deep, in open ground. It is perfectly hardy, though old corms are not.

— THE LIVERPOOL HORTICULTURAL ASSOCIATION’S FRUIT AND CHRYSANTHEMUM SHOW will be held, as last year, in St. George’s Hall on November 30th instead of the 23rd, as stated on the schedules issued. This alteration is due to the Committee being unable to obtain the Hall for their Show on the date announced.

— A SOUTHERN correspondent writes—“Now that the planting season has arrived it will not be out of place to remind intending planters that ILEX AQUIFOLIUM variety PENDULUM is a grand Holly, and when developed into a specimen is a grand ornament to any good garden. This Holly endured the severity of last winter well in the south. Can any of your numerous correspondents say how it succeeds in the north or in the neighbourhood of smoky towns?”

— “LANCASTRIAN” writes—“EULALIA JAPONICA VARIEGATA is a beautiful grass-like plant, the variegation being so

clearly marked, and the white so much purer than the older forms. It is perfectly hardy, and is worthy of being largely planted either in a mass in suitable position on the lawn or at the front of borders of shrubs. In this position it is very conspicuous, and shows to great advantage when surrounded by the green foliage of the shrubs.”

— THE same correspondent says—“EULALIA ZEBRINA is well named, and is not only distinct in character from the other, but a striking and good variety. It produces a very fine effect when planted alternately with the above. This is also perfectly hardy.”

— “SCIENTIA” finds ASTER MACROPHYLLUS a good dwarf variety, and worthy of a place in any collection of herbaceous plants however limited. Aster ptarmicoides is a striking companion to the above, its flowers being white.

— “L. D. W.” considers that “no border of hardy flowers should be without a few plants of STATICES. They are as valuable in the herbaceous garden as a good plant of *S. profusa* is in a collection of greenhouse-flowering plants. They are light, elegant, and distinct. The following are two beautiful varieties—*S. Limonium* and *S. Tomentella*, the latter being the more elegant.”

— IN these days of elaborate and expensive ORNAMENTAL CATALOGUES it is pleasing to observe some attempt at combining originality and attractiveness with simplicity. A very creditable and novel example of this kind from Erfurt is now before us. It is of moderate size, the cover having an oblong chocolate-coloured centre, upon which the name appears; surrounding this is a buff-coloured band, upon which is neatly gummed a neat wreath of dried Grasses, the tips of Fern fronds, and blue flowers resembling a *Centaurea*, the colour of the latter being admirably preserved. This is very carefully and lightly done, so that there is no approach to heaviness, while it imparts a novel and pretty appearance to the cover; but it is not durable.

— MR. C. WARMINGTON, writing from The Gardens, Penllergarc, Swansea, sends the following note respecting a fine VANDA CÆRULEA—“In the Orchid house here we have one plant of *Vanda cærulea* with four spikes of flowers. The two strongest spikes measure 2 feet long, with eighteen flowers on one spike and seventeen on the other. On the two weaker spikes there are fourteen and twelve flowers respectively. Some of the flowers measure 3½ inches in diameter.”

— IT is with regret that we announce the DECEASE OF JOHN RUSSELL, ESQ., OF MAYFIELD, FALKIRK, N.B., which took place on Monday, the 17th inst. Mr. Russell was a liberal patron of horticulture, and one of the first in Scotland to form a collection of Orchids. His original collection was dispersed at Stevens’ rooms a few years ago, but another and larger one has been since formed. Famous as was his first collection of Orchids, his attention was by no means confined to these. Tree Ferns were also, until lately, largely represented at Mayfield, and large numbers of other stove and greenhouse plants were cultivated. The outdoor collections of Conifers, Japanese Maples, shrubs, and trees are unique and extensive. Although not a large establishment, Mayfield is perhaps one of the richest in plants in Scotland. This indicates somewhat the position of the late Mr. Russell as a horticulturist. For many years Mr. Russell was Provost of Falkirk, in which capacity he rendered good service to the town. A year or two ago his services were publicly recognised by presenting him with his portrait in oil by one of the first artists. It now adorns the Council Chamber.

— WE learn from the schedule received that the BRISTOL

CHRYSANTHEMUM SOCIETY will hold their annual Exhibition in the Victoria Rooms, Clifton, Bristol, on Nov. 16th and 17th. Prizes are offered for all the chief sections of Chrysanthemums; miscellaneous cut flowers, plants, and fruit also being provided for. Special prizes form a distinct feature, over fifty being offered in twenty classes. An Exhibition of Chrysanthemums and fruit will also be held at Bath in the Assembly Rooms on Nov. 23rd and 24th.

— THE annual meeting of the Durham, Northumberland, and Newcastle Horticultural and Botanical Society was held in the Alexandra Hotel, Clayton Street, Newcastle, under the presidency of Councillor Thos. Gray, the Treasurer. The balance sheet was read, which showed a deficiency of £396 1s. 3d.; this was partly accounted for by the inclemency of the weather during the Society's shows. The Society this year held no autumn exhibition to keep expenses down, but in future they will be again continued. Considerable discussion arose as to sending members their tickets before their subscriptions were paid, for in the years 1878 and 1879 the Society lost over £120 by people not paying their subscriptions, and for the last two years they have not sent any till the money was paid; but this was not found to act well, so the tickets will be sent as heretofore. The following members were elected on the Council for 1882—Messrs. Dinning, R. Beall, H. Majall, W. C. Forster, G. J. Dean, A. Tindall, and H. G. Watson. The Earl of Durham was elected President, and Alderman Foster Vice-President.

— THE following GARDENING APPOINTMENTS have recently been made—Mr. Thomas Richards, late gardener to Richard Paver Crow, Esq., Ornham's Hall, Boroughbridge, Yorks, has been appointed head gardener to Mrs. B. P. Smith, Ferndale, Burgess Hill, Sussex; and Mr. John Richardson, late gardener to E. F. Duncanson, Esq., Nutwood, Bickley Park, Bickley, Kent, has been appointed gardener to Count Gleichen, St. Bruno, Sunningdale, Berks.

— MR. G. BERRY thus describes in the last issue of the *Journal of Forestry* a REMARKABLE SILVER FIR AT LONGLEAT. "Any tree that has attained a height of 144 feet in Britain may, I think, be fairly entitled to be considered remarkable. Such was the height of a Silver Fir cut down on Saturday, September 17th. It was the highest tree in Longleat Park (probably the loftiest tree in Britain), and formed one of a group of nine Silver Firs, standing on rather an elevated level piece of ground. The site is fully exposed on the north-east side. Its dead withered top has been conspicuous in the group for several years, and it was evident from the appearance of the tree that it was gradually dying from the top downwards; doubtless, however, the severity of last winter hastened its death. The belt is quite sound for about 60 feet up, where it divides into two heads. Although it was the highest tree in the group, it was by no means the finest and bulkiest specimen, as it only girthed 10 feet 10 inches at 5 feet above the ground, and contained about 350 feet of timber; whereas the largest tree measures 15 feet 3 inches at 5 feet up, and contains between 400 feet and 500 feet of timber; its height is 138 feet, and it is still in full healthy vigour. The age of the group I should guess to be nearly two hundred years old."

— *Land and Water* gives the following account of the force exerted by FUNGI IN RAISING HEAVY WEIGHTS—"Some years ago the town of Basingstoke was paved, and not many months afterwards the pavement was observed to exhibit an unevenness which could not easily be accounted for. In a short time afterwards the mystery was explained, for some of the heaviest stones were completely lifted out of their beds by the growth of large Toadstools beneath them. One of these stones measured 22 inches by 21, and weighed 83 lbs., and the resistance afforded by the mortar which held it in its place would probably be even a greater

obstacle than the weight. It became necessary to repave the whole town in consequence of this remarkable disturbance. A similar incident came under our own notice of a large kitchen hearthstone, which was forced up from its bed by an undergrowing fungus, and had to be relaid two or three times, until at last it reposed in peace, the old bed having been removed to the depth of 6 inches, and a new foundation laid."

— FROM a number of districts communications have reached us relative to the GREAT STORM OF THE 14TH INST. Never since the memorable 18th of January last, and the tornado that swept away the Tay Bridge, does the force of the wind appear to have been so destructive as last week. Gardens in all parts of the country have been considerably damaged, but the effects of the storm are most noticeable in the destruction of trees which has occurred. In the neighbourhood of the metropolis the parks have all suffered more or less in this respect, some of the oldest specimens of timber having been uprooted. Young and recently planted trees have also been greatly injured; in one instance, we are informed that several hundreds were completely blown out of the soil. In Greenwich Park twenty-three large trees, principally Elms, were blown down, and about the same number of small trees, including several fine Hawthorns. The park in all directions was covered with large boughs. From St. Mary's Gate to the Broad Walk six large Elms were down, and in the Broad Walk itself one large Elm completely blocked the way. But it was in the Green Walk, a little to the east of the Royal Observatory, that the greatest damage was done, and within a space of 200 yards in circumference not a tree was left standing. At Windsor many of the fine old Elms in the Long Walk suffered severely, large limbs being torn off by the wind. Many of the trees round Windsor Castle, in the Great Park, and at Virginia Water, were also uprooted. The gale did much damage to the timber in the various College grounds at Oxford. Four of the celebrated trees in the Broad Walk were destroyed, and twenty-four in the walks around Christ Church Meadow. At Leamington the ornamental trees in Jephson's Gardens and the Holly Walk have suffered severely. Similar reports are received from all parts of Warwickshire. There has been a great destruction of timber on the Langley estates of Sir R. B. Harvey, M.P., and a correspondent of a daily contemporary states that "the woods look as though they had been subjected to a heavy artillery fire." The Duke of Bedford's park at Woburn has suffered in a similar manner, hundreds of trees having been torn up by the roots. The gale appears to have been felt with great severity near Coventry, for it is reported that within a radius of three miles of that town five hundred large trees have been uprooted.

— FROM many other districts we hear similar accounts, but the three following letters from widely separated counties will convey some idea of the general prevalence of the storm.

Mr. George R. Allis, Old Warden, Biggleswade, Bedfordshire, writes—

"The gale of Friday, 14th inst., was severely felt here, uprooting several fine trees of Oaks, Elms, Cedars, and Arbor Vitæ in the pleasure grounds; and the damage done to the trees in the park has made it a scene of desolation from every point of view. Large branches of Oaks and Elms have been torn off by the fury of the gale like matchwood. On a neighbouring estate a large Cedar of Lebanon has been blown on the conservatory adjoining the mansion, doing considerable damage to the mansion as well as the conservatory. Nearly three-quarters of an inch of rain fell on the preceding night."

Mr. W. Bardney, Norris Green, Liverpool, observes—

"On Friday last a terrific storm of wind, sleet, and rain was witnessed in this neighbourhood. From various accounts its fury was unprecedented since 1839. The damage done in the gardens here is considerable, the majority of the trees being broken and dashed considerably, while seven or eight were entirely uprooted. One fine old Elm, which had an immense symmetrical head and its lower branches sweeping the ground, was torn up with fully two tons of soil to the

roots. Pyramid Pears and Apples were also much damaged. Raspberry canes suffered considerably, and are broken off level to the wires to which they were secured. Much glass was broken, especially in those houses within a short distance of trees, the branches that were broken off being carried with the wind a considerable distance. Lettuces and other winter salads present a shattered appearance, the leaves being turned as black as if that been subjected to a severe frost. Parsley is much broken, and Broccoli and other winter vegetables have suffered proportionately."

Mr. R. P. Brotherton, Tynninghame, East Lothian, writes—

"We have had a storm from the north this forenoon which, I am afraid, has destroyed all our garden flowers. Most of the fine trees near the house, as well as in other parts of the ground and woods, have been blown down to-day. I saw ten trees in as many minutes fall like a row of ninepins at the beginning of the storm, and similar destruction was going on over 2000 acres."

[Many letters reached us too late for insertion.]

#### PEAR v. QUINCE STOCKS FOR PEARS.

YOUR fruit jottings interest me, also the article on Pears on Pear stocks on page 329.

In my case it was a great mistake to plant Pears on Quince stocks. For a few years the trees did well, and for their size bore fair crops of fruit; after about ten years the foliage became yellow in July, and the fruit small in size and poor in quality. To have autumn tints in July is not agreeable. Pear trees on Pear stocks planted at the same time are still with green leaves, and have given quite as good crops in their early years as those on Quince; and it cannot be too widely known that by root-pruning, the Pear on Pear stock can be made to produce fruit as early as the Pear on Quince stock, and the Pear stock will outlast several generations of Quince stocks. My soil is stiff with clay subsoil.

Has anyone noticed the early turning yellow of the foliage after Pears have been about ten years on Quince stocks?—ROBERT WARNER, *Broomfield*.

#### HARDY PLANTS—PROPAGATION.

(Continued from page 330.)

THE preparation of the border and its management having been discussed, something may now be said about procuring the occupants. If you have the command of abundant means this is a very easy matter; but we will suppose that you wish to fill the border as cheaply as possible. In these circumstances the best plan is to order as many plants as you can afford about Christmas time or earlier. When they arrive do not place them in a cold frame, but give them a position in a house where they will grow gently. Some can be divided and potted singly; those that are not in good order for dividing should be encouraged in growth till increase can be effected. Healthy sturdy plants will thus be obtained, and such can be placed out in the borders at any time, and they root in the soil at once. Some may be increased by cuttings, and it is surprising how a large border may be filled by judiciously economising a comparatively small purchase. Again, there are many plants which can be raised from seed, and in every case where this can be done it is best. Florists' flowers are suitable for border cultivation, and I prefer obtaining plants of the best varieties as being the only certain mode of having them satisfactory. Antirrhinums or others that come quite fine from seed I raise myself. By exchanging with your friends you will also be able to add largely to the collection. In dividing plants care must be taken not to go to the extreme, as slow-growing plants take years to become good specimens when divided into very small pieces. Bulbous plants are most cheaply bought by the dozen or hundred. Some of them are expensive to buy even singly, but many fine bulbous plants can be bought cheaply.

As many plants of each kind as are wanted to fill the border are propagated by division, by layers, or by cuttings during the autumn. A layer of old Mushroom-bed material is employed for the plants to form roots in. This causes a quick strong growth and a matted mass of roots to lift with. The other plants are then taken to the rubbish heap, and employed as manure when they are decomposed. Unless marks are placed over bulbous plants it is impossible to lift these, nor is it necessary. As the trenching proceeds just place them into the positions they occupied before dividing the clumps which may have become too large. Small sticks may be placed to show where these are as the work is proceeded with, but most of them will be either above ground or growing before the border is replanted in the spring.

As to arranging the plants in the border, I prefer the mixed plan as being far more effective than any other. There are

certain flowers which surpass others in general effectiveness in their several seasons, and these are planted prominently and in sufficient numbers to impart a decided character to the whole. If you wish the border to yield a successive display of flowers for the longest time possible you must plant for that purpose; if for one season only, say spring or autumn, or both, without reference to the summer months, then you must plant to get effect at these seasons. All our borders are effective during the autumn months; two of them are kept to yield a succession of flowers throughout the whole season of flowers, one for autumn and spring, and another simply for late autumn. Our spring and autumn border is occupied with only free-flowering plants. In spring we have numbers of Crocus clumps in variety, Tulips, and the Polyanthus Narcissus, late Helleborus, large masses of Arabis albida, early Pansies, and plants of similar character. In autumn we have masses of Tritoma, Dahlias single and double, chiefly the single white, which is the best and most effective. Gladiolus brenehleyensis, late Picotees, and Carnations white and scarlet, late Phloxes in three or four distinct colours, Salvia fulgens, and S. patens, early-flowering Chrysanthemums, Pentstemons, Pansies, Japanese Anemones, Aster bessarabicus and A. longifolius formosus, with Marigolds and Enothera Lamarckiana. These are the chief plants employed, and the effect is grand.

The borders at each side of the central kitchen garden path, which is the main one, have been widened to 13 feet each; and in these, in addition to beds of Christmas Roses, Schizostylis coccinea, Lily of the Valley, some of the Narcissus family, and others for cut flowers, the majority of our herbaceous plants are grown. These borders form to me one of the most interesting features of the garden. We have several hundred distinct species of plants in them besides many varieties; several kinds we find a difficulty to keep, and by these means and fresh sorts being annually added there are always a few changes amongst the occupants. I will describe in the next paper the plants employed for these borders and the style of planting.—R. P. BROTHERSTON.

#### GRAPES AT THE EDINBURGH SHOW.

ALLOW me to add a very few words on this subject and then I leave it. In my last I accused your reporter of "not giving a faithful account of what he saw," and he has now furnished conclusive proof of this. He states this week, that "the marks of syringing were so patent on the berries that these alone would have prevented them, if in other respects good, from taking a place as first-rate examples," &c. Now here is a plain and specific enough statement, and yet except, perhaps, in the case of the Muscats, it is totally inaccurate. The Muscats were syringed once or twice during the season, and the bunch sent may have shown it in a very slight way; but in the case of the other seven kinds exhibited, never a drop of water touched the berries or the fruit from the time they were started until now, and your reporter did not see a vestige of what he says was "so patent." I will pay his expenses up and down to here if he can find one bunch of those seven showing a speck of injury from such a cause. Bunches are nearly all hanging yet and to be seen. This fact taken in conjunction with your own note on the Grapes sent to your office speaks for itself; but when a man deliberately states that such and such things "were patent," which means more than usually apparent, but which never existed, what is one to think of his other assertions?—J. SIMPSON, *Wortley, Sheffield*.

#### WINTERING BEDDING PLANTS.

IN many cases the most tender bedding plants may not be so numerous as they were some years ago, but wherever there is a flower garden Pelargoniums and other plants requiring protection in winter are employed. These cause much work in propagating and hardening in spring, and they also require considerable attention at the present time in storing them for the winter. Until there is danger of their being injured by frost all bedding plants should be as much exposed as possible.

In autumn we have a decided objection to striking cuttings in bottom heat, or, indeed, in artificial heat of any kind, as it is a very bad start for them, especially where much heat cannot be supplied in winter. Every cutting that can be rooted in the open air and wintered in a cool frame. Pelargonium cuttings are taken in August and inserted in pots or boxes placed in the open air fully exposed to the sun, and there they should remain until frost is approaching. In November they are placed in a vinery or other house where there is sufficient heat to keep frost out. Iresines and Mesembryanthemums require a little more heat in winter. At the present time we have ours stored on a shelf near the glass in an intermediate house, and as they were taken from

a cold frame they are very dwarf and healthy. Pelargoniums we find take up less room unless in boxes; of other plants we place from six to ten cuttings in a 3-inch pot. A large number of stock plants can thus be stored in a small space in winter.

Coleuses are the most difficult plants to preserve for the next four months. A warm dry place suits them best, but as they are so easily increased in spring a large number of them need not be stored now. Cuttings rooted some little time ago may be kept fresh and healthy with extra attention, but two or three old plants in pots throughout the summer, and grown hardy, are the easiest to winter and they give plenty of cuttings in spring. Although they may lose almost every leaf, so long as the stems are in good

condition they will soon form abundance of shoots. *Centaurea ragusina* is a difficult plant to root in autumn and keep good throughout the winter; old plants which have been plunged in pots in the open air throughout the summer are the least troublesome.

Carpet-bedding plants, such as *Alternantheras*, may be treated like the *Iresine* or *Coleus*. Hardier plants and many succulents may do well in cold frames under glass, but never allow frost to injure a leaf, beware of superfluous moisture, and ventilate freely whenever it can be done. Water should never be applied when the frame is being closed for the night, or it may be for days when a storm should follow. Water thoroughly when the venti-

Fig. 62. —PEAR DOYENNÉ BOUSSOCH.

lators are first opened, and the leaves will soon become dry and little or no loss will occur from damp, which is too often the case in winter through inattention to this.—M. M.

#### DOYENNÉ BOUSSOCH PEAR.

AMONGST Pears in season in October and until the present time in some districts this is perhaps one of the finest in appearance, and is often of good quality when "caught at the right time." A noted fruit-grower has written to us, "Doyenné Boussoch is a splendid Pear, but it is like a flash of lightning," alluding to its rapid decay after being ripe. Some time ago Mr. Record wrote as follows in reference to Doyenné Boussoch—"I have proved it to be a Pear of the finest quality. It is large and noble in appearance, of rich flavour, flesh melting and juicy, skin very thin, and when ripe of a russety lemon colour. It is also a capital cropper,

and does well against a wall with an eastern aspect in the south of England, but northwards it would need a good south wall. Worked on the Quince stock the tree has a moderately vigorous growth, and generally forms plenty of fruit buds; it also does well as a pyramid, though it ripens somewhat later. I have had it in use from the latter part of October to the middle of December, and it was always welcomed at table as a first-rate dessert Pear." Judging by specimens that have been sent to us there are evidently trees misnamed Doyenné Boussoch. The annexed engraving of a fruit grown by Mr. Haycock of Barham Court is a characteristic representation of a well-grown specimen.

#### AGAPANTHUS UMBELLATUS.

THIS is a plant which deserves a prominent place in every flower garden. Its beautiful light blue flowers and dark green foliage have a very pleasing effect, and it is a valuable addition

to our autumn-blooming plants. I have under my charge a bed of the above which I think is worth a note. This bed was formed in April last year with eighteen small plants, which survived the past trying winter without injury, and have now eighty-seven spikes of bloom, many of which bear a hundred flowers each. It is one of the best plants I know for flowering in autumn. My mode of treatment is as follows:—The bed is made of fresh loam and leaf soil, with a liberal sprinkling of coarse sand. In this the plants make vigorous growth during the summer, and on the approach of winter I have some dry leaves worked in between the plants, and the whole then covered with turfy soil. In March this covering was partly removed, and I found the plants had already made some growth, and by the middle of June the bed was one mass of rich foliage and the flower spikes were appearing. During the summer several waterings of liquid manure were given, and the result has been most satisfactory.—A. CAMPBELL, *Ashford Gardens*.

#### HOW TO KILL THE PEAR SCALE.

THAT is the heading that appeared in the *Journal of Horticulture* (page 285), from your correspondent Mr. W. Taylor. Anyone who is so unfortunate as to have scale-infested trees must thank Mr. Taylor for bringing the subject before the public. The writer of the letter introduced by Mr. Taylor recommends the affected trees to be painted all over with boiled linseed oil in January or February, but adds this caution: "Avoid oiling the bloom buds." I believe the plan to be a most effectual one; but I prefer and use pure whale oil for this reason: The whole tree can be painted over—bloom buds and all—without any bad effect, but rather otherwise; and if properly done it is an effectual cure, and may be laid on either in December, January, or February with safety on any sort of fruit tree.—JOHN DOWNIE, *Edinburgh*.

#### THE ROSE SEASON OF 1881—A RETROSPECT.

It is difficult now-a-days to say when the season for Roses begins and ends, for what with Teas and Noisettes on walls and sunny spots in early spring, and late blooms of Hybrid Perpetuals and Teas which all those who grow Roses in any quantity can command until the frost sets in, there are but few months in the year when Roses may not be had; but to the minds of most Rose-growers the Rose season means the exhibition season—means, that is, the quality of Roses as they are seen on the exhibition table. And when July closes most Rose-growers pack up their green boxes, clean and store away their tubes, and regard their work in that respect as closed for another twelve months. And it is in this sense, then, that I must answer the question so often put to me—What do you think of Roses this year? That I have some opportunity of judging may, I think, be fairly conceded when I say that I have judged at the following Shows—Farningham, June 29th; Canterbury, June 30th; Maidstone, July 4th; Reigate, July 5th; Cardiff, July 6th; Oxford, July 7th; Alexandra Palace, July 9th; Uppingham, July 11th; Birkenhead, July 16th; Leek, July 19th; Helensburgh, July 21st; Newton Stewart, July 22nd; Newcastle, July 27th; and Manchester, August 24th; that I was also present, of course, at our National Society's Shows at the Crystal Palace and Sheffield, although unable, owing to my duties as one of the Secretaries fully occupying my time, to act as Judge; and that thus in all parts of the kingdom I have had during the exhibition season an opportunity of seeing Roses which perhaps no one else has had. A judge, it need not be said, has peculiar facilities for seeing the Roses. He has no prejudice in favour of his own flowers, as so many even of the best growers have. He sees the Roses at their best before crowds come in to heat the room or the tents and cause them to lose colour; and if he has been, as I have, year after year honoured with the confidence of Rose societies, he can the better compare those of the present year with those which have preceded it. If, then, my judgment is wrong—if the conclusions I draw from what I have seen seem to other competent judges as incorrect—the fault must be in myself, and not because I have lacked opportunities for judging.

The terribly severe winter of 1880-81 was but a poor preparation for the exhibition season. Tales reached me from all quarters of the havoc that had been wrought amongst Roses. One amateur wrote that he had lost four hundred Teas and Noisettes, another that all his dormant buds were killed, another that he had not a standard Rose left alive, and from all directions that the Roses were killed to the snow line. Those that were left, however, broke well; but then came those late frosts which have for many years visited us in May and June and destroyed the hopes of many a grower. The early shoots were killed, and with them the finest and most promising buds; and consequently, as the season

drew near, I felt that we could not expect a grand Rose year. And so it has proved; and so, I think, everyone with whom I have talked upon the subject has agreed to. It is no discredit to Rose-growers, either professional or amateur, to say that no one has exhibited in their usual form. I cannot call to mind any one stand of any considerable number of which I could say that it was perfect—no such stand, for example, as the thirty-six which Mr. Jowitt exhibited at Birkenhead in 1880. Nor were individual flowers of such pre-eminent merit as that they will haunt one's memory for a long time to come—no such blooms as the Général Jacqueminots of Mr. Cranston, the Niphetos of Mr. Jowitt, the A. K. Williams of Mr. Wollaston in 1880; for although the bloom of the latter Rose shown by Mr. Jowitt at Wirral was grand, yet the colour was somewhat gone. We never went to an exhibition but excuses had to be made; and we may be sure of this, that when they are, those who make them feel that they are not up to the mark. Yea! I think some growers must have been very much surprised at the position which they took, unhopd-for prizes dropping into their lap. Take it all in all, the provincial Show of the National Rose Society at Sheffield must be considered to have been the finest show of the year, not so extensive as the metropolitan, but in the general quality of the blooms superior to it; and yet there was much there we might have wished better. True, the terribly hot weather had had an injurious effect, and perhaps the wonder was that they were so good.

In looking through the lists of awards it is curious to remark how situation and climate have influenced them. Thus, in the earlier shows Mr. Cant of Colchester was the most successful nurseryman, and at the Crystal Palace Mr. Baker of Exeter the most successful amateur; afterwards the Cranston Company carried all before them, and Mr. Jowitt was equally to the front as an amateur; and then when the later shows came on the north asserted its rights. At Newcastle Mr. Whitwell of Darlington beat Mr. Jowitt, and at Manchester no grower for sale could come near Messrs. Mack & Son. It will never be possible to fix a date for an exhibition that can satisfy both northern and southern growers, and therefore it is well that there should be these different exhibitions, that all parts of the country may share in them. And here let me ask, As the National Rose Society is now looked up to as the central sun round which the rosy planets are to revolve, might it not be possible for the authorities connected with our provincial societies, as soon as the fixtures for the National are made, to make theirs also? and if these were publicly announced, and any of them were seen to clash, arrangements for preventing it might be made. I call to mind one or two occasions when such needless clashing did take place, much to the injury of both shows. There was one show this year the date of which was twice altered simply because the date of one of the larger exhibitions had not been fixed. And there is no reason why it should not be done, for it is easy now after a few years' experience to say what will be the most convenient time for an exhibition at Launceston as in London.

I never recollect a season when so little was known of the new Roses, I mean the French Roses. When prizes were offered for new Roses the principal portion were either English-raised Roses or else the characters of which we already knew. Nor were there many new candidates for favour amongst our English raisers. Neither at the Crystal Palace or at Sheffield was there anything remarkable. Indeed at the latter place the prize was not awarded, and considerable doubt was expressed as to that at the Crystal Palace. Later on in the season The Cranston Company exhibited a very fine flower called Mrs. Gretton; while Duke of Teck, Harrison Weir, and Countess of Rosebery maintained their position pretty much in the order that they are here placed. There may be amongst the French Roses some A. K. Williams or Marie Baumann, but as yet they are unknown to fame. Conjectures are indeed given by several of our leading growers as to the merits of some of the varieties, but it is evident that they are only tentative, and that they have not had many opportunities for judging.

"What about the Stapleford Roses, or Pedigree Roses as they are sometimes absurdly called?" I have been repeatedly asked. Well, I have seen no cause to alter in any way the opinion I expressed upon them last season. They have hardly ever made their appearance in an exhibition stand, and as exhibition Roses they are an entire failure. I saw one at a provincial show as hard as a bullet. "I have had," said the disgusted exhibitor, "that brute under a glass for three weeks, and he is as hard as ever." The same thing is said of them as pot Roses with the exception of Duke of Connaught, and this, from its colour and freedom of bloom, is likely to be useful for forcing for cut flowers. Abroad, I understand, they are more appreciated, the warmer climate of both France and America suiting them better; although I perceive that Messrs. Ellwanger & Barry, the well-known American nurserymen, in

their catalogue which I have just received, say that they have not been proved in the open air as yet, and only speak of their value as pot Roses under glass. I think their failure is a matter to be much regretted, for it seemed as if a right line had been taken by the raiser to endeavour to combine the colours of the Hybrid Perpetuals with the free-blooming character of the Teas; but in some manner the cross has not succeeded. It is just possible that from these something may be obtained; but it is rather a Nemesis on the raiser, who so boldly stated that everyone before him had been wrong, to be thus in the wrong himself. A successful hybridiser has much to learn of Nature's secrets, and these are not generally given to the man who rushes into it, but to the patient toiler who learns as he goes on, who essays not to teach but to be a learner.

There can be little doubt that the Rose is not only not losing its popularity but steadily increasing it, and that not a little of this is owing to the operations of the National Rose Society few can doubt. Its authority is as much recognised amongst Rose-growers throughout the kingdom as that of Lord's among cricketers, and its medals are eagerly sought after as a testimony of prowess and skill. And here let me repeat the note of warning I gave last year as to the spirit in which its competitions should be entered into. Let exhibitors be careful that they are actuated by the desire of honour in the contest rather than by the quantity of money to be gained. It might not be well to revive the Laurel and Parsley crowns of the Olympic games, nor must the consideration of money be left out of sight; but surely it is not the one thing which the exhibitor has before him when he enters into the contest. If it be so it will lead to unseemly wrangling and strife and to the injury of the society. And now again the season of preparation is at hand: catalogues are issued, orders given, beds prepared, and hopes eagerly cherished of success in the future. May it be so, and may the year 1882 see such an exhibition of the queen of flowers as has never been seen before; and may you and I, good reader, be there to see it.—D., Deal.

#### CULINARY PLUMS.

HAVING given on page 308 a list of Plums suitable for dessert, some of the leading culinary varieties may now advantageously receive consideration. Early Prolific does equally well as a dwarf or standard, and is an early and great bearer. Where Plums are required early it should be grown against a south wall, and it then ripens earlier by a fortnight, the quality being much improved, indeed is not unsuited for dessert. It ripens usually at the end of July, being closely followed by Czar, which has large red oval fruits, bearing well as a standard or dwarf, and is even suitable for dessert when well ripened. The fruit does not crack with wet, and it is one of the finest culinary sorts. This is a seedling raised by the late Mr. Rivers, obtained from Prince Englebert crossed with Early Prolific. Sultan, another of Mr. Rivers' seedlings, ripens about the middle of August, and is a great bearer, and may be described as an early and hardier form of Prince of Wales. Prince Englebert is not only a large Plum, but one of the finest for culinary purposes, and when well ripened can be used for dessert, the fruit having a fine appearance. Mitchelson's is a fine kind for preserving as well as cooking, and has a flavour not unlike a Damson. It is first-rate as a standard, and bears profusely. Prince of Wales, though a capital sort, and the trees great bearers, is not very hardy, and in cold localities requires to be grown against a wall. Pond's Seedling is another of the large red Plums, and one that bears abundantly. The large Plums are preferably grown as espaliers than as bushes or pyramids, and are more readily protected from birds, similar remarks applying to White Magnum Bonum, which is not only one of the finest preserving Plums, but grown against a wall is good for dessert. Victoria is very prolific in any form, but is very much finer against a wall than as a bush or standard. Autumn Compôte is excellent for preserving and bears freely, as also is Belle de Septembre, and preserved affords a fine highly coloured syrup, that of the other being pale in colour, but with a peculiar agreeable acidity. Diamond bears abundantly as a standard, and is one of the very best cooking and preserving Plums. Winesour is a good bearer when aged, and is highly esteemed for preserving, its briskness being relished by those that are cloyed with the sweet Plums. Wyedale much resembles Winesour in appearance, but ripens three weeks or a month later, and is a very valuable late variety, bearing abundantly even in exposed situations. It is capital for cooking or preserving, and is brisk and agreeably flavoured. Coe's Late Red does not bear freely in a young state, but from its lateness, ripening in late October and early November, is worth a place.

Of Damsons, Farleigh or Crittenden's Prolific is a prolific bearer.

The fruit, however, is not so large as the Prune Damson, in fact, no larger than the common, but it bears early, which is not what the others do. For quality, the Prune Damson is far ahead of any, and though not a good bearer when young, bears freely when the trees are a little aged. Dalrymple is similar to the Prune, and the tree is not so strong a grower; it also bears abundantly and is ripe in October.

Bullaces are esteemed by some, I suppose, for their briskness, and as they usually bear freely a tree or two of each will suffice. The Black or Sloe may be passable after early frosts, but is, I think, too acid. Essex Bullace is larger and not so sour as the White Bullace, and Royal is certainly brisk enough, and with plenty of sweetening may be made agreeable. As it ripens in October and hangs some time it is useful as a late fruit.

Acidity in Plums for culinary purposes is by some looked upon as indispensable, hence Gisborne's, a small yellow Plum ripening at the end of August, is considered good, it being very juicy, with brisk acidity, and a great bearer.—G. ABBEY.

#### COTONEASTER MICROPHYLLA.

AMONGST hardy shrubs suitable for covering walls and trellises, I think none is more elegant than the subject of these remarks. On paying a visit to a friend residing in Wiltshire a few days ago, I was surprised to find how extensively it is grown in some parts of that county and in Somerset. Many cottages that are built a little back from the main thoroughfare are furnished with porches either of brick, stone, or trelliswork. These little porches are invariably covered with *C. microphylla*, and nothing could possibly be more trim and neat for the occasion. In many cases I noticed the front of the cottages was covered entirely with it in addition to the porches. The cottagers are fully aware of its value, and I think it may be used advantageously in many such places that are now frequently allowed to remain unsightly. *C. microphylla* was introduced from Nepal in 1825, and having been in this country so many years, it is surprising that it is not more frequently met with. It is by no means fastidious, for it thrives in any ordinary garden soil and endures much drought. It is easily propagated, either by means of layers or seeds, plants by the former method being of course the most readily obtained. It is also quite at home planted on large rockeries, for massing in front of shrubbery borders; and I have seen it used with good effect tied to an upright stake, and the long arching shoots when thickly berried are very beautiful.—W. K.

#### A WEEK IN LONDON.

##### WINDSOR.

THE elaborate descriptions which have been published of Windsor and Frogmore from time to time leave but little to be written of the beauty and magnitude of the grounds and gardens. From various parts of the park can be obtained splendid views of the Castle, but none was more impressive than that at the entrance at the north-east. The hill side which sloped sharply up the Castle was covered with fine trees, the numerous examples of Mountain Ash being heavily laden with their red berries, and were most imposing. Another grand view is obtained from the long avenue of fine Elms. In passing through the grounds I was much impressed with the grand timber which abounds, especially the Elms, which appear to have been more largely planted than any other forest tree. Many of them are giants in size, and doubtless have stood for centuries. Oaks also freely abound, one being especially noteworthy, having a fine even trunk some 36 feet or more in circumference. Some care is taken of this monster, for when a limb is lost the wounds are carefully covered to keep out the wet. Near this stood a specimen of *Wellingtonia gigantea*, said to be one of the first specimens planted in this country, and which was in those days protected with a handlight and well covered every night during cold or wintry weather. This tree is the parent of a fine avenue of trees planted alternately with Walnuts. The *Wellingtonias* were all raised from cuttings, and are now fine trees, all of similar height and even throughout. Many other grand Conifers exist in suitable portions of these grounds. *Cedrus atlantica glauca* was a wonderfully large well-furnished specimen, and near to it was a smaller specimen growing freely and planted by the Shah of Persia. *Pinus Pinsapo* was also noticeable. The silvery foliage of *Acer Negundo variegata* in sheltered positions was most conspicuous and very striking. These plants had evidently withstood the severity of the past winter uninjured, while many other shrubs were cut to the ground.

The private gardens are by far the most beautiful, and are

known as the Slopes. These grounds are picturesque, with winding walks which rise and fall according to and in keeping with the grounds. In these grounds there are some good Conifers and specimen Hollies growing luxuriantly on a chalk formation, which in some instances comes very near to the surface. The subsoil varies considerably at Windsor from chalk to gravel, but the trees flourish remarkably well, and many kinds, especially the Hollies, do much better than I should have supposed with the chalk so near the surface. The rock garden, which is situated in this portion of the ground, is naturally constructed, and was designed by the late Prince Consort. So well has the work been executed that it is difficult to determine whether it is natural or artificial. The grounds were well and beautifully kept, not a weed to be seen, and the grass slopes are in excellent order.

The terrace or flower garden, which is near to the east front of the Castle, was really grand. Not only was it well kept, but by far the most appropriate and judicious style of flower gardening that could have been employed. If the system too generally practised was carried out at Windsor it would be entirely out of harmony with the Castle and surroundings. Happily this is not the case, and the garden has been judiciously arranged, and what might have looked flat and monotonous was broken and beautifully varied by the introduction of Conifers. For example, one bed had a double row of Golden Hollies about  $3\frac{1}{2}$  feet in height, every plant even and well proportioned; between them a row of Ricinus, and between the Hollies a plant of tall Ageratum, then a band of scarlet Pelargoniums, followed by *Centurea candidissima*, and edged with other suitable plants. Two or three other beds had in the centre four specimens of *Cupressus Lawsoniana* 6 or 7 feet high, and, like the above, close and even. The compact growth of these plants would lead anyone to suppose it was some other variety; but I was informed the young growths of the plants were pinched off once or twice during the growing season to keep them in bounds. This accounts for the compact and even habit of all the Conifers used in this garden. In some beds Golden Yews were employed, in others *Cupressus L. erecta viridis*, *C. L. gracilis*, *Retinospora plumosa*, and *R. p. aurea*. Some of the best Thujas were employed, such as *T. aurea*, *T. elegantissima*, and *T. orientalis aurea*, and other choice kinds, varying in height from 18 inches to the height of the *Cupressus Lawsoniana*, which was the tallest employed. Some were of pyramidal growth, while others were of a bush or cone shape. The shrubs throughout were most tastefully planted, and the golden kinds arranged evenly over the garden, and contrasted admirably with the green-foliaged varieties. In some beds as many as three rows of shrubs were employed, and in one of these beds, containing Silver and Golden Hollies intermixed with Petunias and Verbenas, the effect was very striking.

The beds devoted to carpet bedding were not numerous, but they were very neat, and contained in the centre some of the smallest Conifers, such as *Retinospora plumosa aurea* and *Cupressus L. erecta viridis*. Many plants used for carpet bedding was freely used in the other beds for edging, quantities of *Coleus*, *Iresine*, and *Alternanthera* also being employed. Perhaps of all the Pelargoniums in flower (many different varieties being used) none looked so well or bright or had stood the wet like the old Waltham Seedling, which has been discarded from many gardens for newer kinds, many not being half so good. The arrangement of the plants in the different beds was good, the subtropical, flowering, and fine-foliage plants being judiciously disposed. It is surprising that more of the beautiful and choice Conifers are not planted for flower-garden decorations. Many gardens I have seen would be considerably improved by their introduction.

On the opposite side of the Castle, which is the grand entrance, is a splendid view of what is known as Long Walk, which forms an avenue of magnificent Elms, planted towards the end of the seventeenth century. This forms one continuous drive in a direct line for three miles; the centre being 50 yards wide, and the two side rides 10 yards each. This avenue has a double row of trees on either side, and the Elms are undoubtedly the finest to be seen anywhere. When planting the trees some forethought must have been exercised, and the future effect well considered. Taking into consideration the length of the drive the trees are none too far apart, and appear from the Castle only to leave a very narrow opening at the further end. After crossing the Park I reached

#### FROGMORE,

which is about a mile and a half from Windsor. On entering these gardens I was much impressed with the grand effect produced by *Ampelopsis Veitchii*, which entirely covered the walls at the entrance. The leaves were fast turning to that reddish hue so characteristic of this plant. In front of the main range of houses were numbers of flowering plants in full beauty, principally Zinnias, Phloxes, Petunias, Verbenas, and others. The extent of

glass is very great, and yet scarcely equal to the demand. It is surprising the quantity of produce that is sent out from these gardens. To give some idea, the day of my visit fifty dozen Peaches were packed for sending away, besides other fruit and vegetables in the same proportion. The vineries are large and numerous. The earliest is required ripe in April, and are grown in a small house with bottom heat underneath the border, which is found to be an advantage when judiciously applied. Many of the houses were cleared of their fruit, others being ripe for present use, with a number of late houses in which the fruit was fast approaching maturity. In the houses in which the fruit was hanging the crop was heavy and the quality all that could be desired. Many of the Peach houses had also been cleared of the fruit. The trees in most cases are large, the wood well ripened, and the buds plump. Some fine fruit was hanging in a long narrow house, with just sufficient piping to keep the trees safe from frost while in bloom. Additions were being made to this range. The Peaches on the outside walls were ripening well, the crops being heavy, and the fruit of fair size. Melons are largely grown, and a fine crop was hanging in one of the houses, some fruit being ripe while others were in a more backward condition. All the best kinds are grown.

From time to time much has been written respecting the Pine-growing at Frogmore, and the plants and fruit to be seen fully justify the high compliments paid Mr. Jones. The plants are such as Pine-growers delight to see—sturdy and remarkable for strength, and the fruits in various stages of development were very fine. Some are planted out, while others are kept in pots, and succeed well both ways. Good Strawberries in pots are grown. A long lean-to house was devoted to Tea Roses, which had the lights off to assist in ripening the wood. Other large houses are devoted to Azaleas and Ferns, the plants being principally in 6 and 8-inch pots for decorative purposes. The walls supporting the front stage in the fernery was covered with *Ficus repens*, which looked neat. Houses were filled with well-grown *Dracenas*, *Crotons*, and a variety of other stove plants. *Phaius grandifolius* appears to be a favourite, as a fine batch was growing in one of the houses. *Calanthes* are well and largely grown. *Gardenias* are also grown in large quantities both in pots and planted out, the plants being clean, healthy, and promising a good supply of flowers. *Stephanotis floribunda* receives a large share of attention, and the roofs of several plant houses are covered with it. The large batch of *Poinsettias* was sturdy and dwarf, and promised well for a fine display in due time. A large house was filled with healthy Palms of various sizes, and the roof covered with *Bougainvillea glabra*. Numbers of *Bouvardias*, *Solanums*, and other plants were planted out on a warm border.

The frames and forcing pits employed for growing French Beans, Potatoes, and other early vegetables in season are numerous. The kitchen garden is 30 acres in extent, and was well cropped with all the best of vegetables, was clean and in good order. The walls were covered with various fruit trees, all of them being well trained, and was carrying heavy crops of good fruit. Everywhere neatness and order prevailed—in fact, the gardens throughout were in excellent condition, and testify to the ability and good management of Mr. Jones, and also reflects great credit upon his foremen, which are nine in number, and the staff of men 140.

Here I shall leave the fine gardens, a brief description only being attempted; but before doing so must thank Mr. Jones for his kindness and courtesy, also his foreman Mr. Chennell, who has the charge of the slopes and flower gardens, and by his intelligence and attention rendered my visit particularly agreeable.—A COUNTRYMAN.

(To be continued.)

#### ARRANGEMENT OF CUT FLOWERS.

It may interest your correspondent "HORTUS" (307), who is so severe on gardeners in this matter, to learn that it has been the fashion of late in many places to use a large proportion of yellow flowers for table decoration, and give a preference to the "one-colour" system generally. I am acquainted with several noted west-end establishments where this style has been carried out in its most severe form; and it was suggested, and sometimes the decorations were set up, personally by a well-known amateur artist, whose pictures have for a number of years been admitted and hung in a good light in the Royal Academy, and been favourably criticised. I know the artist, and have assisted him at decorations where this style was adopted. On one occasion, when the low flower glasses—like saucers in fact—were filled exclusively with yellow *Nasturtiums* and *Marigolds* bordered by a very meagre margin of Fern and *Geranium* leaves, I protested against the style, but was informed that it was in accordance with the

principles of good taste for a table. I would state also that it has always appeared to me to be a matter of manipulative dexterity more than anything else—the making-up of bouquets—and in watching practised hands at work in Covent Garden and elsewhere I have noticed that, if provided with a suitable variety of flowers, they never paused to think what should come next, but simply “mixed” the colours well and took care not to crowd the flowers, not forgetting to introduce the right proportion of green. This appeared to result in a very attractive bouquet.—MUG.

#### TEMPERATURES FOR VINES.

As you are discussing the subject of temperatures for Grapes in your pages just now, a portion of the enclosed letter from a gentleman interested in horticulture, and no mean judge of Grapes, may be of some interest. I have not the honour of Mr. Taylor's acquaintance, but I feel sure he will pardon me referring to his excellent practice here. My correspondent writes, “By far the finest sight I saw on my journey, or perhaps will ever see again, was at Longleat—a house of Hamburgh Grapes and a house of Muscats. The Muscat house is 80 feet long, 30 feet wide, span-roofed, and four Vines fill it, one at each corner, and there are between 250 and 300 bunches on each Vine, splendidly finished, and averaging from 2 lbs. to 4 lbs. weight, in every respect perfect. The Hamburgh house is 60 by 30 span, also with four more Vines, equally good bunches, and colour perfect. They are grown on the cool system, and set in a temperature far below the usual figure.” In reference to the temperatures practised by Mr. Taylor it will be remembered that he some time ago stated in your pages that he had never attempted to “set” his Grapes in a higher temperature than 55° or thereabout. Some experienced Grape-growers have stated that Muscats cannot be coloured perfectly in a span-roofed house, but the vineries at Longleat afford a remarkable example to the contrary.—CORRESPONDENT.

#### BOILERS VERSUS WATER.

THE remarks by Mr. Ollerhead in the Journal of September 29th are interesting for many reasons, and ought to have elicited a response from other horticulturists who have suffered in the same way; but possibly none, or only a few, have tried any remedy. There are several compositions sold for removing and preventing incrustation on steam boilers which should answer as well for horticultural boilers, but the water when mixed with these preparations could not be safely used for other purposes, as it often is now. Soda is very largely used in these compounds, and a quantity of it alone mixed with the supply will prevent much furring, and if the boiler plates are smartly tapped with a hammer occasionally the thin scale as it forms will be loosened and fall to the bottom. This dropping of the scale, together with the ordinary sediment found in any water, would be no detriment in the Trentham Cornish, but might choke up the return inlets in other forms. It is said that of the other boilers “We found more or less corrosion in all of them.” Some explanation of the “more or less” might be found if particulars were given of the sizes or forms of boilers, the pipes they had to heat, and the degree of heat maintained. If all had been exactly alike it might reasonably have been supposed that the water alone was at fault, but no mention is made of the pipes being furred up near to the boilers and containing the same hot water. Mr. Ollerhead considers the sort of water used more important than the sort of boiler. This being so, with your permission I will take up the latter question, and at once say that the Cornish boiler from its make is more likely to become furred up than other forms, though a large rivetted plain saddle would be about the same. The reason why may not seem so clear at first sight. The “chief seat of evil” was “on the bolts along the sides of the fire”—in other words, on the projections where the fire was hottest and there was the least movement in the water. If there had been no bolts or rivets, as in a smooth welded boiler, the sediment would be more likely to fall to the bottom; and if the greatest heat of the fire had been directed to some other place than the sides there would not have been the ledge formed there. Wherever the fire has most power it should be arranged that the water is constantly changing, as the continual boiling of the water in one spot causes the incrustation. This is one reason why this simple form of boiler is not good. The water is kept at constant boiling point along two-thirds of its length without any outlet, the actual heating of the pipes being carried on at a great disadvantage, enormous waste, and some risk by the remaining third of the boiler, as is more clearly shown by Mr. Ollerhead's own statement that “the passage from the return pipes along the bottom of the boiler and up the end to the flow pipe was perfectly clear.”

It will be said, “Why, then, does it appear that Gray's tubular boiler was nearly choked in the same way, as this is an entirely different construction, in fact the reverse in principle?” The reason will be the same though the application is different. The tubes used in all boilers of this class are so small that the water inside is quickly at boiling point, and the water has to pass so many corners or ledges of the rings, checking it in its way to the outlet, that the deposit is formed very quickly from these causes. The best boiler I will not attempt to decide on, as there are both upright and horizontal forms advertised which will almost answer my ideal—namely, to send the water directly it is warmed into the flow-pipe without waiting for the whole mass of water in the boiler to be heated; and to confine the fire heat entirely within the boiler, while exposing as much surface as possible to its direct action.

The Editor remarks that “defective circulation in boilers is no doubt often the result of furring;” but I would venture to say also that furring is more often the result of a defective circulation in the boiler, as the pipes themselves, even if only 2 inches in diameter, do not become choked. This brings me to another point to be noticed in connection with very large boilers of any kind, as it will be found that this furring takes place more extensively in the large than in the small boilers, the water being the same. The facts stated by Mr. Ollerhead tell most severely against the “one boiler” system for great quantities of piping. Two miles of piping contain about 5000 gallons of water. This is an enormous quantity to heat even if it were all in one cistern, but when the water has to be heated in one boiler (or two containing 200 gallons each), and forced along 10,000 feet of pipes which give off heat at every foot, and which bend about in every direction, checking its circulation, it follows that the boiler must really be a boiler to keep up the heat under such conditions, some of the pipes, too, being probably 400 feet distant. If there were four smaller boilers, each heating a compact group of houses, there would be less need to have the water so intensely hot, and the circulation would be quicker, with less strain on the boiler, consequently less risk of a breakdown, and with a less consumption of fuel. There is a limit beyond which the economy of the one-boiler system disappears. For instance, in a 5000 feet power boiler there will be, as a rule, water equal to 400 feet of piping. For three months of the year it is wanted to heat only two or three hot-houses with about 500 feet of piping, but to do so you must heat all the water in the boiler and mains amounting to as much more, when a separate boiler for these houses alone would only contain water equal to 40 feet of pipe, and a proportionately less quantity of fuel would be consumed.

To sum up the real cause of the furring referred to, I take to be, not the mere hardness of the water, but the boiling of this hard water; this boiling being almost necessary with such a quantity of piping, though not so injurious if the form of the boiler or the arrangement of its outlets encouraged a free and perfect circulation.—B. W. W.

#### HIBISCUS SYRIACUS.

THERE are numerous varieties of this species, the typical form being purple, and both the light and dark forms are very handsome, but they are not nearly so useful as the white variety, the flowers of which would no doubt prove useful for bouquets. The value of this shrub cannot be over-estimated for late summer and autumn flowering. It may be used with great advantage either as single specimens or grouped with other evergreens. I saw it a few days ago used in both ways. A single specimen about 8 feet high and nearly as much in diameter laden with its beautiful white flowers was indeed charming, and smaller plants dotted amongst evergreen shrubs gave the borders quite a lively appearance. It is easily propagated, and when once established in a rich soil soon forms good-sized specimens. Its hardiness need not be doubted, for it has withstood the last two severe winters without being injured in the least. There is a double form, named *Hibiscus syriacus flore-pleno*, which may be grown for greenhouse and conservatory decoration, and plants are extremely useful at this time of the year when flowers are scarce.—W. A. L.

#### VANDA TERES.

IT is very interesting to read of this Orchid as it is found growing in its native home, and it must be a truly beautiful sight to see it in flower. *Vanda teres* can also be seen well flowered and in good condition in our hot-houses in England. It need not be “scored and starved under a glaring roof of glass,” as is remarked at page 342. This Orchid, like most of its family, has a

season of growth and a season of rest, and under good management it grows almost as fast as a Willow; it will make growths nearly 2 feet long in twelve months. During the time of growth the plants ought to be in a light position in the warmest house, and in winter they ought to be in a position well exposed to the sun and in a temperature of about 50° or 55°. For three or four months in winter very little water will be required—just enough to prevent the plants from shrivelling too much. They do not form so many roots in the sphagnum in which they are potted as they do up the stem. Teak rods should be inserted in the pots for the roots to cling to, and if the plants are syringed with tepid water daily in summer the roots will be formed freely.—  
J. DOUGLAS.

#### TOO-MUCH-ALIKE ROSES.

IN the Rev. C. H. Bulmer's selection of forty-eight Roses for the Rose election printed on page 306, there are several Roses considered synonymous, some of which, I think, may be looked upon as very doubtful; therefore a free and fair discussion may lead to a better understanding amongst Rose-growers on Roses closely allied in point of colour. In distinguishing Roses something more than colour must be considered. There is the habit of growth, the size and prominence of the thorns, the shape of the foliage, and many other details which require attention before giving a decided judgment.

Until the list named above came under notice I had never seen it stated that Abel Grand was synonymous with Marguerite de St. Amand or Princess of Cambridge. I have grown the two first-named varieties for many years, and consider them as distinct in habit as any two Roses can well be that are similar in colour. The imbricated form of the flower of Marguerite de St. Amand is most pleasing, while Abel Grand never, or very rarely, has substance enough for exhibition. Exposition de Brie, Maurice Bernardin, and Ferdinand de Lesseps have for a long time been regarded as very much alike, but when we see them exhibited by some of our large nursery growers they appear different, and there is certainly a difference in the habit of Maurice Bernardin as compared with Exposition de Brie or Ferdinand de Lesseps; besides, Maurice Bernardin has more purple in the flower than either of the others named, while Sir Garnet Wolseley is very rigid and erect in its habit, closely studded with prominent thorns, and therefore distinct in growth as well as flower from the others. The variety Reynolds Hole I know well, but Sultan of Zanzibar I have only grown this year. From what I have seen of the cut flowers, however, I am under the impression there is a great difference in the petals. If it is not so, then we must all feel that our home-raised seedlings are no more to be depended upon for distinctness than those sent over from the Continent. Surely such an experienced firm as Messrs. G. Paul & Son, who, I believe, raised both Reynolds Hole and Sultan of Zanzibar, would never have allowed the two Roses to be sent out from Cheshunt unless they were distinct. Again, the experience of such an exhibitor and grower as Mr. Cranston must surely be considered when he sent us that very desirable autumn-blooming Rose Sir Garnet Wolseley.

In the election they are considered and tabulated as distinct. Let me note their relative positions. Marguerite de St. Amand stands twenty-ninth, and receives a total of forty votes, while Abel Grand is last but one, only receiving ten votes, and Princess Mary of Cambridge is "out of Court." Ferdinand de Lesseps is placed twenty-seventh in the election, Sir Garnet Wolseley forty-eighth, and Exposition de Brie sixty-ninth, receiving respectively forty, twenty-five, and fourteen votes each. Reynolds Hole stands twenty-fifth on the list and has forty-two votes accorded to it, while Sultan of Zanzibar is not mentioned. These figures must show, I think, that the majority of the electors consider them distinct.—J. W. MOORMAN.

#### HARDY FRUIT GARDEN.

ANY vacancies amongst bush, pyramid, or espalier trees should be filled as soon as the trees are in a fit condition to move, the ground being previously prepared for their reception. Under ordinary circumstances it will suffice to remove the worst of the old soil and supply some fresh turfy loam, trenching the border to a depth of

2 feet deep, incorporating the fresh loam with the old soil as the work proceeds. Light soils will be improved by an admixture of clayey marl, and heavy soil may have an admixture of about a tenth of old mortar rubbish. Where it is intended to form plantations of young fruit trees to be grown as bushes, standards, or otherwise, the ground should be prepared by draining and trenching, not employing any manure unless the soil be light and poor, when an admixture of well-pulverised clay and well-decayed manure may be applied. Planting should be done as soon as the leaves have fallen, and by having all in readiness for planting the work can be done as soon as the trees come to hand, spreading out the roots carefully, and only making the soil moderately firm about the roots, as it is best for it to settle down gradually after the first good rain. When moderately dry the soil should be trodden firmly around the stems, applying a mulching of partially decayed manure as far as the roots extend. Some reliable varieties for bush, pyramid, or espaliers are the following:—  
*Apples for Dessert.*—Mr. Gladstone, White Joanneting, Irish Peach, Devonshire Quarrenden, Kerry Pippin, Cobham, King of the Pippins, Cox's Orange Pippin, Court of Wick, Margil, Keddleston Pippin, Braddick's Nonpareil, Cockle Pippin, Reinette du Canada, Scarlet Nonpareil, and Sturmer Pippin. *Kitchen Apples.*—Carlisle Codlin, Keswick Codlin, Lord Suffield, Stirling Castle, Jolly Beggar, Cox's Pomona, Cellini, Ecklinville Seedling, Small's Admirable, Warner's King, Betty Geeson, Alfriston, Dumelow's Seedling, and Norfolk Bearer. *Pears.*—Doyenné d'Été, Jargonelle, Williams' Bon Chrétien, Pitmaston Duchess, White Doyenné, Louise Bonne of Jersey, Comte de Lamy, Marie Louise d'Uccle, Seckle, Durondeau, Doyenné du Comice, Buerré Diel, Thompson's, Buerré Bachelier, and Glou Moreceau, with the late Jean de Witte and Van de Weyer Bates. *Cherries.*—Bowyer's Early Heart, Empress Eugénie, Black Eagle, May Duke, Buttner's Black Heart, Governor Wood, Bigarreau Napoleon, and Nouvelle Royal, with Morello for culinary purposes. *Plums, Dessert.*—July Green Gage, De Montfort, Denniston Superb, Green Gage, Kirke's, Jefferson, Coe's Golden Drop, and Guttrie's Late Green. *Culinary Plums.*—Early Prolific, Czar, Sultan, Prince Englebort, Mitchelson's Victoria, Autumn Compôte, and Belle de Septembre.

*Standards for Orchards.*—*Apples.*—Beauty of Kent, Alexander, Large Cockpit, Keswick Codlin, Manx Codlin, Peasgood's Nonsuch, Nelson Codlin, Lady Henniker, Bedfordshire Foundling, Dumelow's Seedling, Alfriston, Golden Noble, New Hawthornden, Tower of Glamis, Galloway Pippin, Northern Greening, Winter Majetin, and Hambleton Deux Ans, with Yorkshire Greening for sauce and Nonsuch for jelly. *For Dessert.*—Irish Peach, Worcester Pearmain, Court of Wick, Adams' Pearmain, Dutch Mignonne, Reinette du Canada, Herefordshire Pearmain, Court Pendu Plat, Royal Russet, Golden Russet, Lord Burghley, and Sturmer Pippin. *Pears.*—St. Swithin's, Crawford, Williams' Bon Chrétien, Jargonelle, Eyewood, Autumn Nelis, Buerré de Capiaumont, Cockle, Swan's Egg, White Doyenné, Hesse, Louise Bonne of Jersey, Comte de Lamy, Aston Town, Doyenné du Comice, Hacon's Incomparable, Autumn Bergamot, and Red Doyenné, with Catillac for stewing. *Plums.*—Early Prolific, The Czar, Sultan, Mitchelson's, Bryanston Green Gage, Diamond, Kirke's, Oullins Early, Jefferson, Winesour, Belle de Septembre, Wyedale, Prune Damson, and Farleigh or Crittenden Prolific Damson. *Cherries.*—Black Eagle, Governor Wood, May Duke, Early Rivers, Kentish, and Morello. *Medlars.*—Dutch and Nottingham. *Nuts.*—Cosford, Dwarf Prolific, Lambert's Filbert or Kentish Cob, Red Filbert, and White Filbert. Black Mulberry is the best; and of Crabs, Siberian, Transparent, Scarlet, and Imperial.

Gathering Apples and Pears should now be completed as soon as possible, except such of the late varieties that do not part readily from the trees, and which, if gathered before they are ripe, are certain to shrivel and be spoiled. The late Pears and long-keeping Apples are also very often deteriorated by keeping them too dry and warm. They should be placed in a cellar or similar slightly damp position with an equable temperature of a few degrees above 32°. All Apples and Pears which have been gathered some time should be occasionally examined, all decayed fruits being removed. The fruit-room will need top ventilation as a means of regulating the temperature of the room, which should at present be kept as cool as possible.

## FRUIT HOUSES.

*Vines.*—The earliest Vines in pots may now be gently started, and if a slight bottom heat can be afforded it will be an advantage. The pots should be raised on pillars of brickwork, the fermenting material employed consisting of three parts leaves to one of stable litter thoroughly incorporated and placed about the pots, but until the Vines are growing the temperature at the roots should not exceed 70° to 75°. Copious supplies of water at 70° to 75° will be necessary if the soil has been allowed to become dry. The temperature at first should not exceed 55°, but it may be gradually increased to 60° by artificial means at night, 5° more by day, and 70° to 75° from sun heat. The canes should be hung in a horizontal position to cause the eyes to break evenly throughout their length, and should be damped with tepid water two or three times a day. Cover the outside borders of late houses with wooden shutters, tarpauling, or a thick thatch of straw or bracken sloped so as to carry off the water quickly. The inside borders may be covered with mats or a thin layer of straw, which will to some extent prevent the soil cracking. Examine the Grapes frequently, removing decayed berries, but if well ripened and the roof is watertight, very little trouble will be given in this respect as regards the thick-skinned varieties, but Hamburgs will need almost daily attention. The houses should be kept as cool and airy as possible, employing fire heat only to maintain a temperature of about 45°; and by day, when the outside air is dry with abundant ventilation to expel damp, keep the ventilators closed against all damp. Provide a stock of loam for making and replenishing Vine borders. The turf of a pasture taken off about 3 inches thick where the soil is of medium texture, inclined to be light rather than heavy, is snitable.

*Cucumbers.*—The plants for fruiting in winter should be placed out at once on raised hillocks or ridges. Those not having the convenience of a Cucumber house may utilise the roof of a Pine stove or other sufficiently heated structure to produce a winter supply. They may be grown in pots or boxes, and the shoots trained to wires about a foot distance from the glass. Cut the autumn fruiterers regularly once a week, removing all staminate blossoms. Maintain a night temperature of 65° to 70°, and 70° to 75° by day, or with sun heat from 80° to 85°, admitting a little air at the top of the house at every favourable opportunity. Discontinue syringing the plants, damping the paths in the morning and early afternoon of fine days, and keep the evaporation troughs filled with liquid manure. Reduce the supply of moisture at the roots, but do not permit flagging. Attend well to earthing up the roots with turfy loam previously warmed.

*Melons.*—To have late Melons plenty of heat must be at command. Little atmospheric moisture will be required by those well advanced for ripening, and supply water at the roots sparingly, removing all superfluous laterals, and well thin out the old foliage that the fruits may have the full benefit of the sun. Plants with fruit swelling still require the floors lightly damped in the morning and early afternoon, applying water at the roots moderately. Maintain the temperature at 70° at night, 75° by day, and 80° to 85° through the day from sun, giving a little air at every favourable opportunity.

## FLOWER GARDEN.

Some of the ornamental-foliaged plants employed for the decoration of the flower garden in summer are valuable for decorating large conservatories, halls, and corridors, and if lifted before they are damaged by frost they will be serviceable for a long time. Some of the choicest Aralias, Abutilons, Cannas, Chilian Beet, Melianthus, Solanums, Wigandias, &c., lifted carefully, placed in a moist house, and kept well syringed, will soon become established. As soon as the weather necessitates a clearance of the beds attention should be given to refilling them either with dwarf shrubs or spring-flowering plants and bulbs, or a combination of both, so as to impart a cheering aspect during the dull months with something fresh and attractive. Some of the most effective shrubs are *Andromeda floribunda*, *Skimmia japonica*, *Aucuba japonica maseula*, *A. vera nana*, *A. limbata*, *A. longifolia*, small plants of *Cupressus Lawsoniana* and its many vars., *C. nutkaensis*, *Cryptomeria elegans*, *Euonymus japonicus* vars. both gold and silver-variegated, *E. latifolius aureo-marginatus*, *E. radicans variegatus*, *Osmanthus ilicifolius* and vars. *aureus* and *variegatus*

*nanus*, *Thuja aurea*, *Taxus baccata aurea*, *T. elegantissima*, the Myrtle-leaved Portugal Laurel, *Laurustinus*, *Kalmia latifolia*, the Tree Ivies—*Hedera arborea aurea*, *elegantissima*, *fructo-luteo*, and *Rægneriana*; dwarf *Rhododendrons*, as *ovatum*, *myrtifolium*, *Daphnoides*, and *Wilsoni*; *Pernettya mucronata*, *Buxus japonica aurea*, *B. sempervirens aurea*, *B. suffruticosa argentea marginata*, and *Yucca recurva*. In warm situations the *Retinosporas* are beautiful, also *Thujopsis dolabrata*. Early spring-flowering plants are Winter Aeonite, *Seilla siberica*, Snowdrops, Crocuses, Hyacinths, Tulips, Primroses, *Aubrietas*, Pansies, Violas, Daisies, Forget-me-nots, *Nemophilas*, *Silenes*, and many others; whilst for edgings *Golden Pyrethrum*, *Golden and Variegated Thyme*, and *Stachys lanata* are suitable.

## PLANT HOUSES.

*Greenhouse.*—There is perhaps at this season an objectionable sameness in flowering plants available for conservatory decoration, hence the value of plants flowering at this season. *Correas bicolor*, *Brilliant*, and *cardinalis* are flowering where they have been encouraged early in the season; also *Epaerises*. The bright scarlet of *Rochea falcata* likewise is very telling, and the beautiful blue of *Witsenia corymbosa*, whilst in yellow *Cassia corymbosa* is very effective. Some of the Heaths are also flowering where growth was encouraged. Early good winter-flowering varieties are *Ericas grandinosa caeffra*, *persoluta alba*, *colorans*, *gracilis autumnalis*, *Bowiana*, *cerinthoides*, *scabriuscula*, *perspicua erecta*, *candidissima*, *Lambertiana rosea*, *ventricosa* and vars. *hyemalis*, *melanthera*, *mammosa pallida*. *Crowea elliptica*, *C. latifolia*, *C. stricta*, and *C. saligna* are fine in late summer and autumn, their star-shaped pink flowers being very pretty, flowering at this season for several weeks in a temperature slightly warmer than an ordinary greenhouse. *Cytisus racemosus* and *elegans* started early will come into flower readily if in a temperature a few degrees higher than an ordinary greenhouse. *Camellias* have now been placed in their winter quarters. The present is a good time to clean the foliage, sponging both sides of the leaves, also the stems, being careful not to injure the buds.

## QUEEN-INTRODUCTION.

As an instance of the eccentricities of bees in accepting and declining queens possibly the following case may not be without interest, especially if an editorial note will give the reason why.

A fine Ligurian queen in full lay was introduced into a colony of blacks, which had contained a fine black queen, also laying briskly. The Ligurian was eaged on a frame of brood in a pipe-cover eage, which (as Mr. Grace's new Guide states) appears the best eage for the purpose, as it compels inspection when releasing. At the end of twenty-four hours the new queen was examined, but as she was balled she had to undergo another twenty-four hours' captivity. Again she was balled. This time they were so persistent that it was deemed advisable to drop the lump of bees into a eup of water. This was advised by a very able and experienced bee-keeper. When the queen was disengaged and caught she was, alas! to all appearance lifeless and insensible to the warmth of the hand. So she remained for half an hour, and so she would have remained altogether but for timely succour—feminine of course.

"O woman! in our hour of ease  
Uncertain, coy, and hard to please:  
When pain and anguish wring the brow  
A ministering angel thou."

And this ministering angel administered comfort by carrying the limp and inanimate body of the queen into the house, wrapping it in flannel and placing it before the fire. The evening was chilly, though only the end of July. Whether any restoratives in the shape of "pick-me-ups" were administered I cannot say; but this I do know, that to everyone's amazement next morning the bee was as lively as a cricket. After this extraordinary escape she was introduced into another black hive previously deprived, where it was hoped the bees would be more grateful and treat her with the appreciation she deserved; but after two more ballings she was found dead. Why, was always a mystery. In a week

afterwards they had accepted a new imported Ligurian queen. Why?—BUZZ.

[The case is by no means a rare one, and may be thus explained. The strange queen was in the first case caged in the hive before the bees had become aware of their loss, and was thus exposed to a hostile attack. The odour of ejected poison would then remain about the queen and cage, and serve to continue the hostility. Had the repeated caging been persevered in, and care taken that the queen could not starve, which she seems almost to have done, success would have probably crowned your efforts within a day or two. As such cases are rather frequent it is common to allow the bees to manifest their sense of the loss of a queen before caging a stranger. In the second case the odour of the poison remaining on the queen served to intensify the hatred that was probably developed in the same way as at first. By the time the imported Ligurian was introduced the bees had become fully aware of their loss, and were thus prepared to accept a stranger without much ceremony.]

#### POISONOUS HONEY.

[Translated from the "Bienenzeitung." Communicated by Mr. Alfred Neighbour.]

IN No. 10 of the *Bienenzeitung* for 1880 Professor Dr. Münter of Greifswald declared that the question as to the poisonous character of certain kinds of honey was still an open one, which required further investigation. It may therefore interest your readers to know that I am able at least to vouch for the correctness of the assertion that some kinds of honey are poisonous, several cases of poisoning having come to my own knowledge. I especially remember one case where a considerable number of powerful young men had partaken of some honey from a nest of wild bees, in consequence of which all became ill. Those who had eaten but little of it because they did not like the honey only suffered from sickness, vomiting, stomach-ache, and diarrhoea; others who had partaken more freely were attacked with giddiness and pressure of the blood to the head, and other serious symptoms showed themselves. My informant in this case is my friend Mr. Emil Odebrecht, an engineer, who became seriously alarmed at the state of several of his men, who were in the interior of a primeval forest beyond the reach of medical assistance. Unfortunately I have not been able to ascertain with certainty what bees the honey had been taken from, but from the accounts I received I am inclined to think that it had come from the Trigona, called Cagafogo here. Knowing how fond the Cagafogos are of carrion and other nasty substances, I always had such an aversion to their honey that I never could persuade myself to taste it.\*

Blumenau, Sta. Catharina, Brazil, 20th July, 1880.

(Signed) FRITZ MÜLLER.

#### THE CAGAFOGO BEE.

OF our numerous honey bees without stings (Melipona and Trigona) I have never seen any visiting carrion except the Cagafogos. In the highlands of Curitiba I noticed on some pieces of fresh beef, which had been salted and hung up to dry, a few other species of Trigona and Melipona, as well as *Apis mellifica*, which has become wild there, but whether the brine attracted them or the meat I am unable to say. The juice of putrifying meat probably serves as food for the Cagafogos: altogether their peculiar taste distinguishes them from all other bees in this country. I am doubtful whether they collect honey from flowers at all, or whether they visit them for the sake of their pollen only. They are rarely to be seen on flowers, and then usually on those that emit a bad odour, which flowers are generally avoided by other bees. They are also found on offensive-smelling hairs of leaves, stalks, or calyxes of different plants, on parts of trees where the bark has been removed, on newly cut sugarcane, or they may be seen occupied with their milk-cows, the larvæ of membracines. The food of the other species of Melipona and Trigona of this country consists almost exclusively of honey gathered from flowers in addition to pollen. One species only, the *Arapua* (Trigona ruficus), is in the habit of gnawing trees in order to obtain the juice which escapes, and it also frequently destroys the green young shoots of Orange trees. The different species of bees seem to have a preference for different flowers, the probable cause of which may be found partly in the difference in length of their tongues, and partly in their preferring a certain odour or taste of the honey. The pretty little *Jaty* (Trigona *Jaty*), whose honey is highly esteemed here, is most particular in its choice of flowers. It visits hardly any but the choicest sweet-scented flowers, such as Roses, Orange blossoms, &c. *Apis mellifica* is less particular in this respect than any of our native

\* It is well known that at times Melipona honey when collected from certain plants is poisonous, especially that gathered from the Muntubinba, being of a green colour, is said to cause violent diarrhoea. The best honey in Brazil, we understand, is to be obtained from Melipona pallida (the Maneuba). We were not aware that some—perhaps all—species of Trigona visit carrion. It would be interesting to know the reason why the Trigona is fond of carrion. We presume they visit it in order to obtain water if they are unable to find it elsewhere. Even our honey bee does not despise manure water, &c. We should be very much obliged for any information Mr. Fritz Müller could give us on this subject.—(Signed) THE EDITOR.—(From the "Bienenzeitung," No. 4, 15th February, 1881.)

bees. It gathers almost any honey that is accessible, which, by the way, does not say much for its highly developed sense of smell, which Wolff ascribes to it.

To return once more to the Cagafogos. As they prefer odours which disgust us they themselves possess a most offensive smell. They are the only kind of our domesticated honey bees which, though not possessed of a sting fit for use, yet prepare a poison for their defence. Not only near their nests, but also where they congregate in large numbers, as on carrion, on parts of trees where the bark has been removed, on membracine larvæ, &c., they rush against the face of any person who disturbs them and discharge a drop of acrid poison which stings like fire (hence their name), and reddens or even blisters tender parts of the skin.†

Blumenau, Santa Catharina, Brazil, 14th July, 1881.

(Signed) FRITZ MÜLLER.

#### CONTRACTED HIVES FOR WINTER.

IN reply to Mr. Pettigrew's request for results on the subject of contracted hives during winter, in my case it appears to suit the bees best to crowd them on to as few frames as they can be got. That it is good for and healthful to the bees I infer from the fact that few are dead in the spring—perhaps six to a dozen in each hive; and that it is good for the bee-keeper is proved by the small quantity comparatively of food that is consumed. The "why" in this case also I leave to the scientist to be fully explained.—BUZZ.

#### BEE SHOWS.

DURING the last ten years considerable exertions have been made to popularise bee-keeping by having bee and honey exhibitions. Societies and associations have been formed and maintained for the purpose of encouraging cottagers to keep a few hives of bees in their gardens, and by this means add to the comforts of life. Many members of these associations have laboured with commendable industry and singleness of eye to help the working community in the pleasant and self-rewarding occupation of bee-keeping. Great efforts have been made, and yet much remains to be done. It is rather a difficult matter to spread knowledge and excite enthusiasm on the subject of bee-keeping. How it can be best done is a question for the consideration of our apiarian associations.

The first question I would like to suggest is this, Have bee and honey exhibitions been successful and satisfactory? Is there room for improvement? It will be readily admitted that all exhibitions meant to be popular should be attractive and as novel as possible—that stiff monotony should be avoided. The desire of novelty in the human mind should not be forgotten in writing out schedules of prizes, and in making preparations for bee and honey shows. Admiration for the beautiful and the wonderful are also common among men. People desire to see what is new, beautiful, and wonderful. Wherever these can be found people go. What was witnessed at the Manchester Exhibition confirms the belief that bee and honey shows will yet become popular institutions in Great Britain. The novelties of the bee tent at Manchester caused great excitement and delight, and doubtless in the event of another bee and honey show being held there it would be visited by crowds of people.

I am not going to point out defects in or find fault with other exhibitions. It is always an easy matter to find fault. I think that improvement is likely to come from the introduction of variety and novelty of exhibits rather than from an abundance of them. Many visitors in the front tents of the Manchester Exhibition were oppressed with the abundance and grandeur of the Exhibition. One clergyman said to me that the magnificence of the Show was too much for the mind to grasp and realise. One gentleman said that if the bee tent had twice its number of exhibits it could not be more gratifying and satisfactory. More variety and novelty would have made it more gratifying and sensational. And this is what I would like our apiarian associations to aim at in future exhibitions. With comb foundations in use no limit can be put to the possibilities of variety of exhibits in honeycomb. In addition to supers in glass, wood, and straw, we shall have crowns and crosses, stars and icicles, legends and mottoes, done in honeycomb. Bee-keeping will be popularised and become a source of profit to one class of the people, and a source of pleasure to another class.

† The following is an extract from the letter of 14th July accompanying the above article—"Please excuse the delay in replying to your request in No. 4 of the *Bienenzeitung*. I send you to-day the meagre information I possess of our Cagafogos. I have not been fortunate with these bees, none of the colonies which I brought home from the forest remaining alive for any length of time. Indeed it would have been more difficult to observe the doings of these irritable and offensive bees than those of other more peaceful bees."—(Signed) THE EDITOR.—(From the "Bienenzeitung," No. 19, dated 1st Oct., 1881.)

If our friends of the Bee-keepers' Association will not be offended I will state my fears, or rather opinions, about their bee tent. It has been a question with me whether it does more good than harm. At bee shows it is used to give object lessons to show visitors how bees and combs can be handled and changed from one hive to another, and for other purposes or manipulations. I have often said that such object lessons are useful. They teach by example, and encourage some young bee-keepers to practise what they read about. There is another view to be taken of the bee tent and the manipulations therein practised. Does the manipulation tend to encourage ladies and gentlemen to keep bees, or does it frighten them from the very idea of ever handling bees? I once asked a gentleman who had witnessed the wonderful operations of the manipulating tent what were his opinions as to the tendency or effects of the operations on the minds of spectators. He said, "I think it tends to frighten people from keeping bees." In the manipulations of bees in the tent there must unavoidably be a great sacrifice of lives; but probably the ultimate aim and end of the bee tent is the introduction of a better hive to the bee-keepers of England. Whether the effort put forth will end in success and when, are questions that cannot be answered at present. Meanwhile let us endeavour to interest the public by attractive exhibitions and large harvests of honey.—A. PETTIGREW, *Bowdon.*

#### TRADE CATALOGUES RECEIVED.

Wm. Wood & Son, Uckfield, Sussex.—*Catalogue of Fruits.*  
Charles Turner, Slough.—*Catalogue of Roses and Fruit Trees.*  
Thos. S. Ware, Tottenham.—*Catalogue of Trees, Shrubs, Roses, and Hardy Florists' Flowers.*  
Bruant, Poitiers, Vienne, France.—*Catalogue of Fruit Trees and Roses.*  
H. Merryweather, Southwell.—*Catalogue of Roses.*

**Rochea falcata** (*A. Boyle*).—The leaves should remain on the surface of the soil until they callus and then be inserted; if inserted when removed from the plants they are very liable to decay.

**Bitter Almond** (*F. R.*).—Your question was referred to on page 323, the issue of October 6th, under "Names of Fruits." The Almonds are used occasionally for flavouring, but Sweet Almonds are much preferable. We do not remember having received any other question from you. All questions that are submitted to us have our best attention. We thank you for your letter, the other portion of which is referred to in another column. You have infringed no rules, and we shall always be glad to hear from you whether you ask questions or communicate information.

**Tropæolum speciosum** (*Reading Correspondent*).—We are unable to inform you where you can purchase plants of this Tropæolum. Those who have them for disposal should advertise them. If plants established in pots were offered they would no doubt meet with a ready sale, as many people are anxious to establish this brilliant hardy climber in their gardens.

**Natural Orders of Plants** (*W. E. B.*).—Reidia is included in the natural order Euphorbiaceæ, Stephanotis in Asclepiadææ, Bougainvillea in Nyctaginææ, Francisca in Scrophulariaceæ, Palisota in Commelinaceæ, and Stenogaster in Cyrtandraceæ. The loss or change of colour in drying flowers cannot be remedied in the majority of cases. The best plan is to dry the specimens as quickly as possible. Some advocate immersing them in hot water previous to drying.

**Stephanotis Fruiting** (*Willow*).—We have seen many instances of Stephanotis producing fruit, and therefore yours is not a unique case. If the fruit is in a light position near the glass it will probably ripen the seeds; and if you desire to raise young plants the seeds must be sown in very light sandy soil, the pans or pots being plunged in a hotbed. We do not know of any special useful qualities that the fruit possesses.

**Apple Tree not Bearing** (*Market Gardener*).—The name of your Apple is purely local. As the tree is covered with blossom annually and yet seldom bears fruit we cannot suggest any better mode than protecting the blossoms from frost, and as you say the tree is trained to a wall protection can be easily afforded. There is no list of market gardeners published, and your name cannot be included amongst nurserymen until you are established in the business. The "Horticultural Directory" will be announced when ready.

**Planting Marechal Niel Rose** (*D. D.*).—In all probability the Rose would succeed better planted in good soil in the outside border as you propose than grown in a pot. If you procure a strong plant from the open ground we should plant it at once in deep rich loam, and cover the surface over the roots and for a foot beyond their extremities with good manure. If you have a plant in a pot you may defer planting until the spring. This Rose will succeed in a particularly shaded position, but it cannot be expected to flourish if it is overhung with trees.

**Large Apples** (*B. T. W.*).—Warner's King and Gloria Mundi are two of the largest. At the Hereford Show held last year the first-prize five fruits of the former weighed 7 lbs. 3 ozs.; second, 5 lbs. 7½ ozs.; and third, 4 lbs. 12¼ ozs. In 1879 Gloria Mundi secured the first prize, the five fruits weighing 5 lbs. 10¼ ozs. Warner's King is the most useful of the very large late Apples, the tree being a

good grower and excellent bearer. At Maidstone last year Lodington measured 14½ inches in circumference. Ribston Pippin is richer in flavour than Cox's Orange Pippin, but the latter is excellent, a very free bearer, and on the whole more reliable, as being less liable to canker.

**Heating Cucumber House and Early Vinery** (*Totesian*).—In the Cucumber house with the pipes under the bed on each side of the walk in a hollow chamber you will practically have no top heat, so that in addition to those under the beds you will require a similar quantity of piping along the sides of the house immediately above the beds of compost, or they may be placed along the sides of the beds next the pathway. There is no necessity to afford bottom heat to Rhubarb being forced; and the pipes for heating the vinery must be fully exposed, or they will be insufficient for maintaining the needful temperature for the Vines. A 30-inch saddle boiler will heat about 400 feet of 4-inch piping.

**Forcing Lilacs for Flowering at Christmas** (*An Inquirer*).—It is not necessary to grow or bring the plants into flower in a Mushroom house or other dark place. We lift the common white Lilacs, placing them in large pots or tubs at the close of November, and place them in a house with a temperature of 60° to 65° at night and 70° to 75° by day from sun heat, and the plants come into flower at Christmas. All that is required is to damp them overhead occasionally, and to keep them duly supplied with water. The plants need to be in the temperature above named five weeks before they are required in flower. The common Lilac forced in the above manner also affords white flowers by Christmas and the new year, the flowers not assuming their full lilac tints until the spring is somewhat advanced. There is no difficulty in having white Lilac at Christmas, only employ plants well set with buds, and give them a temperature as above indicated. They will succeed in less, but more time will be required to bring them into flower.

**Pruning Stephanotis** (*W. H. W.*).—It is not advisable to prune a Stephanotis severely, and "cutting back" often results in a great loss of flowers, and certainly of early flowers. Even thinning out the growths should be done judiciously, as cutting out a great number at once at this season of the year is more or less injurious to the plant. Thinning-out should be done earlier, when the plant is in free growth, with the object of disposing of the growths thinly, so that the foliage is exposed to the light. Under this treatment the wood is matured, and flowers are produced freely and early the following spring. The little confusion that has occurred was probably the result of matter pertaining to two distinct departments—business and editorial—being included in the same envelope. To prevent mistakes all business letters should be addressed to the publisher, and editorial communications to the editor. Your wishes in future shall be complied with.

**Horse Chestnuts** (*A. G. S.*).—This mishap to which you refer is only, we think, a coincidence having occurred when the nuts abound. We should not destroy the trees, as we have no evidence that the fruit is injurious; on the contrary, in Turkey the nuts are ground and mixed with the provender of their horses, especially of those which are troubled with coughs or are broken-winded. The nuts are well adapted for feeding deer and swine, upon which the latter are found to fatten freely. But, before they can be rendered serviceable for this purpose they must be steeped for two or three days in water to extract their bitterness. In Switzerland they are crushed as food for sheep, and given in meals of 2 lbs. to each sheep, morning and evening. They are said not only to fatten the animals, but to communicate a peculiarly fine flavour to the mutton. The nuts abound in starch, which may be readily obtained in a state of purity, and it is said to excel as an article of diet that procured from the Potato; and the bitter principle which they contain may be effectually removed by macerating them in an alkaline solution. The powdered kernel snuffed up the nostrils causes sneezing, and has been used successfully in diseases of the head and eyes.

**Fruit Trees for Walls and Orchard in North Yorkshire** (*A Yorkshire Rector*).—For walls with a south aspect Apricots succeed, the best being Oullins Early Peach, Moorpark, St. Ambrose, and Kaisha. Plums succeed admirably, the best being July Green Gage, Bryanston Green Gage, Jefferson, Kirke's, and Coe's Golden Drop. Peaches and Nectarines succeed fairly well with protection. Of Peaches Early Beatrice, Hale's Early, Dr. Hogg, Grosse Mignonne, Noblesse, Diamond, and Barrington; of Nectarines Lord Napier, Rivers' Early Orange, Hardwick Seedling, and Pine Apple. East walls suit Plums, and in addition to those named as suitable for a south wall Deniston's Superb, Transparent Gage, Guthrie's Late Green, Ickworth Impératrice, Prince of Wales, Victoria, Belle de Septembre, and White Magnum Bonum; also Cherries, Belle d'Orleans, Empress Eugénie, May Duke, Elton, and Governor Wood. West, also east, walls suit Pears, Jargonelle, Berré d'Amanlis, Berré Superfin, Louise Bonne of Jersey, Marie Louise d'Uccle, Durondeau, Maréchal de Cour, Marie Louise, Berré Diel, Thompson's, Van Mons Leon Leclerc, Berré Bachelier, Glou Morceau, Wiuter Nelis, Josephine de Malines, and Bergamotte Esperen. North walls are most profitably covered with Morello Cherries. For orchards—Apples—Irish Peach, Kerry Pippin, King of the Pippins, Claygate Pearmain, Dutch Mignonne, Reinette du Canada, Peasgood's Nonsuch, Cackle Pippin, and Sturmer Pippin; and for cooking, Carlisle Codlin, Keswick Codlin, Alexander, Cellini, Small's Admirable, Blenheim Orange, Warner's King, Dumelow's Seedling, Bedfordshire Foundling, Northern Greening, and Humbledon Deux Ans. Pears—St. Swithin's, Williams' Bon Chrétien, White Doyenné, Berré de Capiaumont, Aston Town, and Swan's Egg. Plums—Early Prolific, The Czar, Prince Englebert, Diamond, Wine-sour, and Wyedale.

**Names of Fruit** (*J. M. D.*).—Nearly all the Grapes were broken in transit; We can only say that the large one resembles the Golden Champion, and the small one Royal Muscadine. We do not undertake to name Grapes unless a bunch arrives in good condition and with a lateral bearing good foliage. No one can name Grapes with accuracy from a few isolated berries. (*J. Woodliffe*).—Pear, Berré Hardy. Apple, 1, Sops-in-wine; 2, not known. (*Northampton*).—Your seedling Apple is handsome, but it does not possess any merit even for cooking, as it has not sufficient acidity; the fruit also is very light. The other is Hollandbury. (*J. M. M., North Devon*).—Your fruit shall be carefully examined and referred to next week. (*G. S.*).—2, Waltham Abbey Seedling; 3, Suffolk Thorn; 4, Cox's Orange Pippin; 5, Golden Winter Pearmain; 9, Count Pendu Plat; 6, Cox's Orange Pippin. (*T. Norbury*).—1, Berré Diel; 2, Nouveau Poiteau; 5, Berré d'Anjou; 6, Berré de Capiaumont; 7, De Bay; 8, Easter Berré. (*John Dowden*).—You have not sent any numbers with your fruits, and we cannot refer to them individually. (*Carnagh*).—The fee for naming fruit for non-subscribers is 5s. (*G. O. S.*).—Selwood's Reinette. (*T. R.*).—3, Warner's King; 4, not known; 5, Scarlet Nonpareil; 6, and another like it, Striped Holland Pippin. Large Yellow Apple, Bedfordshire Foundling. The labels were not secure, and some of them were shaken off in transit. (*G. B. C.*).—Apples—5, Herefordshire Pearmain; 6, Fearn's Pippin. Pears—3, Gansel's Late Bergamot; 2, Berré Capiaumont; 1, Susette de Bay; 4, not known. The scale is Aspidiotus conchiformis, and may be destroyed by dressing with a solution of soft soap and paraffin, as advised on page 277. (*R. P. Williams*).—

Apples—1, Stamford Pippin; 2, Court Pendu Plat. Pears—1, not known, and quite worthless; 2, Red Doyenné, small. (*J. W.*)—Beauty of Kent. (*W. H. Bunnister*).—Huyshé's Prince of Wales.

**Names of Plants** (*M. H. R.*).—1, *Cratægus eocœnea*. 2, Specimen quite withered, but resembling *Rudbeckia fulgida*. (*G. P.*)—1, *Nephrolepis tuberosa*, which may be increased by placing the tubers in similar soil and temperature to those provided for the plants; 2, *Saxifraga cœratophylla*; 3, not sufficient for identification; 5, *Selaginella Martensii*; 6, *Saxifraga hypnoides*. (*A. A. M.*)—The yellow flower is *Chrysanthemum frutescens* Etoile d'Or, the other is *Serieographis Ghiesbreghtiana*. (*R. O. D.*)—1, *Lonicera sempervirens*; 2, A variety of *Lantana*, but the fragment was insufficient for determination; 3, *Euphorbia splendens*; 4, *Habrothamnus faseiculatus*; 5, *Amaranthus caudatus*; 6, Apparently a weak shoot of *Kalosanthes eocœnea*.

**Bees not Sealing Syrup Given as Food** (*H. M.*).—Store can no more be sealed without the secretion and elaboration of wax than can comb be built. A high temperature is needful for this secretion, and hence in the chilly weather we always get at the very close of the season bees are disinclined to seal the syrup they receive as food. In very strong stocks, in hives contracted until the bees are crowded, comb-building and sealing may be carried on with adverse external conditions; but as a rule all feeding should be completed in time to secure the sealing of the greater portion. Bees never seal quite all their store; that set apart for present use is left uncapped, and in the depth of winter they always in the midst of the cluster retain a certain limited supply of open honey. That the syrup is unsealed in large amount is unfavourable for wintering and may be a cause of failure, but thick-walled hives well contracted will make up often for disadvantages of this nature.

POULTRY AND PIGEON CHRONICLE.

IMPROVEMENT OF THE HAMPSHIRE AND WEST COUNTRY DOWN SHEEP.

IN concluding our observations upon the subject of "Cross-breeding of Sheep" in this Journal on the 2nd of September, 1880, we alluded incidentally to the means at our disposal for the improvement of the Hampshire and West-country Down sheep, but intending on a future occasion to return to the subject, and by stating in detail the manner in which we would proceed to work out so desirable an object based upon our experience as well as that of other flock-masters; we therefore now return to the consideration of the subject *in extenso*.

Within the last few years a strong opinion has prevailed that the breeding flocks of this kind of sheep are becoming deteriorated, notwithstanding the efforts to maintain the style and character. We are by no means surprised that such is the case, for as a rule Nature never stands still, and that those flocks which are not

improving in quality and value are therefore receding. This is a matter not to be lightly spoken of, particularly when we find really practical and intelligent men of great experience are amongst those who complain. It is, in fact, our only object in introducing the subject, in order that an improved type and style of sheep may be established and made available, not only for improving and renovating the present race, but also for maintaining the most approved character of the Hampshire and West-country Downs. Deterioration in the future is sure to happen unless the most practical and experienced breeders and flock-masters take up the matter in earnest, and bring out an improved type of animal adapted for rearing upon the exposed hill farms of the south-western and southern counties. It is well known that certain breeders are perfectly satisfied with their present flocks, and say that they are unrivalled. If we were to admit this we certainly could not go so far as to say that they cannot be improved. Let us now consider what are the points and character of these sheep which should be retained and those which may be improved upon.

In looking back for forty years and upwards we find that at various periods alterations of the style and character of these sheep were effected by experienced breeders, but that they had no object in common in introducing their changes or modifications. Mr. J. T. Twynam of Winchester, a Hampshire farmer who is still living, about the year 1830 used the improved Cotswold ram with his Hampshire Down ewes, and this cross had the effect of increasing the number of lambs, adding to the weight of the carcass, and yielding more wool, with a greater disposition to fatten, which at that time were considered valuable improvements. The flock-masters who possessed at the succeeding period the best style and type of sheep to be obtained at that time were Mr. F. Budd, of Hatch Warren, Hants; Mr. Thos. Saunders, of Watercombe; and Mr. John Fookes, of Cerne, in Dorset. The character of the sheep bred by these gentlemen was what we may term the most approved type of the period—namely, a large size with short wool, of great length, breadth, and depth of carcass; and although not early in lambing they were well suited for their districts, and were very hardy, and adapted for the consuming of root crops in exposed positions in rough and bad weather. The next improver of these sheep was Mr. Wm. Humphrey of Oak Ash, Chaddleworth, Berks, whose sheep were certainly the best style and character we have seen as the representative of the West-country Down, for we noticed the great success of his flock in taking the best prizes at the meetings of the Royal Agricultural Society of England at their meetings held at Salisbury, Chester, and Warwick in the years 1857–58–59, and again at the Battersea International Meeting held in 1862. On each of these occasions the sheep were considered by the Judges to be superior to all other short-woolled sheep, especially on the points of early maturity or weight for age, quality of mutton, and wool of fine and short staple. These animals having been obtained by the use of South Down rams of Mr. Jonas Webb's celebrated flock with the largest and choicest Hampshire ewes, such as Mr. F. Budd's, may be considered to be an enlarged type of Sussex Downs, with all the hardihood and strength of constitution for which the Hampshires have always been famous.

To make our list of breeders complete in the west-country districts we must name Mr. James Rawlence, of Wilton, Wilts, who sagaciously observed the value of Mr. Humphrey's stock, and availed himself of the opportunity of improving the size and character of his flock. Although at the time they were enlarged specimens of the Sussex Down he obtained a valuable improvement by an alliance between his strongest and selected ewes and rams from Mr. Humphrey's, and eventually possessed a flock of west-country sheep second to none, and was often a prizewinner at the Royal and Smithfield Stock Exhibitions. The most un-

fortunate point we have to dwell upon is the loss of Mr. Humphrey's sheep; for although of so much value in their blood, and although his rams were sought for by the best flock-masters, yet not one has ever attempted to maintain this splendid breed of animals in purity, which Mr. Humphrey has told us in conversation on various occasions took him more than twenty years of careful selection to obtain. Some of the best flocks, however, owe their distinguished position at present in the show yard to the influence of the rams obtained from Mr. Humphrey.

We must now call attention of the breeders of this class of stock (Hants and West-country Down), for since this blood is now only to be obtained in a largely diluted degree through the various flocks where used, we ask the question, Which way are we to look for sheep to improve our present stocks of Hampshire Downs? Since we lost Mr. Humphrey's we have not been enabled to obtain any other type of similar value for all the varied purposes for which this breed was celebrated, but more especially for its early maturity, quality of mutton, short fine wool, and adaptation for breeding purposes upon the cold hill farms of the different districts. We cannot, however, pass over without remark the fact that Hampshire and West-country Downs are not good breeders. It is recorded in an article in the "Bath and West of England Society's Journal," contributed by Mr. E. P. Squarey, of Odstock Farm, Salisbury, on the "Hill Farming of Wiltshire and Hampshire" that as the result of a census taken on the 4th of May, for five consecutive years, in a district within a radius of ten miles of Salisbury, Wilts, the average produce of 10,600 ewes was only 89 per cent. of lambs. From the conditions under which these numbers were obtained it is believed that they fairly represent the general circumstances of the flocks of the hill districts of Wiltshire. This return, too, was given in 1861, at a time when the improvements introduced by the use of the best breeds of stock had been in full operation for a considerable period. If we look for fresh blood to renovate or maintain the value of the Hants and West-country Downs we cannot find it in the Shropshire Downs, because we should lose early maturity, as proved by the contests and exhibitions at the Royal from 1857 to 1862; we may, however, and probably should, gain a greater number of lambs. If we take the Oxford Downs we should find early maturity it is true, and obtain a better produce in number of lambs; but we should lose in the quality of the meat and get a longer staple in the wool, which is not calculated to improve a short-wooled breed, nor should we consider them so hardy for feeding on the cold chalk hills like Hampshire Downs. As we are now alluding to breeding flocks, yet we do not deny that the cross of the Oxford Down with off-going ewes has frequently proved satisfactory on account of the increase of lambs as compared with Hampshires. As we have now occupied the attention of our readers by lengthy statements of the attributes and advantages, as well as the disadvantages, of the Hants and Wilts Down stock, it has been only to prepare them for further statements connected with the proposed new style of sheep which we intend to bring under notice.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will still be connected with the Wheat season. All the Clover lea ground should have been ploughed before this time; if not, the sooner it is ploughed and pressed the better. We are becoming more than ever in favour of the presser being used before seeding, especially upon lea ground. When the land is light and dry the ploughing after roots fed off or any other fallow preparation, pressing and seeding with the press drill simultaneously, is to be preferred to drilling in the ordinary. If it be carefully done the Wheat may very well be horse-hoed in the spring, as the lines would be from 10 inches to a foot apart, which is not too wide on strong land. It is of great importance, also, that on much flat land, even after it has been effectually pipe-drained, the ridges should be small—say the ten furrows or five turns with the plough—but they need not at this size be made very round or high in the centre. The chief point is to have the ridges to fit the drill as to width, and not have the land furrows struck out too deeply. Let this work be done with the Potato plough, in order that the loose earth may be thrown out equally on either side, and then the furrow if deep will be very narrow, and not hinder the effective working of the reaping and mowing machines either at harvest or hay time if driven across the ridges. Raising Potatoes should now be finished as soon as possible if the land is flat, as the lifting frame does not act well after heavy rains when the land is tough and sodden. The Mangold crop must be preserved by carting away to heap at the farmstead.

*Hand Labour.*—This may be applied to the storing of Mangold or Swedes, especially when either are pitted in the field. We find the best plan is to let the work on hire to a man, his wife, and family at so much an acre; they will then earn far more money and finish the work in much less time. This is important in the Mangold crop, so that they may be heaped and covered in before the frosts of November set in. Planting Cabbages may now be continued, but the sooner

it is completed the better, and for this time of year the plants ought to be strong, and if the land is stretched and the plants set in the furrows it will preserve and shelter them in the winter. In many districts when the snow is on the land game and wood pigeons are very destructive to winter plants unless covered with snow, which is quickly done when planted in the furrows between the stretches, and in the spring the stretches when split with the double mould plough earth the plants very beneficially.

*Live Stock.*—The young cattle now require attention—both steers and heifers—the latter especially. They, being most subject to the quarter-ill, should now be accommodated either on a very high and dry grass paddock, otherwise in sheltered littered yards and sheds at night time, and receive cotton cake or beanmeal, or both, in connection with cut roots or Cabbage. This will keep them healthy and in good condition. Some farmers we notice lately, in supplementing the grass food for dairy cows, give them brewers' grains laid in small heaps on the pastures even where there is a good bite of grass; but how much better it is to give such food in the mangers at milking time night and morning. As the nights are growing longer and the weather colder the fattening sheep which have hitherto done well upon early Turnips or Rape, or in some cases Cabbage or Thousand-headed Kale without any hay, should now receive some in chaff; but at the present price of the article we think cotton cake and meal mixed with cut roots more profitable feeding than hay chaff. About 1 lb. of the mixture per head per day is an ample allowance, especially if the root food is passed through Gardner's cutter. Some farmers object to cutting common or hybrid Turnips for sheep, as they are so much softer and more easily eaten than Swedes; but it is a mistaken idea, for the waste during their consumption on the land is considerable, and the animals have in fact to work for their living, whereas when cut and placed in troughs the roots are always clean and may be consumed without waste if the troughs are not over-filled. Little and often is the best mode of feeding, and it is the only way of feeding with cake or meal in admixture with the cut roots by which waste more or less can be avoided.

We have looked over lately some of the finest flocks of horned Somerset ewes to be found in the kingdom, and find that they are lambing fast and bring a large number of twins—in fact, all the horned ewes of Somerset and Dorset breed are earlier to lamb this year than in the average of seasons. The Dorset Downs, also, are early to lamb, but these of course lamb in December and January, whilst the Hampshire and Wiltshire ewes lamb in January and February. We have noticed for many years that in dry hot summers like the past season up to the middle of August the ewes of each breed will always breed earlier, and the lambs come better together than in cold sunless seasons like 1879. The early Somerset lambs as they fall should now, together with their dams, be drafted from the flock, and the ewes will bear the best of food, both of roots, cake, meal, &c. As soon as the lambs are strong enough to follow the ewes they may together go into Italian Ryegrass for a while in the daytime, but receive a fold of roots at night on dry ground. Italian grass is, however, the food which will produce more milk than any other food. The ewes should be cooped every day, and those which have more milk than the young lambs can take the shepherd should milk dry by hand, otherwise penned milk will kill the lambs. If the ewes and young lambs go on to young Clovers they should be removed at night; it being the coldest lying for them they often suffer from rheumatic affections and become crippled, for which there is no cure, and we have found that they should then be destroyed and another lamb placed with the ewe. The flocks of Wiltshire and Hampshire ewes should now be regularly kept without a heavy fold of food night or day, especially of roots, for at this period of their pregnancy they are more likely to abort than later on and nearer to lambing time.

We use straw chaff, as it will not answer to give dairy cows hay at present prices and during the winter, when they are comparatively out of profit. As soon, however, as they drop their calves they should receive hay and straw chaff mixed together with a moderate quantity of cut Mangold, and mixed with a liberal allowance of oilcake; and the better they are kept the more profit they will yield, either for making butter, milk for sale, or suckling calves for veal. We do not recommend the fattening of many pigs for sale, as we do not think they pay so well as fattening bullocks. Our mode of feeding, however, is to mix meal with pulped Mangolds at the commencement, using the proportion of two-thirds Mangold to one-third of Barley meal, or a mixture of Bean, Barley, and Maize meal, gradually during the process of fattening increasing the quantity of meal, and finishing off by several weeks of feeding with meal only. Instead of fattening many pigs we prefer to keep a number of breeding sows fed on roots and cheap meal food, and allow them to run in well-littered yards, in which case they make much manure and are sure breeders. The profit arising is by the sale of the young pigs as stores at about 25s. or 30s. each, and when the large white Yorkshire is crossed with the Berkshire breed we obtain large farrows of the most valuable pigs at weight for age.

*LAXTON'S EARLY MAPLE PEA.*—Mr. Laxton is now distributing this new agricultural Pea, which he states was raised by crossing the old Maple or Partridge Pea with the earliest white variety, the result being a Maple Pea which is quite as forward as the earliest garden Pea, and three weeks in advance of the old Maple. The height from 4 to 5 feet. In all other respects it

possesses the good and useful qualities of the old Maple. The advantage conferred by the new Pea will be appreciated by agriculturists, as, if sown in February, the ground can, in an ordinary season, be cleared early in July, and a successional fall crop secured. The yield of this variety in 1880, from unmanured ground under plough, was at the rate of eight quarters per acre. In the past season the crop was harvested in good condition before the autumn rains commenced, and no better exemplification for the necessity of this variety could be afforded, as in most instances late Peas have been harvested in a very unsatisfactory manner in 1881.

## POULTRY AND PIGEONS

### POULTRY HOUSES AND YARDS.

To the fancier that is, or is to be, autumn should be suggestive of the subject of poultry houses. Those who have them may be quite sure that before winter they require some repair and attention. Those who are for the first time going to set up poultry—and be it remembered that the late autumn is a very good time to begin—will find some hints on the construction of abodes to their birds not out of place.

We need hardly repeat what we insisted upon but a few weeks ago, that the absolutely necessary requirements for a poultry house are a watertight roof and a dry floor. We have known birds thrive well in poor draughty sheds, yet dry above and below. Thatch, besides being picturesque where poultry houses are in shrubberies and pleasure grounds, is an excellent covering, warm in winter and cool in summer, if it be well kept up and recovered from time to time; this, however, makes it a somewhat expensive luxury. Where roofing has entirely to be renewed we should recommend corrugated iron—not, however, as the sole covering, for this would be too cold, but as the outside covering of an inner boarded roof. A layer of straw may with advantage be placed between the boards and iron. We need hardly say that the flooring must not be of bricks or stone, but of earth rammed down hard, elevated a few inches above the surrounding soil; over this hard substratum some sand or sifted earth may be thrown, which much facilitates the cleaning process and helps to keep the abode sweet. A house with a damp floor cannot possibly be clean or healthy. To those who have no poultry houses at all to begin with, and are going to construct them, it is only possible to give somewhat vague advice. Circumstances and premises are too various for there to be any stereotyped model house suitable to all; these absolute requisites must be borne in mind, and the best be made of any sheds and appliances to hand. We have houses of very great variety, and suitable to the requirements of fanciers very differently situated. For those whose space is small, and who wish to see the whole of their feathered stock at a glance, a row of small houses under one roof is useful. Each house, of course, has its own small run in front, and the inmates of each in turn are let out on to some grass plot or into some little shrubbery for exercise and recreation. When space is no object entirely detached houses are best; there is in such little fear of disease spreading or of the ground being tainted. Cheap and comfortable dwellings for a family of Bantams or a couple of larger birds may often be constructed in corners of walled yards; two sides only of boarding are required, and if the aspect be good the shelter is complete. For tufted fowls especially such places are very desirable, and in addition the whole of the little run attached may with advantage be covered over. The remote detached house, buried in a wood or in a rich meadow with long grass, which is a perfect paradise for Dorkings or Game, would be death to Polish, which are sure from their impeded vision to lose their way in rough places. The small cage-like abode, on the other hand, which will do well enough for them provided they get an occasional grass run, would be an absolute prison to more peripatetic breeds.

Moveable houses are a great boon to every fancier who has plenty of room; ground may thus be constantly changed without any trouble of its artificial refreshment, and if only ordinary care be taken both garden soil and grass land may be benefited as much as the birds. Moveable houses may be variously constructed. We have seen some among the prize appliances at exhibitions floored and raised high on wheels, not unlike the houses of gypsies, to be moved by horse or donkey. For our part we always prefer house, coops, and all such things of very simple construction. Our own moveable houses are small cabins, some with wooden floors 3 or 4 inches from the ground, and on small wheels. They are easily pushed about from place to place. Others have no floors or wheels, but are lifted by handles. These are specially adapted for

grass fields and for summer use. If they are constantly moved the grass is greatly benefited by the droppings. We put our broods into them as they outgrow their coops. A house is easily brought to the position of the coops and put in its stead. The chickens at once take to it, and then it is pushed off by degrees in any direction desired. The bottoms of these houses, which rest on the ground, are apt to rot if used through winter in damp places.

Yards now require attention as well as houses. The gravel of small wired-in aviaries becomes tainted sooner than one would think, and often is so while it still looks clean. It should be renewed now, or if of a very shingly and rough nature may be taken up and washed by being pumped on in coarse garden sieves and then put back again. Turf which has been eaten and trampled down through the summer should now spring up luxuriantly when the stock of birds is not too numerous for their runs; when it does so it will absorb the taint of summer, but if it fails to grow properly it should now be taken up (for manure and potting it will be very valuable), and fresh laid down in its stead. When poultry run under shrubs and pat down, as they generally do, the earth, it should now be forked over. Shrubs and birds will both profit by the operation. Every enclosed grass run is the better for a grand walk through it; this affords a dry spot, where the birds can always stand in wet weather, and they are at the same time provided with a stock of grit to peek at.

We need hardly say that if poultry runs are in a damp situation and on a damp soil they must be well drained, and if they are already drained this is the time to see that all pipes are clear and in working order. Gallinaceous birds are natives of lands for the most part dry, and if creatures whose delight it is in a state of nature to roll and bask in dusky banks are kept in muddy swamps they cannot possibly thrive. We should be almost ashamed to treat our readers to such simple instructions were it not that we are constantly seeing poultry kept in conditions in which it is quite impossible for them to bring pleasure or profit to their owners, and this not by those who utterly ignore them as unworthy of their attention, but by people who consider themselves fanciers, and believe their arrangements peculiarly good. It is often painful for a real lover of birds to see the misery which many endure through the long English winter from the utter ignorance or indifference of their owners about their nature and habits; we do not therefore let pass a season in which much may be done towards housing them in a humane manner through the coming winter.—C.

PEKIN DUCKS.—Your correspondent "C." appears to miss the point of the especial merits of Pekin Ducks—namely, their hardiness, fertility, and early maturity. My experience has been greatly in their favour on these points; whole sittings hatching out without fail, very few young birds dying, and their being ready for table by the time they are fourteen to sixteen weeks old, and then weighing over 4 lbs. They should be eaten before their first moult.—F. R.

### REMARKS.

- 9th.—Fair, but cloudy and cool; brighter with slight sunshine at 4 P.M.; slight shower in evening.  
 10th.—Cloudy and dull nearly the whole day.  
 11th.—Fine pleasant day, but rather cloudy, especially in the morning.  
 12th.—Fine pleasant morning with a little sunshine; dull afternoon and evening, with slight showers.  
 13th.—Fine morning, dull afternoon, wet evening and night.  
 14th.—Unusually strong westerly gale all day, with occasional sharp showers.  
 15th.—On the whole fine and bright, but with a very heavy shower just after noon.

The chief feature of the week has been the very heavy gale on Friday the 14th and the sudden fall of the barometer which preceded and accompanied it. The temperature was very similar to that of the previous week, and not far from the average.—G. J. SYMONS.

WHAT PLANTS USE.

(Continued from page 249.)

SOURCES OF PLANT FOOD—POTASH.

WE have seen that potash is a principal ingredient in the ash of plants, and especially so in the case of those cultivated for food. It may be laid down, indeed, as a general rule, that any ordinary rotation of garden crops will remove more potash from the soil than any other mineral compound. If the plant food which is being continually added contain potash in sufficient quantities the fertility of the soil, so far as that depends on the presence of potash, will not diminish. At the same time it is possible to cram soil full of manure and yet the soil prove less productive than it ought to be. Our conviction is, that this is the state of matters in nine-tenths of our gardens. Over-manuring is a decided evil, yet we are safe in saying that many over-manured gardens are infertile more for want of potash than because of an excess of other substances. No matter how abundantly lime or soda may be present, if potash be deficient the plants will only grow to the extent of the potash they find. Hence plants may starve—do starve—on a soil that for other plants may be extremely rich. When we examine what is given as plant food in a majority of instances we can easily see that such must be the case. Ordinary farmyard manure—that made of about the usual number of all the different animals usually found on farms—contains the substances we have named in proportions approaching the following figures. We ought to state here that analysis of farmyard manures can only be approximate, as the kinds of animals kept, the state of the drainage, and the food used, all tend to make differences in this respect. Farmyard manure contains of water, 72.48; organic matter, 13.94; potash, 0.32; soda, 0.16; lime, 0.59; magnesia, 0.02; phosphoric acid, 0.31; sulphuric acid, 0.12; carbonic acid, 0.52; ferric oxide and alumina 0.45; sand, 11.09; total, 100.00.

A reference to the above results will show that ground continually enriched with such manure, and cropped with a rotation of garden crops requiring more potash than lime or phosphoric acid, may present these last two in due or over-abundance, and yet fail in presenting enough of potash; or if such manure be applied in quantities sufficient to furnish enough potash, then many other valuable matters are partly lost, or may in time, under certain circumstances (such as we mentioned in a former paper when urging the necessity of washing Vine and other borders under glass), accumulate to

an injurious extent. That in many instances this is so could very easily be proved. In the case of manure from cow houses matters are much worse, as, for a reason to be presently explained, cow manure is originally deficient in potash. We wish particularly to dwell on this, for our aim is to draw special attention to the source of potash, and the necessity of furnishing an abundant supply in order to secure the greatest economy, and economy, always a virtue, has become in many instances a pressing necessity in many gardens.

Those who read this and who may believe that there is "something in it," may wish to experiment in order to prove the truth or otherwise of our assertions. We wish nothing better, and hope the data here furnished may be heeded, so that any experimenting which may be done may be really calculated to produce the right effects.

We have shown that potash is largely demanded by Potatoes, and also hinted our belief that most garden soils are deficient in it. We know of no plant that will more readily show whether this is the case or not than the one named. We have carefully experimented with artificial and natural manures rich in potash salts, and this on maiden soil and in rich old garden soils, with surprising results. Before giving some of these we beg to submit the following well-known facts—1, Potatoes on old rich garden soil produce much greater crops of haulm than of tubers; indeed, great crops of these are not the rule in such soils, and heavy supplies of manure increase the evil. To prove this we intended quoting from different authorities, including the Journal; but the writers of almost every article on Potato-growing so agree with other writers on this that we content ourselves with merely restating a well-known fact, and such as every gardener of any experience is acquainted with. Surprise and astonishment is often expressed at this fact, but it is one which the student of agricultural chemistry would expect, and amply verifies what has been often called mere theory. Considering that garden crops tend, under ordinary manuring, to exhaust the soil of what is necessary for the formation of Potato tubers, and tend to an accumulation of what ought to produce a grand crop of haulm, no surprise need be felt when big shaws and small Potatoes are produced on "rich" garden soil. Rather should the occurrence be taken as proving the accuracy of what the chemists have taught.

No artificial and no natural manure surpasses urine, and especially cow urine, for supplying potash to plants. One would, therefore, suppose that a dressing of urine to soil intended for Potatoes would in all cases prove beneficial. But such is not the case. This seems paradoxical, but a little thought shows that it is not. Urine is also rich in compounds of nitrogen, which excite rank growth. Therefore, although much potash is applied with the urine, the nitrogen supplied with it causes a growth so strong that, small as is the amount of potash needed by the haulm, the extra growth it makes takes much of the potash, and little is left to be available for the formation of tubers. At least, this is how we explain the action of urine when applied to Potatoes on rich garden soil. Whether the explanation be correct or not the fact remains, and with facts we deal.

This experiment we have made repeatedly, and for comparison we have also made another under exactly the same conditions. Wood ashes, as is well known, contain much potash in a form very easily appropriated by plants. On rich soils we have

invariably found that a dressing of fresh wood ashes to the Potatoes at planting time scattered between the drills after the plants appeared, to have a wonderful effect in increasing the crop. It also promotes a robust growth in the haulm—possibly by presenting abundance of lime for their use—at least, the effect of wood ashes in promoting haulm-growth is very much less marked on well-limed land than on land where lime is deficient. Kainit, a salt rich in potash, we have also found to give an increased quantity of tubers; and what is of more value than mere increase of crop, kainit salts and wood ashes, on soil rich in vegetable remains, produce Potatoes of decidedly better quality than do stimulating manures containing much nitrogen, such as ordinary manure and urine. In America it is always found that virgin forest land newly cleared produces immense crops of the very finest Potatoes. The fineness of quality is invariably attributed to the abundant supply of potash present in the soil consequent on the clearing fires.

Recent experiments in plant-growth go to prove that no starch can be formed without the presence of potash, and without starch growth is an impossibility. We quote the following from a lecture delivered by Professor Otway before the Connecticut State Agricultural Society—"If we examine a green leaf with a microscope we may find in it thousands of minute sacs, or cells as they are called. Some of these contain the green substance called chlorophyll. Inside these grains of chlorophyll appear still smaller grains of starch. Starch is composed of the elements carbon, oxygen, and hydrogen. It is produced inside the leaves. The carbon is taken from the carbonic acid of the air by the agency of the chlorophyll, is united with oxygen and hydrogen, the elements of water, and thus starch is produced. After starch is so formed it is conveyed to the other parts of the plant, and stored away as with Potatoes or grain, which consist largely of starch, or is transformed into the other materials of which the plant is made up, and this formation of starch with chlorophyll grains, and transportation, transformation, and storage to build up the plant, is going on continually as the plant grows. If, then, no starch is formed by the chlorophyll in the leaves, normal growth is impossible." Again: As Dr. Nobbe says at the conclusion of over a hundred pages of description of his experiments—"Without potash the plant cannot assimilate (the materials needful for its growth) and shows no increase in weight, because without the co-operation of potash in the chlorophyll no starch is formed." The fact that wood ashes and kainit applied to ground rich in organic remains never fails to produce Potatoes of the best quality, was long a puzzle to us. Indeed, we attributed it to another cause. The fact remained, however, and whenever we possibly could we profited thereby. We have dealt at some length with this division of our subject, but the matter is of much importance, and we may be pardoned for details and quotations in our endeavour to press the matter home on those who may never have given the subject a thought.

Although on rich soils the application of urine failed to give anything like the favourable results we expected, we have again and again found that its application to new land containing very little organic remains, and deficient in ammonia or nitrate salts, to be of great benefit to Potatoes. It must never be forgotten that the leaves manufacture all the substance of the plant, and to expect a full crop of Potatoes or anything else from a stunted growth of shaws is expecting too much. On such soils as produce through poverty only a stunted growth, the nitrogen in urine never fails to increase the manufacturing part of the plant—the leaves; while in the case of many plants, and especially Potatoes, the potash added contributes very materially to the formation of starch in the form of Potatoes, grain, and all other vegetable produce.

We have been led to say thus much on the application of manure to Potatoes, because these stand alone in our experience in being rendered at once stronger and yet less prolific by the application of manure rich in potash, rich in nitrogen. To almost all other garden crops, the Leguminosæ excepted, urine may be freely applied if properly diluted; and on soil long cropped with ordinary vegetables will do good only by supplying the deficiency of potash, while the nitrogenous matters will reinforce the effects of the potash salts. Such is our experience, such is our practice. We have produced results by the use of urine which without it we could not have done, and we consequently strongly recommend others to use it. We ought to caution beginners, though. As it comes from the tanks it is so strong that, applied without being diluted, it is destructive. Never apply it to dry soil unless diluted with eight times its own bulk of water. When the ground is wet and the rain is falling less will be sufficient. When applied in winter it need not be diluted at all. It is much more profitably applied to growing crops, however, but it is a pity to let it run to

waste even in winter. Applied during winter to quarters of small fruits it promotes vigour and increases the crop wonderfully, especially when the bushes are old.

To let every reader of this understand why the application of manures rich in potash is, on economical grounds, advisable in the case of garden ground, we should say that in the economy of all animals, and especially those which are domesticated, the potash which is in their food is excreted chiefly in the urine. Those who only use the solid matters require to use much more of it than is necessary in order to produce a given result.—SINGLE-HANDED.

(To be continued.)

#### FRUIT TREES CANKERING.

I AGREE with what "A NORTHERN GARDENER" stated in the Journal last week about the cause of canker in fruit trees. I have made this a subject of observation for many years, and the conclusion I have come to is identical with his. The general idea is that canker proceeds from ungenial and wet soils, and these are no doubt concomitant causes, but the immediate cause is frost, as I shall presently show. That the cold, wet, ungenial soils have a great deal to do with it in the way of making the trees more susceptible of attacks of frost is true, for in all such soils, especially in wet seasons, the young wood of the fruit trees rarely ripens properly; the tissue is loose and succulent, the sap vessels are full of thin watery fluid, and when winter comes with its severe frosts the tissue is ruptured, the fluids are extravasated, and canker is produced.

There are some varieties of fruit trees which are naturally of a delicate constitution, and are more amenable to such a condition as I have described, even after seasons that are not remarkable for their superabundance of moisture. The Ribston Pippin is one of these. It matters not what soil it may be in, unless it be one that is unusually light and warm it almost invariably suffers from canker. Twelve months ago I planted some standard Ribston Pippins, very handsome trees from a well-known nursery. When I planted them they had all the appearance of rude health, and I indulged the hope that I had got a stock of this favourite Apple that would some day bring pleasure as well as profit to me. But these bright illusions have all been dispelled; for this summer every one of these have been attacked most virulently with canker on the stem, and in some instances it has eaten so deeply into the substance of the stem that during one of those severe winds we had a few weeks ago they have snapped in two as if they had been rotten sticks. Now in this case subsoil could have had nothing to do with it, for these trees had no time to penetrate it, or even to stray from the fine loamy soil in which their roots were planted; but the injury was done before I received the trees from the nursery, and I shall be surprised if many more planters besides myself cannot tell the same tale this year. The reason is that both last winter and the previous one were so severe that great damage must have been done in this way.

What I have said of canker is equally true of gum. Gum in stone fruit trees is merely the analogue of canker in Pippin fruit trees. Its effects and its causes are the same. The dying of large portions of Apricot trees is attributable to the same cause. "How can that be?" I think I hear someone say; "the branches of Apricots die off in summer when the tree is covered with leaves." True, friend, but the mischief was done in winter; nay, perhaps even two winters before. The tissue received its injury then though not destroyed; the branch lived and lingered till it could live no longer, and when the demand upon its resources was made by the fully developed leaves, the wounded tissue failed in its functions and the branch died. Such is, what I believe after many years' study of the subject, to be the true history of canker. It is simply the action of frost on delicate tissue; and as the strength of the tissue varies in different trees either from their natural constitution or from circumstances of soil and climate, so are some varieties more capable of resisting, and others more liable to suffer from its effects.—H. B.

TRANSPLANTING FOR SPRING GARDEN DECORATION.—I have been at this work whenever opportunity offered during the past month. The beds and borders are now nearly all filled, and in general more than a score of small beds are each furnished with three different varieties of hardy flowers, principally propagated from cuttings or seeds during leisure hours. Pansies are great favourites, and I raise all from selected seed. Cuttings are much inferior in flower, and less robust. I grow largely the Dianthus family—Carnations, Picotees, and Pinks. So of the Primulas, Polyanthus, Auriculas, &c. No plant is better than Anemone coronaria

in late spring, when bulbs are failing. Irises, *Alyssum saxatile*, and Variegated *Arabis* make a handsome bed. There are plenty of popular good old plants to select from, including *Phloxes*, *Campanulas*, *Delphiniums*, *Veronicas*. I would recommend good manuring before planting now.—W. J. M., *Clonmel*.

#### OAKFIELD HOUSE, WIMBLEDON PARK.

AMONGST establishments where large and diverse collections of plants are grown Oakfield House has for some years occupied a prominent position. It is not celebrated for large specimen plants of a few kinds such as are seen at exhibitions, nor for an extensive collection of the popular Orchids, but it has a speciality which is scarcely excelled in any other garden of similar size. Hardy plants have long been favourites with the enthusiastic proprietor, G. J. Joad, Esq.; but he has by no means confined his attention to them,

for half-hardy and other plants from temperate regions, requiring in this climate protection from frost during the winter, have been equal favourites, and in few if any gardens will be found such an interesting and well-grown collection so well provided for as regards house accommodation. By personal collection, purchase, and exchange considerably over three thousand species of plants have been obtained, and the number is being constantly increased, so that quite a small botanic garden has been formed. This total includes the occupants of the stoves and intermediate houses, but the two first-mentioned sections are by far the most strongly represented.

The garden is pleasantly situated on the east side of Wimbledon Common, and is sheltered on three sides, but somewhat open to the north, and in consequence the winds occasionally injure the plants outside in the more exposed positions rather discouragingly, but for the rockeries and several collections of hardy plants the positions have been carefully selected with a view to affording them all the shelter possible. October is not the best time to inspect a collection of herbaceous plants, as few besides *Asters* flower so late, and the approach of winter is too evident in the majority of the occupants. When, too, the frosts have destroyed the *Dahlias* the brightness of

Fig. 63.—ABELIA RUPESTRIS. (See next page.)

the outdoor garden is chiefly lost. So, although at Oakfield many very choice and rare plants are grown in the outdoor garden, few were in condition to demand notice except as regards their general health and vigour.

The Alpines and rock plants seemed particularly satisfied with their position. The two rockeries are not elaborate structures, but are well designed and admirably suited for their occupants. They are both made in a similar style—namely, like small dells, the sides sloping down below the general surface level to an irregularly winding path in the centre, which is 3 or 4 feet below the surface. A very sheltered position is thus afforded, and the only circumstance that might be thought to have an injurious influence upon the plants is the probability that there would be an accumulation of moisture during wet seasons. This, however, does not appear to be the case to any great extent, and is no doubt due to careful preparation before the rockery was built. The stone employed is informally disposed in various-sized pieces, chiefly with the object of forming suitable ledges and recesses for the plants; and without any attempt to provide an

imposing effect, it yet has a naturalness which is often wanting in such structures.

The cool houses were, however, at the time of my visit the most attractive; indeed, throughout the year, even at the dullest season, some plants may be seen in flower more or less beautiful or interesting. In many gardens such houses might usefully replace the small greenhouses and conservatories which amateurs like to keep gay with some of the conventional decorative plants that produce a brighter effect as regards colour, but become rather uninteresting when a sufficient diversity is not at command. In establishments where there is abundance of material to vary the display frequently, conservatories even of the most formal construction are always attractive. Mr. Joad's cool houses are, however, especially interesting, because botanical curiosities, though well represented, are not allowed to supersede plants that possess unquestionable beauty in flower or foliage. Again, few plants of one kind being grown, there is no lack of variety, and some are always in flower, though spring and summer are the chief seasons. One great and very satisfactory feature is

that the occupants are all planted out in beds, and we thus escape the unpleasing formality of rows of flower pots, which always have a hard and incongruous appearance even in the most tastefully arranged houses. One of the structures referred to is span-roofed, 40 feet long and 18 feet wide, with a bed in the centre and one at each side, separated from the walk by a brick wall. These beds were carefully prepared, the drainage being good, and upon this is placed about 2 feet depth of turfy soil, the stations for the more delicate plants being specially prepared by the addition of sand or peat according to their requirements. The house is provided with abundant means of ventilation both at the top and sides, and three rows of 3-inch pipes on each side are found sufficient to prevent the temperature falling below 40° in winter. By free ventilation at all times when the weather is not too severe the plants are rendered sturdy and hardy, and their vigorous growth is surprising. Nor with comparatively unlimited root space is the production of flowers diminished; on the contrary, all appear to be as floriferous as could be desired, and more than could be expected in many instances under culture in pots.

To enumerate the contents of this house would far exceed my purpose, but there were some plants which cannot be passed unnoticed. The roof is covered with numerous climbing plants, among which *Bomarea Caldasii* and *B. Carderi* are notable, the former a handsome plant which flowers freely, the latter smaller but progressing well. *Habrothamnus* or *Cestrum aurantiacum* is very distinct in the colour of the flowers from the better-known species, but very similar to these in other respects. The deep yellow or orange-coloured trusses are freely produced, and the plant might be advantageously grown as a companion to *H. elegans* and *H. fascicularis* in many gardens. *Clematis indivisa* is too well known and valued to need description. It is represented at Oakfield by a fine specimen, which produces abundance of flowers early in the season, when they are always welcome. *Hibbertia dentata* is another climber that is very attractive when in flower. In addition to many others, handsome examples are noteworthy of *Abutilon vexillarium*, *Rhodochiton volubile*, *Plumbago capensis*, *Convolvulus Herminieri*, and *Tacsonia insignis*, the latter being extremely vigorous, and is greatly valued for the lengthened supply of beautiful flowers it affords. Of the specimens growing in the side and central beds, the two finest are *Lasiandra macrantha floribunda* and *Abelia rupestris*. The former is a grand example 4 or 5 feet in diameter, and bearing its rich purple flowers 5 and even 6 inches in diameter. The *Abelia* (fig. 63), is of similar size, with small ovate shiny green leaves resembling the common Myrtle, and clusters of white tubular or inflated flowers, which are produced in succession throughout the greater portion of the year. Even in a small state this plant is very useful, but when planted out and having attained to a good size it is especially beautiful. *Calceolaria bicolor*, a free-flowering and attractive species, grows strongly in the side bed, and by cutting the old growths out and taking up the young shoots it is had in flower constantly. Indeed, for the past eighteen months it has not been without flowers, which are borne in large clusters, and are bright yellow and white in colour. Though the blooms are not so large individually as *C. Pavonii* they are quite as attractive. Judicious applications of weak liquid manure are found to assist this plant considerably, forwarding the growth and improving the size and colour of the flowers.

*Burchellia capensis* is quite at home in the central bed, and seldom is so fine a specimen seen, proving the advantage of planting out in this as in many other cases. The curious *Pelargonium tetragonum* figured in the Journal some months ago, is notable for its four-angled stems, so unlike the majority of its genus. Another curiosity is *Crassula lycopodioides*, the chief character of which is well expressed in the specific name. It has small stems with short dark green leaves closely set in an imbricated manner, exactly in the style of the *Lycopodiums*. *Myrtus bullatus*, an Australian species, is, too, one of the most remarkable species of *Myrtus*, the leaves being of a peculiar brownish hue, so suggestive of ill health in most plants, and the surface is blistered, if it may be so termed, between the veins, after the manner of a Savoy leaf, to give a well-known example of what botanists term a bullated leaf. *Beaufortia decussata* is not only peculiar, it is very handsome even without flowers. It is of scrubby habit, and might easily be mistaken for one of the stronger-growing *Epacrises*, the small rigid dark green leaves being arranged closely on the long vigorous shoots. The distinct and pretty *Calceolaria violacea* deserves notice, for it is neat in habit and foliage; and though the flowers are small, the freedom with which they are produced and their delicate violet purple tint render them very pleasing. The Ivy-leaved Groundsel, *Senecio macroglossa*, covers a portion of one end of the house, and may be ranked among the curiosities, though it is not deficient in attractiveness, the dark green leaves possessing a remarkable resemblance to some of the small-leaved *Ivies*. Another useful plant for the roof of greenhouses is *Fuchsia thymifolia*, which there is trained up one of the rafters and produces multitudes of its diminutive rosy flowers. One other plant demands attention, named a non-climbing form of *Rhynchospermum jasminoides*, which in the central bed has grown into a compact shrub-like specimen quite unlike its usual habit.

Another house in two divisions, of similar construction, except that it has a three-quarter span-roof, is occupied with many plants equally as interesting and beautiful as those already mentioned. One of the

most attractive, however, was a handsome example of *Swainsonia magnifica*, which covered the partition in the centre of the house. It is regarded as an improved form of *S. Greyana*, which it resembles in the long pinnate dark green leaves, but the flowers are larger and of a brighter rose colour. The specimen was bearing some dozens of racemes, and in such condition the value of the plant cannot be rated too highly. *Hibiscus Hugelii* is a noteworthy species, the leaves being very neatly divided into narrow segments like some of the fragrant-leaved *Pelargoniums*: the flowers are large, of a purplish hue, and the plant is by no means unattractive. Another form of the same genus not at all common in gardens is *Hibiscus Manihot*, long known in this country. It is chiefly remarkable for its large bright yellow flowers and handsome divided leaves, which average a foot in diameter. Some of the dangerous *Loasas* thrive well in this house, their pretty and curious flowers tempting the unwary to examine them more closely. *Convolvulus mauritanicus* trails downwards from several nooks in the back wall, and the numerous flowers have a pretty effect. *Luculia gratissima* also succeeds well planted out; but a specimen of *Bougainvillea glabra*, though appearing in perfect health with large and glossy leaves, does not flower well, and seems to be deteriorating each year. In this and other houses several species of *Calceolaria* are grown. Indeed there is a very good representative collection, including, besides the two already mentioned—viz., *C. bicolor* and *C. violacea*—*C. Pavonii*, recently figured in the Journal; *C. hyssopifolia*, *C. glutinosa*, *C. crenatifolia*, *C. pulverulenta*, *C. lobata*, and the curious *C. fuchsiaeifolia*, which has leaves precisely resembling those of a *Fuchsia*. With respect to *C. Pavonii*, it may be observed that at Oakfield plants are grown out of doors during the summer months, and fine specimens are produced, especially in sheltered positions near a wall. But it is found that they cannot be preserved through the winter. Covering the roots will not preserve them in such seasons as we have experienced of late years. The best plan is taking cuttings every autumn, striking them and growing the young plants on for the following year, fine specimens being obtained with a little assistance.

What is termed the Fernery is a double span-roofed house about 24 feet square, heated to a tropical temperature, and contains Ferns, various Gesneraceous plants, *Clerodendrons*, *Thunbergias*, and other plants. The central bed has fine specimens of *Canna iridiflora*, one of the best of its genus, with large crimson flowers. *Thunbergia fragrans* is trained on the roof, and its white sweetly scented flowers mingle with the rich crimson blooms of *Ipomæa Horsfalliæ*, which is also trained on the roof and bears fine clusters of handsome flowers. *Stigmaphyllon ciliatum* trails along the rafters, and its yellow flowers afford a fine contrast with the purplish *Convolvulus*-like blooms of *Batatas paniculatus*. The manner in which the side stages are draped and the pipes concealed is noteworthy. Near the edge of the stage is a line of *Selaginella*, and from this a fringe of *Panicum variegatum* hangs down 2 feet or more in length. Below this in front of the pipes a few pieces of rock are placed, and, covered with *Selaginella*, form an effectual screen. The margin of the centre bed is formed of *Fittonia argyoneura* and *F. Verschaffeltii*, and constitutes a pretty finish; the large specimens of *Caladium esculentum* and *Alocasia violacea* imparting quite a tropical appearance to the house, which, though small, is far more attractive than some of much larger dimensions and more pretentious exterior.

To many no house in the garden would possess more interest than the Rockery, a span-roof structure with glass at the top and sides, but having a central wall built of tufa and imitation sandstone disposed in an irregular but natural manner, so as to form numerous ledges and nooks, in which are planted many choice and pretty alpine and other plants. The lower portion and near the sides of the house is constructed in the same way, so as to form a rockery under glass: and though no heat whatever is afforded artificially, the protection is sufficient to preserve many plants that would be lost outside, or would at all events not succeed so well. Small pools of water contain abundance of the curious ally of the *Salvinias*, *Azolla pinnata*, which floats on the surface of the water, and is of a rich deep green colour, quite different from that it possesses in warmer quarters. In one of the nooks *Campanula isophylla alba* was literally a mass of flowers, pure white, and an inch or more in diameter. All the plants are thoroughly healthy and seem to like their position extremely.

Several houses are devoted to tropical plants, many of which are very beautiful and some rare, and much might be written concerning them, but as these notes have already reached considerable length we must confine our observations to two of them. One is a seedling *Begonia*, the result of a cross between *B. semperflorens* and *B. Schmidtii*, the latter parent being a compact-growing form of continental origin, with leaves something like *B. metallica*, only smaller. This seedling partakes of the latter in the habit, but it has small white flowers and green leaves like *B. semperflorens*, but smaller and darker green. It is very free in flowering, and the neatness of its habit recommends it strongly. The other plant is *Rondeletia anomala* (fig. 64, page 377), a scarce species but very beautiful. The specimen referred to is suspended from the roof of an intermediate house, and has numerous clusters of rich coral red or deep scarlet flowers. It is grown in a shallow pot or pan, a compost of peat, light turfy loam, and sand being found to suit it admirably. Why this plant is so rarely seen it is hard to understand.

In these notes a small proportion of the plants at this establishment have been referred to, but it will convey some idea of the

number of species represented. Throughout, the healthy condition of the plants, the cleanliness and neatness everywhere prevailing, are creditable in no ordinary degree to the gardener, Mr. Smith, who takes as much interest as his employer in the welfare of the collections.—L. CASTLE.

#### BRUSSELS SPROUTS—THE AIGBURGH.

As this vegetable is an all-important one to gardeners who have to keep up a supply, the above-named variety is a great acquisition. Although it has not been in commerce long, it is valued by many as a standard variety. Novelties now are so plentiful that when any variety of vegetable proves really good it is worth recording. The middle of March is a good time to sow the seed, choosing an open position away from the shade of trees. The soil for the seed bed if at all stiff should be dug some time previous to sowing the seed. Sow it moderately thick and protect with a net, as bullfinches and linnets are very troublesome about that time of the year. Treading the soil lightly, or patting with the back of a spade, is also an advantage—it helps to retain the moisture so essential to germination.

At the end of May or first half of June the plants will be ready for their permanent quarters, when the soil should be rich and deeply dug. In planting, 2 feet apart each way is a suitable distance, and when the plants are well established and growing run the hoe amongst them to destroy small weeds. The hoeing should be repeated about three weeks after, and when the plants are about 9 inches or a foot in height, earth them up in the same manner as rows of Peas. These hoeings, even supposing the land to be entirely free from weeds, will prove very beneficial. The earthing-up helps to steady the plants. It is also an advantage to tread or roll the ground firmly before planting, as, if the soil be very loose and light, the first rough wind in the autumn will often blow them almost out of the ground. In light soils, and when the previous crop, say such as winter Spinach or winter Onions, has been well manured, I have often found it best not to dig the land at all, but to plant when it is softened by rain. This useful vegetable can be had in season for at least five months, being as hardy as most of the Brassicas, and the variety above named has succeeded well with me, each plant being furnished with large handsome sprouts.—A. HARDING.

#### THE USE OF FIRE HEAT FOR GRAPES.

As "SINGLE-HANDED" says on page 317, facts must be dealt with, and mere assumption left out. It is now sixteen years since I grew a house of Grapes without fire heat, and that was twenty or thirty miles south of London. The Vines were allowed to start of their own accord. Sun heat was turned to the best account when the Vines were in flower, and every advantage was taken of closing the house early. I cannot call to my recollection what the temperature was during night, but I am sure it was never as low as 36° or even 40° from bud-swelling onwards. The setting was generally similar to other houses where fire heat was employed. If there was any difference the fire-heated house had the advantage. The produce of the unheated structure was what would be termed passable, but not to be compared to the adjoining house with fire heat from starting. The Grapes in the former house were very late in ripening, and about one-fourth of them damped-off in the late autumn. The varieties were Black Hamburgh and Black Prince.

I consider it a very simple matter to set Grapes without fire heat provided the sun shines for a couple of hours in the middle of the day when the Vines are flowering. By giving the rods a few strokes with the hand the pollen flies, and the setting is almost instantaneous, and not, as many suppose, a slow process. Anyone that has paid attention to a few individual berries the day after the operation will see they have doubled in size—a sure sign the berries are set. Stoning is another subject.

I can see no reason why Grapes cannot be grown without fire heat, or even a vinery, if the climate is hot enough. We might even have Pines without it; but it so happens our climate is not warm enough, although the setting of Grapes can be done. For growing them to perfection in our country they must have fire heat rather strong (65° for Hamburgh and Sweetwater, 70° for Muscat and lates) or else, I fear, disappointments would be common. In my opinion "SINGLE-HANDED" strikes the nail on the head when he says saving a ton or two of coals in spring or summer, to be compelled to burn as much or more to no purpose in autumn, is not economy. How Mr. Simpson managed to carry off first prize in the summer for two bunches at Sheffield with Alnwick Seedling grown without fire heat surprises me, and also, I daresay, many more. If I am rightly informed this is as late a

Grape as Lady Downe's. In that case, if there was any competition, his principal point was wanting, whatever other points he had. It is a great mistake to give a prize at any show to unripe fruit, let its appearance be what it may. The proof of the pudding is the preeing o'd.—A HIGH TEMPERATURE COMPETITOR.

I HAVE been favoured with some further particulars respecting the Grapes at Longleat mentioned last week as having been grown on the cool system, and send them with this. They are kindly furnished by Mr. Taylor himself on request, and his statements may possibly cause those of your correspondents who are committing themselves so positively against the cool system to reserve their opinions for the present. There is more to be said on the subject evidently. Thomson's book on the Vine is my authority generally on Vine culture, and may be said to reflect general practice fairly; and I find Mr. Taylor's temperatures are very far below Thomson's, and yet he grows and ripens splendid Grapes in good time.

#### "SHADE" TEMPERATURES FOR MUSCATS, &c.

For starting.	Flowering period.	After flowering.
An almost even temp. of about 55° night and day.	57° to 60° night. 65° to 70° day. 75° to 80° sun.	63° to 65° night. 70° to 73° day. 80° to 85° sun.

"The above is something like the instructions given to my young men for temperatures for Muscats and thick-skinned Grapes; but I do not pay so close an attention to figures as most people do, and am more afraid of high temperatures than low ones. I do not know anything about the cost of the stewing system, having never practised it. Were my house a lean-to and facing south I should be content with a minimum temperature of 55° at all times; but with large panes facing east it is a little more difficult to manage the ventilation at sunrise, and rusty berries are apt to follow if there has been much rise before air is given. I am a cool-system man, and it will be found on reference to the *Journal of Horticulture* for 8th January, 1874, 2nd July, 1874, 6th August, 1874, and 25th March, 1875, that I have always advocated what is called the cool system.—W.M. TAYLOR, Longleat Gardens."

Assuming Mr. Taylor's Grapes and temperatures are a fact it is as plain as any simple subtraction sum, from the above figures and statements, that Grapes of the best quality can be produced by the cool system, and at a great reduction in the cost of fuel.—CORRESPONDENT.

#### LIQUID MANURE FOR FERNS.

HAVING been in the habit for several years past of applying the above to Ferns, I can endorse all Mr. Gilbert has said about it. The liquid used here is from a farmyard tank, and is applied in a weak state about twice a week. We have some specimens of *Adiantum cuneatum*, *A. farleyense*, and several others that have not been repotted for three, four, and in one or two instances for five years. All these plants are in excellent health, which I attribute mainly to the watering with liquid manure. Small Ferns that are used for dinner-table decoration are often compelled to be grown in very small pots, and for such plants liquid manure is especially valuable.—W. W.

I CAN quite endorse what Mr. Gilbert says about giving Ferns liquid manure, as I have practised it for a number of years; it produces wonderful results on all *Adiantums*, particularly *A. farleyense*. We divide most of our *Adiantums* every second year, when they receive only clean soft water until they have well filled their pots with roots. When the first fronds have been cut and the succeeding fronds not quite matured, and perhaps rather delicate in colour, which is mostly about the month of July, we commence supplying weak liquid manure. The liquid is taken from what is made up for the *Chrysanthemums*, a mixture of sheep's and cow's manure and soot. The next year we commence supplying the liquid manure as soon as the young fronds start growing. I have used ammonia for Ferns with success. The quantity I used was as much as would cover a shilling to a quart of soft water. We purchased it as a powder, in appearance like nitrate of soda, however. My reason for discontinuing it was, I thought, it had too much of a forcing effect. *Lycopodiums* in my experience do not require liquid manure.—H. ELLIOTT.

JASMINUM REVOLUTUM AND EUONYMUS NEAR THE SEA.—Passing through West Brighton recently we saw a very fine plant of the old *Jasminum revolutum* climbing up the front of a house, and in its progress upwards entwining itself in a graceful manner amongst the

large balcony, thus presenting an elegant appearance, and its value as a climber and adaptability for seaside planting. Notwithstanding the severity of the past winter the Euonymuses seem to flourish as vigorously as ever in Brighton. We noticed a number of large plants of *E. japonica* measuring fully 6 feet high and of proportionate width in a flourishing condition.—A CORRESPONDENT.

#### FRUITS FOR THE NORTH.

I QUITE agree with Mr. Iggulden that brief notes about fruit crops from different parts of England are interesting, but we want also to know what Apples and Pears and other fruits can be profitably grown in the very variable climates we have in England. As there are many sorts which suit the warmer and sunnier southern parts of our island which do not do in the north and east and north-eastern districts, I venture to send a few notes from the North Riding of Yorkshire. Soil light loam, with a substratum of pure sand, which is moist, but not wet. My garden slopes slightly from south to north, and it has nowhere the advantage of a south aspect. We are about twenty miles from the sea, and the sea breezes are tempered before they reach us.

Apples, as a rule, have been very abundant here this year, and in the greatest part of this district; but I cannot say the same for Pears or Plums, and I hardly ever saw such a scarcity of Apricots, which are grown very much on the cottages of many of the villages in this neighbourhood. Though there has been a great crop of Apples on the commoner and hardier trees, such as Keswick Codlin, Cockpit, and Improved Cockpit (Apples much grown in Yorkshire), Scotch Hunthouse, Dumelow's Seedling, Warner's King, Lord Suffield, &c (the two latter more recent introductions), yet I do not think the quality of the Apples is good. The spring was backward, then we had an unusually dry time during June and July, when the young fruit ought to have been growing, followed by very wet weather from the 6th of August to the end of September, which was also very dull, with a very great lack of sunshine. This made the Apples grow, but they ripened slowly, except in favourable situations, and many of the Pears cracked, especially on standards and bush trees.

I append a list of Apples, Plums, and Pears, which I planted against a west wall and as espaliers in a fresh piece of ground, which was added to my kitchen garden in 1875, and planted in the spring of 1876. From some of these I have never had a fruit—namely, Peasgood's Nonsuch, which is a very beautiful Apple, but an uncertain bearer; Gloria Mundi, Tower of Glammis, Duchess of Oldenburgh, and Lord Burghley. Amongst the Pears Doyenné du Comice and Souvenir du Congrès, though against a south wall, and (especially the latter) have made very good growth, have not fruited; nor have Beurré Hardy, Beurré Superfin, or Thompson's against a west wall, or Beurré Hardy, Beurré de l'Assomption, or Fondante d'Automne as espaliers.

The Apples that came into bearing first were Lord Suffield and New Hawthornden, next to them Irish Peach, Margil, and Cox's Orange Pippin. Amongst Pears Zephirin Grégoire came early into bearing, and seems one likely from its hardiness to do well in the north. Amongst Plums Victoria, as is usually the case, was the first to bear; then came Angelina Burdett, which is only moderate as to quality, and Jefferson's and Washington, both the latter exceedingly good. Amongst older established trees I have generally found the following amongst Apples as the most to be depended upon for kitchen purposes—Keswick Codlin, and Lord Suffield its descendant, certainly one of the best and surest bearers, though a somewhat shy grower; then Warner's King, the two Cockpits, the Improved Cockpit being certainly a most useful Apple, and much in advance in point of size to the old one. It is also very good as a bush fruit. Dumelow's Seedling is a tolerably sure bearer, and a good keeping Apple; Alfriston, Old Hawthornden, and New Hawthornden; Glory of Kent, a very sure and prolific bearer with me, and of good quality; Reinette du Canada, Mère de Ménage, and one of the best, which is good also as a dessert Apple—Adams' Pearmain; an Apple which I used to know in Nottinghamshire as Pike's Pearmain. Blenheim Orange is a most uncertain bearer with me. I have it against a south wall of a barn, also against an east wall as a bush tree, an espalier, and as a standard, and they seldom have a good crop of fruit—not two dozen this year on all the trees.

Amongst dessert Apples Cox's Orange Pippin and the old Ribston (if only it would not canker) are the best; then comes Margil, very good, and a surer bearer; Irish Peach, which everyone ought to grow as the best Apple, a good bearer, and good also for cooking purposes; then come Wyken Pippin, an Apple which I am surprised is not more recommended, a very constant bearer, and of very good flavour; Court of Wick, Scarlet Nonpareil, Braddick's Nonpareil, Syke House Russet, Fearn's Pippin, Sturmer Pippin; and for early use Devonshire Qua-

renden, a rather shy bearer here, and Kerry Pippin, small but good. The same I may say, too, of the old Golden Pippin, which is only a shy bearer. There are several others here, both for baking and dessert, from which I get an occasional crop, but the above-named are the best—*me judice*.

Amongst Pears I am surprised so few have named Seckle in the occasional short notes; perhaps it is too small. It is a most hardy and sure bearer here, both as bush and standard, and I wish I had it against a wall, as it used to do well in my father's garden in Notts. The following Pears are fairly to be depended on—Citron des Carmes, one of the best early; Jargonelle, Williams' Bon Chrétien, Marie Louise, Louise Bonne of Jersey, Comte de Lamy, Eyewood; and for walls Winter Nelis, Gansel's Bergamot, Beurré Superfin, Beurré Bose. I have Beurré Superfin, Beurré Hardy, and Jersey Gratioli as bush fruits; but though some years they are good they are most uncertain. Beurré Diel is, in my opinion, not worth growing. Ne Plus Meuris against a south-west wall bears very regularly, but is not so good as further south. Beurré d'Amanlis against a west wall with me is much wanting in flavour.

Amongst Plums I find these are the best (I have about twenty sorts)—July Green Gage, Green Gage, Victoria, Washington, Blue Orleans for early tarts, Mitchelson's, Pond's Seedling, Jefferson, McLaughlin's Gage, Coe's Golden Drop, Transparent Gage, and for late use (when there is a crop) Reine Claude de Bavay. Transparent Gage is very good if left to ripen on the tree and if well protected from birds, which seem to be very partial to them. There are a few other Plums I have tried, as Petite Mirabelle and others, which seem to require a warmer climate than this. Except under glass Peaches, Nectarines, and Figs are hopeless as far north as this. Can anyone suggest a remedy to prevent the Moor Park Apricot from collapsing, as it so often does when on a south wall, whole branches dying off from the graft? I cannot help fancying that the stock on which it is grafted as a rule does not suit it. The following is the list above referred to:—

APPLES.—*West Wall*.—Two Cox's Orange Pippin, one Peasgood's Nonsuch, one Lady Henniker, one Worcester Pearmain, one Gloria Mundi, one Margil, one New Hawthornden. *Espaliers*.—Ribston Pippin, Cox's Orange Pippin, Wyken Pippin, Tower of Glammis, Lord Suffield, Warner's King, Dumelow's Seedling, Duchess of Oldenburgh, Lord Burghley, Early Margaret, Irish Peach, New Hawthornden.

PEARS.—*South Wall*.—Doyenné du Comice, Souvenir du Congrès. *West Wall*.—Beurré Hardy, Beurré Superfin, Thompson's, Beurré d'Amanlis. *Espaliers*.—Zephirin Grégoire, two Beurré Hardy, Beurré de l'Assomption, Fondante d'Automne.

PLUMS.—*South Wall*.—Transparent Gage (Jefferson), Oullins Golden, Jefferson's, Green Gage, Huling's Superb, Coe's Golden Drop, two Victoria, Washington. *Espaliers*.—Petite Mirabelle, Angelina Burdett, Denniston Superb, Jefferson.—C. P. P.

#### THE ARRANGEMENT OF CUT FLOWERS.

I AM inclined to think horticultural societies are the most to blame for whatever lack of taste exists in the arrangement of flowers, as in any schedule you will either find bouquets and table decorations entirely excluded, or such small prizes as 7s. 6d. or 15s. offered for a bridal or ball bouquet; rarely, if ever, does it exceed £1 for a stand of cut flowers, which to obtain a place must contain examples of the choicest flowers. Is it likely any gardener will cut his best flowers for the money, much less arrange them? Again, gardeners and nurserymen are often obliged to compete together, and what gardener is there that would exhibit if there was a chance of Cypher, Wills, Jones, or Hans Niemand competing against him?

There is often a complaint of the absence of novelty displayed in the decorations of the present time. It is suggested that tables for competition should be laid by the Society, the competitors engaging solely in the arrangement of the flowers. There is no doubt we should see more taste displayed by that plan, the exhibitor having more time and less anxiety.

Cut flowers are very attractive at exhibitions, for around them you will always find the greatest crowd, and in neglecting ample provision for the florist in the schedule the society does itself harm. Too much praise cannot be bestowed on the managers of such societies as make liberal provision for the decorator and bouquetist. I hope to hear more on this subject.—EXHIBITOR.

PLEIONE WALLICHIANA.—This is a lovely little Orchid. It is now flowering freely, and will continue so about two weeks. It is a deciduous Orchid, flowering after it has shed its leaves. The flowers are borne singly on a stem 4 to 5 inches in height; flowers rich rose in colour. Both this species and *P. maculata* are easily grown. Any

ordinary stove house would be suitable to grow them in. Many persons object to them because of absence of leaves at the time of flowering, but this is an evil easily remedied by arranging them amidst dwarf Ferns.—S. G.

#### A NEW TESTIMONIAL FOR THE EARTHWORM.

It had been already shown conclusively by several naturalists that the common earthworm is a creature which really renders services to horticulture that quite overbalance the small amount of damage it is occasionally guilty of. To the illustrious Dr. Darwin it has offered a subject that is particularly suited for his patient inquiry and shrewd observation, the results of which, embodied in his little work upon "Vegetable Mould and Earthworms," offer a final testimonial in behalf of a despised, or sometimes persecuted, annelid. The main facts, however, are new. We were aware that earthworms are of utility, because in the course of their life they consume decaying vegetable matter and convert it into humus or mould; also that by their burrows they help to bring about a wholesome drainage, preventing the surface becoming caked or hardened. Dr. Darwin, with an enthusiasm that we cannot wonder at, believes it is to the earthworm principally that the destiny has been assigned of renewing the face of the earth from year to year, and from age to age. In a single year, so he reckons, where the earthworms are in their average abundance, they deserve the credit of producing about ten tons of good mould upon an acre of land. This represents labour performed during only half the year, for earthworms do not generally busy themselves during the severe weather of winter; and of the ordinary day they devote the larger portion to repose, night being their time of activity. A scorching sun of all things they appear to dread, and in dampness they particularly luxuriate.

The earthworm, so this naturalist fancies, has its share of intelligence lodged somewhere, perhaps in the cerebral ganglia he has examined, for it constructs and lines its burrows in a very methodical way, shows also much judgment in the mode it adopts of drawing leaves into these according to their shape and size, and it has preferences for certain foods. They eat much, digesting what they swallow by the aid of a singular alkaline secretion, then ejecting the most of it for the benefit of the soil. Everyone is aware that stamping upon the ground makes the worms quit their holes, but, nevertheless, Dr. Darwin thinks they are deaf as well as blind, they are alarmed through the sense of touch. The popular belief that associates worms with the decomposition of dead bodies has nothing of fact to support it, their food being purely vegetable. "They remove decaying leaves, facilitate the germination of seeds and the growth of plants, and create for us most of our wide, level, turf-covered expanses."—C.

#### RESPONSIBILITY OF GARDENERS.

YOUR correspondent "SINGLE-HANDED" is quite correct in stating, on page 341, that plants are easier to cultivate when planted out than when grown in pots, but it does not follow that the reason he gives for plants in pots in a large garden mentioned not being so healthy as those planted out is the correct one. It would be quite as sensible a proposition to state that because the pot plants in many small gardens are not well grown, nor the gardening generally high class, that there is too much to do for one pair of hands; and that, therefore, the gardener who has a large place to superintend with a sufficient number of hands to carry out his orders can do the work in higher style. Some of the very best gardening is to be found in large gardens, the very worst in small ones. Selecting isolated instances is a loose manner of discussing a question. If it is granted, then, that the highest class gardening is to be found in large establishments, and that the average is higher in these than in small places, there is a reason different from that your correspondent finds. A gardener in a small place who passes everything through his own hands, if attentive to his work, must of necessity grow plants well. A gardener in a large place, as attentive to his work as the man in a small one, will be quite as successful and have much more to show for the labour he expends.

Personally I should find it much easier to do everything myself were I able to overtake the work than entrust it to subordinates, as I am obliged to do; but I do not imagine the work would be

any better done on the whole than it is at present. The task of superintending a number of men is very wearying and not so interesting as engaging in it oneself; nevertheless, it is the work which falls to gardeners in large gardens, and I think it is in that many gardeners fail who otherwise are quite competent. I make a point to show the workmen how I wish work done. I would as willingly take a shovel and show a young man how to stoke a boiler furnace, or the furnace of a flue, as I would show him how I require Grapes to be thinned. I have everything, to the planting of Cabbages, performed according to my own instructions; and although this requires much interference with the work, which I have no doubt young men often do not like as appearing to them only slight and trivial, it is upon doing these trivial matters well that all successful gardening depends. Had your correspondent's labourer been thoroughly drilled to the work the said poundsworth of Orchids would have been saved.—A MANY-HANDED GARDENER.

#### PLEIONES.

PLEIONES, or Indian Crocuses as they are sometimes termed, will very shortly assist in rendering the Orchid house gay. The three species that are most popular and the easiest to cultivate are *P. Wallichiana*, *P. lagenaria*, and *P. maculata*. They will have shed their foliage, and the flowers will have advanced, springing up as they do from the centre of the young growths. Pleiones are generally grown in shallow pans, and it is surprising how pretty those pans can be made to look with the assistance of a few seedling Ferns. I have practised this method for some seasons.

Fig. 64.—*Rondeletia anomala*. (See page 374.)

When the foliage has fallen from the pseudo-bulbs I collect some small seedling Ferns, such as *Adiantum cuneatum* and *Pteris serrulata*, and prick them in amongst the Pleiones, and in a few days the Ferns look quite fresh, provided they have been taken up carefully. After the Pleiones have flowered the Ferns can be removed. These small Ferns answer two purposes—first they conceal the material in which the Pleiones are grown, and secondly they show the flowers off to greater advantage. *P. Wallichiana* is the first of the three to flower; the flowers of this species are very pretty, but only second-rate compared with the two latter. The flowers are extremely useful in bouquet-making, and anyone that has visited the central avenue in Covent Garden about this time of the year could not fail to admire the way in which the charming little flowers are employed in making elegantly arranged bouquets. Like many other plants as well as

Orchids, Pleiones, through being deciduous, are often neglected to such an extent that satisfactory results are not obtained. The two chief requirements are encouragement during growth and a good season of rest without allowing the compost to become excessively dry. With judicious attention to these two matters I have never experienced any great difficulty in flowering them well. I think that the genus is one that will gain increasing popular favour as the merits of the plants become more widely known.—W. K.

WE observe by our advertising columns that our old correspondent, Mr. ALEXANDER SHEARER, late of Yester Gardens, East Lothian, has commenced business as a landscape gardener in Edinburgh. We are glad to know that Mr. Shearer's great experience and well-known abilities are not to be lost to the horticultural community, and we wish him all the success he so justly merits. We hope our northern friends will profit by the opportunity they have of benefiting by Mr. Shearer's services.

— "A. W., *Lincoln*," writes—"I would remind any readers of the Journal who are troubled with WEEDY AND MOSSY WALKS, that nothing has come under my observation so effective for the destruction of weeds and moss as gas water. We give all our walks one application annually about this time through a fine-roscd watering can, taking care that none is spilt on the grass. Moss and weeds are destroyed instantly, and a weed on our walks is a rarity till the following autumn, when another dose speedily disposes of them. Worms, which are so troublesome about this time of the year on the verges of the grass, will not come near their old haunts for the rest of the season. Giving off such a powerful odour of ammonia, the gas water should be cautiously applied near to living-rooms."

— RELATIVE to GRAPES AT THE EDINBURGH SHOW, our reporter writes as follows in reply to Mr. Simpson's letter on page 358—"I frankly apologise to Mr. Simpson for not having clearly stated that it was the Muscats which bore the marks of syringing. In other respects I have nothing to say different from what I have already stated. The faithfulness of the report remains notwithstanding that slip. As the Grapes lay on their boards at Edinburgh I reported on them, and no after-writing, either one way or the other, will alter their condition as seen at that time. I decline further to take the evidence of other Grapes sent to the office in Fleet Street as invalidating statements made on Grapes shown publicly a fortnight earlier."

— A GLOUCESTERSHIRE NOBLEMAN, owning large estates is making a novel EXPERIMENT TO RENDER LAND MORE REMUNERATIVE. He has planted thirteen acres with Gooseberry and Currant trees, eleven with Strawberry plants, and thirty-five acres with Plum trees, while a large portion of park and wood, of two hundred acres, have been converted into rabbit warrens, and surrounded with iron fencing. The erection of a jam factory is contemplated.

— AT the Essex Quarter Sessions, before Sir Henry Selwin-Ibbetson, a curious case was tried from Barking. Joseph Hale, William Preest, and Ruth Preest were charged with stealing 56 lbs. of Grapes, the property of George Phillips. Mr. Fulton, for the prosecution, said the law did not permit an indictment for stealing growing Grapes, and the Grapes in this case were cut from the Vine. The prisoners, however, were also charged with stealing the scissors with which they cut them. This charge was established, and Hale was sentenced to two months' and the two Preests to one month's imprisonment each. "In this case,"

remarks an evening contemporary, "ignorance of the law has helped to vindicate it; but as matters stand it would seem that rogues may cut as many Grapes as they please, if only they take the precaution to use their own scissors, or, at all events, not to take away those they borrow. The sooner the law is amended in this and similar points the better for the interests of justice. Why it should be a punishable offence to take a bunch of Grapes from a fruiterer's stall, and yet be no offence to take them from the hot-house in which they are grown, it would, we think, be rather difficult to explain."

— WE regret to announce the death of Mr. J. C. NIVEN, CURATOR OF THE HULL BOTANIC GARDEN, which occurred on the 16th inst. Mr. J. C. Niven was the son of Mr. Ninian Niven, for some years Curator of the Glasnevin Botanic Gardens, and was born at Dublin in 1828. He was educated for the medical profession, but disliking that he commenced a gardening career at the Belfast Botanic Garden in 1843. Thence he went to Dalkeith, and afterwards to the Royal Gardens, Kew, where he held a position of some importance. In 1853 Mr. Niven was by the influence of Sir William Hooker appointed Curator of the Hull Botanic Garden, which position he retained to his death. He paid much attention to herbaceous and alpine plants, and an extensive collection was formed under his care. Mr. Niven also delivered many courses of lectures upon botany in connection with several of the local scientific societies.

— THE following GARDENING APPOINTMENTS have been recently made—Mr. C. Slade, late gardener to A. B. Knight, Esq., Downton Castle, Ludlow, succeeds Mr. Hossack as gardener to the Marquis of Hertford, Ragley Hall, Alcester; Mr. Hossack succeeding Mr. Sutherland as gardener to Lord Lanerton, Castle Howard, York. Mr. J. Wilson, late gardener to R. W. Gaussen, Esq., Brookman's Park, Hatfield, has been appointed gardener to C. J. Nairn, Esq., Temple Guiting, Winchcombe. Mr. H. West, late gardener to H. Hoskier, Esq., Solna, Roehampton, succeeds Mr. Fairweather as gardener to Edmund Wright, Esq., Halston Hall, Oswestry; and Mr. A. Taylor, late gardener to Lord de Mawley, Langford House, Lechlade, has been appointed to succeed Mr. W. Patterson as gardener to J. Conyers, Esq., Castle-grove, Headingley, Leeds.

— AT a General Meeting of the FINSBURY PARK, HORNSEY, AND WOOD GREEN AMATEUR CHRYSANTHEMUM SOCIETY, held on Thursday, 6th October, 1881, a discussion took place as to whether an exhibition should be held this year, and a Committee was appointed, consisting of Messrs. Nobbs, Rundell, and the Secretary, to investigate and report generally on the Society's position. A special general meeting was held on Tuesday, 11th of October, 1881, to receive the Committee's report, of which the following is an extract:—"Your Committee have to report that after due deliberation they have reluctantly arrived at the conclusion that no exhibition should be held this year. The cost of printing, advertisements, &c., and other expenses attending an exhibition would exhaust the whole of the funds in the Treasurer's hands and leave a deficit, consequently the fund for prizes would be small and totally dependant on the sale of tickets and admission money; this would dissatisfy those gentlemen who might exhibit, and thus injure the Society. It is unlikely that members would care to press their friends to take tickets, knowing that the exhibition would not compare even with that of last year. For the reasons above stated your Committee therefore submit—1st, There be no exhibition for 1881, and that the funds, after payment of expenses, be carried forward to next year's account. 2nd, That to ensure a good exhibition for 1882 classes be opened for gentlemen's gardeners, with a good prize, and that this be announced as early as possible. 3rd, That the advertisements appearing in the Society's schedule for this year be renewed next

year free of expense. 4th, That the number of meetings be increased, so that the members may have more opportunities of discussing the objects of the Society. In conclusion your Committee express a hope that the next year's meetings will be more fully attended, and that the members will take greater interest in its objects, and endeavour to obtain growers, thus insuring the Society's success." The above was, after some discussion, adopted and ordered to be sent to members of the Society. Mr. W. E. Boyce, 14, Gloucester Road, Holloway, N., is the Hon. Sec.

#### WINTERING STRAWBERRIES IN POTS.

VARIOUS methods of preserving these from frosts are, according to circumstances, adopted, and no doubt in the majority of cases with satisfactory results. In the open ground healthy plants are seldom injured by severe frosts, but the best roots of those in pots are at the sides, and liable to be injured in the winter; or if they are not, the pots, owing to the expansion of soil when frosted, are liable to crack. This demonstrates the necessity of protecting, but not, however, of coddling. They are too often stored away in pits and frames, and rarely if ever watered till transferred to their fruiting quarters. At one time at least half the stocks of plants were wintered in a heated pit here, and but little further trouble taken with them. The consequence was a weakly start, then a bad outbreak of green fly, followed later on with a plentiful supply of red spider. This will not happen again. All that is really required is to protect the pots and roots from frosts, as rains will not hurt them. If well drained there is no fear of injury by excessive moisture, and dry at the roots the soil should never be. At the same time, if it can be avoided, I do not believe in subjecting them to extremes of any kind, and for this reason shall fill two rough shallow pits with leaves in which to plunge the Strawberries, covering them with large old lights when necessary. Had I not these old pits (which are, besides, extremely useful for forwarding vegetables in the spring) I should enclose an open dry space with boards, form a good clean bottom with ashes, and, as the Strawberries were stood in, work more ashes round the pots till the rims were nearly buried. The frost must be exceptionally severe if they are at all injured in such a position; but they can easily be protected with dry fern or litter when severe frosts are expected.—W. IGGULDEN.

#### A RUN TO THE WEST.

THE grand view from the terrace at Marston terminates in a range of tree-clad hills, the ridge resembling a rugged wall of foliage far as the eye can reach; but in it there is a distinct break as if a giant had hewed his way, like cutting through a hedge and leaving a sharply outlined gap. "Do you see that break in the trees?" asked Mr. Iggulden, pointing across the valley below us, and continuing, "that is Heaven's Gate where Bishop Ken composed the Morning Hymn; it is four or five miles distant, and there is something worth seeing below it buried between the hills." Driving from Marston by moonlight, about two miles through a park-like country, where ever and anon large trees cast their dense shadows across the road, with a fine expanse of well-timbered and undulated tract of pasturage on each hand, and still more shadows, something like a substance was seen ahead as if obstructing the road. Formidable the barrier looked under the deceptive light, but as we approached it the apparent difficulty, as difficulties often do when faced, began to vanish; the mass was found easily vulnerable, and we entered the domain of

#### LONGLEAT.

Passing through a portion of the well-kept woods we reach the park proper, in which a little further on the grand old mansion stands, a square massive pile, where it has stood for three centuries, and is apparently little the worse for wear. There are no palisades nor sunk fence, at the least on two sides of it, to separate it from the park, but all is open, grand, and free; a curving lake is near, and noble trees tower above and surround us. But we pass on through the avenue of stately Elms; the lamp of night is a magnifier of a scene like this, and we will see it on the morrow; to-night our quest is the gardener's cottage. We find it, a mile distant, a humble happy home.

"What!" is someone prompted to exclaim; "does a man so famed as Mr. Taylor is, the gardener at such a place as this, dwell in a humble cottage? We should have thought he had a handsome Gothic villa, or pretty mansionette." Stay; you do not quite know the man, though his writings tell plainly enough that he is no dandy, and he will not be ashamed that you should know his cottage is

an extremely humble one. He might have had a different dwelling, but he prefers his plain commodious and convenient home where his children were born and trained, and where, from the knoll on which it stands, he can look across a narrow paddock and see over the gardens, with the grand vinery which he created full in view.

The moonlight drive and the evening's chat are over, albeit the latter was a long one and pleasant. How often I have heard words to the following effect, and with which others of my readers are doubtless familiar. "Talk about 'women's tongues,' they are nowhere against gardeners' gossip. Once let two or three gardeners get fairly set to, and what with Grapes, Potatoes, plants, potting, pruning, pinching, stopping—their great results and small conveniences—they never know when to leave off; they will 'pinch' themselves of rest, 'stop' all night, and talk the best of 'talking women' to sleep." Never mind who is the author of that sentiment, it has a hundred authors probably, and I dare not say it does not contain truth; but it at least testifies to the existence of a great fact—the earnestness with which gardeners pursue their calling, their anxiety to learn all that is possible connected with their duties, and their willingness to impart of their knowledge to those to whom it may be of use. But for this devotion to their business, this friendly interchange of knowledge and recounting of experiences, British gardeners would never have attained to the position they occupy, not in this country alone, but abroad, where I know from some experience how highly they are estimated as cultivators and how greatly they are respected. Let us then endure the above reproach, or rather enjoy the compliment, and go on working by day, and talking and teaching by night; yet let not those who are absent from home forget there may be "somebody waiting."

But to resume. My night at Longleat ended. It is daylight now. We are in the garden, and having written a paragraph for gardeners' wives, hundreds of whom I know read gardening papers, I will endeavour to write something for gardeners, for I found, what Mr. Iggulden predicted, "something worth seeing."

It must be a plain matter-of-fact narrative, as anything having the semblance of undue praise would be decidedly obnoxious to the very practical gardener whose works I must notice. I will therefore tell the truth in soberness. First of all it is the simple truth to say that Mr. Taylor does all that he writes about, and more. Kitchen gardening, hardy fruit culture, Grape-production, Rose and Carnation culture, winter-flower growing, forcing in spring, and flower gardening in summer, are all done well. Everything, too, is done with an object. The wants of the family are known, and met in the best manner possible. No fancies are indulged in, nor space occupied uselessly. That which is serviceable is grown largely, that which is not of service is not attempted. Mr. Taylor has the reputation of being a good thrower-away. However great a reputation anything new may have, if it does not after a trial surpass the old it is promptly discarded. It does not suffice that it wins and even merits the approval of others, if it does not meet the requirements of Longleat away it goes. It will be readily understood that not many varieties of either plants, fruits or vegetables are grown. Many of a few is the governing principle, not a few of many. For instance, instead of growing a bushel each of forty varieties of Potatoes, he prefers having forty sacks of two varieties; instead of having forty rows of Peas all different, he prefers ten rows each of four proved varieties; instead of having a hundred Vines in the great vinery, as he easily might, and twenty varieties, he is content with just fourteen Vines and five varieties; instead of a "collection" of Zonal Pelargoniums for winter he only wants two varieties, one of which is fixed, the other not quite determined; instead of a dozen or more varieties of Carnations for winter to meet the great demand, he only has three sorts that he knows can be depended on. Such is the policy adopted, and who can say it is not a sensible one? It will be convenient and perhaps useful to refer as briefly as possible to the more prominent features and objects under separate heads.

#### THE KITCHEN GARDEN.

About five acres are enclosed, and it is difficult to find a rod of level ground; it is all hills and hollows, but apparently fertile, burnt clay and lime having been employed with great effect. Besides an early Potato the Scotch Champion is exclusively grown, and yields at the rate of 160 sacks, or 16 tons, per acre. Never have I seen the Champion so good as from this garden, the tubers being white, floury, and delicately flavoured. No other is desired in the Longleat dining-room. Besides its good cropping and disease-resisting character it is found to be the best weed-exterminating crop in existence. Mr. Taylor finds it a real twitch-killer, and employs it for reclaiming outlying neglected land matted with twitch or couch, and points to results with satisfaction. This is a new virtue of the Champion and worth recording. By growing the following Peas—William I., G. F. Wilson, Veitch's Perfection, and Ne Plus Ultra, superior produce is obtained as early and as late as possible, and no blank in the supply. Summer Spinach is grown for winter, indeed for all seasons, and so on throughout the routine: when the best of everything is found by trials, that is adhered to.

#### HARDY FRUIT.

Some deviations from the popular track are found here, but not without experience of other systems. Mr. Taylor has had the advantage of being trained under some of the most famed cultivators, and is practically acquainted with all methods of fruit-tree manage-

ment, and if he departs from either time-honoured practices on the one hand or fashionable modes on the other, it is not without good reason, as the results show. Being severely practical the great object in view is an abundant supply of fruit of the best quality and at the least cost. He has abandoned the plan of purchasing trained Peach trees and growing them on the good old fan-shaped system. He admits this system is good to a certain extent, but is well satisfied he has found a better. He now plants maiden trees, trims off the weak twiggy side growths, but does not shorten the leader. The trees are planted 4 feet apart, the leader trained upright, and the side branches herring-bone fashion. Every portion of a lofty wall was covered in less than four years, and the crops of fruit from base to summit are, so a first-rate judge tells me (not Mr. Taylor, though his word would have sufficed) remarkable. This is decided upon at Longleat as the best, cheapest, quickest, and most profitable mode of Peach culture for open walls. In reply to a question as to how long such trees would last, the answer was, "I don't know; but if they were worn out now (which they certainly are not) they have more than paid for the cost of purchase, space, and labour, and new trees can be bought for a trifle and prepared when these show signs of exhaustion." A north wall is covered in a very complete manner with Plums that afford valuable successional crops to trees on warmer aspects. There is no vacant space at the lower part of the wall, and to obviate this, the trees being fan-shaped, they have been planted closer than usual, yet "the lower branches will go some time; they always do," is the firmly expressed assertion of the cultivator.

Some Apple and Pear trees are grown as bushes but not pigmies; on the contrary, they are some 15 feet high and nearly as much in diameter and bear bushels of fruit; but for maintaining a large Apple supply orchard standards have a decided preference well planted and not pruned.

#### PEAR VERSUS QUINCE STOCK.

And now to Pears on walls. "JOHN BULL" (page 327) threw a bomb in the camp of the great Quince stock brigade, and no one need be surprised if it has a disturbing effect and the fire is returned. That bold individual has presumably not seen the cordons at Holme Lacy, Barham Court, and the young fruitful trees at Oldlands. It is fair to him, however, to state that he does not stand alone in his good opinion of the Pear stock. It so happens there are some Pear trees at Longleat that would gladden his eyes—a tree of Glou Morceau especially that covers a length of more than 60 feet of wall, the branches being perfectly trained and wreathed with fine fruit from base to extremity. The produce of this tree must certainly be computed by bushels, but how many bushels I dare not guess; and the tree is not alone. Whether it is the example of these fine trees exclusively, or whether Mr. Taylor is in possession of other evidence that has impressed the value of the Pear stock on his mind, I know not; but the fact remains that in planting a new wall of Pears, or rather an old wall, with young trees two years ago he would not have one tree on the Quince. Some burnt clay and lime was worked in the soil of the border and the trees planted. "And what have they done?" may be asked. Truth compels the reply that they have done splendidly. "But when will they bear?" will be the natural retort. Some of them are bearing now, and all are forming fruit buds. "And what of the fruit?" I must record the simple fact and say that finer has seldom been seen. When I described the fine trees and wonderful fruit grown by that skilful cultivator Mr. Haycock I had no occasion to exaggerate, nor do I write incautiously now when I say I have never seen Bergamotte Esperen surpassed, if equalled, as now growing on Mr. Taylor's young trees on the Pear stock. The trees, however, would not have done equally well in all soils, and it will not be wise, satisfactory as their condition undoubtedly is, to regard them as affording conclusive evidence of the general superiority of the Pear over the Quince stock. I have done my duty by stating a fact and recording a caution, and there I leave the matter, which is evidently not yet fairly beyond the region of debate.

#### GOOSEBERRIES.

Gooseberries are about as much valued as Grapes at Longleat, and the "Gooseberry house" cannot be passed in silence. The border on the north side of a wall is planted with the bushes. A row of posts 8 feet apart and about 4 high are affixed next the wall, a strong batten running along the top of them, rafters resting on the top of the wall, and on these front posts, all firmly secured, form the skeleton of the house, which is covered—sides, ends, and top—with strong small-meshed galvanised netting. A door at each end next the wall affords access, and the trees can be attended to with comfort, and birds are completely baffled. The back wall is covered with Gooseberries, Currants, and Cherries, and a Plum is being trained up each rafter. Caterpillars are no longer a source of trouble, as they are easily subdued with Fir-tree oil. This insecticide, however, it may be said parenthetically, to be safe and effectual should be mixed with soft water. By the excellent plan just described an abundance of Gooseberries over a long season is maintained. Healthy young bushes are also grown in the open, and Mr. Taylor finds that, however virulently they are attacked by the caterpillars, if the bushes are removed to a distant part of the garden the pest does not follow them.

#### GLASS STRUCTURES.

Passing a long range of the olden time, in which old Vines, also Figs and Peaches, are grown and afford useful crops, we find three

ranges of very useful half-span structures, each upwards of 100 feet long and 18 wide. These are devoted to Cucumbers, Melons, Tomatoes, and the forcing generally of flowers, French Beans, and Strawberries. Cucumbers and Melons, like the Vines, are grown on the extension system. Two Melon plants fill a house, and continue growing and bearing the whole season. The standard variety is the Cashmere, of which Mr. Taylor had the honour of sending to Kensington last summer, what was pronounced by the Fruit Committee of the Royal Horticultural Society, the finest flavoured Melon of the year. Tomatoes are grown in boxes, stood on the floor and trained on the hack wall, which is about 6 feet high. The variety is the Orangefield (true), which is esteemed the best of all in quality, and the plants are wonderfully productive. They are kept in bearing for two years, then thrown away and new ones raised from cuttings. A struggle has been going on with the Cucumber disease—that form attacking the fruit, and that it could not be conquered is proof of its virulent nature. The plants for winter are, however, looking admirably, the variety grown being the Baron Hill, which was raised by Mr. Gough, gardener, at Baron Hill, Anglesey, and is hardy, prolific, and good. In some of the houses a trellis runs from the floor to the apex of the roof, and there among other plants Bougainvillea glabra affords armfuls of flowers for months. Mr. Taylor points out there are two varieties of this—one having waved or slightly crimped foliage, the other having quite plain and smooth leaves; the former, he says, is the one to be grown, the latter being comparatively useless.

Strawberries are grown in large 32-size pots, in which they are layered from young plants. By this practice a gain of three weeks is claimed by the cultivator. I have seen quite fifty thousand Strawberries in pots this year, but those at Longleat are the finest. They are forced on the floor of the house and 5 to 7 feet from the glass, but the houses are very light.

Beans are grown in boxes or troughs, first on the sills, then on the floor. The boxes are filled with soil at once, and a row of Beans placed down the centre of each. Half filling pots and boxes, and earthing the plants afterwards, is regarded as quite useless work, inasmuch as no top-dressing induces the emission of roots from the stems. Fertilisers are employed for affording support, the plants are never stopped, and the variety is Oshorn's Forcing.

A few kinds of plants only are grown, and those in large batches. As from thirty to forty button-hole bouquets are wanted daily during the dullest part of winter, and these of fragrant flowers, provision has to be made for the supply. These "bouttonnières" are not the dainty gems the swells wear, but three large Carnations are required for each, and Tea Roses must be as large as Hybrid Perpetuals if possible.

#### TUBEROSES.

Hundreds of these are grown of extraordinary strength in a very simple manner. They are potted in spring in 6 and 7-inch pots, and placed on the floor of a vinery until growth commences; they are then plunged in a frame from which the lights are removed night and day through the summer, and are withdrawn as needed. The great secret of producing fine spikes and flowers is liquid manure, of which few plants can appropriate so much and give such quick and good returns. Stems are produced like walking-sticks, and flowers like Gardenias. This is a simple fact, and not a mere figurative expression.

#### CARNATIONS.

Nowhere that I am aware of are winter-flowering Carnations grown so fine as at Longleat. From four hundred to five hundred blooms are expected to be ready for the visit of the Prince and Princess of Wales in December. The three varieties relied on are Miss Joliffe, flesh pink; Belle Rose, cerise (this is the favourite); and Purity, white. Strong healthy cuttings are struck about March, and the plants, as soon as ready, are placed in 9 and 10-inch pots, intermediate shiftings being eschewed. Great care in watering is exercised, and the plants receive the same general treatment as Chrysanthemums through the summer. They are never stopped. At the present they fill a division of the large vinery, the growths, strong and luxuriant, being sustained by twiggy sticks. They are wintered in one of the intermediate span-roof houses, and continue growing and flowering until the summer. Simpler their culture could not be, but skill is required in the conduct even of simplicities, and finer plants have seldom if ever been produced.

#### ROSES.

How Roses are struck in the summer has been clearly described by Mr. Taylor, and largely practised. Plenty of plants are seen at Longleat as the results of it. How they are struck in the autumn was described last week; the results of this simple method, which is the best for amateurs, would surprise the inexperienced. Rapidly vanishing space precludes a description of the rows of yearlings, and it must suffice to say that those who carry out the instructions on page 350 may have some similar next year; this will be better than reading about the successful results of other cultivators. Tea Roses for flowering at Christmas are in 12-inch pots, the plants are 4 feet high and pruned as closely as if they were Hybrid Perpetuals. "Should you not have more flowers by training down some of the strong young growths?" was asked. "Yes," was the reply; "but they would be smaller, and we want them as large as Paul Neyron

if possible." Mr. Hinton (of Rose election celebrity) told me, and he ought to know, that blooms of Catherine Mermet especially are grown large enough for the back row of any stand in any exhibition. Tea Roses are grown outside against the back walls of the houses, and their luxuriant growth and the thousands of fine blooms they produce tell as plainly as Roses can express themselves how they enjoy a cool moist shaded northern aspect.

Gardenias are grown in pots, and as there is no mealy bug at Longleat the free-flowering plants are enhanced in value and beauty. But I must stop. I fully intended saying all I had to say in this issue, but the place is too much for me. A few other things merit notice, also the grand vinery; and of this I may say as an appetiser that taking the house and Vines together, such a sight is not to be

seen in Great Britain, and, unless I am greatly mistaken, a similar example of Vine-growing has not been achieved in the period—eleven years—by any cultivator in the Queen's dominions.—J. W.

### HONG KONG.

(Continued from page 316.)

HORTICULTURE, although it has accomplished a great deal, still cannot compare with English gardening. The nature of the soil is not by any means favourable to high-class gardening. Hong Kong is of igneous origin, and the soil is formed from very much decomposed syenite, containing but little humus. Gardening is

Fig. 65.—THE CEMETERY AT HONG KONG.

confined to small patches surrounding or near to the European houses, where some good vegetables are grown in the cool season, and where primitive dairies and poultry yards are maintained for the supply of the local market. Both eggs and fowls are very small as judged by the English standard, but they are tolerable. What, however, shall we say of the constitution of the Hong Kong cow? To judge by the milk which comes to table, either her solid flesh succumbs to the melting influences of the climate more easily than that of the foreigner, or else the place stands in sore need of an Adulteration Act. Plants in pots for the decoration of verandahs are in much demand, and where the employers look well after their Celestial gardeners the plants are pretty well grown. Where the gardens are of sufficient extent trees and shrubs give the most satisfaction, a great many varieties of which do very well and have a most attractive appearance. As an example of this we give the accompanying engraving, which represents one of the most picturesque portions of the cemetery.—A WANDERER.

ZYGOPETALUM MACKAYII.—This familiar Orchid is now rapidly coming into flower, and the plant is of easy cultivation. Its flowers

are most valuable for cut purposes, they last in good condition for some time after being cut. It will succeed in an ordinary stove house.—A SOUTHERN GARDENER.

### POTATO CULTURE.

As the subject of successful Potato culture is a very important one, I trust that the following particulars may be of use to your readers.

I have always adopted the much-abused system of planting my Potatoes a yard from row to row, and 2 feet 6 inches to 3 feet from set to set, which is steadily resisted by those who do not try it. My garden is a light soil on gravel. The ground intended for Potatoes, in fact all the garden, is laid up in the ridge in the autumn, at which time the manure is applied. I have not applied manure heavily, say from twelve to twenty loads per acre, and I have grown Potatoes on the same land for the last fifteen years in alternate years. There is one thing about which I am very particular—that is, not to grow weeds. In the spring the ridges are raked and the sets dibbled in. I am very careful

to have the sets, either properly grown old tubers or the larger Potatoes, cut by a person who knows how they should be divided.

Adopting this system I generally grow from three to four bushels to the rod. Now for the results of this year's cultivation upon this system. Upon three rods of ground planted with Magnum Bonums (Suttons' seed) I have five bushels to the rod. I weighed the first root taken up, which produced seventeen Potatoes, weight  $6\frac{1}{2}$  lbs.

Then I had twelve rods of Victoria Regents, of which three bushels and three pecks were grown to the rod. The only root which was weighed came to  $6\frac{1}{4}$  lbs. A single tuber on another root weighed 1 lb. 2 ozs. If I had been aware of the quality and quantity my man was lifting I would have been very particular in ascertaining more about them.

Some may say, "It is all very well to give these results of Potato culture on a small scale, but you cannot do the same on a large breadth." I am ready to join issue upon this. I have planted a field of four acres this year cultivated upon the same system, but they have not yet been taken up. There is a good crop, but they are not what I could wish, as the land has only just come into my hand in a very foul state, and in consequence I could not get the Potatoes in until late in the spring, and then the land was in a very bad state for dibbling-in the sets; still I shall have as many as my neighbours if not more, and I only had to plant half the quantity of sets per acre—a very important item in the cost of production. I have also used Lawes' artificial manure instead of the costly process of earthing London or other dung. The only drawback to Potato culture is disease. Even in this respect I have been very lucky. I do not always apply manure, but sometimes give a good dressing of lime. This year I have only about three bushels of Victoria Regents bad, and none of the Magnum Bonum. Last year, in a very poor stony soil without a very large quantity of manure, at a yard apart, I grew twenty-five bushels of the German Reds from a bushel and a half of sets without any small tubers amongst them.—GEO. BIDDELL, *Manor Office, Orsett, Essex.*

#### SCRAPS ABOUT FRUIT.

HAVING upwards of eighty acres of permanent orchards besides a large collection of young trees, I am very much interested in the culture of hardy fruits, and have been much pleased to read the varied experiences of your correspondents on this subject. I would, however, suggest that the information contained in their articles would be of much more practical utility if they in all cases named the district in which they reside. I find that many of the sorts they recommend are quite unsuited to our climate in Nottinghamshire; and if I now point out a few instances in which our experiences differ, I trust your correspondents will not imagine that I in any way call in question the soundness of their judgment. It is simply a matter of soil and climate. "A NORTHERN GARDENER" has hit on a rather ingenious idea as to the relative earliness of bearing in early and late season Apples, but I fear that our experience will point out as many exceptions as cases which prove his rule. The one which struck me first of all is Court Pendu Plat, or, as we call it in this district, Wollaton Pippin, a very late Apple, which bears most abundantly on the Paradise at three years old. New Hawthornden, which keeps till December or January; Sturmer Pippin, February to May; Northern Greening, April; New Northern Greening, Braddick's Nonpareil, December to March, are all examples of late-season Apples which bear early. On the other hand, Irish Peach, Red Astrachan, Mr. Gladstone, and Early Julien, all early-season Apples, do not with us bear freely as young trees. Newtown Pippin, mentioned by "ISLE OF WIGHT," requires a wall or orchard house here. Dutch Mignonne, as with your correspondent "R. P. B.," cracks here. Warner's King, said to keep till March, has only done so one season with us. It is usually over by November. It is none the less a valuable Apple. Manks Codlin, named as an early-bearing Apple, is perhaps more subject to American blight than any variety known, and Jolly Beggar is of very poor quality with us. Alexander, named as a market Apple, is grand when you can get it. With us it bears about once in four years; it has the great defect (in a market fruit) of weighing light. Fearn's Pippin is small for market, though a fair cropper. Doyenné Boussoeh Pear is with us one of the very best orchard Pears. It has borne good crops every season for the last six years. In size and form it corresponds with your engraving, but the quality is not equal to that ascribed to specimens from a wall, being a little coarse and gritty; still it is by no means despicable. Reinette du Canada Apple, recommended for orchard in North Yorkshire, bears very badly with us.—A. H. PEARSON, *Chilwell, Notts.*

CARLISLE CODLIN APPLE.—This variety appears to be but

little grown, the compilers of trade catalogues generally ignoring it. Yet it is one of the best of culinary Apples. It is specially suited to small gardens, as it is not at all robust in habit, in this respect differing widely from Keswick Codlin. It invariably crops well, and is the first of any Apple fit for use. We commenced thinning the fruit for tarts early in August, and we have now a quantity of excellent fruit, which will keep till late in December. The fruit are scarcely so large as the Keswicks, but they are brighter in colour, heavier, and bake and hoil beautifully. For Apple jelly they are preferred to Keswicks, the colour being superior.—W. IGGULDEN, *Marston.*

HUYSHE'S VICTORIA PEAR FOR PYRAMIDS.—We have been favoured with a good crop of this excellent Pear on a pyramid, and I have seen equally as good in gardens less suited to Pear culture than ours. It ripens at a time when good Pears are not very abundant—viz., in December and January.—SOMERSET.

DYMOND PEACH.—I am not at all surprised at the inquiry of "HAMPSHIRE CLERGYMAN" respecting the Dymond Peach. Some ten years ago I planted the following varieties—Early Alfred, Early York, Grosse Mignonne, Royal George, and Dymond (obtained from the nurseries of Messrs. Veitch, Chelsea) on a south wall. Of all the varieties enumerated above Dymond came into bearing first, and fine handsome fruit they were, not unlike Grosse Mignonne in appearance; and, though incredible it may sound, I gathered, during the five years I had charge of the trees, more fruit of the Dymond than from all the others combined. Some of the fruit figured successfully in the prize list at shows both in collections and single dishes. The chief characteristics of this variety are extreme hardiness, moderate but free growth, and its exceptionally free-setting propensities. The fruit usually ripens about the beginning of September. I may add that during the flowering period no other protection was given than a few spruce branches.—A. W., *Lincoln.*

THREE GOOD APPLES.—Galloway Pippin, Hambleton Deux Ans, and Dutch Mignonne, are worthy a place in every garden, the first-named growing to a large size. The first-named is good for dessert or kitchen use. With me it is somewhat a shy bearer. Hambleton Deux Ans is not quite so large, but a more showy fruit, the sunny side being prettily striped. It is an excellent keeper. I have kept fruits till July, and the tree is a good bearer; indeed, the one large tree here has not failed to carry a crop for the past six years. It is good for dessert and kitchen use. Dutch Mignonne is a smaller Apple, though none the less valuable, being good for all purposes. The few large well-shaped old trees here seldom fail to bring us some fine fruit. So pleased am I with these varieties that I have grafted from them on Crab stocks obtained from the immediate neighbourhood, my idea being that stocks would be likely to do better than if obtained from fresh soil. I also sowed some Apple pips last spring and have now thirty nice plants, some of which I shall graft, while a few I shall allow to bear, to prove the results from seed.—A. J. SANDERS, *Surrey.*

ECKLINVILLE SEEDLING AND COX'S POMONA APPLES.—"A COUNTRY SURGEON" says, "I intend ordering, among others, Ecklinville and Cox's Pomona Apples." I have them both, and find them, when compared with our standard varieties, wanting in size and productiveness, especially the former; they are also so mealy and dry and so soon decay that I would rather be without them. They may answer better on heavy clay soils; ours is light and poor.—J. TAYLOR, *Shrewsbury.*

TWO FIRST-RATE MELONS.—These are Victory of Bristol, scarlet flesh, and Hero of Lockinge, white flesh. The former was raised by Mr. Carmichael, and sent out by Mr. Turner of Slough. Fruit nearly round, above medium size, beautifully netted, and very handsome in appearance. Flesh bright scarlet, of good substance and excellent flavour. Plant of a strong hardy constitution, and free setter. Hero of Lockinge was raised by Mr. Atkins of Lockinge Gardens, and sent out by Messrs. Sutton & Sons, Reading. Fruit round, of a rich golden yellow colour, handsomely netted, and medium size. Flesh white, melting and delicious flavour. Plant vigorous and healthy, and sets its fruit freely. I have grown the above Melons both in houses and pits, and find them equally suitable for either purpose, and have the greatest confidence in recommending them.—T. LOCKIE, *Oakley Court, Windsor.*

BALDWIN APPLE.—This is a large, showy, free-bearing variety. As a pruned bush it has not failed to bear with me this last three

years. It, however, never finishes off to so handsome an appearance as those imported about Christmas time from America. As a culinary or dessert Apple to keep sound well till March or April it can be commended, and two or three trees in any collection of Apples cannot fail to give satisfaction. It forms natural fruit spurs freely. Has any correspondent fruited and ripened the Newtown Pippin satisfactorily in this country? and if so, under what conditions? In quality, as imported, it is first-rate, but it lacks the high colour of the Baldwin.—A. HARDING, *Peterborough*.

PEARS ON QUINCE.—On page 358 Mr. Robert Warner gives an instance in which Pears on the Quince stock turned out a failure on a stiff soil with a clay subsoil. My experience of the Quince as a stock for the Pear is on soil of a very different character—viz., a light, dry, sandy loam, with a subsoil of sand or porous gravel, underlaid at 2 to 4 feet from the surface by broken chalk and chalk flints. It is this, that if such a soil be enriched to about 18 inches in depth with any or all of the following materials—viz., clay, roadsilt, leaf mould, bog peat, sods of turf, and rotten stable or farmyard manure (by no means omitting one of these latter) Pears on Quince will succeed well, and may be kept in healthy and fruitful condition for an indefinite period by an annual mulch of the surface with a material which will add to the fertility of the soil, and at the same time tend to keep the root-run cool and moist in hot weather and warm in cold. A capital mulching material may be made by mixing stable or farmyard manure with any one or more of the following:—Spent tan, spent hops, cocoa-nut fibre refuse, leaves, hedge clippings, old weeds, and other rottable rubbish, grass cuttings from the lawn, and such like, letting them lie together in a heap for some time, and turning them over once or twice to mix and assist them to decay. A good way to apply the mulch is as follows:—Rake about 2 inches of the surface soil off from 2 to 5 feet all round the stem of the tree, according to the size and supposed extent of root-run, then throw about 2 inches thick of the mulching all over the uncovered space, after which the soil previously raked off may be thrown back again to cover up the mulching. February, March, or April is the time of year to perform this mulching operation.—J. E. EWING, *Eaton, Norwich*.

BEURRÉ DE L'ASSOMPTION PEAR.—I can confirm the experience of "LEADENHAM" with regard to this Pear. I had it when it first came over from France with a high reputation. It was recommended to me as a fine handsome Pear, ripening at the same time as Jargonelle. I have had it for seven years, and I have never gathered a fruit of it worth eating. I therefore subscribe myself—DISAPPOINTED.

#### BELGIAN CAMELLIAS.

THE Camellia is cultivated very successfully and in large quantities in Belgium, principally in and around Ghent. Only those who have been behind the scenes have any idea of the great number of Camellias which are exported thence annually. As an instance I may mention that in the wholesale catalogues published by the growers the price per thousand is given. It would no doubt be interesting to know the number sent out annually by each nurseryman, but a more important question to us is, whether the plants sent out are of good quality, and such as will give satisfaction to the cultivator.

After my own experience and the opinions I have gathered from others I certainly cannot give a verdict in favour of imported Camellias. Everyone knows that the great fault found with them is that they lose their buds. I named this fact to the representative of a great Belgian nurseryman. He attributed it to the treatment the plants received here, saying that plants which had been for the summer months in the open air were certain to suffer when brought into a greenhouse, allowed very little air, stinted for water, and "coddled." I carefully noted the advice he gave me, and when I received fifty plants from Belgium last year I resolved to follow it carefully. As the plants arrived early in the season they were allowed for a while to stand outside, and every care was taken that they had a sufficient supply of water. When the cold weather came on they were removed to an airy conservatory, syringed frequently, and allowed abundance of air during mild weather. When the plants arrived they were set with an abundance of buds, and at the proper season the superfluous buds were removed in the usual manner. For a while the plants succeeded admirably, the foliage being a good colour, and the buds everything that could be desired; but when the trying weather of last December and January came about 75 per cent. of the buds fell. I had sent several plants to

a friend, a most successful gardener, but his success was no better than my own. In the same house in each case other Camellias were grown which developed their buds and produced an average quantity of blooms. I am afraid, therefore, that I must conclude that amateurs purchasing Belgian Camellias must be prepared for disappointment the first year.

The question now arises as to whether these effects are merely the results of change of climate, &c., or whether the method of culture adopted in Belgium is unsound. Most certainly at the outset appearances are against the grower. We find the plant crammed into a misshapen flower pot much too small and very badly drained, while the compost used is simply leaf soil and sand. An intelligent gardener whose opinion I asked on this matter tells me that such a compost is exhausted too soon. A compost for Camellias should have lasting qualities, as the plant has to grow in it for a considerable period. The general opinion among small growers here is, that the Camellia which is so healthy and full of vigour when it leaves the nursery at Ghent, loses much of its vigour for the first season here. It would be almost too severe to say that the plants are grown to succeed up to a certain point, in other words "grown to sell." It is said that there is a scarcity of really good loam and peat at Ghent, and for that reason mainly the plants are grown in leaf soil. Considering the great numbers grown for the English market, it would certainly not be unreasonable for us to expect the growers to go to a little extra trouble and expense to procure suitable potting material.

When the plants had finished blooming last season and were beginning to grow they were potted. The pots we found in all cases badly drained, and in some we found no drainage at all, some of the pots, in fact, being waterlogged. Considering that the plants came from one of the best and largest growers in Ghent this was very reprehensible; it is only, however, one of the faults into which wholesale manufacturers of plants fall. A considerable quantity of the old material was shaken away, and the plants were placed in pots a size larger, the compost used having for its basis good fibrous loam, a little peat and sand being added. To induce growth the syringe was used freely, and the plants are now healthy and vigorous and fairly well set with buds.

My advice to amateurs is to purchase English-grown Camellias, for though they may cost a little more they are grown on sound principles, and are more certain to give satisfaction. Many thousands of Camellias (small plants which are not budded) are purchased by English nurserymen to be grown a season or two here. Such plants, having formed buds in our own climate, are quite as safe to buy as those grafted in our nurseries.

The foreman in a large English establishment tells me that he never puts his plants outside, the house is shaded a little, plenty of air is admitted day and night, the syringe is freely used, and the whole arrangement produces most satisfactory results.—VINDEK.

#### THEORIES IN GRAPE CULTURE.

PROBABLY no subject connected with horticulture proves more generally interesting than Grape culture, and a properly conducted discussion of the merits of any particular theories or practices is certain to be instructive to many readers of the Journal. It is my intention to comment on some of these theories, and for my own benefit as well as others, trust I shall be successful in eliciting opinions upon the subject. That the list of contributors to this Journal includes many experienced Grape-growers we are constantly receiving ample proof, and if my ideas are in opposition to theirs I am open to and invite correction. It must be understood I have not referred to any back numbers, and do not allude to any particular person's theories, but merely comment upon what I have generally noted.

At present I will confine myself to the practice of encouraging young Vines to make as much top-growth as possible under the circumstances for the first few years, say till they are in full bearing—the aim being to fill the borders with active roots—supposing this to be of inestimable value to the Vines. This has long been believed in and practised by several successful Grape-growers with whom I am personally acquainted, the results apparently justifying its adoption. I should be sorry to be thought bigoted; at the same time I say "apparently," being under the impression that the practice is not so sound as it appears, and much may be said against it. Take as an example, and what may be commonly met with, especially in some districts, a house of Vines planted during the early part of the year. An expensive border is made, as much pains being taken with the composts as a cook takes with the ingredients of plum pudding, the Vines are planted, and encouraged to grow as freely as possible. This may be all well and good, but why induce the formation of a thicket

of growth all over the house, including the back walls? We, of course, all know it is done with the idea of filling the border with roots in proportion to the top growth, and in this success is almost certain. But, I argue, what is the use of encouraging all this growth of roots—roots of the grossest kind, and which quickly rob the borders of much of their fertility—when the whole, or, at all events nearly the whole, of the top growth at pruning time is cut away? Do all those roots maintain their vitality? and if they do, would not one-third of the number meet all the requirements of the Vines? Unless I am much mistaken, a great percentage of the roots perish during the winter; and if they do not, they at all events remain inactive in the spring, simply because there is insufficient top growth to set them in motion.

In a little scientific work at hand we are told, "The roots (not Vine roots in particular) extend themselves in all directions beneath the soil in search of food they require, and chiefly by means of their extremities imbibe water containing mineral substances in solution. By means of the trunk and branches, but chiefly through their external layers, called alburnum or sapwood, this crude sap is transmitted to the leaves, in the cells of which it is destined to undergo a great change." Prior to that it is stated, "The bark consists of a somewhat similar arrangement of tubes to that of the wood, by which the elaborated juices called the true sap are conveyed from the leaves back to the branches, trunk, and roots, by which their volume is enlarged, or, in other words, by which the growth of the plant or tree is effected." I might quote further to prove the necessity of reciprocal action on the part of the leaves and roots; but from the foregoing it is evident if it requires a houseful of top growth to fill a border with roots, it requires equally as much foliage to restart the same, and this, if realised at all, is not till late in the season. If the Vines invariably started well the second or third season, and in addition perfected comparatively heavy crops, I might consider science at fault; but according to my experience they do not always start evenly and well, neither is it safe to crop heavily in the case of young permanent Vines. The very fact of undue encouragement of laterals also sometimes results in the canes swelling to such an extent as to loosen the footstalks of the primary leaves, which are thus liable to fall before performing their functions—viz., perfecting the buds, the consequence being an uneven break the next season. A newly planted Vine with ordinarily fair treatment will form roots and sap in sufficient quantities to meet all its requirements at the commencement of the next season's growth, and, unless unduly forced, the root-action will recommence and continue in proportion to the top growth—in this case not half in vain. To be plain, the roots will be "extending in all directions in search of food" when the said food is most required, and will not therefore impoverish the border in order to perfect growth destined to be burnt.

Were I to plant a house with Vines next season I should employ newly struck Vines, these being previously shifted from the small pots in which they were rooted into 9-inch pots, and planted when the roots were reaching the sides of the pots. The balls of soil should remain intact, care being taken to have them in a moist state when planted, and to keep them so till long after the roots had spread into the borders. But few roots would be twisted, and even if there were many it would not much matter, as well-tended Vines invariably produce many of their best roots from near the base of the stems during any season, but especially during the second year. Vines thus planted and grown steadily will form canes of the best description, the laterals being stopped at the second or third joint, and again when they meet on the trellises; in the case of any weakly starters, stopping these when about 4 feet in length in order to strengthen the stems, and allowing the remainder to grow unchecked till about two-thirds up the roof, then stopping. Supernumeraries would be stopped when about 8 feet in length, and would not be shortened the next season, when they would perfect a valuable crop; the permanent Vines to be cut back to near the commencement of the trellis, afterwards receiving the same treatment as in the first year, with the exception of being allowed to grow to a greater length. The next season these would be shortened to about one-third of the length of the roof, and a fair crop taken, and so on, the canes ultimately attaining their intended length the fourth season. I am quite aware there is nothing original in my practice, and I am equally aware there are many, if they would only take the trouble to write as much, who have most successfully practised it.

When strong "cut-backs" are planted they are apt to make a very vigorous start, especially if well rooted, and this also occurs if hard pruning is resorted to in the case of those grown unrestricted the first season—too strong, in fact; the result, in some instances, being a pithy growth, the reverse of what should occur,

especially if the Vines are to remain in a good bearing state for an unlimited time. If it can be proved by adopting the above practice of rapidly filling the borders with roots much heavier crops in a given number of years can be safely secured than by the method briefly advocated by me, I will readily admit I am wrong. At present I fail to see the utility of allowing so much unrestricted growth, which I might mention is persisted in by some, though in a lesser degree, even when the rods are in full bearing.—W. IGGULDEN.

#### THE ROSE ELECTION—SCRUTINY OF RETURNS.

ONE of the electors, who had kept no record of his votes, requested me to return his paper that he might examine how far his opinion agreed with the general result. As there are possibly some others who would also desire to compare their ideas with those of the great body of electors, I now present our readers with the full result of this scrutiny. It will be seen that the nearest to naming the actual best forty-eight has been reached by one of the Honorary Secretaries of the National Rose Society and Mr. J. Sargeant, these two electors having marked forty out of the forty-eight aggregate selection, and the number gradually lessens until twenty only are named. Here, too, is a curious thing to note—that seven nurserymen out of twenty-two voters, more than one-third, name thirty-one of the forty-eight; but not a single amateur out of forty-five is with them. On the other hand, of those eight who name thirty-two, only one is a nurseryman.

The following is the complete list—Messrs. Mawley and Sargeant name 40; Messrs. Burrell, Soames, Curtis & Co., and Cant, 39; Messrs. Whitwell, Jackson, and Merryweather, 38; Messrs. Mount, Tomlinson, Brown, and Davison, 37; Messrs. Baker, Waterlow, Williams, Cranston, and Farren, 36; Miss Penrice, Messrs. Choyce, Cheales, Grant, and Keynes & Co., 35; Miss Bulmer, Messrs. Biron, Burnside, Laxton, Pochin, Sladden, D'Ombraim, Wakeley, Wilkins, Hinton, Coolin, and Dickson, 34; Messrs. Hayward, Fewkes, Bulmer, Frettingham, Rumsey, and Tresceder, 33; Messrs. Fuller, Watson, Evans, Hall, Humphries, Tranter, Pemberton, and Mitchell, 32; Messrs. Maek & Son, Mattock, Prince, Banyard, Laing, Piper, and Durbin, 31; Messrs. Smith, Slaughter, Gravely, Griffith, and Francis & Co., 30; Messrs. Mayo, Mitchell, and Pawle, 29; Messrs. Jefferies, 28; Mr. Grubb, 27; and Mr. Gale, 20.

Of the Roses that received but a solitary vote five were mentioned by one amateur, four by one of the nurserymen, three by one in each of the two divisions of voters, two by three amateurs and four nurserymen, whilst the single mention of the remainder is formed of seventeen amateurs and nine nurserymen.—JOSEPH HIXTON, *Warminster*.

#### INTERNATIONAL POTATO EXHIBITION.

##### REPORT ON SEEDLINGS, 1881.

MR. SHIRLEY HIBBERD has further obliged us with the following complete list of the seedling Potatoes certificated at the recent Exhibition. The whole of the seedlings that were entered for competition at the Exhibition held on September 20th and 21st have been carefully examined, and their merits decided on, so far as they can be judged by the samples sent, and irrespective of cropping and keeping qualities. It will be seen that very few have been selected as possessing high quality, but it is proper to remark that with very few exceptions fair average quality prevailed amongst the samples, some two or three only of the whole number proving decidedly objectionable, and these may prove good in another season. A considerable proportion of the sorts submitted were neither named nor described. The regulations require "origin and parentage to be fully stated if possible." In many cases no doubt the origin and parentage of genuine seedlings may be quite unknown to the raisers, but the judges are bound to consider this point, and they will of necessity hesitate to give certificates to sorts that strongly resemble known varieties, and that are sent without any particulars whatever. It must be understood that none are disqualified, and none are condemned. Those not now deemed worthy of a certificate may prove so hereafter, for sorts vary with seasons, and several that have been passed by were nearly good enough for a first place.

##### CLASS Q—SEEDLING WHITE KIDNEY NOT IN COMMERCE.

*Ross's Magnet*, W.K.—Raised by Mr. Ross of Newbury, from American Excelsior. In size medium to large; oval or elliptical and flattish. Skin a little rough, brownish white with suffusion of pale purple, which deepens at the heel end. Flesh yellowish, of the finest quality, and most elegant appearance. First prize and first class certificate.

*Kentish Invicta*, W.K.—From Messrs. Lott & Hart of Faversham. It is of Magnum Bonum type, but more handsome and of higher quality in every way. Medium to large, oval or elliptic, rounded at

the ends. Eyes with broad arches, and clustered, with a stain of purple at the nose end. The origin of this variety cannot be definitely stated, as it was selected from a number of self-sown seedlings on ground that had carried crops of Snowflake and Beauty of Hebron. It is believed to be the result of a natural cross of these two varieties, but in its more characteristic features it comes nearest to Mammoth Pearl. Flesh white, very mealy, and of the finest texture and flavour. First-class certificate.

*Myatt's Seedling from Prolific Ashleaf*, W.K.—Raised by F. & C. Myatt, Offenham, Evesham. Very neat, flattish celt-shaped; sometimes with sharp nose. Skin smooth, tawny, with purple stains, which at the heel end darken into slaty purple. Flesh yellowish, dry, mealy, elegant, and of the finest flavour. First-class certificate.

CLASS R.—SEEDLING COLOURED KIDNEY NOT IN COMMERCE.

No award.

CLASS S.—SEEDLING WHITE ROUND NOT IN COMMERCE.

*Fenn's No. 3*, W. R.—Medium to large, roundish or pebble-shaped, very neat. Skin tawny, smooth; eyes few and quite level with the surface. Flesh white, in texture and flavour extra good. First prize and first-class certificate.

*Fenn's Lady Truscott*, W. R.—Medium or smallish, very neat, spherical, much netted, tawny white; eyes few and inconspicuous. Flesh white, fine in texture, firm, flavour delicate. A very fine table Potato. First-class certificate.

*Fenn's No 1 x 3*, W. R.—Described as a late main crop variety, raised from Snowflake crossed with an unnamed seedling. It is of medium size, round, a little flattened and angular. Skin tawny white and rough. Flesh white, very fine in texture and flavour. An elegant and acceptable table variety. First-class certificate.

The foregoing three varieties were raised by Mr. Robert Fenn of Sulhampstead, near Reading.

*Myatt's Seedling from Fluke*, W. R.—Raised by F. & C. Myatt, Offenham, Evesham. It may be likened to King of Potatoes in general form, and probably will supply long and short tubers. It is of medium size, flattish, a little rough, tawny, with faint wash of red; eyes few and inconspicuous. Flesh yellowish, soft, mealy, of the finest flavour. First-class certificate.

CLASS T.—SEEDLING COLOURED ROUND NOT IN COMMERCE.

No award.

#### HARDY HEATHS AND THEIR PROPAGATION.

THE beauty of these plants is beyond dispute, and they deserve to be more largely planted. They are at home on the rockery, and some varieties would be invaluable for this position in the spring months. For planting round Rhododendron, Azalea, or beds of Kalmias they are well suited, and they grow luxuriantly in soil where American plants flourish well. For the spring garden they are delightful, and one of the most conspicuous borders I have seen was principally formed of hardy Heaths mixed with *Euonymus radicans variegatus*. However beautiful and attractive they appear when used on the rockery or planted round beds, their real beauty is not half displayed to advantage in either of these systems. To show them to the greatest advantage they should be grouped or massed together, each variety in quantity. When in flower their colour is soft and subdued, which could not render them objectionable. What could look more beautiful than a good groundwork of Heaths in flower with some noble or choice Conifers springing out of it—on long drives, especially, when much of cutting has been required in levelling to make the road, and in consequence slopes sharply on each side? I remember a drive being made in the north of England which had to be excavated for fully half its length. The rock that was removed from the more hilly portions of the ground was employed in suitable places, projecting well out on each side, which extended almost to the gravel. At short distances and between the projecting rocks was suitable semicircular nooks, in which Heaths were freely employed. Ivy and Cotoneaster were also largely used, and rising amongst them were Conifers, Hollies, and other trees. This is a free system of planting, and when well grown and established the plants have a natural appearance. Nothing could have been more pleasing than the different Heaths when in flower, and no other style of planting could have shown them to better effect. When established they will grow well in any ordinary soil, and only require cutting with a pair of shears after flowering to keep them from becoming loose and straggling.

Propagation is effected by means of cuttings and layers; the former generally is practised, and cuttings would root readily if inserted at once and properly attended to. In the first place, a number of 8-inch pots should be prepared by being more than half filled with drainage. Over these should be placed a little moss or rough peat, the remaining portion of the pot being filled to within half an inch of the top with fine sandy peat. This should be pressed firm into the pots, and the remainder filled with clean silver sand. The portions of wood taken for the cuttings

should be the tops of the shoots, about  $1\frac{1}{2}$  to 2 inches in length. It is wise to insert them before the wood becomes too ripened. The cuttings must be carefully dressed, the end being cut clean with a sharp knife, and the small foliage is readily removed with a pair of propagating or Grape scissors, and the work can be done more quickly than with a knife. The cuttings should be inserted at once, commencing in the middle of the pot with the largest, allowing them to gradually slope to the sides of the pot. It is surprising what care is taken in some nurseries to insert them neatly. They are not crammed in as is often the case in private gardens. The last row round the pot should be so arranged as to leave room for the bellglasses, which must be placed over them at once after a good watering has been given with a fine-rose pot or the syringe. Glazed boxes or a cold frame should be in readiness for them, where they can remain until severe weather commences. If the sun proves strong they must be shaded. This is all the attention they need except opening the frame once a week, or fortnightly, according to the state of the weather, to gently dew the plants. The soil must never become dry.

At the approach of frosty weather the pots may be plunged in cocoa-nut fibre or any other suitable material, and the frame well protected with mats to exclude frost. Fire heat should be avoided as much as possible, only resorting to it when other means are likely to fail. I do not think any harm would result if they became slightly frozen, but it is best to avoid this if possible. Water must be carefully and judiciously applied during the winter. As spring approaches they again require care in shading. It will not be necessary to lift the bellglasses very frequently; if the glasses and pots are well syringed sufficient will drain in round the edges to keep them moist. When growth commences the plants commence rooting, and some free varieties, such as *E. mediterranea*, will make much greater progress than others.

After the young plants have attained this stage the glasses must be tilted to admit a little air, or the plants are liable to draw up weakly. No air will be needed on the frame in which they are plunged until well rooted, when the glasses may be removed, and a little air afterwards given to the frame by degrees until the plants are well hardened for planting out, which will be about the month of June.

When the plants are well rooted and are growing their points should be taken out to cause them to produce three or four shoots. The young plants are too small to be placed in outside quarters, and should be planted under glazed boxes or frames as recommended for the Conifer cuttings. The ground on which they are to be planted should be well forked, and a small trench made and filled with peat and coarse red or river sand mixed together. The sandy peat should be placed round the roots, and the plants placed about 2 inches apart each way. After giving water the frames must be kept close until roots are again produced. They must be shaded for a time until the plants are established, when they can be hardened and the frames removed. The only attention then is watering during the remainder of the season. It will be too late to pinch out the points of the shoots, as growth might be produced only to be injured by the frost. The majority of the kinds will require more room in spring, and can be planted out 6 to 8 inches apart, where they can remain until large enough for permanent positions. The plants should be cut in slightly every season, by which means husby plants are produced.

The *Menziesias*, or Irish Heath, are propagated in the same way. The varieties of *Ledums* require the same treatment, root readily, and make better plants when raised from cuttings than if they are obtained by layering.—WM. BARDNEY.

#### FRUIT TREES CANKERING AND BEARING.

THE short hurried article by "A NORTHERN GARDENER" in this week's Journal is welcome as an introductory lesson on the subject of my letter in the Journal of 13th October; but I wish to point out the following specific points of interest for his and other competent hands to deal with.

The time for planting is just upon us; the bearing qualities and sizes and properties of most good sorts of Apples and Pears are pretty generally known. Now we need these leading kinds of both fruits categorically dealt with in the following respects.

1st, In how many years (about) after planting, say two-year-old standard trees, will each sort come into fair bearing?

2nd, Specify which of the kinds as dealt with is much liable to canker, little liable to canker, or quite free from tendency to canker.

The question as to the causes and cure for canker so far as it can be practically dealt with may be entered into more leisurely

afterwards, and on these points much of an instructive character can be said, as I before remarked.

I had, perhaps, best, to make my meaning clearer, illustrate the kind of information which I think is much needed.

On my soil, which is heavy loam, lies high, but has a gentle slope to the north-east—a cold backward soil in short—Williams' Bon Chrétien Pear as standards fruited pretty freely five years after planting, and are not at all affected by canker. This may also be said of Pitmaston Duchess, also as standards. Marie Louise as pyramids on Quince, double-grafted, canker badly, and have never fruited in the same time. Louise Bonne fruited freely on Quince in four years, but cankers badly, continued transplanting being necessary to keep them tolerably free. Kerry Pippin Apple fruited freely in three years and does not canker, Emperor Alexander ditto; whilst Cox's Orange Pippin, Ribston Pippin, Northern Spy, and many other first-class kinds canker to death, and therefore cannot fruit at all. All these are on the same soil and aspect, and have the same frost, &c., to contend with.—S. S.

EARLY fruitfulness among Pears and Apples is a pretty sure indication of a subsequent abundance. That tendency to develop fruit buds while the trees are quite young, for which some varieties are remarkable, frequently occurs irrespective of stocks, and some care is required to guard against an undue strain upon the health of a young tree from overcropping. While gladly complying with the request of "S. S." on page 332 for information upon this subject, I by no means intend to infer that precocious fruit-bearers should be planted to the exclusion of all others, for many of our best sorts come slowly into bearing, but there should be enough of them in every garden to afford a supply of fruit as soon as possible after the planting.

Of such among Apples I can recommend Margil, Cox's Orange Pippin, Cellini, Duchess of Oldenburgh, Borovitski, Keswick Codlin, Hawthornden, New Hawthornden, Manks Codlin, Kerry Pippin, Warner's King, Small's Admirable, Golden Pippin, Adams' Pearmain, Pomme d'Api. Of Pears, Fondante d'Automne, Williams' Bon Chrétien, Huyshe's Victoria, Comte de Flandre, Doyenné Defais, Red Doyenné, Urbaniste, Comte de Lamy, Desiré Cornelis, Beurré Clairgeau, Winter Nelis, Dana's Hovey, Bergamotte Esperen, Madame Millet, and Doyenné d'Été.

Many of the trees here have suffered badly from canker induced by the thin poor soil. This has been clearly proved, because the trees in the kitchen garden where the soil has been deepened and enriched have no canker; but in an orchard, where nothing has been done to improve the soil since the trees were planted, canker has killed some of the trees and disfigured and crippled many others. The Apples killed are Lord Suffield, Nelson Codlin, Hawthornden, Alfriston, and Kerry Pippin, and those which have suffered badly to the extent of losing branches are Court Pendu Plât, Keddlestone Pippin, Old Nonpareil, Mère de Ménage, Bedfordshire Foundling, Manks Codlin, Fearn's Pippin, New Hawthornden, Ribston Pippin, Cox's Pomona, Cellini, Striped Beefing, and Pomme d'Api.

But there are several sorts which have passed unscathed through this trying ordeal, and are fine flourishing fruitful trees. This immunity from canker cannot be the result of accident in any instance, for there are two trees of each kind planted side by side, so that the test has been a fair and reliable one. Tower of Glammis, King of Pippins, Golden Noble, Court of Wick, Hanwell Souring, Northern Spy, Cobham, Warner's King, Hambledon Deux Ans, Yorkshire Greening, Duchess of Oldenburgh, Keswick Codlin, Blenheim Pippin, Small's Admirable, Dumelow's Seedling, Gooseberry, Ryncer, Brabant Bellefleur, Barcelona Pearmain, Bess Pool, Ashmead's Kernel, Lodgmore Nonpareil, Mannington's Pearmain, have all stood the test well, and there are certainly enough of them to afford a tolerably fair selection of early, mid-season, and late sorts for culinary purposes.

Pears were not planted so extensively in this orchard. Citron des Carmes, Jargonelle, and Swan's Egg have died of canker; both the trees of Hacon's Incomparable are also dying, one of Suffolk Thorn is dead, while the other is only slightly affected and has borne some good fruit. Winter Nelis, Louise Bonne of Jersey, Doyenné Gris, Catillac, Beurré d'Amanlis, and Marie Louise d'Uccle have also suffered badly. Elton is only slightly affected, and Spanish Bon Chrétien, Black Worcester, Knight's Monarch, Fondante de Malines, Eyewood, Beurré Bosc, Duchesse d'Angoulême, Uvedale's St. Germain, Althorpe Crassane, Forcelle, Bishop's Thumb, and Beurré Leon Leclerc, are quite healthy.

Most of the choice kinds of Pears and Apples were not planted in this orchard, and so I am unable to say anything about them in connection with canker. I may, however, state than an espalier of Golden Reinette, despite the advantage of the rich soil

of the kitchen garden, has suffered very much from canker, and is all the more remarkable from the healthy condition of all the other numerous garden trees.—EDWARD LUCKHURST.

#### AUTUMN-BLOOMING ROSES.

WE are growing fully one hundred varieties of Roses here, but out of that number not more than a dozen have yielded really good late blooms. Of these the best were Dr. Andry and Bessie Johnson, which in both instances were in every respect perfect. The former is a bright crimson red, and the latter blush white. Comtesse d'Oxford on its own roots has been good, and still more useful were a number of dwarf plants of Souvenir de la Malmaison, but the blooms in this case were not of good form. Cheshunt Hybrid, Charles Lefebvre, Duke of Edinburgh, Jules Margottin, La France, Ferdinand de Lesseps, Général Jacqueminot, and Mrs. Baker were all giving blooms till quite recently, and where sheltered may yet perfect a few more.—SOMERSET.

#### INFLUENCE OF STOCK ON SCION.

WE send you a small box containing three examples of Beurré Diel Pear grown as a standard here, and also four examples of another Pear which appears to us very much to illustrate the influence of a stock upon a scion. The latter have been gathered also from a standard tree in the garden here, which has borne good crops of similar fruit now for many years. The tree had a label formerly—"Beurré Diel grafted on Jargonelle. J. B., sen." As our late principal died more than twelve years ago this grafting must have taken place at least two or three years earlier, and the tree has had a sufficiently lengthened period to fix its true character. To us it appears a fixed sport of a very excellent type, and we shall be glad to learn if a similar instance has come under your notice. Whilst a good deal of the form of the Beurré Diel is preserved there is some tendency to an elongation of shape in the direction of the Jargonelle; there is also an approach to the colour of Jargonelle. But the great departure from Beurré Diel is in the season of ripening and in the quality. Whilst Beurré Diel is still hard and uneatable our "sport" is fully ripe—perhaps rather passing, if anything; and whilst Beurré Diel only occasionally ripens in this district satisfactorily on a standard the "sport" is always satisfactory, and may be truly called melting, buttery, and delicious, and entirely free from grittiness. For our northern districts it appears to be a Pear of considerable value.—JAS. BACKHOUSE & SON, York.

[This is clearly a case of the stock exercising a very decided influence on the graft. The two fruits sent by Messrs. Backhouse are perfectly distinct, not only in shape but in quality. The specimens of Beurré Diel are excellent illustrations of that variety—so much so as to be typical; and those produced by the scion grafted on the Jargonelle are so distinct as to have all the character of another variety. The true Beurré Diel is now quite unripe, and has no appearance of being ripe for many weeks hence; but the others are over-ripe and in some cases are quite decayed from the core to the circumference, as in the case of the Jargonelle. This is a convincing proof of the influence which the stock exercises on the scion; and the question arises, Why does not this occur more frequently, and what can be the relative conditions which exist to render such a thing possible? We have recorded many singular instances of this transfusion of essences, if it may so be called, in the pages of this Journal—some through the influence of the pollen of one tree on the ovary of another, and thereby altering the whole condition of the fruit—but we have never before witnessed so remarkable an instance of transfusion from the stock acting so strongly on the scion in the case of fruit trees.—ED.]

#### NOTES ON POTATOES IN LINCOLNSHIRE.

THOUSANDS of acres of Potatoes are grown in this county, and I venture to send a few notes respecting them. The disease is not nearly so virulent this year as has been the case for several seasons, yet I have seen no varieties free from it with the exception of Magnum Bonum. Scotch Champion is affected this year quite as much as is Paterson's Victoria. In addition I may safely say that the yield of the Champion is not so good as that of the Victoria, and the quality is not nearly so good. Last year Champions were far ahead in productiveness, hence great breadths were planted this year, which are proving disappointing to many. White Rocks, as they are named here, are yielding immense crops of good quality, whilst last season they were miserable both as to yield and quality. Magnum Bonum is a great cropper, and this season they are fairly good in quality; but no Potato, so far as I

have seen, is in advance of Paterson's Victoria. The Schoolmaster is a good cropper and excellent in quality, and is only very slightly affected with the disease.—MID-LINCOLN.

#### KITCHEN GARDEN.

THE recent frosts are a sure indication of the weather that may now be expected, and will act as a warning not to delay any precautionary measures in protecting or lifting those plants requiring it. Lifting Lettuce and Endive should be attended to, as the plants be kept from frost, for when the midribs become frozen the quality is much deteriorated. Where heated pits are not at command a good supply may be maintained by lifting the plants and packing them in soil in pits or frames, or a late Peach house, where with ventilation in mild weather and attention to protection the plants will remain in good condition a long time. Complete the taking-up of Carrots, Salsafy, Scorzonera, and a portion of Parsnips for immediate use, the main supply being left in the ground, or where this will interfere with the preparation for other crops the roots may be lifted and placed below the surface of the soil in a cool and shaded place and covered with litter. This is a good plan to adopt with Beet to preserve them in a fresh solid state until next year's supply is fit for use. In storing roots avoid placing them in large stacks, or they will decay. Examine late-sown Turnips, and those fit for use should be taken up and stored, which will benefit the remainder of the crop.

On a dry day take up Cauliflowers and stow them away in a pit or other sheltered place where protection can be given. Complete pricking out Cauliflower plants from the seed beds into handlights or frames, some of the plants being placed at the base of a south wall, which in an ordinary season withstand frost, and are useful for spring planting. Complete planting out Lettuce, Endive, and Cabbage as soon as possible, and guard against the ravages of slugs by occasional dustings with quicklime, soot, or dry wood ashes. Earth up late crops of Celery when the weather is suitable, giving a final earthing to such as require it. Clear off the haulms of Asparagus when they die, giving a dressing of well-decomposed manure after clearing the surface of weeds, and cover with soil from the alleys. The decayed leaves of Seakale may be removed and the crowns covered with a little spent tan, sawdust, or cocoa-nut refuse; that required for forcing should be taken up and placed where it can be easily obtained when required.

*Frame Ground.*—Fully expose Cauliflowers, Lettuces, Endive, and Radishes in frames whilst the weather is mild, employing the covers or lights only in case of frost. Stir the soil lightly about the plants, and remove decayed leaves as fast as they appear from Cauliflower and Lettuce plants, keeping a sharp look-out for slugs.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—The earliest trees, as well as those ripening fruit early in June, have shed their leaves, and should be finally pruned—a very trifling affair if former instructions have been attended to. Complete also cleansing the trees and houses. The lights should be placed on the earliest house, and air admitted fully for the present. They may remain off the second house if the weather continue mild for another month. See that the inside borders of these houses do not become dry, and if there be any appearance of dryness afford a thorough supply of water. Succession and late trees are late in casting the leaves, probably owing to the dull weather in August and September; but the buds are well developed, and the wood is ripening well though slowly. Where it is well ripened the heat, if it has been employed to assist this, must be discontinued. On no account must the ripening of the foliage be accelerated by a dry condition at the roots, for although that would cause the foliage to ripen early it would prevent the plumping of the buds, and they would fall later on through their defective development. At no time ought the soil to become very dry, and though a lessened supply of water is needed

when the growth is ripening and the trees at rest, it is essential that the soil be constantly moist.

*Figs.*—Trees in pots intended to be forced early, if they have been placed out of doors to harden, must, if not already done, be taken under cover to keep them from the cold autumn rains. Attending to thinning the shoots or top-dressing the surface soil must not longer be delayed, so as to have the plants ready for forcing in November. Preparation of leaves and litter for making fermenting beds for trees to be forced early in pots must also be commenced. Late trees permanently planted out will now be shedding their leaves, and the houses will need closing in wet weather, giving, however, abundant ventilation on all favourable occasions. Although the Fig will endure a drier condition of the soil when at rest than most other fruit trees, it should not be allowed to become so dry as to have an injurious effect upon the roots.

#### FLOWER GARDEN.

The mixed border is the most suitable position for many bulbous plants, as they are not disturbed, and can ripen their growth without becoming unsightly. Lilliums appear to much advantage, especially where backed up with dwarf evergreens, which also afford shelter from winds. The Lilies should be planted about 6 inches deep and surrounded with sand. The bulbous Irises also are beautiful, and should now be planted; also Hyacinths, Narcissuses, Anemones, and hardy bulbs generally, surrounding each with a little sand. Gladioli having ripened their growth sufficiently should be lifted, and are best wintered in not too dry a place, or they will shrivel and lose strength. Complete making beds of Pinks and Carnations, planting in a good dressing of soot and lime. Plant Pansies and Violas at once for spring and early summer flowering, also other border plants raised from seed as well as those from cuttings, which if planted early have a chance of becoming established before winter. Early autumn is the best time for examining herbaceous borders, and if any of the strong plants have outgrown the space allotted to them they should be reduced. To grow herbaceous plants well good soil and liberal cultivation are necessary, and where any have been long on the same ground removal and replanting will be beneficial, the ground being deeply trenched, working in plenty of thoroughly decomposed manure; by doing this early in the season the plants have time to become re-established before winter.

#### PLANT HOUSES.

*Greenhouse.*—Herbaceous Calceolarias now require potting singly, 3-inch pots being large enough, employing a compost of good fibrous loam, a fifth of leaf soil, and a similar quantity of well-decayed manure and a little sand, placing near the glass in a pit where they will be safe from frost. Should any aphides exist dip the plants in tobacco water previous to potting. Transfer the second batch of Cinerarias into the full size pots, and keep them in a light position where they will be safe from frost. Soil as advised for Calceolarias will suit them. Seedlings or suckers in small pots for late flowering should be potted, which will carry them on until January or February, when they should be again potted. Chrysanthemums must be placed out of danger of frost, and where there is no suitable house a canvas-covered framework may be employed for a portion of the plants in the southern parts of the country, but glass is absolutely necessary in the northern districts. Those required for late flowering in a house with a north aspect, in which they will move slowly and come into flower at Christmas.

*Azaleas.*—Some of the earliest-flowering plants—such as A. Borsig, Narcissiflora, Raphael, alba, Fielder's White, amœna, and its larger form, amœna Caldwelli—will now, if they were well managed after flowering, be in a condition to place in heat. A temperature of 55° will be sufficient, as when they come in without excitement in a high temperature the flowers are more lasting. A. vittata elegans flowers naturally in autumn, especially when subjected to a temperature of 50° to 55°, the flowers being finer and more freely produced than in an ordinary greenhouse temperature. This, though an old plant, is not so frequently met with as it deserves, and, flowering over several weeks during the winter, is very useful for cutting, its white-striped flowers—some spotted, and others entirely purple—lasting long in

water. The general stock if infested with thrips should be washed with tobacco water.

*Bulbs.*—Another batch of Hyacinths, Narcissus, Tulips, &c., should be potted for successional flowering and plunged in ashes for a month or six weeks, or until they have filled the pots with roots. The earliest of these are well rooted, and may be transferred to other quarters before they have made much top growth, and this must be kept from strong light, gradually inuring them to it by covering each with an inverted flower pot. The first batch of Roman Hyacinths, Paper White, and Double Roman Narcissus are coming into bloom. The batch potted early in September will be in a condition to succeed the first, and should be brought forward in a temperature of about 50°, and by keeping a portion in an ordinary greenhouse temperature they will come naturally into flower in December. Those for later flowering should be kept cool, frost only being excluded.

## THE BEE-KEEPER.

### MR. PETTIGREW AND THE BEE TENT.

I TRUST Mr. Pettigrew's denunciation of the bee tent on page 366 will not be allowed to pass without one or two gentle protests.

First, the great sacrifice of lives spoken of is not manifest, as the bees return to their queen, and the stocks are then returned to their owners or sold. Where the weather is hot, and during a honey glut, combs will fall where due precaution is not taken in the packing. But this is before they arrive at the bee tent.

The objection that the operations of the bee tent have a frightening effect on the bystanders is somewhat ludicrous. Here and there, doubtless, is a man who objects to the bee tent in the same way that one or two peculiar individuals object to have their children vaccinated; but any man endeavouring to prove from the latter instance alone that the Vaccination Act is a mistake, would be looked on with some curiosity. It is equally futile to demonstrate from one or two isolated opinions that the bee tent is deterrent to apiculture, while the hundreds who learn, and practise what they learn, prove the exact opposite now daily.

If I described the Manchester Bee Exhibition as "not up to much" because one friend of mine who went said it was "on the one-stringed fiddle pattern," I should not carry much weight with Mr. Pettigrew. Of course that friend might be a lunatic, which for argument's sake I will allow, but that does not affect the logic of the case.—H. V. EDWARDS, *Oakbrook*.

### CONTRACTING HIVES FOR WINTER.

IN bee-keeping, as in other pursuits, one is apt to follow habits that have no merit but their antiquity, and no reason but that they are recommended by book-makers. We are therefore all the better for a veteran driver like Mr. A. Pettigrew checking the rein and calling on us to reconsider our course; and I trust he may follow up the plan by laying his finger on one point after another in the practice of bee-keeping, whether of ancient or modern usage, and let us have its "reason" fairly discussed.

On page 321 Mr. Pettigrew invites discussion as to the healthfulness or helpfulness of the practice of contracting hives for winter. As I have widely recommended the practice, and have full faith in it myself, I beg to submit my reasons for so doing.

In the first place, however, I may state that I have no doubt as to the good results your correspondent has always had with stocks whose combs did not fill their hives. Mr. Pettigrew is no ordinary bee-keeper, and his stocks are no ordinary stocks. His locality and climate are likewise more favourable for wintering than those of Scotland and other parts of Britain. Stocks well cared for, and whose normal populations are doubled by the addition of driven bees in autumn, will winter under almost any circumstances, and to such the vacancy in the hive may be a positive benefit. I have seen some good results in the same line. I once visited the apiary of Mr. Kerr of Mintlaw, in the far north of Aberdeenshire. I found his row of skeps by the north side of a high wall, all well thatched to below their floor-boards, and all doorways closed entirely. This was of course in winter. I found it was his practice to remove his stocks to this location early in October, and return them to the sunny side in March. Thus for five months they remained closed, practically in the dark, and unvisited by a single direct ray from the sun. To my surprise Mr. Kerr informed me that on examining them in March he

usually found very few dead bees and the combs were dry and clean. "And that without ventilation?" I dubiously inquired. "Oh, no," said he; "I put under each stock a small cke of about 2 inches in depth, and raise it from the floor-board an eighth of an inch by wedging in a few small nails." I was no longer doubtful. The position of the hives, their dry dark coverings, and the presence of that ventilating cke explained all. The best conditions for successful wintering were here attained, if we except the closing of the doorway, which seems unnecessary. The temperature of the air immediately surrounding the bees must have been almost uniform throughout the long steady Aberdeenshire winter, and its condition at once dry and pure. The case is almost on a par with cellar-wintering, the most successful of American methods. Why not advise its general adoption? Because so few bee-keepers have the choice of a situation so well sheltered from sunshine, a climate so uniform, stocks so uniformly strong, and maybe the thrifty care exhibited by this bee-keeper of the far north. What succeeded so well with him, and perhaps also with Mr. Pettigrew, would certainly fail in most other hands. As soon would I think of calling on all bee-keepers to follow the example of Mr. Langstroth, who once wintered a stock in good condition by suspending it in the air without a floor-board at all, while other stocks carefully protected perished. No; we believe in the principle of giving bees a chamber proportioned to their number, have had uniform success with it even in the case of very weak stocks, and know of no objection that can possibly be urged against it. If Mr. Pettigrew knows of any let us have them by all means, and thus get both sides of the question. I submit the following reasons for recommending the general contraction of hives in winter.

1, Because it is the only method of wintering that can be recommended for universal adoption, being suited alike to strong and weak stocks, and to localities and climates varying from mild to severe. I should not fear, granted a supply of food, to winter a strong swarm in any locality within these shores, even without combs at all. Strong stocks can scarcely be chilled to death, but weak ones frequently perish from cold. And even if not altogether lost, how frequently do we find seams of bees cut off from the cluster by the contraction of the latter during severe weather and chilled to death. By contracting the hive in proportion to the cluster we bring their food within easy reach; ensure against death by freezing, and by conserving the heat we winter our stock at a less expense in stores and bee life and energy.

2, Because combs not fairly covered with bees are frequently badly moulded in winter, owing to the condensation of the vapours exhaled by the bees. Especially is this the case with exposed pollen. By removing these and storing them in a dry place we preserve them uninjured; also in the event of an attack of so-called dysentery all the combs left in the hive are badly soiled, a trouble almost unknown in well-packed hives.

3, Because of the prospective advantages of a contracted brood nest in spring. In a confined space brood-rearing goes on at a more rapid rate; and under the valuable operation of "spreading the brood" by the restoration of the removed combs, one at a time as the bees are able to cover them, we hasten the swarming season by several weeks at least.

I know of no objections whatever to the plan, unless it be by way of a caution as to the *modus operandi*. If the hive be contracted and packed too early in the season, the comfortable heat of the hive induces the bees to fly more frequently, and the population is often greatly reduced before winter sets in. As autumn advances one comb only should be removed at a time, as it is found to be free from bees and wholly or nearly cleared of honey. At the same time the contracting board should be brought forward, but no packing of chaff or other material should be used till frosty weather sets in.

During the last severe winter in America probably three-fourths of the stocks in the Northern States perished. The returns since published show that the loss was pretty well distributed, all sorts of hives and systems of wintering sharing in the disaster. But one remarkable circumstance comes to light, and one which is sorely puzzling the wisest heads among the bee-keepers—viz., that not merely a few, but a large proportion of stocks wintered in exposed box hives with an open hole in the crown-board covered only with an empty box, and also in bar-frame hives from which the unfinished supers had never been removed, wintered successfully. Doubtless many will claim this fact as an argument against contracting and packing hives. But I venture to give another explanation. The fulness of ventilation in the hives in question kept their bees cool and at home during the autumn months, and they entered the winter stronger in bees than other hives. The bees were thus their own protection—better than chaff, cork dust, or even dead air. That is no reason, however, why we

should adopt such a slipshod method of wintering. If we carry out the contracting plan as I have indicated, we can ensure even weak stocks a safe passage through the winter.

When on a visit to Ireland in November, 1879, I packed two stocks that had each not over half a pint of bees. They were nestled in chaff with only a few bits of comb, and both lived and worked during the following spring till their queens were required elsewhere. Unfortunately there are too many weak stocks this season, unexampled in my experience for the rapidity with which the bees have dwindled since honey-gathering ceased. The early cessation of breeding, the efforts at stimulation by necessary or unnecessary feeding, the neighbourhood of groceries, confectionery works, or cider mills, and other causes, have all worked to this result. For my part I shall join no stocks together so long as I find them able to cover even three Woodbury frames by the 1st November. Such stocks carefully packed about this date often come out as strong as others, more promising, and, though only expected to winter some good spare queens which are valuable in spring, they well repay the little extra trouble they involve.—*WM. RAITT, Blairgowrie.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (J. F.).**—We know the publication to which you refer, and do not entertain such a high opinion of its value as you appear to have; and we do not suppose that a translation of it would meet with anything like a ready sale in this country.

**Nitrate of Potash (A Correspondent).**—The substance referred to is no doubt nitrate of potash, or saltpetre, as it is more commonly termed.

**Salisburia adiantifolia (Lillian).**—The above is the name of the tree, leaves of which you have sent. It is commonly called the Maidenhair Tree, from the resemblance of its leaves to the pinnules of Adiantums. It is the Ginkgo Tree of the Chinese. It is hardy and ornamental, and we think should be more freely planted in pleasure grounds.

**Greenhouse Rhododendrons (C. P. L.).**—The propagation, grafting, and culture of these excellent greenhouse shrubs are described in an article by Mr. Bardney on page 242, the issue of September 15th, of the present volume.

**Ornamental Grass (F. W.).**—*Stipa elegantissima* is a perennial, and will grow again next year if the plants raised from seed have not been crowded too closely together, in which case they not unfrequently decay. Unless the plants have space to develop in the summer they cannot be expected to survive the winter; indeed, the autumn rains often destroy them.

**Fyrus japonica (T. W. N.).**—The fruit is edible, but it is a question entirely of taste as to whether it is palatable. We do not like it, but we have not tried it in Apple tarts. You might make the experiment and favour us with the results.

**Sach's Botany (J. W. D.).**—The book you refer to is published by Macmillan & Co., 29 and 30, Bedford Street, Covent Garden, from whom you can obtain particulars as to the price. The English edition is entitled "A Text Book of Botany Morphological and Physiological," translated by A. W. Bennett, M.A., and W. T. Thiselton Dyer, M.A. It is of large 8vo. size, and contains 558 pages. It is an elaborate work, and much valued by botanists.

**Chrysanthemum Shows (J. T.).**—The principal Exhibitions to be held next month are the following—Richmond (Surrey), November 10th; Kingston-on-Thames and Royal Aquarium, Westminster, November 17th; and Birmingham, November 23rd and 24th. The cut blooms are generally a speciality at Kingston and the Aquarium, and the specimen plants at Birmingham.

**Cordon Trees for Wall (Ignoramus).**—All the Pears you name will succeed on a wall having a west or east aspect in Kent, as also will many others; but as you do not indicate the number you need we presume those named in your letter are sufficient. If, however, you require a greater number we will readily publish a selection on hearing how many varieties you desire to plant.

**Tomatoes (H. T. H.).**—Your letter shall be forwarded to our correspondent, who will perhaps be able to furnish you with the information you need. As you esteem Tomatoes of good quality so highly we advise you to adopt the plan of Mr. William Taylor at Longleat—that is, when you find one that gives you satisfaction preserve it, and propagate from cuttings until you find another variety superior.

**White Clematis (A Constant Reader).**—We do not know of a variety that answers precisely to your description. Miss Bateman is one of the best white

varieties, but the flowers are larger than those of *C. Jackmaui*. *Patens floribunda* has smaller flowers, its colour being French white. *C. montana* has small star-shaped flowers borne in clusters. It, however, does not belong to the *C. Jackmanni* type, but is a distinct species.

**Stephanotis at Christmas (Anxious).**—As you evidently have a healthy plant and free-flowering variety you may probably induce it to continue flowering until Christmas, but much will depend on the weather, especially the absence of fogs. You cannot do better than continue the present temperature, which is evidently suitable, judging by the healthy foliage and fine flowers you have sent. In the absence of sun the day temperature should be about 5° higher than that maintained at night.

**Quinces Cracking (F. H.).**—When a period of hot weather prevails in the summer, as was the case in July, the tissues of the fruit dry up and much of the elasticity of the skin is lost; and then in the autumn, when rain occurs, the great abundance of sap exerts such a pressure on the fruit that it splits, as in the specimen you have sent to us.

**Tree Fern too Tall (Rosa).**—You do not say whether the Fern is planted out or growing in a tub, and the "branches" to which you allude are, we presume, the fronds. If the Fern is in a tub it may be sunk as deep as you require, or the ground will allow, at the present time; if it is planted out it would be preferably removed and placed lower in the spring just as the new fronds are beginning to grow, a number of the old fronds being removed either now or as spring approaches. The old soil will probably need excavating and fresh compost adding, and the work of taking up and replanting must be done carefully and well. We should not cover the stem with a great thickness of soil, but leave it free, the soil being prevented from pressing against it by a wall of bricks or stones. We have known Tree Ferns cut off level with the soil, or where required, and the trunk planted in suitable soil, and the growth has been satisfactory; but they have received the skilful attention of practised cultivators.

**Gathering Fruit (J. E.).**—When the fruits part readily from the tree—that is, when they fall into the hand when gently raised—they are ready for gathering, and if they were not gathered they would be blown down by the first brisk wind. Fruits often shrivel after gathering by being stored in a too warm and dry place. We have often found them to keep better in a cool, dark, and rather damp cellar than in a light, warm, and very dry fruit room, and we have not unfrequently found stray fruits that had been left for weeks hidden amongst the grass in an orchard quite firm and sound, when others from the same tree were more or less shrivelled in a dry and too warm room.

**Tropæolum speciosum (A. B.).**—You are in error. You have not obtained "hills" of this species for the sufficient reason that it is not a bulbous plant; it does not even produce tubers, but is herbaceous, with fleshy roots, like *Musk*. The plant you have secured is possibly *T. tuberosum*; if so, and the soil is fertile and well drained, it is not needful to take up the tubers. The plants will probably grow better next year. If they do not, and you will inform us of the correct name of your plant, and describe the soil and position in which you are endeavouring to grow it, we will endeavour to aid you in your object. There are other tuberous species besides the one we have named, but *T. speciosum* is certainly not one of them.

**Fuel for Furnaces (Kittie).**—The remarks have the same force whether applied to steam coal or ordinary house coal. The question of economy in heating is very much a question of supply of material. In some districts coal is cheaper than coke, in others coke is cheaper than coal. If you can obtain both at a moderate cost we should mix small coal with coke—this is assuming the furnaces have a good draught. We know of instances where even the draught is so sluggish that good coal must be used to supply the requisite heat, one in particular where a nobleman makes his own coke, yet for one of his garden furnaces coal is an absolute necessity. If your furnaces have a good draught, then small coal and coke will be sufficient and more economical than the practice to which you refer.

**Ash Trees not Growing (Planter).**—On soil such as you describe Ash trees do not start freely, but when once established they often grow fairly well. Still, the soil is fully too strong for this tree, and Sycamore would no doubt grow better and be more profitable, there being a great demand for its wood for laundry utensils of all kinds. Further, your young Ashes may have been stunted and hidebound, and in this state they never grow freely. We assume the trees have been planted two years, and are thus in a measure established. In this case your best plan will be to cut them down almost close to the ground, and the probability is they will push fresh growths; and if one is retained on each tree, the others being removed, you may yet form a good plantation. We have seen this practice adopted extensively and with excellent results. The best time for cutting down the trees is in spring after the shooting season is over. When young Ash trees are stubborn and hidebound they will stand still, or nearly so, for years in whatever soil the trees are planted.

**Carnations in Pots Failing (C. E.).**—The first essential for success is healthy cuttings, sturdy and strong. With weakly cuttings or growths from unhealthy plants it is almost impossible to produce satisfactory results. The next point is to allow no check to the plants in their early stages of growth, and especially must care be taken that they are not permitted to be rootbound in small pots before they are shifted into larger. The want of timely potting results in many failures. The pots you have employed are much too small for growing such strong-growing sorts satisfactorily. The plants ought to be shifted, always before the roots are matted, into 8 or 9-inch pots, or even larger, and be grown in frames during the early part of the season, and afterwards in the open air, great care being exercised in watering them. If the plants must be grown in small pots liquid manure is essential after the pots are filled with roots. But whatever system of culture is adopted good plants cannot be produced from bad cuttings.

**Violets in Frames (A Very Old Subscriber).**—Violets to flower freely in frames during the winter are prepared by planting small divisions or rooted suckers in April a foot apart in rich soil and a suitable position, watering them as required during the summer to ensure fine plants, and shortening the runners of those that need it, keeping the beds free from weeds. In September or early October the plants are taken up carefully and planted in frames that have until then been devoted to Melons or Cucumbers; or a gentle hotbed is made of leaves chiefly, and about 3 feet high. This is covered with a good soil about 9 inches thick and made rather firm for the plants. They are well watered immediately after planting, and carefully afterwards. The frame is kept rather close for a few days, and then judiciously ventilated according to the weather, all decaying leaves being promptly removed. The plants so treated become established by the winter and flower freely. The sides of the frame are protected with manure in severe weather, and the glass covered with mats and straw. If Violets are planted in beds of convenient size, and frames are placed over them, the plants flower freely. If your plants are so arranged that frames can be placed over

them you would probably have better results than lifting the plants; but if they must be lifted and transplanted the work should be done at once, planting them so that the leaves of one plant nearly but not quite touch those of the others.

**The Spindle Tree** (*H. P. D.*).—The specimen submitted to us is a small branch of the common Spindle Tree (*Euonymus europæus*), so called from its wood being used long ago for making spindles. It is called Prick-wood and Prick-timber, from being used for toothpicks and skewers. The wood is said to be used by musical instrument makers. For skewers and toothpicks the wood should be cut when the shrub is in bloom, for then it is tough and not easily broken; it is also used by watchmakers for cleaning watches. The berries act as an emetic and purgative, and are fatal to sheep; and when powdered and sprinkled on the hair destroy pediculi; sometimes it is made into an ointment for the same purpose. No animals except the goat will browse upon the plant.

**Violets in Greenhouse** (*C. Diamond*).—Violets will succeed on the shelf of a light greenhouse in the winter provided the house is not too warm. But your description of a house "heated three times a week" is much too indefinite for us to understand its temperature, and if the system is adhered to through the winter few greenhouse plants can be expected to survive, or at least remain healthy. We can understand furnaces being "heated three times a week" for household purposes and ovens for baking, but the method as applied to heating a greenhouse is quite new to us. Violets should be potted in a compost of two-thirds of rather strong turfy loam and one-third of leaf soil or old decayed manure.

**Storing Ice** (*Mrs. S. Fairburn*).—As you have not an ice house you may preserve ice in stacks. A correspondent has described the following method which he has carried out successfully for a number of years. "After getting the ice in proper working order, and the weather continuing frosty, we begin to take it off the pond and cart it home to the stack, which is built on level ground, but has the advantage of being shaded by trees and bushes from the strong sunshine. We begin the stack by emptying the carts on its foundation; after which there are plenty of hands ready to begin pounding the ice with light wooden mallets sufficiently small to pack all large pieces firmly, thereby excluding from the interior of the stack as much air as possible; this should rather be a little over than under done. The people on the stack pound away till the whole is finished, and as the ice draws towards a point, one or two drop off as the room for working becomes less, and begin breaking the ice at the bottom before throwing it up to those who remain. As the work proceeds we now and then throw a quantity of water over all, so as quickly to congeal the whole into a solid mass. We stack in this way from 100 to 110 cartloads every year, and it keeps perfectly well over twelve months, sometimes for a longer period, and we have to open the stack nearly every day during summer. Before covering-up, if the weather will allow us, we leave the stack exposed at least twenty-four hours to the frost; if otherwise, we cover it at once. For covering we use dry wheat straw; covering to the depth of 48 inches at least, and all put on at once. We leave no air-pipe through it, and we have no trouble in consequence of its heating or fermenting. We leave the whole in a conical shape, neatly strapped down to carry off the rain. This may be thought a waste of straw by some, but no less thickness of thatching will enable us to attain our object. The straw, however, will not be altogether lost, as a farmer will know well what to do with it after it has done duty on the stack, when he has his cattle in the fold. We have no faith in having only twenty or thirty cartloads in a heap, however well protected and stored. There should not be less quantity than a hundred loads for a stack, if ice is required all the year round." If the ice is stored in a dry or freezing state snow may be mixed with it, but if stored during a thaw snow is a disadvantage. Snow alone cannot be satisfactorily preserved for any lengthened period.

**Growing Mushrooms** (*Idem*).—They may be grown in any house, shed, or cellar having a temperature between 50° and 60°. The material, horse stable manure with the long litter forked out, should be spread in a shed to be dried somewhat and sweetened, then made into a bed that should not be less than 4 feet wide and 6 long, or the heat will not be retained in winter. The bed must be made as firm as possible by heating and treading. It will probably heat violently, and not until the heat is declining must the spawn be inserted, pressing in lumps as large as pigeons' eggs 8 or 9 inches apart. A few days afterwards cover the bed with fresh loam and beat it firmly down with a spade, the firm soil being an inch thick, then cover the bed with hay or soft straw, which must be regulated in thickness by the heat of the bed or the bed in which it is placed. The great points to be attended to in growing Mushrooms are an equality of temperature and moisture.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*L. Watts*).—The Pear is Beurré Diel, the Apple American Mother. (*H. J. W., Taunton*).—We have carefully examined such of the Pears as were not decayed, and we have failed to recognise any of them. We suspect they are from imported trees which have been selected without reference to their adaptability to this climate, as not one of them possesses any merit to warrant their being retained in cultivation. (*G. S.*).—4, Cox's Orange Pippin; 5, Princess Charlotte; 8, Sturmer Pippin. (*H. C. Prinsep*).—34, 38, and 39, Marie Louise d'Uccle; 40, Dunmore; 41, Thompson's; 50, Napoleon. (*J. Garaway & Co.*).—It is not Cornish Gilliflower; it is evidently not a variety of any merit. (*A. P.*).—The Apples are undoubtedly Blenheim Pippin. (*D. Walker*).—1, not known; 2, Bergamotte Bufflo; 3, Beurré Hardy; 4, Joséphine de Malines; 5, Beurré d'Arcberg. (*J. F. L.*).—Hollandbury. (*J. N.*).—2, Golden Reinette; 3, Franklin's Golden Pippin; 4, Scarlet Nonpareil; 5, Reinette de Canada. (*Peter Morris*).—Apples.—1, Selwood's Reinette; 2, London Pippin. Pear.—Baronne de Mello. (*A. Harding*).—Apples.—1, Adams' Pearmain; 2, Borovitski; 3, Cox's Orange Pippin; 4, Bedfordshire Foundling (?); 5, Minshull Crab; 6, Court of Wick. Pears.—1, Marie Louise; 2, Crasanne; 3, not known. (*R. P. W.*).—We are still of opinion that the Apple received is Stamford Pippin. The Pear is certainly not Doyenné Defays, which is a delicious variety, and yours is worthless. (*Ramatho*).—The Apples sent are not ripe and have not come to their flavour. It seems to be a good keeper, and has the character of being a good-flavoured Apple when ripe. (*J. E.*).—1, not known; 2, Margil; 3, Golden Russet; 4, Scarlet Nonpareil. (*J. T.*).—Pears—not ripe. Apples.—4, Beauty of Kent; 7, Emperor Alexander; 8, Newtown Spitzenberg; 9, Blenheim Pippin; 10, not known; 11, Sam Young; 12, Golden Noble. (*Centurion*).—If you send six varieties at a time they shall be attended to. When fruit is sent by the peck

and even bushel it is impossible for us even to examine it. See the above conditions, which have been inserted in many previous issues.

**Names of Plants** (*H. P. D.*).—*Euonymus europæus*, the Spindle Tree. See reply above. (*Reader*).—*Pyrethrum uliginosum*. (*A. H. G.*).—*Cotoneaster bacillaris*. The fruits, though not hurtful, would have been of little use for the purpose you mention. (*W. H. W.*).—1, Resembles a *Melastoma*, but is not sufficient for identification; 2, *Escallonia macrantha*; 3, *Pyrus japonica*.

**Bees Nearly Starved** (*A Subscriber*).—We fear your prospect is not encouraging. When the weather is cold bees can only maintain their necessary heat by keeping in a close cluster; and with food in abundance at the bottom of the hive they still may starve, because if they were to separate from one another in order to take it they would die of chill. Your only chance is to give food at the top of the skep, and this should take the form of barleysugar put in at the top hole and covered down very carefully so that no heated air is allowed to escape. You may in this way by attention keep them going until we near the spring, when syrup may be supplied. As soon as we get a genial day lift the hive from its stand, and, driving the bees up by smoke, pour some good syrup upon the combs held sideways so that it runs into the cells, but avoid pouring it over the bees; this will give them a little store to help them over their difficulties. Cover the hive well to keep them as warm as possible.

**Bees not Taking Food** (*E. T.*).—See reply to "SUBSCRIBER." If the hive is light it is desirable, of course, to add to the resources which are to last the winter, but if syrup be offered it should be rather less watery than that you mention. With barleysugar you may succeed in wintering the stock even if now it has scarcely any sealed store. Flour cake may be given later on.

#### POULTRY AND PIGEON CHRONICLE.

#### IMPROVEMENT OF THE HAMPSHIRE AND WEST COUNTRY DOWN SHEEP.

(Continued from page 369.)

HAVING previously alluded to the best style and character of certain flocks of these sheep and their breeders which have been available for the past twenty-five years we must refer to a valuable class of sheep called the Somerset Downs, which were common to that county for a number of years following the attempt made by the Somerset breeders to establish the Down breed, and to discard the horned ewes entirely. They thought that they could give up the horned breed and obtain all the advantages they required from a Down stock. They, however, soon found their mistake, for the Down ewes of the pure breeds, either of Hampshires or Sussex Down, would not bring their lambs early, although reared on the same soil and climate where the horned ewes had always done so from time immemorial. The far larger portion of the farmers returned in consequence to the breeding of horned stock. At the same time it must be observed that they could not raise lambs enough from the Downs. There were, however, about that period some farmers who reared stock of the cross between the horns and Downs by the use of the Down ram with their horned ewes, and this was done to some extent in both Dorset and Somerset. They had no definite object in view like that which we shall presently show is our object in introducing the subject—that is, the fixing a new type and character of sheep, and therefore they did not continue the cross. In consequence of the cross and the use of the Hampshire or Sussex rams with ewes of this cross we found numerous instances where remarkably valuable stock was to be obtained at the Appleshaw and Weyhill fairs in Hampshire. We have purchased ewes of this cross at various times, and they answered well; lambing in December, bringing plenty of twins, and being excellent nurses, they reared lambs of the best quality for Easter.

In looking back to the period when we had a choice for selection of some of these cross-bred stock it induces us to believe that a new and improved fixed type and character of sheep would be very desirable at the present time for the improvement and renovation of the Hampshire and West-country Down breed of sheep.

Although the cross-bred stock to which we have referred is not now available, we are induced to recommend the raising of a new style of animal and the fixing of a type and character to be called the Somerset Down, to be raised by mating the Hampshire Down ram with the Somerset ewe. Nor was there ever a time when we had so valuable a stock of Somerset ewes to select from; and there are still some very good flocks of Hampshire Downs from which to obtain rams. Having the object in view of raising superior lambs for the Easter markets we for many years kept the best Somerset ewes we could buy, and mated them with Hampshire Down rams of our selection, and always found the produce in lambs, both in numbers and quality, very superior.

In accordance with the subject upon which we are writing we shall quote from a paper read at the Botley and South Hants Farmers' Club by Mr. Joseph Blundell of Southampton in May last, the subject being "The Cross-breeding of Sheep, with the View of Fixing a New and Improved Breed." He says, "Practical sheep-breeders will admit at once that no objection can be taken against an alliance between the Hampshire Downs and the Somerset horned sheep, because the original sheep of Hampshire were a horned breed; the same with the Shropshire breed. In Wiltshire, too, the original stock of the county were horned animals. In order, however, that no prejudice may arise as to the value and distinctness of character, it must be considered that we are not recommending the original Dorset breed for crossing with the Down sheep, but the improved Somerset, the latter being far superior to the former in all respects. With regard to the Hampshire Downs of the improved and present style and type we highly appreciate them, but yet think they may be improved in some respects by the use of the new cross if farmers can be found who will undertake breeding and fixing a type of sheep such as may be produced through the alliance of the Hampshire and Somerset stock, especially if carried out with intelligence, and for the most part upon those lines which gave us the Oxford Down breed. The advantages which may reasonably be expected from a new type of sheep called the Somerset Down are as follows:—That they would bring their lambs earlier by from fourteen to eighteen days, produce from 10 to 12 per cent. more lambs, and the ewes yield more milk than the Hampshire Downs; that they would be of even more early maturity and greater weight for age.

"As early maturity or weight for age must be considered one of the leading points to be considered in connection with the subject for discussion on this occasion, I have taken some little pains to obtain the weight for age of lambs of the Hampshire Down and Somerset cross breed exhibited at the Easter Cattle Show of the Botley and South Hants Farmers' Club by myself in the year 1845, which gave a dead weight of 10 stones, the pen of ten being about six months old, and a single lamb weighed 11 stones dressed as mutton. Mr. Geo. Gray's prize lambs in 1874 had a dead weight of 10 stones, with the same number and the same age, and a single lamb weighed 10 stones 5 lbs. dressed as mutton. Some Hampshire Down lambs exhibited for prizes at Overton Fair on the 18th of July, being about six months old, gave an estimated weight of 9 stones dressed as mutton. Hampshire Down lambs exhibited for prizes at Winchester Fair on the 23rd of October for several years, ten best out of one hundred (as returned by three layers), being at that time about nine months old, gave 13 stones, and a single lamb weighing 114 lbs. Hampshire Down lambs as exhibited at Islington Hall Cattle Show in pens of three in December, 1880, being at that time about ten months old, were Mr. A. Morrison's live weight of three lambs (first prize), 5 cwt. 3 qrs., the dead weight of each animal being estimated at 15 stones. Sir Edward Halse (second-prize animals) gave a live weight for three lambs of 5 cwt. 1 qr. 4 lbs., the dead weight of each being estimated at 14 stones. In order to decide the dead weight of the animals I have assumed that every imperial stone of 14 lbs. of live weight will yield as many London market stones of 8 lbs., and this is the best way as a rule. In referring to the weights of lambs shown at Botley Easter Exhibition it must be remembered that exhibitors in this case are at some little disadvantage in consequence of nearly all the lambs having been disposed of some time previously, which reduces the number from which to select, besides which it is customary to retain chiefly the ewe lambs, which answer the purpose for exhibition, as they prove the best quality; yet the wether lambs would, if kept, make the heaviest weights. Again, it must be remembered that the lambs compared with them and shown at Overton of the same age are all kept on together, giving a better opportunity for selection of heavier weights, especially when taken from larger flocks. The Hampshire Down lambs exhibited at Winchester Fair have also the same advantage. The Exhibition of lambs at Islington Hall were only in pens of three, and might have been exceptional animals taken from the flocks which

they represent. Besides which it has been stated that they had been housed, in which case they, of course, would have an advantage over animals fed in the open field. In speaking of exceptional animals, we reckon these at 3 per cent., it is sometimes only two, but never more than four.

"We must now refer to the best way of obtaining a fixed type of sheep, exhibiting as much as possible the Hampshire Down character, in order that we may have a breed of animals to fall back upon for the purpose, not only of maintaining the Hampshire Downs, but improving them. It would be well if several flockmasters would take the matter in hand simultaneously, as in the case of Oxford Downs as bred by Mr. S. Druce, who had the advantage of selecting suitable animals from the flocks of those engaged in the same object of fixing the type. We, therefore, recommend and hope that some stock-breeder of sufficient experience and perseverance will take up the question of fixing the type to which we have alluded."

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This year, on account of favourable weather, this has been greatly assisted by steam power wherever farmers have used it. It has, as applied to the autumn cultivation of land intended for Barley or root crops in the spring, been of great importance—not only as to the quantity of work done in so little time, but that it has also relieved the horses from their labour. We cannot say that we approve of rafter ploughing and working the cultivator with the shares on upon Clover leas, because it destroys the Clover roots, which ought to be allowed to remain in the land and afford by their decay a valuable manure for the Wheat or other crop which may succeed. When the Clover lea is encumbered with twitch or couch grass our plan is not to plough and destroy the Clover roots so valuable for the next crop, but to scarify and not to deeply break up the land rough, but only scarify the surface with the points on, not the shares. These will run like the teeth of a comb between the roots of Clover deep enough to loosen the surface and comb out the couch. After repeated work, each passage of the implement crossways with the former one will effectually pull out the greater portion of the couch, especially by the use of the Howard's self-lifting iron drag. Although nothing in following can make a foul Clover lea quite clean where couch has existed during the summer, yet it will be made sufficiently clean to produce a good crop of Wheat with an ordinary dressing of manure if the Clover roots are not destroyed and the land ploughed and pressed in due season. We must now state the difference as affects the future crop of corn between the two modes of cleaning the lea; for if the land is ploughed for the purpose and then cultivated, not only are the Clover roots destroyed but the land is made so loose that the Wheat plants become weak-kneed, as it is called, and break down before harvest. If the land is only scarified on the surface and then ploughed and pressed the young plants get a firm hold of the soil when the seed is deposited broadcast and falls into the presser grooves. Our plan is to plough rather deeply when the couch roots prevail, and then horse-hoe the land in the spring. In this way the Clover roots remain and furnish plant food for the Wheat, and has in our experience generally produced several sacks per acre more grain than treated as what we call a bastard fallow. Winter Beans should have been planted before the Wheat; if not they should now be done quickly. If the land should be heavy and not free for drilling or dibbling it is a good plan to drop the seed in the furrows at certain distances, and with a shallow ploughing cover the seed in, for in this way the birds do not injure them nearly so much as when drilled. Better still is the little seed drill attached to the heel of the plough; this seeds the land with more regularity than hand-dropping, and with less expense.

*Hand Labour.*—Men will still be required in storing or pitting root crops, especially Mangolds, which cannot be allowed longer to remain in the ground without risk and loss by the frosts peculiar to November. As we do not advise the sowing of Wheat after Mangolds, but prefer to hold the land over for Barley, Oats, or Peas, we think it the best plan to heap the roots in the field by employing all the men, women, and boys that can be spared for the work; or otherwise have the work done by the acre by casting together, first twisting off the greens, for we do not allow any knife or hook to be used in storing roots of any kind, but making up into heaps which clear a space of about 10 yards each way. It is therefore a question of hand labour only. The horses are then at liberty for more important work, such as completing or assisting in the preparation and seeding on the Wheat land. Whether the roots are required as a whole or only in part to be consumed upon the land they are well placed, being covered with a little damaged straw or fern and covered with earth; and if required for cattle in the yards or boxes they may be carted off to the homestead the first opportunity after Wheat-sowing is finished, without damaging the land by carting off the roots in a wet time. The greens are carted away daily and given to store cattle, milch cows, sheep, or breeding sows in the yards. We, however, approve of ploughing them in when Wheat follows, as they afford a considerable amount of manure for the grain crop.

*Live Stock.*—The Dorset and Somerset horned ewes are forward in lamb this year, and several flocks which we have visited within the

last few days are lambing fast, and show that the lambing will be completed about the end of November. The ewes which have lambed should be fed upon the Clover seeds at daytime, but a fold at night of mustard or rape is better for the lambs. The ewes should have in addition once a day cut Turnip and eake meal mixed in troughs, and this is essential although they may have plenty of grass, as it prepares them for eating trough food in the future; for we have seen them rather severely checked in condition when removed suddenly from good grass into Turnips or Swedes, which they should be when the lambs are about three weeks or a month old. The mode of feeding the lambs will be matter for consideration further on. The fatting cattle in the boxes or stalls must now receive great attention, in order that those which are intended for sale at Christmas may be ready for the butcher at that time; and a slight increase of bean meal, say 2 lbs. per day, in addition to the usual allowance of oilcake, will make them firm and fleshy at the time of sale. The home farmer in putting his cattle into the boxes at first must not give them any hay with their roots, but only good sweet straw; for if they are allowed hay at the commencement of feeding they will not take to straw afterwards without receiving a check. The feeding with straw in preference is extremely important, for hay is not only too costly to turn to profit in feeding, but in our experience for many years we have found it unhealthy for the bullocks if they receive a liberal allowance of cake and meal with the roots, as we have frequently found them refuse their food for many hours in succession, but never when they get only straw as fodder whether cut into chaff or otherwise. The milch cows should now receive, as supplementary to the grass food, some cut roots mixed with straw chaff and deoortiated cotton eake in the racks at milking time, and another bait afterwards if they lie in the pens at night, as they ought very soon to do.

**KERRY CATTLE.**—The sale of pedigree Kerry Cows at Streame Farm, Horeham Road, Sussex, which was postponed a few weeks ago, will positively take place on the 8th of November. Particulars will be found in our advertising pages.

**THE HARVEST IN SCOTLAND.**—The harvest in the Lothians is said to be the worst that has been experienced for many years. The grain generally is seriously damaged by long exposure, and the stock, Barley especially, is so deteriorated in quality that it is practically unsaleable to maltsters. The Potato disease is still spreading. In some localities the crops are not worth lifting, and in others there is only one-tenth of the Potatoes sound. The disease spreading so rapidly, farmers are fast digging the Potatoes and sending them into the market; consequently prices are falling rapidly. The Potatoes now being sold in London contain a large per-centage of diseased tubers.

## POULTRY AND PIGEONS

### JANUARY CHICKENS.

The passing months render it necessary for the prudent fancier to prepare for next year's work in the breeding yard. If early chickens are to be hatched, it will be expedient before very long to mate up a yard or two of suitable birds. The 11th of December is the day upon which the setting season opens, and lucky is the fancier who on that day has two or three settings of eggs collected, and either hens or a reliable incubator to entrust them to. The birds wanted for the Palace and Birmingham Shows must not be counted upon to furnish the necessary eggs. They will come in a little later, but must be supplemented at first by a few others.

Two difficulties present themselves—firstly, to procure eggs at the right time, and secondly to insure the fertility of the eggs. Both difficulties can be overcome if proper fore-sight has been exercised, and if the advice which we gave early in the year has been followed. There should now be in every yard where early chickens are desired two or three hens of last year which have almost moulted out. These should be mated about the 1st of November with a suitable cockerel not intended for the show pen. There should also be some pullets just about ready to lay. The best mate for these will be a late-hatched cockerel of last year, which has now come to maturity and has up to this period been kept apart from the hens. Either or both of these plans is preferable to mating a cockerel with pullets; but if this last course be inevitable, then the birds of each sex should be as fully matured as possible. Not more than two or three hens or pullets should be allowed to each male bird.

Having mated up the breeding pens, it will be desirable to allot to them the warmest houses and driest runs, and to give them as much liberty as possible. A moderate portion of meat or some other stimulant and a liberal allowance of non-fattening food are the next points to be attended to. We have found that

the laying-on of fat is, at this season especially, a great hindrance to laying, and this should be guarded against. A small feed of oatmeal three times a day will often work wonders in bringing in a few eggs, when other means have failed to check the tendency to fatten. Oatmeal alone is expensive food, but then eggs for hatching in December are worth some extra expense.

We are not advocates of artificial heating as a means of producing early eggs, but any method of preserving the natural heat of the body from too speedy exhaustion may with advantage be adopted. We one winter had an unusually abundant supply of eggs from our Spanish pullets, and found that our poultry keeper had replaced the ordinary roost by a 9-inch plank covered with straw. A few ties of straw rope or cord kept the straw from falling off the plank, and, as the most of the droppings fell clear of the plank, an occasional renewal of the straw was all that was necessary. This plan is better than bedding the birds in straw on the ground, as it is more to their taste and effects a considerable saving in straw.

In very unfavourable weather it a good plan to confine the birds to their houses, but this can only be done when these are fairly large and well lighted, and it should only be done in really bad weather, or the stamina of the birds will be lessened, and the chance of fertile eggs decreased.

We will suppose that the expected eggs are forthcoming early in December. The next trouble will be as to getting them hatched. We generally employ an incubator for hatching purposes, and when once the season has commenced the eggs are put into the incubator as they are laid. It must be borne in mind, however, that eggs which are some days old do not hatch quite so well in an incubator as under a hen, and as there may be some eggs which have been laid some little time before the 11th of December it is well to provide a hen or two for these. If there are any surplus pullets laying towards the end of November, these should be confined to their house and a few eggs left in the nest. These will generally lead to one or two of them clucking. If this can not be managed, a general search amongst friends and neighbours is the only other course. We well remember a few years back instituting such a search just before Christmas. We visited some six or seven villages and some forty or fifty cottages without result. We at last came upon a solitary cottage with some well-kept hens about the door. We were met by an old woman, who answered our "Have you such a thing as a clucking hen?" with an apparently surprised query—"What would anybody be wanting with a clucking hen at this time of year?" Taking this for a denial we turned to go with the reply, "That anyone who had a lot of valuable eggs to set would be glad of a hen even then." It was a lucky remark, for it softened the old lady's heart and led to a confession that she had two clucking hens which were intended to be set upon Duck eggs. A good deal of persuasion and a promise of a setting of Aylesbury Duck eggs led to a transfer of the hens to our possession.

The difficulty we experienced on that and other occasions led us to try an incubator for early hatching, and except for the eggs gathered for hatching out on the 1st of January we have found that it answered all purposes. For the collected eggs the hens are better, but even these should be placed in the incubator if a hen cannot be found.

## CYCLAMENS.

**A**T this season of the year, and onwards through the winter and spring months, few plants are more attractive or useful than well-grown Cyclamens. The foliage alone is attractive independent of the flowers, but when these are produced they are serviceable for almost any purpose, either for bouquets or vases. The plants when in flower are admirably adapted for room-decoration, and not only look beautiful but last a long time; indeed where gas is not used they last nearly as long in good condition, if the position they occupy is light, as if allowed to flower in a conservatory. If rendered useless after doing duty for room-decoration it is of little consequence, as a fresh stock can be annually raised; in fact, I fail to see the utility of troubling with them a second season, when good plants can be grown in twelve or fourteen months from the time of sowing. I have endeavoured to grow old plants, but am now fully convinced that to raise them annually, as is general with Chinese Primulas, is by far the best system that can be practised. Sowing the seed in the spring is too late if good-sized plants are to be produced. The best batch I ever grew was from seed sown the last week in October, and in exactly twelve months good plants in 5 and 6-inch pots were obtained, some of the earliest flowering profusely, and continued in succession to supply flowers through the winter and spring. They are as easy to grow as Primulas when once the right system is adopted, only they take a little longer time.

The primary points necessary to achieve successful results are to sow the seed in October, or early in November at the latest, so that small healthy plants will be produced for potting early in January. A check to the plants while growing must be avoided, and they dislike a dry atmosphere. When growing well they have abundance of water in the leaves in small globules, which are readily discernible if a leaf is torn open, and when in this condition cultivators may rest assured the plants are thriving. Practice has convinced me the plants must not be placed upon dry shelves in any stages of growth. A bed of ashes is the best, keeping the plants close to the glass, or the foliage is liable to become weakly.

If possible Cyclamens should have a small house devoted to them after they are in pots, as they do not grow well when mixed with other plants; but small Ferns and some other plants will adapt themselves to the conditions of the Cyclamen house. Small low houses are too frequently needed in the majority of private gardens. To a large extent the reason of these plants not being well grown in many establishments

may be attributed to this. It is almost impossible, with the medley system of growing decorative plants, to have them all in such fine condition as where separate houses are devoted to them.

In sowing Cyclamen seed pans or 6-inch pots should be employed, well drained, and nearly filled with a light compost of loam, leaf soil, and sand. The seed should be covered with sandy peat and leaf soil mixed. The soil must be well watered, and covered with a square of glass until germination takes place, and the pots be placed in heat. New seed is preferable, as it soon germinates, but old seed takes a much longer time. When the seedlings appear the glass must be tilted, exposing the young plants gradually to more light. They must be kept in a temperature not less than 60° in their early stages, and when large enough to handle should be pricked out into other pans. If the sun proves strong shade is necessary for a few days until they commence rooting. The compost must be light, containing much leaf soil, so that the young plants will have plenty of roots when lifted for potting. The first-size pots should be 2½ inches in diameter, and if established in these by the end of January so much the better. When in small pots they should stand on a moist bed close together, and if a little cocoa-nut fibre can be placed amongst the pots it will prevent them becoming dry too quickly. The next shift should be into 3 and 4-inch pots according to the progress the plants have made. The soil then may be of a stronger nature, employing a greater proportion of loam, and pressing it into the pots more firmly than is necessary at the first potting. By the time these pots are full of roots the plants will be of good size. The temperature can be gradually lowered, and fire dispensed with as the season advances until the plants can be grown under cool conditions. If care is not judiciously exercised the plants may be checked when fire is discontinued. At first air must be sparingly admitted, giving more as the atmosphere outside becomes warmer until they will bear it circulating freely amongst them. If the weather and nights prove warm during June they can be grown afterwards in cold frames.

Cyclamens are greatly benefited by early closing during sunny days in the early part of the summer months. Shade is necessary during hot weather, and must be employed with some forethought so as not to exclude too much light and thus weaken the foliage. For the final potting 5 and 6-inch pots may be employed, the size depending upon the strength of the plants. The potting may be firmer than in any previous case, and a seventh of well-decayed dung or some bone dust can be added to the loam. Leaf soil will not be needed. After potting the frame must be closed for a time until the plants fairly commence rooting, when air may again be gradually admitted until a good supply can be given, and a little ventilation provided all night. A free circulation of air is essential for obtaining Cyclamens in their best condition, as their beauty much depends upon bold stout foliage close over the pots. When plants are in this state and brought gradually into flower as required with a little heat in a position near to the glass, the flowers stand up boldly above the foliage and require no stakes nor ties.

While growing, Cyclamens need liberal supplies of water at the roots as well as on the foliage, but it is prudent to drain the pots well, as the plants dislike stagnant soil. Liquid manure will only be needed after the large pots are well filled

with roots, and then it must be supplied in a weak state alternately with clear water. Nothing is better than that made from cow manure and soot and used in a clear state. The latter stimulates the plants quickly and brings out the beautiful marbled markings of their foliage.

It is surprising what a lengthened supply of flowers can be produced from one good batch of plants all raised at the same time. This is accomplished by bringing them into heat successively, and keeping the remaining portion of the stock cool until wanted. I am inclined to believe that those who grow one good batch of plants in the time and manner described, will not trouble further with growing old plants a second year.

Those who have small plants from seed sown late will do well to remove any flowers that may appear, and keep the plants slowly growing in heat through the winter. By following the details given above the small plants will develop into grand specimens ready for next autumn and winter flowering.—W. BARDNEY.

#### POTATO TRIALS AT GIRTFORD IN 1881.

On the 9th April I planted on a piece of light sandy loam in the Experimental Garden trial rows of thirty-six varieties of some of the most distinct of the older and several of the newer sorts of Potatoes, both early and late kinds. The ground was unmanured, but had been trenched the previous year, and the sets were placed in drills, which were filled in with a mixture of burnt rubbish, to which I added about four bushels of soot to the load; 2 lbs. per chain of Clay's special Potato fertiliser was also sown in the drills, omitting some intervening duplicate rows. The seed consisted of selected fair-sized sets, with the exception of Reading Hero, Woodstock Kidney, Wormleighton's Seedling, and two or three others, the seed of which I found it necessary to economise in order to complete the rows, and of these sorts small cut sets with mostly a single eye only were used. The drills for the early varieties were drawn 2 feet apart, and those for the later and vigorous growers 3 feet apart. Of several of the varieties additional intervening rows were planted without the fertiliser. The objects of my trials were, 1, To ascertain the sorts best suited to the soil of the locality; 2, To enable me to cross-fertilise the best varieties; and 3, To test the value of Clay's special Potato manure or fertiliser. Many of the early varieties ripened off somewhat prematurely during the hot weather of July without having had sufficient rain from the time of planting to develop a good crop. Single roots were tried from time to time, but I did not lift the bulk until the 5th of October, when the late sorts were ready, in order that I might the better compare results.

I found but little difference in the produce of varieties where whole or cut sets were used. For instance, the crops of Wormleighton's Seedling, for which small-cut sets were used, and of Magnum Bonum from whole sets, were about equal, both being very heavy; in other respects the two varieties appear exactly similar. The heaviest crops in the trials were obtained from these. The effect of the special fertiliser on the early sorts as compared with the same varieties planted without it was hardly perceptible, but in the late varieties the difference was very marked; and although I was unable to weigh the produce, I found from the bulk which was removed in market baskets that the rows of the later sorts manured with the fertiliser were on an average 50 per cent. in excess of those not treated with it; the result confirming the opinion I had already formed from previous practice—that artificial manures in dry weather are of comparatively little use for the particular crop for which they are intended, although their value as adding some unconsumed fertilising matter to the soil for future use is important, and sometimes very perceptible in future years. The early Potatoes, which were ripe before the autumn rains saturated the ground, were almost entirely free from disease, the only exceptions being in the case of a few of the American sorts, in which disease had probably been present in the sets.

The earliest and best of the early varieties was a medium-sized kidney sent to me as Fenn's Early Kidney, and which I believe to be Early Market. The haulm is very short, and it may evidently be more profitably grown in rows closer than 2 feet apart. The tubers averaged nearly as large as those of Rivers' Ashleaf, and the produce in quantity quite equal to it. Giant King, usually much diseased, but this season especially free from it, was very fine. The same remark applies to Early Shaw, which used to be grown a good deal in this district for market purposes, but is now almost displaced by the American Rose and others of its type, as they are heavier croppers and are good for sale right through the

Potato season. King Noble I consider inferior to Giant King and Early Shaw. Beauty of Hebron has maintained its position as the best of the early American varieties, its handsome tubers and paler skin giving it an advantage in the market over the Rose, whilst in quality and quantity of produce it is at least equal to the Rose. Red and coloured Potatoes are not, however, popular in the market; and if the white sport from Beauty of Hebron proves to be as productive as its coloured type it will be a material advance. International Kidney was not equal to its usual size, but the quality when cooked was excellent. Disease was, however, largely present at the lifting.

Schoolmaster was handsome, even-sized, large and prolific, with few diseased tubers. The quality and flavour off the dry sandy loam was very good, and I look upon this variety as one of the best light-land market Potatoes of recent introduction, and one which when more extensively known will displace some of the older round whites. Porter's Excelsior was small, and, as usual, much diseased. It is very much like a Potato I had for nearly twenty years under the name of Parker's Ashleaf, and of which I could rarely save more than seed again. Snowflake and Swan's Egg, two varieties of the same type and not much dissimilar, were both very handsome and of fair size, but both cooked heavy, hard, and waxy. Pride of America is certainly distinct from Snowflake, as it is of larger size, of better quality, and the colour a light lemon white. Taken altogether it appears to me to be one of the best, if not the best, of the new American sorts. Covent Garden Perfection did not reach the standard here which has been adjudged it by public opinion. The quality was first-rate, but both in size of tuber and produce it was far below many others, although the sets were of full size. It was not much affected by disease. Woodstock Kidney, on the other hand, from small-cut sets gave large, and, where not grown out, handsome tubers. The quality is good, and although fully one-half the tubers were diseased the produce was amongst the heaviest.

Grampian as a coloured round has good appearance and came of even size, but was much diseased; indeed this variety has especially suffered in this respect during the past three years at Girtford, and has not justified the recommendation of the Committee as a profitable light-land Potato for growth in Ireland. Trophy came large and handsome, and fairly free from disease. The quality of this and the next I have not yet ascertained. Vicar of Laleham, a very large and handsome purplish-red round variety, was the largest of all; and although three or four tubers to a root was about the average, the bulk was very heavy and it was but little diseased. Matchless and White Mountain are both large and handsome white roundish flat varieties, the latter being the largest white in the batch, but both were very much diseased. Reading Abbey is a good-quality white round Potato of somewhat vigorous growth, but the tubers were considerably affected by disease. The largest and best of the Lapstone type is Lady Godiva, but here again disease tells yearly a constant and conspicuous tale. Magnum Bonum and Wormleighton's Seedling were both very free from disease, and both are strong growers, ripening at the same time, very ugly and much grown out, and as I have stated before, not here perceptibly distinct. Scotch Champion planted at the same time was this year considerably diseased and has changed places with Magnum Bonum, which during the two previous seasons has not withstood the disease nearly so well as Champion. Champions are much grown out where planted early, but where late planted are in much better form and freer from disease. The crop was large from the trial row.

The most serviceable Potato for winter use I believe will be Suttons' Reading Hero, as the quality is first-rate, the produce very heavy, and not a single diseased tuber, although the foliage was affected. It is a very vigorous grower, the stem almost wood when ripe; it must have ample space. The only objection to it—and that, I may fairly say, a temporary one, for it is doubtless the result of the exceptional season—is that the tubers were a little grown out, but not so much so as Magnum Bonum or Champion. If others have found Reading Hero as free from disease as it was here it will be the most valuable introduction we have lately had. It is a round, slightly flat, and elongated variety; eyes not very deep, and comes in late. The flesh is light and floury, but sufficiently firm without being so waxy as Champion.

From the newly or recently introduced sorts my selection as the most useful for general purposes would be the following five—viz., Beauty of Hebron, Schoolmaster, Pride of America, Woodstock Kidney, and Reading Hero.

The results of cross-fertilisation were not very encouraging, and from upwards of one hundred crosses, or attempted crosses, I shall have to be content with some half dozen berries. One only from Champion crossed by Victoria, and the only fruit I have ever had from Champion, I shall watch with some interest, as the produce

should, if there is anything in breed, give an improvement on Champion, and lead in the direction recommended by the Potato Commission. Doubtless more success would have attended my work, but the extreme drought of June caused the berries to drop from the sudden ripening at the roots, and later crosses did not ripen.—T. LAXTON, *Bedford*.

#### PYRUS SALICIFOLIA.

A NOTE on this deciduous tree may not be out of place now that the planting season has arrived. It is surprising it is not more planted, and would be perhaps if it was more generally known. It grows into a shapely tree when sufficient room is allowed it to develop naturally. This *Pyrus* attains a large size, and would be suitable for planting in any position singly. When in flower during the month of May a good tree is very beautiful, being covered with its snow white flowers. It appears to thrive well in smoky positions, and cannot be very particular about soil, as it grows here freely in poor soil. When in flower this season the bloom was severely injured by frost, but in spite of this it is bearing a good crop of fruit. The tree fruits annually without fail. The fruits, however, are of no service or beauty, but as a flowering tree it is worthy of a place, and is quite distinct in the foliage from other trees. The great freedom with which it fruits annually has impressed upon my mind that it would in all probability prove a good stock for some Pears. I shall be glad to know if it has been tried, and if so with what results.—LANCASTRIAN.

#### PLUMS.

In the present season we have had a fair supply of Plums, but by no means a full crop. Most of our trees, standards, pyramids, bushes, and espaliers, flowered well; but frost and keen winds left many of the trees without fruit. In other respects it has been an advantage. The trees have made clean healthy wood and promise well for another season. Mildew and aphides have not been so numerous as in some seasons. We commenced gathering at the end of July from trees on the wall having a south aspect, from Rivers' Early Favourite and Rivers' Prolific, two fine Plums for all purposes when well ripened; soil light loam, gravelly subsoil. *Précoce de Tours* is useful for all purposes; south wall and aspect, strong loam, clay subsoil. *Early Violet*, a very desirable early Plum, ripens about the middle of August. I have a doubt about the accuracy of the name: can this be the Royal Hâtive of the "Fruit Manual?" Orleans comes next; and on a wall with a south aspect the fruits are abundant and fine. I cannot dispense with it. *Victoria*, very fine, one of the most useful Plums we have, especially for market. *Kirke's*, a splendid Plum on south and west walls, has not been so plentiful as we could wish, but remarkably fine and of the best quality. The indispensable *Green Gage* has done us good service; the quality needs no praise. Its purple compeer must accompany it. No Plum in cultivation can surpass this for quality. They are free growers, answer well in many places as standards, and are good bearers. *Bryanston Green Gage* is a fine Plum, but lacks the quality of the above when partly shrivelled; it is very good. *Washington* has been remarkably fine; it is an excellent variety, one of the very best, and ought to be more frequently met with. *Jefferson's* has had a moderate crop, but of good quality from a west aspect. *White Magnum Bonum* was not so plentiful as we could wish, but the quality has been all that could be desired. *Golden Esperen* is rather scarce but good; it does well with us in a west aspect. *La Delicieuse* is a fine late variety, with fruits of large size and good quality; it succeeds as a standard, and the fruit hangs well on the trees during September and October. *Reine Claude de Bavay*, one of the very best late Plums, abundant and fine, of first-rate quality, south and west aspects, hanging to the end of October. *Coe's Golden Drop* had a moderate crop and fine; it needs no praise, south and east aspects are the best, the fruit hanging till November. Many others I might enumerate, but those given have ripened in the order named, and have done us good service for all purposes.—P. D., *Yorkshire*.

THE LATE GALE IN ST. JAMES'S PARK.—Although well acquainted with the Park for more than thirty years, I do not remember having noticed so much damage done by one day's gale as in that of October 14th. The line of old Elms on the north side of the enclosure were the special sufferers thereby. In several of the fallen trunks I examined the larvæ of the goat moth had evidently been at work, but I did not, on a cursory inspection, discover any traces of the beetle (*Scolytus destructor*), which was formerly so harmful to the Elms of this and the adjacent parks. Two trees had been torn up by the

roots that were to all appearance sound. This may be attributable to the effects of the drought of last summer, and to the succeeding influence of the heavy autumn rains.—J. R. S. C.

#### BOILERS VERSUS WATER.

I READ with much interest Mr. Ollerhead's account of his boilers on page 281, and must say he deserves commendation for his perseverance and the success of his work. It was a bold act; few would have attempted it, and I am afraid there are not many will begin such a job notwithstanding his example. As Mr. Ollerhead asks for the "experience of others on the furring of boilers, and the means of preventing it," I give my opinion on the subject. It seems strange that the subject has not been noticed before this, at least I do not remember seeing it discussed; and as others in the neighbourhood who use the same kind of water must have their boilers in a very bad state, their coal bills and labour must have been great to keep up the required heat in the past cold winters.

Incrustation is generally caused by the deposition of calcareous matters on the heated surfaces of the boiler. Most water except rain water contains lime or magnesia (or both), held in solution by carbonic or sulphuric acid, and such water is generally called "hard." The effect of this hardness is familiar to most people. It destroys soap in washing, and when water of this nature is boiled in a kettle there is a deposit or cake formed over the inner surface. This deposition or solid hard layer of matter is caused by the decomposition of the bicarbonate of lime or magnesia present in the water when heated. Carbonates of lime and magnesia are insoluble in water, but when there is excess of carbonic acid, invariably the result of decomposed organic matter, the carbonates combine with this excess and become bicarbonate. These are soluble in cold water.

On heating such water this excess of carbonic acid is eliminated, and ordinary carbonate of lime and magnesia are deposited. These as a rule form the scale on boilers. Sometimes, however, the water holds sulphate of lime in solution, and this substance is deposited on the inner surface of the boiler and tubes by the gradual evaporation of the water. This form of deposit is more difficult to deal with than the carbonates, as it adheres more closely, and is much harder and tougher than the deposits caused by carbonates.

In steam boilers for both land and marine engines this deposit is the cause of great annoyance, loss of heat, and danger to the boilers, as well as a fruitful source of accident, causing destruction to life and property. Many nostrums have been sent out to steam users, all of which in some way had a claim to respect: Potatoes, sawdust, seaweed, zinc plates, and chemicals have been tried and used in certain cases, but a general cure has been difficult to provide until the subject was looked at really in a chemical manner.

When water containing bicarbonate is heated the excess of carbonic acid, as has been explained, is expelled, and a deposit of chalk in a hard form adheres to the boiler. So also in water containing sulphate of lime, there is a deposit formed which soon accumulates and forms a solid layer between the heated walls of the boiler and the water inside. This is a non-conductor of heat, and the result soon follows—i.e., that the iron burned or blistered, requiring a great amount of expenditure of fuel to heat through the deposit and reach the water beyond, the water is practically enclosed in a jacket of iron (the boiler), inside which is another jacket of incrustation, which everyone knows is a very bad conductor of heat.

The simplest and best cure for this is to introduce periodically a quantity of ordinary washing soda, the proportion varying with the size and work required from the boiler. From 2 to 7 lbs. will amply suffice for any ordinary boiler, say with 200 to 800 feet of 4-inch pipes: this, introduced once a month, will entirely prevent incrustation. With the number of feet of piping to Mr. Ollerhead's boiler 28 or even 56 lbs. would need to be introduced into the supply cistern of his boiler. The action of the washing soda is peculiar, as it, in place of allowing the deposit to form into a cake, causes the carbonate to fall in the form of a mud, whilst it decomposes the sulphate of lime. This mud must be removed periodically, which is simply done by flushing the boiler and opening the relief cocks. Old dirty boilers must be cleaned as Mr. Ollerhead did his; for while the washing soda, or still better caustic soda, American ash &c., prevent incrustation, it will not dissolve or remove incrustation already formed. Knowing the bad effects hard water had on boilers I always used soft water, and we had never any deposit in ours. After being nine or ten years in, there was only a small quantity of mud, but nothing to injure the boiler. In the case, however, of the boiler behind the kitchen fire in the mansion, where it was boiling

nearly night and day to supply hot water for the house, I have seen the deposit taken off 3 and 4 inches thick, and that every year when the family were at home the whole year. That deposit was a warning to me not to use the water in the garden boilers. Of course, there were doors on the boiler used at the house which could be taken out, but even then it was serious work for the men, but certainly nothing in comparison with Mr. Ollerhead's.

The water Mr. Ollerhead uses in his boiler must be very hard indeed that he obtains such a quantity of deposit as 5 cwt. in nine years, or his pipes must be leaking. Does he use the water in his pipes for warming the cold water in his cistern for watering plants as I have seen some do? The small quantity of water evaporated from any boiler, if all is otherwise right, cannot account to my mind for the quantity of deposit taken out, even with all the length of piping he has. That is one of the difficulties we have to determine—to know the quantity held in solution in the water, and the quantity of soda, &c., necessary to neutralise its bad effects. However, it is best to err on the safe side, and the soda in any form will do no harm.—ALEX. SHEARER, 4, Marchmont Street, Edinburgh.

### ROSE CATALOGUES.

AGAIN come the Rose catalogues; they descend in a shower! I have had the honour of receiving at least a dozen, and that by no means includes all the important firms that now cater for the public. How extensive the trade must be! How pleasant it would be also to send an order for fifty plants from each, and how glad the respective authors must be that the lists are out. All are once more at liberty to read, compare, and be thankful; for certainly a lazy public has thus furnished to it, if only thus to be used, some very pleasant and profitable Rose reading, while there has been hard and good work in the way of writing.

Looking at once to the future I notice a "white Baroness" announced by Mr. G. Paul, which he promises shall have more substance than the otherwise charming Mabel Morrison. Cranston's Company put forward Mary Pochin, raised in a Leicestershire vicarage garden, and having already received two first-class certificates.

"Bonum nomen,  
Bonum omen."

All will hail such a welcome addition to our catalogues. Then Mr. Cant speaks in his prize list of a General Sir Evelyn Wood, with which he gained a new Rose prize in 1880 at the Alexandra Palace; but he does not appear to be sending it as yet into commerce. In the Cranston catalogue—which is largest of all, as becomes a company—there is an engraving of H.P. Mary Pochin, also of Mrs. Jowitt, and even of dear old Devonensis. They publish a grand list of their last year's victories. Both Mr. Cant, Mr. Prince, and Mr. Walters have some pleasant additional reading—the record of visits during last year to their Rose gardens; while Mr. Piper gives a useful list of show Roses of 1879 and 1880. Mr. Turner does not offer a new English Rose this year, but has an evidently carefully drawn up list of the new French Roses. Collating this with Mr. G. Paul's list and that of the Cranston Company I gather that H.P.'s Comtesse de Camondo, George Moreau, and Madame Montel or Montet (?) are the most generally approved; also, all concur in praising Tea Reine Maria Pia, which seems to be very much the same as Reine Marie Henriette, a real vigorous good climbing red Gloire de Dijon; only, luckily for exhibitors, the authorities do not relegate the former to the shut-out H.T. list, which is the hard fate of the latter. Speaking of H.T.'s, I see one grower now offers the Bennett Roses at 1s. each, or 7s. 6d. for the lot. "The world is his who knows how to wait for it" will be feelingly acknowledged by those of us who paid 10s. 6d. for single plants! But even "D., Deal," himself must admit this a bargain, and I do not yet despair of seeing some of them some day in honourable places.—A. C.

### PEARS FOR WALLS.

"JOHN BULL" (page 327) is evidently not a gardener, and is, indeed, not very practically minded, and is rather given to cast "longing lingering looks behind" him. Some fond memories haunt his dreams, and he would fain live the past over again. He remembers, or has heard of—it is not quite certain which—walls covered with "splendid and splendidly trained" specimens of trees on walls, which "bore an abundance of fruit for use and a surplus for friends or the market." Did they? And if we go back to the old system, will they? If they did, why did those "gentlemen and gardeners who have passed the meridian of life" referred to, grub out the trees? "JOHN BULL" thinks it would be advisable to plant trees for "future generations," forgetting that there is always the possibility of future generations being so

much ahead of us in every branch of pomology as to consider our work of no importance. We are pretty sure that a generation hence our finer dessert Pears, Plums, and maybe even Apples, will not be grown either according to our system or the system of fifty years ago, and we are certain that the system after which "JOHN BULL" hankers will not then find a place.

One reason why gardeners now-a-days, more especially those gardeners whose recollections run back a generation, do not plant trees, the branches of which are ultimately to stretch 30 or 40 feet, is that such trees, however handsome and ornamental, seldom bore anything worth naming for the space occupied and the work entailed. It is not to the point to talk of the bushels of fruit borne by such big trees and compare them with the dozens borne by the smaller trees of to-day. The question is, "Which system produces the best fruit and the greatest quantity from a given space? and also, How long are we to wait for a mere question of sentimentality?" Another is the enormous expense necessary to produce such trees and to maintain them in fruitful condition. It is a comparatively easy task to fill walls with handsome trees. Scores of garden walls are so covered which produce very little fruit, and every practical gardener knows that. Those who succeeded with the old system made their borders very much in the way that Vine borders are made; others essaying to succeed, but not going to the necessary expense, succeeded in covering the walls with barrenness. The formation of—if need be—concreted borders at least 30 feet wide and 3 feet deep of good heavy loam, in order to secure the success which assures "an abundance of fruit for use and a surplus for friends" for any reasonable length of time, is an absolute necessity in ninety-nine cases out of every hundred. The idea that mere planting and training is all is a great mistake.

Fifty years ago labour and material were employed in the making of such borders for Pear trees; now the labour and material is spent on Vine and Peach tree borders, which return for the expense an amount of fruit undreamed of fifty years ago. This is another reason why Pear trees are not so expensively treated now. Another is that labour in "fine" gardens was much cheaper and very much more plentiful than now. It is a hard struggle now with far too many of us to make even vinery borders as they should be made, and we are driven to adopt a system of Pear tree culture that enables us to produce fine fruit plentifully with not a hundredth part of the work necessary under the old system. Then first-class results were secured by keeping the roots into the borders, by concreting borders, &c. Even then things went wrong. Digging and manuring and cropping the borders sooner or later produced overluxuriance and sterility. Now, if our trees are smaller and less perfect we grow them in much smaller quantities of material. Instead of concrete bottoms we now keep our roots where they should be by lifting, and, when it is likely to do good, root-pruning. That both processes are sometimes abused is not the fault of the system, but of the operator. In olden times when spring frosts killed the blossom the trees "went in for basket wood" and sterility. Should that happen now we can easily check the tendency, and at least secure flower buds. The consequence is, that now greater quantities of fruit is produced from a given amount of wall than was in the "good old days," concerning which some people are apt to be too enthusiastic and forgetful. Should an abundant crop come we know exactly where the roots are, and we can give them just the support they need, hence we produce much finer fruit now-a-days. If in the olden time inferior sorts were displaced by better kinds, what a loss of wall and time there was till a blank was filled! Instead of two or three years, it took a great part of a man's life. Now we can make room for testing a new kind with little loss, and necessary blanks are speedily filled.

Your correspondent advises gentlemen and gardeners who have new and lofty walls to consider the advisability of returning to the old system. Everyone to his liking, but we ask them to "seriously consider" the conditions necessary to secure success under that system, and to think whether they should incur it. In the present transitional stage—and it certainly is a transitory one—of pomology, and everything else, we think that our motto should be "Sufficient unto the day is the evil thereof." We cannot think that now the world has begun to move all around that pomology is going to stand. Assuredly it will advance. Where, then, is the wisdom of planting trees that will take a generation to perfect, and that at an unjustifiable expense, when a generation hence both the modern and the ancient may be displaced by a system superior to either. We certainly advise a short cut to plenty of fruit, and not to concern about the affairs of our great grandchildren.

But why new lofty walls to cover at all? Your correspondent says that although the seasons may have altered, and although

Peaches may require glass, the objection has no force as applied to Pears. Where does he live? Did he never hear of Pears failing on walls because of bad weather? We do wish the objection had no force. It must be a favoured spot indeed where Pears always crop well, and never fail to bring the crop to perfection.

Mr. David Thomson of Drumlanrig, and we can quote no higher authority, not long ago published the difference in price between a good new wall and a new orchard house of equal extent. The difference was not much. The difference in results secured by that eminent cultivator was very great. Instead of the precarious chances of open walls, there is the certainty of fine crops under glass. Instead of not always the best fruit and little

of it, there is to be placed fruit so much better as to be scarcely recognisable, and abundance. Instead of much outlay (for a great extent of wall) and little returns, there is the smaller outlay (for a comparatively small amount of orchard house) and certain and liberal returns.

We advise your readers to "seriously consider" if the time has not now arrived for the substitution of orchard houses for walls; of uncertain returns for certain ones; of the very finest fruit possible for comparatively inferior. At all events we ask them to consider whether this is the time to return to expensive methods which will undoubtedly be overthrown. We live in times when things must be made "to pay." Handsome wall trees in the old perfection style never did, and will not now. Pears must be

Fig. 66.—THE DISEASE OF CUCUMBER ROOTS, ENLARGED 160 DIAMETERS.

produced quickly, of fine quality, and in quantities to pay interest on the capital and labour. This is the state of matters generally. Of course if expense is nothing, any style fancy may dictate may be adopted. It is, however, worth considering if handsome trees cannot be grown on the newer systems. Your correspondent is hardly consistent on this point. He admits that cordons may be so trained as to be as handsome as ever trees trained on the old system could be, and then begins again to sigh for the old ones. Sentiment in this matter should be laid aside, and when your correspondent does that we fear even he will have little to say for the trees of fifty years ago.—A. H. H.

#### THE DISEASE OF CUCUMBER ROOTS.

I HAVE enclosed a Cucumber root for your inspection. If you can give me any information, through the medium of the *Journal of Horticulture*, as to the cause of the roots clubbing, I should be greatly obliged. I took charge of my present situation on March

25th last, and among the houses here there is a Cucumber house 36 feet long, 12 feet wide, with six rows of 4-inch pipes for top heat, independent of bottom heat. When I took charge there were a few old Cucumber plants in the house all clubbed like the specimen sent. I cleared them all out, cleaned the house thoroughly, raised a good stock of Cucumber and Melon plants, all of which grew well until they commenced bearing, then the roots began to go the same as the specimen sent. When each Cucumber plant had borne about six fruits I had to replace it, and so on all through the summer. The Melons went on all right until the fruit was as large as an Orange, when most of the fruits withered on the plants, and the roots assumed the appearance of the specimen. The soil I use is good fibry turf and old hotbed manure. The water that supplies the gardens is a large pond fed by rain water and drains from the land. On the 20th July I made my last sowing of Cucumber seed. I cleaned the house all through and filled it with new soil, and planted fifteen of the strongest of the seedlings, which grew well until a fortnight ago, when I began

cutting. The specimen sent is the third I have pulled up out of the fifteen. As I have always been very fortunate in the culture of Cucumbers and Melons, I am anxious to know the cause of them failing now.—W. J.

[The disease referred to by our correspondent has been figured and described in the Journal by Mr. Worthington G. Smith; and as the number containing the illustration and notes in question is out of print we reproduce them, as many other correspondents have desired information of late on this subject.

"The root-nodules in question are generally assumed to have a fungus origin, but the Rev. M. J. Berkeley long ago described the disease, and showed it to be caused by a parasite of another nature. The description he illustrated with the utmost accuracy. It would seem that the pest which causes the mischief is not always readily seen, or maybe it escapes into the surrounding soil, or, after working the mischief, perishes; but that it is sometimes difficult or even impossible to detect, Mr. Berkeley himself confesses. For our part we have frequently seen the interior of the nodules just in the condition described by Mr. Berkeley, with the parasites in all stages of growth, from the egg condition upwards.

"Our illustration represents on the left the diseased roots natural size, and on the right a thin slice through one of the nodules of the roots. The latter is an exact reflection from a camera lucida attached to the microscope, and shows the cellular tissue, A; pitted and spiral vessels, B; the worms coiled up in the eggs, C; worms emerged, D; and empty eggs, E, from which the worms have escaped. Mr. Berkeley refers these parasites to vibrios, which belongs to the infusoria (properly confervoid Algæ), common in foetid water, &c., and always, we believe, extremely minute in size; but it will be seen from our figure, which is enlarged 160 diameters, that the animals there shown are just over one one-hundredth of an inch long, whilst vibrios are ten times smaller, and do not arise from eggs, but increase by the formation of new joints and separation at the articulations. The parasite appears to us to belong rather to the oviparous section of the genus *Anguillula*, which includes the 'vinegar eel,' and except that it is only about one-half the size, it is very similar in all stages of growth to *A. Tritici*, an eel found infesting blighted Wheat.

"It is often complained that men of science cannot specify cures for the diseases they describe, but it should always be remembered that in regard to cures pathological botanists considerably resemble doctors of medicine. It does not follow that, because a doctor can tell by certain symptoms his patient may have Asiatic cholera or cancer, that he can therefore cure the disease; or because a fireman sees your house is being destroyed by fire, he can from that mere fact extinguish the blaze. Physic and water sometimes do wonderful things, and in the case of worms in the roots of Cucumbers, the best remedy is to destroy the plants and look to the compost, which probably harbours the parasites."]

## A RUN TO THE WEST.

LONGLEAT.

HAVING on page 379 referred to some of the features of the gardens under Mr. Taylor's charge, and sketched his system of management generally, noting also briefly some leading points in his practice, a few other matters now demand attention. Autumn and winter flowers, it has been said, are in great demand at Longleat, and to meet that demand a great number of a few kinds that have been proved to answer the purpose best are grown extensively and well. Tea Roses, Carnations, Tuberoses, and Gardenias have been mentioned. Passing by Roman Hyacinths, which are largely grown, and Amaryllises, which are remarkably vigorous, also Eucharises and Celosias, there are a few favourites that merit special notice. Achimenes, for instance, are yet in full beauty, masses of them not more than from 6 to 9 inches high being covered with fine flowers. The varieties are *Longiflora major*, *Grandiflora*, which I never before saw so dwarf, *Dazzle*, and *Williamsi*. The tubers are wintered in the pots in the usual manner, started into growth as needed without being disturbed, and the tops of the young plants cut off and inserted as cuttings. It is thus the plants are kept so dwarf for fulfilling the purpose for which they are required in room decoration. A trio now to be referred to demand a little more prominence—namely, *Pelargonium Guillon Mangilli*, *Begonia Knowsleyana*, and *Gesneras*.

### PELARGONIUM GUILLON MANGILLI.

Mr. Taylor detailed his experience of this variety last year in the Journal, and forthwith a demand was created for plants. If all the

readers of these notes could see the stock of *Guillon Mangilli* at Longleat now the demand for plants would be increased tenfold, or probably a hundredfold, for assuredly the display is a brilliant one. Mr. Cannell's magnificent winter display of thousands of plants in 6-inch pots, in a hundred or more of the best and most modern varieties, cannot of course be placed in comparison, as the conditions are essentially different in the two cases, the Longleat plants being chiefly large, huge bushes in 10-inch pots, and all aglow with hundreds of huge trusses. Last winter I saw plants somewhat similar of *Vesuvius* in the conservatory at Norris Green that made the *Chrysanthemums* look dingy; but bright and excellent as Mr. Bardney's plants undoubtedly were—in fact, they were as good as the variety could be grown—yet they were by no means so striking as Mr. Taylor's plants now under notice. This, the cultivator points out, is essentially a stove *Pelargonium*, and is precisely at home in a house with *Gardenias*, *Eucharises*, and *Euphorbia jasminiflora*. There are no signs of the plants being "drawn," but, on the contrary, they are as sturdy and vigorous as if growing in the open air in summer, only the colour in winter is more pleasing, the rosy purple of the upper petals being more clear and distinct, and the scarlet of the lower petals looking brighter by contrast, while the petals never turn mouldy and damp off. The question was asked, "How long will the plants continue producing such trusses?" The reply was, "For seven years if they have the proper heat and support," and the question of duration was settled. Mr. Taylor having tried most of the best *Zonales* has selected *Guillon Mangilli* as the king of the doubles for winter, and now he is trying to elect a queen, a white. At the present *Amelie Baltet* and *Nymph* are the most promising. If anyone can send him a really free-flowering double white variety for winter and they do not possess *Guillon Mangilli*, they will in due time receive a liberal supply of cuttings in exchange; and if they grow the plants as he grows them they will not be likely to part with the variety for some time. Strong healthy plants, a temperature from 55° to 65°, and a light house, are the conditions of success. Numbers of people have had this variety, but newer sorts have pushed it aside before its special merit was discovered. It is known now, and Mr. Taylor and *Guillon Mangilli* will be friends for a number of years—perhaps for life. We now pass on to note a striking contrast. Behind us is a glowing house of purplish scarlet, before us a gracefully drooping mass of white in the form of a row of plants of

### BEGONIA KNOWSLEYANA.

Old but valuable is this *Begonia*. I have seen it occasionally in my travels, but its name was not known. At Longleat it was also nameless, but on a spray being compared with the varieties flowering in the fine collection at Kew its identity was determined, and now that the name of this useful variety is known the plant must be more largely grown; but it needs to be grown well to bring out its full beauty, and this fortunately is easy enough. At Longleat the plants are in 6-inch pots, and are about 18 inches high and the same in diameter. They are clothed with large drooping panicles of bluish white flowers, which show with great effect from the dark green foliage. The great value of this variety is its amenability for cutting. You can cut and come again for months, for as soon as a spray is severed others are produced with flowers from every joint. It appears to be a white form of *B. insignis*, and for winter decoration it is unquestionably worthy of attention. Now that the name is ascertained Mr. Taylor will probably tell us what he knows of this plant and describe his mode of culture. I think he said it came true from seed, but I am open to his correction on this point. Be that as it may, it is most useful, and must not be forgotten; neither must the equally useful and totally distinct *B. semperflorens grandiflora*, as grown at Marston. Another change to brightness again, but not yet so dazzling as the effect will be a month hence, for shortly there will be, about the time of the Royal visit, a right royal display of

### GESNERAS.

Hundreds of these beautiful plants are grown—beautiful in foliage and brilliant in flowers. Only three forms are represented—*G. zebrina* with its rich velvety foliage and its loose spikes of orange-scarlet flowers. This is the first of the trio, and is commencing flowering, and will continue in beauty for a long time. Before it is over *G. refulgens*, with its dark plush-like foliage and closer spikes of bright flowers, will be in and last all winter; then succeeds *G. cinnabarina*, fiery in colour, handsome in foliage, and excellent in habit; its broad dense pyramidal spike rendering the plant most valuable for many decorative purposes, and the colour is highly effective under artificial light. *Gesneras* should be grown by all who have the means of growing them, for few if any stove plants are more strikingly beautiful from autumn until spring; they are also of easy culture. The tubers need potting during June, and the after-management of the plants, where potted in good soil, consists chiefly in careful watering. Handsome plants can be grown in 5 and 6-inch pots, and these pots are generally employed at Longleat, but for certain purposes larger plants are required, and more pot room is given accordingly.

### ROOM AND TABLE DECORATION.

Mr. Taylor has no conservatory to keep gay, but the mansion must be regularly furnished with plants, and not a few are requisite for furnishing it effectively. On this, however, it is not necessary to dwell, and the subject is alluded to for the purpose of noticing the style of table decoration that is adopted. It may be termed the

rustic style, the receptacles for plants being made in the garden. They are like Orchid baskets in miniature but in various shapes, the wood employed being about the thickness of an ordinary pencil. It consists of young growths of some of the *Spiræas*, and yearling shoots of Vines. Maple half an inch in diameter and with rough bark is also used for larger baskets. Another simple method is to cut the stems of young Larches into lengths of 4 inches, then bore a hole through each with a bit and gouge out the rest of the wood, leaving about a quarter of an inch all round; a piece of zinc is nailed over one end, and the miniature rustic vase is complete. Numbers of these baskets and vases are made, and small Ferns and other suitable plants placed in them, and they are more admired on the table by Lord and Lady Bath and their distinguished guests than more showy vessels of glass, gold, or silver. The really great can afford to enjoy simple homely tastes, and they do not, in the Sir Georgius Midas and Ponsonby de Tomkyns style, estimate the beauty of an article by what it costs. I pass now to a greater subject, and what is beyond question the pride and glory of Longleat Gardens.

#### THE VINERY.

It is easy enough to describe a garden, any clerk or schoolmaster can do that; but to do so usefully is another matter. And although I may fail in this, I would impress on others more competent in writing descriptions of places not to exhaust their talents in a flowery glossing-over of the results on the surface, but endeavour to go deeper and find, if possible, the causes of good effects or of failures; or at least to scatter a few good seeds that may be gathered by the way, for there is always ground waiting for their reception.

Much as there is to admire at Longleat, and well as are the different departments of the garden conducted, the great vinery overshadows all. It is a span-roofed structure standing on a wall of about 3 feet of brickwork, with side lights opening all the length, and a lantern in the ridge with two rows of side lights there also. Ventilation is thus amply provided for. The house is 216 feet long and 30 feet wide in the clear. It is not very lofty, the height being about 13 feet to the base of the lantern, which is 3 or 4 feet higher. A broad path runs along the centre, with pillars at intervals along each side, connected by semicircular arches over the path. The house is thus very strong, while at the same time it is light. It was built by Mr. Buckenham, the clerk of the works at Longleat, and the structural part was designed by him. The condition of the house testifies to his skill and competence, which have certainly not been exercised uselessly, but the skill of the cultivation of the Vines is at the least equally prominent, and the noble owner has just reason to be proud of the combined work of his servants. The heating was done by Messrs. Weeks, and is very satisfactory.

The border is about 3 feet deep, entirely inside. Ample drainage was provided, and freshly dug turf was, as has been previously stated in the *Journal*, put together like so many bricks; only no mortar was used, a very slight sprinkling of boiled 1-inch bones, about a handful to a cartload, being all that was mixed with it. The borders are quite hard, as bedding *Pelargoniums* are wintered on them, and other plants in pots are accommodated there, according to requirements, Mr. Taylor knowing very well that the plants do no harm to the Vines—indeed thousands were in the Muscat house when the grand crop was ripening and finishing so well. Besides, the borders are trampled on continually for dressing the Vines, not only by the chief but by his "boy Joc," this being Mr. Taylor's skilled and trusted foreman, who is in excellent keeping with the house and Vines, as he weighs about 17 stone. Many readers will remember it was almost a crime to step on a Vine border without using a board; but these notions are gradually vanishing, as it is being found out that the roots of Vines will not, cannot, take possession of a mass of light loose surface soil; but they come to the surface in this hard border, as may be seen readily enough when the *Pelargonium* boxes are moved, and the fibres, ever multiplying, spread in all directions, and no food escapes them. In light rich borders it is otherwise, for their strong, straight, fibreless roots pierce through the soil like driving a skewer through a bread loaf: hence the very luxuriant canes we sometimes see, and large but not thick leaves and small fruit. Such Vines, however, often come right in time, especially if they are not too severely pruned. But it must be remembered, that while firmness and adhesiveness may be regarded as synonymous terms as applied to cement, they are not as applied to Vine borders, which can and should be firm without being adhesive. So much for the borders, and now to the Vines.

The Vines were raised from eyes in the spring of 1870, and planted about 7 feet apart during the summer of that year. They grew strongly, and were allowed to bear fruit, to check over-luxuriance, the first year after planting. They continued growing vigorously and cropping heavily until 1874, when it became a question of persisting in the practice of mutilating them, or removing some and letting the others extend. Some moral courage was requisite in removing Vines that were bearing so well, but still a few of them were removed, and the end Vines were allowed to extend by training the main rods horizontally, and taking canes from them up the roof. The wisdom of the step was soon apparent, for the fruit on the restricted rods that still remained was clearly inferior in both size and colour to that on the others; therefore the extension Vines were encouraged to extend still further, and more of the restricted rods were removed to make room for them. At present there are just

fourteen Vines left out of about seventy that were planted. The house is in three compartments. The north compartment, which is 58 feet long, contains five Black Hamburgs; the south compartment, which is some 20 feet longer, is occupied by two Alicantes, two Lady Downe's, and one Mrs. Pince; the middle compartment, 80 feet long, is filled with four Muscats. The house is not wired in the ordinary manner, but an arched trellis is formed, starting at 2 feet from the glass at the base of the rafters on each side, and passing overhead 8½ feet from the ground. These four Vines therefore cover nearly 3000 superficial feet of trellis, from every part of which hang noble bunches, producing many berries 1½ inch long and 1½ inch in diameter; but these do not altogether quite satisfy the cultivator, yet as they increase in size yearly it is to be hoped they will do so shortly. They would satisfy most people now, and do satisfy those, as a rule, who see them and eat them.

It was of the Muscat and Hamburg compartments that a correspondent, who is unknown to me, wrote on page 363 that it was "the finest sight he had seen, or would perhaps ever see again." Although it is the finest sight of the kind that I have seen it is not the finest I hope to see, as I intend, if spared, to go to Longleat again when Mr. Taylor has grown Muscats to his satisfaction. He knows they have a fault, and he knows also the cause and the remedy. When he made the border he was not aware the soil did not contain a particle of lime, and there is not a trace of that mineral in the water of Longleat. This accounted for the defective stoning of the berries. By making good the defects of the soil, and adding lime and potash, he is surely overcoming the difficulty, and finer berries follow as a natural result.

The Black Hamburgs are all cut and bottled; they are of the first size and quality, while the colour is not only as dense as it can be on the fruit, but has crept up the footstalks. Many but not all the footstalks are coloured, and there is no mistake about these Grapes with coloured footstalks being decidedly richer than those with the ordinary green footstalks. This colouring of the footstalks is not a common occurrence; wherever it is seen it is evidence of good culture, and the Grapes under notice were of the highest quality.

The Grapes in the late compartment are less striking than the others. Larger bunches of Alicantes I have often seen, but never better finished berries. Lady Downe's has berries decidedly above the average, and the bunches are good. Mrs. Pince is splendid in bunch and berry, but not quite coloured as it should be. Want of colour is the great defect of this Grape, but Mr. Taylor is convinced it will improve—is improving—with age. He states, and few people can speak with more knowledge on the point, that the constitution of this Vine was broken by over-propagation when it was first introduced. At that time Mr. Taylor was Mr. Meredith's right-hand man, and had "something to do" with the Garston Vines when they were in the zenith of their celebrity, and he knows how great was the demand for Mrs. Pince, and how they had to go on topping and striking as fast as growth was produced to meet it. No Vine, he asserts, could endure such treatment without being seriously weakened, yet he is convinced that Mrs. Pince will in time be restored, and prove what it really is, a splendid Grape—a little more colour and it would be splendid at Longleat.

I had the curiosity to take the dimensions of one of the Vines under notice. It was not selected, but was the first at the end of the house which I happened to enter—a Black Alicante. Taking the length of the horizontal rod and the nine rods that arose from it at intervals and were trained up the roof, we found a total length of rod of 250 feet. "What sort of rod?" does someone ask? Well, such as is not common in Vines eleven years old, as just above ground the stem girthed 16½ inches. Nor was this the thickest stem, for one of the Muscats girthed 18 inches. These, then, are the Vines of which I ventured an opinion last week, that a similar example of culture had not been achieved in the time in the Queen dominions. In that opinion I must rest until proof is adduced to the contrary. When the house is entered and you pass under the arch of Grapes, all so near the eye, and see the timber-like stems in the corners and the horizontal rods trailing along the front like huge cobras, the sight is a truly remarkable one, and it shows what Vines will do when they have the chance.

Nor are these Vines tenderly nursed and pampered. They have never been syringed and never been peeled, and yet there is not an insect of any kind on them. Red spider could make no impression on foliage so thick, thicker than leaves of Figs, and which crumples like stout brown paper. The mere size of the leaves does not astonish, but their substance is wonderful. No doubt this is rightly attributed to comparatively low night temperatures. What these are is recorded on page 375; and that Muscats will ripen in Wiltshire under these temperatures the crop shows conclusively, for fine indeed the Grapes are, and superbly finished.

The growths of the Vines are trained thinly; the sun can shine on every leaf, and air can circulate freely between the foliage and the glass, the trellis being 2 feet from the roof at the bottom, and quite 4 feet at the top of the house; let this ample foliage space be a lesson. Laterals are preserved on the Vines down to the ground for thickening the stems and providing free sap channels; let this also be a lesson. In fact the non-peeling, non-syringing, non-steaming, and free-growing systems are all lessons, and sound lessons too, for they are derived from one who has shown their value by a striking and unequivocal example of success.

## THE FLOWER GARDEN.

I have no space left to dwell on this, and can only say it is near the mansion, and that forty thousand bedding plants are employed, and fine herbaceous borders are admirably furnished and managed. Verbenas grow like weeds—Crimson King and Purple King. "They will not grow in my soil," say hundreds in sadness. But perhaps they would if William Taylor prepared the plants. "A puff at last," I think I hear a whisper. But wait for evidence. I have a garden in London, which is certainly not a Verbena city; and soil as light almost as leaf mould and poor, which is certainly not a Verbena soil. Still I tried some Verbenas from three sources, but the plants from two of them lingered and died, while the dozen kindly sent by Mr. Taylor grew with the greatest freedom, and flowered until frost destroyed them. This is a simple fact which readers can deal with as they think proper; for myself I intend turning it to account by asking for a few more Longleat Verbenas. The only scarlet bedding Pelargonium grown at Longleat is Triomphe de Stella, Vesuvius not being nearly bright enough.

## THE PARK.

After a drive through the finely timbered and deer-stocked park, in which the trees and roads are kept so well by Mr. Berry, we creep up the bold Beech-clad promontory and stand in "Heaven's Gate." The view below is indeed grand. The mansion, two miles distant, is in the lowest position in the park. The monks—shrewd men—always chose fertile soil near a stream of water, and a monastery once stood where Longleat stands now. The ground rises from it on all sides—a vast amphitheatre of foliage bounded by the horizon. I said last week that Longleat is "open, grand, and free." It is so literally, for the grand park and mansion are open and free to all, and thousands annually enjoy and doubtless appreciate the privilege so generously accorded. A further enjoyable drive of two miles to Warminster, then a pleasant hour with Mr. Hinton—a man who engages in many good works besides the Rose election—and I am switched back to town by the night express, well pleased, and also, I think, benefited, by my "Run to the West."—J. W.

P.S.—It may perhaps be useful to state that an engraving of the Longleat mansion may be found on page 10, vol. xxiv., the issue of July 3rd, 1873; a view of the large vinery on page 125, vol. xxvii., the issue of August 6th, 1874; and an engraving of the Vines on page 535, vol. xxxi., the issue of December 21st, 1876; but the Vines are, of course, very much larger now. Interesting and useful notes accompany the above engravings.

## STRAWBERRIES FOR TABLE DECORATION.

VISITORS to Cranmore Hall, the seat of R. J. Paget, Esq., M.P., are invariably delighted with the fine plants of Vicomtesse Hericart de Thury, specially prepared by Mr. Moore for the dinner table during the shooting season. We have never seen them grown more successfully even in the spring months, and they well repay the extra trouble taken. The plants for the first supply had been previously forced, the fruit ripening in March, and were afterwards hardened-off and kept watered. About the middle of May they were plunged deeply along the side of a walk, and encouraged to root over the sides of the pots into the surrounding soil, water still being given when required. By the middle of September the plants were lifted, having all outside roots cut away, and placed on a cool airy shelf in Peach house. They are stood in saucers, and these being kept filled with liquid manure no other watering is required, sufficient moisture being soaked up. Six-inch-sized pots are employed. The plants are crowded with good-sized fruit, ripe and unripe, the bunches being supported with a few neat stakes, and in most instances measure fully 15 inches across. Later batches are prepared in precisely the same way, but those for Christmas especially are ripened on a warmer but equally airy shelf. Placed in wine-coolers they are very effective decorative plants, and, of course, the fruit forms a welcome dish at that period of the year.—W. I.

## THE ARRANGEMENT OF CUT FLOWERS.

A PURPOSE and plan in the arrangement of cut flowers is essential, not only as regards the work itself, but even more so in the economical use of flowers. A clear conception ought, therefore, to be had beforehand of what we have to do, how it is to be done, and of the quantity and kind of flowers required. Be very sure it by no means follows that the man who has the command of an unlimited supply of flowers is the most successful; he who has to cut and contrive has his wits sharpened, and learns of necessity how to turn many odds and ends to account that would probably otherwise be overlooked, and really it is surprising how few and simple are the materials requisite to make a room or table bright. Take, for example, three or four leaves of *Ampelopsis Veitchii*, rich in colour as they now are, a frond or two of any favourite Fern, one cluster of Japanese Rose berries with the deep green foliage, and a white Rose or two,

Mrs. Bosanquet for choice. With these the vase for our sitting-room is made bright with colour—colour which is attractive and pleasant, because it is subdued and balanced by the other quieter features and in keeping with the most refined surroundings.

Such arrangements of foliage and blossom taken each in its season are always acceptable and tend to the economy of materials. At the present time the various kinds of autumnal foliage and berries afford so much variety that very little blossom is required. *Ampelopsis Veitchii*, especially, is so beautiful in its many rich and varied tints of colour that we never tire of it, but rather regret that the season of its beauty is so brief. What lovely wreaths and scrolls may be made upon a tablecloth among the dishes with its slender shoots, and how useful such shoots are for other purposes! I have lately again turned them to good account for chandelier decoration. The arrangement consisted of the usual globes of clear glass containing white Roses, medium-sized highly coloured leaves of *Ampelopsis*, and small fronds of Maidenhair Fern. Long slender *Ampelopsis* shoots hung gracefully downwards from each glass, and were intertwined and festooned in a light informal manner. Another and bolder way of using it is to make a wreath of the large leaves just inside the circle described by the globes of the chandelier, and to have sprays with smaller foliage pendent from the wreath in a graceful but irregular manner.

To further illustrate what has been said about economy I may describe my last dinner table. It was a small circular one, having a cup and two tall water-jugs in the centre, and afforded space for a circle around the centre of eight slender vases, four of which had white Carnations, and four had half-opened flowers of Madame Falcot Rose for blossom, two flowers and a bud or two being used for each vase, with a leaf of *Ampelopsis*, two large leaves and a spray of *Pelargonium filicifolium odoratum*, three spikes of dried *Briza minima*, and two of the long slender shoots of the *Ampelopsis* pendent from opposite sides. The Roses and Carnations were placed alternately in the circle of vases, and instead of being festooned the *Ampelopsis* shoots were lightly interlaced outside the vases, the effect being novel and pleasing.

Soon after the autumn Violets became abundant I was requested to make a floral wreath for a grave. A ring of a foot in diameter was made of a couple of hazel sticks nearly as large as one's finger, and a thick coating of fresh moss was tied upon it. It required eleven bunches of Violets, three dozen Roses, and a suitable proportion of shoots of Oak-leaved *Pelargonium* and Maidenhair Fern. The difficulty in making such a wreath is to avoid formality. Bearing this in mind, the Violet bunches were not placed in a formal circle along the centre of the wreath, but upon the outside and inside at irregular intervals, with Roses and foliage clustering between, around them, and along the centre. Mrs. Bosanquet half opened, and Gloire de Dijon fully expanded, were the Roses used, a few fine Gloire de Dijons being put on singly with a suitable foil of foliage as a relief to the clusters of the lighter-coloured Rose. Fresh green damp moss was plentifully used among the flower stems as they were bound securely in position. When finished the wreath was about 16 inches in diameter. It was sent a considerable distance by rail in a circular wooden box, being fastened securely for the journey by fine string drawn through holes in the bottom of the box; a sheet of tissue paper was placed over the top beneath the lid to keep out dust, and the lid fastened securely kept the paper from contact with the flowers.

Violets of the blue shades of colour do not look well by lamp light, yet as the fragrance renders them much in request for the dinner table, all that is possible must be done to relieve the heavy dull look which they have at night. White China figures of animals laden with panniers filled with Violets have been used occasionally. Wreaths of Violets around the bases of cups and vases afford the much-liked perfume, and are comparatively inconspicuous. White Roses and Violets were the flowers lately chosen by a lady for a birthday dinner. I had only the common Russian in sufficient quantity for the purpose, and its flower stems are much too short to arrange with Roses. The difficulty was overcome by mingling tall stands of Roses with low stands of Violets and white Begonias. Such large flowers with long stems as the Czar and Victoria Regina tied up in medium-sized bunches form an admirable mixture with the rich yellow flowers of Maréchal Niel Rose for every purpose to which cut flowers are applied. It is just one of those rich combinations of which we never grow tired.—EDWARD LUCKHURST.

MR. LUCKHURST's recent articles on the arrangement of cut flowers will, no doubt, be justly valued by gardeners generally; still I think the remarks of "R. I. L.," page 271, and "Hortus," page 307, are too severe on gardeners. "Hortus" remarks,

"There is, as a rule, an absence of taste amongst gardeners, simply because they do not take the trouble to cultivate taste for artistic gardening." I do not think there is such a lack of taste amongst gardeners as your correspondent would have us believe; we rather think the true causes of bad floral arrangements are to be found in other directions. In a considerable majority of cases the gardener has not the sole control of the floral decorations. It is very well to write where and how dishes and glasses are to be placed, but it is often the case that when a gardener takes his flowers into the house he is told by others where they are to go. The butler thinks this would be pretty here, the housekeeper thinks it would be better there, and in the end the arrangement is anything but what it was first intended to be. Again, what one lady or gentleman would admire another would not like at all. For instance, Miss L. likes the Maréchal Niel Roses arranged all on one flat dish simply intermixed with Ferns. Master T. abhors such an arrangement, and the gardener, anxious to please, finds himself beset with difficulties on every side. I know establishments where the butler arranges the flowers, others where the housekeeper does it, and one—not a small establishment either—where the governess both cuts and arranges the flowers. These are not cases where the gardeners are not capable of doing the work, but because they have not the opportunity. How many ladies, too, arrange the flowers themselves? We believe that if the floral decorations were left more in the hands of the gardener we should see much better results.

Mr. Luckhurst will pardon me for adding to his already extensive list of requirements for the flower-room. Let a close-fitting shutter be provided for the window, so that if necessary daylight may be excluded while arranging flowers for evening parties. I have found that if flowers are arranged by the same light as that in which they are to be used much better results may be obtained, as it is well known that some colours which look well by daylight will spoil the whole arrangement when seen under artificial light. In conclusion I will add that the less hard-and-fast lines we admit in the arrangement of cut flowers the better, but the following I would recommend: Avoid glaring colours, let white predominate; use a good proportion of light green foliage, and do not crowd the flowers.—W. PLANT.

#### THE HEREFORD FRUIT SHOW.

To pomologists Hereford is the Mecca where their annual pilgrimage is made, and it is certainly well worthy of the distinction, and the visitors increase in number and become more enthusiastic every year. I can heartily congratulate the members of the Woolhope Club on the success of this year's Exhibition, which was held on the 26th and 27th ult., when two thousand plates were staged, but with such leaders it is not to be wondered at. It is to be hoped that good may follow these annual exhibitions in greater efforts being made in the county for successful fruit cultivation, for Hereford is certainly behind both Kent and Middlesex. The soil is peculiarly adapted for fruit culture, and after the magnificent display of Blenheim Pippins and King of the Pippins exhibited this year it would be impossible for anyone to detract from the merits of the county as suitable for improved culture. In travelling through Kent or Middlesex during the last few years visitors have been astonished at the numbers of acres recently planted with fruit trees, but this is not the case here.

On entering the rooms of the Woolhope Club the visitor was struck by the general effect caused by the blending of colour of the different varieties of Apples, well arranged on suitable tables covered with red and green cloths, the cider Apples being especially notable. Nearly every class was well contested, and in some it was very difficult for the Judges to give a decision, the class being so good; this was notably the case with Blenheim Pippins, where out of the thirty-six plates exhibited twenty-six would have taken the first prize at any average show.

In the open class for dessert Apples, fifteen varieties, Mr. Haycock, gardener to Roger Leigh, Esq., M.P., Barham Court, Maidstone, took the first prize with a beautifully even collection, consisting of the following well-known and good varieties—Sam Young, Lord Burghley, Margil, Brownlee's Russet, Mannington Pearmain, Cornish Gilliflower, Court Pendu Plat, Calville Blanche, Cox's Orange Pippin, King of the Pippins, Ribston Pippin, Melon Apple, Reinette Grise, Mother Apple, and Reinette du Canada. In the other collections were good plates of Pearson's Plate, Old Pearmain, Ashmead's Kernel, Court of Wick, and Fearn's Pippin. I think Court of Wick must be profitable, for it is ubiquitous, and has a habit, which I have noticed in previous years, of appearing under different names in many of the classes, and one especially—the Golden Harvey. In the collection for culinary Apples the first prize also went to Kent with the following eighteen varieties—Bedfordshire Foundling, Blenheim Pippin, Tower of Glamis, Round Winter Nonsuch, Lewis's Incomparable, Loddington, Warner's King, Wellington (Dumelow's Seedling), Lord Derby, Minchall Crab, Hollandbury, Golden Noble, Striped Beefing, Beauty of Kent, New Hawthornden, Emperor Alexander, Cox's Pomona, and Lady Henniker. I may mention that the Loddington,

which usually creates a sensation when well exhibited, and was supposed to be unknown in Hereford, was shown twice, in one case taking the first prize for cottagers' fruit. In the other collections were good specimens of Dr. Harvey, an Apple worthy of notice, and apparently identical with the Wormsley Pippin; Broadend, Summer Quening, Waltham Abbey Seedling, and Alfriston.

In the class for fifteen varieties of dessert Pears Mr. Haycock was first with one of the best collections I have ever seen, including the following well-known varieties—Easter Beurré, Van Mons Leon Lecer, Passe Colmar, Beurré Superfin, Doyenné du Comice, Duchesse d'Angoulême, Maréchal de Cœur, General Todleben, Marie Benoît, Pitmaston Duchess, Beurré Hardy, Durondeau, Brown Beurré, Beurré Diel, and Emile d'Heyst. Mr. Young, gardener to Sir H. Scudamore Stanhope, Bart., was second with an excellent collection, including, with others named above, good specimens of Flemish Beauty, Beurré Sterckmans, and Beurré d'Aremberg. In the division for amateurs the first prizes for both kitchen and dessert for nine varieties went to Mr. Haycock. The kitchen varieties consisted of the following kinds—Lord Derby, Bedfordshire Foundling, Belle Josephine, Belle Dubois, Reinette du Canada, Peasgood's Nonesuch, Emperor Alexander, Belle Dubois, Loddington, and Warner's King. In Sir H. Stanhope's collection that obtained the second prize were good Blenheims, Alfriston, Emperor Alexander, and Wormsley Pippin (the latter Apple I say with Captain Cuttle, "When found make a note of it.") In the other classes were many good plates, but they were chiefly repetitions of varieties named above.

In some classes the Judges had a very invidious task—notably where the Apples were exhibited "for flavour." The entries were very numerous, and in many cases ridiculous. In giving a decision of course the period of ripening is the matter under consideration, and if a fortnightly show were held a different variety would naturally take the prize. The early varieties were of course out of the race, but the winners with Cox's Orange Pippin were run very closely by plates of Margil and Cornish Gilliflower. The Ribston Pippin, in comparison with the others, was too hard in texture.

In the class for weight this year there was a notable falling-off, accounted for, I suppose, by the quantity grown. The heaviest Apple exhibited was a Warner's King, 1 lb. 3¼ ozs. Hereford usually produces this Apple in grand form, but this year was an exception. I wish some of my friends the nurserymen would tell me the reason they describe it as a November Apple. The second week in October I have always found the latest time it could be eaten, although it may be shown at Christmas. The old Pearmain was well shown by Herefordshire growers, but with Cox's Orange Pippins they had no chance with the Kentish exhibitors.

I think perhaps there may be an alteration in the class for Seek-no-furthers. Many growers think this Apple is different from the King of the Pippins, but the distinction is impossible to prove. It was exhibited under six different names, and in many cases justly disqualified by the Judges. Messrs. A. F. Barron and Rivers acted in that capacity, and their awards were more thoroughly appreciated than is usual at horticultural exhibitions, but the names are sufficient to prove that the confidence in their judgment was well warranted.—L. A. K.

[Our correspondent has omitted to say that Mr. Killick was awarded amongst other prizes the second honours for fifteen dessert and the first for fifteen culinary Apples.]

WE learn that there is likely to be keen competition for MESSRS. SUTTON & SONS' PRIZES FOR VEGETABLES at the meeting of the Royal Horticultural Society on Tuesday next. Messrs. Sutton will exhibit vegetables largely, and a fine display of Apples is expected from the Kentish growers.

— AT a meeting of the Committee of the CANTERBURY AND EAST KENT ROSE SOCIETY, held at the Rose Hotel on Saturday last, it was determined that the Exhibition for 1882 should be held at the Corn Exchange, Canterbury, on the first Thursday in July.

— MR. E. R. CUTLER writes as follows concerning the Pension Augmentation Fund of the GARDENERS' ROYAL BENEVOLENT INSTITUTION:—"Up to this date the number of the contributors to this fund is 426, and the amount that has been received is £509 7s. 4d., giving an average of £1 3s. 10d. each response. The Committee have decided to close the list for this year on the 15th

November, and they will be greatly obliged by all collecting cards being sent in to me on or before that day."

— WE are informed that Mr. J. Caven Fox has been appointed agent for the sale of objects that will be exhibited in the SMOKE ABATEMENT EXHIBITION that will shortly be held at South Kensington. All communications relating to the sale of objects should be addressed to Mr. Fox as soon as possible at his office, East Arcade, Royal Horticultural Gardens.

— WE hear that two of MESSRS. J. WEEKS & CO.'S HYDRO-CALORIC WARMING AND VENTILATING COILS have been attached to the existing warming apparatus in the grand saloon at Sandringham, for the purpose of improving the somewhat defective ventilation of that apartment.

— THE *Journal of Forestry* for the present month publishes nearly a hundred letters from all parts of Great Britain, showing the effects of the GREAT STORM OF OCTOBER 14TH in parks, plantations, and woods. The violence of the wind appears to have been general, and in many places the results are disastrous. It is stated that "the damage done to the Tynninghame policies of the Earl of Haddington cannot be less than £50,000."

— AMONG the novelties in vegetables that will be sent out in the ensuing season by Messrs. Sutton & Sons of Reading, a distinct main crop Pea of their own raising, and which they have tested for four years in their grounds at Reading, will be included under the name of "President Garfield." We also understand that Messrs. Sutton have purchased the stock of the fine white-spined Cucumber which was awarded the first prize at the Manchester International Horticultural Exhibition, and which we believe will be sent out as "Suttons' Victory of Manchester."

— WE have received the second volume of BULBS AND BULB CULTURE, by Mr. D. T. Fish (London: The Bazaar Office, 170, Strand), which gives exhaustive cultural notes upon the Cyclamen, Dahlia, Gladiolus, Iris, Ixias, Lachenalias, Ranunculus, and Scillas. From these it will be seen that the author has by no means confined himself to bulbous plants only, as the title of the work would imply. Several of the woodcuts are badly executed, especially *Iris lusitanica* and *I. Kämpferi*. A good representation of *I. Histrio* is given, but under the erroneous name of *I. Xiphium*. The book is neatly printed and bound in cloth.

— WE regret to announce the DEATH OF G. J. JOAD, ESQ., OF OAKFIELD, WIMBLEDON PARK, which occurred on the 24th ult. Mr. Joad will long be remembered as an ardent lover of plants, especially of the hardy herbaceous and cool house sections, of which he formed an extensive and interesting collection, many rare alpine being collected personally in his annual continental tours. His delicate health had for some years rendered it necessary to seek a warmer climate and clearer atmosphere on the approach of winter, but this year he was too unwell to undertake his usual trip. Mr. Joad was a Fellow of the Linnæan Society, and last year was elected member of the Scientific Committee of the Royal Horticultural Society.

— AN Isle of Wight correspondent sends us some sprays of *BACCHARIS HALIMIFOLIA*, the "Ploughman's Spikenard" or "Groundsel Tree," as it is popularly denominated, and remarks upon its hardiness and the way in which it thrives near to the sea—in fact, exposed to the spray. As inquiries are often received respecting shrubs or trees suitable for cultivation near the sea this hint may prove of value to some. The shrub is not strikingly attractive, but it grows freely and produces its small white or purple-tinted Groundsel-like flower heads in great numbers late in the autumn. It attains the height of 10 feet or more in favourable situations, and grows very

quickly. The leaves are small, 1 to 1½ inch long, and of a slightly glaucous tint. The species is a native of North America, being found upon the coast of Florida and neighbouring States.

— THE annual EXHIBITION OF CHRYSANTHEMUMS IN THE INNER TEMPLE GARDENS was opened last week, and will doubtless attract many visitors during the present month. The old position has been forsaken, and a new one chosen near the Victoria Embankment, where a convenient glass structure has been erected. It is built against a wall, forming two sides of a square; and thus, though a larger number of plants are employed, the effect is not quite so striking as it was in the old structure, where all the plants could be seen from one end. There is a good show of buds, the plants being in satisfactory condition, and some of the early Japanese are already attractive. Several handsome blooms of James Salter are notable, with Elaine, The Cossack, and Gloire de Toulouse. The incurved varieties are not quite so forward, though Mrs. George Rundle and Mr. Bunn are fairly advanced. The arrangement has been carefully superintended by Mr. Newton and with good results, which, however, will be more evident in a week's time when the flowers have expanded.

— A SIMILAR display of CHRYSANTHEMUMS IN THE MIDDLE TEMPLE GARDENS, under the charge of Mr. Snelling, also deserves a note. About five hundred plants are arranged in the long glass structure described last year when referring to the first display. Most of the best varieties are represented by healthy plants, which are bearing abundance of stout promising buds. When at their best no doubt the general effect will be considerably better than last year, a satisfactory improvement being observable in the condition of the plants and the arrangement.

— IN the fine collection of ORCHIDS AT THE FIRS, LAWRIE PARK, SYDENHAM, there are always some of interest or beauty in flower, but at the present dull season the brightness of colour and diversity of form presented by the flowers of Orchids are especially pleasing. In one of the houses *Lælias*, *Oncidiums*, *Pleiones*, and numerous plants of *Vanda cærulea* produced a most charming effect. The beautiful blue *Vanda* was represented by several uncommonly fine varieties with broad sepals and petals, and possessing a great depth of colour. *Pleione Wallichii*, *P. maculata*, and *P. lagenaria* were flowering profusely, their bright rosy crimson and white flowers clustering just above the soil in pans and shallow pots arranged along the edges of the stages. *Lælia autumnalis atro-rubens*, the same handsome variety as that recently exhibited at Kensington by Mr. W. Bull, was flowering excellently, the crimson colour of the flowers being remarkably rich. The showy *Oncidium Rogersii* was flowering freely, the flowers having unusually large bright yellow labellums. Many other handsome and useful Orchids were flowering, the healthy condition of all indicating the attention they receive from the gardener, Mr. Coningsby, who well understands the requirements of such plants.

— THE first on the list of COMING CHRYSANTHEMUM EXHIBITIONS is Richmond, which is fixed for Thursday, the 10th inst., and though the date is somewhat early no doubt a satisfactory show will be produced. We may remind our readers that Mr. G. Eyles, Lesham Villa, Kew, has succeeded Mr. H. Chancellor as Secretary to this Society. Croydon and Stoke Newington follow on Monday, the 14th inst., the schedules indicating provision for the various sections similar to previous years. On the 15th inst. Exhibitions are to be held at the Brighton Aquarium, and by the Walton and Weybridge Society, the latter being noted for the excellent quality of the exhibits generally. For the 16th there were two fixtures—one, Finsbury Park, which, as was intimated last week, has been deferred to next year; the other is at Bristol. On the next day, the 17th inst., three notable Exhi-

bitions are to be held—Kingston-on-Thames, Westminster Aquarium, and Brixton. At Kingston the competition for the twenty-five-guinea champion challenge cup will undoubtedly attract much attention. The winners in the two preceding years were Mr. G. Harding, gardener to T. Golburn, Esq., Putney Heath; and Mr. W. Tunnington, gardener to Chas. MacIver, Esq., Liverpool. Should either of these win it this year it will become his property, but if another competitor should succeed in obtaining it the competition next year will be confined to those three.

— A WRITER in an usually very practical journal, who appears to know all about the subject, is good enough to inform us that the article on TREES NEAR TOWNS that recently appeared in a daily paper, and on which we commented on page 314, was not a burlesque. We did not assert that it was; but let that pass, although the disclaimer is no compliment to the author of the remarkable effusion. Special articles in the daily papers are usually contributed by those who have special knowledge on the subjects on which they write, and this is undoubtedly a prudent course, seeing the great influence the leading journals exert; but when a writer, as our friendly critic admits, “displays a want of practical knowledge on the subject,” he simply states the incompetency of the writer as a sound instructor; and when the writer draws “upon his fancy and admiration,” and denounces the Plane as a suburban tree, and extols the Elm, the late storm may be left to supply the answer as to the soundness or the danger that attaches to such teaching. The defence of nonsense is not a pleasant task, and those practical individuals whose good nature prompts them to undertake it merit sympathy.

— UNDER the title of “FRUIT FARMING FOR PROFIT,” a very instructive manual has been sent to us. The author is Mr. George Bunyard of Maidstone, who has produced an unassuming work of considerable practical value. Having spent a lifetime in the study of hardy fruits, and had the advantage of gathering information in the orchards and fruit gardens of Kent, Mr. Bunyard has enjoyed special facilities for acquiring sound knowledge on the subject, and this he has placed before his readers in a plain manner, easy of being understood. After alluding to the uncertainty, as a profitable pursuit, of market gardening by farmers, and the superiority of English fruit over foreign produce, the author has prepared useful chapters on soil, situation, and shelter for fruit trees, planting, and pruning; then follow separate chapters on Apples, Plums, Pears, Cherries, and bush fruits of all kinds, with carefully selected and descriptive lists of varieties. Serviceable hints are given on the purchase and propagation of fruit trees, and packing fruit for sale. There are articles also on the probable profits of fruit culture, including the cost of planting and maintenance, also on the enemies and diseases of fruit trees, and approved methods of dealing with them. The work concludes with an appendix in the form of a report of a meeting of the Rochester Farmers' Club, at which fruit culture was discussed by members who have had much experience on the subject. In the preparation of this pamphlet of seventy-nine pages Mr. Bunyard acknowledges his indebtedness to Mr. Whitehead's work on “Fruit-Growing in Kent,” (Effingham Wilson); and “Small Farms—How They Can be Made to Answer by Means of Fruit Culture,” by Rev. Canon Lea, published at our office, and these works he recommends. We recommend them too, together with the manual under notice, to all interested in the important subject of profitable fruit culture. The manual to which we have directed attention is published by Messrs. Frederick Bunyard of Maidstone, and Edward Stanford, Charing Cross, London.

BULBS *versus* MICE.—As I have lost all my Tulips and part of my Crocuses the last two winters with mice I should be glad to know

how I can prevent their doing the same damage this winter. I have thought of trying paraffin as with Peas, but I am afraid it may destroy the bulbs. Perhaps some of the readers of the Journal will kindly give me advice, founded on experience, on the matter. Any information that will enable me to save the bulbs will be valued.—S. B.

#### DENDROBIUMS.

PLANTS of *Dendrobium nobile* that finished their growth early and had them well ripened are now showing signs of flower. The little buds that were scarcely perceptible a week or two ago are pushing from nearly all the joints, and the plants can be removed to a warmer house in order to hasten them into flower. I find it a good plan now to give the growths occasionally a slight dewing with the syringe in order to soften their buds, care, of course, being taken not to allow the roots to become too wet, as they are very liable to start into growth prematurely. Anyone who has a few plants of *Dendrobium nobile*, and, in fact, any other species of that section, may, with a little care, have a display of flowers for a long season. It is, perhaps, the best plan to have only medium-sized plants for decorative purposes and cutting, but if for exhibition plants of a larger size will be desirable. After one or two plants have been introduced to warmer quarters, the others, or later plants, should be kept dry and cool till such time as they are required to flower. There are several very distinct varieties of *D. nobile*, and one variety, called *D. nobile pendulum*, has perhaps one of the largest and brightest coloured flowers. The growths are more erect and also thicker than in the true species. *D. nobile* var. *cærulescens* is a desirable form; the latter can be retarded so as to flower as late as April and May. I think it a great pity that this grand old Orchid is not more extensively cultivated than it is. If plants in the first place had to be purchased they can be bought very reasonable, particularly imported plants; and when once a plant has attained a medium size there is always a possibility of propagating it by taking off the young plants that are produced from the upper portion of the old pseudo-bulbs. These young plants should be potted, or, what is better, they should be placed in baskets, placing four or five of them together in a small basket, and hang them up near the glass in the stove. It is surprising how soon they become healthy little plants if properly attended to.

A very good and cheap plan of growing *Dendrobiums* came under my notice two or three years ago, and I think it worth relating. It was at an establishment where *D. nobile* was grown in quantity to yield flowers for buttonhole bouquets. The gardener only started with two or three large plants, and when I saw them he had about a dozen and a half fine baskets. His plan of making baskets was a very cheap and simple one. There were several large Elder bushes in the shrubberies and plantations, and from these the wood was cut for his baskets. The wood selected being about an inch in thickness, it was cut into suitable lengths according to the size of baskets required, and made in the usual way. It was surprising how the roots clung to the sides of the baskets. Whether it was the rough surface which the roots so much liked I do not know, but evidently they enjoyed the treatment they received. Elder wood is not nearly so durable as Teak, but still baskets made from Elder should with care last at least three or four years. The roots of the Orchid in a great measure keep them together.

One of the earliest of the *Dendrobes* to flower is *D. formosum*: this is certainly a showy and desirable plant, lasting a long time in perfection. The next to succeed the last-named species is *D. aureum*, and the new and rare variety *D. aureum* var. *philippinense*. The earliest plants of *D. aureum* will in many cases be showing their flower buds, and may be removed to a warmer house provided they have been kept dry and in a cool house for some time past. This is one of the most beautiful and useful of the genus. The flowers are not so showy, perhaps, as some of the others, but what they lack in colour is more than balanced by the delicious perfume they possess, suggestive of Cowslips. *D. crassinode* and *D. Wardianum* are a little later and are still growing. Every attention should be given them in order to have their growths completed as soon as possible. *D. Wardianum* ranks amongst the leading species of the genus, but is not always the best to grow. When a good plant with several long pseudo-bulbs is in flower it is very handsome, the colours are so pleasing; and another point in its favour is, the flowers last in perfection for a long time provided the plants are removed to a drier and cooler atmosphere. *D. Pierardii* is one of the oldest species in cultivation, having been introduced from the East Indies so far back as 1815, and well deserves to be grown in every collection. It is of free habit, and flowers profusely from every joint when the wood is well ripened. The above-named species can be grown in baskets, and

well deserve the extra care and attention they require more than ordinary stove plants.—W. K.

#### WINTERING STRAWBERRIES IN POTS.

AFTER the severity of last winter there need remain no doubt on the minds of those engaged in forcing Strawberries extensively in pots, that the plants are as well outside during the winter as stored in frames and cool houses. Frames even in the most extensive establishments are frequently required for other purposes than protecting Strawberries, and it is a serious matter where there are few frames and these crowded with Strawberries, when at the same time they are wanted for Lettuce, &c., to maintain a supply of salad. This state of things compelled me in 1878 to try a few Strawberries outside, and a larger number in 1879. The result having proved very satisfactory, I resolved to leave all the plants out last winter, and I am now convinced that they are as well or better outside than in. Left outside they enjoy a more complete rest, and when they are introduced into heat growth commences at once and the plants come quickly into flower. It appears to me that no advantage is gained by placing even the earliest batches in frames for protection against heavy rains, as if the pots are well drained and full of roots autumn rains will not injure the plants nearly so much as placing them in frames and keeping them dry to bring about rest. This results in injury to their roots, as Strawberries cannot endure drought during any stage of development, while if kept watered in frames the plants have a tendency to prolong their growing season instead of being allowed to go naturally to rest outside.

Those plants protected in autumn will not start into growth so early as those left outside until wanted. For instance, a batch is protected in autumn and placed on a vinery or Peach house shelf in November to be started into growth. Another lot is left outside until the end of the following month and cold weather has induced rest. These will start more vigorously into growth and throw up their flowers both better and stronger above the foliage than the earlier plants. Both may ripen their fruit much about the same time, but the heaviest and best crop will be from those started at the end of December. Nothing is gained by bringing Strawberries prematurely to rest and starting too early. An early growth of the plants succeeded by an early natural rest is by far the most satisfactory system of producing early fruit. This is best accomplished by obtaining a few early runners from young plants on a warm border, and growing them afterwards in 5-inch pots. These are filled with roots earlier than pots of a larger size, and thus the plants complete their growth in time to receive a good rest. In no previous season have my plants of *Vicomtesse Hericart de Thury*, which I regard as the best Strawberry for early work, forced so quickly and easily as last spring, which I entirely attribute to their being left outside until introduced for forcing.

After the severe weather was past several remarked that my plants had suffered dreadfully because all the old foliage was gone and only the crowns left. They certainly looked miserable objects, but the pots were well filled with roots which were in splendid condition, and the crowns were large and plump. These plants, however, soon produced new strong foliage, and fine crops of fruit.

The pots are very liable to break if left out during hard frosts, but this can be reduced to a minimum if they are plunged in ashes or partly decayed leaves. This involves but little more labour than packing them in frames and attending to them afterwards. If extra labour, however, is occasioned, it is well repaid by having a number of frames for other purposes. The system of stacking Strawberry pots upon their sides one row above another, cannot be too strongly condemned, as the plants suffer considerably from drought during dry winds.

When the winter is past the plants should be lifted out of the material in which they have been plunged and the decayed foliage removed. The soil should be well pressed to the sides of the pots and the whole top-dressed with rich soil. It is surprising how a little rich top-dressing assists the fruits when swelling.

I may just mention that Sir Charles Napier appears less hardy than the majority of Strawberries, and if left outside during such a winter as the last would be injured more or less; in fact, many plants were killed that were established in the open ground.—WM. BARDNEY.

#### A ROCKERY FOR ALPINE PLANTS.

(Continued from page 349.)

THE rockery I have described will give a surface of more than 100 square yards—we may call it in round numbers 1000 square

feet—to cover with plants. This sounds a large space, but the difficulty generally is not how to cover it with plants, but after a few months how to find room for choice rockery plants when they come into our possession. We must remember that nearly every plant, whether alpine or not, flourishes and increases more rapidly on a rockery than on a flat border, and the rapid spread of many of our old friends becomes astonishing. Plants which we have been accustomed to nurse in frames through the winter become quite hardy on the slopes amongst the stones. This causes a strong temptation to plant some on a rockery which have no business there, and a careful discretion in selection must be exercised. It is hard to define an alpine plant, and there is no occasion for us to do so, especially as many which are undoubtedly and strictly alpine in habit are by no means desirable occupants of a choice rockery, and many pretty and delicate plants which are not alpine may properly be cultivated in this way.

Those who are ambitious of covering their new rockeries with hardy perennial alpine in one season will have no difficulty in doing so. They may have resort to advertisements which offer a hundred choice alpine for £1, and their friends who have rockeries will readily supply them with a stock of rapidly-spreading plants. At the end of the first year they will be congratulated on the success of their rockery which has been built in so short a time, and will, perhaps, think that they have much to be proud of. Masses of many sorts of *Vinca*, major and minor, plain and variegated; cascades of *Cerastium* reaching from the top to the bottom and spreading over the flat ground below; large cushions of *Saxifraga cæspitosa* and *hypnoides*; irrepressible *Sedums* of the acre and rupestre type, and *Sedum spurium* of several colours, will quite hide the soil and the stones. Then there will be luxuriant masses of *Arabis* and large tufts of *Columbine*; and the common *Primrose* with leaves grown to a gigantic size will have occupied all the slope beneath it and round it with seedlings. Add to these *Coronilla varia*, *Corydalis lutea*, and the large-flowered running *St. John's Wort*, and the insidious *Asperula odorata*, and the still more insidious, because it looks so innocent, *Campanula pumila*.

These and many others which would make up a list too long to enumerate, you will have a well-covered rockery, which through autumn and winter you will think a success, and it will certainly look very rustic and pretty; but with spring the struggle for the survival of the fittest will begin. Every nook and corner will rapidly be occupied, and when the hamper of new alpine which has been waiting favourable planting weather arrives, you will carry them along the rockery in vain looking for a vacant spot, and being reminded at every step of the proverbial advantage of possession. If you try to clear a space, you will find that the roots you are looking for are more than a good way from the space you wished to clear, and are so firmly and deeply entangled amongst the stones that no digging or pulling will extricate them, and before the end of the summer you will conclude that you must either leave the rockery a hopeless wilderness and build another for the choice plants, or pull the old one entirely to pieces, and, having entirely cleared away every root, begin again to plant it more cautiously and slowly, with plants of which you know the habit.—C. W. DOD, *Edge Hall*.

(To be continued.)

#### AERIDES ODORATUM PURPURASCENS.

MANY species and varieties of *Aerides* are grown and valued in gardens, but among those requiring comparatively little trouble to ensure fairly satisfactory results, *Aerides odoratum* is especially esteemed by many Orchid-growers. It is very seldom, however, that such a large and vigorous specimen is seen as that represented in the woodcut, fig. 67. The variety there shown, *A. odoratum purpurascens*, is, moreover, not so common as some of the others, though it is, when well grown, equal to any other form of the species. The engraving was prepared from a photograph taken last year when the plant was in flower, and recently forwarded to us by Mr. C. Warmington, gardener to J. T. D. Llewelyn, Esq., Penllergare, Swansea, who gives the following cultural and descriptive particulars concerning it.

"The *Aerides* is growing in a basket 2½ feet wide and 10 inches deep. The centre growth is over 6 feet high, and there are five other principal growths about 5½ feet high from the top of the basket. There are also many young growths from 1 to 4 feet high. Last June when in flower the plant had seventy-eight spikes, with from fifty to sixty flowers on a spike.

"My mode of treatment is very simple. About the third week in February I remove all the old sphagnum moss and crocks that can be done without injury to the roots. I then supply fresh moss and clean crocks. The moss is then syringed, the water

Fig. 67.—*AERIDES ODORATUM PURPURASCENS.*

causing it to settle down. Through the summer months the plant is supplied with water when it is required, the basket and the roots being syringed twice daily. I seldom syringe the foliage, only occasionally after a very hot day."

[We congratulate Mr. Llewelyn on the possession of such a splendid specimen, and his gardener on his skilful cultivation.]

#### SCRAPS ABOUT FRUIT.

**STRAWBERRY JAMES VEITCH.**—Can any of your readers who have grown this Strawberry tell me if it is a good bearer and a good-flavoured fruit, and suitable for growing for the market? I should feel much obliged for the information.—F. W.

**BROWN BEURRÉ PEAR.**—With us this Pear on a west wall has not afforded us an eatable fruit for the last three years. Is it the same in other gardens? I believe this variety requires a warm locality, and then perhaps there are many better Pears at this season; it decays so soon.—J. TAYLOR, *Shrewsbury*.

**KESWICK CODLIN AND LORD SUFFIELD IN CORNWALL.**—Of the many varieties and number of Apple trees planted in Cornwall every season, none are in so much demand as the two above. Indeed they are two of the best culinary Apples I know of. Lord Suffield is now much more extensively planted than the Keswick, and is preferred, it being a very good improvement on the old sort.—WILLIAM ROBERTS, *Dersingham*.

**LA DELICIEUSE PLUM.**—I send you an account of this Plum which may be of service. We have a tree here, planted Nov. 26th, 1838, which now covers a wall 30 feet long by 10 feet high. This tree invariably bears good crops of fruit, and is still in a healthy condition. The fruit in shape is like the Victoria, but is larger and of a darker colour. It is excellent either for dessert or kitchen purposes, and if "A COUNTRY SURGEON" is in want of another good Plum I would advise him to plant La Delicieuse.—F. HOPKINS, *Oxon*.

**PROLIFIC APPLES.**—About eight years since I planted several varieties of Apples, and have found the following the most prolific. *Espaliers*—Lord Suffield, Prince Albert, King of the Pippins, and Wormsley Pippin. The last named is an extraordinary bearer. *Standards*—Pott's Seedling, a first-rate kitchen Apple, and Court Pendu Plât, a good dessert Apple. From old trees I get the best crops from Keswick Codlin, Dumelow's Seedling, Blenheim Pippin, Wyken Pippin, and Rymer, commonly called Caldwell. This should be in every collection, as it is a good cooking Apple and suitable for sauce or baking.—F. J.

**KNIGHT'S MONARCH PEAR.**—Some few years since a discussion was carried on for some time as to the cause of this variety prematurely dropping its fruit. So far as I can remember nothing definite seemed to have been arrived at. Every year since a healthy tree of some ten or twelve years' growth has performed this same phenomenon. Can anyone give an instance of its better behaviour, and how situated? I remember seeing this grand Pear (when you can get it) at Stackpole Court, Pembroke-shire, very fine some years since. A misprint occurred in my note on Ecklinville Seedling and Cox's Pomona Apples last week. I desired to say they were good bearers, especially the latter, and the fruit is large, but turns mealy and soon decays.—J. TAYLOR, *Shrewsbury*.

**MARKETABLE FRUITS.**—There are two fruits which invariably realise remunerative prices—viz., Damsons and Black Currants. Few nurserymen near London have a stock of either remaining on their hands, the numbers of the latter especially that have been planted of late years being really remarkable. Black Currant jam is very popular in this and probably other countries, as much fruit is annually exported, and this may account for the ready sales. Damsons, in addition to making good jam and "cheese," are also extensively employed in dyeworks. Shropshire appears to suit the Damson, and from that county immense quantities of them are in favourable seasons bought up for the manufactories. There is no doubt the Prune Damson is the best in quality, but for a heavy crop grow the Farleigh or Crittenden's Cluster.—ESSEX.

**ROOT-PRUNING AND MULCHING.**—Those who periodically root-prune their fruit trees with a view of keeping the roots fibry and close to the surface do well; but those who root-prune periodically

and mulch heavily the ground underneath the trees every autumn with solid half-decayed cow manure—not disturbing the surface in any way—do better. We have no patience with those who keep encouraging faggotism by thoughtless pruning. "CANTAB'S" ideas are excellent about pruning Apple trees, or Pears and Plums either. If the roots were more attended to and the growths left alone they would become wreaths of strong flowers—at least such is the case with ours.—H. ELLIOTT.

**PLUMS, BAD AND GOOD BEARERS.**—We have many Plums, and several of them bear only a few fruits and others none. Brahy's Green Gage is a very fine Plum, rich, juicy, and excellent, but the tree seldom bears for two years together, and I have never known three consecutive crops. Diamond, oval, purple, large, one of the finest culinary Plums, blooms every spring, but only once have I known a good crop of fruit. Washington, a very fine Plum, never bears freely. I have a Plum with no name, which I am told is Jefferson; it bears well every year. Reine Claude de Bavay seldom bears well. There are only a few varieties that bear every year alike, and them we depend on for a supply. Orleans is a good cooking and preserving Plum, and a good bearer. Victoria is also a good Plum, and a great bearer too. Coe's Golden Drop, one of the very best Plums, is very juicy, sugary, and rich, also very late; we gathered the last on the 3rd of October. I think this variety ought to be in everyone's garden.—F. WALKER, *Isle of Wight*.

**DOYENNE BOUSSOCH PEAR.**—This Pear may answer in a deep heavy soil, but I certainly cannot recommend it for a thin light soil however highly cultivated it may be. I have a palmette verrier of it as an espalier out in the open garden, and a cordon against a wall; both trees are in full health and vigour, and the fruit is large and so handsome that I have once more ventured to send a dish of it to table. But it was again condemned as worthless, and a welcome substitute found for it in the delicious little fruit of Comte de Lamy. I have carefully tested the fruit of this Doyenné at various stages of ripeness, and as the flavour has invariably proved poor and insipid year after year, it will in future be used only for stewing.—SUSSEX.

**DOYENNE DEFAYS PEAR.**—"A most delicious Pear, one of the best," says the "Fruit Manual," and I entirely agree with it. The first fruit of it is just ripe, and would evidently keep good for some time. The crop was a full one of fine fruit, and it is very sweet, rich, aromatic, and very juicy. Like so many other Pears it is somewhat capricious about the time of ripening, but it may be classed with the late autumn and early winter varieties. The one fault of this valuable Pear is the tendency of the fruit to crack, sometimes so badly that the entire crop is spoilt. This year there is hardly any cracking, but I would as a safeguard always plant it in a sheltered situation. Apart from the fruit cracking, it answers well as a pyramid on the Quince stock.—EDWARD LUCKHURST.

**EARLY-BEARING APPLES.**—I am obliged by Mr. A. H. Pearson for naming some late varieties of Apples that are early bearers. Mr. Pearson's field of observation is so extensive that he is undoubtedly in a position to communicate useful information, and letters from his pen must be generally acceptable. His father was one of my most esteemed friends, and I was indebted to him for the idea that early Apples as a rule are early bearers, and the produce of a number of trees obtained some years ago from Chilwell proved him right; but he said there were exceptions to the rule, and there are, but I find they are not numerous when the observations are taken over a number of years. Irish Peach, one of the very best early Apples, has with me also proved an early bearer; so has Red Astrachan. Court Pendu Plât came into bearing early, but scantily; I regard it as a safe rather than an early bearer, and a variety well worth planting. The Hawthorn-dens I regard as early, as they attain a good size early. The other late varieties named on page 382 bear tolerably well in an early state, the most prolific in this respect being Sturmer Pippin. Small's Admirable is also an excellent Apple for early profit. Mr. Luckhurst's notes on page 386 on this important aspect of fruit culture are instructive.—A NORTHERN GARDENER.

**INFLUENCE OF SOIL ON FRUIT-KEEPING.**—From many observations I have made I find that soil has a wonderful effect on the keeping properties of fruits, and I am reminded by the remarks of "A KENTISH GROWER" on Warner's King that this is the case. My experience is that Apples and Pears grown upon light soils and in warm situations ripen earlier, and consequently keep a

shorter time, than fruit grown upon heavier and colder soil. In my own case I have Blenheim Pippin, which keeps till April and May. Cox's Orange Pippin keeps till long after Christmas, and Marie Louise Pears keep till February. My soil is a heavy one on the Hastings sand, and 300 feet above the sea, which it overlooks on the south coast. This late-keeping does not in the least deteriorate the quality of the fruit. I remember many years ago the late Mr. Robert Thompson being greatly puzzled with fruit of Marie Louise which was shown at the meetings of the Royal Horticultural Society by the late Mr. Moorman of the Clapham Road long after all the fruit-rooms about London had ceased to have it. This used to occur not at fitful intervals, but annually, and fruit-growers puzzled their brains as to how Mr. Moorman preserved them. Mr. Thompson was commissioned to investigate the matter, and with his usual application and incisive mode of inquiry he set about the matter. He visited Mr. Moorman's fruit-room, examined it, took measurements and made plans of it, and these were published accompanied with some learned remarks both philosophical and physiological on the manner in which the fruit-room was constructed. The mystery was thought to have been solved, and ardent fruit-growers took to altering and building fruit-rooms upon Mr. Moorman's principle. But it all came to nought. Their fruit kept no better than before, and it was not till it was discovered that Mr. Moorman's fruit was not grown in his garden in the Clapham Road, but in another garden at Bexhill on the Sussex coast, and on the same Hastings sand formation to which I have already alluded, that light dawned on the mysterious cause of the long-preserved Marie Louise Pears.—H. B.

#### HARDY PLANTS—SELECTION AND ARRANGEMENT.

IN describing the chief plants and their arrangements I will take as examples the borders in the garden here to illustrate what I consider the most effective mode of treating these plants from a decorative point of view. This should never be lost sight of, as being the main one to work out. On this principle more and more of what are termed hardy florists' flowers are admitted to the borders. It is impossible to satiate the appetite for flowers well grown and well arranged. I advise intending planters to plant most largely old kinds which are well known as being good border flowers, instead of trying a large number of sorts many of which may be found of no value whatever.

Commencing with the spring display, which is also that to which the most interest is attached, clumps of bulbous plants are largely employed for this season, at least for the earlier part of it, and at that season there are really no plants more effective than Snowdrops and Crocuses, yellow Crocuses especially. The best Snowdrop is the double variety of the common form, though of course others are grown. A great variety of Crocuses are also employed, though the common yellow predominates. *Iris reticulata*, *Sisyrinchium grandiflorum*, much finer than its white variety, and *Myosotis dissitiflora* are all beautiful. The various double forms of the common Primrose, of which the rose-coloured and purple are the most effective, are freely employed; there are also single Primroses in a great variety of colours, but these are grown in acres amongst the grass in the pleasure grounds, and are not in consequence placed in the borders. *Narcissus minor* is largely used, being early and very bright. Christmas Roses make quite a show in themselves, but they are best in separate beds. Many clumps of *Scilla siberica* are planted over the front half of the border; *S. bifolia* and its white variety are also grown, but not in such numbers. Hepaticas again are employed freely, the most useful being the double pink variety, the white, and *H. angulosa*. *Aubrietias*, which we are obtaining in many shades to deep crimson, and *Arabis albida*, are both used to a great extent. The *Arabis* alone makes a border quite showy. Then Pansies, either old plants or firm strong summer-struck cuttings planted in autumn, come in with effect; and the dwarf Phloxes, of which *P. verna*, *P. Nelsoni*, and *P. frondosa* are the most useful, follow closely, and are planted sufficiently thickly to make a feature in the border. The large purple and the large white Dog's-tooth Violets are also very beautiful; Grape Hyacinths, Anemones, *Doronicum austriacum*, and the several species of Evergreen Candytufts, with several Daffodils bring us into summer, when the flowers come on in the greatest profusion.

Taller-growing plants then commence flowering, and foremost amongst these must be named the double Pyrethrums. Two old varieties of singles we have grown, and do not think them so showy as the doubles; but some of the new single forms may surpass them. *Delphiniums*, *Lupinus polyphyllus*, *L. p. albus*, and *L. p. bicolor*, *Aquilegias*, early Phloxes, and *Lilium candidum* are the finer tall plants chiefly planted. Roses, especially Moss Roses, are well represented. Nearer the front are many

clumps of *Lychnis dioica* fl.-pl.; Globeflowers; *Ranunculus*, the double yellow and double white; *Polcmonium cæruleum album*. Nearer the front still are many clumps of *Sanguinaria canadensis*, *Dodecatheons*, of which *D. Meadia elegans* is the best. Pinks are thickly planted, also many *Saxifragas* and *Sedums*, close to the front, with *Gentianellas* and dwarf *Veronicas*. *Iris cristata* is also much used. Then very many beautiful plants are found in the Bellflowers. Of these *Campanula persicifolia alba* fl.-pl., *C. p. coronata cærulea*, and *C. p. c. alba* are most used as tall plants; *C. Van Houttei* as a medium-growing variety, *C. Hendersoni* and *C. carpatica* as lower-growing still, and *C. turbinata* and its varieties in the front. We have very many more of these, but none so prominent. *Adenophora Lamarckiana* is used as a characteristic plant. Single Sweet Williams are very attractive, and the double dwarf crimson variety is a most useful plant. The English Irises are indispensable. *Iris germanica* and *I. pallida* are grown largely. *Lychnis viscaria* is always attractive, either the common sort, the white variety, or the double sorts. *Achillea aurea* is distinct and good, so is the taller *Achillea Ptarmica* fl.-pl.; and then the *Aconitums* come on as a great feature, the two-coloured form of *A. napellus* being the best. *Sida malvæflora* is a useful plant. Some of the *Geraniums* are pretty, but none is better than the double form of *G. pratense*, of which a good figure was given in the Journal, July 29th, 1880.

Then we reach a period when flowers are not so plentiful until the autumn brings its stately floral attendants and the second flowering of many of the spring and early summer plants. Take the last weeks of September as representative for autumn flowers, and we have the borders at their showiest. Wind is the great enemy of the autumn-flowering plants, rain having comparatively little effect on most of them. The stateliest plant is the Hollyhock, and I am glad to say that I have at last obtained a healthy stock of plants from a nurseryman at Hawick, and are the only plants free from disease which I have received for five years. Show, fancy, bedding, bouquet, and single Dahlias are very floriferous and brilliant. I have grown single varieties for four years, and the only one which equals the doubles is the single white which I received under the name of *D. alba*. Then the late-flowering Phloxes, some of the earlier Asters, *Campanula pyramidalis* and its white variety, *Delphiniums*, *Tritomas*, *Rudbeckia Newmanii*, *Helianthus multiflorus flore-pleno*, *Gladiolus*, of which *G. Brenchleyensis* is the most useful for borders, *Alströmarias* and *Japan Anemones*, are some of the most beautiful tall plants. Plants of medium height are well represented by border Picotees, self Carnations, of which Duke of Wellington is the showiest, early-flowering Chrysanthemums, *Tradescantias*, *Aster bessarabicus*, *A. longifolius formosus* and *A. horizontalis*, *Monardas*, *Sedum spectabile*, *Antirrhinums*, summer-flowering *Campanulas*, *Chrysoeoma Linosyris*, *Coreopsis*, *Stenactis speciosa*, *Erigeron grandiflorum*, *Pyrethrums* and *Corydalis solida*, as being the showiest. In the front lines there is not so many in flower at this date; but dwarf *Campanulas*, *Polygonum Brunoni*, *Primulas*, *Potentillas*, Pansies, *Waldsteinia carinthiaca*, *Colchieums*, *Achillea aurea*, *Prunella grandiflora*, *Crucianella stylosa*, *Vittadenia triloba*, and some variegated plants lend a certain cheerfulness even close to the front edge. Later Asters, of which the best are *A. turbinellus*, *A. novæ-angliæ*, *A. novæ-belgiæ*, and *A. lævis*. The continued flowering of some of the plants above named in good seasons prolongs the display, though of diminished effect, down as late as November.

I have repeatedly seen the enjoyability of these borders destroyed by the manner in which the plants have been arranged, especially as regards the height of the occupants. In another communication I will describe the plants in one of the borders here, as a means of helping those who are not so well acquainted with these plants as to be able to regulate the heights properly.—R. P. BROTHERSTON.

#### SCALE ON PEAR TREES.

HAVING some Pear trees badly infested with scale, and after trying several remedies with little or no effect, I applied linseed oil. I had the trees carefully painted, also some Apple trees. The work was done about February. The result was, it quite killed the scale, but nearly killed the trees, which were three years before they recovered from the application. During the three years the trees grew very weakly and bore very few fruit. Some of the trees were painted only as far as the scale was seen. The parts not painted were quite visible 50 yards from the trees, as the leaves were much larger, and those portions of the trees only bore fruit. I wish to caution others who think of using oil of any kind. I once applied a weak solution of paraffin to kill blight on a Peach tree. The oil only remained on the tree about

an hour before it was washed off, but the work was done and the tree died early the following summer.

I would also caution young gardeners not to use Gishurst compound too strong—in fact, only half the strength recommended, and be sure to keep it from the buds, or they will be much injured. I once lost the whole of the bloom buds by applying it only half the strength recommended. It was applied with a syringe in January, and the whole of the trees were covered with a thin spray.—R. OWEN, *Yewden*.

#### VIOLETS IN LATE SUMMER AND AUTUMN.

THE flowering of Violets in autumn and winter depends quite as much on the weather or the temperature to which they are subjected as on the varieties blooming naturally at that season. None will flower freely in a temperature below 40°. To secure blooms continuously through the late autumn and winter months a temperature of 40° to 45° at night and 50° by day are essential, accompanied with a circulation of air whenever the external temperature is above 32°. Many Violets that flower in autumn cease to do so on the approach of cold weather, and again flower freely in February, March, and April, would keep on flowering through the winter were they treated so as to favour the development of the flowers.

Violet *Argentæflora* (Lee) produced its first blooms on the 18th July, was in flower generally on August 1st, and was as regards the late summer and autumn at its best on September 1st, blooming profusely up to the 15th of October, when the flowering received a check by frost. This variety is decidedly a summer, autumn, winter, and spring bloomer, but to secure this the runners must not be removed, as from every joint of the runners proceeds a flower, and the runners themselves commence flowering directly their leaves attain full size; the old plants as a rule not producing flowers until September is well advanced, and this season their blooms were scarce even in October, whilst the flowers were being borne freely by the runners.

I am not by any means certain that the removal of the runners of Violets during summer is contributory to the maximum production of flowers. I have proved that plants placed 18 inches apart in spring, and the runners layered as formed, give more flowers than a number of old plants occupying a similar space. The parent makes much finer crowns with its progeny around, the runners not impairing the vigour of the parent, but are a source of strength from the increased leaf-development. It is only when the connection between the parent and progeny is severed that the former shows any symptoms of enfeeblement, and then only from a score or more of separate plants seeking support from space that in the previous season was devoted to one. The removal of runners only increases the production of others, and this certainly is not invigorating to the plant. The runners may be allowed to remain on the plants through the summer, and being layered they will root and bloom as freely, if not more freely, than the old plant, also will yield quite as fine flowers as plants that have had the runners removed. I mention this in order that those who have few plants may raise a stock quickly. In the case of *Argentæflora* it is absolutely necessary to encourage the runners so as to secure flowers at a time when no other kind affords them so profusely—*i.e.*, in summer. The silver-grey flowers with their purple spurs are very elegant, and the fragrance delightful. Unlike most single Violets it does not produce seed, or very rarely. I have only noticed one seed pod, which accounts for its prolonged flowering.

*Victoria Regina* commenced flowering on the 2nd September, and was very free in late September and up to October 15th, when after the frosty weather the flowers made little progress. This, notwithstanding what was stated last spring in the *Journal* in favour of *odoratissima*, is the grandest of all single purple Violets, and has never failed to flower freely with me in September since it was first sent out by Mr. Lee. Its flowering in autumn may be in a measure due to the plants placed out each spring being taken from those wintered in frames, which would tend to promote an early-flowering habit. This I think can, however, hardly be the case, as their runners exhibit the same tendency, and plants left out flower in autumn. *Czar* is often confounded with *Victoria Regina*, but is not so good in any respect.

Prince Consort is the finest in appearance of all single Violets. It may differ from *odoratissima* and *elegantissima*, but I cannot mark the difference. I had it under the name of Prince Consort, and shall keep it until I am proved to be in error. It yields flowers moderately in autumn—the first blooms expanded on September 6th. The foliage is larger, rounder, and the plant more stately than *Victoria Regina*; the flowers larger, light purple, petals well rounded, and the footstalks longer, and is very fra-

grant; but for profusion and continuity of flowering over a lengthened period it is not equal to *Victoria Regina*.

*Princess of Prussia* (Lee) has a deep purple glossy flower, showing thick-textured leaves, the plant being dwarf and not free in growth, producing runners sparingly. It bore its first blooms on the 6th September, and is a good autumn flowerer, but is not so free as *Victoria Regina*.

*Devoniensis* produced the first blooms on October 10th, and promises abundantly. The flowers are deep purple and very sweet. The only other that has flowered to this date (October 21st) of the single varieties being *V. odorata*, the common Sweet Violet; bright blue, the bluest of all, and very sweet. Russian, which is the same as London; Russian Superb, a little larger than Russian; *suavis*, the true Russian, and type of London; with White Czar are as yet only in bud, and so are *obliqua striata* and *odorata alba*. White Czar I may mention as the purest of any white and very free, but is not good until late autumn. *Rubra simplex* is decidedly a spring bloomer.

The doubles that flower in autumn and onwards are confined to the Neapolitan forms. *Blandyana* may give a few blooms, also *Parmæensis plena*, *Belle de Chatenay*, and double Russian, along with King and Queen, but they have no claim to be classed as autumn bloomers. Of the Neapolitans I still give first place to *De Parme*. It has produced twice as many flowers as any of the others, and the plant is hardier than any of the others, and not so prone to lose the crown and break into many crowns or runners. Its first blooms were gathered August 21st, and were abundant through September, and still are numerous, keeping on until May, occasionally into June. In *Marguerite de Savoie* we have a fine robust plant, a large flower streaked with red in the centre, with a good footstalk. This variety as often seen is only the old Neapolitan. It commenced flowering October 1st free and good.

New York, or *odorata pendula*, commenced flowering on the 10th of August, were generally in flower on the 10th of October, having flowered freely in September. The blooms of this and *Marguerite de Savoie* are very similar, but it does not appear so hardy, and becomes blind quite as much as the old Neapolitan. It is, however, a fine Violet, having large double flowers, very fragrant, freely produced, especially in early spring, and has longer footstalks than most double Violets.

*Marie Louise* is, perhaps, the freest flowering of the Neapolitans, and certainly is the nearest in colour to the old one of any, being deep lavender with a white eye. It does not flower until October, and then very freely. The start Violets of this class make in autumn is soon ended by the cold; hence to have flowers in winter a temperature of 40° to 45° at night, and 50° in the daytime must be secured to them, with plenty of light, and ventilation on all favourable occasions.

*Duchess of Edinburgh* shows none as yet of its alleged perpetual-blooming character, and appears to be a very indifferent grower. Its Neapolitan origin is manifest in the foliage, as well as in the flowers and fragrance.

Venice may be classed as very like New York. It flowered well through September. It appears to have a tendency to become blind, and this is a serious drawback as regards the production of flowers.

Neapolitan, pale lavender with a white eye, does not commence flowering until late autumn, and to bloom in winter must have the protection of glass and heat. In March and April in frames it is very free, and for delicateness and fragrance is unsurpassed. Nice is very similar, but the plant is more hardy, with flowers deeper in colour.

*Patrie* is one of the forms of Neapolitan, and one of the finest for winter flowering, it being very similar to *De Parme*, but with a little red in the centre of the flower, which *De Parme* occasionally exhibits. *Princess Louise*, another of the Neapolitans, is very floriferous, deep lavender, white eye, with a dash of red; flower large, highly fragrant, and footstalks as long and nearly as stout as those of *Victoria Regina*. It blooms from August right through to May.

What a promise there is of Queen, *Belle de Chatenay* and its variety *cærulea*! indeed the spring bloomers have abundance of buds already. This single Neapolitan, I am told, is the sweetest of all, and blooms in Italy all the winter. How does it thrive in this country?—G. ABBEY.

WIRE NETTING FOR PEAS.—I purpose next summer supporting my Peas with zinc wire netting, about 2-inch mesh, instead of the usual Pea rods. Have any of your readers adopted wire netting? with what sized mesh? and how many rows—one or two? and how were the Peas kept against the netting? Any other suggestion

that would be of use will be thankfully received by—B. G., *Cz. Down.*

#### THE SULTAN APPLE.

I SEND you a box containing two Apples of the Grand Sultan and two of the genuine Cornish Gilliflower, gathered from an old tree in a very old-established garden where the tree has been for the last forty years. This is the true type of the Gilliflower, and, as you will see, differs materially from the Sultan. The flesh of the Sultan when ripe is white, that of the Gilliflower yellow. They differ in shape. The Sultan is much larger and ripens earlier, and does not keep as well as the other. I also send with them a piece of the wood and foliage of each Apple, which are very different in every respect. The wood of the Sultan is strong-growing and the foliage large, the leaf rounding at the point. It spurs freely and does not bear at the extremities like the Cornish Gilliflower, the growth of which is slight and the leaves rather pointed.

The Sultan is a very old Apple, is found in all the oldest gardens and orchards in this neighbourhood, is largely grown and much esteemed as a table Apple. The early windfalls are much used in making "Devonshire Biffins," and are the best Apples for the purpose.

I have never seen the Sultan elsewhere. Do you know it under another name? Is it at Chiswick? If desired I would forward grafts of it to yourself or Mr. Barron. It is a great bearer.—  
JOHN M. MILLER, *Raleigh House, Barnstaple, North Devon.*

[There can be no doubt that Grand Sultan is distinct from Cornish Gilliflower. The nearest approach it has to any other variety is to Winter Red Calville, but we are not prepared to say that it is the same as that variety. It is a very fine and good Apple.—ED.]

#### DULWICH HOUSE,

THE residence of Lieut.-Col. Page, is pleasantly situated on a rising ground about two miles from the town of Cardiff, and within a short distance of the ancient city of Llandaff. Looking west a fine view is obtained for some distance up the Vale of Glamorgan, and the low but picturesque hills of Leckwith form a good background, with a broad stretch of level country lying between on each side of the river Ely. To the south-east we have a fine view of Cardiff and the shipping in the docks, and beyond this Penarth Head and the shipping in the roads. The land in the vicinity is rich and fertile, and well adapted to the cultivation of fruit trees and shrubs. Amongst the amateur devotees of horticulture who constitute, we are happy to say, so large a class in this country, there are few who have shown more constancy or exhibited more enthusiastic intelligence in the pursuit than Col. Page. He is a gentleman who derives great pleasure from the cultivation and daily acquaintance with fruits and flowers. The ground attached to his mansion is but eight acres in extent, but we have rarely seen a garden anywhere laid out to better advantage. Without any crowding the ground has been most skilfully arranged to furnish accommodation for a large number of choice fruit trees, shrubs, and flowers. His idea apparently is to rear everything of the best, and by the process of selection of the fittest he has been able to produce fine specimens of hardy fruits and shrubs suited to the place. Col. Page is fortunate in having a gardener such as Mr. Amytage, who, to the experience of long years, adds the quality of an aptitude for receiving new ideas and new suggestions, which is rare amongst men of his age. He is always ready to co-operate with his employer in carrying out the improvements which his zeal, practical skill, and carefully acquired knowledge are constantly suggesting.

Adjoining the house is a neat conservatory gay with choice flowering plants, and from the terrace in front of that structure a walk runs to the forcing houses and kitchen garden. The lawn, which is on a lower level, slopes to the south, and is neatly laid out with geometrical flower beds filled with some of the best varieties of bedding plants. Beside the beds the lawn is furnished with fine examples of ornamental trees and shrubs. The lawn-tennis ground lies to the left of the lawn on a higher level, and is divided from it by a grass terrace and the walk leading to the forcing houses, &c. The lawn and lawn-tennis ground are enclosed in the south by a large shrubbery running parallel with the terrace walk in front of the mansion, which completely screens from view the back wall of the forcing houses and kitchen garden; while between the shrubbery and the grass is a long herbaceous border filled with Phloxes and other plants in full flower.

Proceeding to the forcing and plant houses, the first we entered

was devoted to Pine Apples, Melons, Cucumbers and Grapes. It is span-roofed, 24 feet long by 12 feet, with a bed on each side of the path, one of which is filled with Pine Apples in pots, the varieties consisting of Queens, Smooth Cayenne, and Jamaica. The other bed is occupied with Cucumbers and Melons, which are trained to a trellis near the glass. At the end of the house were two Vines in pots trained over the walk, forming an arch, and bearing a good crop of Grapes. The Melons had also been fine. The Cucumber plants, Tender and True, were still bearing fruits nearly a yard in length. Though this is an exhibition variety, we cannot see where its usefulness lies compared with other varieties in cultivation. Near this is a span-roofed plant stove, 30 feet long by 20 feet wide and 11 feet high, with a raised bed in the centre, and a walk round and side stages for placing the plants on. It was well filled with medium-sized plants of Ferns, Lycopodiums, Dracaenas, Caladiums, Allamandas, Coleuses, and others in fine condition.

A lean-to vinery 30 feet by 15 feet and 13 feet high next received attention. The Vines are planted in an outside border and brought inside and trained on the intermediate system of pruning. The canes are allowed to grow to the top of the house in three years, and then they are cut clean out in the fourth at pruning time. By following this method a regular succession of young wood is obtained all over the house, which never fails to produce good crops of the best quality. The house was filled with seven Vines, one each of the following varieties—Black Hamburgh, Muscat of Alexandria, Madresfield Court, Gros Colman, Lady Downe's Seedling, Foster's Seedling, and Bowood Muscat. Besides the Vines we observed some Tomatoes in pots trained on the back wall, and a large plant of *Eriobotrya japonica*, which fruits there and is much appreciated. In a lean-to greenhouse 24 feet long by 12 feet wide some Vines growing up the rafters were carrying a fair crop of useful-sized bunches of well-coloured Black Hamburgh Grapes, which had never received any fire heat from the first. While in this house we were forcibly reminded of an enthusiastic friend who once wrote "that he was never satisfied unless every space and corner of his vinery was filled with plants." We admire his enthusiasm, but object altogether to the practice of growing plants and fruit in the same house, and would advise all those who can to avoid it.

Passing out of this we entered, what to us was the most interesting house of all, a lean-to orchard house 60 feet long by 15 feet wide, containing Peaches, Plums, Pears, Apples, Figs, and Vines, some in pots and some planted out in the border. A walk extends up the centre of the house its entire length. The roof is strengthened in the middle by a light beam supported at equal distances by five neatly turned wooden pillars. Vines were planted at each pillar and trained up and along the beam for the space of 6 feet on each side. Twelve Vines were planted in the border in front of the house, and trained up the rafters as single rods to meet the cross beam just mentioned. The other half of the roof was bare, and allows plenty of light and sunshine to penetrate to the Peach trees planted against the back wall. Some Peach trees close to the front lights were trained in bush form, and between them and the walk was another row in pots. Then between the walk and the back wall were two rows of trees in pots of various kinds, and the back wall was covered with Peach trees as already stated. They were clean and healthy, and bearing a heavy crop of large fruit. For the trees, pots 14 inches in diameter are generally used. The trees are never potted oftener than once in two years, and they seldom fail to produce good crops of fruit.

We might here mention a little peculiarity respecting the quality of the fruit of the Peach grown under different treatment in this house. Colonel Page informed us that the fruit of the Peach trees planted out in the front of the house and grown as bushes is inferior in flavour to the fruit of those grown in pots, and that the fruit of those grown in pots was still inferior to the fruit of the trees grown on the back wall. We cannot account for the fruit of the trees in pots being superior to those of the trees planted out in the border, unless it is that their roots penetrate deeper into the soil, and are consequently much farther from the sun's influence than the roots of those in pots. It is easily understood the fruit will be of better quality from trees spread out and trained in fan-shape, every shoot receiving the full benefit of the sun's rays (whether on a back wall or trained close up to the roof of a house) than those grown on bushes. Amongst Peaches we observed the following varieties carrying a fine crop of good sized fruit—Rivers' Early York, Royal George, Grosse Mignonne, Bellegarde, and Prince of Wales. Of Nectarines, Rivers' Pine Apple is reckoned here as one of the best varieties. It has a strong constitution, is a fine bearer, and scarcely ever fails in producing a heavy crop. Plums are grown in great variety, but Jefferson's is the favourite. The fruit under glass grows to a

large size, is of a beautiful amber colour, and has a most delicious flavour when ripe. Apples and Pears are grown in great abundance. Of Apples, the following varieties were heavily laden with fine fruit—Ecklinville Seedling, Cox's Orange Pippin, Worcestershire Pearmain, Margil, and Irish Peach.

The kitchen garden is in front of the houses, on a somewhat lower level, sloping to the south-west. It is divided from an orchard lying to the south by a row of good Austrian Pines, and beyond them another row of large Black Italian Poplars. It is enclosed on the west side by a boundary wall covered with Pear trees, and on the east by a paddock, some five acres in extent, including plantations. A broad gravel walk runs parallel with the houses, and from this other walks at right angles divide the garden into quarters. The borders near the walks were planted with pyramidal Apple and Pear trees, some 6 or 7 feet from the Box edging, and 12 feet apart. The Pear trees were in vigorous health, shapely specimens from 8 to 10 feet high, and were, at the time of our visit, loaded with fruit. The Apple trees were sickly, cankered, and not suited to the soil and situation. Colonel Page states that he had obtained both the Apple and Pear trees from France, that the Pear trees grew well, but that Apple trees did not succeed with him. In passing, we might say the garden was well cropped, and everything in it looked neat and orderly.

The fruit garden is to the west of the mansion in a line with the lawn, and is divided from it by a large shrubbery, in which we observed some fine flowering trees and shrubs, and a Siberian Crab loaded with its bright red fruit. The sides of the walks were furnished with espalier Pear and Apple trees about 4 feet high covered with large fruit of superior quality, and all the quarters inside were filled with standard and pyramidal-trained trees of the best varieties. Beside espaliers, standard and pyramidal-trained trees, there was a long wire trellis about 8 feet high covered with single cordon Apple and Pears, trained obliquely, carrying the finest crop we have ever seen. To use a hackneyed phrase, "the fruit was hanging like ropes of Onions." We were never much in favour of growing single cordons, but after seeing such fine examples as those described we intend to give a few a fair trial at the earliest opportunity. Between the outer walk and boundary wall of this portion of the garden there is a large shrubbery which completely hides the wall from view; it also shelters the fruit trees from the prevailing stormy west winds of this district, besides giving this portion of the garden a warm comfortable appearance.

To the west of this is another garden an acre in extent, which is separated from the eight acres attached to the mansion by a public road. It is divided into four quarters by a walk down the centre, and another across the middle. One of the quarters is planted with 150 bush Apple plants of the best varieties properly named, obtained from Messrs. Smith of Worcester; and one with 150 pyramidal Pear trees from Messrs. Rivers of Sawbridgeworth. The varieties are planted in rows by themselves, and Strawberries and Gooseberries are grown between the rows. The other two quarters are devoted to vegetables. The trees and bushes individually are pictures of health and remarkably well trained. Some of the varieties both of Apples and Pears were borne down to the ground with heavy crops, whilst others had scarcely any fruit. Of Apples the following had good crops—Ecklinville Seedling, Cellini, Cox's Orange and Sturmer Pippins, Reinette du Canada, Court Pendu Plat, Betty Geeson, Irish Peach, Claygate Pearmain, and Pine Apple. Some of the earlier varieties had been gathered, of which Lord Suffield, Stirling Castle, and Hawthornden had borne fine crops.—EUPHRASIA.

#### KITCHEN GARDEN.

*Forcing Department.*—Make successional sowings of French Beans in pots or boxes, in quantity proportionate to the requirements and means, earthing up those previously sown, being careful not to give too much water in the early stages of growth, but affording it in a tepid state copiously after they commence flowering. Damping off at this season is the great evil to be contended against, and should be avoided by ventilating constantly. Keep the pods closely picked, affording a temperature of from 60° to 75°. Commence making periodical sowings of Mustard and Cress. Train Tomatoes as re-

quired, earthing up the roots with fresh rich compost, supplying them occasionally with tepid liquid manure. To ensure a healthy and fruitful condition of the plants through the winter plenty of light must be afforded, and a temperature secured of 55° to 65°, with an advance from sun heat to 75°.

A few roots of Seakale and Rhubarb may now be placed in the Mushroom house or other warm structure in rich moist soil, bringing it well up to the crown of the plants. It is necessary that light be excluded from the Seakale to insure its blanching. The best kind of Rhubarb for forcing is Johnstone's St. Martin's, Linnæus being good, also Victoria later. Dung and leaves in the proportion of three of the latter to one of the former should be thrown into a heap, damped if necessary, and turned over occasionally to insure fermentation, the thorough mixing of the materials, and to sweeten them; after which they may be formed into a bed on which Asparagus may be planted—indeed, if the materials are already in readiness a bed may now be planted, but unless the demand be urgent and the resources adequate there is little gained by starting very early.

*Mushroom House.*—When the surface of beds in bearing becomes dry water them moderately at a temperature slightly warmer than that of the atmosphere, being careful not to give too much or to have the atmosphere overcharged with moisture, as is likely to be the case from the fermentation of the horse droppings when taken into the house and used for making successional beds, expelling superabundant moisture by a little top ventilation. To secure a regular supply of Mushrooms a somewhat moist atmosphere and temperature of 60° to 65° is necessary. Make up successional beds as materials are available, spawning and earthing as advised in former calendars. Watch closely for slugs, and trap woodlice with a boiled potato in a little hay placed in a flower pot on its side, and shake out the woodlice into a bucket of boiling water.

#### HARDY FRUIT GARDEN.

Where it is intended to form fresh plantations of Gooseberries, Currants, and Raspberries the ground should be well trenched and liberally manured. It is always advisable to plant early in autumn as soon as the leaves have mostly fallen. Some of the most desirable Gooseberries, when the object is flavour, are the following:—*Green*: Green Gascoigne, Green Walnut, Pitmaston Green Gage, Glenton Green. *Yellow*: Early Sulphur, Yellow Champagne. *White*: Crystal, Whitesmith, Bright Venus. *Red*: Champagne, Keen's Seedling, and Red Warrington. For a combination of size and quality with free bearing the following are desirable:—*Green*: Lofty, Shiner, Greta Green, Keepsake, Random Green, and Telegraph. *Yellow*: Broom Girl, Garibaldi, Catherina, Leveller, Leader, High Sheriff, and Mount Pleasant. *White*: Snowdrop, Overseer, Antagonist, King of Trumps, Careless, and Queen of Trumps. *Red*: Speedwell, Yaxley Hero Companion, Slaughterman, Ploughboy, and Talfourd. Currants.—*Red*: Red Dutch, Houghton Castle, and Warner's Grape. *White*: White Dutch, White Dutch Cut-leaved. *Black*: Lec's Prolific and Black Naples. Raspberries.—*Red*: Antwerp, Carters' Prolific, Baumforth's Seedling, and Semper Fidelis. *Yellow*: Brinckle's Orange and Yellow Antwerp. The autumn bearers are Large Monthly, October Red, and October Yellow.

Gooseberries and Currants should be planted 5 feet apart every way, allowing more distance if the soil be rich, or diminishing the distance in poor soil. Raspberries may be planted in rows 5 feet apart, and 3 feet asunder in the rows, whilst in rich soils the rows should be 6 feet apart and the plants 3 or 4 feet in the rows. When planted to be trained against an espalier the plants may be 2 feet apart, and 6 feet between the espaliers. Brambles, or Blackberry, may be planted at a similar distance as Raspberries, and be trained similarly to espaliers. The Lawton and Dorchester are good varieties, giving a quantity of fruit in late summer and autumn much esteemed for tarts and for jam. Strawberries should be cleared of weeds, removing perennial weeds by the roots and lightly stirring the soil about the plants; give a good top-dressing or mulching of partially decayed manure.

#### FRUIT HOUSES.

*Pines.*—At this season, from the absence of sun and ventilation, condensed moisture will abound and, accumulating on the glass, inter-

feres with the free access of light to the plants, which now more than at any other time is essential to their health, therefore a little ventilation should be given whenever an opportunity offers. In order to keep young stock sturdy ventilate liberally houses or pits when the weather is suitable. Water at the roots will not be required so frequently now as when absorption by the plants and evaporation is more powerful, but the plants must be looked over at least once a fortnight, and a supply given when required. Make the most of sun heat in the fruiting department, closing early in the afternoon with sun heat at 80°, and when the weather is mild keep the night temperature at 70°, and under adverse circumstances 5° less.

*Vines.*—Where it is necessary to have new Grapes ripe in April the first early house should now be started. The border outside should be covered with a good thickness of Oak or Beech leaves, with a third or fourth of horse dung incorporated, and in addition to this wooden shutters should be provided to throw off cold rains and snow. If the supply of these materials is not such as to admit of fresh additions being made to those on the border as the heat declines and requires renewal, it will be advisable not to put on the material so thick as to cause much fermentation, but only a foot thickness to preserve the roots from frost, with shutters to throw off rain and snow. Applying fermenting materials at starting, and allow them to become cold for want of renewal when the Vines are in active growth is injurious; a foot depth of bracken, or dry leaves, or litter, with means of throwing off rain or snow, is better. To facilitate the commencement of growth a good bed of leaves and litter inside the house by producing a moist genial ammonia-vapour-charged atmosphere will be beneficial as well as lessening the necessity for fire heat. The inside border should receive a thorough supply of water at a temperature of 85° to 90°, repeating it as needed to render the soil thoroughly moist. Sling the rods in a horizontal position to insure their breaking regularly, lowering young canes to cause the bottom buds to start. Syringe three times a day, and keep every part of the house moist by sprinkling in bright mild weather.

The Vines at this season will need a temperature of 50° to 55° at night and 60° to 65° by day to start them into growth. Those to be started early in December for fruiting early in May must be prepared without delay, thoroughly cleansing the house, and keeping it cool for the present. Collect leaves and stable litter for making a bed when the time arrives for closing the house. Push on the pruning and cleansing of succession houses as fast as the crops are removed and the foliage has fallen. Remove the loose surface soil from the roots, and supply good loam, to which has been added a little bone meal. The advantage of early pruning and a long rest for Vines cannot be over-estimated, and the past season having been highly favourable to the increase of red spider extra care in washing and dressing the rods will save much trouble another season. Remove all leaves from Vines going to rest, keeping the house cool, dry, and airy. The fruiting Vines in pots for successions should be pruned, washed, and dressed with an insecticide, placing them where they will be dry and cool, having protection from frost until they are wanted.

#### STRAWBERRIES IN POTS.

Plants intended for early forcing and having well-developed crowns may now have the surface soil stirred without injury to the roots, and be top-dressed with fresh horse droppings made fine and placed on compactly, leaving sufficient space for watering. The drainage also should be attended to, any accumulations of dirt being removed from the outside of the pot by washing. Where there is a house for forcing this useful plant, and the fruit is required ripe early, the plants may be introduced, it being necessary that they be raised near to the glass on shelves with means of admitting air freely. A temperature of 50° is sufficient to commence with, admitting air freely above that heat, not allowing an advance above 65° without liberal ventilation. When the flowers are opening the temperature may be raised to 55°, and 60° to 65° in the daytime; and when the fruit commences swelling, 60° to 65° at night and 70° to 75° by day will be necessary. Supply liquid manure, and secure a genial atmosphere by lightly syringing overhead, and damping available surfaces in the morning and afternoon. When the fruit is ripening a drier condition at the roots and in the atmosphere will be necessary. The

general stock of plants may be plunged in ashes in cold frames, exposing them fully when the weather is mild. Where frames are not at command the pots should be plunged in ashes in a sheltered position, and in severe weather a covering of mats or dry fern will afford the needful protection.

#### MR. PETTIGREW AND BEE SHOWS.

AS a young bee-keeper I beg to tell Mr. A. Pettigrew that he is mistaken as regards the work of the British Bee-keepers' Association through their tents. I can state without fear of contradiction that never in the memory of man has there been such a desire to keep bees as at the present time. In this district people have been so encouraged in bee-keeping as taught through the tents, that the agents in the north of Ireland have had to repeat their orders again and again for bar-frame appliances, as Messrs. G. Neighbour & Sons could testify. Further, new manufacturers have started in all parts of the country; and besides all this I have almost daily applications for instructions concerning the bar-frame hive. When Mr. Pettigrew says that the tent manipulations tend to frighten people, I am tempted to ask him if he is serious. As regards sectional supers, nothing could be more taking than they are, and those who exhibit them at shows are pressed all day to dispose of them; while on the other hand, few "spear the price" of a glass super 21 lbs. at 2s. per lb., or a big straw skep filled with honey, brood, bee-bread, &c. Mr. Pettigrew does not like the honey-extractor, as he says it throws out crude honey. But can he not wait until it is sealed, then uncap it and extract it? It would scarcely be crude honey then. Is not honey in frame hives as good as honey in straw skeps? Having learned much from the British Bee-keepers' Association I must protest against Mr. Pettigrew, in his enthusiasm for the straw skep, trying to throw cold water upon a system that for pleasure or profit is in the estimation of thousands the best that has yet been introduced. Mr. Pettigrew is no doubt an excellent judge of bees, but many dispute his competency to be a sound and impartial judge of systems.—COMBER, *Co. Down.*

#### A RETROSPECT.

THE season of 1881 has been favourable for honey-gathering in some localities and very unfavourable in others. In the south of England and in the East Riding of Yorkshire, in Lincolnshire, and other parts bordering the German Ocean, bees on the whole have done well, and, so far as I can learn, the bee-keepers in those parts are satisfied with their harvest of honey. The bee and honey exhibitions in London and at Louth, Lincolnshire, were considered good and satisfactory. In many other parts of England, bees, during the hot weather in June, gathered great stores of honey, and thereby created great interest in apian circles and expectations of large profits; but in the flush and glut of honey from white Clover the weather became bad and did not improve till the Clover season ended; and as hives were then full of bees, and as bees in summer need and consume much food, their large stores were soon made less. During the last half of July and all August bees lost weight very fast. Though the season has been encouraging from some points of view, it cannot be considered a first-rate one for honey in some of the midland and northern counties of England. The quality of the honey taken, however, has been excellent.

In this neighbourhood in the month of May the aphis or plant louse which produces "honeydew" appeared on the leaves of Sycamore trees, and a little of its produce was gathered by bees, which partly discoloured better honey stored with it in the combs. Honeydew on trees near an apiary is a great nuisance and discouragement to many bee-keepers.

The Scottish bee-keepers, who during the last dozen of years have been favoured with some good seasons for honey, while the English have had to contend against some very unfavourable ones, have this year been more unfortunate than we, for the honey season in the north has been a failure. Even on the moors in Scotland this year bees gathered little if any honey at all. In the north of England no heather honey has been obtained this year.

From Ireland I have not had any particulars as to the success or non-success of bee-keepers there this year. I have seen some Irish honey of this season good enough of its kind, evidently gathered from the yellow weed of cornfields, known by the name

of Ketlock or Field Mustard. This plant yields rather clear honey with a greenish or yellowish tint, and does not taste well beside honey gathered from fruit trees and Clover fields. Though the honey of Ketlock is not first or second-rate, yet fields of Ketlock in the neighbourhood of an apiary are of great value to bees, for they yield much honey and pollen when the fruit blossoms disappear and before the white Clover comes into flower.

We are all glad that 1881 has given English bee-keepers some very good honey and great encouragement to look hopefully forward to future years.—A. PETTIGREW.

#### A RARE AND UNPLEASANT INCIDENT TO A QUEEN BEE.

[A Translation from the "Bienenzeitung." Communicated by Mr. Alfred Neighbour.]

I AM always pleased to look at queen bees, but Tuesday, the 12th July last, formed an exception. On that day, between five and six o'clock in the afternoon, I discovered a queen in my garden about fifteen paces from the place where my hives are kept, resting on the ground and surrounded by a cluster of bees, to which my attention was directed by a number of workers hovering over the queen. The bees behaved exactly as they do when a swarm loses its queen, but I was quite certain that no swarm had issued from any of my colonies. I at once thought of a stock from which the queen had been removed twenty days previously. In this hive a young queen appeared on the 7th July, but the bees did not tear away the superfluous royal cells until the 10th July. On that day the weather was most unfavourable, nor did any drones venture out of their hive on the 11th, but I confidently expected the young queen of this stock to become impregnated on the 12th July, which was a lovely day. I picked up the poor queen, and finding that one of her wings was dislocated I put her into a queen cage, which I fixed inside the hive above the comb bars. The bees surrounded the cage joyfully; and as the queen did not try to get away from them, but evidently allowed herself to be fed, I liberated her a few minutes afterwards, and I soon saw her walking about among the bees.

It had to be ascertained now whether the queen was incapable of flying when she left the hive or whether she had met with an accident after the act of impregnation. Unfortunately the former turned out to be the case, for on the following day (Wednesday) I found her again in the garden at the same time running backwards and forwards alone, but some workers were hovering over her again, which attracted my attention. I picked up the queen, who was now minus one of her wings, and allowed her to enter the hive by the entrance. She was again well received by the workers.

On the following day (Thursday) I noticed nothing unusual in the morning, and in the afternoon I was obliged to leave home. When I returned late in the evening I did not think it necessary to examine the interior of the hive, as the outside presented its customary appearance. I looked for the queen on the ground in the garden, but she was not to be found there. At half-past seven the next morning I paid a visit to my colony whose existence was in danger, and as soon as I opened the hive I knew at once that the stock was without a queen. I found the queen on the ground in the garden for the third time, surrounded again by a few workers. Of course she had not left the hive the same morning, but the previous afternoon, which accounted for the colony being in such an excited state. Knowing that it was impossible for the queen to become fertile on account of her being unable to keep on the wing I placed her in a queen cage among the bees, and a few hours afterwards I introduced a fertile queen in her place.

Though this is a case of rare occurrence, nevertheless it will show that when a queen leaves the hive on her wedding trip she remains in communication with her colony by worker bees which accompany her. This was the interesting part of the affair, which inclines me to hope that queen bees do not so easily lose their way and perish, as is often stated in books on bees.

It was the first time that I have lost a young queen, and in this case it was perhaps through some fault of my own, as I performed some operations on the stock between the time of the queen leaving the cell and her wedding excursion. The exterior of the hive was, indeed, not interfered with, but I made some alterations in the interior, during which the wing of the queen may have become damaged by the workers or otherwise. The queen certainly appeared faultless to me when I saw her immediately after she was hatched.

"One misfortune seldom comes alone," and this saying seems to be true with regard to bees also. Last summer this same colony killed their own queen—the best one I possessed—after I had deprived them of all their honeycomb, which was replaced by empty combs, of which I had a sufficient number from previous bad times to enable me to make artificial swarms. When I gave them a new queen and liberated her after two days' confinement the bees immediately attacked her, and would have killed her if I had not rescued her from their fury in time. After this a royal cell was inserted, which was very late in hatching, and when at length the queen made her appearance she first laid drone eggs only, but afterwards she also produced workers. She did not prove very fertile, however, so that her population increased but slowly this spring. I therefore removed the queen, leaving the colony to rear a new one. What happened to this

queen has just been related. The new queen having been accepted by the stock, I trust all its troubles will now be at an end.—(Signed) THD. ZINCK, Kleinheilbach, 18th July, 1881.

#### TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12 and 13, King Street, Covent Garden, London.—*List of Specialities.*

Ewing & Company, Eaton, Norwich.—*Catalogue of Roses, Fruit Trees, and Shrubs.*

George Cooling & Son, Bath.—*Catalogue of Roses, Fruit Trees, and Hardy Shrubs.*

Dammann & Co., Portici, Naples, Italy.—*Catalogue of Flower and Vegetable Seeds.*

Ormiston & Renwick, Melrose, Roxburghshire.—*Catalogue of Trees and Shrubs.*

Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (J. F.).**—There is no book in English of the exact nature of the French work you name, which is not at all a complete work, and not likely to be translated and published in this country. If you do not possess the "Cottage Gardener's Dictionary," your gardener will find it very useful. It can be had post free from this office, price 7s. 2d. A work on Lilies likely to suit you will be "Notes on Lilies and their Culture," by Dr. Wallace, post free 5s. 6d., from the New Plant and Bulb Company, Colchester. The "Vine Manual," published at this office, price 3s. 2d., contains reliable information.

**Treatment of Orchids (J. B.).**—The Stanhopea may be allowed to complete its growth in the stove, supplying water freely but judiciously. When growth is completed it may still be kept in the same structure, but a drier position should be assigned to it, also greatly diminishing the supply of water to the roots to insure a thorough rest. The Oncidium would be better grown in a pot, providing plenty of drainage and a compost of peat and sphagnum. Both would thrive in the same house.

**Rose Cuttings (Cuttings).**—We also inserted cuttings at the same time and in the same manner that you have done, but we managed them better, as we did not allow the soil to become parched, and we had no Mustard seed mixed with it. Our plants are now established in pots, and some of them are producing flowers. Remove the glass, water the soil and keep it moist, the box being wintered in a cold frame, and pot off the plants when they commence growing in the spring. The method of striking Roses is a good one, but you have not carried it out properly. Two good early dessert Apples are Irish Peach and Kerry Pippin; two large culinary Apples, Gloria Mundi and Warner's King.

**Pine Apples (F. C.).**—The work that you have ordered will give you all the details of culture. If you make a pit in your house—that is, enclose a space with walls so as to form a pit 4 feet deep, and fill it with leaves for affording bottom heat, and can maintain a minimum atmospheric temperature of 65° in the winter, you may grow Pines in the house; but you can scarcely expect in so small a structure to grow Melons and Grapes also. If Vines are attempted the rods must be turned outside in the winter and be wrapped with haybands, as a temperature suitable for Pines would be too warm for them; the temperature would also be too warm for Peaches. You might grow Melons by training a plant or two thinly on the roof, also on the back wall. A well-grown Pine Apple is esteemed by many the richest of fruits, and is totally distinct in character and flavour from all others. We have known amateurs to succeed in growing a few Pines in a house not larger than yours, but have seldom considered the space was occupied profitably.

**Vines Unhealthy (Idem).**—We have seldom seen worse wood than the specimens you have enclosed. It is both weak and immature. It is impossible for such wood to produce good Grapes. Strong young Vines would in all probability give you greater satisfaction than those of which you have sent us portions. It is not at all unusual to see Black Hamburg Grapes 1 by 1½ inch in diameter.

**Hotbeds (Idem).**—The leaves should be used moist, but not very wet. Oak or Beech leaves produce a more steady and lasting heat than manure does, but the best hotbeds are made with a mixture of the two in about equal parts. Woodlice may be entrapped by placing boiled potatoes in flower pots and covering the potato with loose dry hay. If these are examined frequently numbers of the insects may be destroyed.

**Sowing Pansy Seed (M. E. H.).**—If Pansy seed is sown thinly in boxes in April, the plants being raised in a cool frame, and subsequently transplanted in a suitable position outdoors, they will flower freely during the summer. Seedlings grow much more freely than plants do that are raised from cuttings, but a great number of seedlings are usually worthless from a florist's point of view. If the young growths are pulled from the old plants now many of them

will have roots attached, and if these rooted slips are planted deeply in gritty soil they will grow freely. If strong seedling Pansies are required for flowering in the spring the seed should be sown in a cool position soon after it is gathered from the plants.

**Bone Meal for Lawns (F. R.).**—Bone meal is an excellent manure for lawns, and if you scatter 56 lbs. very regularly on the lawn now, and give a similar dressing in March, it can scarcely fail to prove beneficial. The benefit, however, would probably be still more marked if you could mix the bone meal with very fine soil and spread the whole on the surface a quarter of an inch thick, or even less at the present time; in this case a second dressing of the bone meal would probably not be required in the spring. If it is—that is, if you do not use the soil, add to the bone meal 10 lbs. of nitrate of soda for the spring dressing.

**Potassic Nitrate (A. S.).**—Considerable alterations have been made in chemical nomenclature of late years, and the name you mention is a case in point. The old chemical name of nitre or saltpetre was nitrate of potash, now it is termed potassic nitrate. Other examples are the following—Sulphuric acid (oil of vitriol) is now dihydric sulphate; nitric acid (aqua fortis) is hydric nitrate; acetic acid (vinegar) is hydric acetate; carbonic acid is carbonic dioxide or carbonic anhydride; oxide of calcium or lime (quicklime) is calcic oxide; and chloride of sodium (common salt) is sodic chloride. An elaborate comparative table of common, old, and new names for chemical substances is given in the twelfth edition of "Johnstone and Cameron's Elements of Agricultural Chemistry and Geology," published by Messrs. Blackwood & Sons, Edinburgh and London.

**Sashbars for Glazing (F. J.).**—The rafters referred to were for supporting the lights; if you glaze from the sashbars, which you may safely do, 4 by 2-inch bars will suffice for your roof, especially if they are kept in their positions, as they must be, and supported by a bar of T iron affixed to the bars in the inside of the house. Ordinary flat bars will not be strong enough. The holes for the screws must be made in the iron with great exactitude, or you will have a difficulty in glazing.

**Brachycome iberidifolia (X. F. Z.).**—The Australian annual of which you desire information is, we presume, *Brachycome iberidifolia*, as we know of no other having flowers so much "like a *Cineraria*." It is a native of the

Fig. 68.—*Brachycome iberidifolia*.

Swau River district. It is quite hardy, and is very attractive in borders when the variously tinted purplish or lavender flowers are expanded. It thrives in almost any light soil, but excessive moisture is very injurious to it. Sow the seeds in spring either in the border, or earlier in pans under glass, transplanting the seedlings when the weather is suitable.

**Packing Grafts for Ceylon (J. C.).**—If you tie wet moss round the end of each and envelope it closely in skin, indiarubber, or oiled silk, and also wrap the same material round the grafts, we think they will not be dried in transit, especially if they are packed in a closely fitting tin-lined case; nor do we think they would fail if packed in damp cocoa-nut fibre refuse, the cuttings being placed in layers and quite covered with the material. Your other question will be answered next week.

**Geometry (A Young Gardener).**—You will find Gill's "School of Art Geometry" a very useful elementary work; it is published by Philip & Son, Fleet Street, London, or Heywood, Manchester, price 1s.; or if you send four penny postage stamps to Messrs. W. and R. Chambers & Co., Paternoster Row, London, and ask them to send you Nos. 91 and 92 of "Information for the People," you will obtain instruction that will be serviceable.

**Azalea Leaves Falling (F. J.).**—The plants are semi-deciduous, and a number of leaves always fall at this period of the year. There is, however, a difference in this respect between the varieties, some retaining their foliage better than others; the mode of culture also has an influence on the matter, unhealthy or injudiciously treated plants losing more leaves than plants do that have careful attention in potting and watering. Chrysanthemums lose their leaves in consequence of the plants having received a check at some period during growth, and the flowers come deformed by the same cause; a sudden and rather sharp frost also often injures Chrysanthemums and checks the free expansion of the flowers.

**Grapes Decayed (E. D. C.).**—You do not afford sufficient data for enabling us to answer your question satisfactorily. If you will state how the border was made and drained, with the nature of the compost, and also send fair examples of young wood and foliage, we will give the subject our best attention.

**Picotees (D. N.).**—If the plants are large we doubt if you would derive any advantage by taking them up and potting, as a number of them would probably die; but small plants may be lifted safely and wintered in cold frames. It is too late for layering the growths now. You had better remove any decayed leaves and cover the stems, not the foliage, with cocoa-nut fibre refuse, or, failing this, light gritty soil, through which the rain passes freely, and the plants may pass the winter safely. We have seen them thus preserved in colder districts than Staffordshire.

**Tuberous Begonias (Subscriber).**—The note to which you allude has reference to these plants as grown outdoors during the summer, but we presume you require instruction on growing the plants in pots. The tubers may be wintered in a greenhouse in the pots in which they were grown. In the spring they require to be started in heat, such as is afforded by a Cucumber frame or a cool propagating house, removing them from the old soil and placing in pots according to their size, using a compost of peat, loam, and leaf soil, with plenty of broken charcoal or sand. They must be watered with great care at the first, as an excess of moisture causes decay. When the plants are growing freely they must be shifted into larger pots, employing richer and stronger soil, keeping them in a genial atmosphere and a temperature of from 55° to 60° at night. Further particulars will doubtless be given in time to be of service to you.

**Roses for Exhibition (S. B.).**—If you desire to exhibit twelve varieties you must grow twenty-four or thirty-six to enable you to do so with any measure of success. You cannot do better than select the Hybrid Perpetuals in the order they are named in the recent Rose election which is published on page 306, our issue of the 6th ult. The following thirty-six varieties are published in the order in which they were named in the election of Teas and Noisettes, and you cannot do better than plant the number you require of the varieties first-named if you do not desire to plant them all:—Catherine Mermet, Souvenir d'un Ami, Devoniensis, Gloire de Dijon, Marie Van Houtte, Niphetos, Perle des Jardins, Maréchal Niel, Souvenir d'Elise, Rubens, Souvenir de P. Neron, Jean Ducher, Belle Lyonnaise, Madame Willermoz, Madame Lambert, Madame Falcot, Anna Ollivier, Céline Forestier, Madame Margottin, Alba Rosea, Madame Berard, Comtesse de Nadaillac, Madame C. Kuster, Triomphe de Rennes, Homère, Adam, Madame Hippolyte Jamain, President, Bonquet d'Or, Boule d'Or, Madame Welsh, Jean Pernet, Marie Guillot, Madame Bravy, Perle de Lyons, Isabella Sprunt.

**Scale on Phormium (W. B.).**—It can be readily washed off with a solution of soft soap or Gishurst compound at a strength of 2 ozs. to the gallon of water and applied when warm with a sponge. It is almost a wonder you did not think of this simple remedy. You had better, however, not let much of the solution drain to the roots. Even sponging with pure water would be of great benefit, as the scale is so readily displaced from the leaf you have sent. The plant of which you desire the name is *Sedum Sieboldi*.

**Red Spider on Vines (W. B. C., Ramsgate).**—You have made your case quite clear. When two or three Vines only are attacked with red spider the most efficient mode of riddance is to sponge the leaves with a solution of Gishurst compound at the strength of 2 or 3 ozs. to a gallon of water, or other approved insecticide, and not syringe them afterwards. Two or three hours thus spent is labour well applied in a case of this kind, as we have proved by experience. The insecticide can, however, be applied much quicker by a vaporiser such as was advertised in our columns a short time ago. As soon as the leaves are ready to fall gather them from the Vines and destroy them; after pruning well scrub the rods with soapy water as hot as the hand can bear for a moment or two, and then paint them with sulphur, with a little clay added to make it adhesive.

**Names of Fruits.**—We have many times notified that only six varieties of fruits can be named at once; still large packages reach us, the contents of which cannot be examined. Some fruits are not named because the sender's name does not accompany them, and we cannot always determine to whom the respective parcels belong, even by the aid of letters received by post. Pears, we have previously intimated, ought to be ripe or approaching ripeness when sent, or a number of them cannot be identified. All packages must be carriage paid; unpaid parcels are sent every week that are not taken in. The fee for naming fruit to non-subscribers is 5s. It is important that these conditions be attended to for preventing disappointment. (*J. Ellis*).—1, Dumelow's Seedling; 2, Stirling Castle; 3, Court Pendu Plat; 4, Pearson's Plate; 5, Besspool; 6, Beauty of Kent. We cannot name the others. (*Crediton*).—It is quite impossible to recognise your parcel, as several hampers have been received without names in them, and as the direction labels have been destroyed we cannot trace the districts from which the parcels were sent. If you send other specimens with a note enclosed we will endeavour to name them for you. (*Reader*).—1, Yorkshire Greening; 2, Norfolk Beefing. (*X. H. P.*).—1, New Northern Greening; 2, not known; 3, Sturmer Pippin; 4, Verulam; 5, Beurré d'Aremberg; 6, Reinette Van Mons. (*F. J.*).—1, Van Mons Leon Leclerc; 2, Emperor Alexander; 3, Reinette du Canada; 4, not known; 5, Beauty of Kent; 6, Cox's Orange Pippin. (*J. E.*).—1, Adams' Pearmain; 2, London Pippin; 3, Coe's Golden Drop; 4, Braddick's Nonpareil; 5, Golden Russet; 6, Nonpareil. (*J. T.*).—1, Beurré Sterckmans; 2, Beurré Diel; 3, Colmar Van Mons; 4, Beurré Scheidweiler; 5, Beurré d'Aremberg. (*G. S.*).—1, Winter Ambrette; 2, Marie Louise; 4, Beurré Sterckmans; 7, Beurré Clairgeau; 8, Seckle; 10, Colmar Delahaut. (*G. P.*).—2, Autumn Red Calville; 3, Reinette du Canada. Pears: 1, Epine du Mas; 2, Emile d'Heyst; 3, Beurré Scheidweiler. The others not known, probably local varieties. (*G. R.*).—1, Napoleon; 2, Beurré Clairgeau; 3, Beurré Diel. (*H. H.*).—1, Beurré d'Amanlis; 2, Swan's Egg. (*Ed. Leigh*).—We are most willing to assist our subscribers in determining the names of fruits, but it is imperative that they comply with the above conditions; large quantities of fruit cannot possibly be examined. (*John Watton*).—We regret we cannot aid you, as the numbers were all off the fruits, and were mixed together at the bottom of the box owing to the shaking in transit. If you will send other specimens with the numbers attached to them they shall have our careful attention.

**Names of Plants (F. G.).**—1, *Acer platanoides laciniata* (Eagle's Claw Maple); 2, *Mesembryanthemum imbricatum*; 3, *Cupressus Lawsoniana fragrans*; 4, *Sequoia sempervirens*; 5, *Abies Albertiana* (Prince Albert's Fir). (*R. C. D.*).—The shrub is *Baccharis halimifolia*, a native of North America, and known in English gardens since 1863. (*W. D. H.*).—The flower was in a complete state of decay, but it resembles a Phajus. (*J. H.*).—*Hedera Helix palmata*. (*G. D. T.*).—The Fern is *Lygodium volubile*, a native of the West Indies and South America. (*Somersct*).—*Chrysanthemum coronarium*.

## POULTRY AND PIGEON CHRONICLE.

## IMPROVEMENT OF THE HAMPSHIRE AND WEST COUNTRY DOWN SHEEP.

(Continued from page 391.)

IN continuation of the quotation from the paper read at the Botley and South Hants Farmers' Club relating to the raising and fixing a new type of sheep to be called the Somerset Down. It says, "It should, however, be only attempted by an owner of a farm or the holder of a long lease, for with all the experience at command of those who have gone before us it would take from fourteen to sixteen years to fix a new type of sheep for the purpose of improving the style and character of the Hampshire Downs. We therefore propose that in case only one person should engage in the raising a new breed that three selections of not less than twenty-five Somerset ewes each should be obtained from three of the best flocks, and that three ram lambs should be also selected from the best Hampshire Down flocks, and in mating the animals this would furnish a change for three years. In selecting the ewes these should be maiden animals, because if they have never bred a lamb previously the full potency of the ram would be obtained (a matter of the highest importance in this case) as to fixing the colour of the face and legs of the offspring. We have, then, in fact, three separate flocks, and from the offspring of each we have the opportunity, in mating the animals, of securing a change of blood without deviating from the cross or object in view, and if the offspring of each flock are marked it will be of some consequence in the future in various ways. For it is necessary that all defective ewes (of each family), either in colour or character, should be withdrawn, and that the most masculine and robust male animals only should be selected for use, keeping steadily in view colour, form, and weight for age. After using the above precautions we need not be afraid of what is called in-and-in breeding, for when we have obtained a good family likeness of the type we require we must not think of change of blood outside the boundary; but we may, after the type is fixed and the increased stock has passed into other hands,

go to them for a change, which may prove advantageous through the influence of soil and climate on which they may have been reared."

Quite irrespective of the opinions of the reader of this paper a discussion ensued by various practical flockmasters, and a unanimous resolution was passed at the meeting, and moved by Mr. Blundell, as follows:—"That in the opinion of this Club cross-breeding is a matter of great importance, and it is to be hoped some person or persons will be found who will take up the question of fixing a desired type for renovating and improving the Hampshire Down breed of sheep." We cannot give the discussion in full, but we cannot omit a few practical observations made by Mr. J. D. Barford, V.S., of Southampton, who said the subject was a very wide one, embracing the relative merits of the pure breeds and cross-breeds of the country, with especial reference to the Hampshire Downs. In commencing a new breed, or trying to improve an old one, there was nothing so important as to study the relative advantages of the different animals adapted for the soil on which they were to be reared. He left to more practical men than himself to say if a new breed of sheep was required here; but he could say from experience there were improvements needed in the present type, but these improvements must be carefully begun, breeders being very tenacious that the present type and contour of the Hampshire Downs should not be materially altered. He alluded to the present large per-centage of losses in lambing, and said the present fine prize specimens of Hampshire Downs seen in the markets were more costly to obtain than fine animals in other types, such as the Leicesters and white-faced breeds. The relative influence of the male and female in the produce was a very difficult question, but the broad rule laid down by Mr. Blundell in his paper would probably be generally a correct one. He had abundance of evidence in regard to all breeds of animals that the impress of the parent was made apparent in future generations. The 89 per cent. of lambs mentioned was far too low, and said these losses were worthy of most serious consideration, and indicated some defect in the Down breed. Most unquestionably by careful selection and mating the shape could be improved, and in improving it they would be doing great service to the breeders of the district.

Before proceeding further with the subject we will state the defects which are to be found in the Hampshire Downs, or to which they are reverting in consequence of the tendency to depreciation. The faults of the original breed were the shallow chest, the straight ribs, the light scrag and bare shoulder top, and the breeding their lambs at a late period, with but very few twins, and a weak constitution, which subjects the animals to great losses in the adults as well as in the lambs at different periods. Practically, however, we have found that in improving the shape of the animals we improve their constitution; but let us inquire how the outline and character are to be improved. If we take the long-woolled breed for the purpose we have more lambs, but we deteriorate the quality of the flesh by laying the fat on upon the outside of the carcass, the loose open wool is prejudicial in adverse climates, and the lambs come late, although we obtain a large proportion of twins. Still, as in the Oxford Downs, we have a better outline and heavier weights for age. Again, as various flocks at present contribute animals to the prize pens in the show yards, and are called Hampshire Downs, but they exhibit the use of long-woolled blood in their parentage, still they attract the eye of the public, and often the approval of the judges; but they are not Hampshire Downs or West-country Downs as we recognise them, nor as they are really required for flocks to be reared and fed on the chalk hill farms in various districts; in fact, our definition of a typical Hampshire or West-country Down sheep is, as we have before alluded to, and which we have called the Somerset Down, which can only be obtained by mating the improved horned Somerset ewe with a short-woolled Hampshire Down ram, and producing as nearly the style and type of the late Mr. Humphrey's breed as possible.

We must now allude to the character of the improved pink-nosed Somerset breed, which may be described as follows: Some of the very best flocks of which we have lately visited are now lambing, and show a great length of body presenting a barrel-like form, deep in the chest, a well-covered shoulder top, and short full scrag, with wide hips and short legs; the body well covered with short fine wool, coming down before and behind to the knee and to the hock. This is their formation, but their attributes are many and valuable such as no other breed can reach, except a few of the best horned Dorsets. They are the most prolific, not only yearning at the earliest period a greater number of twin lambs than any other breed, but will, if required, yield two crops of lambs within the year; added to this fecundity they are the best of nurses, furnishing more

milk than any other breed, and at the same time will fatten quicker whilst suckling their lambs than any other known breed. They are of excellent constitution and very hardy, being frequently reared on very exposed hill farms in the south-western counties. When fat they yield flesh with the fat most intimately mixed with the lean, and furnish joints for the table yielding a larger amount of rich gravy than can be obtained from the mutton of any other breed of sheep, although rather coarser in the grain than the meat of the pure-bred Sussex Downs. We have described the advantages of the Somerset horned ewe in detail, because so few breeders understand their characteristics and attributes, and because we can obtain what we require in a new type from no other source or breed; and to illustrate this let us ask what we require the Hampshire Down ram to contribute towards the fixing the new type. We desire to obtain his colour both of face and legs, and his hornless or polled head, and character only; every other point of consequence is to be found in the description we have given of the Somerset ewe. As it is admitted by all professional and experienced practical men that the male animal contributes in cross-breeding the colour and outward characteristics in a superior degree, and that the female may be said to furnish nearly all the important functions of the animal, such as constitution, internal structure, together with breeding and milking capacity. But we can assure breeders that this cannot be obtained with absolute certainty; it must, therefore, in all cases be supplemented by judicious selection, following our object in view. One thing, however, is certain, that if we wish for complete success we must select maiden ewes to breed from, for in case we take aged animals which have previously bred to other rams than the sort we require, no defined style or type can with reason be expected in the offspring; and we have no hesitation in saying that to this circumstance the failure of many breeders who have attempted the cross-breeding of sheep may be attributed.

#### WORK ON THE HOME FARM.

*Horse Labour.*—The weather upon the whole has been so favourable for the autumn tillage by steam power that it has been continued until the time we write. The horse labour has, however, of necessity been employed lately in preparing the land and drilling the Wheat. Some farmers say that the land is too dry for Wheat-sowing, but that is not our experience. We have known several seasons during the past fifty years when fine dry weather without frost has prevailed through October and the first half of the month of November; it, however, requires different management to some extent. Where the land is not ploughed and pressed and sown after the presser it should be drilled so deep that the young plants may root in the subsoil not moved by the last ploughing, in order that they have firm holding in the soil. When drilled shallow in light fine tilth after the rains and frosts of winter the plants are very liable to be lifted out of the soil. Another point is that in the case of a very light dry seed time for Wheat a great number of weeds will often prevail in the spring of the year. If the corn has not been drilled at 10 or 12 inches apart the land cannot be effectually horse-hoed in order to destroy the weeds, more particularly if the Wheat proves what is termed winter-prond. It later on frequently turns off very sickly and loses colour, in which case if not drilled so as to be effectually horse and hand-hoed the weeds will overpower the crop. Even if the land should be free from weeds the horse-hoeing is nevertheless a necessity, in order that the surface soil may be moved and thus give life and energy to the growth of the Wheat, without which it would continue to lose colour and produce a small ear. Practically, an effectual horse-hoeing is of far more consequence than a dressing of nitrate of soda under such circumstances.

We have personally inspected much land lately, and we find that whole districts are almost worthless as arable land for want of a dressing of chalk or lime, the latter being well adapted for the heavy lands whether resting on chalk or clay. We have seen hundreds of acres of Wheat land where last year the crop was hardly worth harvesting in consequence of blight accelerated, if not actually caused, by want of chalk. We find a general impression prevailing that when chalk underlies the clay the land cannot require chalk. That is a great mistake, for land containing rubble only is called chalk, and is actually expected to assist vegetation, when it has been for long periods robbed of its carbonate of lime and the plant food which it originally contained by a long series of cereal crops, and has become comparatively worthless. As if to teach the farmers a lesson the chalk dells and pits of former days, which are numerous, should show them that formerly the farmers were wise in their generation, and used an abundance of chalk in the districts where its use is now seldom or never attempted. We therefore advise the home farmer to look well to his crops, and notice the kind of weeds which prevail, and which exhibit the want of chalk; but we must refer the reader to our article upon chalking given in this Journal on the 20th and 27th days of November, 1879. In fact, we go so far as to say that it is impossible to farm profitably where land is exhausted of chalk and lime, because corn or grain of any kind will not yield and root crops cannot succeed in its absence. On heavy land it is also necessary

that the small ten-furrowed ridges should be made the rule. Although the water may not often stand upon the land, yet it passes away and does not charge the subsoil so much when it can pass quickly off the surface by the action of land and water furrows properly made out. It is, however, of still more consequence when the strong land rests upon strong clay, for even after it has been properly drained the surface-lying of the land cannot be neglected with impunity.

*Hand Labour.*—The women and boys are assisting the men in pulling and storing the Mangold crop, which we are glad to say in the mixed soils on the vale farms of the southern and midland counties is nearly or quite an average produce. Should this crop be required for feeding on the land in the spring the roots may be pitted in the same manner as we find necessary in some cases to treat them and preserve the Swede crop, Carrots, &c., especially upon farms where ground game is reared to any considerable extent. In other cases the wood pigeons prevail to an extent sufficient to cause immense injury to the root crops during the winter months. Water-furrowing on the Wheat land will now be going on; also hedging, ditching, &c., as well as work in the woodlands by converting the Hazel and other woods into hoops, hurdles, hop poles, &c., The cutting of Ash and Elm timber may now be done with better effect than in spring.

*Live Stock.*—All fattening bullocks which have been feeding on grass land during the summer should now be sold if ready, or otherwise be put into the boxes or stalls, the former being the preferable mode of management. As barns are not now wanted in winter they can be made to act as cattle boxes during winter, spring, or summer, and by having moveable fittings they may also be filled with corn for early threshing, and thus be made available as harvesting barns and cattle-feeding apartments combined—in fact this has been our plan of proceeding for the past thirty years. Milch cows and young stock should both lie in at night, the former in their stalls, the latter in littered yards and sheds, and receive their roots, fodder, and cake, which will then be used with advantage. The fattening sheep must now be treated as we have often stated, being fed with cut roots and cake or bean and maize meal mixed with the roots twice a day, and twice with hay and straw chaff mixed with the cut roots. Down ewes must now be carefully treated during pregnancy, and if they have not been allowed hay at night time they will eat a fair quantity of sweet straw chaff—enough to keep them in health; but in case the wet harvest has injured the straw it may be spiced with some of the foods now sold for the purpose, the aroma from which makes it attractive and more palatable for the animals, especially when feeding on grass in the daytime. But the home farmer must beware of trusting the ewes upon the water meadows, for there have been instances of rot taking place in the present autumn where sheep were fed upon flat-lying grass land, although not under irrigation.

## POULTRY AND PIGEONS

### POULTRY NOTES.

A Poultry and Pigeon Show was held at Shepton Mallet on September 6th. The exhibitors have recently received a portion of their prize money, accompanied by the following curious notice:—

COPY.

“Taylor’s Paddock, Shepton Mallet.

“DEAR SIR,—We beg your acceptance of enclosed cheque for prize money, and very much regret it has not been paid before; also, that we are compelled through a heavy loss, which you will see by our balance sheet enclosed, to make a reduction of 36 per cent. on all prizes. Should we in future be in a position we will pay you the balance.

“Yours truly, (Signed) W. J. N. PERRY.”

We understand that an exhibitor at the late Show will lay the above document before the Committee of the Poultry Club.

EXHIBITORS are constantly troubled with the careless way in which labels are sent out by the secretaries of shows. A number are tied together in a bundle, the exhibitor’s address is written on the reverse side for the return address of the birds, and so they are posted. To begin with, we are frequently charged double postage, as such a bundle is not a book, and to send it at book rate is contrary to postal regulations; but besides this, it more often than not happens that the postal address of an exhibitor is not the railway address, consequently the direction has to be altered for the return of the birds, and confusion results. Considering the high fees commonly paid for entrance, committees may surely afford an envelope to each exhibitor.

We hope in an early number to describe another most interesting and, we believe, unique “Famous Poultry Yard,” that of the Rev. M. H. and Mrs. Ricketts, at Knighton Viarage, Radnorshire.

We remember several excellent poultry shows held at Ipswich. They fell into desuetude chiefly, we believe, from the poor attendance of visitors at them. We have received the schedule of another, to be held there on November 22nd and 23rd. Unfortunately it will clash with the old-established Show at Oakham; but November is a month in which poultry are generally in show trim, and so we may hope that it will be well filled and successful.

In reply to the remarks of "F. R." upon our estimate of Pekin Ducks, we do not in the least deny that they are excellent layers of generally fertile eggs, though we have not found them to surpass in fertility those of Aylesburys. They are also hardy, but so, in our experience, are all Ducks, and attain maturity—or rather, we should say, large size—very rapidly. What we assert is, that this early maturity is rather apparent than real, and that birds which to the eye appear immense are only more thickly feathered, but not so large as Rouens and Aylesburys of the same age. We have seen a great inclination on the part of breeders of Ducks, not for fancy but for table, to discard our old favourites, carried away with enthusiasm for the beauty and size of Pekins. We simply warned them that there is something to be said on the other side, and that our experience leads us to think it a mistake to make all give way to the new breed before it has been thoroughly tried. As layers we find Pekins unsurpassed on a run of moderate size. On a large piece of water they do not lay nearly so well. As table Ducks we believe them to be a failure.—C.

#### COVERING POULTRY HOUSES—BALLAST FOR RUNS.

I WAS struck by one or two points in the advice of "C." on page 370 of your Journal, and I would like to add a few facts gathered from experience.

In the first place, for covering of poultry houses I find nothing so cheap as plain wrought iron. As soon as it is cut for the place required—for the sheeting can be had 6 feet long by 4 feet wide, or even larger—I have the pieces tarred on the inside, and they are then nailed with short clouts, and when tarred again form the cheapest and most enduring roof. I obtained the idea from Mr. John Harvey, who came into some large estates in Scotland, and in covering the farm houses he found that nothing was more lasting or cheaper than this mode of roofing.

Anybody can understand that corrugated metal requires double the quantity of flat, and there is really nothing gained by it.

On another point. When land is very light, if the surface is scratched or dug over, it is sufficient for poultry; if it is very heavy (in all probability it is clay), then by some judicious management and a small collection of rubbish, a good fire can be ignited and the clay piled round it. This when burnt forms an excellent covering for poultry yards, and a small sprinkling from time to time answers every purpose, to say nothing of the neat red appearance.

For footpaths, I find on clay that if I cut out any loose wet material and place a layer of about 2 inches of this burnt ballast on the dry ground and on this "ashpan breeze" that can be had at any gasworks, or fine ashes, however wet the weather may be, there is always a dry path. Anyone living on a clay soil will appreciate this hint.

If the poultry runs are well protected, and there is any good dry space in them, advantage may be taken by allowing the litters of young rabbits to run in them. If they are bred from the large varieties of Giant de Flanders or Leponides, I find that the stock is greatly improved for breeding purposes if they are allowed to run as soon as they are taken from the does for some months. If not frightened they do not become very wild, particularly if the same person feeds them.—THOS. CHRISTY.

#### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at the Clarendon Hotel, Oxford, on the 27th of October. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Revs. E. H. Morgan and W. Serjeantson; and Messrs. R. A. Boissier, A. Comyns, O. E. Cresswell, A. Darby, H. R. Dugmore, L. Norris, and G. Vigers.

NEW MEMBERS.—The following new Members were elected:—The Hon. Mrs. Augustus Calthorpe, Perry Hall, Birmingham; T. Jenkins, Bexley Heath, Kent; John Metcalfe, Auburn Cottage, Narborough, near Leicester. The following new Associate was elected:—James Metcalfe, 11, Sheendale Terrace, Richmond.

RETURN CARRIAGE FROM RAMSGATE SHOW.—The Secretary reported that he had written to the Secretaries of the Ramsgate

Show as directed, and had received an answer to the effect that the Station Master at Ramsgate had verbally authorised the statement made in the schedule that the South-Eastern Railway would return exhibits sent by their line from the Show carriage free; that he had further written to the Station Master at Ramsgate, and to the General Manager of the South-Eastern Railway, both of whom denied that any such authority had been given. Under these circumstances the Committee recommended that application should be made by Mr. Boissier (one of the exhibitors who had complained to the Committee) to the Secretaries of the Ramsgate Show for the payment of the amount of return carriage paid by Mr. Boissier, and decided that the further consideration of the matter be adjourned to await the result of that application.

CLUB SHOW.—The report of the Sub-Committee appointed to make arrangements for the holding of the Club Show at Cambridge, was read by Mr. Norris, and it was resolved—

"That a Club Show of Poultry be held at Cambridge on Wednesday and Thursday, January 4th and 5th, 1882, in conjunction with the Show of Pigeons and Cage Birds of the Cambridge Ornithological Society, and that the report of the Sub-Committee and Schedule of prizes prepared by them be adopted, subject to some slight alterations."

The matter was referred back to the Sub-Committee to carry the arrangements into effect.

SHOWS TO BE HELD UNDER POULTRY CLUB RULES.—An application from the Secretary of the Wolverhampton Show was considered, and it was resolved—

"That in the event of a Show being held at Wolverhampton under Club Rules as heretofore, the Club do subscribe £5 to the funds of the Show."

Applications for subscriptions from Belfast, Darwen, and Doveridge Shows, which are to be held under Club rules, were considered and granted. Communications from Witney and Wellingborough, as to holding the Shows under Poultry Club rules, were considered.

ANNUAL REPORT.—It was resolved that the annual report of the Club should this year be presented at the General Meeting at the Crystal Palace. A draft of the report was read, but the further consideration of it was necessarily postponed until the next Committee meeting, which was fixed for Monday evening, November 14th, at the Crystal Palace Hotel, at 7 P.M.—ALEX. COMYNS, Hon. Sec., 47, Chancery Lane, W.C.

#### OUR LETTER BOX.

Book on Turkeys (W. Fowler).—We do not know of any book treating solely on Turkeys. You had better procure from Messrs. Cassell, Petter, and Galpin the parts of the *Illustrated Book of Poultry* which contain the chapter upon Turkeys.

Beet as Food for Stock (T. P.).—There is no doubt about Beet being of higher feeding value than any variety of Mangold, but only as it contains more sugar than common Mangold. As, however, the yellow Tankard Mangold is most valuable as regards nutrition, and the weight grown per acre is greatly in excess of Beet, we should prefer it as farm produce for the feeding of stock.

Green Fodder Crops (J. Mackenzie).—We cannot recommend the Bromus Grass in preference to Lucerne, because the latter is a permanent crop when kept clean, and will give a quick succession of very valuable green fodder for all kinds of stock. We have no doubt that the damage done to the Drumhead Cabbage and sprouts was caused by small white slugs or small snails or both, which feed at night but recede and hide themselves at daytime. They may, however, probably be detected early in the morning and late in the evening, but can only be checked by hand-picking and destroying them. Your other question as it is put is unanswerable.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

23rd.—Heavy rain in morning; damp and dull throughout.  
 24th.—Dull damp morning; latter part of day fine, but not bright.  
 25th.—Generally fine, bright, and cold; slight showers in afternoon.  
 26th.—Very bright morning; afternoon overcast, shower at 3 P.M.  
 27th.—Fine bright cold morning; afternoon overcast and slight showers; fine evening.  
 28th.—Fine bright cold morning; cloudy afternoon; slight rain 10.30 P.M.  
 29th.—Generally fine and cold N. wind, few flakes of snow, and slight showers at times.  
 Not as cold as the previous week, but still the temperature, especially by day, has been below the average; very little rain.—G. J. SYMONS.

10th	TH	Richmond Chrysanthemum Show. Two days.
11th	F	
12th	S	
13th	SUN	22ND SUNDAY AFTER TRINITY. [two days.
14th	M	Croydon and Stoke Newington Chrysanthemum Shows. Each
15th	TU	Brighton Aquarium, Walton, & Putney Chrysanthemum Shows.
16th	W	Bristol Chrysanthemum Show. Two days.

### MANAGEMENT OF HEAVY SOILS.

**T**HE question of tillage is an important one both to the gardener and farmer, and possibly many may be lamenting that this cannot be carried on in such a thorough style as formerly owing to reduced capital. If any such happen to be located on heavy soil, let me tell them that possibly poverty is their true friend. The mania for deep cultivation has in some cases been carried too far, and many a good field and many good gardens have been injured for a generation simply by attempting to make a deeper tilth. It is quite true that we cannot grow Parsnips a yard long where there is only 9 inches of soil resting on a stiff clay; but, on the other hand, there are few crops that will not succeed in such land if the cultivation is well managed, and possibly some corner may generally be found elsewhere in which to grow Parsnips.

Not only is it hurtful to turn up clay on heavy soil, but it is also hurtful to turn up the heavy soil itself more than a spade's depth unless sufficient material can be worked in to keep it permanently open so as to admit air to its lowest depths. Double-digging and trenching may be good for light hungry soils, not merely for the purpose of aerating them as is generally supposed, but because the operation gives a chance to work-in decaying matter to a greater depth, thereby furnishing moisture as well as food for the coming crop. But with heavy soils it is different. They are generally moderately rich in most of the ingredients necessary for plant life, they are retentive of moisture and of whatever is applied to them. Of course, to keep them fertile they require a corresponding amount of fertilising material applied to replace that which is drawn from them by the plants; but there is very little waste, there is no washing-out as there is with light soils, and I cannot see any advantage in breaking them up to a great depth.

We may see any season where old-fashioned farming is still carried on, that merely scratching such soils 4 or 5 inches deep with a plough in suitable weather, and a dressing of farmyard manure with an occasional liming, is followed by results at least equal to those which succeed steam cultivation and special manuring on similar soils. By double-digging heavy soil we not only bring up heavier material to the surface of that which was already sufficiently heavy, but we bury the most fertile of the soil so deeply that the air cannot reach it, and it becomes sour. Again, the clay when once broken into never drains itself so well as it did before it was disturbed, and as a loose soil is more retentive of moisture than

that which is hard, we may wait a long time in an average season before planting and sowing can be done safely.

As, with all our scheming, crops will generally be later on heavy soils than on those which are of a medium or light nature, the object should be to have them warm and pulverised by seed-time. It requires some skill and forethought to accomplish this. Anyone may manage a medium soil fairly well and pass for a good cultivator, but before he takes his credentials he certainly ought to have a trial on either a light or a heavy soil, both of which are difficult to manage in certain seasons, and the requirements of each are totally different. I have known plots of ground of both natures which have been pronounced as not worth cultivating simply because they had not been properly tried.

There is no ground so heavy that it cannot be made to produce enormous crops, and there is none so light that it cannot be made to hold moisture during a hot summer. To accomplish these objects may not be worth the cost for simple agricultural purposes in these days of cheap corn, but whenever it is desirable to have a garden in a particular position, it is certainly always worth while to make it as fertile as possible, whether it be for a source of pleasure or profit. I have endeavoured many times to guess what could have been the object of placing the kitchen garden I have to manage in the position it occupies. It certainly was not its excellent soil, for there could have been none then. I suppose it does not average a foot in depth now after, perhaps, a century's cultivation, and there is no lack of good soil in the neighbourhood, though I can only look on it and break the tenth commandment. It was not because it was convenient to the mansion—it is three-quarters of a mile away. Perhaps it was chosen on account of its adaptability for drainage; if so, I must compliment its originator, as there is a fall of about 50 feet towards the east in its length, and a considerable fall from each side to the centre; but as one of these necessarily faces the north I would rather be without it, and the incline is not favourable for wheeling and rolling. However, now we are beginning to learn how to manage it we have some splendid crops, and we find that simple cultivation answers very much the best.

The plan is to fork the ground over roughly as soon as the crops are cleared off in autumn, and if any portion requires liming it is done then; but no manure is applied at that time, as it has a tendency to keep the soil wet, prevents the ingress of air and breeds earthworms, which, whatever their beauty and utility may be in the eyes of Mr. Darwin, are not welcome guests in our heavy soil. As soon as the ground is in good working order in spring it is forked again, and yet again if the season will allow it, the manure being added at the last forking. For tender crops which do not require early sowing such as French Beans, the oftener the ground is forked the better during sunny weather in spring, thus raising the temperature of the soil. We have for several years burned as much clay during autumn and winter as we could find time for, and this, together with the ashes from the wood consumed in the operation, is both a stimulant and a rectifier of the texture of the soil.

I prefer the manure for heavy soil to be decayed, and to assist decomposition it is turned over two or three times during winter, but is not allowed to heat. It is a good plan to mix soil with it in the heap whenever it can be done.

We cannot plant such crops as Celery and Cardoons in trenches, or they would be in the clay; we therefore plant them on the surface rather wider apart than usual, and the plan answers perfectly.

Once again I would say to those having a heavy soil on a clay bottom, and anxious to deepen their tilth, Do it by additions to, and by well working the surface, but do not go down unless you are prepared to spend more money than the land is worth to render it fertile.—WM. TAYLOR.

#### A ROCKERY FOR ALPINE PLANTS.

(Continued from page 404.)

HAVING warned those who are inexperienced in rockeries what not to plant, we will now tell them what to plant and how to plant them, first mentioning some of the materials desirable for the welfare of the plants. These are leaf soil well decayed and about a year old; good fibrous peat, for which leaf soil mixed with cocoa-nut fibre is the best substitute; clean coarse sand, the coarser the better, up to the size of Mustard seed; stone—limestone is best—broken to the size of Wheat; and lumps of rough hard stone from the size of a Filbert to that of an Orange. Fine seashore gravel the size of Wheat is also very good for a top-dressing in the hollows, but on the slopes it easily gets washed off. Old mortar is also useful.

The surface of our rockery is about 1000 square feet, and the average room required for an Alpine plant is not more than a foot, making allowance for alternations of spring, summer, and autumn plants. A thousand plants sounds a large number, but some favourites deserve to occupy several places, and you will soon find that you have too little room even for plants of high merit. Later on I shall give directions for raising Alpines from seed, in which I have had moderate success. It is not wise to be over-fastidious or sentimental about admitting none but Alpines to your rockery, at any rate until you have collected together your thousand Alpines. There are many choice and neat annuals, and half-hardy plants and shrubs, which do better on a rockery than anywhere else, and may fitly be admitted to keep the vacant places gay till the Alpines are ready, and being annual or tender they cannot refuse to give room. It is hardly possible to define an Alpine, and some true Alpines, as I said before, are the very reverse of desirable. Beware also of the fallacy of considering generic names any test of habit, or you may find a choice compartment encumbered by an *Astragalus* or an *Achillea* 6 feet high, or your rockery spoilt by a *Coronilla* which comes up everywhere but where it is wanted, and is inextricable. The limits proposed for this series of notes will not admit of anything like a complete catalogue of the Alpines and other plants which my rockeries contain, much less of all the species cultivated in England in this way; but I shall mention from fifty to a hundred, all of which grow here, and are therefore not particular about climate.

I will begin with Saxifrages, though the name has nothing to do with their habit of growth amongst rocks, many of them not being rock plants at all, but it refers to supposed medicinal properties in which the ancients believed. The genus is practically endless and the habit very various. The rapidly growing and spreading kinds, chiefly varieties of *S. cæspitosa* and *S. hypnoides*, luxuriate in leaf soil with a retentive subsoil, and spread their tufts of brilliant green over bare surfaces of rock; but you must strictly limit their bounds, and be inexorable about allowing them to pass them, or they will become a nuisance. I find it best to place such plants, since they spread downwards, in such a way as to allow them a free fall to the bottom of the rockery. All the Saxifrages with stiff crowns resembling small Artichokes or Pine Apple tops, are less encroaching, and may all be planted without fear of the consequences. They like crevices of rocks where they can grow resting against the sides; leaf mould or peat helps their roots, and loose stone and gravel over the surface of the soil is good for them. They are represented by *S. aizoon* and its varieties, *S. cotyledon* and its varieties, *S. longifolia*, and many others. Some of the choicest sorts, as *S. valdensis*, require packing round with stone to keep them from the soil, and all seem to like this attention. Another distinct class flowering in very early spring is represented by *S. oppositifolia*; it is a lovely little plant, liking bare rocks, of which the surface is constantly damp, as its native home is usually in the clouds. Others have leaves shaped like large stiff Lichens, the best of which is *S. wallacei*. A neat little annual, *S. cymbalaria*, must not be admitted too freely, from the trouble it gives in weeding out the seedlings. This list of Saxifrages will be largely added to as you learn the habits and merits of other species of the genus. One important point must not be omitted here, which refers not only to Saxifrages of the *S. Coty-*

*ledon* and *S. longifolia* class, but to plants of similar growth in some other genera. The crown which produces flowers dies after flowering, after the manner of a biennial plant. If, therefore, you have a choice Saxifrage with a single crown, and it seems likely to flower, nip out the bud directly it appears, and it will then probably form more crowns, by which you can increase your stock.

Of the genus *Sempervivum* little need be said, not because it lacks merit or number, but because you may safely plant any of them you can get. They delight in the angular cavities amongst the rocks, and appear to grow almost without sending any roots into the soil. *S. tectorum* may be taken as the type of one class, of which *S. calcareum* and *S. Reginae Amaliæ* are also choice representatives. *S. arachnoideum* represents another form. The name should be spelt "arachnoides," but it is thankless work trying to reform the barbarisms of botanical names. It is a Greek word and means "spider-like," not that the plant is at all like a spider, but it looks as if the leaves were interwoven with fine silky webs of gossamer. *S. spinosum* is interesting, almost like a little sea urchin; and *S. triste* is of a distinct dark purple colour. I meant to speak also of the *Sedums*, but what I have to say about them would make this article too long.—C. WOLLEY DOD, *Edge Hall, Malpas.*

(To be continued.)

#### LIFTING FRUIT AND OTHER TREES.

WE have recently re-arranged many of our fruit trees, and so easily, and I can confidently assert so successfully, was it performed, that I have decided to briefly describe the operation. There is nothing novel about it, yet it may be of service to the inexperienced. Not only is it absolutely necessary to move some of the fruit trees, or shrubs, as the case may be, where crowded; but the operation if properly performed is often really conducive to fruitfulness in the case of the fruit trees, and to floriferousness and healthy growth in other instances. It is more especially in its infancy that a tree is disposed to form deep-running roots, and these, coming into contact with cold uncongenial soil, injuriously affect the top growth. Arrest the growth of these deep-running roots, and a healthier growth of surface roots will invariably result. I have noticed, especially in the case of Peach trees this autumn, those that are deep-rooting—that is to say, with a tendency to strike downwards and form but few fibres—are less healthy and profitable accordingly.

The transplanting in the nurseries does much to prevent deep rooting, but in our case I find it really necessary to lift and re-plant several Apricot and Peach trees received from the nurseries in the autumn of 1879. If this had been done in the case of a number of old trees in a Peach house and on the open walls we should not now be obliged to undermine, and to cut some and bring up other roots nearer the surface. It is useless to take the precaution of bringing up the roots nearer the surface and then to neglect to feed them in order to keep them there. Starve the roots, and down they will inevitably strike.

Shrubberies when first formed are generally planted thickly to insure immediate effect, and not a few are allowed to remain undisturbed till the most valuable specimens are spoilt. If properly planted the choicer specimens, and which are to be permanent, are thinly disposed according to their respective habits, the intervals being planted with commoner shrubs. These, as the first-mentioned extend, should either be cut away or transplanted elsewhere. To successfully transplant large specimens proper mechanical appliances and some skill in their use are requisite; but any small tree or shrub, say with about 2 cwt. of soil attached, may as a rule be easily shifted without any machinery. Where the soil is very light and gravelly it is almost impossible to secure a ball of soil without previous preparation, such as cutting a trench round or forking a quantity of leaf soil in to induce the formation of fibres; but in heavier loamy or clayey soils no previous preparation is necessary for small specimens.

Labourers as a rule are disposed to drag the trees up, but this will not do. What should be aimed at is a good-sized ball of soil in proportion to the size of tree, and as many roots all round as can be secured. What the size of the ball should be, or the distance from the stem to commence operations, it is useless for me to attempt to determine, as all depends upon the size of the tree and the nature of its roots. Disproportionately large balls are liable to break away in large pieces with the roots attached; therefore it is advisable to be satisfied with a moderate amount of soil with a certainty of preserving all the best roots. The simplest, if most laborious method, is to cut a trench round the tree 18 inches wide, having the tree at your side so as not to cut the roots, and throw out the soil to below the depth of the principal

roots. The soil to be then forked away from the carefully preserved roots and thrown out, working-in to as near the stem as it is decided to go. In order to lighten the ball it is advisable to lightly fork off any surface soil not occupied with the roots, and then to carefully tie back to the stem all the strongest. Next commence to carefully and gradually undermine the ball with forks till only just sufficient soil is left to support the weight. A broad strong board of sufficient length to admit of two or four men to lift with, as the case may be, is then to be placed under the side most undermined (if there is any difference), a fork or forks worked-in on the opposite side, and the ball carefully eased over so as to balance on the board. To attempt to lift on to a board generally ends in the breaking-up of the ball, and it is also very advisable to make the ball as flat and thin as possible, this favouring lifting and replanting. As boards are awkward to carry it is a good plan to have a strong hand-barrow conveniently near with which to carry the loaded board, taking care to lift the tree out of the hole carefully and to carry it steadily. On reaching the previously prepared position, the tree is then to be taken exactly where it is to stand slightly pitched on one side, the other side slightly raised with one or more forks, and after the board is withdrawn carefully let down. The roots are unloosened, having their broken ends and all bruised pieces cut out to facilitate healing, and then the soil is filled-in.

The fact of securing a good ball of soil, however, does not alone ensure the successful transplanting of a tree, it being of the utmost importance to have the new site properly prepared. In this matter, again, much must depend upon circumstances. To dig a hole only just large enough to hold the roots is decidedly false economy, especially where the surrounding soil has not been deeply stirred previously; yet how often do we see orchard and park trees planted in this manner. In such cases as these, supposing comparatively young trees to be planted, the holes ought at least to be 4 feet in diameter, and be still larger if larger trees are to be transplanted. The turf should be roughly pared off, next a moderate spit of soil and shovellings thrown out, and the subsoil broken up with a fork—not, however, to induce a downward root-action, but only to insure drainage. The turf may then be roughly chopped up and thrown in, as this on no account should be replaced over newly planted trees. On this may be spread a thin layer of the best soil, mixing with this if possible a small quantity of either light well-decayed manure or other light leaf soil, or perhaps better than either would be the ashes from a heap of burnt garden rubbish. The tree being then placed on this even bottom the lower roots should be evenly disposed and carefully covered with soil, the next tier then laid out, and so on if there are many till the whole are covered, all being nearly flat and having a little of the above-mentioned light material about them. When finished off the mounds should be rather above the level, as they will sink considerably, and this also predisposes to surface-rooting. Unless the ground has been recently trenched the holes for trees in the kitchen garden or pleasure grounds should be prepared much in the same manner, and for fruit trees if a little fresh turf can be added so much the better; but on no account manure the bottom spit, as the roots will go down fast enough without encouragement.

Newly and properly planted fruit trees invariably require staking. If they do not the chances are they are planted too deeply and will not thrive. What is technically termed the "collar" of a tree or shrub—that is to say, the starting point of the topmost roots—should only be slightly covered. Better the collar be above than 6 inches below the level of the surrounding soil. Newly-planted deciduous trees will not, as a rule, require any water at this time of year; but in the case of evergreens with matted roots it may be found advisable to soak the soil soon after planting, and again in the spring. The soil about the roots of either should on no account be allowed to become very dry, and should be frequently examined when dry or hot weather is experienced. To properly soak them form a basin with the loose soil, and fill this with water occasionally; afterwards mulch with short fresh manure or other material. It is a good practice to mulch newly-planted trees at this time of year, the mulching enclosing warmth and excluding frost.—W. IGGULDEN.

#### CYPRIPEDIUM INSIGNE.

MOST growers who possess a house affording a little more heat than a greenhouse grow a few plants of this old favourite, which yields abundance of flowers just at the right time, when flowers are scarce. It is very easily grown in fact, for nothing short of the worst ill-usage will prevent it growing and flowering. The consequence is that many are contented with very mediocre results, but it may be worth reminding some of your readers that some methods are better than others. Great numbers use loam wholly

or partly, and nearly all use peat. Having tried both systems, we now use only good sphagnum and charcoal. When the pots are full of roots we once a week immerse the pots in very weak liquid manure, generally sewage, but very weak guano is quite as good. Great luxuriance of growth and floriferousness are the results of this treatment. It is, we find, advisable not to disturb the roots too often—once in two years is quite often enough. They thrive all the better for being root-bound, if treated in the way indicated.—EDINA.

#### BOILERS v. WATER.

AS caustic soda in the water used for hot-water pipes will not have a good effect on the valves, I would advise a simpler and cheaper remedy for the incrustation, and that is crude petroleum, or the commonest quality of paraffin that can be obtained. A quart of this in a steam boiler here containing about 250 gallons of water is found effectual in loosening old scale formed before its use, and in preventing such formation since then; so that, I think, one gallon in each of the 8-feet Cornish boilers when next emptied before passing in the fresh water so as to let it pass over the plates as the water rises, will be of great advantage and can do no injury to pipes, joints, or valves. This remedy will do for any water, whereas soda alone, or oak sawdust, starch (in the form of Potatoes, &c.), and other remedies are only suitable for certain different classes of water which cause furring when heated to boiling point.

I may add that I have just examined five boilers taken out in the same district of Surrey, and find that three of them which have been in fifteen to twenty years are not furred at all, while two others fed with the same kind of water that have been in use two years and a half and five years only are furred a little, the fact being that the two last have had the hardest work to do, and the water has been kept nearly if not quite boiling, while the others had very little to do—only one house each in fact. The three old boilers were conical, the two newer ones saddles; but the form alone will not account for the difference, though there was, no doubt, a less continuous circulation in the saddles than in the old conicals owing to the arrangement of outlets.—B. W. W.

I AM sure your readers must be much indebted to Mr. Shearer for his lucid explanation of boiler-incrustation on page 395, and having got through the long and hard names which must have nearly taken their breath away, and arriving at the soothing and softening powers of the "ordinary washing soda," felt that they would have been under a deeper debt of gratitude if he had informed them when, where, how often, and the kind of boiler he had periodically operated upon, and with the result. Perhaps he will kindly do so.

We had better not just now say much about Mr. Ollerhead's boiler with the patch upon its side. Let the invalid work through the winter and then—but we must not anticipate, but be—PRACTICAL, NOT THEORETICAL.

#### SOWING PEAS IN AUTUMN.

IT is an old-fashioned plan to sow Peas in autumn, and in many cases it has advantages, while in others it is a loss of seed and time; but this is generally more the fault of the operators than the system. It is seldom that autumn Peas are sown too early, but they are often sown too late, and this is the mistake which leads to the failures which often occur. We never sow Peas in autumn before the beginning of November or after the 10th or 12th of that month. In the north we have seen them sown from the middle to the end of October, but we have also seen many sown there early in November, and this time is very suitable in most parts.

It is important that the Peas germinate freely and be through the soil before midwinter. If there is a fortnight of good weather after sowing, it is surprising how quickly they will appear through the soil and assume a healthy green colour. After this they are safe for the winter, as a good covering of snow or many degrees of frost will not injure them then. On the other hand, if the soil is constantly cold and wet after sowing, growth is retarded and many of them perish. To insure a free healthy growth at first is the one object to keep in view, and those who wish to succeed with them should do all they can to secure this.

A good position should be selected for the seed. None is better than a south border with a sharp incline. There they have the benefit of the best weather, and damp does not injure them so much as in more unfavourable positions. Sowing along the base of walls might give them more shelter; but it is not only shelter they want, as too much of this at first generally spoils

them later on. This may often be seen by growths which have been sheltered so much as to make them fall over, and then their produce is never so fine; but the rows may be sheltered by one another, and with this object in view the whole of the autumn-sown Peas should be kept together.

When dwarf varieties are grown they may not be far apart in the rows, but taller kinds want more room, and such as William I. which grows about 6 feet high, 8 feet is not too much between the rows. When they are about this distance, and if they are staked just as they are coming through the soil, they shelter one another and grow up sturdily and healthy.

In the ordinary way of growing Peas the seed may be sown some inches apart in wide rows, but with autumn-sown Peas it is different, as they succeed best when close together. For this reason we now sow our Peas at this time in narrow drills about 4 inches wide and as much in depth. The soil is made rich with manure, and over the seed some rather light soil is placed, only a day when the soil is dry and in good working order is selected for sowing, and the whole are sown at once, as sowing in succession is not a good practice in autumn. As to the advantages of sowing Peas now there can be no doubt providing they can only have a favourable start, but much depends on this.—M. M.

### THEORIES IN GRAPE CULTURE.

No sensible correspondent of the Journal will consider that Mr. Iggulden is bigoted in communicating his thoughts on restricted *versus* unrestricted growth in Vines on page 383. It is, perhaps, wise your correspondent thinks differently from some others on this subject. The great difference of opinion displayed on gardening subjects has undoubtedly sharpened our judgment and intellect, and but for the freedom of discussion gardening might not have been brought to the same standard of excellence as it is to-day. At the outset I may say my views on this subject are widely different from those of Mr. Iggulden, and in consequence I am tempted to defend a system I am practising. However, I am almost outside the range of those who grow Vines entirely on unrestricted principles. I have never yet seen a vinery without some form of restriction being employed. While I give the Vines under my care a large amount of freedom, allowing the shoots to extend liberally, they are restricted in a sense, but not to the extent that Mr. Iggulden says he would restrict young Vines if planting a house; therefore I must be classed with those who grow Vines on what may be called the unrestricted system.

I do not think the subject fairly approached if the remarks have to be confined to Vines two or three years old. Perhaps Mr. Iggulden intends to deal with older Vines in another paper; if so, I am content to confine my remarks for the present to young Vines. Mr. Iggulden tries to advance the unsoundness of an unrestricted system when he says "much may be said against it;" but, unfortunately, he has established nothing either against the system or in favour of the one he advocates. He seems to infer that those who allow liberty of growth have in view only the filling of the border with roots; but the primary object of my practice is to obtain, if possible, good well-finished Grapes. The roots I delight to see protruding through the border, which keeps the cultivator well informed that all is going right. While the roots are working vigorously and actively there is little fear of the crop of Grapes not finishing well on young Vines, provided ventilation and other conditions are favourable. If your correspondent will take a number of Vines in pots and restrict the growth by stopping the laterals a joint or two beyond the bunch, and keep other growths rubbed off as they appear, the fruit—if a moderate crop—will soon bring the Vines to a standstill, and the berries in the end will be small. Take other Vines, and if the laterals are stopped the same as the others, but unrestricted growths are allowed at the bottom and top, the roots will be more numerous and active, and better able to bring to perfection a greater weight of fruit. I am not referring to heavy cropping. This year I took from eleven Vines in pots sixty-six bunches of Grapes which averaged 1 lb. or more in weight each. They finished well and the berries were a good size. The top growth was allowed to extend 6 feet and was then stopped, and the laterals were removed as usual. The growth at the top was not interfered with again until after the Grapes were ripe. The wood is strong, and from all appearance the Vines will produce good fruit again next year. If they had been closely pinched the one crop would have exhausted them.

Now to Vines planted out. I stop the young Vines when about 9 inches high until they make roots, and again when 3 or 4 feet long. They are then allowed to grow as much and as fast as they can, even if they resemble a thicket at the top of the house,

the laterals only being pinched up to the place where the leader was stopped the second time. Vines grown under this condition produce twice the quantity of roots of any grown on the restricted principle. If the whole of this unlimited growth were cut off at a stroke I do not doubt that many of the roots would perish, but if gradually removed from time to time as the wood matures the roots will not perish during the winter. They have just the same chance of ripening to remain in good condition throughout the resting period as those grown on a more restricted system. Practice and observation have convinced me they do not perish, and if Mr. Iggulden considers they do it is a matter upon which he must advance proof.

Hitherto I have found Vines treated as I have described start vigorously in the spring and show abundance of fruit, as many as three bunches on nearly every lateral. I removed early last spring over one hundred bunches before the flowers opened from twelve Vines that had been planted three years last July, and raised from eyes the same season.

The statement of Mr. Iggulden is the first I have seen where it was considered possible to have too many roots in a Vine border. My object has always been to have as many roots as possible and to keep them in good condition. It is an impossibility for Vines with limited root-action to carry a crop of fruit as heavy and finish it as well as Vines with abundance of roots. Restricted growth in Vines is often carried too far, and the crop which may only be apparently light is really too heavy, as may be seen by the crop failing to finish satisfactorily. This is entirely the result of deficient root-action, and a sufficiency of roots can only be obtained by allowing the Vines greater freedom of growth.

If Vines are grown on the restricted principle, and if there are only sufficient roots to maintain the foliage, how will the Vines perfect a crop of fruit? Mr. Iggulden argues further that the roots of unrestricted Vines are of the grossest kind; they are exactly the same as those produced by restricted Vines, and if the border is made gradually by increasing its width not more than 2 to 2½ feet at a time, gross roots can be prevented and the border filled with feeding fibres. If the roots have free liberty when grown on either system they soon run through the border, and the greater portion of them are fibreless.

Another point. Vines are not so liable to throw off their main leaves when the laterals are allowed to extend freely as when they are closely pinched and confined to a single cane. The sap in the first case has abundance of sources in which to exhaust itself, but when the laterals are restricted and the channels for the supply of sap insufficient the stem increases rapidly, and the leaves are forced off. Vines with abundance of lateral development are never so pithy as when all the strength of the Vine is concentrated in one stem.

If science teaches "the roots extend themselves in all directions beneath the soil in search of food, &c.," it also teaches there is nothing lost in Nature, and the growth burned is not lost, but can be returned to the border for food again for the Vines.—W. BARDNEY.

In all that Mr. Iggulden advances under the above heading, at page 384, he never once shows that he has the slightest glimmering of the reason why most growers encourage as much growth in young and old Vines as possible. Most intelligent growers understand that it is the leaves that manufacture the fruit and wood, and for this reason they encourage as many as can find room to do their work properly. Nor is this so much for the mere purpose of filling borders with roots, but rather that the Vines may bear large crops without exhaustion, and later lay up an abundant store in the Vines for a strong start and an abundant fruitfulness in after years.

I think I am right in saying that gardeners look on their Vine stems as so many reservoirs in which to store in autumn as much organised material as will enable them to produce the best results possible the following year. Mr. Iggulden thinks, at least he says, that great masses of roots are useless in spring because they do not move when the buds move. No, they do not, and neither do they when the roots are few. And why should they? What would it benefit a Vine before it has its leaves mature enough to elaborate sap, to be filled with watery crude sap fresh from the border? Until Vines have made leaves working roots are not wanted; they must both work together. In the case of young Vines which are cut hard back, whence are they to find material to furnish young stems and working leaves if there are no stores in the underground stems generally called roots?

In great numbers of instances—in Orchids, Potatoes, Lilies—Nature makes special contrivances for thus storing material to be ready to hand just when wanted; indeed, in Vines she makes just the same provision, and, whether we understand exactly the

reason why, it is just for this that thorough ripening and ample nourishment in autumn is so beneficial: and just for this reason that those who are careless then never secure first-class results. The idea that Vines when extending their shoots in spring need support leads many to apply liquid manure to their borders when neither leaves nor roots are working! They do need support, and should have it from the top stems and root stems, which should be primed with it in autumn, and if it is not then available there it is not available anywhere.

Mr. Iggulden quotes "science" to support his theory. Science is very helpful, but those who think to command the helping hand of science must needs dip deeply. Not only have those who encourage the manufacture and storage of sap by extended growth ample working power of foliage, ample room to work in, ample feeding, ample supplies of heat and air and light—"results apparently justifying" such course; but when Mr. Iggulden dips a little deeper he will find they have science too on their side! - SINGLE-HANDED.

#### RESULTS OF THE POTATO TRIALS AT CHISWICK.

A MEETING of the Fruit and Vegetable Committee was held at Chiswick on the 3rd inst., Mr. John E. Lane in the chair. The collection of Potatoes grown in the gardens was again examined. Several sorts were selected as good cropping, very handsome, and distinct varieties, and on being cooked the following awards were made:—

##### FIRST-CLASS CERTIFICATES.

Fortyfold White (Farquhar) .....	Large round white.
Vermont Champion (Bliss) .....	Large round white.
Queen of the Valley (Bliss-Hooper) .....	Large and oblong pale pink.
Adirondack (Bliss-Hooper) .....	Medium round white tinged with pink.
Brownell's No. 11 (Bliss) .....	Large roundish white.
Victoria Kidney (Edwards) .....	Large flat white.
Rand's No. 30 (Bliss) .....	Large oblong white.
Rand's No. 12 (Bliss) .....	Large long flat white.

##### SECOND-CLASS CERTIFICATES.

Criterion (Ross) .....	Round white.
Sir Walter Ralcigh (Ross) .....	Large round white.
Trophy (Bliss) .....	Large kidney-shaped red.
Vicar of Laleham (Dean) .....	Large round purple.
White Elephant (Daniels) .....	Large long-flaked.
Victoria alba (Donaldson) .....	Large round white, purple eye.
St. Patrick (Daniels) .....	Large long white.

#### ORCHIDS AT KEW.

THERE are now in flower in the Kew collection several good Orchids that are worth noting—in fact, two or three varieties are such as are seen in few collections. It is rarely we visit Kew without seeing some interesting plants in flower in the Orchid house, for the collection comprises nearly all kinds, and there is always some little novelty to please the botanist as well as the horticulturist. Amongst the most noteworthy may be mentioned the following:—

A handsome variety of *Lælia pumila*, the flowers of which are fully 4 inches across, of a bright rosy purple. The peculiar tube-shaped labellum is of the darkest colour, approaching black. It is, as the name implies, a dwarf-growing species, and well adapted for growing in baskets or on blocks. It seems to be quite at home growing in a basket suspended from the roof. It is evidently a close relation to *L. Dayana*, which is also in flower, but will not bear comparison with *L. pumila*. They both delight in a cool temperature, such as the *Odontoglossum* house, and always require to be kept moist at the roots. The several varieties of *L. Perrinii* are very showy just now. One variety, which is pure white excepting a blotch of dark purple on the tip of the labellum, is extremely handsome.

*Cattleya labiata*, named "old variety," is a great acquisition to any collection. The plant, which is rather a small one, is producing three flowers on one spike; the colours are almost indescribable, for there are so many. I think this is rather a scarce variety, and will always be valuable.

*Pleione Wallichiana* is very pretty, and a fitting associate to *Oneidium excavatum*. This is a good old Orchid, but rather neglected by many growers. It produces long-branched spikes of bright yellow flowers barred with light brown.

*Oneidium ornithorhynchum* is always welcome on account of its deliciously fragrant flowers; they are certainly not of the brightest colour, but when a plant has several panicles fully expanded it is by no means to be despised.

*Odontoglossum cariniferum* is rather a peculiar flower. The sepals are a dull brown, the heart-shaped labellum being pure white.

*Burlingtonia candida* is a little gem, and is flowering freely in

a basket suspended from the roof. The flowers are snowy white, except a blotch of sulphur yellow on the labellum. The racemes are about 6 or 8 inches long, and droop gracefully over the sides of the baskets. *Zygopetalum Maekayi* completes this short list, and is so well known that it requires no description.—W. K.

#### LOBELIA SYPHILITICA.

THIS border plant (a spray of which is figured) is a native of the Northern States of North America. All the herbaceous *Lobelias* like moist retentive soils, and may be treated successfully as bog plants, being liable to suffer from parching east winds in spring and from drought in summer; but *L. siphilitica* may be grown in any good garden soil, being quite hardy and truly perennial, though it is likely to disappear in some soils, probably from the causes mentioned above. It is a handsome plant, producing

Fig. 69.—*Lobelia siphilitica*.

throughout the summer flower spikes from 2 to 3 feet high bearing abundance of close-set flowers. The normal colour is clear light blue with black spots in the throat surrounded by lighter shades of blue, but varieties in colour are common when it is raised from seed, some of them being pure white. I have heard also of others with rose-coloured flowers, but have not any of these in my collection. If seed is sown early some of the plants will flower late the first year, and all will make good plants, bearing several spikes of flower the second year; and as the vigour of growth enabling the plants to survive unfavourable conditions is far greater in seedlings than in divided plants, this *Lobelia* may successfully be treated as a biennial.

I can also recommend for similar treatment the herbaceous *Lobelias* of the cardinalis class, which come to us from North America under several specific names, including *L. cardinalis*, *L. fulgens*, *L. splendens*, *L. ignea*. If these are really distinct they are very similar and often confused in collections. In their native country they grow in bogs, and are said to be biennial and during their first winter capable of resisting any degree

of frost; but in English gardens they are treated as perennials, and in most parts of the country have to be protected in winter, though they appear to be hardy in some very cold and exposed places, and it is difficult to say what conditions ensure their hardiness. The natural colour of the leaves of *L. cardinalis* is green, but the garden varieties generally have purple leaves. The flowers are for the most part of an intense scarlet, but sometimes vary to dark crimson.

A very handsome class of hybrids between *L. syphilitica* and *L. cardinalis* has been raised, some of them having been in cultivation for many years, two especially, named *L. Villarsii* and *L. violacea*, possessing great merit as ornamental plants, and having flowers of dark rich violet colour. Many of these hybrids are perennial and perfectly hardy, but they seem to vary much in this respect.

I plant the seedlings out as soon as they are large enough in a bed of good rich soil, where many of them flower late the first year. Those which survive the winter I plant out in spring in the mixed borders, to the gaiety of which they form an important contribution in late autumn. Seed of all these *Lobelias* may be obtained cheaply and abundantly from that invaluable treasury of choice seeds, the shop of Mr. W. Thompson of Ipswich.—C. WOLLEY DOD, *Edge Hall, Malpas.*

#### SHORT NOTES ON GOOD GARDENS.

As the gardens of Cardiff Castle were referred to a few weeks ago (page 288), and those at St. Fagan's Castle were described on page 264, vol. i., new series, it is not now necessary to say more than they merit all that has been published about them, the cultivation being excellent at both places. Less known are the two following establishments.

##### TREDEGAR PARK.

Newport, Monmouthshire, is the station for this celebrated place. From Newport the house is some three miles or more, but an extensive finely wooded park is entered before going thus far. Lord Tredegar is well known as an ardent agriculturist and considerate landlord, and many proofs of both may be seen on the estate. Horticulture, too, is well represented, and much good practice may be seen. The glass houses are not erected in long imposing ranges, but they are in two or three different gardens. In one there is a fine span-roofed stove, which contains many well-grown specimen plants. The Palms and Crotons are fine exhibition plants, and besides them the side shelves are well filled with small healthy plants for room and table decoration. Not far from this stove there are two vineries of large size, planted chiefly with Black Hamburgh and Muscat of Alexandria. The Hamburghs were very fine, and the Muscats were especially so, as might be expected, as Mr. Raffill the gardener secured the Veitch Memorial Medal and prize for Muscats at the Manchester International Exhibition. The bunches and berries were large and very regular, and the colour was more golden than is generally seen on Muscats. The vineries are not entirely devoted to Grapes, but contain many plants and Figs.

The next important house is a long curved span-roofed Peach house. The trees have only been planted about twelve months, and their growth is most satisfactory. We noticed good substantial loam formed the basis of the border, and we are informed that abundance of water is given to the roots during the time the trees are growing. Besides the fruit trees this house also contained many softwooded plants all in good health. Pines are grown there, and the largest house was full of fine successional plants, and many in fruit. The kitchen garden is about eight acres in extent, and every inch of it was filled with well-grown crops. Wall trees and espalier trees were more numerous than in any garden we have visited lately, and most of them were in excellent health and bearing heavily.

The flower garden is not in a great mass as we often see, but is much divided into old-fashioned borders, which were effectively planted with the ordinary bedding plants, and many herbaceous plants and annuals were mixed with them. In the pleasure grounds there were many unusually fine specimens of Conifers and deciduous trees, amongst which some very large Tulip Trees were conspicuous. In this short note we feel that there is much in this well-managed and liberally supported garden of great interest which must be omitted at present; but all who may visit it will find something to please at every turn.

##### BRYN GLAS.

Though not, perhaps, very familiar to a number of readers this is a place of no small importance. It is situated on the opposite side of Newport from Tredegar, about a mile and a half from the town, and from the elevation on which it stands one of

the finest and most extensive views in Monmouthshire may be obtained. The pleasure grounds are six acres in extent, and the kitchen garden about two acres. There is a long conservatory attached to the mansion, and there are many small convenient plant and fruit houses in other parts of the garden, all bearing evidence to the interest the respected proprietor, T. Cordes, Esq., takes in horticulture, and in which he is so ably assisted by his gardener, Mr. Wattie. Those who know this place from report regard it as a good plant-growing establishment, but other branches of gardening are equally attended to. Plants are certainly well grown, as not long ago some of the specimens were placed before those from Messrs. Cypher and Tudgey at an important show. The Crotons are of great size and beautifully coloured. The Dipladenias are well grown, and they are regarded as the most useful of stove plants, as they bloom for such a length of time. Mr. Wattie has succeeded in raising a seedling of much promise; it is somewhat after the style of *D. amabilis*, but larger in the bloom and more pleasing in colour than that variety. The blooms are whitish, beautifully suffused with crimson.

Stephanotis is largely grown both planted out and in large pots, and in both cases it is in fine health, and blooms almost all the year round. *Eucharis amazonica* is another plant grown in quantity and well. *Salvia patens* is grown in pots, and some fine clumps of it in the conservatory were in full bloom, and we thought it most lovely. In future we shall grow some in this way.

Peaches under glass were all gathered, and the trees gave grand promise of fine crops in future. Grapes, especially Black Alicantes, were extremely fine, and Vines in pots to fruit early were strong and well grown. Pines, particularly the successional plants, were healthy; late Melons were a fine crop both in number and size; Cucumbers for autumn supply were answering their purpose well; Strawberries for spring fruiting were the finest we have seen this season; in fact, better could not be desired. The kitchen garden was well filled with useful crops; and here, again, espalier fruits were so fine that we are much inclined to think that this is a good system of growing fruit.

Roses are extensively grown, and a small glass house in the pleasure grounds has been erected specially to secure late and early blooms. In this house there is a very fine *Maréchal Niel*. About the lawns there are some grand young plants of the choicest kinds of *Rhododendrons*; and the flower garden, in which beds grouped together, is more tastefully planted than any we ever saw out of London. All departments indicate the care of a good gardener.—TRAVELLER.

#### THE USE OF FIRE HEAT FOR GRAPES.

MR. TAYLOR'S temperatures for Grapes, as quoted by "CORRESPONDENT" in a recent issue (page 375), are so much above Mr. Simpson's that I fail to see how they can be taken as evidence in support of the "cool system," as it would take considerable fire heat to keep them up to that figure. I venture to say not many good cultivators would object to Mr. Taylor's temperatures—in fact, I think they are more generally followed than higher or lower are; but I do not think many would like to adopt the temperatures so persistently advocated by Mr. Simpson. These may do for Grapes that can be grown outside, but not for the production of first-class examples of Muscats and late-keeping kinds. We do not want "fair" or "tolerable" Grapes, loose in bunch, wanting in colour and flavour. We want them well coloured, highly finished, and of the very best flavour—Grapes which we can place on our employers' tables or exhibition boards without a blemish, and with a feeling that whoever looked at or tasted them their verdict would be "First-rate." Until advocates of the "cool system" can show such Grapes, produced from year to year from the same Vines, they may write about it in vain.

The economy of the system has yet to be proved, for against the fuel said to be saved must be placed want of finish, size, and flavour in the Grapes, and unripe wood. There may be exceptions to this in favourable localities and good positions, but generally such would be the result of the fuel-saving, which cannot be called true economy. The use of fire heat for Grapes can, I think, be summed up in a few words—it enables us to grow the best kinds to a higher state of perfection than we could do without it, and to cope with dull and sunless seasons; it also enables us to ripen the wood in good time for the Vines to have a season of rest before starting them again.—A. BARKER, *Hindlip.*

LIQUID MANURE FOR FERNS.—I can fully corroborate what Mr. Gilbert says on this subject on page 352. Most of our plants for cutting from are in pots absurdly small compared with the size of the plants; but as we prefer to keep the red tiles in our houses as

inconspicuous as possible, we think it better to have them thus. Vigorous luxuriance we maintain by treating the plants to plenty of water—no fear of overdoing it with pots so full of roots as ours are—and liquid manure from the sewer twice a week. It is quite clear, and by no means strong, but is all the better for that. Some time ago, when visiting some gardens in Forfarshire, we called on an old friend, Mr. W. Alison, at Seaview, Monifieth, who is well known over a wide district as one of the best of gardeners, and hardly equalled as a Fern-grower. The Ferns were grand examples; so we, as is our manner, asked the secret. The answer was, "There is no secret beyond the fact that they are liberally supplied with very weak liquid manure." We came home, commenced the practice, and advise all your readers to "go and do likewise."—EDINA.

#### THE POTATO CROP IN IRELAND—THE CHAMPION.

WE have been taking up a considerable square of Potatoes, and have been noting the merits of the varieties, the produce, the quality, and the relative yield as compared with other years, and have been trying to form a general opinion from information procured from all sources. I had been through much of Ireland and England in August, and the then promise indicated by the Potato crop has been amply sustained, with the exception of particular varieties to be immediately referred to. While as anxious as any (and this is the view of all intelligent gardeners and farmers of my acquaintance), that experiments should be made with new varieties so as to obtain established kinds of undoubted merit, I think the system pursued by Mr. Taylor of Longleat, to grow two or three reliable kinds for general purposes, a good one. I had at least twenty varieties in a small experimental plot, and had planted six varieties the previous autumn, as mentioned then in the *Journal*, and have come to the following conclusions, and it is nearly twenty years since I commenced experiments as a pupil at the Government Farming Institute at Glasnevin near Dublin.

I never saw the general crop of Potatoes turn out so free from disease, and the oldest inhabitant has to go back to the time before the blight appeared, I believe in 1847, to find Potatoes selling in the public markets in Ireland at 4*d.* per stone as here, and less in other towns at present. Small Potatoes, such as are frequently employed for seed, from 1 to 1½ inch in diameter, I saw sold at 2*d.* per stone, and so on. Now this means plenty for the humbler classes all over Ireland, and, as at Longleat, the general crop is the Champion. Not one in every thousand of this variety seems injured under ordinary culture in this country. This would be of little importance if the quality was inferior—say as bad as American Reds, which seems suitable for cattle-feeding. I believe the great test of a Potato is quality, and it is to be hoped that characteristic will be substituted for beauty of appearance at Potato exhibitions in future, while "keeping" properties should, perhaps, come next. This is one of the points in which the Champion has caused some disappointment. I found it almost useless after April, owing to a tendency to become spotted darkly all over when cooked, though to all outward appearance quite sound. Though the Champion is considered and grown generally as a late-crop Potato, in this locality White Rock and Scotch Down must be grown as well to carry growers over the intermediate months of May and June.

In this district the usual early and second early varieties are Early Rose, Ashleaf, and more generally a variety not common in England, called the Flounder. This last is large, flat, and rather soft, but comes in early and yields heavily. It is, however, the worst keeper I know. We have shovelled quantities out as manure, and a gardening friend showed me portion of a pit, a few days since, he intended for seed used similarly. The Magnum Bonum as a field crop in this locality is splendid in size and yield, but I am bound to say for quality or table use it is by no means equal to the Champion. Both are the freest from disease, though in several districts of Ireland a bluish-tinted late kind called the Skerry Blue has maintained that quality for twenty years. The quality for table use is, however, inferior. I agree with Mr. Biddell (page 381) that the Champion, at least, requires a greater distance asunder owing to its enormous leaf and stem-growth than the other varieties. If not, I am afraid at no distant day degeneracy from imperfect ripening will be inevitable, and this would be in Ireland a national misfortune.—W. J. M., *Clonmel*.

**SHORTENING ROSE SHOOTS.**—We do not know whether anyone has ever recommended, in the *Journal of Horticulture*, the shortening-back in autumn of strong shoots of Roses. Rose-growers invariably prune in spring, and in a great majority of cases that is the only proper time to perform the operation. Still much mischief ensues, especially in exposed gardens, as ours is, to Roses which are left unshortened and unstaked till spring time. Long strong shoots amply furnished with strong foliage turn and twist with every blast of

wind till many are ruined. Staking secures shoots but takes time (to say nothing of the stakes required), which is not always available when other duties press. Shortening back half way is quite as effective and is easily done. We invariably practise this, and the sight of numbers of spoilt bushes in a neighbour's garden—spoilt by a furious north-easter just three days after ours were safely shortened—reminds us that the practice may be worth mentioning, although it may seem trifling to those who have not lost fine strong shoots of Roses by autumn gales.—N. B.

#### BEGONIA SEMPERFLORENS GRANDIFLORA.

SEEDS of this were kindly sent me in the spring by Mr. Iggulden. They were sown in a pot filled with turfy loam and a little well-reduced leaf soil, the surface being made smooth, the seed distributed regularly, and covered with a light sprinkling of silver sand. The pot was placed in a hotbed and shaded to prevent the surface of the soil becoming dry until the seeds had germinated, care being taken afterwards to keep the soil constantly moist, as drought is fatal in a few hours to the seedlings. The young plants appeared in a few days, and when large enough to handle were potted singly in thumbs. They were returned to the hotbed, and when the thumb pots were filled with roots the plants were transferred to 4-inch pots; at the same time the remainder of the plants from the seed pot were lifted and placed in the first instance (as they were much larger than those first potted) in 4-inch pots. After potting they were transferred to another hotbed, and from the 4-inch pots they were shifted into 6-inch, and placed in a frame, which, though used for Melons, had little if any heat beyond that derived from the sun.

Although the seed was sown early in April (the 6th) the plants were showing flower by the middle of July, and by the early part of August they were sufficiently in flower to admit of their being employed for decorative purposes. About a hundred of the plants in this condition were placed in a greenhouse, and in association with the bright-flowered tuberous varieties the effect was highly pleasing. There they remained until the close of September, when they were placed in a cool stove temperature, and they commenced flowering again most freely, and are now (Nov. 1st) flowering better than they were in the greenhouse; indeed some that had shoots with their flowers taken off some 6 inches long have grown again, and are likely to continue in flower through the winter. It is a plant of the easiest culture, and in a few months from sowing the seed plants can be obtained of considerable value for decorative purposes in the greenhouse or conservatory during late summer. It is also valuable as yielding a supply of flowers for cutting in late summer and autumn (and no doubt in winter), as sprays can be taken with a certainty that a successional supply will be forthcoming in a short time. The sprays have a very good effect from the deep shining green colour of the foliage. The plant attains to a height of 15 to 18 inches, commencing to flower at 6 to 9 inches, branching well from the base and upwards, forming compact plants with flowers borne profusely from every growth. The foliage is bold, the trusses of bloom large, erect; flowers pure white, twice the size of the old *B. semperflorens*. This new variety is a valuable acquisition, and is certain to become highly popular.

The plant and flowers contrast admirably with those of *Begonia insignis*, *B. Ingrami*, *B. ascotiensis*, *B. fuchsoides*, *B. Saundersi*, *B. hybrida multiflora*, and *B. weltoniensis*, and cuttings of these inserted at the same time as the seed of *B. semperflorens grandiflora* was sown are fine plants in flower, and will continue flowering in a house with a stove or intermediate temperature through the winter. *B. parviflora* with its neat foliage and numerous small white flowers is also very useful. There need be no scarcity of flowers at the dull season with so many easily grown plants as these at command.—G. ABBEY.

#### LIQUID MANURE FOR ORCHIDS.

LIQUID manure is not generally given to Orchids, but it is a question if great numbers would not be benefited if it were. Peat is too much used under the mistaken impression that it yields something beneficial to the plants. We do not say that peat should never be used in Orchid culture, for we know that great numbers require some such material; but we feel assured, from experience, that great numbers would be much better without. All Orchid growers admit that decaying peat is an evil; but few seem to understand that only decaying material can yield plant-food. A friend, who has on more than one occasion brought us plants from the East Indies and elsewhere, tells us that all the good roots he has seen on Orchid plants in the wild state were either attached to fresh hard bark, or growing among living vegetation, or dangling in the air. He also assures us that many, or

most of the kinds which grow on trees, are fed with liquid manure naturally. He has almost invariably found the branches of the trees bespattered, often plentifully, with the excreta of both birds and mammals. This is washed by rain within reach of the roots of the Orchids, and we cannot doubt that they are thereby benefited.

Is not this a hint worth thinking about? Orchids, however, are not to be tampered with, but we are sure that weak liquid manure applied to those plants which have filled their pots or baskets completely with healthy roots helps them greatly, as in the case of *Cypripedium insigne* and many others.—A. H.

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, Col. R. Trevor Clarke in the chair, the following candidates were duly elected Fellows of the Society—viz., Theodore George Ensoll Herman, J. R. Gaskoin, Mrs. Billingsby Parry, Sir Rawson W. Rawson, K.C.M.G., C.B.

— WE learn that THE PELARGONIUM SOCIETY will hold its eighth annual Exhibition in the gardens of the Royal Horticultural Society, South Kensington, on Tuesday, the 27th of June, 1882.

— WE are informed that a collection of Mr. King's beautiful NEW COLEUSES, many of which have been certificated during the year, have passed in the hands of Messrs. James Carter & Co. for distribution. The bold foliage of these Coleuses and their brilliant colours cannot fail to arrest the attention of all who see them when the plants are produced in their best condition.

— THE *Daily News* correspondent telegraphs:—"A novel FEATURE OF THE IMPORTS TO AMERICA FROM ENGLAND is the arrival of Beans, Cabbages, and Potatoes. Forty barrels of Champion and other varieties of Potatoes grown in the north of Ireland were offered for sale on the 2nd inst. In size and quality they were inferior to American Potatoes. One firm imported 2400 bushels of tubers, grown in the vicinity of Liverpool, and has 4500 more on their way here. These can be sold here from 2 to 2½ dols. per barrel, whereas native Potatoes bring 3 and 3½ dols. Liverpool varieties compare favourably with the native. Owing to the drought both the Potato and Cabbage crops are short this year."

— WE are requested to state that it is proposed to close the list of subscribers to the fund now being raised to make a PRESENTATION TO MR. E. S. DODWELL at the end of the present month. The object of the presentation, it may here be stated, is to show the sympathy of his brother florists with Mr. Dodwell in his debilitated state of health, which has made it necessary for him to remove from the suburbs of London to a purer country air; and at the same time to cheer his declining years by an expression of their appreciation of the services rendered by him during an active life to the cause of floriculture—the advancement of the Carnation and Picotee in particular—including his successful efforts to bring about in the southern portion of the kingdom the revival of a taste for floriculture, in some at least of its phases—*e.g.*, the Auricula and Carnation Societies. Those friends who have not yet subscribed, and who intend to do so, are reminded that they should at once send in their contributions either to the Hon. Treasurer, Mr. C. Turner, Royal Nurseries, Slough, or to the Hon. Secretary, Mr. T. Moore, Botanic Garden, Chelsea, London, S.W.

— THERE is now what may fairly be described as the FINEST

DISPLAY OF NEPENTHES IN EUROPE in Messrs. Veitch's nursery at Chelsea. *N. sanguinea* is magnificent, but it is surpassed in colour by the new and yet small *N. madagascarensis*. *N. Rajah* is still small, but growing in the most satisfactory manner; and in striking contrast is the bold and vigorous *N. bicalcarata*, the pitchers of which now hold a pint of water. The more established forms have a profusion of beautiful pitchers, thousands of which are hanging from the roof of one house, producing a remarkable effect. The wall at the end of the house is being covered with the new *Pothos cclatocaulis*, which somewhat resembles a *Marc-gravia*. It is associated with *Ficus minima*; the contrast is striking, and the effect quite unique. In an adjoining pit are numbers of fine plants in the best health and colour of the curious *Cephalotus follicularis*, some of them with from one to two hundred pitchers clustered together under a large bellglass. Many other singular and valuable plants in the same pit are also worthy of inspection.

— IN another house the most striking plant is ANTHURIUM WARROQUEANUM. The finest leaf the plant has yet produced is 3 feet 6 inches long by 2 feet wide in the broadest part. It is an excellent colour, the ivory-like midribs being very clear. The leaf resembles a richly wrought shield, and its effect is extremely imposing.

— IN the ORCHID HOUSES the miniature *Oncidium ornithorhynchum* and *O. cheiroporum* render one of the structures pleasant by their fragrance; in another the strikingly beautiful *Cypripedium Spicerianum* is in superb condition, and near it is the small but rich *Phalænopsis violacea*. In another house some new *Lælias* are flowering, and the grand old *Cattleya labiata* is gorgeous. *Miltonia candida* is also flowering freely, and is very distinct and attractive.

— WE understand that the fixtures of the NATIONAL ROSE SOCIETY for next year are for the metropolitan show, July 4th, at South Kensington, and for the provincial show, June 28th, at Bath. Negotiations are in progress for a third show later in July to meet the northern and midland growers.

— "WEALD OF KENT" would feel greatly obliged to know the cause of CIDER BECOMING OILY, and the best method of clearing it previous to bottling. Some was made in November, 1879, racked in about twelve days after making, and then 1 lb. of raw sugar was added to each gallon. It was bottled in February, 1880, and kept in a cellar never over 60°. It did not appear oily when bottled, but soon became a little so, and so continues, but is well up like champagne. Some other had half the quantity of sugar with the same effect, but of course not so sweet.

— "The SHOE-BLACK PLANT," says the *American Cultivator*, is the popular name of *HIBISCUS ROSA-SINENSIS* in New South Wales. Its showy scarlet flowers contain a mucilaginous juice which gives a glossy finish to leather. The plant grows freely in almost any kind of soil, and the flowers are much used when dry as a substitute for shoe-blackening. They may be used with or without a brush."

— PART 21 of LETTS' "POPULAR ATLAS," contains five maps representing portions of France, Germany, Spain, and Portugal on a large scale. The clearness and accuracy of the delineation continue as satisfactory as in the earlier parts to which we have frequently referred.

— THE utility and beauty of SINGLE DAHLIAS are generally recognised, and a supply of their flowers is always acceptable. Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston, practises a simple but effectual mode of prolonging this supply. Before the frosts become sharp enough to do much damage a number of plants were lifted, potted, and placed in a vinery,

being liberally supplied with water to assist them in overcoming the effects of removal. They are now flowering as freely as could be desired, and are likely to continue so for several weeks.

— "G. G." desires to thank Mr. Pettigrew for his ADVICE TO YOUNG GARDENERS that he gave a few weeks ago, and says that it is because some young men have faults and drawbacks that the experience and counsel of others prove so advantageous.

— "J. H." writes as follows relating to PEAS FOR EARLY CROPPING—"On the 29th November last I obtained four quarts of William I., also some Early Prolific, and sowed them on an early border near Peterborough. William I. came up strong and endured the winter best; and although I was able to gather Peas from plants of both varieties on May 29th, William I. produced fully double the quantity of fine green colour Peas, and of excellent flavour. This Pea is undoubtedly a very great acquisition for early crops."

— THE CRYSTAL PALACE SCHOOL OF GARDENING.—Mr. F. A. Fawkes, author of "Horticultural Buildings," has been appointed to give a course of three lectures to the students and the public at the Crystal Palace at 5 P.M., on November 16th, 23rd, and 30th, upon the construction, fitting, and heating of greenhouses, conservatories, and other horticultural structures. The lectures will be illustrated by numerous specially prepared diagrams.

— AT the ordinary meeting of the METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 16th inst., at 7 P.M., the following papers will be read:—"On the Gale which Passed across the British Isles, October 13th-14th, 1881," by G. J. Symons, F.R.S., President. "On the Structural Damage Caused by the Gale as Indicative of Wind Force," by J. Wallace Peggs, Assoc.M.Inst.C.E., F.M.S. "On the Meteorology of Mozufferpore, Tirhoot, 1880," by C. N. Pearson, F.M.S.

— MR. F. WALKER has sent us samples of GRAPES GROWN WITHOUT FIRE HEAT. The Bowood Muscat is of good flavour and well finished. Lady Downe's is well coloured but not quite ripe, and Mrs. Pince is above the average as to colour and is of very good quality; they are very creditable yet not large examples. It must be added that they were grown in the Isle of Wight.

— "W. J. M., *Clonmel*," sends the following remarks upon SCOTCH CHAMPION POTATO—"Since sending you some observations on this subject, I have read the very instructive notes of Mr. Laxton on the Potato trials at his Experimental Gardens at Girtford, page 394, and so far as my experience, and that of all the gardeners I have spoken to goes, the Champion can in no sense be described as "waxy," quite the reverse, a term used by Mr. Laxton when comparing it with Suttons' Reading Hero. In this country the Champion is so dry and floury with ordinary treatment as to be almost impossible to cook without bursting. I heard one gardener describe it as "gritty"—in the same sense as Pears are so described—certain they are anything but waxy."

— AS regards the neighbourhood of London, it appears probable that the CHRYSANTHEMUM SHOWS will not be quite up to the average, for many of the chief growers are complaining that the condition of their plants is unsatisfactory in an exhibition point of view. Indeed one of the most successful exhibitors of the last few years states that he is quite unable to compete this season. Fortunately, however, there is good promise in several of the leading collections, and visitors to the principal shows will undoubtedly find something noteworthy. Amongst the finest plants and blooms we have seen this year are those grown by Mr. G. Harding, gardener to T. Galpin, Esq., Bristol House, Putney

Heath; and although Mr. Harding considers they are much below his usual quality, he will prove a formidable competitor wherever he exhibits. Mr. J. Stevens, St. John's Nursery, Putney, has also a large and handsome collection, some of the plants and blooms being likely to obtain prominent positions at the metropolitan shows. In both establishments the blooms are of good substance, the colours bright and clear, and the plants vigorous.

— REFERRING to the case of GRAPE-STEALING, recently noticed in these pages, a correspondent remarks:—"Although the prisoners Hale and the Preests could not be convicted of stealing because they did not take the Grapes from a stall but cut them off the Vines, it does not necessarily follow that it is an unpunishable offence to take Grapes the property of other people off their Vines. Taking the scissors was no doubt larceny, and for cutting the Grapes the prisoners ought to have been charged under the Malicious Injuries to Property Act, upon which a conviction might easily have been had. Morally thievish though it may be, it is not larceny at common law to take Grapes from the Vines, but a punishable offence nevertheless."

— MR. H. MARTIN, Paris, writes as follows in reply to Mr. J. Jackson, in our issue of October 6th, relative to the French "BETTERAVE CRAPAUDINE"—"Your correspondent's experience of this Beet does not prove at all against the plant, but against the seedsmen who sent him the strain. The true type of the crapaudine is 4 inches broad at the superior part, and becomes very regularly thinner until it reaches the length of 11 inches, which is the average. The top is rather flat, and does not stand more than 1 inch out of the ground. The leaves are not abundant, laying on the ground, of a dark green colour washed with crimson; the leafstalks violet red. The skin is rough, harked, and the pulp is very dark and succulent. In all a very distinct and good vegetable, much valued on the Continent. If Mr. J. Jackson would try a second experiment I should be very glad to send him some seeds, hoping that next time his labour will not be lost in obtaining nearly a Mangold Wurtzel instead of a Beet."

— WE announce with regret the DEATH OF MR. A. INGRAM OF ALNWICK CASTLE GARDENS. Mr. Alexander Ingram, says the "Newcastle Journal," who for the last fourteen years has been head gardener to His Grace the Duke of Northumberland at Alnwick, died on Saturday last after a short illness. Mr. Ingram was a native of Aberdeenshire, but after serving his apprenticeship in the gardens of the Earl of Aberdeen at Haddo he went as foreman to Newby Hall in Yorkshire, afterwards removing into the south of England, from which he came to Alnwick Castle Gardens in 1867. Mr. Ingram was well known, not only as a judge, but as a successful exhibitor at some of the principal fruit shows in the United Kingdom; and his services were always in request to act as judge at the various local shows, in none of which, except at Newcastle, did he ever enter the lists as a competitor. He was thoroughly devoted to his profession, every branch of which he was master, and he had the gift of being able to impart his own information to others. His advice was eagerly sought after by all the amateur Grape-growers in the neighbourhood as to the best means of constructing vineries, planting the Vine, &c. He will long be remembered by those who have visited the gardens at Alnwick Castle, which, under his superintendence, have been greatly extended and artistically laid out.

— A CORRESPONDENT sends the following note upon ORCHIDS IN FLOWER AT THE TRINITY COLLEGE BOTANIC GARDEN, DUBLIN—"Vanda cœrulea has been in bloom five weeks and is still fresh. *Odontoglossum grande* is bright and clean, with a spike of large flowers half a yard long. *Pilumna nobilis* bears twenty or thirty flowers; and the bright golden *Oncidium Rogersii* sets off the rosy lilac blooms of the pretty little Indian *Crocus*

Orchids. *Odontoglossum madrense* has a charmingly fresh almond-like odour. *Epidendrum vitellinum majus* and *E. prismatocarpum* are pretty, and the true *Cattleya labiata* is opening two spikes of eight flowers. The plant of this is of the true old autumnal-blooming variety, having plump, long, smooth, fluted pseudo-bulbs and a double sheath, from which its stout flower-spike protrudes. *Odontoglossum Alexandræ*, *O. Rossii majus*, *O. pulchellum majus*, *Oncidium cucullatum*, and the winter-flowering *Laelias* of the *L. anceps* section, are fast throwing up their bloom-spikes; so also *Calanthe Veitchii*, *C. nivalis*, and *C. vestita*. *Dendrobium heterocarpum*, *D. nobile*, and other species are also showing for bloom. *Lady's Slippers* are a feature. *C. Sedeni* is nearly always in bloom. *C. Harrisianum* and *C. villosum* var. *Boxalli* are also coming into flower. The true *C. insigne* var. *Maulei* and the still more rare and lovely *C. violaceum punctatum* look well, and will shortly become very effective."

— A WEEK or two since we noted that the annual public EXHIBITION OF CHRYSANTHEMUMS AT FINSBURY PARK had been opened, and as the plants are now in excellent condition a better opportunity could not be chosen for visiting the collection. A great improvement is observable since last year both in the cultural results and the accommodation provided for the plants. A substantial span-roofed structure 100 feet long and 18 feet wide has been erected, with moveable lights, abundant means of ventilation at the sides, and two rows of small hot-water pipes (2 and 3-inch) are laid on each side, which when necessary assist in removing excessive moisture, or affording protection if the weather prove very severe. The plants are arranged in a bank in the centre, sloping to the sides with a path round, so that visitors can view the plants both individually and collectively. Eleven hundred plants are included in the house, representing about two hundred of the best varieties in cultivation. The blooms are abundant, and in the majority of instances very fine; indeed many are quite up to exhibition standard in size, substance, and quality, and there are several which it is doubtful if the most skilful dresser could improve. To enumerate all the varieties that are represented by really good blooms would occupy too much space, but the following are especially noteworthy—*Refulgence*, *Prince* and *Princess of Wales*, *Bronze Jardin des Plantes*, *Golden George Glenny*, *White Globe*, *Barbara*, *Empress of India*, *White Beverley*, *Julie Lagravère*, *President*, *Comte de Morny*, *Elaine*, *Le Negre*, *James Salter*, *Mons. Charles Hubert*, *Criterion*, *Gloire de Toulouse*, *Triomphe du Nord*, *La Nympe*, *Mons. Crousse*, *The Cossack*, *La Charmeuse*, and *Bouquet Fait*. As compensation for the liberality of the Board of Works, and the efforts made to render the Exhibition attractive by Mr. Cochrane and his assistants, it is satisfactory to state that its popularity is thoroughly established, and on Sunday last it is estimated that several thousands of visitors passed through the house.

#### NOTES ON POTATOES.

I THINK if a few more cultivators would follow Mr. Laxton's example and give their experience, it would be both acceptable and useful, especially when it has reference to new varieties. I have tried a few of them this season, and the best I find is Suttons' Reading Hero. I planted 7 lbs. of that variety, and the produce was 262 lbs. of good sound tubers grown without manure. I left them in the ground until the middle of October before lifting, and then they remained on the ground another fortnight before taking them in to weigh them.

I am of opinion that no variety of Potato will retain a robust constitution with good quality more than ten years, consequently the public are very much indebted to the successful raisers of new varieties which combine quality, quantity, and disease-resisting properties. We can easily enumerate many good varieties, or rather what were good in their day, that are not reliable now, the Fluke for instance. Lapstone Kidney, an excellent and special favourite of mine, is now suffering from blindness and debility.

Paterson's *Victoria* is this year worthless with me, and many others are going the same way. And, again, what a mainstay was the *Champion* two years ago; nothing withstood the wet, cold, sunless season like it. *Magnum Bonum* was in its infancy at that time, at all events with me, but last season and this there has been nothing to equal the *Magnum Bonum* here for general purposes. Now, I think, is the most convenient time for growers to give their experience for the public benefit; but I am afraid many good gardeners, like cooks, consider the Potato beneath their notice.—C. A. PEARSE, *Grey's Court, Henley-on-Thames*.

#### ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 8TH.

VISITORS to this meeting, in what is usually regarded as one of the dullest months in the year, were no doubt somewhat surprised at the abundance of exhibits. Plants, fruit, and vegetables were all largely and well represented, the Council-room and vestibule being completely occupied. Both Committees were also well attended by the members, and the meeting was altogether highly satisfactory and interesting. The collections of vegetables staged in competition for Messrs. Sutton & Sons' prizes also formed an important feature.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Mr. J. Read, The Gardens, Moat Mount, Mill Hill, Hendon, sent six bunches of *Lady Downe's* Grapes of moderate size but well coloured. A letter of thanks was awarded. Messrs. Carter & Co., High Holborn, staged samples of Carter's Silver Globe Onions from the south of Europe. They were of moderate size and very even. Fine examples of the Giant Rocca Onion of Naples were also contributed. A letter of thanks was awarded. Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, sent a green-fleshed Melon very neatly netted. Four varieties of seedling Apples, mostly small, were also staged. Mr. C. Howe, The Gardens, Benham Park, Newbury, had a good fruit of the scarlet-flesh Melon *William I.*, well netted. Mr. Burnett, The Gardens, Deepdene, Dorking, exhibited a dish of *Ecklinville* Seedling Apple for comparison with *Lane's Prince Albert*.

Mr. J. Hudson, gardener to H. J. Atkinson, Esq., Gunnersbury House, Acton, sent two bunches of *Alnwick* Seedling Grape well coloured. A cultural commendation was awarded. Some fine Pears were sent by N. J. Vivian, Esq., Sion House, Longueville, Jersey. One dish of six *Chaumontel* weighed 7 lbs. 6 ozs. One fruit of this variety weighed 1 lb. 13 ozs., and was said by the exhibitor to be the heaviest Pear that has been grown in Jersey. Six fruits of *Doyenné du Comice* weighed 5 lbs. 10 ozs. A cultural commendation was awarded. Mr. Charles Turner, Slough, showed several seedling Apples, one of which was considered very promising, and the Committee desired to see it again. Mr. T. Sells, The Apiary, Uffington, Stamford, sent a seedling Apple said to be "of vigorous growth, a heavy cropper, good for cooking or keeping." Mr. Valentine Richards, South Woolton Rectory, King's Lynn, contributed eight samples of a seedling Apple gathered from a tree said to have been raised from seed and never grafted. The variety is said to keep well till April or May. A letter of thanks was accorded, but the Committee could not express an opinion as the fruit was unripe; they wished to see it again. Mr. R. Nisbet, The Gardens, Aswarby Park, Folkingham, exhibited a dish of *Beauty of Aswarby* Apple very neat in form. Mr. Thomas Taylor, gardener to J. McIntosh, Esq., Duneevan, Weybridge, staged fine examples of the Apples *Landsberger Reinette* and *Golden Noble*. The former was characterised by the Committee very handsome, but they desired to see it again earlier next season. Mr. J. Roberts, gardener to the Baroness Rothschild, Gunnersbury Park, exhibited seven fine even fruits of *Queen Pine* Apples. A cultural commendation was awarded. Mr. J. Ollerhead, gardener to Sir H. Peek, Bart., Wimbledon House, exhibited a bunch of the new Grape *Ollerhead's White*, which was not considered sufficiently distinct from *Foster's* Seedling to merit an award.

Messrs. H. Lane & Son, Great Berkhamsted, were awarded a first-class certificate for their seedling *Apple Prince Albert*, which has been now tried for some years, and is considered by several growers to be one of the finest culinary Apples. The fruits are of good size, varying considerably in shape, green or yellowish, with streaks or a suffusion of red on the side exposed to the sun. They are remarkably solid and heavy.

In the vestibule the following collections were staged. Mr. T. Mainwaring, Marl Place, Brenchley, Kent, was awarded a bronze medal for a fine collection of 113 varieties of Apples, but many wrongly named. Mr. W. Skinner, Beresfords, Maidstone, was awarded a silver Knightian medal for a large and very handsome collection of Apples, comprising a hundred dishes, most of the fruits being in fine condition. Messrs. Sutton & Sons, Reading, had large collections of Potatoes and Kales, for which a silver Knightian medal was awarded. Messrs. Veitch & Son were awarded a bronze medal for a collection of about a dozen varieties of Celery and a large number of Turnips. Mr. Ollerhead sent a sample of his *Amateur's Friend* boiler formed of inch pipes to constitute a boiler and firegrate combined. It was about a foot square, and was stated to be capable of heating 70 to 80 feet of 4-inch piping.

MESSRS. SUTTONS' SPECIAL PRIZES.—The competition in all these classes was very keen, and the exhibits generally of fine quality.

The chief class was that for twelve distinct kinds of vegetables, in which eleven competitors appeared. Mr. J. Austin, Ashton Court Gardens, Bristol, was first with a clean, even, handsome collection including Suttons' Superb Brussels Sprouts very fine, Hollow-crowned Parsnips, Improved Reading Onions, Suttons' King Cauliflower, Leicester Red Celery, Hathaway's Excelsior Tomato, Sir Joseph Paxton French Beans, Scarlet Intermediate Carrots, Suttons' Snowball Turnip, St. Patrick Potatoes, and Nutting's Dwarf Red Beet. Mr. R. Phillips, gardener to Capt. Jackson, The Deodars, Meopham, Kent, was a very close second with good Trophy Tomatoes, King of Cauliflowers, Student Parsnip, Sulham Prize Pink Celery, Suttons' Matchless Brussels Sprouts, Ne Plus Ultra Peas, and Early Snowball Turnips among others. Mr. Meads, The Gardens, Beckett Park, Shrivvenham, was third with good samples, especially of Celery, Beet, Carrots, and Cauliflowers. Mr. W. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Winchfield, was fourth; and Mr. Lloyd, The Gardens, Brockwood Asylum, Woking, fifth.

For twelve Suttons' Improved Reading Onions there were ten entries. Messrs. Wildsmith; C. Howard, Bridge, Canterbury; T. Haines, gardener to Earl Radnor, Coleshill House, Highworth; and C. Ross taking the prizes in that order. For twelve tubers of Suttons' Magnum Bonum Potatoes Messrs. Meads; H. Millen, gardener to the Marquis of Donegal, Hamstead Park, Newbury; C. W. Howard, and C. Herrin were the successful exhibitors, all showing good samples. For twelve tubers of Suttons' Reading Abbey Potatoes there were nine competitors; Messrs. G. Donaldson, The Gardens, Keith Hall, Inverurie, N.B., W. Meads, R. Lloyd, and T. Haines securing the prizes. In the two other classes for Reading Hero and Woodstock Kidney there were collectively seventeen entries; Messrs. Howard, Mead, Millen, Phillips, Emson, and Haines being the chief exhibitors.

**FLORAL COMMITTEE**—W. B. Kellock, Esq., in the chair. Mr. J. Woodbridge, The Gardens, Syon House, was accorded a vote of thanks for a dozen vigorous Bouvardias in 12-inch pots. The specimens were in some cases a yard in diameter, and flowering very freely. Messrs. James Dickson & Sons, Newton Nurseries, Chester, sent plants of a sport from the variegated *Euonymus radicans*. They were more erect in growth with much larger leaves than is usual in the common form. Mr. H. James, Castle Nursery, Lower Norwood, contributed a pretty group of Orchids, including good specimens of the bright yellow-flowered *Oncidium varicosum*, the brownish *O. prætextum*, the deep red-striped *Odontoglossum Insleayi leopardinum*, and the bright brown *Oncidium Forbesi*. Small plants of *Adiantum cuneatum* were arranged with the Orchids, and served to enhance the effect. A vote of thanks was accorded. Mr. C. Turner, Slough, exhibited a number of Tree Carnations, some of which were very handsome. Scarlet Nonpareil (Turner) was particularly fine with full rich scarlet flowers, and very freely produced. Brightness (Turner), bright scarlet, was also very attractive.

Messrs. H. Cannell & Sons, Swanley, Kent, had a large group of Primulas, including Swanley Carminata; Swanley Purple, very rich crimson; Lilacina Rubra Improved, very large flowers, deep crimson; Delicata, light pink; Swanley Red, deep and rich in colour; and Swanley White, flower very large, of good form and pure white. These Primulas were greatly admired for their excellent condition, the richness of the colours in the red varieties being surprising. A cultural commendation was accorded, but some members of the Committee thought the award of a medal would have better signified their appreciation of the plants. Mr. Hudson, The Gardens, Gunnersbury House, Acton, was awarded a vote of thanks for a specimen of *Chamaedorea glaucifolia*, 10 feet high, in a 32-sized pot, in fine health and bearing three panicles of flowers. Messrs. S. Mahood & Son, Windsor Nurseries, Putney, sent several seedling Chrysanthemums, the most noticeable being a bronze-flowered Japanese named Mrs. Townsend. Mr. Wiggins, gardener to Henry Little, Esq., Hillingdon Place, Uxbridge, was awarded a vote of thanks for a group of Pompon Chrysanthemum Sœur Melanie, a floriferous and beautiful variety with pure white neatly formed flowers. Several handsome seedling Primulas were also shown. Messrs. Smith & Larke, Kensington, exhibited a pretty bouquet and wreath of yellow and white Chrysanthemums.

Messrs. James Veitch & Sons, Chelsea, exhibited a group of Chrysanthemums raised by the late Mr. Alfred Salter. They included Brunette, a neat bronze Pompon; Purple Pompon, with purplish pink shell-like florets; Mary Major, a white Japanese; Lord Beaconsfield, a peculiar Japanese variety, the florets red on the upper surface and yellow below; and Marquis of Lorne, something of the reflexed type, deep red tipped with yellow. Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, sent a group of dwarf Scabious, the plants being in 32-size pots, and flowering freely. Mr. H. B. Smith, Ealing Dean Nursery, was accorded a vote of thanks for a group of fine Cyclamens, flowering extremely well. Mr. H. Bennett, Shepperton, Middlesex, sent a large specimen of the Tea Rose Madame de St. Joseph bearing a large crop of fruits, which was said to be "the second crop this season produced by manual fecundation." Mr. R. Clarke, Twickenham, exhibited a fine group of Cyclamens, the flowers being large, the habit compact, and the foliage vigorous. A cultural commendation was awarded. A vote of thanks was accorded to Messrs. Heath and Son for blooms of their double *Lapageria rosea*, each with from eight to ten petals. From the Society's Garden, Chiswick, a group of Primulas was shown, and cut blooms of the scarlet *Salvia Bruantii*, the bright blue *S. Pitcheri*, and the deep pink *S. Betheli*. A pan of

six plants of *S. Pitcheri* bearing some dozens of spikes was very handsome.

First-class certificates were awarded for the following plants:—

*Begonia socotrana* (Veitch).—A handsome and distinct species of Begonia from the island of Socotra, where it was found by Professor Balfour and introduced to Kew. The leaves are peltate, about 6 inches in diameter, and the flowers are bright rose, even in form, and borne in loose panicles.

*Chrysanthemum Rex Rubrorum* (Veitch).—A pretty Japanese variety, with blooms of moderate size, full, and even in form, deep maroon in colour, with narrow twisted florets.

*Chrysanthemum Lady Selborne* (Salter).—The white sport from James Salter which has been frequently noticed in this Journal. Six blooms of the sport were shown with the same number of the parent, and a certificate was awarded for it almost unanimously.

*Coleus Columbine* (King).—A peculiar and striking variety, with leaves 3 to 4 inches long, ovate, crenate margin, and irregularly dashed and streaked with crimson, maroon, green, and white.

*Heliconia aureo-striata* (Bull).—A Musaceous plant, with ovate leaves 8 inches long and 5 broad at the base, tapering, green veined with yellow. The under side of the leaves has a reddish tinge.

*Dracena Lindenii* (Bull).—An attractive plant, with leaves a foot to 15 inches long, tapering, about 3 inches broad in the widest portion. A band of dark green with a few greyish streaks extends down the centre, the margins being yellowish white. The leaves are slightly recurved. It was shown with *D. fragrans variegata* for comparison, the latter having a light band in the centre of the leaves.

*Davallia fijiensis plumosa* (Bull).—A graceful Fern, with leaves a foot long and about the same across the base; slightly triangular in form, drooping towards the apex, which is tapering. The fronds are finely divided into linear dark green segments, imparting a feathery appearance to them.

*Masdevallia chimera* (Bull).—This was certificated as the true *M. chimera*, described by Prof. Reichenbach. It has erect scapes, bearing one or two flowers with long-tailed sepals spotted with deep red. The labellum is small, white, and shell-like.

*Primula sinensis variegata*.—Mr. C. Herrin, The Gardens, Chalfont Park, Gerrard's Cross, was accorded a certificate for this plant, a clearly and distinctly variegated form of the common Chinese Primrose.

*Croton Laingii* (Laing).—A distinct and pretty Croton, with long narrow drooping leaves slightly twisted, dark green for about half their length from the apex, the remaining portion being bright yellow, the stem having a tinge of red. It is very graceful in habit.

**SCIENTIFIC COMMITTEE**.—Sir J. D. Hooker, K.C.S.I., in the chair.

*Gravel*.—Mr. Pascoe exhibited a specimen of disintegrated granite from Roche, Cornwall, resulting from the washing of china clay, and recommended it as a gravel for gardens. The Chairman remarked that it had been previously suggested to be utilised for that purpose, but its white colour was objectionable, as also was its want of binding power unless clay be mixed with it.

*Ehret's Paintings*.—A series of beautifully painted plants 130 years old with well-preserved colours, and done on vellum by Ehret, were exhibited by Mr. Scofield.

*Mycelium of Polyporus Squamosus*.—Mr. W. G. Smith showed specimens of this found beneath the bark of Elm trees about London, to which it does much damage. It appears to follow the tracks of the beetle *Scolytus destructor*, so common in Elms.

*Pears Malformed*.—Dr. Masters showed Pear stalks swollen, but without any real fruit within, received from Mr. Burbidge of Dublin Botanic Gardens. It was said to have more flavour and sugar than the Pear itself.

*Monstrous Cyclamen*.—Mr. Boscawen forwarded a flower with leafy sepals, a not uncommon state.

*Cycas revoluta*.—A number of seed-bearing abortive leaves in fine condition was sent by Mr. Hudson of Gunnersbury.

*Laurustinus*.—The Rev. G. Henslow showed branches and roots to illustrate a common condition of many Rosaceæ. The leaves grow pale, curl, and the epidermis separates easily from the subjacent tissue. The stems die and are then overlaid by a fungus (*Corticium* sp.), the roots being brown and dead. The cause appeared to be in this instance want of nutrition, as the roots penetrated a dry gravelly subsoil. Mr. Scofield remarked he had experienced the same thing with *Laurustinus* on the London clay, and attributed the death to similar cause of want of nourishment. Sir Joseph D. Hooker remarked on the frequent want of power to ripen its wood in this country.

**LECTURE**.—The first group of plants referred to by Rev. G. Henslow was a series of Bouvardias of Mexican origin. He called attention to the fact that they belong to the same family as the Coffee, Cinchona, Madder, and our humble English Galiums, which, though so different in appearance, had their flowers constructed on the same plan. The little burr-like fruit of *Galium Aparine*, or Cleavers, is said to have the same flavour as Coffee when roasted.

As illustrative of methods of fertilisation the lecturer took *Salvia*, showing the peculiar oscillating motion of the stamens, which is adapted to insects, so as to convey pollen from one flower to another. Certain species with long-tubed corollas have apparently "degenerated" from the forms which best illustrate that process, as the stamens have become straight and rigid, so that they cannot oscillate at all. He also showed the method of fertilisation in Primroses

and Amaryllis. A Tea Rose exhibited by Mr. Bennett, profusely covered with fruit, showed the beneficial effects of artificial fertilisation, the crop being the second of this season.

A branch of *Hippophaë rhamnoides* covered with fruits gave occasion to describe the different organs utilised in forming succulent fruits, it being a fleshy calyx in this plant, as in Mulberry, while in Pears and Apples it was the flowerstalk. A curious illustration was seen in a specimen from Dublin Botanic Gardens, in which the stalk had alone swollen, but contained no fruit whatever within it. On the other hand, in *Cycas revoluta*, fruiting specimens of which were forwarded by Mr. Hudson of Gunnersbury, it was the fleshy coat of the seeds, which are borne on the edges of reduced leaves, and not within pods.

In alluding to *Cycas*, Mr. Henslow remarked on the former abundance of Cycadaceous plants in England, as testified by the fossil remains found at Gristhorpe near Scarborough, and at Portland, Dorset. Trunks of these trees form part of the rockwork in the conservatory of the Royal Botanic Gardens, Regent's Park.

### MULCHING ROSES.

We have long been maintaining against all comers that the mulching of Roses in cold late localities does nothing but mischief, and is only good for warm districts when the coddling given would not so readily result in weakening the constitutions of the plants, but since Mr. Taylor condemns it we are now convinced that it is a mistake everywhere. We will answer for it that it is ruinous in the north. So long as we continued to mulch, the results of the arctic winters experienced here for the last decade have been disastrous. Two or three years ago we lifted all our Roses, planted them deeply in well-prepared soil, left them without a mulch, have given no manure since, and the results are such as were never heard of before, while the death rate has become very low. We intend saying more on this subject soon, as justice cannot be done to it in a brief note. It is worth adding, however, that we now invariably plant our Roses so deep that, though cut to the ground line, they are not destroyed but speedily become own-rooted plants, and perhaps this is the best way of obtaining Roses on their own roots when this is thought desirable.—A SCOTCHMAN.

### PEARS FOR WALLS.

"A. H. H." is evidently a man of valour, if not a man of might. His presence is of a very unusual kind, and enables him to know that I am "no gardener," on the mere evidence of a short article—not of my work, which he knows not. In caution he is a little wanting, but that is only according to nature, for it is observable that if a man is very strong in one faculty he is usually weak in another. I am, says this authority, "no gardener," but a "sentimentalist and a dreamer." As to my non-gardening capacity I certainly regret that I have not better use of my time; but there are at least a few friends who have a slight idea of gardening, who, too generously perhaps, estimate me more favourably, and one of them happens to be Mr. David Thomson, who was once good enough to write his estimate of my competency, which I now possess. The question now stands thus: There is the mere word of one man against the experience of another; if the former will not yield his point he has only one alternative, and that is to regard my friend Mr. David Thomson "no gardener" also. This is rather awkward for "A. H. H.," but I cannot help it, and a little more caution and a little less dogmatism would have avoided the dilemma. I am writing in the best possible humour, and under the impression that I am rendering myself quite agreeable to my critic, whose article, according to my reading of it, invited remarks of this nature.

Before proceeding further I must remind your correspondent that the subject of my letter was Pears for walls, and not walls *versus* glass structures. I am not likely to say anything against a well-appointed orchard house. I know by much experience how valuable such houses are, and I wish all gardeners had one of them, therefore I am not to be hooked by that bait so adroitly thrown out; in fact, I am inclined to go further than "A. H. H." and say that I suspect glass shelters for fruit trees and boundaries for gardens can be erected even cheaper than walls. But that is not the question, and they are at least not likely to cause many garden walls to be removed. I like walls and orchard houses too, and I have nearly always observed that gardeners in unenclosed or hedge-enclosed gardens have generally a strong desire for walls, as I have to see them profitably covered with well-managed trees.

Your correspondent not only in his wisdom accuses me of being "no gardener," but he charges me also with inconsistency, inasmuch as he says I "admit that cordons may be so trained as to be

as handsome as ever trees trained in the old system could be." I now ask "A. H. H." to reproduce a sentence from my article which carries that as its natural meaning. If he can do this he will be justified in declaring me inconsistent; if he cannot, the inconsistency will rest somewhere else.

I have said "A. H. H." is a bold man, not so much because of his strong expressions towards me, but because he could have penned his article after reading Mr. Warner's evidence of the advantages of Pear stocks on page 355, and the report of Mr. Taylor's trees and practice on page 380. Although the writer of that article qualified his remarks with references and a caution, he could not ignore what he saw, and Mr. Taylor can scarcely be described as "no gardener." But I suspect I unwittingly misled "A. H. H." in my last paragraph when I asked if there were no readers who desired with me to see the old English culture and training of Pears on walls, and who could at the same time say "how the work should be done." It was not because I did not know how to grow and train such trees that I penned that sentence, for in truth I can do the work better than describe it; but I thought there might be others who could describe the practice as well as carry it out. Yet the fact that I have grown and trained and gathered fruit by bushes from such trees as I referred to and advocated, does not constitute me a gardener, still I submit my experience does excuse me for writing the article that your correspondent honoured me by dissecting.

I will now return the compliment and endeavour to dissect his article on page 396. As I have disposed of the question of orchard houses *versus* walls at the end of the communication I may as well continue from that point and read the letter backwards. I first pause at the extraordinary question as to whether I have "never heard of Pears failing on walls because of bad weather?" I have never been so foolish as to imply that bad weather does not affect Pears on walls. I will now ask my friend a question quite as reasonable as the one he has submitted—namely, Did he ever hear of bad weather spoiling the Wheat and Potato crops? Assuming he has heard of such a calamity, I will further ask him if he would discontinue the culture of such crops? If he does not do this he cannot consistently object to such trees as I recommended being grown against walls, unless at the same time he can give an assurance that Pears on the Quince are *not* injured by bad weather. Such questions, however, as applied to the subject under consideration are vain and not worthy of discussion.

I pass next to the celebrated transitional theory. Pomology will soon be revolutionised. Let us adopt a mere hand-to-mouth policy in fruit culture; "Sufficient unto the day," &c., never mind our grandchildren. These are the plain teachings of "A. H. H." He is confessedly a disciple of Sir Boyle Roche, who refused to do anything for posterity because posterity had done nothing for him. This is the jerry builder's creed. I prefer something more solid, more really profitable, and more permanent. The new varieties of Pears were going to drive the old ones away thirty years ago, but the old sorts are with us yet as popular and as good as ever, and I am not sanguine of the speedy fulfilment of "A. H. H.'s" prophecy, seeing how many thousands of Apples on Crab stocks and orchard Pear trees are now being planted. Experience is proving that the millions of toy trees that have been planted have not improved the market fruit supply, and a reaction is setting in in favour of the old English standard trees for affording an abundant supply of useful fruit at a minimum cost.

And now to border-making for Pears for walls. My critic has weakened his case by exaggeration. That "concreted borders 30 feet wide and made of turfy loam are necessary in ninety-nine cases out of a hundred" is a simple fallacy. Why should a Pear tree require such a waste of labour and material to grow against a wall when it will grow freely without in an open field or garden? My friend himself must be the dreamer here; and then when he says that trees can be grown with a "hundredth part of the work" by "lifting and root-pruning" that is necessary under the old system, he must be indulging in mere sentiment. When he has tried both systems fairly he will modify that statement. The fruit farmers who pay £5 an acre for their land do not indulge in "root-pruning and lifting," and they would assuredly do so if it was a "hundred times" cheaper than the "old system."

Let no one be deterred by this border bugbear from planting Pear trees on Pear stocks. It is a mere phantom. I am certain I have had more experience on the subject than "A. H. H." has, or he never could have ventured on such a statement. But your correspondent goes on to say what I agree is the main question—namely, "Which system produces the best fruit and the greatest quantity from a given space?" On this point I can adduce evidence founded on a fair trial of both systems—trees that I

myself planted, trained, and tended for a number of years. Can he? If so I await proof of the "hundred times" better results of the "root-pruned and lifted" trees on the Quince. I challenge him to produce them, and when he has failed, as he will fail, I will show him the other side of the question. I am simply on my defence, and it is for my assailant to prove his statement.

There remains only one more question to deal with. After a peculiar allusion to the "splendid and splendidly trained trees," I am asked why such trees were grubbed up. Who told my critic they were "grubbed up?" All of them have happily not gone. Many trees have been removed, and properly, after being worn out by generations of good work; many have been removed by mistake. I am able to adduce some rather striking evidence on this point also, but not now. In the first place I fear I am

encroaching on valuable space, and in the next I am desirous of hearing further from your correspondent, who, I feel, has the advantage over me as a writer, but I question very much if he has had better facilities for gaining a knowledge of fruit trees and their culture than has fallen to my lot during an experience of thirty-five years, even if I am "no gardener."—JOHN BULL.

#### THE MAIDENHAIR TREE.

SEVERAL inquiries have reached us of late respecting this distinct deciduous tree, and many sprays of it have been sent for identification, that we answer them and anticipate other inquiries by submitting the annexed engraving and extract from Messrs. Veitch's excellent "Manual of the Coniferae."

Fig. 70.—GINKGO BILOBA. (1) Leaf of sterile branch; (2) of fertile branch; (3) male, or pollen-bearing flowers; (4) female flowers; (5) fruit.

"In the Ginkgo or Salisburia we have a remarkable exception to the Yew-like aspect which characterises all the other hardy Taxads. So greatly does the Maidenhair Tree differ from all other coniferous trees, that its affinity to them would scarcely be suspected on superficial inspection. An examination of the flowers, and especially of the fruit, and comparing them with the same parts of the common Yew, will show, however, that the Ginkgo belongs to the same tribe, although an isolated member of it.

"The fruit or berry is by no means common in this country, for the Ginkgo is dioecious, and the greater number of the large trees growing in England are stamiferous, or males. Fertile trees are still rare, and both kinds require in our climate to attain a considerable age before they produce flowers.

"Not much can be said of the economic value of the Maidenhair Tree. The wood is yellowish white, with a fine close grain, and moderately hard. It is easy to work, receives a fine polish, and resembles in its general appearance citron wood; it is more solid

and strong than the ordinary white woods of Europe. The Ginkgo is peculiar among coniferous trees for the absence of resinous secretions. In China and Japan it is cultivated for the sake of its fruit, the nuts being much esteemed; and in Japan, in Kämpfer's time, these formed part of every entertainment.

"The Ginkgo is of geological antiquity. In the Miocene period it included several species or forms which were spread over the greater part of the northern hemisphere in company with the Glyptostrobus and Liriodendron, trees that are still associated with it in its present habitat.

"Ginkgo is the Chinese name, meaning 'deciduous.' This name was adopted by Linnaeus, and by priority of application should be preferred to Salisburia, the scientific name hitherto generally current in this country. It is called the Maidenhair Tree from the resemblance of the leaves in shape to the pinnules of Adiantum Capillus-Veneris, the Maidenhair Fern."

We have only to add that the Ginkgo biloba, or Salisburia adiantifolia, is one of the most distinct and picturesque trees that

can be grown on lawns and in pleasure grounds. It is quite hardy, and many fine specimens are established in various parts of the country. The leaves usually assume a bright yellow colour in the autumn, and the trees then have a beautiful appearance.

#### GRAPES AT THE HANDSWORTH (SHEFFIELD) SHOW.

IN the *Journal of Horticulture*, Oct. 13th, page 341, allusion is made to the Grapes shown at Handsworth by Mr. Simpson of Wortley, who was awarded the first prize for black Grapes. As one of the judges in the open class, I had every opportunity of examining the exhibits very closely, and I must certainly say the two bunches of black Grapes (Alnwick Seedling) were fine samples, being large both in bunch and berry, and carrying a fine bloom, showing the careful treatment they had received, there being no rubbing or marks to spoil the appearance of the fruit. As regards the brushing-up advised by your Edinburgh reporter to the gardeners in the neighbourhood of Sheffield, had he seen the quantity of good fruit shown at Handsworth I think his opinion would have been changed of the ability of Grape-growers in the locality of Sheffield; for I believe they are able to keep their own ground against others, no matter from what part of the country they may come, especially if such excellent Grapes as those staged by Mr. Simpson at Handsworth are forthcoming.—*J. JEFFERSON, Worksop.*

#### SEASONABLE NOTES ON GREENHOUSE PLANTS.

IN all well-ordered establishments the operation of removing indoors such plants as Camellias, Azaleas, Cytisuses, and other hardwooded plants which were placed outside during the summer months, is now completed. Previous to arranging the plants in their winter quarters a careful examination should be made of the drainage, removing all worms. Should it be difficult to find them, a few waterings with weak lime water will have the desired effect. If the drainage is foul carefully remove it, and supply clean material. See that the exterior of the pots receive a good cleansing—this is an operation too often neglected by many gardeners; also carefully remove all inert soil from the roots of the plants, and apply water with care and judgment.

Camellias, Azaleas, Cytisuses, and similar plants are greatly benefited by occasional supplies of clear soot water. The latter produces excellent effects upon Camellias, causing their leaves to assume a fine, dark, glossy appearance, and greatly assisting the formation of flower buds. Some growers repot their Camellias and Azaleas at this season; but we question the soundness of such a practice, since from close observation we are convinced that the best period to repot these plants is in spring, when they commence growing. By so doing the soil does not become soured and saturated before the roots penetrate it. Again, unless the repotting be performed very carefully at this period the plants will shed their flower buds. Care must also be taken that the operation is skilfully performed.

Cytisuses, Coronillas, and Acacias should have their drainage examined also, and subjected to the same cleansing as directed for Camellias. Occasional applications of weak liquid manure will be found highly beneficial during their flowering period.

Ericas and Epacris should be treated similarly to the foregoing as regards cleansing. The plants should occupy a light airy situation and receive careful attention in watering. Those useful and indispensable Ericas, *hyemalis*, *gracilis*, and *Wilmorei*, will soon be in flower. Chrysanthemums are now rendering greenhouses and conservatories gay with their large brilliant flowers. Some growers plant these out and lift in September, but for ordinary establishments we do not consider the practice a commendable one. The system may doubtless answer well where large plants are required, but, like your correspondent "SINGLE-HANDED" (page 341), we prefer those grown entirely in pots. It is, however, an excellent practice to plunge those grown in pots in a bed of coal ashes or cocoa-nut fibre refuse. Thus treated the labour of watering is considerably reduced.

Callas (*Richardia aethiopica*) are useful plants for winter flowering. With some growers these are also planted out and lifted in the autumn. This is a good and speedy plan for growing young plants, but for flowering purposes we prefer those grown in pots.

*Eupatorium odoratum* is a useful free-flowering plant, and deserves to be grown much more than it is. It is of easy cultivation, and would certainly amply repay for the little attention bestowed upon it by a bountiful supply of its pure white flowers. By judicious management the plants may be had in bloom from

the present time till spring. Liberal applications of weak liquid manure should be given to each of the foregoing plants.

*Habrothamnus Aubletii* and *H. elegans* are useful free-blooming plants, especially the former, when planted out.

Cyclamens are growing freely, and in some cases flowering freely too. Occasional waterings with weak soot water will greatly assist them.

Primulas are coming rapidly into flower. They should not be subjected to a lower temperature than 55°, and occupy a position as near the glass as possible. Water them with tepid clear soot water. The double varieties, especially Gilbert's strain, are lovely in form and colour, and valuable for cut purposes. Cinerarias will need all the light and air that can possibly be given. Supply them frequently with liquid manure in a weak state.—*A SOUTHERN GARDENER.*

#### SCRAPS ABOUT FRUIT.

NEW APPLE THE QUEEN.—There is nothing the public are more sceptical about than new fruits, and we need not wonder at it when there is so many old favourites that have stood the test of time. But in the new Apple The Queen, which the Messrs. Saltmarsh & Son of Chelmsford exhibited last autumn in London, and to which the Royal Horticultural Society gave a first-class certificate, the public will be able to secure one of those sterling novelties which only appear perhaps once in half a century, and which all fruit-growers will welcome. In appearance The Queen is one of the most beautiful of Apples, being regular and even in its outline. Skin pale lemon yellow nearly covered with bright crimson, with here and there broken dashes of colour, which gives the fruit a beautiful marbled and highly ornamental appearance. Flesh white, juicy, and of fine quality; will be highly appreciated as a dessert fruit as well as for culinary purposes. No doubt the public will soon become acquainted with it, as exhibitors will find it to make one of the most telling of dishes, and market growers, from its beauty, quality, and general productiveness, one of the most desirable to grow. We therefore cordially welcome Her Majesty, as she promises to take the same rank amongst Apples that the Black Hamburgh and Muscats do amongst Grapes.—*W. F. BOWMAN, Hylands.*

TWO SELECT APPLES.—A dessert Apple of the first quality, though small and beautiful in appearance, is the Jefferson. The Frogmore Prolific is well worthy of a place even in a small collection, the former succeeding well as an espalier, and the latter as a bush.—*W. H. C., Tunbridge.*

RASPBERRIES.—It was only a few days before I left Cornwall that I went through the excellent fruit gardens of Mr. William Thomas, Ridgeovan near Penzance. Mr. Thomas was then forwarding Raspberries in large barrels of about two bushels each. These went by rail, arriving at their destination safely. Mr. Thomas sends away many tons in this way every season. The variety is Fastolf, a good all-round sort.—*WILLIAM ROBERTS, Dersingham.*

BROWN BEURRE PEAR.—Generally this Pear disappoints cultivators in cold districts. Many trees have been planted as pyramids, but they are rarely satisfactory, and the only certain mode of obtaining good crops of fruit that will ripen is to grow the trees against walls. Are there not too many late Pears planted in the open, and too many early varieties occupying walls?—*A. H., North Notts.*

PEAR *versus* QUINCE STOCKS.—I find the Pear is the only stock I can obtain fruit from here. I have about equal number of trees on Pear stocks as on Quince. The latter are all unhealthy and very much cankered—in fact, all the Pears on the Quince stock are worthless. Those on the Pear stock are in very fair health and very little cankered, and produce good crops of fruit. The soil is light and gravelly, resting on a bed of flinty gravel. The trees are heavily mulched every spring. From my experience I find the Quince stock only suitable for heavy or loamy soil, and the Pear stock for almost any kind of soil.—*R. OWEN.*

PEASGOOD'S NONESUCH APPLE.—The above is without doubt one of the finest Apples grown. It is of splendid shape, size, and colour, and the flavour is nearly all that can be desired. The tree is very prolific, and bears fruit in quite a young state; therefore it is suitable for small gardens. I strongly recommend it to intending planters, as I am certain it will give satisfaction.—*R. OWEN.*

THE WASHINGTON APPLE.—Having the privilege of seeing

and comparing a great variety of Apples during the season, I have seen none of this year's crop to compare with the above-named sort. In appearance it is most handsome, somewhat resembling a huge King of the Pippins in form and colour, with a large and open eye like that of the Blenheim Pippin. If grown to the same perfection as the samples lately seen at Tunbridge Wells (said to have been grown in Kent), it would be an invaluable exhibition variety. Upon making inquiries as to the price of this very striking Apple, not believing my own eyes neither the card in the window, I was politely informed that there was no mistake, and in all sincerity the moderate charge of £6 for the six fruits would not be deviated from upon any condition. This is fruit-growing at a tremendous pace, it must be conceded.—*W. H. CHISHOLM, Oxon Heath, Tunbridge.*

**JAMES VEITCH STRAWBERRY.**—It is a question if this becomes a standard market variety, and "F. W." will act wisely to grow it on a small scale at the first for proving its merits. The fruit is large but generally flat, by no means rich in flavour, and, what is a defect for market purposes, it is deficient in colour. It is firm, and travels well, and that I think is its greatest recommendation.—*A SALESMAN.*

**FIRM SOIL FOR FRUIT TREES.**—Mr. Elliott's note on page 403 is significant. Much injury is done by digging amongst young fruit trees injudiciously. Surface fibres produce firm and fruitful wood, but by destroying or preventing such fibres strong roots inevitably penetrate the subsoil, and strong succulent growths necessarily follow.—*R., Berkshire.*

**LATE RIPENING OF MARIE LOUISE PEAR.**—Like "H. B.," I am growing Marie Louise upon the Hastings sand formation, but I do not find the fruit from trees fully exposed to the sun at all behind the usual season in ripening. All the trees of it had an abundant crop of fruit this year, and with one exception it ripened early in September, and was in high favour for several weeks. The fruit which did not ripen with the others, and is in point of fact still green, is from a tree against a north wall, and affords agreeable proof of the value and importance of planting trees of such a well-tried favourite in various positions, so as to prolong the time during which it is possible to enjoy its delicious fruit.—*EDWARD LUCKHURST.*

**OUR STRAWBERRY BEDS.**—The dull wet autumn has induced Strawberries to make growth of extraordinary vigour, which, if it be not destroyed by a winter either exceptionally damp or cold, may yield fruit of large size and great abundance next summer. After the crop of the current year was gathered no time was lost in securing the requisite number of runners for potting, and new beds. This done, runners, weeds, and rubbish were forthwith cleared from the beds, a heavy dressing of manure spread and dug in between the rows, and subsequently Strawberries and fresh weeds grew so fast that hand-weeding had twice to be resorted to. Where the soil was not so broken up there will be considerable risk of loss should the winter prove very wet and mild, the compact mass of soil about the roots being apt to retain the superabundant water too long.—*SUSSEX.*

**LATE CURRANTS.**—I observe in your Journal for the 6th of last month, on page 316, that a correspondent residing in Surrey mentioned having gathered Red Currants "as late as September 21st." A quantity of fine Red Currants were gathered in my garden in the north of Yorkshire on the 2nd of November, and were in flavour quite equal to the fruit in summer. The trees had, of course, been netted to keep off the birds.—*N. S. N., Ripon.*

**APPLES AND PEARS AT CRANMORE HALL.**—Apples and Pears have been both abundant and good. The former are principally standards, and in great variety. The best twelve varieties this season, and which are invariably found to be the most profitable, are Cellini, Stirling Castle, Hawthornden, King of the Pippins, Domino, Lord Suffield, Keswick and Manks Codlins, Royal Somerset, Spice Apple, Devonshire Quarrenden, Hollandbury, and Golden Reinette. Of Pears Marie Louise on west and south walls has perfected excellent crops of fine fruit. Winter Nelis on a south wall is unusually large, and when ripe will be equalled by few and surpassed in quality by none. Beurré d'Amanlis and Williams' Bon Chrétien, both on south walls, have produced good crops, and the early little Doyenné d'Été proved very serviceable. Joséphine de Malines invariably crops well, as does Zephirin Grégoire; but the quality of the latter is not considered first-rate. Easter Beurré on east and south walls produced good crops of valuable fruit. At one time the spurs of many of the trees pro-

jected a considerable distance from the walls, from which they thereby derived but little benefit. Before proceeding to alter this Mr. Moore, the competent gardener, on taking charge severely pruned, and brought up many of the deep-running roots nearer to the surface, working-in much fresh loamy soil at the time. The following season the old spurs were sawn off to within an inch of the main branches, the result being good clusters of fruit buds followed by valuable crops of fine clean fruit. The garden is low-lying, in a valley near Shepton Mallet, Somersetshire, and the soil is heavy and shallow, resting on a sandy clay subsoil.—*W. I.*

#### RESPONSIBILITY OF GARDENERS.

WE are in the habit of making yearly pilgrimages to famous gardens to see them, and to try to gain some knowledge if possible. As it would not be possible, nor yet wise, in our case to visit all the gardens in any given district, we generally confine our attention to those the fame of which has reached us. Now, many gardens are famed because they are great gardens, and not always because gardening is well done. This is generally only found out by personal inspection. On the other hand, small gardens only gain fame because of the way they are kept. The consequence of this is that one who only visits gardens which are famous is very apt to come to the conclusion that gardening is best done in small establishments. This is perhaps our position, and possibly we have arrived at a wrong conclusion—a conclusion to which "A MANY-HANDED GARDENER" objects, and at the same time says what I think is unwarrantable. He says very distinctly, "The very best gardening is to be found in large gardens, the very worst in small ones." That may be true, and the opposite may be true if such examples are sought and searched for, which is what we understand your correspondent to mean when he uses the word "found." But in looking at samples without searching and finding we still think that plants in pots are better grown, as a rule, in small than in large gardens. We say small gardens advisedly, for we do not think those places come under the category where no real gardener at all is employed, but perhaps some improved labourer, whose dense ignorance and incapability is only equalled by the "cheek" which made his imposture possible, and which sustains it.—*SINGLE-HANDED.*

I THINK it must have been a kind of a "birds of a feather" feeling that prompted your excellent correspondent "SINGLE-HANDED" to draw an invidious distinction between the productions of single-handed and many-handed gardeners. I am afraid he is "pulling the long bow," or "drawing a bow at a venture" rather, in stating that "fine specimens of Heaths or other hardwooded plants are seldom seen except in single-handed places where the gardener supervises everything himself." Has your correspondent been in the habit of attending the Edinburgh and Glasgow Shows regularly, or has he ever visited a metropolitan exhibition, or an English provincial show, and will he tell your readers where the hardwooded specimens staged at such exhibitions come from? Almost without exception they come from gardens where all the work is done by subordinates. I quite agree with him that the best way to do a thing well is to do it oneself, but "SINGLE-HANDED" is wrong in this matter. I happen also to know much about the locality of Eskbank, and when "SINGLE-HANDED" exemplified an excellent gardener there, and whom all will acknowledge as such, whom "competitors at local shows knew well"—meaning to their cost we suppose—because "he had personally to attend every plant himself;" he should also have stated that there was only one show in that locality, that it is so poor it cannot afford to offer a prize for even one bunch of Grapes, and that it would not be worth any gardener's while going off the street to see if the room was not occasionally, as it at least used to be, half filled by the "famous gardener in the neighbourhood" for nothing. I am speaking from knowledge, and it will therefore be seen that your correspondent's statements are based on an exceedingly slender foundation. Then as regards washing Orchids, we all have to contend with indifferent men and indifferent wages; but I presume "SINGLE-HANDED'S" man is paid the market price of his labour, as elsewhere, and I should think there is something wrong with the superintendence which permits a man in spite of repeated warnings to break off pounds' worth of shoots from valuable plants.—*ANOTHER MANY-HANDED MAN.*

**AUTUMN PROPAGATION OF ROSES.**—Your valued correspondent Mr. W. Taylor gives some excellent directions at page 350 on striking Rose cuttings late in autumn. We cordially endorse everything he says except one point, and that is for cold districts his date for taking cuttings is thirty days too late. That is our expe-

rience, but of course there is a great difference between the midland counties of Scotland and Somersetshire, which makes all the difference. North here, too, handlights or cold frames over the cuttings are a great advantage, making "assurance doubly sure."—N. B.

#### LIQUID MANURE FOR PLANTS FORCED IN DARKNESS.

FORCING is expensive considering the results obtained. To obtain the greatest amount of produce of the finest quality is an object, and a worthy one, with us all, but we doubt if some of the practices yearly recommended are good. Indeed we are sure some of them are hurtful. The application of liquid manure to plants forced in darkness is one of these cases. The judicious supply of liquid manure to plants growing on soil not very rich in summer time proves that it is a valuable aid to growth. On no plants does it produce more marked effects than on Rhubarb or Seakale, but only in summer time. Then the roots take up part of the materials of which growth is made, and these materials are in the leaf, in addition to what the leaf itself obtains in the air manufactured into material from which the plants build their structure. This only goes on in the leaf under the influence of light. Liquid manure given to plants forced under conditions

Fig. 71.—*Begonia Madame de Dumast*.

which preclude the possibility of sap being elaborated simply poisons the produce and secures no resulting good.

Liquid manure, as it is ordinarily understood, contains either ammonia, or nitrates, or both. These in water for domestic use are rightly regarded as dangerous; in what respect are they otherwise in Rhubarb? Does Seakale forced in darkness turn the nitrates or ammonia into something beneficial or even harmless? Does their application to plants under circumstances which prevent their being changed even accelerate growth or postpone exhaustion, as is often pretended? Let anyone who thinks so try it fairly against pure water and he will find he has made a mistake. The extension of the parts of plants forced in darkness must always be at the expense of the material stored up in the plants, and how to increase this store should always be the question, and not how often to apply hurtful matter to plants that cannot use it, but which thereby become no better than sewage-tainted wells. Rich soil is also objectionable and useless for the same reasons.—SINGLE-HANDED.

#### NEW BEGONIAS.

No plants during recent years have made such remarkable progress as Tuberosus Begonias, and M. Crousse is certainly not the least successful raiser of them, as his new varieties, Blanch Jean Pierre, Madame Comesse, Madame de Dumast, Madame Leon Simon, and Mathilde Giraud, now in the hands of Mr. Cannell,

testify. It was one of these, Madame de Dumast, that we suggested on page 291 resembled a Camellia. The flower was sent by us to the engraver, and it is now represented in fig. 71. The plant that produced this flower among others was by no means strong, being in a 6-inch pot, and there is thus reason to suppose that the character of the variety will at least be maintained. The colour is blush, faintly tinted with salmon pink, the centre creamy white, and the flower is very striking.

#### ORCHIDS IN NOVEMBER.

THIS month brings us dreary days and cold chilly nights, with thick fogs, especially in the neighbourhood of London. It is the most difficult season with which the Orchid-grower has to contend, being the resting period, when great care has to be exercised as regards watering and firing. The many changes occurring in the outside temperature necessitate a careful look-out before damping down, taking advantage of what fine days we may have to give all the ventilation we can. It ought to be the first consideration of the grower to see to the watering and damping-down in the forenoon, by which time he will be able to predict how the day is to turn out, and so act accordingly.

The night temperature should now be kept so as not to excite growth, and should be from 60° to 65° in the East Indian house, 55° to 60° in the *Cattleya* and *Dendrobium* house, and 45° to 50° in the cool house.

In pleasing contrast to the bleak aspect out of doors the winter-blooming Orchids make a cheerful and welcome display of floral beauty well worth the trouble and care bestowed upon them. *Calanthe vestita* is now in perfection, producing as many as twenty-five to thirty flowers on a single spike, and is invaluable for cutting purposes. *C. vestita rubro-oculata* and *luteo-oculata*, and *C. Veitchii*, are also attractive, the latter with an erect stem bearing pink flowers with a white eye. These plants require no water now, and will continue a long time in flower if kept free from damp. After flowering they should be placed in a dry warm place, water being withheld from them, and should be potted in March or April, when they again start growing.

*Cattleya Dowiana*, undoubtedly the best *Cattleya* grown, is now in full beauty with its lovely nankeen-coloured flowers. This plant requires to be grown in a strong light in order to insure it blooming to perfection. *Cattleya exoniensis*, a garden hybrid between *C. Mossiae* and *Laelia purpurata*, with its rich purple lip, orange throat, and rosy-tinged sepals and petals, is a most desirable plant for this time of the year. *Cattleya Trianae*, now in their sheaths, promise a good display shortly. This being their resting period water must be sparingly given; sufficient only to keep the pseudo-bulbs from shrivelling will also insure an abundance of flowers for next year.

*Cypripedium insigne* is an old favourite, with its varieties *C. Maulei* and *C. Chantinii*, are producing their blooms. One great recommendation of these is that they succeed well in a cool house, and we have even turned them out into a cold frame with satisfactory results. *Cypripedium venustum* and *C. venustum spectabile*, with its spotted petals and fine mottled leaves, remain a long time in bloom, and should not be allowed to become too dry at the roots, though at this season the plants require to be kept drier than during their time of growth.

*Dendrobium superbiens* is a decided acquisition amongst winter-blooming Orchids. It thrives in a stove temperature, and produces a profusion of bloom which is invaluable during the winter months on account of the length of time it continues in beauty. *Dendrobium heterocarpum philippinense*, with cream-coloured flowers differing somewhat from the ordinary *D. heterocarpum*, though not so fragrant, is yet valuable at this time of year. The pseudo-bulbs are sometimes seen 4 feet long, and it flowers the whole length of the bulb after the manner of *D. Pierardi*.

*Laelia autumnalis* is now in fine condition, as is also *Laelia autumnalis atro-rubens*, an extra dark variety, more floriferous than *L. autumnalis*, and bearing as many as eleven flowers on a spike. *Laelia anceps*, *L. albida*, and *L. Perrinii* will now be in bud and bloom, and will enliven the dull months of December and January if care be taken not to sprinkle the blossoms with water. *Laelia pumila* and *L. Dayana* are now swelling their buds, and may be expected soon to be in flower.

*Oncidium crispum marginatum*, better known as *O. Forbesii*, is a grand variety for this time of year, its fine spike of yellow-margined chocolate-coloured flowers rendering it exceedingly attractive.

*Pleiones maculata*, *P. lagenaria*, and *P. Wallichiana* are now at their best, and are extremely useful for the decoration of our

Orchid houses during the dull winter months. Many people kill these little Orchids with too much heat. We find the cool house suits them best, but when in flower we remove them to the intermediate house, as they are liable to spot in the cool house then. After they have done flowering they should be allowed to remain in their old pots for about two months, giving them very little water, and when beginning to start fresh roots they should be potted and removed to their growing quarters. Treated in this way anyone may grow them with success.

*Zygopetalum Mackayii* with its long spikes of Hyacinth-scented flowers is also now in perfection.—ORCHIDIST.

#### NOTES ON CIRCUIT.—No. 4.

AMONGST the many pleasant memories of the last summer I must reckon a short sojourn I made at Chester-le-Street in the County of Durham. I had just finished my assizes in Scotland and was on my way to the Newcastle Show, intending to pass the Sunday at the cathedral city of Durham, when, on looking at Bradshaw, I found we passed through Chester-le-Street; and it occurred to me that the Red Rose Vineries, of which the readers of the Journal have often read, were there, and that on the days when he grew *Gladiolus* Mr. Witherspoon and I had met, and so I telegraphed to him that I would spend a few hours on my way. In its own time—a very liberal calculation—the train left me there; but of the many tedious journeys I have had I think there are few which exceed that from Carlisle to Durham. Mr. Witherspoon not only met me at the station, but induced me to spend Sunday there, and held out the additional inducement of showing me Lumley Castle and Lambton Castle on Monday morning. I was very glad that I fell in with his kind wishes, for I saw much that was interesting at his own place, and was intensely delighted by my visit to the very old and very modern Castles on Monday.

Mr. Witherspoon is another example of how when the love of gardening is in a man it overleaps all boundaries, and enables him to achieve success with little theoretical knowledge of the pursuit. Mr. Witherspoon was a wheelwright, but it is evident that he was a born gardener, and the proof of it is in the results he has achieved. The piece of ground on which his garden stands was a few years ago a field, and on this he has erected his greenhouses and made himself well known in the north of England by the excellence of his culture. I have seen vineries and fruit houses, but I do not think that I have ever seen any so thoroughly utilised, and, so to say, made the most of, as these two houses of Mr. Witherspoon. In one house were the Vines covering the lean-to portion; at the back were Peaches and Nectarines, with occasionally an upright cordon Pear. There were Tomatoes along the border; Peaches, Nectarines, and Figs in pots, and all bearing a fair crop of fruit. The Vines especially were good, particularly in the second house, which was exclusively devoted to them. I should say that it is Mr. Witherspoon's object to grow for market, and that therefore he is guided in the selection of his fruit by what is most likely to pay. He is not, therefore, inclined to try new varieties which are introduced with high-sounding names and descriptions unless he finds them available for this purpose. Nor will Grapes that require very much heat answer his purpose; nor is he desirous of obtaining very large bunches, bunches of about a pound or three-quarters of a pound being the most available for market purposes. Hence the greater portion of his Vines are Black Hamburgs and Gros Colman, the latter from its size and handsome appearance being a great favourite in the north. In the second house, which is exclusively devoted to Vines, they are planted on the back wall as well as in front, and from this house last year Mr. Witherspoon cut 1400 lbs. of Grapes, and expects to cut a larger crop this year.

It must not be supposed that Mr. Witherspoon confines himself to indoor fruit. On the contrary, he has made some interesting experiments as to the Pears and Apples which will suit the less sunny skies of the north. He says that the idea that it is the freezing of the flowers which causes the loss of crops is not correct, but that more frequently the bud has been frozen in the winter, yet has sufficient vitality to flower, but, having expended its energies thus, can do no more, and the bud perishes. The more hardy sorts will break through this and make up their loss. This is much the same as we find sometimes in Roses, especially this last season. They have commenced growing, the shoot has gone a certain length; then the strength of the plant seems exhausted, the stem blackens and it dies. By these experiments he will be able to determine as to what fruits he shall grow in future—information, too, which will be useful for others besides himself.

There are few remnants of olden times which strike one more forcibly than does Lumley Castle. There are but few like it in England, Bolsover and Roly being something in the same character. It is not a ruin, and it stands there to be seen from all parts around, a strange and weird-looking building, bringing us back some seven or eight hundred years when the fighting Lumleys, whose effigies are on its walls, held revel there. Under the intelligent direction of Mr. Hall, the steward, explorations have been made and much that is interesting brought to light. As we walked through the many spacious apartments we could almost expect to see the ghosts of those who dwelt in them in former days walking through them, and to live in it when the wind was howling through its embrasures and

making all kinds of strange and unearthly noises must be a trial of courage; but as it presented no features of horticultural interest I must not dwell on it. Far different is the scene at Lambton, to which place Mr. Hall kindly drove me, and where Mr. Hunter, whose fame as a gardener, and as a Grape-grower especially, is so widely known, kindly met us. Here everything was in the perfection of order. What shall I say of the vineries? That their whole aspect was wonderful. Here were those grand examples with which he gained so many honours a few weeks after at Manchester. There were ranges of houses, conservatories, stoves, &c., and the same order and excellence reigned throughout. Out of doors it was the same save in the woods, where the havoc wrought by last winter's storms was truly deplorable; but in the garden, whether fruit, vegetable, or flower, all evidenced the presiding care of an able and intelligent gardener. The view from the upper terrace down the long walk was very beautiful, and the bedding-out was most tastefully arranged; but as I know that the beauties of Lambton have been described in the pages of the Journal I did not take any special notes. The surroundings of the Castle with the river Wear rolling beneath it are very fine, and afford many lessons for a landscape gardener. Of Roses, as in so many of those grand places, I saw but little; for them we must look in the smaller garden of the amateur who can give special care and attention to them.

Thus ended my visit to Chester-le-Street—a totally unlooked-for one when I started on my northern circuit, but of which I retain pleasant memories; and I would certainly advise anyone whose business might bring them in that direction to stop for a few hours and see both the Red Rose Vineries and Lumley Castle.—D., Deal.

#### LESSONS OF LIFE FOR YOUNG GARDENERS.

I HAVE read with pleasure Mr. Pettigrew's advice to young gardeners at page 273, which, in my opinion, is as good as could be given, and the rising generation of young gardeners should be proud to see that Mr. Pettigrew is one of those who remember that it is the duty of age and experience to warn and instruct youth. He says, "Except a taste for gardening be acquired in early life it will be hard work to make any advance on the high road to success." Time will prove the truth of this warning. We all know the good effect which correct opinions and sound principles established in early life have upon us as we ripen into years. Gardening differs widely from all other callings, as it appeals to such a variety of tastes. Hence it is when a young man is apprenticed to learn gardening he has a wide field of culture before him. Young men should always bear in mind that they cannot know too much about that on which their living depends. A stock of knowledge which has an almost immediate effect on their financial interests, and upon which the happiness of their future homes will principally depend, is the most practical and valuable. Neither should they be discouraged in seeking knowledge if they do not make the progress they expected. Having planted their acorn they must remember it cannot grow into an Oak at once; they must therefore cultivate the habit of endurance and perseverance, or, in other words, they "must learn to labour and to wait."

A rock on which many young gardeners are wrecked is by beginning too soon to look on their labours as a marketable commodity. This evil is a growing one; they prefer a place where they obtain a shilling or two more a week and learn little, than one where less wages are given and much more is to be learned in their business. Mr. Pettigrew justly observes that education in gardeners is uplifting in every sense, and no doubt it is one of their best aids. There is no excuse now for the rising generation not being educated, since cheap instruction is at the command of all; but it was not always so, and to those who begun gardening some few years ago with a defective education, as well as to the youth who has begun it now, we tender the same advice, and urge them not to lose a moment in self-improvement. Mr. Pettigrew truly says that young gardeners during the winter months have plenty of spare time: let them employ it wisely. In the first place, we would advise the keeping of a diary of all that is transacted about the garden, both inside and out. This diary should be written at a certain time every evening, pains being taken that it is plainly written and well spelled. This would be a very good lesson on writing for every evening. Then for ordinary instructive reading there are two books which we have found most valuable; the title of the one is Smiles' "Self-Help;" and, as its author says in the preface, the chief object of the book is to stimulate youths to apply themselves diligently to right pursuits, sparing neither labour, pains, nor self-denial in prosecuting them, and to rely upon their own efforts in life rather than depend upon the help or patronage of others. The title of the other book is Cobbett's "Advice to Young Men;" and then there is also Cobbett's "English Grammar," which is a famous self-instructor. We are glad to see Mr. Pettigrew is of our opinion concerning these two works of Cobbett's.

The reading of works on gardening is very essential, and should be particularly attended to by every young gardener. As standard works we can recommend Thompson's "Gardener's Assistant" and Anderson's "Practical Gardener;" but we give preference to the reading of weekly gardening papers. My employers have paid for two papers every week now for nearly ten years for me, and I take out one on my own account. Of the three I may, perhaps, be allowed to say I give preference to the *Journal of Horticulture* either for young gardeners or old. The matter which it contains is instructive and reliable, and bears testimony to the abilities of its staff of contributors, composed as they are of the leading practical gardeners of the day. Young gardeners should also attend to the study of history and geography; and as they spend years of their youthful prime in bothies, exposed to many allurements, we wish to caution them against the reading of novels. No doubt there is the old adage that "reading makes a learned man, and writing makes a correct man," but in our opinion reading novels never added anything to any man's learning. Many of them are so alluring that it requires great steadfastness to resist their temptation. Much trashy reading corrupts the mind of the young, and is too often the promoter of alternate follies taking the sway, and when such is the case with young gardeners they will rue it. We have said, Neglect novel reading; we say also, Neglect dominos, draughts, and card-playing, and, above all, neglect the beerhouse, and things will go well with you. In the first place you will be more respected by the gardener whom you are under, you will also be more respected by those who are above you in every station of life. The crown and glory of life is character. Smiles says it is the noblest possession of a man, constituting a rank in itself; it exercises a greater power than wealth, and secures all the honour without the jealousies of fame; it carries with it an influence which always tells, for it is the result of proved honour, rectitude, and consistency—qualities which, perhaps more than any other, command the general respect of mankind.—H. ELLIOTT.

#### REVIEW OF BOOK.
