Herbs.—A good quantity of the most useful of these should be cut and dried before the season advances further. Mint, Sage, and Thyme are amongst the principal, and may be cut to within 3 inches or so from the base. The best place to dry the tops is an open shed. Sometimes they are spread out on the tables and floors, but we often tie them up in loose bundles and hang them up to dry. The main thing is to dry them so as to retain their colour, and this may be done if they are not frizzled in the sun. About this time every season we are in the habit of sending a quantity of herbs to the cook to be dried for the winter, and for some purposes her plan of drying is the best. They are spread out in front of a large fire, and after being there for an hour or two they become so dry as to be easily powdered. In this state they are placed in bottles and firmly corked. There they are kept quite dry, and they retain their flavour for a great length of time. Parsley and Celery leaves

may also be similarly dried, and it is an excellent way to preserve them for winter use.

Winter Spinach.—Continue to make successional sowings of this useful winter vegetable, and as the plants from the previous sowings become large enough to handle, thin them out to 6 inches apart. When not thinned out it comes in a great mass, but it is only by timely thinning that those large succulent leaves so much valued by cooks can be secured.

Early Carrots.—The surplus Horn Carrots which were left in the border after the others were drawn in spring are now full grown, and should be taken up and stored for future use. Lately we have lifted a large quantity. The tops should be cut off, and the roots will keep well for a long time in any cool shed.

Salad Plants.—Lettuce and Endive sown a few weeks ago are now ready for transplanting. This should be done when the ground is moist and the atmosphere humid, as they grow freely then, receiving little or no check. Through lifting Potatoes, taking up Carrots, and clearing away old Cauliflower plants there is plenty of empty quarters for winter salads.

Seed-saving.—Birds are very fond of emptying Pea pods, and as a rule it is not safe to allow any of them to remain hanging after they are ripe. We gather our seed pods every other day, and spread them on a table in an airy shed, dampness or a large heap of pods together being very unfavourable to proper harvesting.

Celery.—Much of this is now ready for earthing, and we would remind cultivators to give it timely attention, as such an important winter crop as this should be regarded as one of the very foremost to be dealt with at this season. Earthing instructions given some time ago apply to the present time and onwards.

Hoeing and Cleaning.—The summer has been one of the most favourable we can remember for the growth of weeds, and some little time ago when it was raining daily they had a fine time of it; but the weather is now against them, and every effort should be made to destroy them before they seed. If the garden is well cleaned now it will prevent many weeds from appearing next spring, and as none of the winter crops can have too much sun now to mature them, time now spent in cleaning cannot be regarded as being wasted.

FRUIT-FORCING.

VINES.—*Houses of Late Grapes.*—Whether the Grapes are intended for keeping through the winter on the Vines or in the Grape room, the houses will require very liberal ventilation; and as the days decrease in length gradually reduce strong laterals, keeping the foliage in a clean healthy condition by damping paths and walls sufficiently early in the day to admit of the atmosphere becoming dry before night. Assist Grapes which have not much colour by a little fire heat and ventilating early. Allow the temperature in the day to range from 80° to 90° or 95°, falling to 70° at night.

Ripe Muscats.—The Grapes hanging on Vines having their roots in outside borders will keep a considerable time if protected from the heavy rains that may be expected soon. A covering of dry fern or bracken disposed so as to throw off the wet, shutters, or, better than anything, glass lights placed in a slanting direction, answer for throwing off the wet and allow the sun heat to pass into the border. Where the foliage is insufficient for the protection of the tender skins of the berries a light shading on bright days will be found very beneficial, nothing answering better than hexagon netting, and it is equally useful in excluding wasps.

Lifting Vines.—If this be found necessary with early and midseason Vines, lifting and relaying the roots should be preceded with without further delay. See that the drainage is satisfactory, and protect this with large turves grass side downwards. Use fresh turf liberally intermixed with brick and lime rubbish, charcoal, and crushed bones. Let the roots be kept near the surface. Plenty of roots in a comparatively narrow border are preferable to a large mass of soil, as they can be fed when necessary, and the Grapes always set, swell, and colour well. Dry weather should be chosen for making the borders. Cover the border when the operation is finished with good stable litter, keeping the house close and moist until the foliage shows signs that fresh root-action has set in, when the house must be freely ventilated. Vines in most cases should be planted inside and have the run of both internal and external borders, as the roots can then be lifted in either border without in the least injuring the following year's crop.

Vines in Pots for Early Fruiting.—These should at once be removed to a dry airy house, giving only sufficient water to keep the soil moderately moist for the preservation of the roots in a healthy state, and if the pots are covered with dry fern or litter the necessity for its application will be almost nil.

Strawberries in Pots.—The earliest potted plants have made good progress, the crowns beginning to become plump and prominent, so that the fruiting plants can be detected; those that will evidently not be productive should be cleared away at once. The pots should be at such distance as to allow the crown to have full exposure to the sun. The plants should not be allowed to suffer from insufficient supplies of water.

PEACHES AND NECTARINES.—*Early and Midseason Houses.*—These should always have moveable lights, the removal of which exposes the trees to the cleansing and invigorating influences of dew and the late summer and autumnal rains, and the inside borders are thereby evenly and thoroughly moistened, so that there is no danger of the buds falling.

Lifting and Root-pruning Early Trees.—Where the trees in early houses grow too luxuriantly and do not set freely or stone well, they may be lifted with advantage; the time to do this is when the leaves give

indications of falling, or a little before. The best way to operate is to take out a trench around the stem at a distance from it of one-third the extent the trees cover of trellis, and down to the drainage. Then remove the surface soil, and pick the soil carefully from amongst the roots, and without disturbing the small fibres near the collar. The roots should be laid in fresh compost, and nearer the surface, working it in with the hand as firmly as possible; a good watering should then be given, and the surface mulched. This should be practised both on the inside and outside borders. Where root-pruning is only contemplated, baring the roots, removing some of the strongest according to the vigour of the trees, will be left to the discrimination of the operator. A good turfy loam, strong and calcareous, with a free admixture of burnt earth and old mortar rubbish, forms a suitable compost. Where it is intended to plant fresh trees the borders should be prepared without further delay; 24 inches depth of border is ample, of which 9 inches should be drainage, beneath which should be tile drains, having proper fall and outlet. A 6-foot width of border is ample to commence with, planting inside, and keeping the roots there for two or three years, when they may be allowed a similar run of outside border.

Late Houses.—As the trees become cleared of fruit remove the fruit-bearing wood of the current year, in order that the young wood for next year may have the ripening influence of sun and air, and if at all crowded thin the shoots well. Admit abundance of air, and when the wood is thoroughly ripened the roof lights may be removed for a few weeks.

Trees in Pots for Early Forcing.—These should be seen to at once, the drainage rectified if it has become defective by removing it, and replacing with clean crocks and crushed bones, top-dressing, and placing in the open air on a bottom impervious to worms. Place some dry fern or litter around the pots to protect the roots from the drying influences of the atmosphere, watering as needed to keep the soil moist. Alexander, Prince Alfred, Royal George, and Large Early Mignonne are good for fruiting early in pots; and of Nectarines Hunt's Tawny, Lord Napier, and Stanwick Elruge.

PLANT HOUSES.

Azaleas.—Where these plants are kept under glass instead of standing them outside, shading must be discontinued and abundance of ventilation given night and day. In no stage should they be unduly shaded, especially during the completion of their growth, or their wood will remain in an unripened condition, and the plants when required to do so will not flower satisfactorily. When the flower buds are formed early and allowed to develop naturally under the influence of light and air they will expand when required much more readily than when a more careless system of preparation is accorded them. The plants to flower late next season should now be pushed forward as rapidly as possible, and every encouragement given them to complete their growth and form their buds before the days become short and sunless; they can, after the flower buds are once formed, be retarded to suit the convenience of the cultivator. Any of these plants that have their pots full of roots will be much benefited by the application of a little Standen's manure. Azaleas require some stimulating agent even after their growth is completed and their buds formed, and a few applications of liquid manure assist them wonderfully when root-bound to retain their foliage during the autumn and winter months.

Where these plants require tying and training no time should be lost in completing this operation with all the early batches, so that the foliage will have time to turn again the right side before they are wanted for forcing.

Camellias.—Where shading these plants is practised it should now be discontinued, for if employed after this date it will prove detrimental. Ventilate freely day and night. Where the buds have set, apply water liberally and syringe freely; in fact, stimulants should be given more abundantly to these plants during the time their flower buds are swelling than at any other period of growth. Care must be taken that they never suffer by the want of water at their roots, or their flower buds may fall prematurely instead of expanding properly. If the plants are densely crowded with flower buds, disbudding should be resorted to at once before they exhaust the plants. Cleaning or tying should be pushed on rapidly, and if scale or other insects infest the plants syringe them with petroleum and water at the rate of 6 ozs. of the oil to 4 gallons of water. After this operation the plants must be shaded for a few days from bright sun, and then no injury will follow.

Abutilons.—Plants that have become too tall should be cut down without delay, and the tops inserted in the centre of 2 and 3-inch pots. These, if plunged in a close frame with a little heat, will soon form roots and make useful dwarf specimens for decoration during the winter. As soon as they are rooted they should have an intermediate temperature, and by the time they are ready for other pots 2 and 3 inches larger they should be placed under greenhouse treatment until the temperature is likely to fall below 45° at night. Few plants are more beautiful during the winter either in the stove or intermediate house than these when well grown in small pots. This is readily accomplished if good tops are selected and frequently rooted at frequent intervals.

Hybrid Perpetual Roses.—Those used for forcing in pots and plunged outside should be turned out of their pots, and the old soil carefully picked from amongst their roots until the ball is reduced to about half its size. This done, they should be again potted. Place a little moss or the roughest of the compost over the drainage, and then press the new soil moderately firm round their roots. When repotted at this season of the year while the foliage is fresh, they become established in the new soil before autumn, and are ready for early forcing when the time

arrives. After potting, syringe frequently in order to keep their foliage fresh, and water carefully until their roots are growing freely. Use for a compost good fibry loam; if light, add a little clay that has been pounded into dust, a seventh of decayed manure, a 6-inch potful of bone dust, and the same quantity of soot or wood ashes to each barrowful of soil; a little coarse sand may also be employed with advantage.

THE BEE-KEEPER.

STIMULATIVE FEEDING.

MR. JOSEPH COOK, the great Boston lecturer, says that nursing children can be done scientifically. A great deal in the apiary can be done scientifically, and when it is so done it is done with advantage. But much feeding is done unscientifically, without thought or advantage. Many hives in many places require feeding up for the winter at the present time. Hives not taken to the moors have not laid up much stores—they have not winter food enough, and require feeding. How can they be fed with advantage? No point in apiculture is more important than that of having hives—I mean stock hives—well filled with young bees in autumn, for these outlive the winter and see hatches of spring brood come to life and activity. Hives made strong in autumn by additional young bees from honey hives, or by hatches of brood, are strong in winter and spring, and can be depended on for great results. Sound practice or true science in feeding bees aims at the production of brood. Early feeding is resorted to when pollen is abundant. Syrup continuously given when pollen is plentiful stimulates bees to breed, and if some large cakes of brood are produced and hatched in August or September, our bees will be pretty secure against weakness in early spring. As soon as it is evident that some autumn feeding will be necessary it should be commenced, for it is more easy to keep queens laying that have not stopped than it is to make those that have stopped recommence laying. All autumn feeding should be finished not later than September. When breeding is aimed at it should be done as early as possible, and continuously. Feeding for storing purposes merely in autumn should be done as rapidly as possible, for continuous feeding keeps bees in motion and causes them to consume more food. The more rapidly winter food is given to bees the quieter they sit, the less they consume; but while warmth is in the atmosphere and pollen is in the flower, stimulative feeding is most likely to be successful in the production of brood.

True science in full play seeks large hives and strong ones. By increasing the strength of hives in autumn we add to the value of them and the comfort of the population.

Some bee-keepers, or rather one class or school of them, try to improve the condition of their hives by contracting their space during the autumn and winter—that is to say, by shutting off and outside the line of the bees' action so many bars of comb. The hives are thus contracted and made less so many months of the year, autumn and spring at any rate. Whatever end this practice may serve it does not strengthen the population of hives; it does not increase their number of bees in autumn, and that is a point of prime importance. Far better fill a good-sized house with bees than break it up or break it down by contraction for the comfort of a smaller number. I have never been able to see anything scientific in the practice of cutting up and contracting hives in autumn. Advanced apiarians who follow the swarming system of management strengthen their stocks in autumn by adding to them the populations of other hives. In good seasons the honey hives make the others strong, and in poor seasons the bees of the weak hives make the strong ones stronger. By ever adding to the strength of our hives, we thus keep within the lines of safe and successful practice.—A. PETTIGREW.

SADDLER'S TABLET CANDY—FLOUR CANDY.

As I am a sugar-boiler by trade I hope I may be able to make it plain to every bee-keeper how to make this excellent bee-food. To 7 lbs. of sugar—Dutch crushed is the best—add 6 gills cold water and a teaspoonful cream of tartar; put it in a brass or copper pan, and stir it occasionally to melt the sugar; do not stir any after it comes to the boil, but see that the sugar is properly melted. Boil it until when taking a little out with a spoon and putting it among cold water it will form a soft ball between your fingers; set it to cool till it is lukewarm, and get ready as many broth-plates as you will require to hold it;

put a sheet of paper into each plate, grease the paper if you want it to come off. Then take a stick and stir your sugar, work it on the side of the pan until it turns white or "greasy," as confectioners term it, then empty it into your plates and allow it to cool. To make flour candy add half a pound of peas-meal before you commence to stir it. But it will not need to be quite so high boiled if you are to add the flour; do not add the flour before you boil it unless you want it to boil on the fire; and before you take a second boiling be careful to wash all the flour out of your pan. Mr. Hewitt advises the use of salt, but salt will not kill the grain of the sugar so well as cream of tartar, and unless the grain is properly killed bees carry a lot of the large grains of sugar out and it is lost. In using these cakes all you have to do is to lift the quilt and place one on the top of the bars, or with skeps set them on top with a hole cut to let the bees get at it. I sell a large quantity of it to bee-keepers here, and have used little else for the past four years. Last September I took all the honey from a stock covering twenty-eight Woodbury bars, and gave it 27 lbs. of tablet at three times, two cakes 4½ lbs. each time, and in spring it was very strong and only needed 2 lbs. of cake.

I am convinced that if the above tablet is made as I have directed, it is only to be tried to bring it into general use. Putting it on the top of bars in autumn serves two purposes—viz., for food, and as a passage for the bees from one comb to another, and that in the warmest part of the hive.—JAS. SADDLER, 31, East High Street, Forfar.

P.S.—No honey here this year yet, top swarms starving.—(*British Bee Journal*.)

TRADE CATALOGUES RECEIVED.

W. Cutbush & Son, Highgate, London, and Barnet, Herts.—*Catalogue of Bulbs*.

Harrison & Sons, Leicester.—*List of Bulbs*.

Louis de Smet, Ledeburg-lez-Gand, Belgium.—*Supplement to the General Catalogue*.

B. S. Williams, Upper Holloway, London.—*Bulb Catalogue*.

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Bulbs (illustrated)*.

W. Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Bulbs (illustrated)*.

Joseph Schwartz, Route de Vienne, Lyon, France.—*Catalogue of Roses*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (*F. F., Euston Road*).—There is no work published on the subject you mention. (*T. D.*)—Our "Garden Manual," price 1s. 6d., post free 1s. 9d., we think answers to your description of being "cheap, comprehensive, concise, and practical." (*Windsor*).—A new edition of the "Fruit Manual" is in preparation, and will be published as soon as possible. (*La France*).—As a "large and complete" work on the subject, "Vines and Vine Culture" by Mr. Barron surpasses all others, and can be had from this office, price 10s., 10s. 6d. post free.

American Blackberries (*Rosarian*).—The Parsley-leaved Bramble that has been mentioned approvingly in the Journal is one of the best we have seen. This is not the time for procuring plants, and those who have them for sale will act wisely by advertising them during the planting season. We never recommend dealers.

"Jeregabseybacki" (*A. H.*).—We do not know a plant bearing the above name, but it resembles some of the native names of the Japanese Maples, of which numbers have been imported of recent years, and one firm sends them out under the native titles.

Leaves for Skeletonising (*Elgie*).—One or two of the specimens you require would not be readily obtained in the manner you suggest. We will first see what we can do in the matter, and you shall hear from us in the course of a week or two.

Parnassia palustris (*W. M. B.*).—This plant is a native of Great Britain and Europe, being found in bogs and damp positions, and is often cultivated in gardens for its simple beauty and its structural interest. There are five stamens, and alternate with them are five nectaries, flattened and fan-like in form, fringed with small filaments having globular heads. Its structure has puzzled botanists, some having assigned it a position in Droseraceæ, others in Violaceæ, and still others in Saxifragaceæ. It is popularly termed Grass of Parnassus, and is fabled to have originated on Mount Parnassus.

Asters (*J. S.*).—The flowers you have sent are very handsome on account of the clear and rich colours. In this respect they are highly satisfactory and a credit to your seedsman. The plant in the pot is admirably grown. The cut blooms are quite up to the average as usually grown in gardens, but they lack the size and fulness requisite for staging successfully at good exhibitions. For producing magnificent blooms Asters should be planted, like Celery, in well-manured trenches, and be similarly treated as regards watering and supporting with liquid manure.

Myrtle Rust and Fungus on Sycamore Leaves (*C., Malvern*).—The Sycamore leaves are affected with a fungus that is very common, and is known as *Rhytisma acerinum*. It invariably forms large black spots on the upper surface of the leaf like ink blots, and these are regularly and numerous distributed on the leaves. The Myrtle rust is also a fungus (*Capnodium Footii*), which often grows on matter excreted by insects, but sometimes on the leaves themselves.

Productive Pea (*C. B.*).—There is such a bewildering variety of Peas that it is utterly impossible for anyone to name a sample such as you have sent. The only means of determining the name of a variety is by examining it in a growing state in comparison with others. We will endeavour to ripen some of the seed and grow the Pea with the object of ascertaining its name next year. It is evidently a very useful variety, and we have not often seen finer examples grown in light soil.

Tacsonia Van-Volxemi (*C. D.*).—Your plant appears to have made good progress, and flowers could not be expected this year under the circumstances. You may take off the points of the shoots if they have extended as far as you desire, and then, the growths being trained thinly—that is, fully exposed to the sun, will mature and probably produce flowering sprays next year. This plant is a rampant grower, and not suitable for a very small greenhouse. It soon covers a roof densely, and when flowering freely a very handsome effect is produced.

Azaleas (*Idem*).—In a light well-ventilated greenhouse the plants mature and set their buds freely. They also ripen and set them in the open air; but in very hot weather, such as prevails at present, a light shade, such as a screen of hexagon netting, is advantageous. It is also of great importance that the pots be shaded, or the sun will burn the hair-like roots. The soil must always be moist, great care being taken that worms do not enter the pots, and the plants should be freely syringed every afternoon when the sun is declining. The night dews will be very refreshing to the plants. When the buds are set they may be felt by pressing the tips of the growths with the finger and thumb.

Dahlia Leaves Eaten (*Lancashire*).—The leaves you have sent denote that your plants are being attacked with earwigs, which often, when not molested, commit great damage amongst Dahlias, occasionally ruining the plants. The insects feed chiefly at night, and lurk in obscure haunts during the day. If you provide them with hiding places you will probably be able to reduce the number considerably. We know of no better plan than placing a little hay or moss in small flower pots, and inverting the pots on the stakes that support the plants, and laying them near the stems. We have caught thousands of earwigs in a day on examining the traps so provided every morning, and if the insects are shaken into boiling water they are killed instantaneously and painlessly. Hollow Bean stakes are also employed for entrapping the pests.

Vines not Thriving (*M. T.*).—We have carefully examined the roots you have sent and find no trace of the phylloxera, nor do we think the stubborn condition of the Vines is the cause of any insects on the roots. The soil does not appear to be of the best character for Vines, at least that adhering to the roots is of a light, soft, and effete nature, and the manure that has been intermixed has excited a little fungoid growth, but not by any means to a serious extent. Recently planted Vines occasionally assume a "rusty" appearance, and growth ceases. It does not appear easy to account for this, and the cause can only be determined by a close examination of all the circumstances that influence the condition of the Vines. We have known Vines thus affected when partially cut down produce fresh and healthy lateral growths, and eventually form good canes.

Slow-combustion Boiler (*A. J. S.*).—Were we to publish your letter you would be more bewildered than instructed by the conflicting replies it would be certain to evoke—that is, if we published the whole of them, and we know from past experience we should be unable to do so. You do not mention the particular apparatus to which you allude. All furnaces consume fuel slowly when the draught is excluded from the fire, and are then slow-combustion furnaces. The manufacturers of all boilers of repute will send lists of testimonials to applicants, who are thus placed in a position to write to the individuals who have had experience with the boilers in question for any particulars that may be required.

Inarching Vines (*A. J.*).—You say the Muscat Vines are not satisfactory and you desire to retain them as stocks on which to graft or inarch other varieties. You can do this in the spring provided the stocks are healthy and make free and good growth. The Muscat, and especially in an inside border, is a good stock; in outside borders in localities where the rainfall is great it is not so reliable. The condition of the Vines must be your sole guide in deciding on grafting or removal. If they are satisfactory in this respect we should retain them as stocks, otherwise we should plant young Vines.

Inside and Outside Vine Borders (*Idem*).—We receive no questions that are more difficult to answer satisfactorily than such as the one before us on this subject. You have neither stated the age of your Vines, the length of the rods and roof, nor the depth and character of the inside border, all of which are important elements in the case; but even with this knowledge our difficulties would not vanish, as so much depends on the skill of the

cultivator. Some persons can grow Grapes admirably with the roots of the Vines wholly inside the house, others fail to do so. Amateurs, as a rule, do not succeed so well as when the roots have access to an outside border. Such persons do not always judge accurately when to apply water and how much to give; in fact, their engagements do not always enable them to attend to the Vines in the right manner and at the right time. When this is the case it is the safest to make provision for the roots outside the house as well as in. If there is soil outside they will generally find their way into it whether it is suitable or not, even if they force their way through the seams of the brickwork, as we have known them do in many instances; with the wall on arches they are sure to pass through, if there is even a gravel walk for them to take possession of. Perhaps some of the roots of your Vines are outside now. If this is so, and the soil is not suitable, you will not err in improving it, as you will have evidence that they are not altogether satisfied with the border inside the house. If you require further information, and will supply us with such data as we have indicated, we will endeavour to aid you.

Datura Stramonium (*J. Smith*).—The plant is occasionally found wild in Britain, having escaped from the gardens, and its habitat is generally among rubbish and on dunghills. It is easily known by its large oval seed-vessels, thickly covered with stout sharp spines. The whole plant has a disagreeable, nauseous, and heavy odour, particularly when bruised, and an acrid bitter taste. It loses much of its odour by drying, but retains its properties. When taken internally in moderate doses it causes numbness, vertigo, dimness of vision, dilation of the pupils, produces a slight delirium, intoxication, and forgetfulness, and these effects pass off in five or six hours; but if the quantity taken be large, then all the symptoms of poisoning are presented, as heartburn, intense thirst, a feeling of strangulation, delirium, madness, convulsive movements, and paralysis; congestion of the brain ensues, symptoms of inflammation are manifested, and death follows in twelve or fifteen hours. M. Orfila states that Stramonium acts with more force on the brain than Belladonna, and produces more furious delirium. Stramonium smoked like tobacco is a popular remedy for the cure of asthma. Its use in this way has been derived from the East Indies, where other species are used for this purpose. It is the root and lower parts of the stem which are so employed, and the smoke excites a sense of heat in the chest, followed by copious expectoration, and sometimes attended with temporary vertigo and drowsiness. The seeds have the same nauseous bitter taste as the leaves, and in them Brandes discovered an alkaline principle, called Daturia, combined with an excess of malic acid. It is in the form of colourless crystals, inodorous, and when first applied to the tongue is bitterish, but afterwards of the taste of tobacco; its action is poisonous.

Woodlice in Mushroom Bed (*W. B. B.*).—Your only safe plan is to entrap the pests. There are various ways of destroying them, the most wholesale plan being to place some pieces of boiled potatoes near to the places they infest and cover with a little hay, and in the morning pour boiling water over the hay, so that the baits must be laid where no injury will accrue to the Mushrooms by the scalding water. Another plan is to wrap a boiled potato in a little hay very lightly, and place in a flower pot laid on its side near to where the woodlice congregate or commit their depredations, and the following morning shake the pests from the hay, in which they will be secreted about the bait, into a bucket of boiling water. Repeat for a time, and the pests will be reduced so as to do very little injury. Parsnips boiled nearly soft, cut into slices, and dressed with arsenic form deadly baits. These, if placed where the insects abound, will reduce their numbers considerably. It is, of course, necessary to so place the poisonous baits that no accident can possibly arise by their misuse.

Second Growths of Fruit Trees (*G. J. E.*).—When trees are pinched early they always, if vigorous, produce second growths, just in the same manner as Vines produce sub-laterals. At once remove the growths by breaking or cutting them off at the first leaf—that is, leaving one leaf at the base of each second growth. They are best removed when a few inches long, as they then snap off with ease, and a good-sized tree can be dressed in a few minutes. When they have attained a considerable length and become hard, as very probably is the case with yours, the knife or pruning shears must be employed in their removal. Where trees are unusually vigorous some good cultivators, instead of cutting off the shoots, give each a violent twist, or partly break them, so that the ends hang down and appropriate a share of the sap, which otherwise would be directed to the base buds, and might induce some of them to start that it is desirable should remain dormant. This is a safe method of procedure, as, so far as we know, it never does harm, but is often decidedly beneficial.

Mushroom Bed not Heating (*P. P.*).—If the manure is of the kind recommended in the treatise, and has been prepared as there described, its non-heating now can only be attributed to its having been made up in too dry a state. This frequently happens during hot weather, such as has been general in most districts. In such a case the remedy is to turn over the bed, well sprinkle the materials, and when fermentation commences make them up again. It is never safe to spawn a bed when the requisite temperature is indicated and the heat is yet rising. The bed should first be allowed to attain its maximum heat, and when this has declined to the proper temperature the spawn should be inserted, and that temperature should be maintained as long as possible by coverings of straw if needed. A strip of border 18 inches wide on the north side of a wall is too narrow for a Mushroom bed, as, except in summer, the material would not be kept warm enough; while in hot weather it would be very likely to become too dry if not in charge of an experienced cultivator.

Analysis of Soil (*W. K.*).—We have examined the soil and considered your letter, and this is our reply. It is not by subjecting soils to chemical analysis that advanced agricultural chemists now-a-days ascertain what manures are necessary. They read the lessons the plants themselves teach—a certain and sure method, which the older plan is not. In testing the value of a manure chemical analysis is of great service; in the case of soils it is different. But it has been ascertained without any doubt that Turnips will not grow without phosphates being present in an easily available form, and that the application of these alone, even in inferior soil, will produce good crops. Your soil without manure grew Turnips, and "immense" ones too; also "large Cabbages." "Immense" Cabbages and Turnips are not

possible in the absence of nitrogen. Without manure good crops of Peas and Beans were produced. Now, without sulphur, lime, and potash being plentiful that would not have occurred. The fact that the Potatoes were poor may prove the soil over-rich, and if the shaws were strong—a circumstance that often occurs accompanied with a poor crop of tubers—you may consider that was the fault of a soil rich enough to grow "large Cabbages." Too much food, even in good Potato land, often has that effect, and heavy clay is not good Potato land. So much for the lessons read us by the crops. Let us now turn to the soil. It is a rather heavy yellow loam on the "rag-stone" formation, and was formerly a Hop garden; red clay is mixed with the rest of the subsoil. Some of the richest soil occurs on the formation you name, and the sample you have sent is good. It is heavy, but a good fruit soil. Such always retain the phosphates and potash applied, besides being rich in such of themselves. The clay that is apparent in the subsoil, and which is also present in the upper soil, perforas this office. The fact of its being yellow indicates that humus is deficient. Whether such land needs manure now depends on the present state of the vegetation. You do not say when the trials of Turnips, Cabbages, &c., without manure were made, nor whether your trees and bushes are vigorous and fruitful or not. If they are not it is probable that nitrogen alone is needed in your case; but the time for applying such, at least when in the form of nitrate of soda or sulphate of ammonia, is in early summer during showery weather. At any other season it will be lost. Peruvian guano is also good, but should be lightly forked-in in spring. These only for trees that are fruitful but not vigorous. If vigorous, but not fruitful, then bones or ground coprolite (and possibly kainit) forked-in in spring will be suitable. But, considering that your soil is yellow loam, ordinary stable manure, which will furnish all these, and humus (the black mould of soils), will probably be best if it can be had really good for from 7s. 6d. to 10s. per ton, according to quality and distance. This should be well made and very lightly forked-in in spring. Without more data we cannot give you a more precise answer, but we know that with such soil as the sample you have sent us there ought to be no difficulty in growing healthy fruit trees and good crops of fruit when the seasons are favourable.

Names of Fruit (E. F. B.).—The red Apple is the Red Astrachan; the green unripe specimen is not known. (G. E.).—1, Cellini; 2, Lord Suffield; 3, Ecklinville Seedling; 4, Tower of Glamis; 5, Beauty of Kent; 6, Kerry Pippin. (Colville Broune).—1, Red Astrachan; 2, Irish Peach; 3, not recognisable. By having been placed loosely in a basket without any packing material the fruits were bruised almost beyond identification. The Apple sent subsequently to the above is Gravenstein. No post-office order has been received from you, and you have not sent your address.

Names of Plants (H. Mayer, Bavaria).—The plant is Parnassia palustris, a member of the natural order Saxifragaceæ. See reply above. (R. O.).—Cattleya crispa. (Agent).—Centaurea ragusina. (J. Smith).—1, Malope trifida; 2, Datura Stramonium; see reply above. The Potatoes we cannot undertake to name, as the varieties have now become so numerous that it is impossible to determine them without comparison with a large collection. (Dr. Mackenzie).—It is a fine form of Phlox Drummondii Leopoldina, very richly coloured.

Brood in Hives—Uniting Stocks (G. C.).—Your hives will not be free of brood so long as the bees find a good supply of honey, which will be till the end of the Heather season or the Ivy has done blooming where it is plentiful. Your best plan will be to drive at once or as soon as you bring them from the Heather. Select the youngest and best-shaped queens (the old queens always go with first swarms of the season, and young ones in after swarms) to place at the head of the colonies, and unite at once. Cut out the portions of brood in old combs and arrange them carefully in supers, so that the bees can get amongst them, and place them over the crown holes of your hives until the brood is hatched out, when they can be removed and your hives fed up for winter if needed. We cannot recommend dealers.

[Some other letters in hand will be answered next week.]

COVENT GARDEN MARKET.—AUGUST 29TH.

BUSINESS remains quiet, the supply of soft fruits being almost over, a good supply of foreign Pears arriving realising high prices.

MOUNTAIN BREEDS OF SHEEP.

(Continued from page 174.)

THE Cheviot sheep to which we have referred are now being used for crossing with other types of mountain sheep, not only in Scotland, but in the northern counties of England. Mr. Dixon, in his prize essay of the Journal of the Royal Agricultural Society of England upon the subject of mountain breeds of sheep, says:—"It is to the Robsons of Belford, who were flourishing when the century began, that the earliest improvement of the Cheviots is generally allowed to be due. Their tups were all bred on the Cheviot ranges, and seventy or eighty of them would sell and let for about £700 when they were marshalled each year in the great barn. It was said that there was a cross from Dishley in the flock, but it was, at all events, with sheep of this blood that the late Mr. Reed left Reed Water on the south side of the Cheviots, to push his fortunes in Sutherlandshire, and drive the Blackface out of the county. We hear of him, as years went on, with 18,000 sheep upon a farm of eighteen miles by eight along the banks of the Helmsdale and Brora, and handing over 2006 three-year-old wethers, and 1500 cast ewes, one September, to a Hawick salesman. In the north of Scotland it is all Heather, and in the south all grass, but the lower range at which Cotton Grass grows on the hills of Sutherlandshire enables the sheep to tide it better over the winter without the aid of mountain hay. The southern Cheviots are thus brought up more artificially, and it seems a question whether tups are quite so hardy and so active in following the ewes; but still all the present prizetakers came out of their ranks, and the northern breeders do not care to meet them in the Highland Society's ring. The most improved type of Cheviots, like Mr. Brydon's—for whose tups between 100 and 200 guineas have been given recently at his biennial Beattock sale—have good Roman-nosed heads, flat crowns covered with hard white hair, and that 'cock of the lug and glint of the eye,' which tell of mettle that will make them hunt the hill for food, and not hang listlessly round the hay hecks after a storm. They have also a fine 'park ranging neck,' rather Leicester-like girth and width between the fore legs, light and elefthy bone, and plenty of wool under the belly as well as on the arms and thighs. A good fore arm, or 'butcher's grip,' is as great a point as white legs and a black nose."

This quotation is from an essay written in 1866, since which time this breed has greatly extended itself throughout the mountains of Scotland—some of which reach to 2658 feet above the level of the sea—and in many instances has supplanted the Blackfaced sheep; but the change has only been partially advantageous, the latter being somewhat hardier and more capable of subsisting on heathy pasturage. Still they are a hardy race, well suited for their native pastures, bearing with comparative impunity the storms of winter, and thriving well on poor keep. Though less hardy than the Blackfaced Heath sheep of Scotland, yet they are more profitable as regards their feeding, making more flesh on an equal portion of food, and making it quicker. They have white faces and legs, open countenances, lively eyes, and hornless. The ears are large and somewhat singular, and there is much space between the eyes and ears; the carcass is long, the back straight, the shoulders rather light, the ribs circular, and the quarters good. The legs are small in the bone and covered with wool as well as all the body, with the exception of the face. The Cheviot wether is fit for the butcher at three years old, and averages from 12 to 18 lbs. per quarter. In the hands of some of the best breeders and feeders they make sufficient weight for the trade in six or eight months, but earlier after having been artificially fed; the mutton is, however, of good quality, though inferior to the Southdown, and of less flavour than the Blackfaced.

The "Blackfaced Heath sheep," is a very peculiar breed, inhabiting the lofty but barren and heathy hills which extend from Derbyshire on the south to the confines of Scotland, through the counties of Cumberland, Lancashire, Westmoreland, and Yorkshire. This range of highlands is a tract much exposed to the winds on either side, and this, with the poverty of the soil, permits only a hardy race of animals to live and thrive. Though this is its native locality, the breed has for many years consider-

ably extended itself through the Highlands and mountains of Scotland, penetrating also to the Orkney and Zetland Islands, where it has to a great extent displaced the original and more inferior breeds. "This breed of sheep," observes Professor Low, "possesses characters which distinguish it from any other in the British Islands. It is of the smaller races of sheep with respect to the weight at which it arrives, but is larger and more robust than the Zetland, the Welsh, and the ancient soft-woolled sheep which it displaced. The male and female have horns, very large and spirally twisted in the male, but sometimes disappearing in the female. The limbs are lengthy and muscular, but the shoulders are not so low as in the Welsh breed, nor are the posterior limbs so long. The face and legs are black, and there is a tendency to this colour in the fleece; but there is no tendency to the brown or russet colour which distinguishes the older fine-woolled races. The fur is shaggy and the wool coarse, in which respect it differs from that of all the other mountain breeds of the country. It is of medium length, and weighs about 3 lbs. the fleece when washed. The sheep are very hardy, and capable of subsisting on the coarsest Heaths." They do not, however, like the sheep of Wales, prefer the summits of the mountains, but feed wherever pasturage can be obtained; nor are they so nice in the choice of herbage as the South Downs, Merinos, and other races peculiar to countries yielding the finer grasses. But although wild and singular in their habits they are not so restless as the mountain sheep of Wales and other districts, but can be induced to remain in enclosures when sufficient food is supplied to them. We have brought them from Perthshire into more southern latitudes and milder climates. They remained quiet under ordinary shepherding within the hurdles. They have also made good weights for age and size; but with respect to the quality of their mutton, they have certainly lost their venison flavour, so predominant when taken from their native districts.

The ordinary weight of the wethers, when killed at the age of about four years, is 15 lbs. per quarter, but they will frequently exceed this when fed and fattened with artificials in the same manner as the long-woolled sheep are fed in some of the enclosed arable lands, and getting also a full quantity of roots and hay in addition, but especially when they have been fed in this way from an early age, they have, in such cases, been known to reach very much heavier weights. Although the mutton is not so delicate as that of the Welsh breed or the South Downs of England, yet it is more juicy, has more of the venison taste, and is preferred to every other kind by those who have become accustomed to it. It is this mutton which is principally consumed in all the larger towns of Scotland. An important property of this breed is adaptation to a country of Heaths, in which respect it excels all others. It is this property, as much as its hardiness, that has rendered it so suitable to the heathy mountains, where it is acclimatised, and where it finds subsistence beyond the ordinary range of other sheep. The animals feed on the loftiest mountains, up to the very verge where the Heaths give place to other plants of the higher latitudes. Feeding much on the shoots of Heaths, they also find subsistence in the times of frost and snow better than any other breed to be found in the kingdom. The mothers are hardy nurses, and are able to bring up their lambs even when they themselves have been exposed to severe privations. Sometimes lambs of this breed are born with short fine wool. It may, therefore, be possible to establish a short and fine-woolled type in place of the present coarse-woolled variety.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are now principally engaged in carting the crops to stack and barn; the former is now, however, the most prevalent practice, because if the stack or stacks are made in the field where grown, or near to it, the labour saved at the important and busy period of harvest is great. In the early districts the crops of Oats, Barley, and Wheat have been stacked in good condition, and the best practice is now considered to be, both as regards the stacking and threshing, to build the stack round and in pairs, so that both may be threshed without a removal of the threshing machine. It is also an advantage to build the stacks of a size which can be built and topped up in half a day in anticipation of adverse weather, for in the building of large stacks, if rain occurs when the rick is only half built, more or less injury is sure to be done to both straw and grain. A favourable time has lately occurred for cutting and making into hay the second growth of Clover and Grasses. We have made some good hay of the second growth of Clover and Italian Rye Grass, and have also ploughed under for manure in preparation for Wheat another portion of the mixed grasses, and it will be important to ascertain the result whether that ploughed in proves equally or more valuable than the hay crop if sold with all its attendant expenses and risks. The ploughing-in of Clover of the second growth is by no means a new idea, for in certain districts it has been in use for many years for some lands, especially

those situated at a considerable distance from the homestead and the manure made therein; it has, however, fallen into disuse, especially on farms where a large number of sheep are kept, and has been revived particularly by those farmers who hold the opinion that sheep do not pay when compared with the growth of a large acreage of sale crops, grown under a system of artificial manuring, accompanied by the ploughing-in of green or root crops as manure.

Hand Labour.—On many and various large farms in the eastern and north-eastern corn-growing districts of the kingdom hand labour has undergone a considerable change and revolution; for instead of paying the men by the acre by a money payment with other allowances for beer or cider, it has now become more customary to pay the men, especially where all the improvements in a reaping and self-binding machine are available, but particularly on the largest farms and occupations, by letting everything connected with the harvest work at fixed prices per acre—such as so much for cutting, tying, stacking, raking, in fact every kind of work including thatching the ricks, and allowing the men free use of the farmer's horses, waggons, reaping machines, horse rakes, and other implements as part of the contract. The advantages to both farmer and the labourers are considerable, and will be found in a great degree by expeditious transfer of the crops to barns or stacks, for loading the grain on to waggons, carting it, and building into ricks, can be performed in nearly half the time usually required when the men are on day pay, more particularly when we consider that the men are not so tractable under orders or such willing workers on day work as formerly, nor will they do so good a day's work for a day's pay. It is, therefore, almost compulsory to have an arrangement with the harvest labourers in which their own interest guides them in their undertaking. Hoeing the root crops must not be neglected, and to save some of them from becoming stunted in growth they may be dragged across the drills, or, what is better, use the horse hoe across the drills, setting the shares at such a distance as may leave plenty of plants, so that they can be easily singled as hand labour by women or lads, and thus secure their continuous growth.

Live Stock.—Cattle are still dear, also sheep, and we know various persons who from their experience find that at such figures as now prevail sheep do not pay sufficient profit for feeding, and they are now asking themselves a very proper question—If they do not pay why should we keep them? can we not dispose of our roots for the dairy cows, fattening bullocks, &c., and plough in the residue for manuring the land? At the same time the fact of sheep-breeders keeping sheep to manure the land chiefly ought to induce them to consider whether manure cannot be obtained or purchased cheaper than sheep can furnish it under a system which, if it does not lead to profit, must be commercially wrong from every point of view. All the cold meadow lands under the influence of the late hot weather will yield grass most abundantly for the dairy cows and store cattle. Swine now will be required on many farms to run in the stubbles, Bean and Pea eddishes, where they will get a fair living for a short time, especially if on their return to the farmyard for their night lodging they get some nourishing liquid or ripe roots, such as Cabbage and Carrots, but the all-important point to be considered is, Have we got for the purpose the best and largest breed of pigs as the stock of the farm? Many farmers are satisfied with the small white, the Sussex, or other small breeds, but our own practice tells us that the large white Yorkshire in cross-breeding with the Berkshire are much the most profitable, as yielding the greatest weight for age.

OUR LETTER BOX.

Seeds for Foreign Birds (A. Henly).—Dry white millet in the husk; also the different varieties of foreign millet, such as Indian, Algerian, and Senegal, are suitable for the smallest ornamental Finches. The larger varieties should be given Canary seed as well as millet. Much information as to birds is to be found in *Poultry*, published weekly at this office, price 1d

REMARKS.

19th.—Fine generally, misty at times.

20th.—Morning fine and bright, afternoon dull and oppressive.

21st.—Warm and close.

22nd.—Hazy in early morning, fine with slight shower in afternoon.

23rd.—Clear, warm, and fine.

24th.—Very fine and warm.

25th.—Fine and warm.

The general clearness of the sky and almost entire absence of rain have led to a very unusually large range of temperature. The difference between the highest and lowest on each day has averaged 24.2°, and on the 20th reached the very large amount of 33.7°. The maxima have averaged 77.3°, which is higher than in any other week of this or last year.—G. J. SYMONS.

FIRM SOIL FOR VINES AND FRUIT TREES.

A SENTENCE in the letter of "J. W. R." on page 181 last week relative to the roots of Vines penetrating the carriage-drive-like floor of a large vinery at Clapham is not without significance. It will be in the recollection of not a few readers of this Journal that there was a time when it was considered little short of a crime to set a foot on a Vine border. If a spout needed cleaning out boards must be laid down for walking on even if a mile had to be traversed for obtaining them. During a rainy day, when the surface of the carefully dug border was "podgy," the precaution was wise; but the prohibition against stepping on the soil was not confined to wet weather; it was a rule that was applicable to all circumstances—a rigid, inflexible, almost sacred rule, and to ignore or forget it was to court opprobrium if not dismissal on the part of the unfortunate transgressor. Ranking now as an old practitioner rather than as a young student in the art of gardening, it is not to be expected that I am enamoured of every "new fangled" notion. Many of the old fashions and methods of culture are as good as the new, and some of them better; but the time-honoured practice of systematically digging Vine and fruit tree borders cannot be defended on either philosophical or practical grounds, and yet the custom in question is by no means obsolete.

Some time ago a gentleman came to me with the Journal in his hand to express his astonishment that the Editor should permit such an exaggerated statement to appear as was contained in a sentence having reference to the Vine borders at Clovenfords, in which it was intimated that they could not be firmer if a regiment of soldiers had been exercising in the house. That was putting the case strongly no doubt, yet it was not stronger than the example first alluded to in these notes, and there is no reason to question the substantial accuracy of either of the descriptions. Many persons must have visited the Tweed Vineyards since last September, and it would be easy for some of them to have corrected any inaccurate expression relative to the character of the borders; yet no one, neither visitor nor employé, so far as I have seen, has attempted to controvert the "exaggerated statement" that the Editor "permitted to appear." It will be similarly easy for any of the many gardeners near London who are non-believers in the virtues of firm soil for Vines to judge for themselves as to the correctness of the comparison of the interior of the vinery of Mr. Wallis with a carriage drive. It is sometimes well to adduce bold, even extreme, examples as proof of the soundness of a principle that it is sought to enforce, as mere commonplace statements often fail to arrest attention.

Firm soil for Vine borders and fruit trees is sound in principle. If it were not so, what becomes of the practice which all competent writers advocate, and all good gardeners pursue, of potting Vines for fruiting, Peach trees, Fig trees, and Strawberries, firmly if not hard? It may be urged that this is incumbent because of the limited quantity of soil, and

that it is imperative to press as much as possible in the circumscribed space at disposal. Granted, yet Vines, trees, and Strawberries thrive under the treatment, and thus show that the firmness of the compost is the reverse of injurious. This may be regarded as negative evidence, and hence not conclusive. Then try the positive. Pot a Vine firmly in a 10-inch pot and another lightly in a 15-inch; afford a Peach or Fig tree a bushel of soil pressed firmly, and give a corresponding tree a bushel used lightly; place a Strawberry plant in a 6-inch pot and make the soil round its roots nearly as hard as a board, and another plant in a 9-inch pot with the soil as loose as if potting a Balsam; and in all these cases note the result of the experiments. In every instance the advantages will be seen of firm potting. But something besides firm soil and pure water may have contributed to the results. Certainly it may, and if the cultivator did not afford the aid he perceived was needed, he would not be worthy of his calling; but—and here is the point—give whatever he might to the lightly potted examples, they would not be similarly good.

The very fact of firm soil lessening the necessity of using so much compost is in itself advantageous, because economical, and if this is so in pot culture it is equally so in border-formation. As a rule Vine and fruit tree borders are made needlessly large, because unreasonably light. They involve both an undue expenditure of labour and waste of material. What is the use of food if it is not consumed? It is quite certain that a vast quantity of food in large loose Vine and fruit tree borders is never appropriated. "What then becomes of it. Surely the roots of the Vines and trees will find it some time!" is a question that may possibly, if not probably, be asked. The roots never will find it. First, because much of it is certainly washed away; and, secondly, because loose soil is never permeated with fibrous roots that are essentially health-giving and fruit-producing in character.

For the multiplication of fibrous roots there must be a resisting medium. An examination of the roots of the Vines, trees, and Strawberries above alluded to will show this. Examine those in light soil, and a limited number will be very apparent radiating from the centre straight to the pot; the great bulk of the soil in the interior will be for a long-time unoccupied with fibres, and in the meantime the virtues of the soil are being washed away. It is not until the roots reach the hard sides of the pot that they materially increase in number—that is, produce fibres for absorbing nutriment from the soil for the support of the plants. In time several of these small foraging roots will no doubt find their way into the centre of the soil, but they always appear to leave the pot reluctantly. This is chiefly because in the interior there is not the necessary resisting medium for inducing their multiplication, but partly because much of the food they are seeking has passed through the drainage, the natural result of the frequent applications of water that are necessary for keeping loose soil moist. In firm soil the roots are very different in character. By the obstruction they meet they are divided and subdivided at every point of extension, and the entire bulk of soil becomes netted with fibres that with their million mouths gather the food that is distributed through the soil, and the Vine, tree, or plant is proportionately benefited. They have, in fact, appropriated the virtues of the soil instead of their having been washed away, firm soil not requiring half the quantity of water that a loose mass does, and consequently the latter escapes the rinsing process to which the former is perforce subjected.

Thirty years ago I was taught that the reason of there being so many more shoots near the sides of the pot than in the interior of the soil was because they fed on the air that reached them through the pores of the earthenware, and that consequently the pots should be soft and clean. That they should be clean I admit, but that the material should be soft (that is, rough and very porous) I deny. I have, in fact, outlived the air notion entirely. The whole theory is exploded by the simple fact that the roots of trees and plants in glazed

pots and in zinc vessels are precisely the same as in ordinary pots as regards their increase and multiplication when they reach the resisting medium of the barrier which surrounds them.

The aim of the cultivator should be the production of the greatest possible number of fibres. They should be induced to form an interlacing network and penetrate every portion of the soil. This desideratum cannot be attained without firmness and moisture. In a loose medium, no matter how rich in plant food it may be, strong fleshy roots will extend in a straight line through it, leaving the bulk of the food behind and between them. Having met with no resistance they practically make no fibres, and the growth corresponds with the roots, being "fat," long-jointed, pithy, sappy, and fruitless in character. The effect of a resisting medium in the soil may be illustrated by driving a jet of water through a syringe not having a perforated nozzle. Fill the cylinder, apply the pressure, and the water escapes in a straight smooth line, and is not divided until it strikes an object of greater resisting power than itself; but impede the outflow of water by the obstruction of the finger, and the stream is divided into a thousand points and an infinitely greater surface is covered in a moment. Every young gardener knows this, and he may also do well to remember that by a proper resisting medium in the soil fibrous roots are similarly increased, and not much food will be left behind and between them.

But in making firm borders it is of the greatest possible importance that the soil be in the right condition of moisture when used. To pack wet soil closely together would be fatal; for, just in proportion to its wetness will be the absence of air, and without air, moist air, in the soil, there can be no free root-extension nor satisfactory growth. Similarly, to trample on a loose border when the surface is wet with the object of making it firm would be a serious error, for what air the soil contained would be driven out of it by compression. It is only when soil is sufficiently dry that it will not adhere to the feet that it can be firmed with advantage, and then the benefit resulting is often very great indeed. If it were not so the system of rolling even strong land would not be adopted by intelligent and successful farmers in preparation for their crops. The condition of the soil for border-making should, as regards moisture, be exactly the same as that which a skilful cultivator would use in potting either Vines, fruit trees, Roses, Chrysanthemums, Pelargoniums, or any plants of a free-growing yet more or less woody nature, and he would pot them firmly. He would then secure the maximum number of fibres, and, by giving food as needed, would attain success, whereas if he potted lightly and loosely he would fail. Pots as small as possible, firm soil, and attentive care in applying support when it is needed, are the chief elements of success in plant culture; and smaller, firmer, and better managed borders for Vines and fruit trees would result in a saving of labour and material, and hence of money, while the returns would be better than under the greater outlay misapplied in making large, deep, loose borders, and keeping them loose by digging them systematically.

A more precise guide relative to the requisite degree of firmness of the soil may perhaps be required by some reader. Any old pasture will afford the information. Dig up a portion the size of the spade and 3 inches deep, examine its texture, and in ninety-nine cases out of a hundred it will be found not too firm for trees and Vines. Yet how many borders are as firm as this? They are few, yet where they exist in conjunction with otherwise good management fruitful trees, healthy Vines, and excellent Grapes are almost invariably found.

One of the most important points in the good management alluded to consists in keeping the borders uniformly moist. Surface roots, which are the best roots, cannot be insured if the soil is not firm, also moist, where the roots are required. It is absolutely futile and utterly unreasonable to expect roots to form near the surface of a frequently dug

border that is exposed to the sun during hot dry weather; and it is impossible that the surface of such a border can be kept moist without mulching. That is a truth that is not yet sufficiently impressed on the minds of half the persons in this country who are endeavouring to grow Grapes in a satisfactory manner. Let them consider well this subject, comprehend fully the conditions of and influences surrounding each case, and by intelligent action they may yet succeed where they have hitherto failed in the attainment of their object.

A word may be necessary in explanation of what is meant by "small" borders. With soil medium to strong in texture and reasonably compressed a border 3 feet wide and 2 feet deep is quite sufficient for newly planted Vines the first year, while a less bulk of soil—that is, a border 6 inches less in depth—will be ample for one or two-year-trained Peach trees. But these narrow borders must be mulched in summer so that the surface and edge do not become dry. Regular and uniform moisture being secured—and nothing can be easier than to secure it—these small firm borders will lay a better foundation for good Vines and trees than a rich loose feeding ground of four times the size can do that is dug and dried in the orthodox manner by many amateurs and not a few gardeners; yet not the best of them, as these proceed in a more rational manner such as I have endeavoured to describe.—A NORTHERN GARDENER.

A NEW GARDEN.

THE KITCHEN GARDEN.

MAKING a new garden is one of the apparently easy things "which anybody can do," for at the first glance what can appear more simple? Can the laying-out of a plot of ground for the cultivation of vegetables possibly require much thought or skill? Look at the market gardens of London or of any large town. What are they? Just so many fields in a high state of cultivation—nothing more, and yet what abundant crops of excellent vegetables do they yield! Such reasoning, however, is by no means applicable to private gardens, for they have literally to be made in the fullest sense of the word—frequently upon land altogether unsuitable for the purpose both in soil and situation; and when space is so limited as to admit of no choice there is, of course, nothing to be done but to make the best of things and adapt our plans to circumstances as well as may be. Such an unsatisfactory state of affairs often occurs when a new house is built in a position selected only with an eye to the picturesque. The site is commanding, the scenery lovely, the air pure. What more can be required?

It has fallen to the writer's lot to be engaged for many years in the laying-out of new gardens and in the alteration and extension of old ones, and it is purposed in this and subsequent papers to turn the experience so gained to account for the benefit of readers of the *Journal*, by setting forth in clear detail the general features of the work, the difficulties which occur, and how they may be overcome or avoided. It is by no means intended to imply that new gardens are only required for new houses; but as the building of a country house invariably involves the making of a garden, and in order that these papers may be as comprehensive and useful as possible, it will be well to turn our attention first of all to the selection of

The Site.—In low-lying flat districts turf, timber, and water are the chief features of such scenery as can be commanded by the windows of a house, consequently the position of the garden is easily decided; but in a hilly country, such for example as we find in Sussex, Derbyshire, and Cornwall, abounding in rich scenery spreading far and wide, overlooked by many a sunny slope and breezy hilltop, much caution and sound judgment must be exercised in the selection of a site if we would avoid the subsequent annoyance and vexatious expense so often experienced when due care has not been taken beforehand. The natural advantages, therefore, which we would endeavour to secure in addition to an elevated position commanding fine scenery, or shelter from dangerous cross winds (the cruel cold north-eastern blasts so fatal in spring to tender blossom and foliage, and the tempestuous south-western gales to which no tree laden with fruit nor tender growth can be exposed with impunity), an abundant supply of pure water, and a fertile soil. Not simply from timber would we try to obtain shelter, but rather from hills clothed with timber, precisely such as so frequently occur at the head of a valley. Under such favourable conditions we would have house and garden both on a sunny southern slope sufficiently low down for shelter from behind, and also from the valley slopes on either hand, and yet high enough

to enjoy air and scenery fully. To dwellers in the lowlands a position so snug and so highly favoured in natural advantages may appear merely an ideal one, but it is not so. Living amidst the Sussex hills I could point to similar nooks that are well known by the dozen, and which, strange to say, have been overlooked by builders of many pretentious villas which are perched in elevated positions exposed to every wind that blows, simply for the scenery, without a thought of aught else. Nor are the villa builders only at fault, for two large houses of recent construction within a couple of miles of each other might also be pointed to as equally faulty in situation, and the mistake appears all the more glaring from the fact of really good positions being available close by.

Water.—This is generally abundant where hills and valleys abound, but it is not always so. Here on the Hastings Sand formation we have a spring of excellent water high up on the hill full 60 feet above the highest part of the garden, and in one of the

Fig. 35.

 B.—Suction pipe, 11 feet long from bottom of pump, but which may be 28 feet long.
 C.—Delivery pipe, 350 feet long and $1\frac{1}{2}$ inch internal diameter.
 D.—There is a stopcock here on the branch pipe which passes through the wall into the cesspool to empty the delivery pipe when not in use.
 E.—Cock for filling waterpots at pump.

valleys there are actually fifteen springs, each with its tributary rill running into the main stream. In less favoured places water can almost always be obtained from the valley by means of an hydraulic ram, and it cannot therefore be said to so seriously affect the selection of a site as shelter and fertility of soil do. Due provision should, however, be made for an ample supply of water, and when storage has to be resorted to enough water may generally be obtained by putting gutters and pipes to catch the rain water on every part of the houses and outbuildings and convey it to open tanks or ponds—preferably to the latter; for a pond is easily made, and the water may be distributed from it with as much expedition and economy as is possible under the circumstances by a moderate judicious outlay for its conveyance about the garden in the first instance. The primitive method of taking it from the pond in waterpots can only be done economically for crops growing near it. For the entire garden a somewhat expensive, but undoubtedly the best, plan is to fix a force pump by the side of the pond to throw the water into a cistern sufficiently elevated for it to flow thence through a pipe to one or more cocks or hydrants fixed at the most convenient points

of the garden; and if leather hose with the requisite unions and jet is provided for watering, the apparatus will be complete.

A much less expensive arrangement of a force pump and pipe, which has been in use here for several years for throwing up house sewage from a cesspool to the kitchen garden, is shown in fig. 35, and is, of course, equally applicable to a pond of water, for the suction pipe below the pump may be bent so as to rest upon the pond bottom and be continued to the deepest water. Particular attention must be given to the position of the pump, which should always be at the side of the cesspool or pond, so as to lessen as much as possible the labour of lifting the water through the pump and suction pipe. The pump in use here lifts the sewage vertically 14 feet, and forces it through a $1\frac{1}{2}$ -inch pipe 350 feet long to a height of 16 feet above D, fig. 35, where it falls into an open cistern. One man can do this so easily as to leave no doubt that the sewage might, if necessary, be forced to a longer distance and much greater height if necessary. Sewage being wanted occasionally for plants growing close by the pump, a hole was drilled at E, and an ordinary stopcock screwed into it answered the purpose admirably.

A, fig. 36, part of a transverse section of a pond with a raised bank, is given to show how by turning to account the excavated soil for raising the sides of the pond above the common level of the surrounding surface, the work of excavation and consequently the cost of the pond may be materially lessened. Due care must, however, be taken to make the puddle well, and to take it down well below the ground line, E, which usually proves the weak point of raised ponds. If the pond rests upon a loose substratum of shattered rock, gravel, sand, or chalk, the puddled clay must be continued as shown at D, so as to form an artificial bottom so thoroughly worked and kneaded together as to be absolutely impervious to water.—EDWARD LUCKHURST.

(To be continued.)

SEASONABLE NOTES ON CHRYSANTHEMUMS.

Most of the buds will now be taken to secure large flowers. Those taken the first week in the present month will be about as large as small peas; these plants will require a top-dressing as I have before directed in this Journal. I use an admixture of rather heavy loam and half-decayed fowl manure. About a third of an inch of this is spread on the surface of the soil in each pot. The roots very soon take possession of this dressing, and in a week they appear quite through it, especially in dull or showery weather. In watering the top-dressed plants a rose should be used for the first two or three applications to settle the soil firmly on the surface. Where fowl manure is not obtainable sheep manure is a good substitute. Some use cow manure, which I think is too cold; it also has an untidy appearance when plastered over and about the tops of the pots; this is often done, nevertheless, in the south. Amies' manure has a marked effect when used as a top-dressing, as also has Clay's Fertiliser; these are obtainable when the others sometimes are out of reach.

Fig. 36.

- A.—Surface of pond.
 B.—Pond bank raised above the common level, E.
 C.—Puddled clay.
 D.—Additional puddled clay at the bottom of the pond when it is on gravel, sand, or chalk.
 E.—Surface of land surrounding pond bank.

Some growers prefer guano, but in my opinion it should not be used until the end of October or first week in November. Another good fertiliser is clear soot water. Where flowers are wanted to be forwarded, if this is used twice or three times a week moderately strong with the dressing I advised above, the buds will swell with marvellous rapidity. The dressing should be repeated at the latter end of September.

For trained specimens I find Clay's Fertiliser invaluable. These plants are difficult to dress with anything more than can

be administered by the thumb and finger or the watering can. A small dressing of Clay's may be given once a week until the buds are a good size. I then add a small portion of guano at each dressing, which answers admirably for foliage and flower. A change of Standen's manure is very good about the middle of October. This improves the colour and development of the flowers.

Large-flowering plants should be raised on inverted flower pots or anything that is available, so that the pots can be made secure after being placed there, as the wind has great power upon plants raised in this way. Why I recommend this practice is in order that the plants can have all the air possible. This is a good preventive of mildew, which always shows itself on the foliage nearest the soil. When it appears means must be promptly adopted to stop its progress. Sulphur or soot (which I prefer) are both good, but the latter disfigures the plants.

Insects will now be troublesome, especially earwigs. I know of no preventive. The only way to keep these pests down is to examine the plants very carefully early in the morning and kill all the insects that can be found. Aphides will not be so numerous now as they were a month or six weeks earlier. Tobacco powder or snuff are good remedies, also cigar or tobacco ashes.—
GROWER AND EXHIBITOR.

CULTIVATION OF RASPBERRIES.

WHEN well grown it is questionable if any small fruits are more remunerative than Raspberries, and none can be produced with less labour providing the ground is suitable. A heavy crop of fine fruit is certain to be obtained from well-grown canes, as they come into flower late in the season and are consequently safe from spring frosts. Nevertheless, in spite of the freedom with which the Raspberry fruits under the negligent systems of cultivation, it is in most cases worse treated than other small fruits, as may be seen by the poor appearance of plantations in many gardens.

The Raspberry thrives best in what may be termed an intermediate soil—neither too light nor too heavy; yet on light as well as on heavy soil the canes, by good management, attain a height of 10 feet and fruit abundantly. To achieve success the first consideration of importance is to make light soil heavier and heavy soil lighter. This can be done by adding a moderate percentage of clay to the former, and coal ashes, coarse sand, or other gritty material to the latter. The best system of incorporating clay with light soil is to reduce it to powder, which can only be accomplished by drying it either in the sun or by artificial means, and then store the powdered clay until the ground is ready for trenching. It can then be worked into the ground as evenly as possible as the work of trenching proceeds, and then the whole turned back again, thus finishing where the first trench was opened. This entails nearly double the labour, but the mixing is thoroughly done and the foundation for success laid. During the second turning a liberal quantity of manure should also be worked into the ground. Heavy ground can be worked in a similar manner with the materials advised.

Planting should be done early in autumn where practicable, after the young canes have turned brown and before the foliage falls, and then secured to the wires or stakes to be employed for training them to. When planting is deferred until after the foliage has fallen, the young canes should be pruned back to within 8 inches of the ground, which will prevent them producing fruit the first season, and moderately strong growths will be the result, which the second year will bear an average crop of fruit. It is a great mistake to allow canes to carry fruit the first season they are planted, which they naturally will do if left their full length, the result being puny growths and a small crop of inferior fruit the second year.

After planting, a good layer of clay should be scattered on the soil between the rows to become pulverised by the action of the weather, and when dry in spring it will crumble to pieces, and should then be forked into the surface soil at the first opportunity. I prefer planting in rows about 1 foot from root to root, and the rows about 8 feet apart. This is a greater distance than generally given, but if they grow strongly they would be better 2 feet further apart. I am convinced nothing is gained by planting too closely, and thus have double the quantity of rows on the same space. On the contrary, one good row fully exposed to light and air will produce equally as much fruit as two rows planted closely. The row exposed to light and air will fruit abundantly down to the base, but crowded canes will not do so.

I prefer, for the purpose of training the canes, to have three moderately strong wires running lengthways of the rows, and supported at each end with angle irons secured into stone and supported with an iron stay. Upright iron bearers can be used along the rows at intervals to support the wires and keep them straight. The angle irons should stand at the least 5 feet 6 inches out of the ground.

The top wire of the three should be as near the top as possible, the lowest 18 inches from the ground, and the middle one at even distance between the two. The canes, when secured to this trellis, have a neat appearance, and when substantially erected it gives no further trouble for some years.

Attention is needed during the early summer months, and especially at the present time or immediately the fruit has been gathered. Early in the season, after the young growths have fairly started, some of the weakest should be thinned out instead of being allowed to crowd the row until late summer. These should not be thinned too severely, but a third more canes than are required to be retained at pruning time may be left, and then cut down close to the ground, and from these the following season strong canes will be produced. At this season of the year all the old fruiting canes should be removed, and those for next season's fruiting secured to the wires, so that every opportunity will be given for ripening the wood thoroughly. Shorten the canes to the desired height as soon as all fear of the lower buds bursting is past. I do this while the foliage is quite green; in fact, the necessary pruning is accomplished when in this stage, except the few canes to be removed, and this is done directly the foliage commences falling. By carrying out a system of early pruning the buds are plumped from the base to the top, and the canes in consequence fruit freely near the ground. This feature is most prominent especially with those that have ample room from row to row. I may add the canes are left 1 foot above the top wire, making them 6 feet 6 inches high.

Pruning and tying are completed early before the weather is severe or cold, and then at the first opportunity the annual dressing of manure is wheeled on and spread between the rows, in which condition we prefer to leave it. Digging amongst Raspberries cannot be too strongly condemned, as it injures numbers of roots, which are always near the surface. Often for the sake of appearance this has to be done, and in cases of this description the manure employed should be short and pricked in as lightly as possible with forks.

The Raspberries here grow on light land, and were very unsatisfactory when I took charge of them; but by giving them the treatment detailed they have attained great size and bear heavy crops of large fruits. I may add I have found an occasional application of lime very beneficial. The variety grown is Prince of Wales.—
WM. BARDNEY.

GARDEN CHEMISTRY.

SULPHUR.

SULPHUR is one of the essential elements. Without its presence in the soil plants could not grow, nor albuminoid be formed. It is always present in plants as sulphuric trioxide, and in their ash as sulphuric anhydride. For long it has been applied in Germany and in America in the form of gypsum, generally with benefit; but the accounts of most of the experiments, especially the American ones, are very conflicting. In this country the use of gypsum has not produced results equal to what it is reported to have done in the countries named, and when it has succeeded abroad it is not always because of the sulphur afforded, but the lime. In France, Ville makes gypsum take an important place in what he calls normal manure, but not with the idea of furnishing sulphur: it is to furnish lime. Gypsum (calcic sulphate) is readily soluble, calcic carbonate not so, hence M. Ville rejects the carbonate for the sulphate. It is to be regretted that he did not try them pitched against each other, and then the value of the sulphur would have been seen, for calcic carbonate is soluble enough in ordinary soils.

Peas, Beans, and Clover generally benefit from applications of calcic sulphate, yet sulphur is not largely present in the ash of Beans or Peas. One hundred parts of the ash of common Beans contain only from 1.3 to 2.4 of sulphuric anhydride (SO₃), and that of French Beans from 1.5 to 3.9. Peas contain from 4 to 5 per cent., Clover from 1 to 2.5. This is very little compared with the phosphoric acid and potash in their ash.

Turnips and Cabbages have at times been largely benefited by the use of calcic sulphate, and Messrs. Lawes and Gilbert have told how much the Clover crop increased by its use, as well as with sulphate of soda, magnesia, and potash. The ash of Swedes yields 10 per cent. of sulphuric, and of common Turnips as much as 20 per cent. In such a case one can understand how sulphates have a favourable effect on the Turnip crop, and can well believe that, sometimes at least, the favourable effect of superphosphate, in which calcic sulphate is largely present, is partly owing to the sulphur at the disposal of the crop as much as to the solubility of the phosphates, especially when we find insoluble phosphates giving equal results to soluble when ammonia sulphate is given along with it—nitrogen in equal quantities being supplied to both. The ash of Cabbages contains from 10 to over 20 per cent. of sulphuric acid, and in most mem-

bers of the Brassica family it is largely present. As members of this family are largely grown in gardens, much more so than in the fields, and as common stable manure as well as most other manures contain sulphuric acid in but trifling quantities, some 0.1 per cent. (at most 3.5 in the ash of), there is reason for believing that the use of sulphates in the garden would be beneficial.

In the form of gypsum (plaster of Paris) and salt-eake, or sodic sulphate, it is to be had cheaply, and also as sulphate of magnesia and Epsom salts; but when sulphate of ammonia is used to supply nitrogen, or superphosphate to furnish phosphoric acid, or gas lime to furnish lime, there will be no need to go into the market for gypsum. On a plot of Cauliflowers and Cabbages, as against an equal quantity of ordinary lime, gas lime, with us, gave much better results even when ordinary manure was liberally supplied. On poor ground to Savoys, Brussels Sprouts, and Swedes its effect was even more marked still, and one could tell at a considerable distance that something extra had been applied across one end of the plot containing our winter Brassicas. In ordinary lime sulphur is present, but generally in quantities too small to be worth noticing. In gas lime the sulphite, sulphide, oxysulphide, and hyposulphide are present to the extent of from 20 to 30 per cent. in addition to from 4 to 5 of sulphur. These all in time become sulphate, but only after some months' exposure. Applied at cropping time, gas lime kills; applied in October or November to land not to be cropped till spring, it feeds. It should always be applied very sparingly—not over half a ton an acre.

Sulphur exists in soil chiefly as calcic sulphate, and occasionally as magnesian sulphate. As calcic sulphate is not retained by soils, but is washed out by rains, heavy dressings are a mistake, and soils are generally deficient in sulphur. Even in calcareous soils little more than traces are to be found, and seldom as much as 0.5 per cent.

Not unfrequently the floras of irrigated meadows will be found largely composed of plants which are favourably influenced by sulphates. This is owing to the presence of calcic, sodic, and magnesian sulphates in the water. The water of the Trent contains not less than 21 grains per gallon of calcic sulphate, the Dunne Canal nearly 4, the South Esk 1, the Severn $\frac{1}{2}$, Loch Katrine 0.64, St. Mary's Loch 0.81, Ben Rhydding nearly 3, the Critchmere (Surrey) 1.07, and the Punchbowl (Surrey) 0.590. At London Bridge at high tide $4\frac{1}{2}$ grains per gallon have been detected. When such waters are used for irrigation purposes in the field or in the garden, more sulphur is supplied than is needed. In what are known as mineral waters sulphur is much more largely present, but we have given examples of what is common everywhere. For instance, 191 grains of sulphuric acid are in every gallon of the saline water of Purdon, N. Wilts. This is an extreme case, but most spring waters contain a good deal. From the clay slate 2 to 4, and the Muschel chalk 1 to 2 per cent. is present. Calcic sulphate is present in the waters of Bath, Buxton, and Bristol, and also sodic sulphate to a lesser extent. In a pound of Kilburn water 18 grains of sodic sulphate and 13 of calcic are present; 7 per cent. of magnesian sulphate is present in the chalybeate waters of Melrose. Sulphates are present in sea water. Strangely enough there are only traces in the intensely saline waters of the Dead Sea.

IRON.

In the majority of garden plants iron does not exist in large quantities. Ferric oxide is seldom present in their ashes in larger amounts than 1 or 2 per cent. An exception is found in Cabbage leaves; when in the ash it exists to the extent of 8 per cent., but possibly not always. It is generally present in greatest quantities in fruits. In the ash of Strawberries 11.12 per cent. of the phosphate has been found, and in that of the Orleans Plum 7.45. In Spinach 8.37 per cent., in Onion stalks 10.61, and in Kidney Beans 5.24 is present, at least sometimes, but these are quite exceptional cases.

Iron is regarded as an essential element of plant food. It is always found in them, and when absent in the soil the resulting plants are sickly. Under such conditions very weak solutions of copperas (ferric sulphate) have produced good effects according to Professor Johnson. We have heard of Roses being benefited by applications of iron salts, but no scientific experiments that we know of have been conducted to prove its value when artificially applied. Iron salts turn Hydrangeas blue, and white Hyacinths red.

Iron is present in sufficient quantities in ordinary manure, and is being continually added to the soil by the waste of tools. Naturally it exists in plenty in very nearly all soils, with the exception of pure quartz sands, which are sterile at any rate. In not a few it is too plentiful, and appears as red oxide in

ordinary soils, and as black in black bands. In cultivated soils phosphate of iron is present. Wherever phosphates are applied, even in the ordinary form or as bones and stableyard manure, iron phosphates form sooner or later. The soluble phosphate in superphosphate speedily takes this form in soils where iron oxide abounds. This salt is very insoluble, but some plants have the power of appropriating it. Potatoes and the Leguminosæ do so. Turnips and the Brassica tribe generally do not.

In addition to furnishing plants with food, ferric oxide has the property of "fixing" phosphoric acid, potash, ammonia, a property possessed by alumina, and humus.

CHLORINE.

Chlorine is found in all plants, but whether it is essential or not is disputed. It is used in the form of sodic and potassic chlorides. The first of these is always present in greater quantity than is wanted in ordinary manure, but as it is very soluble, and is not retained by soils, rains wash it out. It thus happens in inland situations that it is often deficient. Near the sea, however, chlorides are always present in the rain. At Cirencester it is calculated that the amount gained by the soil from the rain amounts to 53 lbs. per annum, at Rothamstead 22, and at Penicuik near Edinburgh no less than 640 lbs. per acre.

SODA.

This is not regarded as essential by the more forward of modern agricultural chemists. As to its supply, what we have said in regard to chlorine applies to soda, for in common salt the two are joined. Essential or not, common salt often has a beneficial effect on many crops. In inland situations on poor soils we have never seen it fail to tell on Cabbages, and for Asparagus its good effects are well known. It certainly furnishes food to plants, for although it is true that plants may be grown in soils containing no soda, though plants will not grow in soil containing no potash; yet, as a matter of fact, the very much cheaper soda will at least partially replace potash. For instance, *Salsola tragus*, according to M. De Gasparin in the "Cours d'Agriculture," in the valley of the Rhone contains no soda, potash alone being present. The same plant between Frontignan and Aignes Mort is used as a source of soda. In ordinary soils the common Ice Plant, *Mesembryanthemum crystallinum*, is covered with glands filled with oxalate of potash. In Teneriffe and near the sea in France this oxalate disappears, and sodic oxalate takes its place.

With the exception of the Mangold, which contains quite a large amount of soda in its composition, and is decidedly benefited by applications of common salt, garden crops use much more soda than field crops. While cereal crops remove no more than from 3 to 5 lbs. per acre in the crops, Cabbages and others of the same order take up fully ten times as much. Salt is a very cheap manure, and a few experiments will soon show whether a crop is the better for it. When its application is beneficial it will have the same effect as an extra amount of ordinary manure. Along with other salts common salt has the property of rendering otherwise insoluble matters soluble. Whether this is a benefit, as it is usually regarded, may be doubted. It may contribute to the loss from the soil of valuable phosphates.

SILICA.

This is held to be a non-essential by most scientists, although M. Georges Ville maintains the opposite, plants grown in calcined sand by him failing when supplied with it in a soluble form. Sachs grew Maize—decidedly a silica plant—without silica, yet it perfected its growth. Oats and Buckwheat have also been grown in perfect health without its aid, and Pierre has shown that the weakness in the straw, attributed to the want of silica, is due to other causes.

Silica is mostly found in endogenous plants, such as the cereals and grasses. In them it is found on the outside of the plant, covering the straw or the husks of seeds. In these positions it certainly looks as if it were an excretion when we consider the peculiar anatomy of endogens. In the *Equisetæ* it occurs in the same way as in the grains. In the "Pottery Tree" of Para—actually used for making pottery—as much as 77 per cent. occurs in the bark of old branches. It is absent from the grass which grows in peat bogs. In exogens it is chiefly found as a deposit inside the older cells of stems. They are present rather as incrustations than as part of the cells proper, and so may, even in such positions, be regarded as excretions. In trees it is most abundant in the bark and the older leaves.

Silica is most probably taken up in the form of silicates of potash. Evidently the cereals and grasses are endowed with a special capacity of attacking these silicates. When they are

present it is not necessary to give potash. Few garden crops possess this power—hence little silica is found, either as a part of them or as an excretion in or on them. For this reason an application of potassic chloride or sulphate may tell effectively when applied to many garden soils, and yet have little effect on cereals in the same soil.

Silica is abundantly present in all soils and in all ordinary manures. It is not, therefore, necessary to trouble about its application.

MANGANESE, &c.

Very little is known about the part taken by this metal in vegetation. In most plants mere traces are found, although in one instance as much as 11 per cent. was found in Beech ashes. Professor Johnson mentions that "gardeners mix it with the soil to improve Roses;" but in what way they are improved we cannot say.

Aluminium has been found in Lycopods by Professor Church, but is seldom present in ordinary plants.

Fluorine is found in the teeth of animals which derive their nutriment from plants. Iodine is extracted from certain seaweeds, and is occasionally detected in garden plants, but only in the merest traces.

Bromine, copper, lead, lithium, cesium, and rubidium are also occasionally to be found in plants, but it is supposed that their presence is an accident. Among the matters which plants must get in the soil nitrogen ranks first, phosphorus next, then potash, lime, and magnesia. In what order we rank chlorine, soda, silica, manganese, &c., does not greatly matter. Possibly they are here placed in their proper order.—SINGLE-HANDED.

SOWING ANNUALS.

THE present is a good time to sow a few seeds of some of the better class of annuals, such as the Cornflower, *Schizanthus pinnatus*, Sweet Scabious, &c., for conservatory use in the spring. The seed pots should be placed in a cold frame, and as soon as the plants are up they should be pricked off singly into small 60-pots and kept close for a few days; afterwards gradually expose them to full sun and air. When 2 or 3 inches high pinch out the points to make the plants bushy. When the small pots are filled with roots give the plants a shift into 4 or 5-inch pots. Winter in a dry airy pit free from frost, or, better still, in a cool greenhouse. Annuals treated in this way amply repay the labour bestowed upon them. A few plants of *Chrysanthemum coronarium* grown in the same way will also be found very useful.—E. B.

COLOURING OF GRAPES.

AT page 91 of your present volume "Dunedin," who is evidently a careful observer, mentions a fact, "that one grower, the intense colour of whose black Grapes is the admiration of all who see them, puts himself to much trouble to keep the air of his vineries moist while the Grapes are finishing. . . . but it is only the black Grapes which are thus brought to perfection. White Grapes are never of the golden tint we wish to see."

He goes on to say that "not far off in the same locality is another grower, by no means even a fair one, whose black Grapes are never more than rusty, but (and this point is worth noticing) his inferior Muscats . . . inferior—that is, as a crop, and in bunch and berry are generally beautifully golden. He practises extreme dryness. Now, we personally have always had the finest-coloured black Grapes in wet almost sunless seasons, and the worst whites. When dryness and bright sunshine prevailed the whites were better and the blacks worse," and he concludes from this that sunshine and dryness spoil black Grapes, and that shade and moisture spoil white ones.

Now, although your correspondent's observations and conclusions are highly creditable as confined to the small area to which they extend, and we are indebted to him for bringing to the front a subject which has no doubt puzzled others as well as himself, yet if he takes a wider range he will, I think, soon find that his conclusions are not entirely sound. For instance, it is possible to point out certain places where both blacks and whites are finished perfectly and simultaneously under exactly the same treatment, and where the management is such that, although a fine season is preferred and highly appreciated, yet a bad season does not prevent the production of first class fruit of both colours.

"Dunedin" rightly says that "the dry air and dry borders aimed at in finishing black Grapes is a mistake." Most assuredly it is, and I thought such a practice was now obsolete. I will add that it is an equal mistake to have any dry air and dry borders for the finishing of Muscats, and will try to show that your correspondent has put the saddle on the wrong horse.

First, let me say that the effects of damping down a house when it is open and when it is shut are entirely different. Pour a quantity of water down with the ventilators wide open on a bright sunny day,

and you will lower the temperature somewhat and soften the atmosphere considerably. This treatment with Hamburgs, Alicante, Mrs. Pinee, Madresfield Court, and some others which do not require a high temperature during their second swelling will have a beneficial effect whenever the temperature is likely to rise much above 85°.

On the other hand, Muscat of Alexandria, Lady Downe's, and some others which require a high temperature during their second swelling as much as at any time, are not benefited to the same extent by the damping-down unless there is provision made for keeping up the mean temperature somewhat in excess of that required for the first-named class of Grapes.

But it is not the state of the air as to humidity at all which makes the difference observed by "Dunedin." It is the amount of light received by the leaves and fruits. Muscats cannot be coloured in a sunless season except in the lightest and best managed houses. Black Grapes can be coloured in any season, but of course we vary our treatment somewhat to meet the different conditions.

There is not one garden in twenty where Muscats are allowed sufficient room, and consequently they do not get sufficient light. In a hot dry season the light of course penetrates the thicket to some extent, and better coloured fruit is the result, while in a dull season it may often fairly be said that the fruit does not ripen at all. All this, however, is entirely under the control of the cultivator if he has a good house and knows how to use it.

Black Grapes will colour under the densest foliage even in a dull season, but they will not keep as well as those which have been only moderately shaded and have had the wood pretty well ripened.

With regard to the case mentioned by "Dunedin" of the inferior Muscats becoming a beautiful golden colour, he is probably again in error in attributing the colouring to the dryness of the atmosphere. Undersized fruit, provided the foliage is kept healthy, is much easier to colour than large fruit; and undersized fruit generally, too, means undersized leaves, so that the light has a better chance of acting on them.—WM. TAYLOR.

CYANIDE OF POTASSIUM FOR WASP NESTS.

YOUR correspondent "T. W. S.," in mentioning cyanide of potassium as the best thing for taking wasp nests, has certainly spotted the right remedy; but it is by the remarks given made far less convenient than it really is. I have used it for many years, and always with the greatest satisfaction; indeed, only yesterday I submitted it to the severest test I have yet given it, and nothing could be more complete. Indeed, the young lady of the house describing it to a friend said I had sent "hundreds of wasps to rest, the charge of Balaclava being nothing to it," and I daresay many of those noble fellows would have preferred that death ride to my little experience of yesterday.

What I wish to impress on your correspondent, and on all who try the cyanide, is, that it is quite unnecessary to take hours over it—generally half an hour is ample. My plan is to make a strong solution of the cyanide, which your correspondent rightly remarks is most poisonous and needs care in using. I then repair to the nest armed with my bottle and a piece of moistened lint, generally two thicknesses, and the water squeezed out as dry as possible. I treat the wasps as I do the bees—I am as gentle in all my manipulations as possible. Firstly, if necessary, I enlarge the hole with a knife, and then wetting my lint with the solution I take it on a piece of stick, so as not to handle it more than necessary. I place the lint on the lower margin of the entrance hole, so as to form a poisoned alighting board for the wasps. The effect is speedy, each wasp alighting on it either quickly falls on one side or enters the nest never to come out again, for the vapour goes into the hive, and soon the passage is choked. While the wasps are returning home one may notice that none come out, and soon in ordinary cases at the end of fifteen minutes there is absence either of those coming out or going in. When this condition has arrived you may begin to dig out. All the wasps will be found motionless, though here and there some may be sluggishly moving. The nest being dug out it may be put in a pail of water or otherwise broken up.

The nest taken out yesterday was without exception the very largest I have seen—about 15 to 18 inches in length, 12 in breadth, and 9 in depth. It was situated under the tiles of the roof of a bow window. The house being an old one, the cement between the tiles was lacking almost everywhere, and the wasps being particularly numerous I found they used half a dozen apertures. Some of these were stopped up with difficulty, and pieces of lint steeped in the solution were placed at some of the openings; but the points of ingress and egress were so numerous that the progress was very slow, so many of them escaping the lint. It was more than an hour before I found matters sufficiently quiet to allow me to remove one or two of the tiles. The huge nest then showed up beautifully; it occupied the whole space between two of the rafters, and extending under the inner was continued in the space beyond. It was, however, built over the wood supporting the rafters, and, after sawing through three or four of the laths supporting the tiles, I was able to glide a spade along under the nest and lift out the greater portion, which was deposited in a large washing tub. The nest was, however, so large that great numbers of the wasps were alive on the lower portion, the spade having divided the nest. A little more solution dropped on the nest enabled me to get the remainder out and place it in another tub. Float-

ing on the water afterwards there must have been at least a thousand wasps, whilst the sealed brood must have been many thousands.

This nest had been attacked by a mason, who soon beat a precipitate retreat; then a young gentleman in the neighbourhood was going to burn it out, and the rafter was charred in one place, but he too retreated, using forcible language, for which he afterwards apologised; tobacco, sulphur, &c., had been tried, but the looseness of the tiles rendered them useless, but the cyanide was a great success.—Y. B. A. Z.

I HAVE during the whole of this season and also the latter part of last been using powdered cyanide of potassium for this purpose. I find one teaspoonful quite sufficient for effectually killing all the winged members of the strongest nest when placed carefully just inside the passage to the same.

I find all times of the day equally effective, as after having been placed in the mouth about one minute no wasp ever comes out, and all coming in from work after once passing over the powder are quite unable to take wing again.

I consider this the best and cleanest remedy I know at present, although where difficult to apply as described I have used paraffin with equal success.—ROBT. GRINDROD, *Whitfield*.

THE LONDON PARKS.

CROSSING the "silent highway" from the Chelsea Gardens, one of the most popular and beautiful of public London gardens is reached—namely,

BATTERSEA PARK.

The great charms of this establishment are its diversity of aspect and constant freshness. In none of the other metropolitan parks are these features so strongly marked, and in none do we obtain more beautiful landscape effects, though these are entirely artificial and quite unaided by natural characters. It was, indeed, an admirable work to convert a swamp into a picturesque, varied, and lovely park that has yielded pleasure to millions of the great city's toilers, and it is doubly satisfactory to see its attractions maintained in all their power, and even annually increased where opportunities offer. Improvements have been repeatedly effected in recent years; diversified, well-wooded, and considerably elevated mounds have been formed with winding and undulating paths that in several cases, especially at the east side of the park near the Chelsea Bridge Road, command extensive and pleasing views. Close attention, too, has been given to what might be termed the more minute details. Flower beds or borders in previously uninteresting positions in many cases supply agreeable surprises, while the shrubberies have been thinned where necessary to bring some fine specimen into prominence, or planting done where a denser screen was needed, and in hundreds of other ways the observant visitor who is well acquainted with the park may constantly notice a steady advance. The freshness which has been already referred to as one of the charms of this park has been severely tried this season. Turf, trees, and bedding plants have all suffered from the prolonged drought, but the two former especially, as by the liberal use of the hose the beds in the subtropical garden and elsewhere have been kept in good condition. Earlier in the season it appeared at one time as if the bedding would never reach its usual condition, but within the past month there has been a vast improvement. The beds are well filled, the combinations and designs proving in the majority of cases eminently satisfactory.

Entering the park from the west side near the Albert Bridge the visitor can readily inspect the principal features without travelling over the same ground twice, and can either take his leave from the York Road gate, the Chelsea Bridge gate, or the pier. A short distance from the entrance first mentioned will be noticed on the right a series of oblong beds with rounded ends, radiating from a circle in the centre. There are seven ways, and each pair of opposite beds are planted alike, mostly in the mixed style now becoming so popular. *Alyssum variegatum*, *Verbenas*, and *Pelargoniums* form one combination, *Tropæolums*, *Ageratums*, and *Tagetes* another, and *Phlox Drummondii* and *Centaureas* a third, margined respectively with *Pyrethrum Golden Feather*, *Alternanthera versicolor*, and *Iresine Lindeni*, outermost edge in each case being a neatly kept band of *Euonymus radicans*. The borders near the shrubs around this, and extending by the road for some distance, are filled with *Anemone japonica alba* very fine, scarlet *Pentstemons*, *Chrysanthemum frutescens*, and *Calceolaria amplexicaulis*, which have a beautiful effect.

A short distance beyond the above is a refreshment lodge, and around this are several pretty beds, chiefly carpet designs, that well merit attention. One, a chain of three circles, is tastefully planted, a central star of *Alternanthera versicolor* being lined with *Leucophyton Browni*; the angles filled with *Mesembryanthemum cordifolium variegatum*, margined with *Echeverias* and *Sedum acre elegans*. An elliptical mixed bed of *Calceolarias*, *Pelargoniums*, *Abutilons*, and *Heliotropes*, edged with *Lobelias* and *Golden Treasure Fuchsias* pegged down, with *Mesembryanthemum cordifolium*, has a distinct appearance, perhaps the only fault being that rather too many kinds of plants are employed. In mixed beds the most pleasing are those occupied with several varieties of one species, or a few very distinct varieties of different species; when so many are employed a bed has a heterogeneous appearance that is rather objectionable. A carpet circle of simple but striking design is also notable near the above; it consists of a ground of *Golden Feather*, in the centre of which is a design of brightly coloured *Alternanthera amoena*, a series of bands curving outwards and downwards from a main axis; the

bed is margined with *Mentha Pulegium gibraltarica* and *Lobelias*, and is undeniably effective.

A few minutes' walk from this portion of the park brings the visitor to the great feature, the subtropical garden, which has been so well managed for such a number of years that it has gained considerable fame. The position is suited for work of this kind, being sheltered and low, so that the plants are not exposed to the full effects of the sun or wind, either of which prove injurious to tropical or tender plants out of doors in England. Palms, Ferns, *Ficus*, *Grevilleas*, *Solanums* of various kinds, the silvery-leaved *Eucalyptus globulus*, the majestic *Polymnia grandis*, *Wigandia caracasana*, with elegant *Beaucarneas* and *Dracenas*, all assist in imparting a most distinctive aspect to the garden, whether singly or in large beds. The fine clumps of *Polygonum cuspidatum* also have a grand effect, and there is one specimen of a plant or small tree that is rarely seen, but which is eminently fitted for such positions—namely, *Griselinia macrophylla*. This has broad, rounded, thick leaves, resembling some of the *Ficus*, or more nearly the *Clusias*, and as they have a shining dark-green surface it is very telling. In several cases where single specimen Palms are placed out in the turf they are surrounded by small circular borders of miscellaneous or carpet-bedding plants. One of the best of these is a good specimen of *Phoenix reclinata*, around which is a band of the distinct *Begonia ricinifolia*, next to that a band of *Centaureas*, and a margin of *Pyrethrum selaginoides*. The last-named is in better condition there than we have seen it elsewhere: the leaves large, flat, neatly and regularly divided, quite frond-like in appearance, and of a good clear yellow colour. When it does as well as this it is a most desirable plant for the margins of beds. Where large masses of the *Polymnia*, *Wigandia*, or *Eucalyptus* are employed the spaces between the plants are filled chiefly with *Chrysanthemum frutescens*, *Heliotropes*, *Lobelias*, *Pelargoniums*, *Petunias*, and in some instances a few examples of *Agapanthus umbellatus* are introduced. Some fine clumps of single *Dahlias* attract much attention, the colours of the graceful flowers being so brilliant and varied. The silver-variegated *Acer Negundo* is employed as usual with good effect, and a long border next the shrubs of the variegated *Willow Herb*, margined with *Pelargoniums*, has an excellent effect in contrast with the dark-leaved shrubs.

The majority of the carpet beds are in the subtropical garden, and though none is distinguished by any extraordinary novelty of design they are all tasteful, and some are extremely so. A few of the best may be noted to give an idea of the plants employed and combinations most approved. One circle has a ground of *Gibraltar Mint*, with small circles and a central square of *Alternanthera magnifica*, edged with *Leucophyton* and *Stellaria graminea aurea*, the outermost general margin consisting of *Alternanthera aurea* and *Cerastium tomentosum*. Another, also a circle with a ground of the same *Mint*, has a scroll of *Mesembryanthemum cordifolium*, a centre of *Alternanthera versicolor grandis*, a marginal chain of *Alternanthera aurea*, and an edge of *Echeveria pumila* and *Sedum acre elegans*. A trio of beds (a centre circle and two oblongs) near the lake are invariably planted in good taste, and this season they are exceptionally good. The ground is of the *Gibraltar Mint*, on which is a neat but somewhat intricate design in *Alternanthera aurea* with isolated circles of *A. versicolor grandis* and *A. amoena*, with a margin of *Sedum acre elegans*. Several beds are of a composite character—that is, partly carpet and partly subtropical. One of the best of these has a ground of *Lamium maculatum aureum* brightly coloured, with heart-shaped clumps of *Iresine Lindeni* and *Mint*, with Palms, *Agaves*, *Pelargoniums*, and *Centaureas*. An oblong bed of similar character has four circles, the two outer of *Stellaria graminea aurea* and *Dracena marginata*, the two inner of *Sedum acre elegans* and *Beaucarnea recurva*; the centre is *Pandanus Veitchi* on a ground of *Sedum glaucum*, these circles being lined with *Sedum Lydium*, white *Lobelias*, *Spergula pilifera aurea*, *Alternanthera amoena*, *Echeverias*, and *Sedum glaucum*. The Ferr nook is as usual filled with healthy specimens of the most suitable kinds for the purpose, and the long beds a short distance beyond generally planted in the carpet style, are this season of an exceedingly mixed character, but possess the attractions of novelty and diversity.

Many other pleasant walks may be taken, especially that round the east side of the park, where there are some charming Fern dells and good examples of mixed bedding, while nearer the boat-landing stage at the lake are some extremely bright borders of *Calceolarias*, *Zonal Pelargoniums*, *Lobelias*, &c., *Chrysanthemum frutescens* and *C. coronarium* being largely and well employed. Throughout abundant evidence is afforded of Mr. Rogers' careful and efficient system of management, and a horticulturist can never regret a few hours spent in Battersea Park.—L. C.

THE CRYSTAL PALACE FRUIT SHOW.

THIS is the only great Exhibition of fruit that has, as yet, been provided this year in the neighbourhood of London, and there is little doubt it was the finest show of its kind held in this country during the present season. In every respect it far surpassed the Show of last year, which was disappointing; yet in some respects the present display was faulty. Several examples of Grapes, for instance, were not ripe, while others were very inferior and quite unworthy of a place at any show. But such were in a minority, the majority being very good indeed, and not a few excellent. The collections of fruit were admirable, the winning stands superior, and the whole most creditable to the exhibitors. Peaches were extremely fine, and Nectarines good. Plums were sparsely represented, and Pines and Melons were of good average quality. Altogether the Exhibition was one of the best that has been seen at the Palace during recent years, and Mr. Head managed—and this is no small feat—to have all ready in good

time for the Judges, and consequently the public had early admission to criticise and admire what was evidently as great an attraction as the magnificent display of Dahlias in the other transept.

COLLECTIONS.

Liberal provision was made in the schedule for collections of fruit, three classes being devoted to them, in which the prizes ranged from £15 to £2 in value, yet the competition was not so keen as might have been expected, comparatively few exhibitors beyond those named as securing prizes entering the lists. To balance this, however, the quality of most of the fruit in these collections was above the average, and in several cases examples of great excellence were staged. This was particularly noticeable in the case of the Grapes, some bunches of which were in general finish superior to any in the classes devoted to Grapes alone. Peaches and Nectarines, too, were well shown throughout, of good size, and finely coloured. The leading class, and that in which chief interest centred, was for a collection of fruits not less than twenty-four dishes, to contain four dishes of Grapes, three bunches each, two white and two black varieties; three Pines, two Melons, two dishes of Peaches, two of Nectarines, and two of Plums, the remaining dishes to be distinct varieties. Three prizes were offered—namely, £15 as the first, £10 as the second, and £5 as the third; but only two competitors appeared—namely, Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, Ledbury, and Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, who were respectively awarded first and second honours. Mr. Coleman's collection comprised Foster's Seedling and Muscat of Alexandria as the white Grapes, both good, especially the latter, Alicante and Black Hamburg as black Grapes, the last-named being very handsome in size of berry and bunch and in colour; Bellegarde and Violette Hâtive Peaches, large and ripe; Lord Napier and Stanwick Elruge Nectarines, fine; Victory of Bath and Eastnor Castle Melons; well ripened examples of Moorpark Apricots, Magnum Bonum and Kirke's Plums; excellent Williams' Bon Chrétien Pears, Quarrenden Apples, Negro Largo Figs, Morello Cherries, three fine Pines, Strawberries, Gooseberries, Filberts, and Oranges. Mr. Goodacre's fruit was similarly good, but he lost a few points in some of the dishes. Very notable was a grand example of Charlotte Rothschild Pine, large, of fine shape and colour; Smooth Cayenne and Queen Pines were also good. The Muscat Hamburg Grapes were in admirable condition, the colour and bloom perfection; Madresfield Court Grapes were similarly excellent, and Buckland Sweetwater was well ripened. The other principal dishes were Royal George and Barrington Peaches, handsome Violette Hâtive and Pitmaston Orange Nectarines, Williams' Bon Chrétien and Jargonelle Pears, Morello Cherries, Read's Scarlet-flesh and Lockinge Hero Melons, Brown Turkey Figs, Red Astrachan Apples, Moorpark Apricots, Pond's Seedling and Goliath Plums, and Filberts. Both collections were very praiseworthy, and were greatly admired by numerous visitors and horticulturists.

The next important class was for a collection of twelve dishes, to comprise two dishes of Grapes, one Pine, two Melons, but only one dish of the other varieties needed to constitute the requisite number, the prizes being £8, £6, and £4. Of the three competitors, Mr. J. Coomber, gardener to J. H. Rolls, Esq., M.P., The Hendre, Monmouth, deservedly won first honours with a most satisfactory collection of well-ripened fruits; but the leading feature was his three grand bunches of Alnwick Seedling Grapes, which for size of berry, evenness of bunch, colour, and general finish were unsurpassed in the whole Exhibition. The Muscat of Alexandria were not quite so ripe. One bunch was, however, in fine condition. Royal George Peaches and Humboldt Nectarines were of good size and colour, Hemskerk Apricots fine, Jargonelle Pears, Hendre Seedling Melon large and regularly netted, Kirke's Plums, Vicomtesse Héricart de Thury Strawberries, and Smooth Cayenne Pines well ripened. Mr. Goodacre was adjudged the second position, his best dishes being the Madresfield Court Grapes, handsome bunches, and excellent in colour. The Muscats were well ripened, Bellegarde Peaches, Pitmaston Orange Nectarines, Goliath Plums, Williams' Bon Chrétien Pears, and Smooth Cayenne Pine being similarly praiseworthy. Mr. J. Roberts, gardener to the Baroness Rothschild, Gunnersbury Park, Acton, followed closely, having three fine bunches of Madresfield Court Grapes, the berries of great size and bearing good bloom, Belle de Doué Peaches, Red Astrachan Apples, and Williams' Bon Chrétien Pears being other noteworthy dishes.

The third class in this section was provided for a collection of eight dishes, and in this Mr. G. F. Miles, gardener to Lord Carrington, Wycombe Abbey, gained the chief position with beautiful examples of Gros Maroc Grapes of moderate size but well finished, Foster's Seedling Grapes, Elruge Nectarines, Morello Cherries, Victory of Bath Melon, Crawford's Early Peach very handsome in colour and size, and a good Queen Pine. Mr. Elphinstone, gardener to E. M. Munday, Esq., Shipley Hall, Derby, was a close second, his Muscat Hamburg Grapes, Pine Apple Nectarines, and Goliath Plums being the best dishes. Mr. Nash, The Gardens, Badminton, Chippenham, took the third position, perhaps his finest dish being good bunches of Alicante Grapes. The three classes above noted occupied considerable space, and formed a most satisfactory feature of the Exhibition.

GRAPES.

Altogether there was a great display of these. Some of the finest bunches, however, were in the collections of fruit. Mr. Goodacre staged Madresfield Court splendidly, but the most notable examples in the Show were grand bunches of Alnwick Seedling from Mr. Coomber. Mr. Coleman and others above noticed exhibited well.

The principal class was that for ten varieties, six black and four white, two bunches of each. Mr. Roberts of Gunnersbury was the champion, gaining leading honours with a fine collection, comprising the following:—Muscat Hamburg, good colour; Buckland Sweetwater, well ripened; Gros Maroc, large but not quite ripe; White Tokay, fine berries but a trifle green; Madresfield Court, bunch and berries large, colour good; Alicante, fine in bunch but not fully ripe; Muscat of Alexandria; Alnwick Seedling, large bunches; Black Hamburg, fine; and Golden Champion, good. Mr. A. Barker, gardener to Sir H. Allsop, Bart., Hindlip Hall, Worcester, was second with fairly finished examples of Mrs. Pince, Madresfield Court, Alnwick Seedling, Foster's Seedling, Trebbiano, Alicante, Muscat of Alexandria, Gros Colman, and Black Hamburg.

For a collection of five varieties, two white, two bunches of each, the competition was much keener, seven lots being entered. Mr. G. F. Miles was the most successful, being first with Black Hamburg, fine in bunch, berry, and colour; Foster's Seedling, Gros Maroc, Muscat of Alexandria well ripened, and Lady Downe's, good colour. Mr. G. Tucker, gardener to J. L. Lovibond, Esq., Start's Hill, Farnborough, was second, the best Grapes in his collection being Alicante and Madresfield Court. Mr. Woodbridge, The Gardens, Syon House, Brentford, followed; Alnwick Seedling, Alicante, and Muscat of Alexandria being the finest.

Coming to the classes of three bunches Black Hamburgs as usual headed the list, but they were scarcely worthy of the honour on this occasion. Mr. Coleman well won the first position with well-filled 2-lb. bunches and medium-sized and well-finished berries, Mr. Roberts, Gunnersbury Park Gardens, following with smaller bunches, but better berries; third honours going to the veteran cultivator, Mr. Bailey of Shardloes, for small bunches, but berries of good size and quality, cut from a Vine which has produced a crop of 250 similar examples this year. Ten stands of Muscats were staged, but several of the bunches were scarcely finished, and in some the berries were small. Mr. Middleton, gardener to R. Pilkington, Esq., Ranford Hall, St. Helens, secured the first position with good, full, well-shaped bunches and very fine berries, Mr. Woodbridge, Syon House, being an extremely close second with larger bunches and perhaps better finished yet smaller berries, Mr. Coleman being third with excellent produce. There was not great competition in the Gros Colman class, but the examples staged were very good indeed. Mr. Coleman secured the first position with large, full, and fine bunches of admirably coloured and good berries. Mr. Elphinstone, Shipley Hall Gardens, Derby, closely followed with smaller bunches, the berries being of the first size and quality, third honours going to Mr. Tucker for creditable examples.

Thirty bunches of Madresfield Court were placed in competition, but many of them were not ripe, while a few were very small. The first-prize bunches, however, from Mr. Goodacre were splendid in size, shape, and finish; as also were, in size of berry especially, the second-prize examples of Mr. Roberts; Mr. Coleman, who was third, staging smaller but admirably finished produce.

A similar number of Alicantes was staged, and the class was a good one. The first-prize bunches from Mr. Nash were very fine indeed in every respect, and fully merited their position. Mr. Elphinstone followed with smaller examples, but splendidly finished; Mr. Howe, gardener to H. Tait, Esq., Park Hill, Streatham Common, securing the remaining prize with large bunches and good berries, but not equal in finish to the preceding. Mr. Folkes, gardener to J. F. Halsey, Esq., M.P., Great Gaddesden Place, Hemel Hempstead, staged very fine examples, but they had been unfortunately much disfigured in transit; but for this mishap they would presumably have had a place in the prize list.

In the class for white Grapes the result would please Mr. Thomson of Clovenfords, if it pleased no one else; the first and second prizes going to the Duke of Buccleuch and Golden Champion respectively, the third to Buckland Sweetwater. Foster's Seedling and Golden Queen were the remaining varieties in the class. The bunches of "the Duke," staged by Mr. Tucker, were not large, but the berries were very fine, ripe, and clear. They merited the position. Golden Champion, exhibited by Mr. Roberts, was fine both in bunch and berry, but not perfectly ripe. Buckland Sweetwater, staged by Mr. Adams, gardener to H. Trigg, Esq., The Brokes, Reigate Hill, being very good, and if anything overripe. The bunches of Golden Queen, exhibited by Mr. Coomber, were very fine, full, and regular, but we understand were defective in quality, otherwise they would have found a place in the prize list. They were not quite ripe.

PEACHES AND NECTARINES.

As previously remarked the Peaches and Nectarines in the general collection were remarkably fine, and again in the classes specially devoted to them similar excellence was notable, though there were a few dishes of unripe fruits. The principal class for a collection of not less than six dishes of Peaches and the same number of Nectarines, four fruits each, and though prizes of £4, £2, and £1 were offered, only one collection was staged—namely, from Mr. Coleman, who secured the first prize with beautiful fruits of the following Peaches—Prince of Wales, Violette Hâtive, Vanguard, Bellegarde, Galande, Royal George, Exquisite, and Noblesse. The Nectarines were Elruge, Violette Hâtive, Albert Victor, Pine Apple, Lord Napier, and Pitmaston Orange, all of good size and mostly of good colour. Five lots of four dishes of Peaches were staged, Mr. Coleman again securing first honours with Violette Hâtive, Bellegarde, Royal George, and Alexandra Noblesse, very handsome. Mr. Roberts followed, having Belle Beauce in fine condition, and Mr. Coomber was third. A dish of Thames Bank, a fine golden yellow variety, was very notable. Fourteen single dishes of Peaches were contributed. Mr. Blair, gardener to Sir G. M. Middleton, Bart., Shrubland Park, Ipswich, was first with large handsomely coloured fruits of Barrington; Mr. Coleman was second with Bellegarde, equally as fine; and Mr. Nash was third with fine examples of Barrington.

Two classes were appropriated to Nectarines, one for four dishes and the other for single dishes. In the former Mr. Coleman continued his successful career, and gained the first position with Stanwick Elruge, Lord Napier, Albert Victor, and Pitmaston Orange, all beautiful fruits. Mr. Goodacre was a close second, his examples of Violette Hâtive, Elruge, and Pine Apple being very noteworthy. Mr. Hanagan, gardener to R. C. Naylor, Esq., Hooton Hall, Chester, was third, Pitmaston Orange being well shown. Nine competitors entered with single dishes, Mr. Coleman leading with Stanwick Elruge of moderate size but superbly coloured. Mr. Elphinstone took the second place with Elruge; and Mr. Ridout, gardener to T. B. Hayward, Esq., Woodhatch Lodge, Reigate, third with Lord Napier.

PINE APPLES.

These were not largely shown, but the fruits were of fair size and well ripened. The best pair of Queens were from Mr. Bailey, The Gardens, Shardloes, Amersham—fine even fruits. Mr. Goodacre was second with slightly smaller examples. There was no entry in the class for a pair of Smooth Cayenne Pines, but in the Any other variety class Mr. Miles was first with two handsome unnamed fruits somewhat like Black Jamaica.

Mr. Barker second with Charlotte Rothschild, and Mr. Goodacre third with Black Jamaica small but well ripened.

MELONS.

The competition was remarkably keen in the two classes for these, the green-flesh varieties being represented by thirteen fruits, Mr. Goodacre being first with Hero of Lockinge, small, but neat, and excellently ripened. Mr. T. Bailey was placed second with a finely flavoured fruit of Bailey's Green-flesh, which is a very old but excellent variety, and still one of the best in its class. We understand that Mr. Bailey was awarded a Banksian medal by the Royal Horticultural Society for this variety as early as 1827. Mr. Coomber followed with William Tillery. Nine fruits of scarlet-flesh varieties were entered, Mr. Barker leading with Blenheim Orange evenly netted; Mr. Miles was second with Scarlet Hybrid, and Mr. Coomber third with the same variety as the first.

PLUMS.

Only one collection of four red varieties was staged—namely, by Mr. J. Bolton of Sevenoaks, who was awarded the premier prize for good fruits of Cox's Emperor, Victoria, Pond's Seedling, and Prince of Wales. For four yellow and green varieties Messrs. Goodacre; W. Johnstone, gardener to the Marchioness of Camden, Bayham Abbey; and J. Bolton were the prize-takers, the best shown being Magnum Bonum and Washington. Mr. Goodacre had the best four purple varieties—Prince Englebert, Kirke's, Diamond, and Emperor; Mr. Bolton followed with similar varieties.

MISCELLANEOUS.

Prominent amongst the exhibits not in competition were the large collections of Apples from Messrs. Veitch & Sons, Chelsea; Messrs. Paul & Son, Cheshunt; and Messrs. J. Cheal & Son, Crawley, which included a great number of varieties, a total of about four hundred dishes being staged by the three firms. Extra prizes were awarded for each collection, also for the following:—Group of Chrysanthemums from Mr. Davis, Camberwell; Tuberous Begonias, tastefully arranged with Ferns, from Messrs. J. Laing and Co., Forest Hill; collection of Asters and Godetias from Messrs. J. Carter & Co., Forest Hill; a number of spikes of Gladioli from Messrs. Kelway & Son, Langport; Peas, Gooseberries, Currants, and very handsome Frilled Asters from Mr. J. Walker, Thame; Balsams from Messrs. F. & T. Smith, Dulwich; and a fine collection of fruit from Mr. J. Neighbour, Bickley.

AS this year is universally allowed to have produced the best crop of Apples which we have had in this country for many years past, it has occurred to some who are materially interested in fruit culture to take advantage of this opportunity for examining and comparing the numerous varieties that are grown throughout the country. The importance of such a course is apparent to everyone who has watched the progressive development of fruit culture during the last few years, and who are, at the same time, painfully conscious of how little even growers of fruit know of the varieties they possess. Every week, and indeed every day, for months to come, we shall have evidence of this in the numerous packages of fruit that are received at this office to be named and to have some information obtained respecting them. The only way to arrive at a satisfactory solution of the subject is to bring together as many varieties of Apples from all parts as can be obtained, and to have them exhibited in one place, where they can be studied and examined as to their identification and comparative merits. Some progress has already been made in this movement. We hear that Mr. Killick of Langley, an enthusiastic Kentish orchardist; Mr. Bunyard of Maidstone; Mr. John E. Lane of Berkhamsted, and others who have long been engaged in fruit culture, are silently working to promote the desired object, and we sincerely trust that they will find a large accession to their numbers and strength in carrying it out. What is contemplated is to have this great gathering at the Chiswick Garden of the Royal Horticultural Society, and to apply to the Council for the use of the spacious conservatory for the purpose. We feel sure that the Council will afford every facility for carrying out a work of such great importance to the commercial industry of the nation, and no more suitable place could be found for the purpose. Let all who take any interest in fruit culture—and who does not?—give their support to carry out this good work. It may be years before another opportunity occurs, and if we do not seize it when we can many may live to regret the loss of it. All who are willing to unite in carrying out this great pomological project are invited to communicate with Mr. L. Killick, Langley, near Maidstone.

— THE brilliant period of summer-like weather that has prevailed

in the south during the past month was succeeded by a STORM OF GREAT VIOLENCE on Saturday and Sunday last. Many gardens were wrecked. In the district of Sittingbourne and Faversham the damage is very serious indeed. Hundreds of poles of Hops are lying upon the ground, and in the gardens in which the string system is adopted immense numbers of strings have been broken. The Hops, especially in exposed plantations, are terribly "cut up," bruised, and battered, and discolouration is setting in to an alarming extent, the cones turning brown and black. It is, of course, impossible in the case of many gardens to say exactly what the permanent damage will be for two or three days, because the Hops are not yet fully grown out, but those which are "whipped," as it is technically called, or bruised, will become "flyers," unfit for picking. The damage must amount to hundreds of pounds. The fruit orchards present a desolate appearance, the trees having been completely stripped by the wind, and the ground strewn with hundreds of bushels of Apples and Pears. Great injury has been done by the storm to the fruit crops in the market gardens near Twickenham and Isleworth, the ground being strewn with Apples, Pears, and Plums; and from Bridport and Canterbury we learn that thousands of bushels of Apples have been blown down. In some orchards three-fourths of the fruit is spoiled.

— THE total number of bunches of Grapes on the great VINE AT HAMPTON COURT this year is about 1,300, or 130 in excess of last year. In previous years 2,200 bunches have been borne at one time.

— RELATIVE TO DESTROYING THE PHYLLOXERA a Belgian correspondent writes:—"I saw in your last number that at Ashton Court the phylloxera having attacked the Vines these were destroyed, no remedy being known against these dreadful parasites. As you seem to endorse that opinion, allow me to inform your readers that the use of sulpho-carbonate of potash effectually destroys the phylloxera without injuring the Vines. The cost of the ingredient forbids its use on a large scale, but in vineries it can be afforded." [We have not asserted that phylloxera cannot be destroyed; but with Vines so seriously attacked as those in question there was no other proper course to adopt. Some less seriously infested in the same garden were not destroyed, and there is a prospect of their recovering. The sulpho-carbonate of potash remedy was published in our columns a fortnight ago on page 155. We may add that the phylloxera did not reach Ashton Court in any mysterious manner, but we have no authority for stating how it was obtained.]

— MR. JOHN FORBES, Buccleuch Nurseries, Hawick, N.B., sends us a number of flowers of BORDER CARNATIONS, which include several very pretty and useful varieties. They differ considerably in colour, the streaked, flaked, and bizarre varieties comprising some with salmon ground streaked with crimson and rose, others are pink and white, maroon and white, salmon-rose and buff, crimson and yellow, and pink and yellow. The selfs are pink, white, purple, and crimson of many shades; one Picotee-like variety has a heavy rich crimson edge, and is very attractive. The blooms of all are full, but neat and useful for cutting.

— MR. E. BUTTS describes ERIGERON SPECIOSUM as "a first-class plant for the mixed border. It has been in flower with us for nearly three months, and the late flowers are still fresh. It is well worthy the attention of all lovers of hardy plants. In a well-prepared border it grows about 2½ feet high. The flowers are a beautiful mauve colour, and resemble the perennial Aster, but are better in form and much larger. In addition to its good qualities as a border plant it is invaluable for supplying cut flowers, as these will keep fresh for at least a fortnight if occasionally supplied with fresh water."

— MR. W. GIBSON, Superintendent of the Ranelagh Gardens, Chelsea, sends the following particulars in reference to the PENSIONERS' ALLOTMENT GARDENS noted last week in this Journal, page 181:—"There are 144 plots, each 15 feet square, and any of the pensioners who desire to have a plot apply to the Sergeant-Major, and if there is one to spare he has it, or if not he has to wait his turn. A corporal superintends these gardens, and if any man neglects his plot he reports it, and it is taken from him. They are allowed to sell the produce to the public."

— "AT Carbrook, the seat of J. C. Bolton, Esq., M.P. for Stirlingshire, Larbert, N.B.," writes a correspondent, "may be seen some good examples of LEEK AND ONION CULTIVATION. Mr. Glass, the gardener, is well known as one of the first vegetable exhibitors in Scotland, his

Lecks and Onions being always extraordinary. This year he has surpassed himself, if one may judge from appearances, and though he has shown none yet they will likely be heard of ere long. In the same gardens the Grape and Peach houses are very badly situated, being placed in a bog, in fact. In the stokehole is a spring of water largely impregnated with iron. Under these circumstances mildew is a constant enemy, and has constantly to be fought. Dusting with sulphur Mr. Glass finds quite useless for this purpose; but a preparation made by boiling lime and sulphur in water, afterwards decanting the brandy-looking liquid into bottles, using a little in the water with which the trees are syringed, he finds effectual."

— A WILTSHIRE correspondent writes:—"We have recently cut an AUTUMN GIANT CAULIFLOWER 4 feet in circumference. This may possibly be interesting to some of your readers. Such a production however, is quite unfit for a gentleman's table, and at best should be regarded only as a monstrosity."

— THE nineteenth annual Exhibition of the RICKMANSWORTH COTTAGERS' HORTICULTURAL SOCIETY was recently held in the Old Pleasure Grounds, Moor Park, the seat of Lord Ebury, by permission of his lordship, who is President of the Society. The vegetables and fruit shown were of excellent quality and more largely shown than usual, especially Potatoes and Apples, which this year exceed the average.

— RELATIVE to examining THE SUBSOIL OF GARDENS, "F. J." asks "If there is an instrument made something like a carpenter's gouge that could be worked into the soil and take up a sample from 3 or 4 feet deep, for the purpose of seeing whether it is moist enough? It would be much more expeditious than digging a hole."

— THE statistical bulletin of the German Empire reports that the number of persons who cultivated the TOBACCO PLANT IN GERMANY was 215,249, and that the area under cultivation was about 55,000 acres, showing a decrease of 30,000 planters and 13,000 acres on the year 1881. The largest area of land under Tobacco cultivation last year was in the Grand Duchy of Baden (17,000 acres), and then came Prussia (8,200 acres), Bavaria (8,000 acres), Alsace-Lorraine (7,500 acres), and Hesse-Darmstadt (2,400 acres). The total weight of the Tobacco crop when dried was 38,850 tons, as compared with 61,315 tons in 1881, and of this quantity 11,670 tons came from the Grand Duchy of Baden, 9,884 from Prussia, 8,383 from Bavaria, 6,674 from Alsace-Lorraine, and 1,129 from Hesse.

— THE finest specimens of DARLINGTONIA CALIFORNICA to be found in any private collection, or, we almost incline to add, public collection either, is one in the gardens at Mount Merrion, Co. Dublin. In height, size, and breadth of dome its pitchers exceed even those of the famous specimen in the Glasnevin Gardens, and nothing can exceed the health, cleanliness, and vigour of the plant, which numbers, large and small, some score of its marvellous leaf-developments, some of them fully 3 feet high, their tessellated and semi-transparent domes being fully a span or more across. Whatever Mr. Duncan Welsh, the deservedly esteemed and very capable gardener at Mount Merrion, takes in hand he is sure to make it a success, and he is to be congratulated on having been pre-eminently so in his treatment of this, one of the most singular productions of the vegetable kingdom.—(*Irish Farmers' Gazette.*)

— THE result of planting operations in the Government CINCHONA PLANTATIONS IN BENGAL during 1882-83 shows a total of 50,000 trees less than in the returns of 1881-82, which is attributed to the uprooting of a large number of hybrid varieties, and about 160,000 Red Bark trees. The total number of Cinchona trees of all sorts at the close of the year was 4,711,168, and the crop was the largest yet harvested, amounting to 396,980 lbs. of dry bark. The whole of the produce was made over to the factory, except about 41,800 lbs. of bark, which, at the request of the Secretary of State, was sent to London to be there converted into various forms of febrifuge, and returned to this country for trial by the Medical Department.

— THE *Tropical Agriculturist* gives the following respecting BURMESE FRUITS. Every steamer from Moulmein and the south now brings large consignments of Durions to Rangoon. The fruit, the rind of which has a most overpowering and peculiar smell, is in high favour with the Burmese and with many Europeans, and is borne by Durio zibethinus, a member of the family Sterculiaceæ. Another fruit or seed with a still more noxious odour than the Durion finds great favour with

the Burmese, who eat it with their nappi and curries. It is called Tanienthee, and, like the Durion, is just coming into season. I never heard of its having any bad effect on the Burmese, who consider it an excellent tonic, digestive, and appetiser. I have met with some old stagers among Europeans who can stand this fruit too, but their numbers are insignificant compared to the European lovers of Durion. The Mangosteen, too, is brought here in large quantities from Moulmein and the Straits. I never heard of anyone who did not appreciate this cooling and delicious fruit. We have a few trees in some of the gardens here, but they do not thrive well. In Moulmein the Chinese gardeners grow large quantities, and the fruit is very plentiful here at times. In the Burmese times no subject was allowed to own a Durion tree, which was as strict a Government monopoly as the Teak tree is in our own time. Possibly to this fact may be attributed the small number of fruit-bearing Durion trees there are in Rangoon. In the southern districts, which have been under British rule so much longer, they are plentiful enough.

— THE DURION, or CIVET DURION, specially referred to in the above note, is considered one of the most delicious fruits of the Indian Archipelago. At first it is regarded with great repugnance, the foetid odour which it yields being, it is said, almost intolerable; even the rind emits such an offensive smell that in Amboyna it is prohibited by law from being thrown near the public highways. The smell has been compared by some to decaying animal matter, and by others to rotten Onions; but all who have experienced these agree in stating that, when once overcome, the fruit of the Durion is most enticing and delicious. The fruit is as large as a very large Melon, and covered on the outside with soft spines, like the pod of a Chestnut. The eatable part of it is that aril-like substance which contains the kernels, and which most resembles cream or blancmange. It is called duryovon by the natives, who, when they have eaten too much, chew the betel to promote digestion. This fruit is said to be used as a bait to entrap the civet cat, which is very fond of it, and hence its name.

— MR. J. MALLENDER, The Gardens, Hodsock Priory, Worksop, Notts, sends the following record of the WEATHER IN AUGUST—"Amount of sunshine 162.7 hours, being 36 per cent. of possible duration; only one sunless day. Total rainfall, 0.99 inch; rain fell on thirteen days—less rain than in any of the previous eight Augusts. Mean temperature of month, 58.7, being the lowest for several years except 1881. The hottest day was the 26th, 76.0°; coldest day, 24th, 41.2°. Maximum in the sun, 133.3°; minimum on grass, 39.2°. Mean temperature of air at 9 A.M., 60.7°; mean temperature of soil 1 foot deep, 59.5°. Highest reading of barometer on the 23rd, 30.311°; lowest on the 10th, 29.411°. The harvest began generally about the 20th ult. Wasps very numerous, I have destroyed thirty-six nests during the last fortnight within half a mile of these gardens, and still the wasps come."

ROYAL HORTICULTURAL SOCIETY.

CHISWICK, AUGUST 30TH, 1883.

At a meeting of the Fruit and Vegetable Committee, held at Chiswick on the above date, Charles Silverlock, Esq., in the chair, the collections of Tomatoes, Potatoes, and Onions growing in the garden were severally examined, first-class certificates being awarded to the following:—

Tomato Improved Large Orange (Henderson).—Fruits large, round, smooth; deep orange-yellow in colour. Very handsome.

Tomato Chiswick Red.—A selection from General Garfield. Fruits medium-sized, obovate, smooth; deep red. Very productive.

Onion White Globe (Vilmorin).—Bulbs medium size, of a true globular shape, remarkably firm and solid, with a very white silvery skin. Very handsome and distinct.

Potato Welford Park Kidney (Ross).—White kidney, fine handsome shape, clear skin. Excellent cropper.

Potato Beauty of Eydou (Hughes).—Large, oblong, fine clear skin. Very heavy cropper. Fine quality.

Potato Midsummer Kidney (Dean).—Large, long, clear skin. As early as the Ashleaf and with larger tubers. Fine quality.

Potato Snowdrop (Perkins).—Somewhat resembling Snowflake, but of firmer texture, and better colour and quality. An extraordinary cropper.

Potato Clarke's Maincrop (Clarke).—Type of Magnum Bonum. Early. Great cropper and fine quality.

Potato Desideratum (W. Smith).—Long kidney, skin of a dull fawn colour. Moderate cropper. Extra fine quality.

GAILLARDIAS.

THE genus Gaillardia, though small, includes some of our most useful hardy flowers, and it is surprising in how few collections these beautiful plants are cultivated.

G. pulchella, the subject of the accompanying woodcut, is a perennial

of great beauty, and compares favourably with many plants we see used in the flower garden at the present day. It grows from a foot to 18 inches high, with alternate lanceolate leaves; flowers purple and orange yellow, between 2 and 3 inches in diameter, with a dark purplish disk, making an agreeable contrast with the ray florets. *G. pulchella* has a trailing habit, which adds greatly to its usefulness either for the flower garden, herbaceous border, or rockery, and well deserves a place in every collection. A sunny position, where the soil is light and rather dry than otherwise, suits this plant admirably. It is easily raised from seed, and also by root-cuttings. It was cultivated in the Royal Gardens,

seeds. It flowers July and August, and grows about 2 feet high. The flowers are not so large as *G. pulchella*, bright yellow; rays deeply toothed; leaves lanceolate, hairy; stem branched.

G. bicolor is a handsome herbaceous plant with large yellow fragrant flowers, although very variable both in size and colour; flowers May to August; should have a place in every garden.

G. bicolor var. *Drummondii* (*G. Drummondii*, *Hort.*) is a pretty *Gaillardia*, supposed to have been raised in the Botanic Garden, Glasgow, from seed collected by Mr. Drummond at Rio Briazos in Texas in 1833. The leaves are entire or more or less toothed, and differing from all the

Fig. 37.—GAILLARDIA PULCHELLA.

Paris, as long ago as 1784 from seeds brought from Louisiana by Comte d'Effales, flowers from July until October, and is one of the parents of the many hybrids which we sometimes see from continental gardens.

G. aristata, the Awned *Gaillardia*, a native of North America, is a showy herbaceous perennial of comparative easy culture, and very desirable for the herbaceous border. It increases moderately, and a sufficient stock may be obtained by division of the roots in spring, and also by

others in colour of the flower, which are entirely of a reddish purple or sanguineous, unless the tips, which are yellow; ray florets sometimes having a bilabiate corolla; good rockwork plant. *G. bicolor* var. *Drummondii integerrima*, is synonymous with *G. picta* of "Sweet Fl. Gard.," and differs in no respect from the above, except in having quite entire leaves and larger yellow edge to ray florets. Found in Texas, and introduced by Mr. Drummond, 1835. Very pretty.

G. amblyodon, although annual, is very pretty, having large deep red florets deeply cut, and when sown in patches is very effective in the border. The leaves are alternate, lanceolate, serrated.

G. grandiflora, supposed to be hybrid between *G. bicolor* var. *Drummondii* and *G. aristata*, but I am inclined to think *G. pulchella* has had something to do with the parentage. The flowers exceed 4 inches in diameter, and are of the same colour as *G. pulchella*. The leaves are entire.—D.

JUDGING GARDENS AND THEIR PRODUCE.

PERHAPS there is no more difficult question to find a satisfactory reply for than those propounded by "Reader" on p. 111; and as criticism is solicited, or rather suggestions invited, I may be allowed briefly to make some remarks upon the subject that may help exhibitors of gardens to a solution of the frequently perplexing awards. The point to aim at is this—arriving at a satisfactory adjudication which will not only be clear to the adjudicators but carry with it the weight of public opinion. Judges are not infallible, and unless their awards are such as to meet the views of exhibitors, many of whom are as cognisant of the points that ought to guide them in arriving at a decision satisfactory alike to the unsuccessful as to the successful competitors as the judges themselves. It is well to bear this in mind, for many are of opinion that no one knows anything of the law of judging except those within its pale. It must be conceded, however, that there are many skilled cultivators which, though not exhibiting or adjudicating, are, from their extended experience both in growing and seeing produce upon the exhibition table repeatedly, quite capable of forming a sound opinion on the matter. Some persons say that judging is only correct when it meets the approval of the general public. This is hardly accurate, for the general public know little of the merits of plants, flowers, fruits, or vegetables, yet the observant and appreciative visitors at shows somehow seldom fail to see the justice or otherwise of the awards. This is what I think "Reader" desires to make clear—viz., that the awards may convey their meaning—that is, show why such an exhibitor is first and so on, alike to prevent unpleasantness between competitors and to render the awards instructive and contribute to the general good.

Now there are mistakes in judging. The greatest I know is that of the laudable endeavour shown by the committees of local shows to keep down expenses by asking some gardener in the locality to act as judge, who, however competent and impartial, is sure to be charged with partiality if he happen to be at all intimate with any of the competitors. I might go further by stating that none having the patronage of the manse or manor should be selected as censors. The adjudicator ought to be one in no way interested in the result and personally unknown to any of the exhibitors. Perhaps no better judge could be found than one having an insight into the social and domestic life of the cottager, and this would point to a successful exhibitor of a cottage garden in a distant locality being the most likely person to appoint as judge. But as the object of cottage shows is to improve and advance the art of growing plants, fruit, and vegetables, someone that has made a study of the special failings of cottage cultivators, and himself a practical grower of things calculated to contribute to the cottager's benefit and pleasure, would be an admirable adjunct in judging; if, indeed, a better judge could be found. I allude to the country clergymen, most of whom have gardens, and for pecuniary reasons cultivate them so as to contribute in the highest degree to the use and adornment of the household.

The first consideration in judging a cottage garden should be superiority of cultivation, as to excel in this there must be order and thorough cleanliness. Means should be entirely excluded. By this I intend to convey that a cottager with his few shillings a week, and the artisan with his more liberal allowance, should be placed on an equal footing—judge the gardens by their occupants, and not by their size and conveniences for production. The artisan may have a greenhouse and frames for raising plants in spring and wintering them, but the more humble labourer has no such means, and shall he be excluded, because of his means, from having a chance against his more advantageous competitor? By no means. He may show skill in the cultivation of hardy and even common plants to which the other can lay no claim, and to be not more worthy of honour than one who shows but very indifferent skill in the cultivation of tender plants. Another point is this. A garden may be all aglow with *Pelargoniums* and *Calceolarias*, yet very little skill is needed in the cultivation of bedding plants as compared with that of the *Rose*, *Carnation*,

Stocks, *Asters*, and other plants that cost little, and yet are so appropriate for home cheerfulness.

As to "Reader's" query, "Should a flower garden be placed before a kitchen garden, both showing great excellence of cultivation?" is one that meets its answer in the axiom—viz., Use first, then ornament. Still, studying excellence of cultivation, it would rest entirely as to which of the two had the highest marks in point of cultivation. The owner of the flower garden cared nothing for vegetables, and the owner of the vegetable garden set little store by flowers. They may ride their hobbies. If equal in point of merit it ought to go to the vegetable garden, for the simple reason that vegetables are more useful to a cottager than flowers.

In respect of vegetable-judging and the relative value of vegetables, much depends on circumstances and the time of holding the examination. As to circumstances, the cottager may have an allotment, as everyone ought, and he may grow such crops as *Potatoes*, *Beans*, and *Onions* there, so that any comparison of the garden of one who has an allotment and another who has not must be fallacious. It is extremely difficult to do justice in such cases; or, if justice be done, to convince the competitors that it is warranted. *Potatoes* stand first, *Peas* would come next, then *Cauliflowers*, then *Runner Beans*, and following in order, *Onions*, *Carrots*, *Turnips*, *Broad Beans*, and *White Cabbage* ought to rank high from their usefulness, then *Celery* and *Beet*. Those are all in season when judging cottage gardens takes place—viz., in late August and early September. *Red Cabbage* at such time would stand higher than *White* in the estimation of most judges, and *Parsnips* with *Leeks*, as they are winter crops, and not then in season, would bring up the rear. Your correspondent omits mention of either *Ridge Cucumbers* or *Vegetable Marrows*. These ought certainly to follow after *Runner Beans*, and would by many censors be placed next to *Peas*; but I should not be disposed to do so from the great usefulness of the *Cauliflowers* and *Runners* to cottagers. *Dwarf Kidney Beans* from their more delicate flavour stand no chance against *Runners*. To conclude, I may say that a few well-managed fruit trees in a cottage garden ought to carry great weight with a judge, especially if the trees were bush or pyramid of useful kinds of *Plums*, *Pears*, and especially *Apples*.—G. ABBEY.

INTERNATIONAL HORTICULTURAL, FLORICULTURAL, AND FORESTRY EXHIBITION FOR 1884.

I HOPE we are now within measurable distance of this much-desired and long-talked-about Exhibition, judging from the report which appeared a few days ago as to the result of the International Fisheries Exhibition and the proposal made before the Executive Committee by the Chairman, Mr. Birkbeck, that the Commissioners were inclined to try what effect an exhibition of horticulture, floriculture, and forestry would have upon the public of this and other countries who have contributed so much to make the present Exhibition such a gigantic success. In my opinion there cannot be the slightest doubt as to the result if immediate publicity is given first of all that such an Exhibition will take place next year, and that an immediate intimation is given through the press which shall speedily reach all parts of the Continent and the colonies; and, secondly, that the Executive Committee should as early as possible call a meeting of the principal horticulturists in this country, and also invite as many as could attend of our foreign brethren, or in the event of foreign horticulturists not being able to attend, the Commissioners representing the various parts of the world at the Fisheries Exhibition, and who are still in London, might be invited to attend, and through them the idea might be transmitted to their countrymen.

I believe such an Exhibition might be made even more attractive and instructive to the great mass of the people than the Exhibition now being held in the gardens of the Royal Horticultural Society at South Kensington, because it would or could be made to embrace a much greater variety of subjects and an ever-varying change of exhibits from the month of April to November. The whole of the space now occupied by the piscatorial exhibits could be filled by exhibitors with plants, seeds, and all kinds of horticultural implements and appliances, together with the food products of the colonies, &c.

On the 25th of October, 1878, whilst engaged at the great Paris Exhibition, I had the honour of offering to His Royal Highness the Prince of Wales, and Her Majesty's Commissioners for the Exhibition of 1881, some suggestions respecting a proposed Colonial Museum for London (a copy of which I herewith enclose) some of which I respectfully submit might be usefully adopted in connection with the proposed Horticultural Exhibition next year; such, for instance, as an exhibition of grain, seeds, roots, &c., from the colonies and the United Kingdom of Great Britain and Ireland.

I am of opinion that the Exhibition should open about the 15th of April, in order that the Belgian horticulturists should exhibit their marvellous collections of *Azaleas*, &c., whilst splendid collections of *Cyclamens*, *Primulas*, *Auriculas*, &c., would be staged by English growers, and French horticulturists might be induced to exhibit many

of the specialities, both in flowers and vegetables, they cultivate so successfully in the early part of the year. During the month of May grand displays of Roses, Azaleas, Orchids, Pelargoniums, stove, greenhouse, foliage plants, Ferns, Palms, &c., our own countrymen know so well how to cultivate. About this time one of the finest displays ever seen might be made by the market growers, which would be highly attractive to foreign exhibitors as well as the general public. In June the finest display of Rhododendrons could be sent up from Knap Hill, Bagshot, and elsewhere, to be followed in July and August with Pelargoniums, Carnations, and many other well-known favourites. September would furnish a glorious display of Dahlias, Gladiolus, Phlox, Pentstemons, and many other well-known gems so plentiful at that period. October and November, fruits, vegetables, and Chrysanthemums would make an exceedingly attractive display. I have only mentioned a few of the leading objects for exhibition; hundreds of others will naturally occur to the minds of those who may have the compiling of the schedules. I think I have sufficiently indicated what may be done, and have shown in as concise a form as possible how such an Exhibition might be brought to a satisfactory issue by the amalgamation, to some extent, of horticulture, floriculture, and forestry with agriculture.

In order to make the Exhibition still more attractive, and to give greater variety, the aquarium part of the present Exhibition might remain with advantage.

I trust all will join heartily in endeavouring to make this Exhibition worthy of the age we live in, and dispel the opinion too firmly taking root in the minds of continental horticulturists, that Englishmen could not organise and develop a grand international horticultural exhibition, although we have greater means and more facilities than any other nation in the world.

Now that the opportunity is opened to us, with everything pointing to success, we have only to organise our forces and pull together, when success will be assured.—JOHN WILLS.

PROPAGATING BEDDING PLANTS.

As my practice differs slightly in some respects from that recorded by Mr. Ward recently I will briefly refer to the chief points, for the time has now arrived when the propagation of plants for next year's requirements must be taken in hand, at least so far as regards the majority of half-hardy plants. Late-propagated plants, owing to the fact of their not being well established and their growths insufficiently ripened, are generally a source of trouble and disappointment, and are apt to die during the cold, damp, sunless days of midwinter; moreover, they require a certain amount of coddling and more heat than plants which have rooted earlier. It need hardly be said that of some kinds of bedding plants, say a Pelargonium, an early autumn or late summer-propagated plant is worth half a dozen of spring-rooted ones.

Before a cutting is taken the arrangements or plans for next season should as far as possible, and where practicable, be taken into consideration and fully matured. By exercising a little forethought in this respect, and estimating carefully the number of each likely to be required, much space, time, and trouble may be saved. Where work of this kind is done in an unmethodical way there is sure to be confusion.

For many years now Pelargoniums have held the first place amongst plants for the flower garden, and with these I will enter into the more practical part of the subject. Having prepared a good supply of compost, which should consist of three parts finely sifted soil, one part leaf mould, one part sharp sand, and one of dung from an old Mushroom bed, the whole being turned over two or three times, a beginning should be made with the variegated section, taking the tricolors first. These I prefer inserting singly in small pots, giving them a shift into larger ones in the spring. Select cuttings which are fairly well ripened and 3 or 4 inches long, take off the bottom leaves, make a clean cut just below the bottom joint, and press the cutting down in the pot quite firmly. The commoner varieties of bicolors of the silvery and bronzed-leaved sections may be put into 6-inch pots, but for the green-leaved and Zonals I find boxes 18 inches by 14 inches the most convenient to root and winter them in. Stand them outside in the full glare of the sun, and water them overhead occasionally if the weather is very dry and warm when they are first inserted. Each box should be stood on a couple of 3-inch pots to keep them off the ground, which will be a preventive against worms entering the soil, as well as tending to keep the soil in a better condition than would otherwise be the case. In about three weeks or a month they will be rooted and growing, and towards the end of September or the first week in October should be moved to their winter quarters.

Coleuses, Iresines, Verbenas, Ageratums, and Lobelias, with such carpet-bedding plants as Alternantheras and Mesembryanthemums, should be taken in hand next. For these and sundry other tender plants a frame over a half-spent hotbed will be found a convenient place to root them in, and if cold wet nights set in it must not be forgotten to add linings thereto. Much the best plan with these will be to insert them in 6-inch pots, always bearing in mind to use plenty of drainage. Fill the pots with the above-mentioned compost, with a layer of sand on the surface, to within an inch of the top, press it down firmly. Water it, insert the cuttings, and sprinkle them sufficient to settle the sand round them. Until rooted the cuttings must be shaded with mats from bright sunshine, and be daily syringed and ventilated according to the state of the weather. When rooted they must be gradually inured to more air and sun to harden them, thereby better enabling them to pass safely through the winter.

Many other plants used for bedding may be propagated in cold frames; such, for instance, as *Gnaphalium lanatum*, *Leucophyton Brownii*, and *Calceolarias*. The latter should not be inserted before the first week in October. Turf pits or frames 18 inches high at the back and 12 inches in the front are admirable contrivances to root and winter them in; of course they must be covered with ordinary frame lights. Fill the frames nearly half full with partially decayed leaves and litter, tread it down quite firm, and put about 3 inches of soil on the top, finishing off with a layer of sand. In this insert the cuttings 2 inches apart each way, and after having watered them through a fine-rose pot keep the lights close till rooted, when little or no shading will be required. When struck air must be freely admitted on all favourable occasions, at the same time not forgetting to protect with straw or mats in severe weather. *Herniaria glabra*, with most of the Sedums and other hardy plants, should be divided and planted in rows on south borders. Violas are now very popular, and deservedly so, for spring and summer bedding, and may be increased either by cuttings on warm sheltered borders outside or by sowing seed. With some of those mentioned in this paper it is the practice with many gardeners to pot old plants and propagate from them in the spring; and although I have nothing to say in condemnation of this plan, I much prefer propagating again in the spring from autumn-rooted young plants. The latter have certainly in some instances a great advantage over the former, inasmuch as they not unfrequently pass safely through the winter where old plants will not. This is frequently the case with *Alternantheras* and other tender plants.—H. J. H.

NATIONAL DAHLIA SHOW.

THE expectations of the projectors that exhibitors would again come forward to assist in establishing an annual exhibition of Dahlias were fully realised at the Crystal Palace on Saturday last, for the majority of the classes were well filled, the blooms of excellent quality, and the general effect admirable. A pleasing break to the long, necessarily formal, lines of Show and Fancy varieties, was furnished by the stands of Pompon and single blooms, which were most elegantly and gracefully displayed, in many instances being freely grouped with foliage as cut from the plant. The miscellaneous collections of Gladiolus and Dahlias not for competition, with many other plants and flowers, also furnished an important addition to the Show, while the Palms, Ferns, and similar fine-foliage plants arranged in the centre of the table between the lines of stands still further helped to diversify the effect.

NURSERYMEN'S CLASSES.

Show Varieties.—Three classes were devoted to these, for forty-eight twenty-four, and twelve blooms, distinct varieties, the prizes ranging from £7 to 10s. The largest class attracted much attention, all the collections being of great merit. Mr. C. Turner, Slough, secured the first prize with forty-eight even blooms, of great symmetry and very rich in colours. The varieties were as follows—Prince Bismarck, Constance, George Smith, Ethel Britten, W. H. Williams, Cream of the Valley, Muriel, Alexander Cramond, J. Stephen, Drake Lewis, Chas. Lidgard, Michael Saunders, Royal Queen, Cardinal, Clara, Canary, Wm. Rawlings, Hugh Austen, H. Walton, J. Wyatt, Cecilia, Champion Rollo, Herbert Turner, T. Godwin, Lizzie Leicester, Pioneer, J. Green, Rosetta, Lady Gladys Herbert, Bessie, Julia Wyatt, Lord Chelmsford, Flag of Truce, Rev. J. Godday, J. N. Keynes, Prince of Denmark, Lily Ward, Ovid, Lady Antrobus, J. Cocker, Hon. Mrs. P. Wyndham, J. B. Service, Harriet Fetterill, J. Standish, H. W. Ward, G. Barnes, Georgiana, and J. Vick. Messrs. Keynes & Co., Salisbury, followed very closely; indeed, it was only by a most careful comparison of the blooms that their position could be determined. Many of the varieties were similar to those in the first collection, and equally good in colour. Messrs. Harkness & Sons, Belleby Grange Nurseries, Yorkshire, and H. Clarke, Rodley, near Leeds, were respectively third and fourth, each showing fine blooms. The five collections entered in this class occupied considerable space, and constituted the main features of the Show classes.

The stands of twenty-four blooms were similarly good in all the leading characters, but as the varieties were mostly the same as in the forty-eight class they need not be repeated. Messrs. Rawlings Bros., Romford, took the lead with blooms of moderate size, very even and symmetrical, and of good colour. Messrs. Paul & Son, Cheshunt, Saltmarsh & Son, and J. Cheal & Son, Crawley, Sussex, were the other prizetakers, five collections being staged. Eight pretty collections of twelve were entered, but in these there was a great diversity of quality. Mr. J. Walker, Thame, Oxon, won chief honours in this class with beautiful blooms of Prince Bismarck, Hon. Mrs. P. Wyndham, Joseph Green, Emily Edwards, Duke of Connaught, Prince Arthur, James Cocker, Alexander Cramond, Shirley Hibberd, John Standish, Goldfinder, and James Vick. Messrs. J. Gilbert & Son, Ipswich, were second; Mr. W. Burbury Crew Farm, Kennilworth, third; and Mr. J. Humphries, Kingston Langley Chippenham, fourth.

Fancy Varieties.—Only two classes were appropriated to these—namely, for twenty-four and twelve blooms. In the former Messrs. Keynes & Co. won chief honours, staging large but compact, deep, and handsome examples of the following varieties: Rebecca, Sport from Gaiety, Mandarin, Gaiety, Hugh Austen, Professor Fawcett, Hercules, Mrs. N. Hall, Seedling, James O'Brien, George Barnes, Oracle, Mrs. Saunders, Henry Glasscock, John Lamont, Florence Wyatt, Madame Lonbeyne, John Forbes, Fanny Sturt, Charles Wyatt, Annie Pritchard. Mr. C. Turner was second with blooms but few points behind the leading ones. Mr. H. Clarke was third, and Messrs. H. Cannell & Son, Swanley, fourth. The stands of twelve included some fine blooms of the leading varieties. Messrs. Saltmarsh & Sons were placed first with the following:—Egyptian Prince, Gaiety, Mrs. N. Hall, Mrs. Saunders, J. Lamont, Enchantress, Peacock, Flag of Truce, Octoroon, Grand Sultan, Fanny Sturt, and Florence Stark. Messrs. Rawlings Bros. secured the second position, their stand containing good examples of Egyptian Prince, Hercules, Professor Fawcett, Mrs. Saunders, George Barnes, John Forbes, Barnaby Rudge, Galatca, H. Glasscock, and Mrs. N. Hall. Mr. J. Walker followed with a neat collection, some of his best blooms being Mrs. Brown-

ing, Miss Lily Large, Magician, John Salter, Fanny Sturt, Oracle, John Forbes, Flora Wyatt, Maid of Athens, Mrs. Saunders, Parrot, and Lady Paxton.

AMATEURS' CLASSES.

Show Varieties.—As in the preceding section three classes were devoted to these, but for smaller numbers—viz., twenty-four, twelve, and six. The premier collection of twenty-four was that from Mr. H. Glasscock, Rye Street, Bishop's Stortford, even, handsome, highly coloured blooms, of moderate size, but extremely symmetrical. The varieties were Prince Bismarck, Emily Edwards, Black Knight, Joseph Ashby, W. Rawlings, Hon. Mrs. P. Wyndham, Mrs. Spofforth, Earl of Ravensworth, Cardinal, Goldfinder, James Cocker, Modesty, Alexander Cramond, William Laird, Revival, Countess of Ravensworth, Harry, Mrs. Harry, Shirley Hibberd, Harrison Weir, Mary Nisbet, Ethel Britten, Rev. Dr. Moffat, and Georgiana. Mr. J. Nation, Whitmore, Staplegrove, Taunton, was a close second with many fine blooms. Mr. R. Petfield, Diddington, Buckden, Huntingdon, was third, and Mr. W. Butterworth, Green Hill, Kidderminster, was fourth, all with creditable collections, but slightly wanting in refinement, though the weak or rough blooms were by no means numerous. The competition was very keen in the class for twelve blooms, no less than a dozen stands being entered. Mr. J. West, gardener to W. Keith, Esq., Cornwall, Brentwood, took the lead with fresh and brightly coloured blooms, representing a good selection of the leading varieties. Mr. B. Clarke, Shottisham, All Saints, Norfolk, was adjudged secondary honours; and Mr. J. Tranter, Upper Assenden, third, with good blooms, Ethel Britten being especially noteworthy. The winning stands of six blooms were contributed by Mr. G. Boothroyd, Woodville Hill; Mr. F. Masters, Penender Heath, Maidstone; Mr. J. E. Shrimpton, Englefield, Reading; and E. Mawley, Esq., Lucknow House, Addiscombe, Croydon, all of whom had praiseworthy examples.

Fancy Varieties.—The two classes devoted to Fancy varieties were well filled. Premier honours were adjudged to Mr. Glasscock for twelve fine blooms, which comprised the following varieties:—Viceroy, John Forbes, McIntosh, H. Glasscock, Fanny Sturt, Edward Pick, George Barnes, Egyptian Prince, Mrs. Browning, Barnaby Rudge, Mrs. Hall, and Professor Fawcett. Mr. Nation was second with large and effective blooms of good varieties, and Mr. R. Petfield third. Eleven collections of six blooms were staged, the prizes being secured by the following exhibitors in the order named:—First Mr. West, gardener to W. Keith, Esq., Cornwall, Brentwood; second Mr. J. Tunbridge, gardener to W. Bott, Esq., Bloomfield, Chelmsford, Essex; third Mr. Boothroyde, Woodville Hall, Dover; and fourth Mr. J. Wigan, Cromwell House, Mortlake.

OPEN CLASSES.

Two prizes of £1 were offered for the best Show and Fancy blooms selected from the entire Exhibition—a task of considerable difficulty where so many were good. After a long and careful search the Judges decided upon a bloom of Georgiana in Mr. C. Turner's first-prize stand of forty-eight as the premier Show bloom—an honour which its merits well entitled it to, as in freshness, purity of colour, and substance it was all that could be desired. The premier Fancy bloom was found in Messrs. Rawlings Bros' second-prize stand of twelve Fancies, a beautiful bloom of a sport from George Barnes, pale purple ground with crimson streaks, very even, full, and deep.

Pompon Varieties.—The competition in the classes for Pompon Dahlias was excellent, and these beautiful and symmetrical flowers were deservedly admired. Apart from the excellence of the varieties in this section, the compact growth and extremely floriferous nature of the plants render them admirably adapted for garden decoration, and they are yearly growing in public esteem. In the class for twenty-four varieties, shown in bunches of not less than ten trusses, Mr. Turner won premier honours with a grand collection, the bunches of blooms with buds being most effectively staged. The varieties were Wilhelm Nitche, Little Duchess, Titania, Grass au Wien, North Light, Favourite, White Aster, Comtesse Von Sternberg, Adonis, Gem, Cupid, Professor Bergeat, Mabel, Lady Blanche, Prince of Liliputians, Mdle. de Facoret, Garnet, Nympe, Isabel, Fair Helen, The Khedive, Little Arthur, E. F. Jungter, and Hedwig Polwicz. Messrs. Keynes & Son, Salisbury, were second with extremely neat blooms, more thinly, and consequently less effectively, staged than the preceding. Particularly attractive were Rosetta, Isabel, Darkness, Nemesis, Pure Love, Sappho, and a bright yellow seedling. Messrs. Cannell & Sons, Swanley, were a very close third with an imposing stand, but some of the blooms were, perhaps, fully too large, notably the variety Conquest, but the majority were very fine indeed—Coquette, Lydia, Little Nigger, Model, Geoffrey de St. Hilaire, Lady Bird, Venus, Infancy, and Meteor, as differing from those in the other stands, all being eminently worth growing. Five collections were staged.

In the class for twelve varieties six excellent collections were staged. Messrs. Paul & Sons, Cheshunt, secured premier honours with a charming stand of flowers, Butterfly, A. Hubner, Little Mabel, Little Nigger, Pure Love, White Aster, Fanny Weimar, Dr. Webb, Dora, Nemesis, Doré, and Forstmeister Gschwina, were the winning varieties. Messrs. James Gilbert and Sons, St. Margaret's Nurseries, Ipswich, were second with excellent blooms, but the stand had not quite such a smart appearance as the other. Fair Helen, and H. Milesky are noteworthy additions to the previously named varieties. Mr. Henshaw, Harpenden, St. Albans, was an exceedingly close third with a rather crowded stand, but the majority of the blooms were of undeniable merit. Sensation, quilled, sulphur; Princess Sophia, rosy crimson; and Guiding Star, white, were the best, dissimilar from those previously named, in this good stand. The open class for six varieties, distinct, was disappointing. We only observed two stands—namely, from Mr. West, gardener to W. Keith, Esq., Cornwall, Brentwood, and Mr. Tunbridge, gardener to W. Bott, Esq., Bloomfield, Chelmsford, who were awarded the prizes in the order named.

Single Varieties.—The display of single varieties was considerable, and the effect of the stands gorgeous. In Class 2, for twelve bunches, Mr. Turner surpassed all rivals in arranging the finest stand that has ever been exhibited of these flowers, and secured the first prize for grand bunches of Alba, Mauve Queen, Rob Roy, Yellow Gem, Firefly, Beatrice, Paragon, Beauty of Cambridge, Duke of Teck, Purity, and Gracilis elegans. Messrs. Keynes of Salisbury followed closely with splendid bunches, beautiful

amongst which were Picturata, Althea, Red Gauntlet, Acquisition, Evening Star, Bertha, White Queen, Yellow Queen, and Defiance. Messrs. Paul and Son, Cheshunt, secured the third prize; Harlequin, White Queen, May, Broxbourne Beauty, Helen, and Beauty of Cambridge being particularly attractive; Messrs. Cannell & Son following with a crowded stand of massive bunches of very large and brilliant flowers.

Eight stands of six varieties were placed in competition, Mr. G. Humphries, nurseryman, Knighton Langley, Chippenham, securing the first position with remarkably fine bunches of Golden Star, Beautiful, Gracilis Perfecta, Beauty, rose-yellow centre; White Queen, and Pictus, crimson, with a yellow ring. Messrs. Gilbert & Son, Norwich, were second, Mr. Walker, Thame, Oxford, third, and Messrs. Cheal & Sons, Cranley, fourth, all with good stands; but one of the best, if not the very best, stand in this class was disqualified. It was from Messrs. R. Veitch & Sons, Exeter, and contained Daisy, one of the best whites in cultivation, and other superior varieties admirably staged; but one or two of the flowers of the striped variety Pantaloon having made an attempt to produce two rows of florets, was such a pantaloonish freak that the Judges could not overlook. Exhibitors of single Dahlias may take the hint and not allow their flowers to commit such pranks—at least if they do they must be punished by not being allowed to appear on the stage. Still, Pantaloon is a single Dahlia, and the stand was worthy of a better fate.

Certificates were awarded for the following varieties of Dahlias and Gladiolus:—

Dahlia Duchess of Connaught (Turner).—A handsome Fancy variety, the blooms of great size and substance, buff ground streaked with rich crimson.

Dahlia Mrs. Hurst (J. Hurst, Enfield, Middlesex).—An extremely pretty Show variety, the blooms of moderate size, but most symmetrical and of a delicate blush tint.

Dahlia Mrs. Bowman (Saltmarsh).—One of the single varieties, remarkable for the breadth of the rounded florets, the general outline of the flower very even. The colour is a rich shade of crimson-purple, very distinct and pleasing. A charming variety.

Gladiolus Mr. Gladstone (Kelway).—Flowers large rich scarlet, white in the centre; spike massive.

Gladiolus Duke of Buccleuch (Kelway).—Bright salmon, light centre, fine flower and spike. Very handsome.

Gladiolus Duchess of Teck (Kelway).—A charming variety; flowers large, white with crimson streaks at the tips of the petals and in the lower petal.

Gladiolus Sir Stafford Northcote (Kelway).—Flowers brilliant scarlet with a dash of purple in the lower petal.

Gladiolus T. Moore (Kelway).—Very dark scarlet, lower petal crimson. Very distinct and effective.

Of the miscellaneous exhibits, the single and Pompon Dahlias from Mr. T. S. Ware, Tottenham, were the most extensive and beautiful, some hundreds of very distinct and handsome varieties being represented, and well merited the extra prize awarded for them. The Gladiolus, though shown with the Dahlias, came under the cognizance of the Judges of the Fruit Show, and are referred to in that report.

The Committee, Judges, principal exhibitors and friends, were entertained at luncheon in the afternoon, the usual toasts being proposed and responded to by Messrs. T. Moore, Shirley Hibberd, George Paul, R. Glasscock, J. Downie, and W. Dodds. The last-named replied for the Judges, as being the oldest present, stated that he first exhibited Dahlias in 1833, since which time they had been the objects of his constant attention. The opinion was general that the National Dahlia Show would become one of the firmly established horticultural institutions, and would be welcomed by the public with increasing favour every year.

ON FAIRY RINGS.

[A paper read by Mr. Worthington G. Smith before the Essex Field Club.]

EVERY person who has walked in the summer over grassy hills and through fields and woods must have noticed fairy rings. Sometimes they present themselves as circles and curves of bare ground, at other times the barren circle of ground has a rim of luxuriant grass outside; in some instances this circle or curve of dark rank grass has a third circle of Fungi beyond its outer line. In a perfect fairy circle we have, then, starting from the centre, a ring of barren ground, a ring of rank grass, and a ring of Fungi. In some instances a fairy circle of Fungi is only to be seen. Circles, curves, and quadrangles of rank grass of Fungi are sometimes seen that are not fairy rings, and it will, perhaps, be better to mention and dismiss these spurious rings and other geometrical forms at once. For instance, anyone who has walked in open spaces in plantations must have frequently observed a ring of Fungi encircling a tree, at a line on the ground indicated by the spread of the branches above. These growths are especially common in Fir plantations. Something drips from the tree, some resinous or other substance that favours the growth of certain Fungi, and they come up in an irregular ring at the drip of the tree where this substance has fallen. Such a ring is not a true fairy ring, and such a ring can never extend itself beyond the drip of the trees. Similar spurious rings and sometimes quadrangles may at times be seen around old hay and corn stacks, and even barns, at the place where moisture and decayed vegetable material has dripped from the overhanging edge. Such lines of rank grass and Fungi have nothing whatever to do with fairy rings. Sometimes an old horse may wear away the grass and make a circle of barren ground; but such a circle is not a fairy ring. In some places where moles disturb the ground, such disturbed ground is found occasionally to bear a crop of Fungi, but a crop of Fungi on a mole's run, whether curved or no, is not a fairy ring. Fairy rings, then, are not caused by haycocks, tethered animals, the drippings of trees and barns, circular fertilising exhalations from the earth, or electricity. That they are not caused by haycocks is proved by the frequency of true fairy rings on lawns opposite to the drawing-room windows, where haycocks are not allowed to ornament the scene. If one walks on the edge of the cliffs on the south coast numerous true fairy

rings and semicircles will be seen, the centre frequently on the very verge of the cliff, and the semicircle inland. Such semicircles prove that tethered animals do not cause fairy rings, for no owner of an animal would be such a lunatic as to drive a stake into the very edge of the chalk cliff, as at Beachy Head, and there tie his animal to it. Besides, some fairy rings are only 6 inches across, and what quadruped or insect could be tethered to make such a ring? That moles do not cause fairy rings is proved by the presence of the ring where moles are unknown, and on expanses of rock only covered by an inch or two of humus where moles cannot exist, and never have existed. Circular exhalations from the earth where fairy rings abound must, I think, be very rare, for I have seen thousands of fairy rings, but I have never seen a circular terrestrial fertilising exhalation! Electricity is not a speciality of mine, but as I know fairy rings to be invariably caused by something else it follows that they cannot be caused by electricity. As for the rings being caused by the tripping feet of fairies in a circling dance, few people now, unfortunately, believe in fairies. They have gone the way of the giants, dryads, gnomes, and wraiths, since

"In Briton's isle in Arthur's days
The midnight fairies danced the maze."

We could ill spare any of them, but in these times, when even the very youngest men are teaching us about the origin and evolution of all the phenomena of Nature, there is scant room for the fairies. The best known Fungus occupant of fairy rings is the Fairy Ring Agaric or

Fig. 38.—Fairy ring fungus (*Marasmius oreades*, Fr.), slightly reduced. A, Section.

Champignon, *Marasmius oreades*, termed in the older botanical books *Agaricus oreades*. It was termed *Marasmius* from the habit possessed by all the species of drying up and shrivelling in decay, as distinguished from *Agaricus* proper, which all speedily putrefy. It has derived its name of *oreades* from the Oreads, the playful nymphs of the hills and mountains. The Oreads were the companions of Pan or Hylæos, the forest god, and they danced and circled to his piping. The feeling of loneliness belonging to hilly places was attributed to the presence of Pan, and from this old belief has arisen our modern word 'panic,' which means fear without a visible cause. Pan is said to have terrified people by sudden loud shouts, and to have sometimes ill-treated the inoffensive dancing fairy ring Oreads. If the botanist who walks over grassy hills happens to be an archæologist as well as a fungologist, he will possibly light on arrow heads of flint in country places, and especially in Ireland. These flint arrow heads are termed fairy darts or elfin shots, and they are associated with the sports and quarrels of the nymphs and fairies. Fairy rings are common in Ireland, but moles do not occur there; this is a difficult point for the mole theorists. Fairy darts of flint were at one time common in Ireland, but of late they have nearly all been bought up by Irish cow doctors, who lend them to rustics to boil in the same pot with hot mashes prepared for ailing cows and pigs, for these fairy darts are supposed to have a mystic and potent power for curing the diseases peculiar to oxen and hogs.

After this slight digression in reference to the classic name and associations of the Fairy Ring Agaric, we may now notice the Fungus itself. *Marasmius oreades* is generally about 2 or 3 inches high; its colour is slightly more buff than a biscuit. The same colour pervades every part, the top being sometimes a shade darker than the gills and stem. Every part of the Fungus is rather firm, and the stem tough, solid, and smooth. The gills are free from the stem, unusually broad and thick, and unusually distant from each other. The top is smooth and fleshy, and commonly furnished with a central elevation. It grows on grassy hills, sometimes on precipitous hillsides or lawns in exposed wind-swept pastures, and amongst the short grass of roadsides. One of its chief characters is that it grows in and causes fairy rings. The Fungus is edible; indeed it is one of the safest and most delicious of all edible Fungi. It seems just possible, however, that occasional examples are bad eating, and cause stomach-ache and other unpleasant symptoms; but I am inclined to think that these indigestible examples are very rare, and may be classed with such things as stale eggs, tough beef, high venison, and rank butter. In fact, the high gastronomic character of the true Fairy Ring Champignon shines with a more brilliant lustre by contrast with a few alien individuals unfit for the table. However, in case of accidents, errors, or inconvenience, I always advise beginners in fungophagy to be provided with a bottle of sweet oil. If dizziness

delirium, and cramp are found to be coming on, a draught of sweet oil is invaluable, for if enough be taken it causes immediate vomiting, and it tends to heal any damage that may be done to the throat and stomach by fungus-poisoning. The Fairy Ring Agaric is extremely common, and grows from late summer to late autumn, so that it may be well esteemed as one of the greatest boons given to us by good fairies and the great god Pan.

The true explanation of the nature of fairy rings has been so often printed that I am almost ashamed to refer to it before this Society. Several persons have written to me of late to ask what my "theory" and what my "hypothesis" is as to fairy rings. My reply has every time been that I have got no "theory" or "hypothesis" either, for the facts are so perfectly well known that they do away with any necessity for a "theory." Many Fungi have a great tendency to grow in circles. The spawn from which Fungi spring commonly starts from a spot made up of germinating spores. This spot becomes a centre from which the spawn extends outwards in every direction; a crop of Fungi appears on the outer circular line of spawn (see fig. 39). Such ring-like Fungus growths are very common on decaying fruit and leaves. The Fungus of ringworm is another very familiar example. Fairy rings, as formed by Agarics, probably start from a single Fungus which has grown from wind-carried spores. The growth of the spawn of this single Fungus in the ground renders the spot where the individual grew unfit to produce another Fungus of the same class. The spawn then extends itself from the central spot, and grows all through the winter and following summer a circular patch in the earth. One year's growth will give a circle of about 6 inches, and on the outside of this little circle a small fairy ring of Fungi will appear the second year. When this ring of Fungi dies it acts as a rich nitrogenous manure for the grass, so that in the third summer a circle of rank fungus-matured grass is seen. The grassy circle is often in strong contrast with adjoining dead grass killed by the Fungus spawn infesting the roots. If circumstances are favourable the underground spawn will now keep on extending itself for forty years or more, until at last an enormous circle is made that may sometimes be seen on hillsides from a distance of a mile or more. If an obstruction occurs a semicircle may sometimes result; at other times, when numerous rings grow near each other in the same pasture, or on the same hillside, various ogee curves and wavy lines of rank grass, barren ground, and Fungi are originated. The whole phenomenon of ring-growth is comparable with a stone thrown in still water. The stone is like the first few germinating Fungus spores, and the ever-extending rings produced by the impact of the stone on the water are like the ever-extending rings produced by the underground spawn of the Fungus. Sometimes a large fairy ring will appear in a place, as on a lawn, where no Fungi have been seen before, and where no smaller rings have preceded the large one. This phenomenon is caused by the first Fungus being overlooked, and then a series of seasons have followed unsuitable for the production of the Fungi. The spawn, however, has been alive underground, and has

Fig. 39.—Fairy Ring. The ground partly shown in section, A centre, where the original Fungus has decayed, and whence springs the underground spawn, B. B, of the Fungus (*Marasmius oreades*), which gives rise to the fairy ring.

kept on year after year extending itself till at last a suitable season arrives, and a crop of Agarics is the result at the circular margin of the underground spawn.

It must not be supposed that the Fairy Ring Agaric is the only Fungus capable of making a true fairy ring, for many Agarics and other Fungi are capable of doing this. Puff-balls frequently form fairy rings. The St. George's Agaric, *Agaricus gambosus*, which grows in April, makes very strongly marked fairy rings. The spawn of this Fungus chokes the grass in a remarkable manner, leaving the ground almost bare, and the Fungus itself is so fleshy and large that it manures the circle where it grows in a most striking manner. Another very large Fungus named *Agaricus geotropus* causes unusually large and bold fairy rings. The common Mushroom does not make rings, but a close ally, if indeed it is not a mere variety of the same plant—viz, the Horse Mushroom, is said to produce rings. If so, this should be one reason for making the two Fungi distinct species. There is also an extremely small Agaric named *Higrophorus niveus* that I have seen growing in perfect rings only an inch or two across. Some fairy rings are found in woods, and a notable example is found in *Agaricus fastibilis*. This forms grassy rings inside woods quite distinct from the drip of the trees, for the rings often envelope

several trees and many bushes in their circumference. Such rings, I suppose, are the dancing places of the Dryads, nymphs who also danced and frolicked to the pipe of Pan. As far as I know, Fungi which grow in circles have never been catalogued and distinguished from those which grow in an irregular or sporadic manner. Some certainly can grow in a line, for I once noted a number of specimens of *Helvella crispa* which grew in a line for several years. Such a catalogue if made would be very valuable, and if members of this Club will note and measure rings and determine the Fungi growing upon them they will be doing good service and new work. Why some Fungi grow in rings and others in a straight or an irregularly branching line it is difficult to say, but if Fungi have been evolved from other Fungus forms, and Fungi as we now see them have descended from one or more common ancestors, then those ancient precursors may have taken up with different habits which are still retained by their descendants. Fungi growing in rings or branched lines appear to me to be comparable with regular flowers, alternate and opposite leaves, and similar phenomena seen amongst flowering plants. It is known that the flora of the inside of a ring itself will support plants that neither grow outside nor inside the ring. A most useful piece of work would be the making of lists of Grasses and other plants seen outside and inside the ring. During the present summer I noticed a profuse flowering of the Common Rock Rose, *Helianthemum vulgare*, amongst the luxuriant grass of fairy rings. The plant occurred elsewhere, but it only flowered well on the rings. To such an extent was this the case that I could distinctly see the rings as yellow circles from a long distance. The change of the flora is caused by the Fungi exhausting the ground and then remanuring it with highly nitrogenous manure. This manure causes luxuriant vegetable growth for one year, which exhausts the circle to a still greater extent. The soil inside the ring is therefore different from the outside, and supports different plants. Another point that requires investigation is the source of the nitrogen so abundant in fairy ring Fungi. These Fungi only grow in bare pastures and other places where nitrogen is rare, yet they acquire so much nitrogen in themselves that when they perish they deposit so much of this material and potash on the soil that the manured circle resembles rather the grass of the richest meadow than an upland pasture. It has not yet been decided whether Fungi are capable of acquiring their large store of nitrogen direct from the air or from material in the soil.

SANDY HORTICULTURAL SOCIETY.

THE annual Exhibition of this progressing Society was held in the pretty and conveniently located grounds of J. N. Foster, Esq., Sandy Place, on Friday last, the gardens attached to which and those of the Rev. J. Richardson of the Rectory adjoining were both opened to the public; and as each of these gardens is admirably kept and just now at its best, a more attractive and suitable spot for a show could hardly be found, the distance from Sandy station being within a quarter of a mile. This was the fifteenth annual Exhibition the Society has held in the same place; and from a small beginning Sandy, favoured by its pretty situation and convenient railway facilities, has become a popular and important Show, and now that the Society has emerged from its leading strings it would hardly be detrimental to its future prosperity nor a reflection upon the management to suggest the desirability of a few additions to and alterations in the schedule, which has remained with little change for some years, but is nevertheless a liberal one. In the meantime, however, the public taste in horticulture has in some respects altered if not advanced.

The open classes might with advantage be extended and a slight re-arrangement of the others effected without a material increase in the gross amount offered in prizes. For ten stove and greenhouse plants in flower three collections were staged, the first prize being awarded to Mr. E. Tudgey of the Exotic Nurseries, Waltham Cross, for a well-flowered and well-matched lot, his finest plants being *Clerodendron Balfourianum*, *Allamanda nobilis* and *Hendersoni*, *Anthurium Schertzerianum*, *Erica Uhria*, *Bougainvillea glabra*, and *Ixora coccinea*. Mr. Rabbitt, gardener to General Pearson, The Hazells, Sandy, was second with *Vallota purpurea* (very brilliant and densely flowered), *Ixora Fraseri*, *Lasiandra macrantha*, *Allamanda Hendersoni* and *floribunda* amongst his best; Mr. D. Bloodworth of Kingswood Hill, Bristol, running him very close with a very creditable collection. For the collection of six plants in flower, open to all except nurserymen, Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynsburys, St. Neots, was first with *Bougainvillea glabra*, *Justicia carnea*, *Stephanotis floribunda*, *Statice profusa*, *Clerodendron fallax* and *Balfourianum*, all well-grown specimens in good bloom. For six foliage plants Mr. Rabbitt was first and Mr. White, gardener to Capt. Sidney Stanley of Longstowe Hall, Cambs. (the President of the Society), second, both staging very healthy and well-grown collections. For six *Coleus* Mr. Rabbitt was first and Mr. J. Meyer of Orwell second, but the colours were not intense, although the specimens were well grown. For six stove and greenhouse Ferns Mr. Tillbrook, gardener to Bateman Brown, Esq., Houghton, Hunts, was first with a grand plant of *Cyathea dealbata*, *Adiantum concinnum*, *concinnum latum*, and *farleyense*, and *Platyserium alcornu*. Mrs. Tindall Lucas of Foxholes, Hitchin, who staged smaller but well-conditioned specimens, was deservedly second. For six Zonal Geraniums Mr. Redman was first with fine bushy plants full of colour, the best being Colonel Holden, Henry Jacoby, and A. F. Barron (fiery scarlet); Mr. Rabbitt was a good second. For a specimen stove or greenhouse plant Mr. Redman came in with *Bougainvillea glabra*.

In cut flowers Roses were a prominent feature. For the forty-eight single trusses in the open class Messrs. Paul & Son, of the Old Nurseries, Cheshunt, had a first-rate stand, and were well to the front, their best blooms being *Baronne de Medeni* (a good autumnal Rose, not often seen, of a purplish carmine with darker centre), *May Quennell*, Mrs. Jowitt, *Senateur Vaisse*, *La Rosière*, *Alba Rosea*, *Etienne Levat*, *Paul Neyron*, *A. K. Williams*, *Emilie Hausberg*, and *Madame Willermoz*. Mr. J. House, of the Eastgate Nurseries, Peterboro', had second place with a stand of very fresh but smaller blooms, including *Helen Paul*, a good tinted light flower in the way of *Hippolyte Jamain*, but more incurved; *Merveille de Lyon*, as white as *Mabel Morrison*

and larger, but as shown somewhat thin. Mr. House had also fine blooms of *Alfred Colomb*, *Marie Rady*, *Camille Bernardin*, and *Baroness Rothschild*. For the twenty-four blooms in the amateurs' class the Rev. W. H. Jackson of Stagsden Vicarage, Bedford, was well first with blooms little inferior to those shown in the previous class, a grand and almost perfect flower of *Charles Lefebvre* being very conspicuous. Duke of Connaught, Star of Waltham, *A. K. Williams*, *Belle Lyonnaise*, *Xavier Olibo*, and *Pierre Notting* were also very fine. The Rev. E. L. Fellowes of Wimpole Rectory, Royston, was second with a stand of older blooms, containing a great many Teas. Mr. Fellowes also took first honours with some grand Dahlias, his stand of twelve containing a promising new variety named *Gwendoline*, of a distinct mauve colour, a sport from the dark claret-coloured *Burgundy*, and forming a singular contrast to that variety; also Mrs. Keynes, a fine flower, approaching mandarin red, but slightly shaded maroon; *Jas. Ashby*, *F. Burbank*, *Emperor*, *F. Tiffany*, *Ovid*, *J. C. Quennell*, and *Jas. Cocker*, all in first-rate form.

Mr. Fellowes also showed some remarkably fine Asters, and Mr. P. Meyer of Orwell twelve African Marigolds—in size, form, and colour rarely approached. Mr. J. House showed thirty-six spikes of *Gladiolus* in fine condition, and also a stand of single Dahlias, including blooms of the lovely little mauve repens; Messrs. Paul & Son thirty-six Dahlias, all masterly blooms; and Mr. Laxton of Bedford a very attractive stand of herbaceous and hardy cut flowers, amongst which were noticeable Dahlias *Juarezii*, *Constance*, *Pantaloon*, *Zulu*, *White Queen*, and *Christine*; *Lobelia cardinalis*; *Helianthus globulosus fistulosus* and *argyrophyllus*; *Rudbeckia Newmannii*; *Nicotiana affinis*, *Lathyrus latifolius* in several, from pure white to deep rose; and *Anemone japonica* *Honorine Jobert*.

Fruit was largely shown, but probably Grapes, which are usually a feature at Sandy, have in some former years been seen better. Mr. Allis, gardener to Major Shuttleworth, Old Warden, had, however, two superbly finished bunches of *Buckland Sweetwater*; and Mr. J. Shephard, gardener to J. Murfin, Esq., Great Staughton, Hunts, two well-ripened and highly coloured bunches of *Black Hamburg*, each taking first honours. For two bunches of any other variety of black Grapes Mr. Tillbrook, gardener to Bateman Brown, Esq., Huntingdon, was first with very fine *Gros Maroc*, and for two bunches of *Muscat of Alexandria* Mr. Allis was to the front. For the basket of six varieties of fruit, Pines excluded, five collections were set up. Mr. Tillbrook was first with good *Black Hamburg Grapes*, a handsome netted Melon, Peaches, &c. Mr. Allis, who had *Black Hamburg* and *Foster's Seedling Grapes* in good condition, and *William Tillery Melon* very fine, was placed second; and Mr. J. Vines, gardener to Harry Thornton, Esq., Kempston Grange, Bedford, was third. For a scarlet-flesh Melon Mr. J. Cook, gardener to Col. Stuart, Tempsford Hall, was first; and for a green-flesh Melon Mr. R. Carter of Waresley Park Gardens was also first. Apples, Pears, and Plums were largely shown in all classes. Mr. Allis had a superb dish of Tomatoes of a variety selected from *Trophy*, the fruits being perfect in colour, ripeness, and form, and all evenly sized—a better dish is rarely met with. Vegetables, as usual at Sandy, were in great force. Potatoes and Onions, being the staple of the district, were especially well represented, the usual show varieties of the former mostly coming to the front: *International* in the white kidney class, *Schoolmaster* in the white rounds, *Mr. Bresee* in the coloured kidneys, and *Reading Russet* in the coloured rounds. Amongst attractive and newer varieties white *Beauty of Hebron*, a selection from the coloured form of this now well-known and largely grown market Potato; *Snowdrop*, a very handsome white kidney of good quality; *Carters' Eight-weeks*, a very fine rough-skinned white round; and *Beauty of Kent*, a handsome round purple-flaked variety, were noticeable as advances in their respective classes. In the market gardeners' class for white kidneys a very rough, dirty, and not well-ripened sample of *Magnum Bonum* was selected for honours. For the basket of eight varieties of vegetables Mr. C. Ellis, gardener to Mrs. Orr, Pemberby House, Bedford, was first with good Tomatoes, *Snowdrop Potatoes*, and *Omega Peas* in his collection, and Mr. G. Vynes second with fine *John Bull Peas*, Tomatoes, and Cauliflowers as the cream of his lot. In the various competitions for Peas the *Ne Plus Ultra* and *Omega* types were in nearly all cases preferred to those of the *Telegraph* race. Mr. Laxton showed (not for competition) grand samples in the straw and in the pod of his new *Pea Evolution*, showing the great size and productiveness and beautiful colour. These with other specimens, the property of various exhibitors, seem to have been appreciated at the close of the Show, as they were removed without the consent of the owners. Unfortunately too, such depredations were not confined to vegetable productions, as a large number of valuable watches and purses were reported missing. Probably the management and the police experienced some extra difficulty from the downpour of rain which occurred just at clearing time, when a rush was made for the tents by the large concourse present, and which was on this occasion swelled by the despatch of a special cheap train from Moorgate.

The Exhibition was a very comprehensive and extensive one, and was comprised in about a dozen large tents, poultry, farm produce, honey, and cage birds being included. Amongst these, perhaps, the fine glass super of honey, weighing 9½ lbs., shown by the Rev. H. Wood of Biddenham, from a swarm on the 6th of June last, the glass put on on the 20th of that month and taken off on the 12th of July, is worth noting as winning the leading prize in that department. The Society was last year, from bad weather on the show day, debtor to its Treasurer, but continued prosperity is now assured, as the weather on the late occasion was until the close all that could be desired, and the receipts satisfactory.

HARDY FRUIT GARDEN.

Branch-twisting.—The coming of September heralds the swift approach of colder weather, and all possible means should be adopted to

prevent useless growth, to accelerate bud-development and wood-ripening. Discontinue stopping lateral growth, for it will only induce an untimely growth of spray that cannot reach maturity from buds which should be made as plump as possible in readiness for an early and robust spring growth. Carefully consider how many buds it is desirable to add to each spur, and then, instead of cutting off the lateral at the required point, twist it carefully slightly above the point of severance, and bend it downwards, leaving it so till winter; and then, when pruning, the buds below the twist will, though dormant, be plump and full, in striking contrast to the half-developed buds of useless autumn spray. Remove netting and tiffany from the trees as soon as the fruit is picked, so that there may be no obstruction to the air and sunshine.

Insects.—Without healthy foliage it will be useless to expect a full crop of fruit next year. Leaves of Peaches or Nectarines damaged by red spider cannot elaborate sap sufficiently for the requirements of the wood, which on infested trees is usually so weakly that when growth ceases the buds are quite unfit for the production of wood or fruit. This debility is also undoubtedly a cause of bud-shedding in spring. See, therefore, that any appearance of red spider induced by the recent hot dry weather is promptly met by a free use of the syringe, taking especial care to force the water well under the leaves.

Watering.—A hot dry September ripens the wood, gives finish and flavour to fruit, crowns the current year with success, and does much for the crop of next year. But for the trees to derive full benefit from it there must be no parched soil about the roots, watering must be closely attended to, and if the drainage be sound and thorough there need be very little fear of overwatering.

Fruit-gathering.—Look over ripening fruit frequently, especially early autumn Pears and Apples, many of which ripen quickly and soon spoil if left too long upon the trees. Remove overhanging leaves from contact with the fruit of late Peaches and Nectarines to obtain high-coloured fruit. Brunswick Figs are so much more luscious and tempting when fully ripe and with the skin splitting before gathering, that the trees should either be covered with hexagon netting or muslin bags put over each fruit as it become fully grown. Wasps are very fond of this Fig, and they are so numerous just now that no fruit is safe without some such protection.

FRUIT-FORCING.

PINES.—*Potting Rooted Suckers.*—Suckers obtained from the stools of the successive fruiting plants and potted about the middle of July, will, if treated as previously advised, be now in a fit condition for shifting into larger pots; but before this is done it is well to consider what the future requirements are likely to be, so that there may not be any surplus stock, as it is very important that the plants retained have every advantage of as much room as their wants require. It is advisable to divide the plants into two sections—viz., first, the strongest Queen plants and others, putting these into the fruiting pots at once, placing them in a close light pit about 2 feet asunder, and the surface of the bed in which they are plunged not being more than 3 feet from the glass. The heat at the base of the pots should be 95°, the night temperature kept at 70° to 75°, 75° by day from artificial heat and advancing from 80°, at which a little ventilation should be given, to 90° from sun heat, and at this close the house when the sun's power begins to lessen, giving a light syringing two or three times a week. Watering will need great care until the roots are growing freely in the fresh material.

The second section of plants comprises the smaller ones, selecting the requisite quantity and discarding the remainder. These should be placed into pots 6 to 8 inches in diameter according to their size, giving them moderate heat to insure a steady and sturdy growth, and be in good condition in spring for shifting into the fruiting pots early in spring. These will form a succession to those above referred to. A temperature at the roots of 80° will be ample for these plants, the night temperature 60°, and 70° by day, advancing to 80° or 85° from sun heat, ventilating freely on all favourable occasions.

CUCUMBERS.—*Planting Winter Fruiters.*—The plants from the sowing made the second week in August will now be ready for planting out in hillocks or ridges, or transferring to pots or boxes. They will need to be supported with sticks fastened to the first wire of the trellis. If the weather be sunny shade for a few hours at midday until the plants become established, when it should be discontinued, and water must be given with great care. The young plants should be stopped when they have reached the third wire, or about two-thirds of the allotted space.

Treatment of Fruiting Plants.—These will require examining frequently in order to effect the needful stopping, thinning, and removing of superfluous growths and fruits, tying and regulating the shoots, the object being to keep up a succession of fruitful wood. Close early in the afternoon, damping the house at the same time. Fire heat will be necessary to prevent the temperature falling below 65° or 60° at night.

Plants in Pits and Frames.—Damping plants in pits or frames heated by fermenting materials should be discontinued, as the moisture given out by the materials will be sufficient, and watering should be done without wetting the foliage more than can be helped. If mildew appear dust thoroughly with flowers of sulphur, keeping the foliage dry, and ventilate freely. The linings will need to be seen to regularly to maintain the requisite heat of the beds.

MELONS.—*Late-fruited Plants.*—The latest plants have set their fruit, and should have a warm, rather dry, and freely ventilated atmosphere, the blossoms being impregnated daily until a sufficient number of fruits are set on a plant, when all the remaining flowers should be removed. Stop one joint beyond the fruit, and keep subsequent growths

closely pinched to one joint as made; and if this has a tendency to crowd the principal foliage, the laterals so interfering therewith should be removed, but care should be taken not to make great reductions of foliage at one time, removing the unnecessary parts gradually. When the fruit is swelling freely earth-up the roots, feed copiously with weak tepid liquid manure, and maintain a moist genial atmosphere by damping two or three times a day, and on bright afternoons the plants may be moderately syringed overhead. The night temperature should be maintained at 65° to 70°, 75° by day, advancing to 85° or 90° from sun heat, with a little ventilation at 80°, increasing it with the sun heat. Close at 80°, and so that the heat will rise 10° to 15°. If mildew appear dust with flowers of sulphur, and keep rather drier and more freely ventilated. Black aphides, or aphides of any kind, are best subdued by careful fumigation. If canker appear rub quicklime into the affected parts, and repeat as necessary. Afford supports to the fruit before they become very heavy.

Fruit-ripening.—The present weather is not favourable to the production of highly flavoured fruits, especially in the case of those in pits or frames solely heated by fermenting materials. The heat generated by fermenting materials is moist, but is not therefore useless in expelling damp, as by its aid the ventilation can be freer, and a circulation of warm air, if it does not dry the atmosphere, reduces the evils of damp to a minimum. Moisture must be used in any form now very sparingly, and if it be absolutely necessary at the roots to prevent flagging, it should be given without wetting the foliage. Keep the laterals well in hand and the foliage thinned, so as to admit as much light and air as possible. Attend well to the linings, and admit a little air constantly. Canker must be subdued by rubbing quicklime into the affected parts. After the close of the month Melons from pits and frames are not of much value, but the case is different with those in light well-heated structures, as well-swelled and fairly flavoured fruit can be had until a late period of the season—even into November or later.

PLANT HOUSES.

Gesneras.—These are the most satisfactory when standing upon some moisture-holding material, where they receive a little warmth from beneath, and the atmosphere in which they are growing not overcharged with moisture. If they have been properly treated they will now be growing strongly, and should be placed in the pots in which they are intended to flower. Any moderately light soil suits them well in which a fair per-centage of leaf soil and coarse sand has been intermixed, pots 5 or 6 inches in diameter being large enough. After potting keep them close for a time and water them carefully at their roots, but when thoroughly established give them weak stimulants, nothing being better than clear soot water. Do not syringe these plants.

Gloxinias.—Seedling plants that are now growing in 2 or 3-inch pots and have not been checked will, if placed in 4 and 5-inch pots and liberally treated, make fine flowering plants in autumn. These plants delight in a rich compost, but will, nevertheless, succeed very satisfactorily in almost any soil. Place these plants in a warm pit or on a shelf close to the glass, and water carefully, but when established never allow them to suffer from insufficient supplies. A batch of old plants that flowered early and have been rested for some time in a cold house can now be shaken out and repotted. These, with the application of heat and moisture, will soon start into growth; and although they may not be so fine as when grown during the spring of the year, they will be found acceptable for the decoration of the stove and for cutting.

Calceolarias.—Plants raised from seed sown as advised some time ago, and pricked out singly into pans when large enough, should now be ready for placing into 2 and 3-inch pots. Use a light compost of fibry loam, leaf soil, a seventh of decayed manure, and coarse sand. Lift the plants out of the pans as carefully as possible with a small ball of earth attached to them, and pot them low in moderately drained pots. After potting give the plants a good watering, and stand them on a bed of ashes in a cold frame. Keep them close for a time and shade them from strong sun. Prick out successional batches into pans, placing them 1 or 2 inches apart according to their size, and treat them exactly the same afterwards as the early batch.

Cinerarias.—Where plants are grown to flower during November and December these should now be strong and well established in their flowering pots, and will need weak stimulants made from cow manure, and clear soot water will be found most beneficial, and should be given every alternate watering. Ventilate liberally, and shading should be gradually discontinued from this date. The second batch should now be in 6-inch pots, and so on in succession to the latest batch, which should now be ready for pricking out from the seed pan into others for flowering late next spring in small pots. Take care that these plants do not become root-bound until they are placed in their largest pots, or they flower prematurely, and only poor heads will be the result. A sharp look-out must be kept for green fly, and at its first appearance fumigate with tobacco paper. Syringe during the afternoon of bright days, and never allow the plants to suffer by the want of water at their roots. The material on which they are standing should be kept moist.

Hydrangeas.—Cuttings in which the flower buds have formed should now be taken off and rooted, if neat, dwarf, well-bloomed plants are appreciated, in small pots for purposes of decoration during spring and early summer. These cuttings strike readily in a little heat if kept in a close frame or under handlights and shaded from the sun until they are rooted. Insert them singly in the centre of 3-inch pots, place a little sand for the base of the cuttings to rest upon. As soon as the cuttings are rooted gradually harden them and place them in a cold frame, all the attention needed afterwards until the time to start them

into growth being supplying water and protection from frost. Care should be taken that the cuttings do not start into growth after they become rooted, or results anything but satisfactory will follow. This system, if properly carried out, will be found a very successful one, and decidedly preferable to retaining old plants in pots for flowering, unless larger specimens are required.

THE BEE-KEEPER.

HIVE-CONSTRUCTION, HONEY-PRODUCING, AND PRACTICAL MANAGEMENT OF BEES.—No. 2.

It would be greatly to the advantage of bee-keeping as a pursuit if a little information was given occasionally as to the difficulties which beset beginners, and with this view we propose to pay particular attention to this portion of our subject; because, though we occasionally find an apiarian "to the manner born," who begins to keep bees and succeeds in almost all he does by instinct as it were, these are the exception, not the rule, and the great majority are those who are induced to begin bee-keeping in consequence of something they may have seen at shows or read of in bee books, and who think it is only necessary to stock a hive, set it up in the garden, and appropriate the honey each season as it is accumulated. We need hardly say that the experience of a season or two will undeceive them. They will find that if apiculture is to be made a success some trouble must be taken to insure it, and that their new hobby must be carefully followed up and attended to if it is to yield them pleasure and profit. Now there can be no doubt that the first point to which special attention should be given is the hive itself, because if it has faults and errors in construction no satisfactory result can possibly be hoped for. Much may be said as to what a hive should be, and what sum should be expended upon it; but we think it will make our position clear at the outset by saying we cannot accept the idea so prominently put forward by most of the bee associations throughout the country—that the main object of such associations is to teach the agricultural labourer how to make money by his bees. If it were so all notion of the frame hive might be given up, and the straw skep (of course with a flat top) accepted as the best hive for all practical purposes. We have had a somewhat extensive experience of the matter, and find, so far as it goes, that the bar-frame hive is altogether beyond the agricultural labourer; he cannot grasp it. A very intelligent man of this class who had kept bees for thirty years remarked to the writer, after having had the advantages of the frame hive explained to him, "I see all the benefits you get, but it would take a seven-years' apprenticeship to learn that trade," and he stuck to his straw skeps as long as he lived. So much for the agricultural labourer.

When we come to the cottagers we include many intelligent men of the artisan class whose occupations enable them to dwell in rural districts. These men can understand a frame hive, and often make their own; but they are generally keen thrifty fellows, with a strong predilection for winning prizes at shows, and of that particular temperament which makes them delight in any amount of labour when incurred on account of their favourite hobby. It is to be regretted that these do not form a more numerous class, for they are most useful in their way. Few county associations that we know can boast of more than a dozen such bee-keepers, so that, after all, the chief reliance in sustaining and carrying on the work of bee associations must, as we have said before, be placed in a class distinct from either of the above, and it is to these we propose to address our remarks on the matter. We believe the soundest method of spreading abroad a knowledge of apiculture among the labouring classes will be to establish successful bee-keeping among those who will give it a fair trial with reasonable hopes of success, and encourage these to take a personal interest in showing their humbler neighbours a more excellent way of managing their bees on modern principles. It may be different in the southern counties, but here in the north such has been the experience gained during a long and rather active acquaintance with the subject.

Before endeavouring to point out what we consider a really good hive should be, it may be well to notice a few of the defects in hive-construction which will be found to give most trouble in honey-producing and general management. In the first place, fixed or immoveable floorboards are a great nuisance, because there will always be a certain amount of refuse, such as cappings of comb, &c., which is blown into the corners of the hive in the course of ventilating, where it accumulates and receives the condensed moisture always found running down the sides of a populous and flourishing hive in spring.

2. *Frames without Distance Guides.*—This is, we know, a moot

point with some of our high authorities; but it does not, in our opinion, need one moment's argument as to which is best for general use. If we were to say that 10 per cent. of the bee-keepers in this country could gauge distances for frames with the finger we should be going beyond the mark, and why hives should be made to cause trouble and annoyance to ninety out of every hundred is a mystery. We shall have more to say on the point when considering the construction of a hive.

3. *Play for Frames.*—It is curious to note the nicety with which the frames of most hives are made to fit—not the thirty-second part of an inch to allow for the numerous contingencies that are constantly cropping up where frames are supposed to be interchangeable—where, for instance, you cannot insert a queen cage without removing and leaving out the dummy, or the slightest irregularity prevents the insertion of a comb in any position other than that in which it was built by the bees. The moveable sides introduced a few years ago were excellent in remedying this defect, but somehow they have not come into general use.

4. *Space under the Bottom Bars.*—We had occasion to inspect some hives in an apiary where efficiency was aimed at, and expense had not been spared to insure it. The hives had only been in use a few months, and so no ill effects were visible, but there was a space of $1\frac{1}{2}$ inch under the bottom bar. The consequences of this will not be apparent till next year, when comb will be built on the under side of the bottom bars, probably across the frames in some instances. Sometimes the other extreme is reached, and less than three-sixteenths of an inch allowed under the bottom bar. We have always found these to make convenient homes of the larvæ of the wax moth.

5. *The "Dip" between the Hive Sides and Tops of the Frames.*—This is a fault found in some hives which are excellent in all other respects, but it is nevertheless a most glaring one. It is not difficult to see how it has arisen. It works well on a show bench, and has the seeming advantage of keeping the quilt from blowing off while manipulating, and of making the carpet covering fit nice and snug. Here, however, the advantages end, and when it comes to supering the "dip" becomes an intolerable nuisance. The zinc adapter must be dropped in, crushing bees of course. The crate of sections, on being let down into the "trap" (for it is little else) repeats the crushing, and when the unfortunate amateur has to remove his sections, &c., in the autumn his difficulties reach a climax. The crate is securely fastened down with propolis; he cannot insert a lever under the corners to prise it up, and he has to remove it as best he can, but not without great trouble to himself and annoyance to his bees.

6. *Close-ended Frames.*—It is not without some diffidence that we find ourselves at variance with one of the ablest bee-masters in this country (whose opinion is entitled to the greatest weight) on the question of close-ended frames. We have had no experience of them in our apiary, and only form an opinion from what we have seen of them in the hands of others. In one case, where the owner of a Giotto hive enlisted our services, the effects of the close-ended frames were simply dreadful, and the "setting things to rights" formed one of the few occasions when we were almost beaten by the bees; as it was we retained a lively recollection of an hour's work with close-ended frames, and a strong stock of hybrid bees, for some time afterwards. Of course these frames may be well enough in the hands of an expert, but for ordinary use we think they will never find favour, and so we are compelled to include them in the category of "faults" so far as our opinion goes.

7. *Section Crates.*—The use of sections for storing surplus honey in has become so general that a fault in the construction of either section or crate is soon felt, because, to say the least, they are rather shaky things to handle when full of bees and honey. The original crates as sent out by the leading hive-makers kept the rows of sections half an inch apart, and as they were wedged together at each end it gave great facilities for handling; but unfortunately the thinness of the material from which the sections were made allowed of the escape of heat to such an extent as to cause the bees to desert them on a cold night, besides the sudden chill given to the brood nest, if a crate of sections was set on without careful wrapping to retain the heat. This fault led to the introduction of another form of crate, in which the sections fitted close together in a box with high sides. This effectually prevented the escape of heat, but unfortunately it was "out of the frying pan into the fire" as the homely phrase goes, and the sections are almost unmanageable in the latter. The maker's catalogue described how a full section could be removed and replaced by an empty one in an instant; but we saw an apiarian make the attempt who could not remove a section at all until the crate was taken off bodily.

We could name many other defects in hives which have come under our notice, such as the disarrangement of the frames and general misfit caused by the removal of the dividers or dummies to

the centre of the hive when contracting the internal dimensions for winter, which often necessitates the removal of one frame altogether from hive before all can be made straight.

No doubt manufacturers are doing their best to produce hives which will be as perfect as possible in working, and if defects are pointed out when proved to exist it will enable those who are interested to choose the best article for this purpose. But, here again we are confronted with a new difficulty. Bee-keepers consist of two varieties, which may be called the active and the passive, whose systems of management widely differ. The first-named is always up, and doing all he can to insure success; he stimulates his queens in spring, and spreads the brood as soon as breeding warrants it. In short, it is to be feared he occasionally meddles with his bees more than is conducive to their welfare.

The other only looks into his hives when compelled to do so, gives the bees as wide a berth as possible on all occasions, puts supers on, and never looks at them again till they have been ready for removal for several weeks; never dreams of renewing queens when they are old—in fact, keeps no record of any kind as to his bees, and yet is an earnest bee-keeper withal.

It will be seen how difficult it is to construct a hive which will meet the requirements of apiarians whose plans of managing bees are so greatly at variance; yet we have no hesitation in saying that a hive, to be a really good one, should be equally well adapted for both systems, and we hope to show that such a hive can be made.

The long-continued controversy as to the most suitable size of frame for general use seems to have been settled, so far as it can be, by the adoption of the British Association standard size. This fixing of a particular-sized frame with a special name, the exact dimensions of which have been carefully given, and which all makers are supposed to adhere to, cannot but have a good effect on hive-construction generally, because the bee-keeper knows exactly what he is going to receive when he orders that frame. To suppose, however, that the question of the best size of frame is for ever settled by the decision arrived at, is to put an end to all progress in hive-construction, and we having tried and used for a long time a frame which we believe to be better than the Association standard one, we shall respectfully submit the hive and frame to our readers in a future paper, leaving it to stand or fall on its merits, as the case may be.—W. B. C., *Higher Bebington, Cheshire.*

TRADE CATALOGUES RECEIVED.

Stephen Brown, Weston-super-Mare.—*Catalogue of Bulbs and Flower Roots.*

J. Carter & Co., 237 and 238, High Holborn, London.—*Catalogue of Bulbs (Illustrated).*

E. Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Bulbs (Illustrated).*

James Cocker & Sons, Aberdeen.—*Catalogue of Bulbs.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Sigma).—You will find our "Greenhouse for the Many," price 9d., post free from this office 10d., a useful work on the cultivation of plants for a cool house. Mr. B. S. Williams' "Stove and Greenhouse Plants," two volumes, 12s. 6d., also contains full particulars of plants for both warm and cool houses. It can be obtained from the author, Victoria and Paradise Nurseries, Upper Holloway. Your other question will be answered next week.

Back Numbers of the Journal (Mrs. J. L., Norwich).—The only mode that we can suggest is to advertise the numbers for sale, stating the particulars and price required.

Retinosporas Unhealthy (T. G. T.).—Evidence of Conifers suffering from drought is always unmistakably visible in the dull parched appearance of the foliage. As you make no mention of this, but rather of dead and shrivelled bark of the stems, by which sap-action has been so seriously

checked that "the top of one is nearly dead," it is clear that your theory of a want of water being the cause of the mischief is wrong. There are two ways by which the stem bark may be injured, either of which may apply to your case. The first and most common is by being eaten by rabbits. We have lost many young plants of *Juniperus excelsa*, *Cupressus funbris*, and *Juniperus virginiana* from rabbits eating the stem bark, yet numerous other sorts of Conifers have been left untouched; and the other is the exposure to wind, frost, and the almost equally trying extreme of scorching sunshine of young trees taken from crowded nursery quarters. The effect of such exposure is to check growth so severely that the trees are often four or five years recovering from it, and even then are frequently excelled in growth by younger trees that have escaped so trying an ordeal.

Large Caterpillar (G. S.).—What you enclose is the larva or caterpillar of the goat moth, *Zylcutes cossus*, or *Cossus ligniperda*, of almost adult size. This creature is occasionally found at large, taking a journey from one tree to another, but it usually lives out of view in the heart of trees, where it proves itself the destroyer of many a Poplar, Willow, and Elm; even the sturdy Oak sometimes succumbs to its attacks. The larva state lasts three years, the moth generally appearing in July, when it deposits a large number of eggs. Occasionally it visits our fruit trees, but these are more commonly infested by the leopard moth, *Zeuzera Aesculi*.

Insect upon Rose (H. B. B. Lymyne).—The leaves you enclose have been disfigured by a beetle, seemingly one of the weevil tribe. We are not aware that a similar instance is on record. Could you forward more specimens enclosed in a small box with a little wool about them? Those you obligingly sent, owing to the mode of transit, were not in a condition to enable us to identify them with certainty. The most likely way to keep the beetles from attacking the leaves would be to moisten these with some liquid which would render them distasteful to the insects. Decoction of quassia might answer the purpose, and it would not render the Roses objectionable to human beings, as solutions of a malodorous kind that are destructive to insects probably would, unless so far diluted as to interfere with their usefulness.

Propagating Cineraria acanthifolia (F. J.).—Stout short-jointed growths slipped off from the outsides of plants, divested of their lower leaves, and inserted in pots of gritty soil will, with proper treatment, strike now in a cool frame. They must not be kept moist, close, and shaded, as if propagating Verbenas or Ageratums, neither must they be so fully exposed to light and air as is suitable for Pelargoniums. They need to be kept only moderately moist, shaded only when the sun is bright, and ventilated sufficiently to prevent much atmospheric moisture. The foliage will flag, but eventually a number of the cuttings will emit roots. Good judgment is requisite in selecting the cuttings, and the inexperienced amateur might probably lose 50 per cent. of them. Soft growths taken from the interior of the plants will not strike at this season of the year, but young growths produced in heat will strike in heat in the spring.

Cutting Down Zonal Pelargoniums (Idem).—Plants that have flowered in pots may be cut down to any extent desired, and when fresh growth is starting they should be shaken out, the old soil and roots being considerably reduced, then placed in clean pots of the same size as those in which they were grown. Plants that are cut down in June and well cultivated flower freely during the winter. Those cut down now make dwarf specimens for flowering in spring and early summer. It does not follow that all should be cut down; some are dwarf and dense enough without, but those that need it should be pruned at once, and the cuttings inserted if young plants of the same varieties are required. Relative to your question about the Raspberry, all we can say is that no one variety is superior to all others in all soils and districts.

Forcing Roses (Keswick).—Select the strongest plants wherever they have been grown, and give them a slight shift at once, potting very firmly in turfy loam with a little decomposed manure added, and a twentieth part of the bulk of bonemeal. Place them in a sunny position in the open air for ripening the wood, and prune them when the leaves have fallen. You had better not attempt forcing too early. January will be soon enough to place them in gentle heat, and even then probably all the plants will not flower, as some varieties are not well adapted for forcing.

Mushrooms (A. Wilson).—Your mode of gathering the Mushrooms is quite right. No harm results from the process of pulling and leaving cavities in the beds; in fact, these are what the most successful cultivators like to see. But, of course, if you prefer to cut the produce you can do so. Mushroom spawn is usually found in manure that is neither wet nor dry, but where the material inclines to dryness rather than otherwise.

Pruning Laurels (H. C.).—The present is an excellent time for shortening the summer growths of the shrubs. You may cut them as closely as you desire, using a knife and not the shears, as these sever the leaves, and shortly afterwards the specimens have an unsightly appearance. The sample of moss you send is sphagnum, which is used extensively by cultivators of Orchids. They do not like dead moss, however, but prefer to see it growing healthily, as then usually the Orchids grow too.

Weeds in Lawn (J. W., Deal).—The plant of which you have sent a specimen is *Prunella vulgaris*. It is often a most troublesome weed in lawns, and as you have found, most difficult to eradicate. According to your letter you will soon spend as much money in weeding your lawn as would suffice to make a new one. There is no easy method of getting rid of the weed that as you say it seems almost "bopeless" to extirpate. In all probability you will never have a good lawn until you fork up the old one thoroughly, clean the land, and sow it with a suitable mixture of lawn seed. Dry weather is essential for cleaning the land, and this needs to be carefully done. The seed may be sown either in September or towards the end of March; and if showery weather follows the site will be green in two or three weeks. Perhaps, however, you will not adopt this plan, but prefer to continue the work of weeding; still if you require any further information on making a new lawn we shall be glad to supply it if you will state the nature of the soil.

Fern Fronds Browned (J. S.).—We are quite unable to account for the brown appearance of the frond, and can only suggest that you try the plant in another and more shaded position in the house, and if the pot is filled with roots give liquid manure, clear soot water being very suitable for Ferns. We have rarely seen a finer frond, and the size and description of the plants generally

denote that you are a skilful cultivator of Ferns. The old fronds of *Adiantum concinnum latum*, which we consider one of the most beautiful of the genus, are rather apt to become discoloured towards the end of the season. We will readily publish a letter from you on the cultivation of these plants, which you can evidently grow so well.

Market Gardening (H. T. G.).—However willing we are to advise you, the data before us is quite insufficient to enable us to do so satisfactorily. You allude to a garden of which you do not state the size, nor do you appear to know whether the glass structures are suitable for your purpose or not. You must satisfy yourself on this point, also on the character of the soil, taking note also on the fruit trees. In a garden of 2 or 3 acres with good fruit trees an industrious and competent man ought to be able to get a living if, as in the case to which you allude, there are good markets for the produce. The best advice we can give you is to inspect the garden closely and estimate its resources carefully, and if you can induce a practical gardener to accompany you, you will be the better able to arrive at a sound decision on the matter.

Vines Unhealthy (J. T. S.).—The portion of lateral you have sent is very unsatisfactory, being weak, soft, and containing too much pith. As you say all the Vines are not in this state, the best course you can adopt will be to train additional growths from the healthy Vines and remove the rods that are the most disappointing. You have done right in encouraging lateral growth, but if you are doing this to such an extent as to obstruct the light from the main leaves near the base of the laterals you are carrying out the principle of extension to excess. You had better take off the points of the laterals now as you suggest, and in all probability some of the weaker will be better removed entirely to admit light and air freely to those remaining with the object of maturing the wood. The temperatures you quote are correct, and syringing should not be resumed.

Chrysanthemum Culture (C. P. H.).—Practical hints on culture are, as you suggest, never unwelcome; but your note is so extraordinarily concise as to fail to convey practical information. You say, "watering as practised by many cannot lead to good results," but omit to say how it should be practised. The chemical constituents you quote, even if correct, are of no value as they stand; they at least should be quantitative. You say, "manures rich in animal matter are productive of mildew," but do not indicate what to apply. Your note on pegging down a practice with which we are well acquainted with, is quite unintelligible. If you will write more fully and clearly on the subject, which no doubt you well understand, we will readily publish your notes. You do yourself an injustice in the scrap before us.

New Pea (A. S. D.).—Although we do not remember a Pea exactly like the one of which you have sent pods, we are not prepared to say the variety is distinct from all others, as we know that others have "selected" from the same variety that you have with the object of improving on an excellent Pea. You must at least grow your selection another year and note all the characters of the variety before its merits can be sufficiently tested. The Pea pods you have sent are alone quite insufficient to enable us to answer your question. We can only say they are too tapering to be considered first-rate, but you admit you can grow them finer. We advise you to do so, especially as you will not lose if you do not gain anything by another year's trial. While the variety appears promising, we are not sanguine that it will possess any great commercial value; it is, however, worthy of further trial.

Aspect for Lean-to Fruit Houses (J. Chapman).—Peaches and Nectarines should for choice have the south and west aspects, and Apricots the east. All three fruits answer so well, however, on either aspect under glass that it would be well to mix them, so as to obtain successional crops of all, and thus add to the utility of your long ranges of glass. The position and method of training the trees is ruled by the width of the house. A house 12 to 18 feet wide has ample space for the trees to be planted in front and trained upon a trellis under the roof; but in a narrow house the trees answer best trained against the back wall, in which case you may take a single cordon up each principal rafter from the front. Such rafters are usually about 8 feet apart, and cordons at that distance throw no hurtful shade upon the back wall. If you adopt this plan have fan-trained trees of Peaches, Nectarines, and Apricots against the back wall, and cordons of Plums to the rafters. Sometimes, instead of cordons up the rafters, Grape Vines are planted near the front about 20 feet apart, each Vine having a single rod trained horizontally along under the glass 2 feet from the bottom of the roof. We have seen excellent Black Hamburg Grapes grown in this manner equal in every respect to any we have ever had from a vinery.

Collecting Plants (Collector).—Your letter does you very great credit. We admire your earnestness, and not less the endeavours you are making to fit yourself for the arduous duties pertaining to the work in which you desire to engage. We are glad also to observe, to quote your own words, that you are "fully aware that hardships, dangers, hunger, and disease may beset the plant-collector at every step;" but then you ask, "What, to the scientific naturalist, are the weary days of toil and wandering he has passed through in comparison to the delight experienced in discovering some new and rare exotic unknown to science and commerce?" To fit yourself for this work you must first be intimately acquainted with all plants that have been introduced. A sojourn at Kew would afford you the best facilities for acquiring knowledge, and if you write such a letter to Mr. Smith, the Curator, as you have written to us it will be sure to receive his attention. As you cannot for some time leave your father's nursery you might with advantage study Oliver's "Elementary Botany" (4s. 6d.) and Hooker's "Elementary Botany" (1s.), both published by Macmillan. Lindley and Moore's "Treasury of Botany" (Longmans), and Lindley's "Vegetable Kingdom" might also be useful, but the latter can only, perhaps, be obtained second-hand. The price of the former two volumes is 12s. At Kew the students have access to a complete botanical library.

Wool Waste as Manure (T. B.).—Wool waste from a carpet manufactory is not "a good manure for garden crops in general," for it supplies nothing but nitrogen to growing crops, unless it be sulphur. The trouble is to get it to supply even these, for, as you observe, there is no getting it to decay. When dug-in in the ordinary way the masses are crushed into pieces of felt that are rather worse than nothing in the soil, as they remain undecayed, and produce often enough a crop of bad fungus. If you can

find time to shake out the "shoddy" or "cadis," so that it can be thoroughly diffused through a heap of ordinary manure, and then subjected to a long fermentation, it will greatly add to the value of the manure, as such contains 4 or 5 per cent. of nitrogen, and ordinary manure about an eighth of that only. As nitrogen is the most valuable ingredient, although by itself not sufficient, in manure, the thorough decomposition of the waste in mixture with the manure would be a highly desirable object. The mixture of waste with sewage is even more valuable still, but the same process is necessary to make it of any use. If a market could be got for it, perhaps you could not better do than sell it and buy manure with the proceeds, for it may fetch £2 per ton from the manure manufacturers, who, to render it fit for use, subject such material to a prolonged digesting process with sulphuric acid. We do not suppose you have the apparatus for doing so, or we would recommend you to digest it. But for the trouble in properly mixing it with manure, fermenting it is the best way for you. The closet mixture might be laid up, mixed with half its bulk of soil, and this would, in a year or two, if protected from rain, form a very valuable manure indeed; but merely digging it in as you do is of little or no use for anything.

Names of Fruits (E. F. B.).—No one can possibly name a Peach from a solitary fruit, and that perhaps not a well-grown typical specimen. We can only say, if the tree bears small flowers and there are no glands on the leaves, that your variety is probably Royal George. (J. Charlton).—The Apple is Keswick Codlin. The Rose is very fine and very fragrant, one of the sweetest scented we have seen. Send it to the Floral Committee of the Royal Horticultural Society on Tuesday next.

Names of Plants (Lady King).—The petals of the flowers had quite withered and curled up in transit, but judging by the character of the stems and seed pods the annual appears to be a *Viscaria*, probably *V. oculata*. (Capt. Preston).—*Abies alba*, the White Spruce, a hardy and useful tree for general planting, but the wood is of little value. (T. S.).—Tall umbellifer, *Smyrnium olusatrum*; Aster-like flower, *Stenactis speciosa*; white flower, *Malva moschata alba*; 10, *Francoa ramosa*; 11, *Caucalis Anthriscus*. The others will be named next week. (J. W. A.).—1, *Veronica incana*; 2, *Saxifraga (Megasea) crassifolia*; 3, insufficient; 4, *Tradescantia virginica*.

Transferring Bees (F. J.).—Although expert apiarians would not hesitate to move bees from one hive to another at any time between the end of March and September, yet the any-period system is always attended with more or less sacrifice of brood. We would advise you to move your bees out of your old hives and put them in clean sweet hives at once, and place them on the same stand as before. Utilise any patches of brood by placing them in a super, and wedge them apart by small pieces of comb, so that the bees can run amongst them, and place them over the crown hole of your hives to hatch out, when they may be dispensed with; or, if you prefer, you may wait until twenty-one days after the issue of your first swarms next year, when the bees may be transferred without the loss of a single cell of brood, other than a few drones, which will be of no value at that season of the year; indeed, drones are at all times too plentiful.

COVENT GARDEN MARKET.—SEPTEMBER 5TH.

BUSINESS remains quiet, the supply of soft fruits being almost over, a good supply of foreign Pears arriving realising high prices.

MOUNTAIN BREEDS OF SHEEP.

(Continued from page 198.)

The next breed to be noticed is the Lank, and this from

the earliest period has found its home on the hill ranges of Yorkshire and Lancashire principally, although they are occasionally kept in Scotland, and also in some districts of Northumberland. They possess great merit in various respects, and are certainly the largest of any mountain sheep. They are black-faced when pure bred, but some have shown copper colour on the nose, and have the face and legs of the same hue, which was a sign of pure breeding by some; but a white face is generally considered as opposed to hardihood, and any tendency to a brindle shade as a sign of cross-breeding. However strong and weighty the Lonk may prove, yet the lightness of the forequarter is a characteristic of the breed; and as in great milking capacity in cows, so it shows or indicates good nursing power in the ewes for their offspring. Their necks are usually light and their legs long, and loin as frequently lacks strength. The lambs drop or shoot their horns with the new year, and the wethers never exceed one curl. Breeders, however, think much of the horn, and consider it when strong a great proof of constitution.

For sagacity the Lonks are unequalled. They are, in fact, continually working for their own benefit, with a zeal and cunning which makes them very difficult of restraint by ordinary fencing. It is said if there happens to be one better acre than another of grass land in a district or parish, whether it proves to be an orchard or churchyard, these breed of sheep quickly make themselves tenants at will. In consequence it is frequently necessary to "hopple" them in the spring season. Upon the hills they are said to run up walls or abrupt precipices like a cat, but a wire fence about 5 feet high is too much for them, and proves almost the only safeguard against their intrusion. A curious anecdote is told of one animal having broken bounds, and wishing to return to its comrades found a canal in the way and the bridge gate strongly barricaded, but the Lonk bided his time till a canal boat sailed past, and then jumping on to its deck cleared the canal at twice.

These ewes begin to drop their lambs at the end of March, when they are brought to the enclosed grounds under the hills, and stay there during the lambing period. They are not especially hardy, and require to be liberally fed with hay during the season of frost and snow. Feeding on the fells, however, for a certain period of the year is considered essential to the Lonks, as the Heather shoots and blossoms are said to give them more bone, and acts as an antidote to the foot-rot. The hogs are generally fed in the vales from September to April, and those which are intended for stores or Christmas shows are scarcely ever trusted with a run upon the hill ranges.

As an instance of what the Lonks will do when carefully and judiciously fed and managed, we must give the result of Mr. Jonathan Peel's wethers shown at the Smithfield Club in the year 1863 and fed below the hill, proved that his pen of three prize shearling wethers 215 lbs. each when they were weighed on October 25th, and their clip of wool on the April previous averaged 11 lbs. The Herdwicks are another important breed found chiefly on the mountain ranges of Cumberland and Westmoreland, where they enjoy the reputation of being not only a hardy but profitable race of animals, well adapted for the rough and bleak country where the hills are covered with Heather and short wiry grass. They are without horns, and have usually mottled or speckled faces and legs, which gradually shade off into grey or white as the age of the animal increases. When fed on these hills the fleece weighs about 3 or 4 lbs., the wool being coarse and open. Left on the hill pasturage the wethers usually remain until they are four years old before they become fit for the butcher, as to weight and quality; they will then average from 40 to 50 lbs. each, the quality of the meat being first-rate.

The ewes are good mothers, and generally produce fine strong lambs. They display great sagacity on the approach of snow storms by choosing situations free from the peril of deep drifts. When a storm reaches them they seek the most exposed part of the hills, which by the power of the wind is often swept clear of snow, and here they remain herded and congregated together until the storm has passed, taking the precaution to keep up a constant movement, and in that way to trample down the snow as fast as it falls. They possess at the same time a particular feature for a mountain breed, inasmuch that they remain attached to a certain district or locality, and it is rare for them to stray away from it. These are very desirable habits, instincts, and peculiarities for a mountain breed of sheep, because there is no doubt that with all the care which the owners and shepherds can take with various races of sheep, natives of the mountains, that great losses during exceptionally severe and deep snows have occurred, and which difficulty and losses can only be more advantageously met by the instincts of the animal combined with the experience and faithful services of the shepherds and caretakers.

The advocates and breeders of the Herdwick sheep are often jealous of their rivals the Lonk, and disdain any cross with them. On the ranges which the Herdwicks occupy Black-faces have been tried, but the ewes, more especially, failed because of the climate and the scanty nature of the grass; and it has proved the same when the Cheviots have been tried. In fact it has been found impossible to farm against the Herdwicks, which have been improved in the hands of certain breeders into and yielding a thick and heavy carcass, with points which a few years ago might have been looked for in vain. At the Royal Agricultural meeting at Carlisle they had a local class to themselves, and all the prizes went into Westmoreland, whereas at the Newcastle meeting in 1864 the Messrs. Brown and Mr. Edward Nelson represented the two native counties of the breed, and shared the prize list between them. The last named of these breeders, whose Herdwick prizes number between 200 and 300, and furnish in fact an excellent example of enterprise for other breeders to follow. It must be understood that each fell preserves the same earmark for generations, and the farmer takes to the flock with his farm, and leaves it at a fresh valuation to his successor. All the marks are registered in a quarto shepherd's guide, "The Star," and the raven, which typifies "Ravencrag Black as the Storm," are among its symbols. It is, however, in their ability to tide through a Siberian winter that the real blue blood of the Herdwick comes out.

The Penistone sheep is a breed found on the borders of Yorkshire, Lancashire, and Derbyshire on a heathy tract of land about 26 miles in length by 20 in breadth, and they are called the Penistone from the market town of that name where they are sold. These are no doubt descendants of the original Lonk, but by their advocates and breeders have established a character and conformation of their own, as they are a shorter and thicker animal than the pure Lonk; their wool is of medium length, of a silky appearance but harsh and wiry in texture, and weighing from 4 to 5 lbs. the fleece; they have white faces and legs. The rams exceed the size of the ewes and wethers in an unusual degree, a peculiarity which may be ascribed to their being taken to the lower country to be reared. The rams have horns which are very large, lying close to the head and projecting forward. A distinguishing character of this breed is an extreme coarseness of form, and particularly of the extremities. The feet are large, the limbs bony, the shoulders heavy, the sides fat; but the most singular formation is the length and muscularity of the tail, in which respect Penistone stock differs from all other sheep in this country. This enlargement of the tail is merely muscular and bony, and not at all analogous to the growth of fat which takes place in the tails of certain sheep of eastern countries. The mutton of these sheep is, however, highly valued for its juiciness and flavour. In the statement of the breeds of various sheep we have named as mountain breeds and their localities, great changes are going on, and sheep of superior type have been lately introduced.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Men have been employed mostly in the harvest carting of Wheat, Barley, and Oats. At intervals some latter cutting of Clover for hay has been taken to the stack in first-rate condition, and of far superior quality and make to the general crop of first cutting throughout the country. It is a simple fact that none of the first or early crops either of field or meadow produce has been made into superior hay, and this peculiar state of things will increase the value of late growths stacked in good condition. The work on the fallows, as well as sowing and preparing the land for late Turnips, has not been neglected; the land, too, is dry and favourable for the seeding of the corn stubbles not only with Turnips but also with the seed of Mustard, to be fed off or ploughed in as the case may be as a manurial preparation for Wheat or Lent corn in the spring. Without doubt where the autumn rains commence vegetation will receive a great impulse, the land being so hot and dry previously. The seeding of Trifolium, too, should now be proceeded with, using the three sorts of seeds—viz., the Early Crimson Blossom, the second early Pink Blossom, and the latest sort Perfect White Blossom, and these if cultivated with care are, or may be, mixed with Italian Rye Grass of foreign growth, in which case the Clover is protected during winter, and also is found to fill up vacancies caused by the slug eating the young Clover or other casualties; it is also better adapted for hay when in admixture with early Grasses. The weather has been inviting to farmers to thrash Wheat in the field, and much has been done in the early districts. It is, however, a questionable practice in our fickle climate, for the latter part of the harvest may be endangered, unless in those cases where a large staff of manual labour is available or extra horse power is at hand.

The last cross-ploughing of the fallows on heavy land should now be done, and the weather being favourable the cleaning of the land will be insured; but soon after this is done and the land worked sufficiently the important question of manuring arises. In outlying fields the use of

guano and bone superphosphate may be applied with great advantage, as the distant cartage of farmyard dung is costly, and at the same time dangerous on clay soils if early or heavy rains should occur, as the surface would then be tracked and injured, for these soils ought to be seeded in the first or second week in October. Then the question of drilling arises, for we consider that no farmer is master of his position on heavy land subject to yellow cress and black bent, unless the corn is drilled at 10 or 12 inches between the rows, in order that horse or hand-hoeing in the spring may be done if required. We have frequently seen the Wheat crops entirely ruined by weeds when sown broadcast; in Clover lea, however, broadcast sowing often proves best, especially when sown after the presser.

Hand Labour.—In harvest this is frequently much neglected for want of labourers, and the root crops become foul with Charlock and other weeds, especially on the chalk hill farms. We must also call attention to the importance of thatching the corn and hayricks as fast as made, but in some localities none but professional or journeymen thatchers can be obtained; and as they are of insufficient as to time, we advocate that every farm of importance should be able to command a thatcher as one of the staff of labourers on the farm. For many years we brought up several young men for this purpose, and although they were reluctant to undertake the work at first, yet in every case we found them after practice to make good rick-builders as well as thatchers.

Live Stock was rather falling in price at the recent fairs, and should the dry weather continue long into September the grass will be scarce, and the root crops will prove lighter than they previously promised to become. It may be a question, however, if sheep can be purchased at a price to pay for root-feeding on the land next winter, because of the short numbers in the country, as shown by the recently circulated statistical account of numbers of live stock in this country. Sheep during the hot sunny weather should always be in fold during the heat of the day on the arable land, in order that their droppings may be available, but have their range of park or pastures during the night and remaining period of their feeding. We have frequently noticed that sheep resort to shade where they can, and in the case of ornamental or other trees or hedges they frequently shelter themselves, and leave what should be manure not only without benefit, but in fact is entirely lost. Where the grass is short this dry weather, and after having been fed during the summer with the dairy cows, is now getting stale. They should, therefore, now get a good change of fresh grass, Clover in the troughs, or early roots mixed with cake or corn meal in order to keep up the milking power of the cows, and also that they may not be let go dry too early; for with great milkers it is dangerous for them to dry off their milk too soon, in which case they are sure to form fat internally, and likely to produce downfall in the udder and puerperal fever at the time of calving.

MANURES VERSUS STIMULANTS.

It is an undoubted fact that great harm has resulted to agricultural progress from a misapprehension of the effect of manures in assisting plant-growth. The word "stimulation" is at the bottom of this difficulty. Properly speaking there is no such thing as stimulating plants except by feeding them. Men sometimes take whisky, wine, or opium, which, though they contain no nutriment to support strength, operate on the nerves to impel them to abnormal vigour. The vegetable world indulges in no such excesses, if for no other reason than that plants and trees have no nerves to be stimulated. We may, indeed, force a more rapid growth of plants by giving such food as is easily assimilated; but it is food none the less, and not stimulant. Some kinds of fertilisers may after a time become inoperative, yet it is because the soil has been fully supplied with that which the particular fertiliser in question furnishes and is deficient in some other ingredient. It has no parallel in the stimulating drug which loses its effect on the human system after repeated dosing.

In the apparent effects of some fertilisers, such as salt, gypsum, and potash, on certain soils, there is something akin to stimulation; but the effect is on the soil rather than on the crop. Salt, for example, is a powerful solvent and often produces effects inexplicable from its own manurial value. This beneficial effect, however, is due to the power which salt has in making available latent mineral fertility in the soil. By the use of salt the compounds of potash and phosphate previously insoluble are released and fitted for plant food. In other cases salt may decompose vegetable matter and release ammonia. Thus the crop may be greatly assisted by a dressing of salt without showing more than a trace of the salt in its chemical analysis. This, however, is not stimulation of the crop, for the plants only grew as they were fed, as truly as if the feeding had been a dressing of stable manure instead of a solvent to develop latent fertility in the soil itself. It is indeed true that the soil is stimulated to produce more than it naturally would, and unless feeding manures are used these fertilisers, which only act by making plant food available, will in time cease to produce any effect.

A common objection among the mass of farmers to commercial fertilisers is that they act as stimulants; but it is certain that the same objection might be urged with equal propriety against every kind of manure. The decomposition of stable manure in the soil gives off carbonic acid gas, which decomposes the particles of earth with which it comes in contact. So, too, in greater degree with Clover or other green herbage turned under in June, which decompose with even greater rapidity than manure. A well-worked summer fallow has its chief advantage in exposing as much soil as possible to the influences of air and heat, so as to make its fertility more available. Yet there are many farmers who scout the idea of using concentrated manures lest they exhaust the soil, while they think everything of the naked fallow. The effect of the latter is much the worse in this

respect. The concentrated manure generally adds some fertility, while with the naked fallow the increased crop has been produced through taxing the soil to part with more of its strength than would occur naturally.

The thorough cultivation which farmers should give hoed crops answers much the same purpose of this so-called stimulation. It develops ammonia and other plant food. Often the passing through corn with hoe or cultivator in the growing season will start the plants into such vigorous growth as to make one think the corn had been "taking a drink," to use the language of a certain observant farm labourer. The expression was literally true, yet the drink was ammonia, which the loosened soil had absorbed from air, and rains, and dews. The ammoniated water of dews is the most stimulating of all manures; but it is only so because it supplies food just in the right condition for plant roots to take it up. The same is true of liquid manures generally. They are immediately available, and thus help the crop to which they are applied. If it were possible to make the greater share of the latent fertility available each year the soil would soon be exhausted. On light soils this is sometimes the result, unless the land is manured as soon as cropped. Heavy soils cannot be exhausted to the same extent. The crop falls off while there is apparently plenty of fertility in the soil, but it is locked up in clods where the roots of plants cannot reach it. On such land under-draining and thorough tillage must precede and in part take the place of manure.

The use of guano has been objected to by some because after a few years it leaves the soil poor. This is, however, only the result where continuous cropping with exhaustive crops is practised. With frequent seedings to Clover, selling none, but either ploughing it under or cutting and feeding on the farm, the use of guano should never leave the farm poorer. Purchasing stable manure, yet making none on the farm, tends to sterility as surely if not as rapidly as purchasing guano. The stable manure is not so immediately available, and hence the process of exhaustion would be slower. The immediate availability of the concentrated manure gives it an important advantage. The nimble sixpence is better than the slow shilling in manuring, as in business matters. It is, however, easy by diverting a part of this available fertility to growing Clover and other renovating crops, to get not only the nimble sixpence in the first crop, but also the slower shilling in the greatly increased fertility of the soil.—(*American Cultivator.*)

BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.—At the Council Meeting held at Bristol on August 28th, Sir J. T. B. Duckworth, Bart., in the chair, a letter was received from the Hon. Secretary of the Royal Agricultural Society of Guernsey, stating that the Society having obtained a grant from the Island States of £130—an increase of £40 on the amount usually voted—it was their intention to spend this surplus in partly defraying the expenses of their poorer farmers (owners of good stock) in exhibiting at the meetings of the Royal Agricultural Society of England and Bath and West of England Society and Southern Counties Association, the object of the Society being to strain every nerve in order to encourage and guarantee the representation of cattle from the island at the shows of these Societies. A letter was received from the Town Clerk of Brighton proposing that a deputation of the Society should meet the Local Committee for the purpose of inspecting the proposed site, &c., for the 1885 Show, on Tuesday, September 4th. A deputation, with Sir J. T. B. Duckworth, Bart., as Chairman, was appointed to visit Brighton on the date named, and power was given them to sign and seal conditions on behalf of the Society. The usual sums were granted for stock and poultry prizes at the Maidstone Meeting in 1884, and for the horticultural department of the Show.

OUR LETTER BOX.

Sowing Vetches (S. W.).—If your Carrots are raised about the middle of this month they will keep very well if carefully stored. The land may then be sown with winter Vetches, the sooner the better. Two and a half bushels of seed per acre will be enough. If half a bushel of winter Barley or Oats be mixed with the Vetches, then two bushels of the latter would be sufficient.

REMARKS.

26th.—Thick mist in early morning, fine hot day.
27th.—Calm and warm, but rather overcast.
28th.—Fine, bright, and warm.
29th.—Dull at first, fine afterwards.
30th.—Breezy, good deal of cloud, and slight rain at night.
31st.—Dull and calm, with slight rain; heavier in evening.
1st.—Fine morning, cloudy afternoon, rain in evening.
With a more cloudy sky the exceptional range of temperature has ceased, and the past week presents no exceptional features. The temperature was above the average but only slightly.—G. J. SIMONS.

19	W	

PEAS IN 1883.

THIS season has been a very favourable one for Peas. Early crops came in well to time, and midseason crops were luxuriant and prolific. Late ones are now suffering from the gales and wet, and the crops generally for this year will soon be over. Some new varieties have come very prominently to the fore with us this season, and several of the old standard sorts retain their position. The most noticeable of all these is Telegraph, which may be said to be the best midseason Pea in cultivation. It grows robustly, fruits profusely, is dark green in colour and superb in flavour.

Day's Sunrise we have ceased growing, as with us it did not equal its reputation. It is not so early as William I. The pods do not fill quickly, and they frequently remain empty at the points.

Culverwell's new Paragon sent out in 1883 is a grand new variety. It is not the earliest, but it fills its pods wonderfully well. In fact, it has a peculiar point to each of the pods, as they are quite square across, and always filled to the end. With us it attained a height of 5 feet, podded profusely, and each pod contained nine or ten peas. It is a robust grower, and has an excellent constitution. It will soon become a favourite, as it possesses all the qualities which could be desired.

The Stourbridge Peas always turn out well, and Electric Light, Kinver Gem, and Stourbridge Gem are amongst the finest of our Peas. The Messrs. Webb strongly recommend the Electric Light as the best, and, from experience, I can thoroughly confirm their advice.

Messrs. Carter have of late years mainly confined their Pea list to four varieties—*i.e.*; Telegraph, Telephone, Pride of the Market, and Stratagem, and they would do well to adhere to these, as it would be difficult to find other four to surpass them. Telephone is a second Telegraph, only it has not the deep dark green colour, and its pale pods tell against it, especially in competition; but apart from this nothing can be said against it. Stratagem and Pride of the Market are not unlike each other. Neither of them grows tall; both produce long handsome green pods, which fill up and become magnificent, but they are longer in doing this than the other two. We always gather Telegraph and Telephone a fortnight at least earlier than those two, and anyone who sowed the four to come in at the same time would not find them do so.

Giant Marrow, which is another of Mr. Culverwell's productions, is a splendid Pea. It might be described as Telephone extended, as it has all the qualities of the latter, but the pods are very much larger. Two years ago Mr. May, seedsman, Leeds, became the owner of one of Mr. Culverwell's new Peas, and the few I had of it have been grown here for two seasons with much satisfaction. It is not yet in commerce. It could not be distinguished widely on any particular point from the Giant Marrow, yet it is undoubtedly a few degrees better in every respect than that variety—more prolific, larger pods, and a better Pea. Large-podded Peas

as a rule are considered bad fillers; but this charge could never be sustained against any of Mr. Culverwell's Peas, because they fill as well as any of the small varieties.

Last autumn a Pea attracted my attention at Drumlanrig. It had grown about 6 feet high, and was bearing many pods about the size of William I., and each one was covered with a moss-like deposit. Mr. Thomson called it the Moss-podded Pea, and after growing it this season I find it of most excellent flavour. The only objection to it is that the haulm is rather high before it begins to bear, and this is the chief objection I have against Ne Plus Ultra.

Laxton's Omega and Veitch's Perfection are two late Peas of the highest value. Last spring I had a variety sent from Messrs. Sutton with no name, but under a number, and after growing several rows of it I am highly impressed with its qualities. It is of the Omega type, grows about 6 inches taller, produces pods an inch or so longer, and is unique in flavour. It does not require to be used young to secure its flavour fully, but it retains all its deliciousness until it is quite large. Another new Pea I had on trial from Canada was represented as the "earliest in cultivation," and I believe it will turn out to be so, as this year it came in many days earlier than Dickson's First and Best. It is longer in the pod than William I., fills well, grows 4 feet high, and has a very hardy appearance. As to its flavour I cannot speak, as every pod was saved for seed.

Last year a new Pea named Duke of Albany was described by Mr. J. Wright in the Journal. I secured a small supply of seed, and have now converted it into some quarts, as, like the Canadian, it proved so good as to induce us to save all the seed possible. This variety is not unlike Telegraph in its habit of growth, and it is equally as prolific and good in colour. The pods, however, are a little narrower and most handsome in appearance.

I had the pleasure of inspecting the Chiswick Peas in July last. They numbered over a hundred sorts, but amongst them all I did not see one so good as most of those named in these notes.—J. MUIR.

ROOT-PRUNING—LARGE PEARS.

THE time for this operation is now near at hand, and although most gardeners know the good results that arise from careful root-pruning, judging from the majority of gardens which we see from time to time, it is not half vigorously enough carried out, as is evidenced by the mass of breastwood, or the paucity of fruit on the extremities of the branches. The best results are probably attained by preparing the trees one year before in the case of wall trees, and two years before in the case of espaliers. In the former trees the roots are certainly confined by the wall, and the latter have the power of feeding themselves on all sides; and if the roots are shortened on the face of the tree one year, the next season the back can be operated on, and so treated the tree will feel no check. Fertility will thus be induced, and the fruit also gains in quality; the warmth of the surface soil will greatly benefit the newly-formed roots, which it is as well to protect and encourage by a summer mulching of leaf soil and manure.

I am led to refer to this subject, having recently seen remarkably heavy crops of fine fruit on the large wall Pears at Kenward Yalding (Lady Fletcher's), where the gardener, Mr. Smith, has very successfully operated on the unfertile trees, and I was shown sections of the coarse roots as much as 3½ inches in diameter that had been removed. Many of the trees had been bodily transferred (after preparation) to more suitable sites, and were forming a host of plump fruit buds. A large tree of Doyenné Boussoch was carrying a grand crop of probably twenty-five dozen fruit, which were all clean and of large size, while the rather shy-bearing Beurré Rance was fully covered all over with fine fruit free from specks or cracks. I counted thirty dozen on the tree. Trees that have been wholly or partially prepared or entirely lifted will require syringing in very dry weather, and watering at

the roots as well. I am inclined to think that our wall Pears have too much manure as a rule. Would it not be preferable to manure or mulch only when a full crop is set as is generally done now with pyramidal trees on Quince?

A very useful instrument for severing the roots will be found in the French hoppers—a pair of parrot-billed shears with long handles—which give immense leverage power, and enable a clean cut to be made through any root that they can grasp. The same tool is useful for taking off boughs from trees, or pruning old standard fruit trees from a ladder. They are supplied by most seedsmen, and can be had wholesale of Messrs. Corry, Soper, Fowler, & Co., of 18, Finsbury Street, London, in three sizes. While on this subject, too, let me note the great improvement in Aubert's secateurs, the latest being that one handle is lengthened and then returned to the pin that fastens the blades together, so that the spring cannot get broken or fall out. The hoppers and these secateurs (No. 193a) are used in the continental vineyards, and are very handy tools in a nursery or garden. I would also call attention to the American "Lightning" saws, which cut on both edges, one being for fine work and the other a perfectly new arrangement of teeth for green wood, while the handle being on a level with the centre of the blade, all the force of the arm acts directly on the cut, and they work with great ease. In the old saws the hold is rather above the blade, thus necessitating some pressure in sawing.

In the same garden were remarkably well-managed Peaches and Nectarines on open walls—quite a treat to see such—after the bad seasons for these fruits we have had for some years. Noblesse, Royal George, and Bellegarde Peaches were large in size, and I saw a tree which produced fifteen dozen of the finest Early Beatrice Peaches I ever saw. Pine Apple and Elruge Nectarines were loaded with highly coloured fruit. These trees had no more protection than a 9-inch board at the top of the wall. Every precaution had been taken to ripen the wood by laying in only suitable shoots somewhat thinner than usual.—GEORGE BUNYARD, *Maidstone*.

HARDY FLORIST FLOWERS.

SEASONABLE NOTES.

ANTIRRHINUM.—We have two long rows of striped and spotted Antirrhinums which have been very beautiful for a few weeks past, and which it is expected will continue flowering until winter. These were from seed, and are not so fine as named varieties; still they are good enough for ordinary decorative purposes, and in the majority of flower shows would be superior to common strains usually grown. The present is a good time to sow the seed, either on a warm border or in a box to be placed in a cold frame during winter. In spring prick the plants out where they are to bloom, and about a foot to 18 inches apart. Self flowers should be weeded out as they come into flower, otherwise the strain will soon degenerate.

AFRICAN MARIGOLDS.—A good strain of these is well worth growing. The flowers range in colour from a very light shade of yellow to a deep orange tint. Like Antirrhinums a really good strain is not easily obtained. In general the flowers have strap-shaped florets and are coarse in appearance. In a good strain the florets are quilled like an Aster, only much larger. Marigold seed is sown in April in a cold frame, and the seedlings are transplanted in June.

PENTSTEMONS.—For two years some plants of these have been lifted and potted, the flower stems cut off, and the pots plunged below the rims amongst coal ashes in a cold frame. In April they are planted out, and flower in early summer, not with one spike but half a dozen. There is no more floriferous plant than the florists' Pentstemon if the weather does not become too dry or cold. Our old plants consequently yield a continued supply of spikes from June till October. All that is required is to cut the old spikes off and not let too many appear at a time. Named varieties should be grown.

PHLOXES.—It is surprising that the florists' Phlox is so seldom seen in any quantity in gardens. It is perhaps the best of hardy flowers. Bold in appearance, chaste or rich in colouring, deliciously scented and free-flowering, only ignorance of its good qualities could have kept it so long in the background. The

best for effect are doubtless such richly coloured sorts as Bryan Wynne, Coccinea, and Souvenir de Berryer, but many of the light-coloured varieties are also worth growing. Early-flowering varieties cut down after flowering are again yielding a crop of bloom, but the colours in these are not so fine nor the decorative value of the plants as a whole so good as the late-flowering sorts. To have these very late plants are divided and planted in spring, the result being that these flower much later than older-established plants. Five stems are quite enough for one plant to carry. We often have individual spikes much larger than any we have seen elsewhere as the combined produce of a stool unthinned and tied closely up to a stake. In staking there is no necessity to tie the plants higher than half the height to which they will attain.

HOLLYHOCKS.—Last year our plant stock were free from disease; the year previous they were covered with Puccinia. The plants were cut down before winter and left to their fate. Strangely enough most of them started into growth late in spring and are now in great beauty, most of them with three or four 9-foot spikes of bloom and not a trace of disease to be seen. As we grow only named sorts, and such fine old varieties as Cygnet, In Memoriam, Queen of Yellows, W. Thomson, Champion, Hercules, Memnon Improved, &c., the plants, which were left in disgust last year, will this autumn be lifted and wintered in large pots in a cool house, and the most made of them by propagation in spring. Mr. G. Rudd kindly gave me a hint two or three years ago that Hollyhocks would strike freely from cuttings in spring if sufficient bottom heat was given. Since then I have proved his advice to be good. Where the heat is not strong, however, I would still prefer root-grafting.

PANSIES.—It is worth noting of these that cuttings unprotected through the winter do better than those protected by a frame. There are plenty of rooted slips on the plants just now, and these should be pulled up and dibbled out in preference to cuttings. Is there any good reason why Pansies, both Show and Fancy, should be kept to little rectangular beds with small footpaths between? They are quite as floriferous as bedding Violas and much more interesting. All that is required to cause a prolonged bloom is soil in good condition in the first place, and all seed pods removed during the season. All our Violas require going over twice to remove the seed capsules, and the others require the same treatment, but Pansies are especially valuable for filling small vases. If the flowers are picked singly and crammed together thickly the effect is bad; but gathered, each flower on the growing shoot and loosely arranged by themselves, it is necessary to go to exotics of the best class to get a better flower for this purpose than the simple Pansy.—B.

MAIN CROP APPLES.

Of the dessert Apples mentioned in my letter (p. 175), Worcester Pearmain and Yellow Ingestre (in the London markets called Summers) will last some time longer. In the kitchen list Small's Admirable, Warner's King, and Stone's may be considered as belonging to the main crop, as they will keep good till nearly Christmas, and in the north no doubt longer. There is one other Apple that ought perhaps to be included in the early varieties. This is Yorkshire Beauty. It makes a handsome tree, suitable either as bush or standard, but preferable, I believe, as the former. It has a very clean and distinct growth, the wood having a purplish appearance. I believe it to be identical with Red Hawthornden and Counsellor. I wish those of your readers who grow these varieties would compare them; I can find no difference either in fruit or wood. Yorkshire Beauty would be the best name for it, as it has nothing in common with a Hawthornden.

The late gale has done very serious damage to the orchard fruit; in many places more than half of the crop is on the ground. Many bushels of Ribston Pippins, Blenheim Pippin, and Cox's Orange Pippin will thus be lost. This latter Apple will of course be planted by everyone, but it does not fruit well in every locality. I believe a light loam on gravel or any light soil is preferable. I should not advise any grower to plant more trees than would be required for home consumption until he has proved it. I have this year, when almost every variety is cropping, over 700 trees which will not apparently bear more than seven bushels. King of the Pippins (Golden Winter Pearmain) is an Apple that is very popular in the London markets, and in consequence of its hardiness and free-cropping properties should be grown by everyone. It is very handsome in appearance and usually of good flavour, but at times the quality is second-rate—due perhaps to the soil on which it is grown. There is another dessert Apple that I did not allude to in my list of early ones that is very popular in the north—Lady Derby or Whorle Pippin. This is a small Apple, in shape like the Wyken, but with a bright

crimson colour streaked with a darker colour, and is a good bearer. The Ribston Pippin will continue to be grown on account of its agreeable flavour; but where the Cox's Orange will fruit I have not the least doubt it will supersede it, as the texture of the flesh is not so firm, and therefore easier of mastication. The same remarks will apply to that old favourite the Margil.

Two comparatively new Apples, the Melon and Mother, if they will generally succeed out of doors, are sure to be favourites, but I fancy they are more suited for pot cultivation. This applies also to Calville Blanche, which will only obtain quality in a house or on a wall. Another good Apple but doubtful bearer in ordinary cultivation, the Reinette de Canada, is suitable for all purposes. Mr. Haycock grows them well on the cordon system, and says they require to be grown in the open to obtain the benefit of the sun. There are many large orchard trees of the Wyken (Warwickshire) in cultivation, and when well grown it is a beautiful dessert Apple. I have found it succeed well as a bush. I suppose it will be long ere the Blenheim Pippin goes out of cultivation, as it is a favourite with all; but the number of years it must be grown before it repays by fruiting will prevent its being extensively planted now that we have so many early bearers.

There are many good dessert Apples that I shall only casually allude to now, as it will be impossible in this letter to enumerate them all, and there will be many opportunities during the autumn, especially after the proposed show at Chiswick, to discuss their merits with a better knowledge of their respective values. The Aromatic Russet, Braddick's Nonpareil, Adam's Pearmain and Mannington are all of the highest quality, and will be appreciated by the grower. Later on we have the Sturmer and the Baddow (Spring Ribston or D'Arcy Spice). Both of these are good, and should be grown by everyone. There is another which is a favourite with many, and justly so, although its size is not in its favour. This is Sam Young, a highly flavoured Apple of Irish origin. Pearson's Plate and Cornish Gilliflower are also of good quality, but the latter is a very shy bearer. Many of the Russets are worthy of cultivation, and Brownlee's will become more popular as it is better known. I think, also, that Beauman's Red Winter Reinette is worthy of trial. There are many other good dessert Apples which I will allude to another time.

In kitchen Apples there is not the necessity to name so many sorts. With the addition of the New Hawthornden and Grenadier to those I have already named there will be a sufficient variety up till Christmas. The Grenadier is a fine useful Apple. Some two or three years since I asked your readers whether they could inform me of the origin of Grenadier or Lord Derby, and I am still in ignorance. I believe at that time in some nurseries they were mixed, but there is no doubt now of the difference. Lord Derby is much greener than the other, and in shape like the old Catshad. Grenadier can now be seen in perfection at Messrs. Bunyard's nursery.

With Lord Derby in the winter months must be associated one of the most prolific and valuable late Apples we have, that is Lane's Prince Albert. It is a handsome compact Apple, and a good keeper. The tree will require space, as it is of a free growing nature, and might be alternated with some Apple of upright growth, such as Worcester Pearmain. It is worth a visit to Berkhamstead to see the numerous trees there in full bearing. The Wellington (Dumelow's Seedling) still remains popular on account of the delicacy of its flesh. Peasgood's Nonesuch is the handsomest Apple in cultivation, and this year is remarkably fine; but I do not think it is a sufficiently good bearer for general cultivation. One of the best late Apples, but which would precede Prince Albert, is Tower of Glamis. It will grow in any form, but its lengthened shoots make it especially suitable as an espalier. Dr. Harvey is also a favourite in the London markets. In the varieties I have mentioned a sufficient selection could be made for succession.—L. A. K., *Maidstone*.

P.S.—Since writing the above notes on the Yorkshire Beauty, I have found true types of the Red Hawthornden (as described by Dr. Hogg) on the trees. As I find the Apple is known in Covent Garden Market under the name of Red Hawthornden, although but few fruits are typical of the class, it will be better to continue it. As the Apple is so worthy of cultivation, it will no doubt be cleared up.—L. A. K.

ACACIA GRANDIS.

THE vast genus *Acacia* stands pre-eminent among the plants of the Leguminous family, if not for its utility to mankind, at least for the considerable number of species included within its limits. A large proportion of them are natives of Australia, and numbers are exceedingly beautiful when in flower; from these we select one of the neatest and dwarfest species, more especially adapted for window or frame culture.

The *Acacia grandis* is a native of Western Australia. It forms a

shrub of moderate size, and flowers freely while small. The stems are angular, grooved, and usually, but not invariably, quite glabrous. The leaves consist of two pinnae articulated at their base, each pinna being about an inch long, and composed of from eight to ten pairs of linear, alternate, smooth leaflets, the rachis or stalk to which they are attached being flattened, and terminated by a small leafy point.

A. grandis is a most charming window plant for spring flowering, being at that season loaded with its golden yellow halls; and at all periods of the year its elegant foliage gives it an ornamental character.

Its propagation is effected either by seeds or cuttings, usually by the latter method; they should be inserted in white sand, or very sandy soil, and covered with a bellglass or tumbler. As they are impatient of damp, they require a little more care during the rooting process than those of the leafless species. The inside of the glass should be wiped daily, and as soon as the cuttings are fairly struck they must be potted-off into sandy peat, and eventually into good fibrous peat containing less sand.

Though accorded specific rank when first introduced, *Acacia grandis* is now universally regarded by hotanists as but a variety of the polymorphous *A. pulchella*, and it differs chiefly from the type in having more numerous and longer leaflets. Several other desirable forms of

Fig. 40.—*Acacia grandis*.

A. pulchella are in cultivation, one of which—*A. hispidissima* of catalogues—is specially deserving of mention on account of the long spreading hairs with which the branches are clothed. This variety is also cultivated under the name of *A. lasiocarpa*. As a companion plant to *A. grandis* may be recommended *A. Drummondii*, a plant of more recent introduction, and perhaps somewhat more delicate in habit. Many other desirable species occur in catalogues, but a large proportion of these flower only when the plants have attained an inconvenient size.—W. T.

CHANGE OF CUTTINGS AND FRUITS.

A CHANGE of cuttings of hedging plants is often very desirable. It is not only in hedging plants that a change is desirable, but it is the same in fruits. Strawberries, for instance, are very much benefited by a change. I know a garden where Keens' Seedling would not grow at all well, though formerly it had succeeded admirably; but plants from another district grew, and fruited with their former vigour. It is the same with Apples and Pears. I have seen varieties that have been propagated on the place refuse to grow well, and eventually die; whilst when the same varieties have been obtained from a distance they have been most satisfactory, and even grafts from a distance have been beneficial. I read with pleasure in the Journal of the success of the Woolhope Club in their endeavour to prove that the old Herefordshire orchard Apples and Pears would not die out, which a few years ago they were in danger of doing. In many fine old orchards the trees were in different stages of decay, and no means were taken to preserve the varieties; and I often

thought if grafts were sent to a distance the old varieties would be easily reinvigorated. I suspect the old Golden Pippin in Thomas Andrew Knight's time was in the same condition as the Foxwhelps, Skyrme's Kernel Apples, and Taynton Squash Pears were when the Woolhope Club took them in hand. But I find on referring to "Knight's Treatise on the Apple" that the Foxwhelp, Redstreak, and Taynton Squash Pears were in nearly the same condition as the Golden Pippin, especially the Taynton Squash Pear, which was quite as bad. It seems that he was very careful in his experiments, and the results of those experiments led him to suspect that varieties of Apples have their limits fixed by Nature, like the seasons—spring, summer, autumn, and winter—and that it was impossible to perpetuate the old varieties. But I should think if he had tried his experiments at a distance, or procured grafts from a distance, the results would have been better. To make matters worse he cautioned planters from receiving trees out of the district.

It may be of interest to some of the readers of the Journal to know how his experiments were carried on. In his "Treatise" he says:—"When I first observed the unhealthy state of all the young trees of these kinds I suspected that it arose from the use of diseased grafts taken from old trees, and that I should be able to propagate all the valuable varieties by buds taken from young newly grafted trees, as these can scarcely be said to take any of the wood of the old stock with them; but to remove still further every probability of defect which might be communicated from the old trees, I inserted the young shoots and buds taken from newly grafted trees in other young stocks; and I repeated this process six times in as many years, each year taking my grafts and buds from those inserted in the year preceding. Stocks of different kinds were also used; some were double grafted, others obtained from the branches of Apple trees which had emitted shoots from cuttings, and others from the seeds of each kind afterwards inserted in them, under the idea that there might be something congenial to the fruits in stocks of this kind. The grafts grew tolerably and equally well in all, but there was always a want of hardness and elasticity in the wood; and at the end of three or four years all began to canker. Several kinds of fruits were subjected to these trials, but principally the Redstreak and Golden Pippin (particularly the latter); and as these had formerly grown well in the same soil, I began to suspect that their diseases arose from the debility of age, and would consequently be found incurable."

It will be seen by the above that his opinion was not theory.—
A. YOUNG.

NOTES FROM MY GARDEN IN 1832.—No. 5.

HERBACEOUS AND ALPINE PLANTS.

CONSIDERABLE attention having been directed of late in the columns of the Journal to these plants it may be interesting, perhaps, to some to know what can be done in a small garden with the careful use of means, and, I flatter myself, with an eye to the selecting of proper subjects for it. I have often advocated the more liberal use of these plants, but the multitude of varieties has often deterred persons from attempting them. This has been somewhat intensified by the desire that many people have to possess complete collections of different genera. This is all very well in its way for scientific objects, and doubtless those who thus grow them are benefactors to horticulture; but it may be desirable for Mr. Maw to grow a complete collection of Crocus, or Mr. Barr of Daffodils, or Mr. Wilson of Lilies; but we cannot all do this, and my object has been to get together such herbaceous plants as are interesting for their flowering qualities and not merely as botanical curiosities, and also to insure through them and a selection of a few annuals and other plants a succession of flowers from the early spring to the late autumn, so that at any period I may be able to have something in bloom in my garden, and this is how I have managed it.

In front of my greenhouse there is a border about 4 feet wide and about 30 long. This is an early bulb border. There are Crocuses at the edge, and just behind them alternate clumps of *Chionodoxa Lucilæ* and *Galanthus Elwesii*, and behind them again some clumps of different varieties of *Narcissus* and *Jonquils*, and when the grass of these has decayed I sow it all over with *Mignonette*, which is now (August) filling the beds and sending out its delicious fragrance much to the gratification of passers-by and also of the bees which are busy over it. I do not care much for a scentless garden, and I have walked through many a one gorgeous in its colouring and neat in its carpeting, but as far as perfume went you might as well have gone through a series of Turkey carpets; therefore *Lavender*, *Mignonette*, and *Sweet Peas* always find a place with me.

There is a border alongside of my lawn which is not (Goth that I am!) dedicated to lawn tennis. This border is about 15 feet wide and 80 feet long, and contains a variety of herbaceous plants and bulbs. It is edged in its entire length with *Campanula pumila alba*, which is always green, and when, as it has been lately, it is in full flower, is exceedingly pretty. The Crocuses push their way up through it in the spring, and it forms a good groundwork for them. When they are withering

I cut off the grass, and then the *Campanula* has its way. At the back of the border I have some of the taller-growing varieties of Lilies, some grand clumps—*e.g.*, of *L. testaceum*, *L. davuricum*, *Sappho*, *L. incomparabile*, *L. auratum*, *L. superbum*, and *L. lancifolium rubrum*. Intermixed with these are tall plants of good varieties of *Delphiniums*, and in front the smaller-growing kinds *L. Leichtlinii*, which has not done well, *L. pomponium verum*, *L. Batemannia*, &c.; also *Fritillarias*, *Ornithogalum umbellatum* and *arabicum*, *Gladiolus Colvilli albus*, &c. The upper end is occupied by a large mass of *Anemone Honorine Jobert*; and amongst the herbaceous plants used are *Hypericum*, *Farfara*, *Senecio pulcher*, *Achillea Ptarmica fl.-pl.*, several species of *Campanula*, &c.; while interspersed amongst them are a few clumps of such annuals as *Sweet Sultan*, *Chrysanthemum Dumetia*, and also some plants of *Pelargoniums*, especially *Marshal McMahon*, which tends to lighten up the border with its brilliant foliage. At the upper end of the lawn I have a wide bed about 10 feet wide by 20 long. This is planted with tall flowering *Delphiniums*, and *Phloxes* at the back, *Galega officinalis* and *officinalis alba*, *L. candidum*, &c. In front are, in the spring, clumps of *Narcissus poeticus*, *Hyacinths*, &c., and amongst them *Sedum spectabile*, which is dwarf when they are in bloom, and as soon as they die down fill their places. I have besides at each end clumps of the old *Orange Lily*, and in the bed the old *Tiger Lily*, *Anthericum Liliastrum*, *Allium Moly*, *Aquilegia chrysantha*, *Doronicum austriacum*, *Epimedium pinnatum*, &c. The *Sedum* makes the bed very gay in autumn, when its large heads of purplish lilac flowers attract large numbers of butterflies, especially *Vanessa atalanta* and *V. Io*, besides my friends the humble bees, who seem to get almost tipsy with the honey they obtain from it.

I have besides this a long border opposite my *Rose* garden in which there are a number of the larger-growing plants. Here I have *Harpalum rigidum*, *Telekia speciosissima*, the *Winter Cherry*, some clumps of *Irises* and *Campanulas*, *Gypsophila*, various *Asters*, and a number of *Aquilegias*, many of them self-sown seedlings of various colours, seedlings from *chrysantha* and *californica*, *Bupthalmum salicifolium*, *Papaver orientale*, tall-growing Lilies, &c. It will thus be seen that I have throughout the season something in flower. There are a number of other plants which I have not enumerated which fill up the spaces in the beds, but I have named the principal ones.

The rockery is, however, I think, my special favourite in this department of the garden, and in it I have endeavoured to get some of the best plants I could afford to. It is about 100 feet long and about 4 feet wide. The stones are placed, I hope, in not a very formal way, and I have endeavoured to give it as natural an appearance as possible. There is a dip in the ground about two-thirds of the way, and here is the only place where I can grow plants that like a damp situation, and as it is very limited there are but few. On the rockery I have the following plants—A delightful group of *Ramondia pyrenaica* under the overhanging shelter of a large stone, keeping it from the sun's rays. Here is a mass of the *Pyrenean Rose*, which, however, I have to keep within bounds, as it spreads rapidly in all directions. Amongst it are some plants of *Hepatica angulosa* and some roots of *Crocus Imperati*. Then there is a clump of *Anemone apennina*, very lovely in spring; *Triteleia uniflora*, *Silene alpina*, *Lychnis alpina*, *Dianthus neglectus*, *Gentiana acaulis*; and over-running the stones and creeping all over the ground *Arenaria balearica* and *Mentha minima*, which form a green carpet for the other things. Here again on an elevation are *Androsace carnea* and *carnea eximia* (the *Mont d'Or* variety), and the *Edelweiss*, which is quite at home and has propagated itself from seed in other parts of the rockery. *Campanula turbinata* and *turbinata alba* are here, and running all over this portion is *Acana novæ-zealandiæ*, which is now conspicuous with its crimson spikelets. This forms a capital groundwork, as all other plants seem to push themselves up through it. Here, too, are *Anemone stellata fulgens*, conspicuous in early spring with its brilliant blossoms. *Erinus alpinus* seeds itself over the rockery. *Phlox Nelsoni* makes a brilliant display in spring, but the slugs, one great bane of the rockery, have finished off *Phlox divaricata*. *Androsace lanuginosa* is here also; then *Ajuga reptans variegata*, although this will go back to the green form. *Æthionema grandiflorum* has flourished well here, while *Campanula Allioni* has quite disappeared. *Dryas octopetala* flourishes, but is a shy bloomer; but a large clump of *Aubrietia* (Ingram's variety) is beautiful in spring. Here, too, *Linaria alpina* is very pretty. This is the lowest part of the rockery, and here I have a nice clump of the very beautiful *Cypripedium spectabile*, which has established itself well and flowers in abundance every year. *Orchis foliosa* I have not succeeded so well with, but *Primula rosea* does very well here and in the upper part of the rockery. I have

various plants of *Primulas pulcherrima*, *cashmeriana*, &c., and *Omphalodes Lucilæ* is flourishing. *Dianthus neglectus* and *alpinus* are also well established, and *Androsace sarmentosa* has made a large plant quite a foot square, but has disappointed me by not flowering this year, although nothing can be more vigorous than the plant itself. *Dianthus deltoides* is somewhat too vigorous as it spreads itself all over the rockery, but is very pretty when in flower. At the back of the rockery *Myosotis dissitiflora* has established itself and requires very close watching; it seeds itself all over the place, and must be pulled up or it would overrun everything.

I have, in giving a description of these parts of my garden, not done so because I flatter myself that there is anything peculiarly excellent in my culture, far from it; but I wish to show how in a limited space much real enjoyment may be had by those who prefer this style of gardening. Had I been addicted to bedding-out what would have been the state of things? I should have filled my greenhouse with bedding-out plants, which would have deprived me of the pleasure that it has afforded me all through the year; my garden would have been bare for eight months at least, and then I should have had a blaze of colour to be dashed by the first heavy rain and cut up by the first severe frost. As it is, there is hardly a day in the year that I cannot find something in flower and at most times something to cut; and one great feature in it is that you are continually coming upon something fresh, something that you had forgotten was there, and which all at once has revealed its beauty. I may add that I have other pieces of rockwork and other herbaceous borders, but these are the principal ones; and although I have not enumerated anything like the whole of the plants that I grow, yet I have given the names of the principal ones, and of such as I am pretty sure would give satisfaction.—D., Deal.

THE GREAT STORM OF SEPTEMBER 2ND.

So calm and bright was the morning of "Partridge Day" that one might suppose the barometer had risen to "set fair," and that the soft balmy air of that smiling morn was an augury of the month's fine weather for which we were longing to crown the growth of fruit and grain with ripeness and full maturity. Much corn was still out in the fields, Apple trees were bending beneath a heavy crop of fruit, hop-picking was only just beginning, and the hops were so abundant and so fine that the growers were confidently looking forward to recouping themselves for the losses of last year. But as the day wore on clouds from the south-west gradually overspread the sky, rain began to fall and wind to rise as evening closed in; it blew harder and harder through the night. On Sunday morning there was a great storm. The barometer had fallen in parts of the country as low as 28.44; the pressure of the wind was 17 lbs. to the square foot, which indicates a velocity of sixty miles an hour. The storm continued till noon on Monday, doing incalculable mischief. In hundreds of orchards most of the fruit was swept from the trees, and that which was left on the branches is so battered and bruised that its speedy decay is inevitable. Hops suffered severely, for the heavy crop had just reached maturity. Many of the heavily laden poles were dashed to the ground, and upon those which were not blown down the branches were dashed about violently, and the bulk of the crop so much bruised that an inferior sample and low price must follow.

In the flower garden the beds have just reached the perfection of summer beauty, and were all aglow with colour rich and unblemished. Much colour still remains, but all the freshness and much of the beauty passed away on the wings of the storm. Not a perfect truss, hardly a perfect flower, was left behind. A huge *Gloire de Dijon* Rose, that has reached a height of full 30 feet upon the west side of a lofty building, had several dozen magnificent blooms clustering among the large handsome foliage before the storm. After it not a flower remained upon the tree, which is a wreck of broken branches and lacerated foliage. To show how powerful and searching the wind was, I may also mention an *Aristolochia Siphon* covering a trellis in a snug south-east corner, apparently quite screened from the south-west by lofty buildings, yet its foliage is quite spoilt. I need not enumerate further details of damage that is painfully visible on all sides. Some good may come of it if its baneful effects arouse attention to the importance of shelter for growing crops as thorough as is possible. No mere hedge or narrow belt is of much use to break the force of such a storm, for it blew with such violence that the foliage of a belt of Hazel some 30 or 40 feet wide is shrivelled and dry as though it had been scalded, the side farthest from the wind having suffered equally with that which was fully exposed to it.—EDWARD LUCKHURST.

JUDGING AT COUNTRY EXHIBITIONS.

I AM rather an old judge at country exhibitions. I have judged at one village horticultural show for twenty years, except one year, and then I could not possibly go, and so badly did the officers and my usual co-judge get on with the substitute in my place, that I was appealed to not to let

anything, except a life and death affair, interfere again with my attendance. I may say, then, without any affectation, that I must have given satisfaction. In the twenty years, of course, I have had a good few colleagues, and some rather difficult to deal with—viz., the uncertain, or weak-minded man; he who took such a long time to make his mind up, who "liked to be qu're sure, you know;" the narrow-minded, or one-class man who was great in one thing, say Potatoes, but little in everything else; the bumptious man, the solid man, the know-every-man, a village shopkeeper, or publican, perhaps, who looked down upon you over his spectacles as much as to say, "Young man, don't you think to take me in, I know all about it;" the crotchety man, the judge with a fad or idea, to which everything must square or he cannot pass it. These men are all difficult to deal with, but the best way is to appear not to see these oddities, and get them to talk over their different standards and try to arrange a common ground of agreement as to certain points before judging, with the understanding that an arbitrator shall be called in on any point of strong disagreement. I find it the best plan again first of all on going into the show to take a general survey of the whole and set up in your mind the standard of judgment from what is exhibited. Make a local standard of judgment, and work up to it, rather than fix before you go to the show an ideal standard in your mind and expect everything to come up to it. I like to begin with the lowest class, the labourers, and judge upward, through the tradesmen's class up to the amateurs' and gentlemen's gardeners. In the labourers' class, of course, quality is not insisted upon to such a degree as quantity is, and food exhibits are encouraged more so than anything else, and the standard of judgment is gradually raised up to the highest, the gentlemen's and gardeners' class. In judging, it is wise for the judge, in case of an exhibit looking as if should have the first prize, to expose to view the blemishes that have put it down, to turn up the decayed portions to the light, or to cut open, or otherwise display to anyone who looks at it, what it is that has caused the judgment to go in the way it has; or, if that cannot be done, and the judge is not a good one at taking a mentagraph of the special exhibits, to make a note of it, and either give in the note to the Secretary, or keep it himself for reference if he is pulled up about it. One of the best things a judge can do is to clear out of the place as quickly as he or they can. If they stay, and they are men that are easily approached, they will most assuredly be "called over the coals" on something in their judgment that does not suit some exhibitor.

I forgot to say, in speaking of the difficulties of judging, that officers that are themselves exhibitors are dreadful people to have to do with. If they are men of strong opinions, as in my experience I have generally found them; if their exhibits are not adjudged first, or very nearly first, they can be, and often are, uncommonly unpleasant to the judges. No officer who is himself an exhibitor ought to have anything to do with the judges. Sam Slick says that "there's a deal of human nature in men," and a man must be a very unselfish and generous man indeed who can see his productions put down and his neighbours' put up, and that under his very eyes, and be satisfied. We all cry out more or less in our several ways when we are trod upon; but of all the virtues required in judging at country exhibitions there is no virtue so necessary as plain common sense, added to quick discernment and rapid judgment. These will settle most things timely and satisfactorily.—H.

BATH FLORAL FÊTE.

IN some of the principal cities and towns in Belgium there is a formal alliance of music and flowers. Societies of harmony and of horticulture combine, each strengthening the other, and concerts and flower shows, not necessarily in combination, are held in the gardens of the twin organisation. Something of the same kind would appear to exist in Bath, Sydney Gardens forming the head-quarters of the Floral Fête and Band Committee. Horticultural exhibitions under the auspices of this Committee have been held for upwards of a quarter of a century, the one to be noticed being the third of the present year, and another has yet to be held. The Gardens referred to are most enjoyable, and a better position for a floral fête could scarcely be imagined. The ground is boldly, almost abruptly, undulated, and beautifully timbered. A railway in a deep cutting runs through them, also a canal, these being spanned by a series of fine bridges. The marquees containing the exhibits are placed in different parts of the grounds, being almost hidden by the overhanging branches of the trees. Quite a promenade, and in fine weather a very agreeable one, is thus involved in inspecting all the products.

These floral fêtes, as they deserve to be, are evidently much appreciated not only by the inhabitants of the "Queen of the West," but by those of adjacent towns, special trains being provided for their accommodation, and the weather being fine, as on the present occasion, visitors are very numerous. In honour of these fêtes flags are seen here and there. Very conspicuous was one floating from the tower of the grand old Abbey, the bells of which rang merrily in honour of the occasion, while the horses of the trams were gaily decorated with Sunflowers and Dahlias, and now and then a conductor decorated himself by wearing a fine specimen as a *boutonnier*.

The Exhibition of last week, taking it in its entirety, was considered the finest that has ever been held in Bath, although the fruit was below the average, and cut flowers had been injured by the storm of the first two days of the month; yet these were excellent—Dahlias, Roses, Phloxes, Gladioli, and especially Asters, these being admirably represented; while the display of wild flowers, neatly staged and accurately named, was the most creditable we have seen at any exhibition. Vegetables were also good; but the feature of the Show were the Fuchsias, which were of extraordinary merit, and the grand specimen stove and greenhouse plants staged by the redoubtable and ubiquitous Mr. Cypher.

PLANTS.

Fuchsias.—These had the place of honour in the schedule, and well did they merit their position. There are numbers of persons in the country who consider themselves good Fuchsia growers, founding their claim probably on their success at local or metropolitan exhibitions; but let all whom it may concern be very respectfully told that if they have not seen the specimens that are grown in the counties of Wilts and Somerset they do not know what a good Fuchsia is. The third-prize specimens at this Show, and even some of the plants that did not win a prize at all, would be easily first at most of the shows in the kingdom that are held beyond the radius of this Fuchsia-growing district. After this rather bold yet perfectly sober assertion not a few readers will be anxious to know what the specimens were like. To adequately describe them is impossible, but a general idea of their character may perhaps be conveyed.

The most valuable prizes were offered for nine plants, the amounts being £5 10s., £3 10s., and £2 10s. These prizes were won, and more than merited, by Mr. Tucker, gardener to Major W. P. Clarke; Mr. Lye, gardener to the Hon. Mrs. Hay; and Mr. Wilcox, gardener to Miss Barrow respectively. Mr. Tucker's specimens were magnificent pyramids, 9 to 10 feet high, and 3½ feet in diameter at the base, the pots being almost obscured by the pendant growths, and every inch of the plants from base to summit covered with flowers, resting on clean and healthy foliage. The following are the varieties:—Charming, Bountiful, Doel's Favourite, Elegant, and Lead-me-well (darks); and Queen Victoria, Flower of the Flock, Arabella, and Emily Doel (lights). Mr. Lye's plants were close columnar specimens of wonderful symmetry, clothed with fine foliage, and bearing large fresh and beautiful flowers, in the latter respect far surpassing the first-prize examples; but they did not equal them in size, nor did the drooping sprays hide the pots. They were about 8 feet high, and nearly 3 feet in diameter at the base. The varieties were similar to those above named, except Mr. Bright, which was perhaps the finest light Fuchsia in the Exhibition, and the Hon. Mrs. Hay, a superior dark variety. Mr. Wilcox's specimens were less formally trained—grand, free, vigorous, obtuse pyramids, 4 feet in diameter at the base, and from 5 feet to 7 feet high. A plant of Arabella was of marvellous excellence, the pot being quite hidden, and the flowers resting on the ground. For luxuriance of foliage and size and substance of blooms these were unequalled; it, in fact, seemed hard to have to admit that such splendid examples of culture should only obtain a third prize. Without questioning the justice of the awards it may be observed that the natural elegance of the Fuchsia is better displayed by plants of this nature than by hard, close, and severely formal training. This latter, however, appears the "fashion" in this district, but is there not a danger of its being overdone? At any rate, we consider the plant of Arabella referred to the premier Fuchsia of the Show.

Only briefly can the remaining classes be referred to. Mr. Fletcher, gardener to C. H. Gabriel, Esq., was well placed first in the class for six plants with beautiful pyramids 6 to 7 feet high and 2½ to 3 feet in diameter at the base. Mr. Snell, gardener to Mrs. Counsell, was second with equally large but less dense specimens, and Mr. Drummond third. Whether Mr. Drummond is the owner of the plants or the cultivator we are unable to say, the prize cards failing to indicate this, as they did in many other classes, while in few, if any, cases were the addresses of the exhibitors given. If the Bath shows are to win more than local fame, as they should do, the prize cards cannot be too complete. The excellent and evidently too hard-worked Secretary needs more assistance, or rather the entire system of placing the awards needs remodelling; but more of this in a future issue.

To resume. In the class for four specimens the prizes were awarded to Mr. Riddick, gardener to Mrs. Pinder; Mr. Bailey, gardener to Mrs. Phayre; and Mr. Wilcox in the order named, all with admirable examples of culture. In the single-specimen class (light varieties) Mr. Wilcox was first with Emilie Lye, 6 by 3 feet; and Mr. Lye second with Harriett Lye, 6½ by 2-foot columns. In the corresponding class for dark varieties Mr. Tucker was first with Charming, 9 by 3 feet; and Mr. Wilcox second with the same variety, 7 by 4 feet, only two prizes being offered in these classes.

In reference to such specimens as the above many admirers of the Fuchsia may not unnaturally remark that they have no room for growing similar examples, as their houses are not sufficiently large and lofty. The growers of some of the plants under notice would not admit this as a valid excuse, for the simple and sufficient reason that the best plants were not grown under glass at all, but in the open air. If anyone should smile incredulously that will be conclusive proof that he has something to learn in the cultivation of Fuchsias. They succeed just as well outdoors as Chrysanthemums do, and both are better out than in provided they are rightly treated. The largest plants above alluded to are really "trees" several years old, having trunks as thick as a man's wrist. They are rested, pruned, placed outdoors to break, shaken out, repotted, and grown outdoors, being placed under shelter, not necessarily under glass, during stormy weather after the flowers are expanded. There is nothing surprising about all this when it is considered that if Fuchsias are planted in rich soil in the garden, just as they are starting into growth in May or early June, they will grow far more healthily and flower much more profusely than plants will that are grown in an ordinary greenhouse. The cultivators above mentioned have simply recognised this fact and acted on it. They have read the lesson that Nature has taught them, and deserve great praise for their aptness at learning; especially, perhaps, to Mr. Lye is credit due both as a raiser of superior varieties and a pioneer in this simple path that has led to success.

Now a word on varieties may not be out of place. Let it be remembered that only those of naturally free growth are suitable for making huge specimens in a reasonable time; and also it should not be forgotten that these same varieties are not as a rule the best adapted for growing, as small com-

compact decorative examples in 5-inch pots. Here endeth—what some not very successful grower may possibly term—this "fuss about Fuchsias."

Stove and Greenhouse Plants in Bloom.—Time after time during the season the plants exhibited under this head have been enumerated, and we have no intention now of repeating a string of names that are quite sufficiently familiar to all readers. In the class for nine plants Mr. Cypher was a competitor, and of course first, staging most effective specimens, as the premier exhibitor invariably does. Mr. W. Long, gardener to C. Gardiner, Esq., was a most creditable second, *Ixora Williamsi* being splendid, and most of the others very fine indeed. Miss Ethel Brown secured the third prize; whether this lady was the cultivator or not, or whether she keeps a gardener the card did not denote, but at any rate the grand old autumn plant *Vallota purpurea* was brilliant with its fifty or sixty heads of flowers. Prizes were offered also for six plants, but the small boys who were entrusted to attach the cards were too busy racing and "boxing" to get them placed before we left the tent. Mr. Cypher secured the chief prize in the class for single-specimen stove plants with *Ixora Duffii*, bearing brilliant trusses a foot in diameter—the most effective plant in the classes. Mr. Long followed worthily with an admirable example of *I. Williamsi*. This exhibitor was first in the corresponding class for greenhouse plants with *Lapageria alba*, Mr. Cypher, by way of a change, being placed second with *Phacocoma proliferata Barnesii*.

Ornamental-foliaged Plants.—These were not so striking as we usually see them at large exhibitions. In the class for sixteen varieties Mr. Cypher was prominent, followed by Mr. Mould, gardener to E. G. Bryant, Esq., with fresh, bright, and clean examples which are destined probably to win future honours, as, though not large now, they were in excellent condition, and evidently in good hands. Mr. J. F. Mould, gardener to somebody we presume, secured third honours with a creditable collection. Mr. Shadwell, gardener to J. Chandler, Esq., and Mr. Bloodworth were the representative winners in this class for ten plants, both exhibiting fresh medium-sized healthy specimens. Messrs. Cooling distanced all competitors with *Lilium auratum*. The above plants were arranged in a marquee 200 feet long, and the general effect was highly imposing. The following were arranged in another tent:—

Miscellaneous Classes.—The best six Orchids were staged by Mr. Cypher, these including *Saccolabium Blumcii*, *Cypripedium niveum*, *Odontoglossum Roezlii superba*, and *Cattleya Eldorado*, all in good condition; Mr. W. C. Drummond was second. Mr. Cypher also had the best six Heaths, these including *E. Marnockiana*, *E. tubæformis*, *E. McNabiana*, and *E. ampullacea Barnesii*. Mr. G. Hart, gardener to Mrs. General Studd, had among others good plants of *E. cerinthoides coronata* and *E. Bandoniana*, and was deservedly awarded the second prize. Three Heaths were well shown by Mr. Gardiner and Mrs. West. Mr. W. J. Mould, gardener to E. C. Bryant, Esq., took the lead with six stove and greenhouse plants, among these being well-flowered specimens of *Erica Eweriana*, *Clerodendron Balfourianum*, *Allamanda nobilis*, and *Ixora amabilis*. Mr. Tucker was a very good second, his best specimens being *Bougainvillea glabra*, *Lapageria rosea*, and *Statice profusa*. Mr. H. Jones, gardener to General Doherty, took the third prize, his best plants being *Dipladenia Brearleyana* and *Eucharis amazonica*. In the corresponding class for three plants Mr. Hawkins, gardener to T. Jolly, Esq., was first, among these being a good *Stephanotis floribunda*; the second prize was awarded to Mr. Cole, gardener to Mr. R. B. Cater; the third prize going to Mrs. West, the exhibits in each instance being very creditable. Single-specimen flowering plants were well shown by Messrs. Cypher, Mould, and Long. Several capital groups of Ferns and Lycopods were arranged, the best twenty, staged by Mr. Tucker, including good specimens of *Adiantum concinnum latum*, *A. farleyense*, *A. gracillimum*, *Gymnogramma sulphurea*, and *G. peruviana cristata*. Mr. J. Coke, gardener to A. P. Stancombe, Esq., followed closely, his best plants being *Adiantum rubellum*, *Cibotium Schiedii*, and *Gleichenia spelunca*. The third prize was worthily awarded to Mr. W. C. Drummond. With twelve Ferns and Mosses Mr. E. Smart, gardener to H. Brook, Esq., was a good first, and the remaining prizes were well won by Messrs. L. Carr and F. Mould. Messrs. H. Jones, E. Smart, and J. Lye were the successful exhibitors of Coleuses, as were Messrs. Cooling & Son, T. Jolly, and H. Kemp of *Lilium auratum*; J. Lye and E. Smart of *Petunias*; T. Jolly, *Verbenas*; W. Jordan, T. Jolly, and J. Lye of *Cockscombs*, the exhibits and competition generally being very close and good. Ten good lots of Tuberous-rooted *Begonias* were shown, Mr. H. Hooper taking the lead with fair-sized plants of such fine sorts as *Queen of Yellows*, *Mrs. Laing*, *Sulphur Queen*, *Mr. R. Whyte*, *A. J. Soomes*, and *Mrs. Freeman*. The second-prize group of Mr. H. C. Mayel included good examples of *Prince of Denmark* and *Duchess of Edinburgh*. The third prize was awarded to Mr. W. Clifford. *Geraniums* were well represented. The first-prize six staged by Mr. Tucker were remarkably fine, the varieties being *Lucius*, *Craven Fox*, *Rev. Atkinson*, *President*, *Lizzie Brooks*, and *Jenny Dodds*. Messrs. H. Jones and E. Hall were respectively second and third, both staging creditably. *Variegated Pelargoniums* were well shown by Messrs. J. Lye, C. H. Gabriel, Mrs. Counsell, C. Smart, and E. Hall.

CUT FLOWERS.

A great quantity of these were shown, every class being well filled, and following so soon after storms the quality generally was surprisingly good. Mr. S. Brown had a grand stand of thirty-six spikes of *Gladioli*, and was followed by Messrs. H. Hooper, and A. R. Tanner, who also had many good spikes. Twelve *Gladioli* were creditably shown by Messrs. S. Tottle, W. C. Drummond, and A. R. Tanner, who were awarded the prizes in the order named. The twenty-four *Dahlias* which won Messrs. Keynes & Co. the first prize were particularly good, and Mr. T. Hobbs was a close second; the third prize going to Mr. J. Nation for another good lot. Mr. J. Humphries had the best twelve *Dahlias*, and was followed by Messrs. G. Horsell and J. Nation. Messrs. Keynes & Co., W. Shaw, and G. Humphries were the successful exhibitors of *Fancy Dahlias*. Very attractive and good were the boxes of single *Dahlias* as shown by Messrs. G. Cooling & Son, G. Humphries, and A. A. Walters. They were shown in bunches, and among Messrs. Cooling's premier collection the most conspicuous were *Magenta Queen*, *Paragon*, *Distinction*, *Sir W. Scott*, *Hon. J. T. Boscawen*, and *White Queen*. Single and *Pompon Dahlias* were also extensively shown by Messrs. Keynes & Co. *Roses* were rather the worse for the rough weather experienced, but the first-prize stand of twenty-four bunches put up by Mr. J. Mattock were still most

creditable, and Mr. W. Smith had many good blooms in his second-prize stand. Very good also were the twelve bunches which were shown by Mr. T. Hobbs, Mr. J. P. Budd, and Mr. J. Burgess, who received the awards in the order named. The German and French Asters as usual were very numerous and very fine. The winners with the former were Messrs. H. Hooper, J. Nation, A. A. Walters, and H. Catley, while the latter were best shown by Messrs. G. Cooling, H. Poeock, J. Burgess, and A. A. Walters. Phloxes were well shown by Messrs. W. Luton, H. Hooper, and J. B. Blackmore. Hollyhocks by Messrs. J. Burgess, A. A. Walters, and H. C. Mayall. Cut flowers in twenty-four bunches by Messrs. E. C. Bryant, E. Brown, and H. James. Messrs. J. Cypher, Mark Hookings, and H. James had good floral devices. Messrs. M. Hookings, E. T. Hill, J. Bland, and R. B. Cater, table ornaments, and Messrs. Cypher, Hookings, and A. George hand bouquets; the competition in each instance being very close, and there were several meritorious unplaced exhibits. The stands of named collections of wild flowers were very numerous, and the specimens remarkably well selected and named, the whole with the bouquets and vases of wild flowers forming quite a feature in the varied display.

FRUIT.

As previously observed, there was a falling-off in this section of the Show. No collections of twelve dishes were staged, and it may be assumed that the comparatively few gardeners who could show creditably in such a class would regard the prizes as quite inadequate for so great an effort. Twenty persons can stage six dishes more easily than two can stage twelve. No Pines were exhibited.

Grapes.—In the class for eight bunches of Grapes in four varieties there were three competitors; Mr. Nash, gardener to the Duke of Beaufort, securing first honours with very fine Alicantes, good Black Hamburgs and Lady Downe's, with small Muscats. Mr. Alderman Chaffin was a rather close second with very neat examples of Madresfield Court, Black St. Peter's, Black Hamburg, and Alicantes, but not perfectly ripe. Mr. Jones, gardener to General Doherty, had the remaining prize. There were eight competitors in the class for three bunches of Black Hamburgs, the prizes falling to Mr. Rye, gardener to James Denham Esq.; Mr. Bannister, gardener to H. St. Vincent Ames, Esq.; Mr. Smith, gardener to A. Shipley, Esq.; and Mr. Coles, gardener to Mrs. Smith, for produce of fair average quality and close in order of merit. Of two bunches of the same varieties there were five exhibitors, the produce being better than in the larger class, and the prizes went to Mr. Loosemore, gardener to H. Cooper, Esq.; Mr. Shelton, gardener to T. Waite, Esq.; and Mr. Lintern, gardener to W. Butler, Esq. Only three pairs of Muscats were staged, the prizes going to Messrs. Loosemore, Shelton, and H. Smith, the two former staging fairly good examples. In the Any other white variety class Mr. Loosemore was again to the fore with Foster's Seedling, followed by Mr. Rye and Mr. Cole, gardener to W. Pethick, Esq., with Buckland Sweetwater. This was the worst class in the Show, as the corresponding class for black Grapes was the best, eight lots being staged. Mr. Nash secured first honours with very fine Alicantes, Mr. Coles following with good average bunches of the same variety, Mr. Loosemore having the remaining prize for small bunches of Alicante. Some good Madresfield Court in this class, but by whom staged we know not, must have been passed with great reluctance by the Judges.

Melons.—Twenty-six fruit were staged in the two classes—namely, green-flesh and "any other variety" class; and although many of the fruits were of good appearance their quality was not satisfactory. In the green-fleshed class Mr. Iggulden, gardener to the Earl of Cork, was first with Masterpiece, the best Melon in the Show, Messrs. Tucker, Rye, and Carpenter following; but all the fruits were certainly not correctly named. In the remaining class Mr. Oatbert, gardener to H. Oldland, Esq., was well first with Blenheim Orange, Mr. Smart, gardener to H. Brooke, Esq., following. Other prizes, we presume, were awarded, and if so the "boys" were not successful in attaching the prize cards.

Peaches and Nectarines.—The winning dishes of these were fairly good, six dishes of nine fruits being staged. Mr. Shaw was first with fruit named the Prince of Wales, very pale; Mr. Crothers second with Exquisite; Mr. Gouldsmith third with Goshawk. There were eight dishes of six fruits, the prizes going to Messrs. Nash; King, gardener to W. Leach, Esq., and Iggulden, all staging Barrington. Nectarines were perhaps better than Peaches, and the competition was good. The prizetakers were Messrs. Rye, Bannister, Gouldsmith, Rice, and Shadwell, the varieties Pine Apple, Pitmaston Orange, and Victoria.

Plums.—The competition in these classes was excellent, and the display the best we have seen this year. In the class for twelve dishes of dessert Plums, Green Gage excluded, the first prize was awarded to Mr. H. Smith for Golden Drop, the second to Mr. Clifford for Kirke's, the third to Mr. Cator for Angelina Burdett—a good class. Of culinary Plums, the first and second prizes went to Messrs. Carpenter and Mr. A. T. H. Hall, both with Fonthill or Pond's Seedling, Mr. E. Hall following. A fine class of twenty-one dishes. For Green Gages the prizes went to Messrs. Lye, Weston, J. Hall, and Cole.

Nine dishes of Figs were staged, but as there was evidently some mistake in the awards, inasmuch as the best dishes were without cards, we are unable to indicate the winners. Cherries were very fine from Messrs. Cox and Jones, Filberts good, Apples numerous and excellent, and Pears generally satisfactory. All the most popular varieties of Apples were represented in creditable condition, but we did not obtain the names of the successful competitors.

VEGETABLES.

A remarkably fine lot of vegetables, principally in collections, were shown. As a rule, immense heaps were formed, and the vegetables also were, as a rule, much too coarse. Tomatoes were included in very large quantities, and Cucumbers, Cauliflowers, and Peas were conspicuously good. The winners in the classes for collections of twelve varieties were Messrs. Barnfield, W. Smith, and W. Tylee; of nine varieties, Mr. G. Garraway, Rev. C. C. Layard, and Mr. W. Fisher; of six sorts, Messrs. J. Walter, Shadwell, and W. Ragbourne, the awards going in the order named in each instance. Mr. W. Mead had a fine collection of Gourds, Squashes, and Vegetables Marrows; and seedling Potatoes were shown by Messrs. J. Walters, G. Garraway, and E. C. Laurence. The cottagers also had a great display of very fine vegetables.

At the luncheon, which was presided over by Mr. Alderman Chaffin and Mr. Cater, and which the Mayor of Bath attended, it was easy to perceive that more than ordinary amount of interest is taken in horticultural pursuits by influential personages, and with the support that the directorate richly merit, the Bath Shows will become more widely famed and add materially to the attractions of the beautiful city in which they are held.

ŒNOTHERA RIPARIA.

UNDER the incorrect name of *Œ. prostrata* this pretty dwarf Evening Primrose is now somewhat generally known; and though its flowers are smaller and less showy than those of some other species, we have no doubt that its hardiness, free-flowering habit, and especially the extreme neatness of its foliage, will cause it to rank among the most useful of the tribe. It seems to succeed in any good garden soil.

It is a near ally of the polymorphous species *Œ. fruticosa*, some form of which is to be met with in most gardens, and resembles that species in its inflorescence, but is of weaker habit of growth, and differs in its narrower and more elongated foliage, as well as in the distinctly stalked

Fig. 41.—*Œnothera riparia*.

flowers and seed vessels. Though popularly known as an Evening Primrose its flowers are diurnal, as in the case of many other species of this genus, and remain expanded several days. It is worthy of note that this species is described as biennial by American botanists, though so far as our observation has gone the plant cultivated under this name in England is certainly perennial.

When first introduced it was much recommended by the late Mr. D. Beaton as a yellow bedding plant, its prostrate growth rendering it very suitable for an edging to beds of taller plants; but the duration of its bloom is by no means co-equal with that of the plants usually employed as bedders, and of late years this species has been mostly confined to the mixed border. Though naturally more or less procumbent, it may, if thought desirable, be tied-up, and will then form a bush 1½ to 2 feet high. It is easily propagated by cuttings, division, or by seeds, and when pegged down the shoots root freely.—T.

APPLE MR. GLADSTONE.

AS I have seen the Editor's request for the history of this very fine early dessert Apple has not been responded to, I beg to say that I have for some years tried to find out its history in vain. Our stock first came from Sawbridgeworth and other sources in 1875, and a few years later the same Apple was imported from France as the Scarlet Pippin, while at Messrs. Cranston's I saw it under the name of Jackson's Seedling. I heard that it was grown largely at Evesham and that district, but my inquiries there have led to no results. My own opinion is that it will

prove an ancient but local variety; in the meantime we must keep to the name of Mr. Gladstone.

It is a somewhat weakly grower, but is very prolific, and is by far the earliest good Apple grown—not, perhaps, so early as the old white Joanetting, but a fruit that is fit for any select dessert, not only on account of its rich colour, but for its flavour and quality. It makes a fruitful pyramid on the Paradise stock, and is quite at home on the Crab as well. The Kent growers have noted it, and one East Kent farmer planted some hundreds of trees from here about five or six years since.—GEORGE BUNYARD, *Maidstone*.

ON Tuesday last a meeting of fruit-growers was held at South Kensington in connection with the Fruit Committee of the Royal Horticultural Society, with the object of promoting an EXHIBITION OF APPLES, to be held in the large conservatory at Chiswick early in October. The chair was occupied by Mr. John Lee. There were present Mr. Henry Webb; Mr. R. D. Blackmore; Dr. Hogg; Mr. Philip Crowley; Mr. Killick; Mr. William Paul; Mr. George Paul; Mr. John E. Lane; Mr. Smith, Mentmore; Mr. Roberts, Gunnersbury; Mr. Burnett, The Deepdene; Mr. A. F. Barron; Mr. Goldsmith, Hollenden, and others. It was unanimously resolved that, in consideration of the favourable opportunity which the present abundant crop of Apples affords for bringing together a complete collection of all the varieties that are grown throughout the country with the view of correcting their nomenclature, ascertaining their synonyms, and comparing their relative merits, an effort should be made to procure a representation of all the fruit-growing districts of the country, which shall be exhibited in the great conservatory at Chiswick from the 4th to the 18th of October next. A Committee was appointed, consisting of Mr. John Lee, Dr. Hogg, Mr. Barron, Mr. Killick, Mr. Roberts, and Mr. Woodbridge, to make the necessary arrangements and prepare the details, all of which will be duly announced by circulars and through the medium of the public press. Mr. Barron was appointed Secretary, and all communications are to be addressed to him at the Gardens of the Royal Horticultural Society, Chiswick.

— WE regret to have to announce the death of the REV. HENRY HARPUR CREWE at the age of fifty-four, which happened on the 7th inst. Mr. Crewe's name has been so long associated with horticultural matters, not only as an ardent cultivator of hardy flowers, but as a member of the Council of the Royal Horticultural Society and of the Floral Committee, that we are sure that this intimation will be read with universal regret. He had for a long time suffered from a painful disease of the liver, which, notwithstanding every effort to relieve him, at last proved fatal.

— A CORRESPONDENT informs us that "MR. WILLIAM MOULT, gardener to the Right Hon. Earl Ravensworth, Ravensworth Castle, who has been in his situation for thirty-five years, and has served three Lords Ravensworth, has deemed it necessary to tender his resignation. He is succeeded by his foreman Mr. Lindle, who has been trained under him. Mr. Moulton leaves with the good will and best wishes of his fellow gardeners. He has now retired, and well merits the independence he has gained by his honesty and industry."

— THE NYMPHÆAS AT KEW are just now in excellent condition, They have been growing well during the summer, and are now flowering most freely—indeed, we have never seen them looking better. Their handsome rich green leaves and large brightly coloured flowers remind us of the Nymphæas in the Oxford Botanic Garden, which Mr. Baxter grows so well; but the old Victoria tank at Kew is even more suitable for showing these plants off to the best advantage than the Oxford tank. The collection is now a large one, comprising most of the finest species and varieties in cultivation, one of the latest additions being the rich blue *N. stellata* var. *zanzibarensis*. Unfortunately they can only be seen at their best before noon, as the flowers soon close, so that visitors who are interested in these beautiful aquatics should endeavour to see them as early as possible in the day.

— THE superb VANDA INSIGNIS VAR. SCHROEDERIANA shown at Kensington on Tuesday last by Mr. Ballantine, gardener to Baron

Schröder, The Dell, Egham, is certainly one of the most distinct varieties ever brought before the notice of the Floral Committee, and it well deserved the first-class certificate awarded for it. The flowers are very even in form, the sepals and petals yellow with darker, but scarcely perceptible, dots, while the lip is large and pure white—a most pleasing contrast with the other portion of the flower. The plant shown was only a small one, but an experienced Orchid grower stated that he would willingly give 50 guineas for it as a speculation. It is indeed a valuable addition to what is fast becoming one of the choicest and best grown collections of Orchids around London.

— THE ORNAMENTAL GROUND on the river side of the Palm House at Kew is undergoing some alterations, and is certainly being greatly improved. The large Rhododendrons in the beds have been reduced in size, the Hollies are being restored to their original symmetrical shapes, some shifting and replanting also being necessary to preserve the characters of the ground. According to the original design, which we believe was by Nesfield, it was intended that the portions on each side of the Syon vista should exactly correspond, but this has been lost sight of for some years, and in consequence nothing but severe measures can restore the balance. The appearance has, however, been already greatly improved, and still further good results may be expected.

— MR. J. WILLIAMS, of the Brierley Hill Glass Works, Staffordshire, sends us a sample of his handsome GLASS VASES FOR HYACINTHS, which are admirably adapted for the purpose. The specimen submitted to us is about 8 inches high, and nearly the same in diameter at the mouth, vase-shaped, with small handles, and a leaf moulded on each side resembling one of the undulating forms of *Scolopendrium vulgare*. The glass is slightly tinted with blue, and within it is placed a white-porous earthenware pot to contain the bulbs. It is very artistic in design and well finished.

— THE exhibitor of the ROUSHAM PARK ONION at Kensington on Tuesday last claims that since it was purchased of the raiser, Mr. H. Wingrove, The Gardens, Rousham Park, Oxfordshire, in the spring of 1882, no less than fifty first prizes have been awarded for it at horticultural shows throughout the country. The bulbs shown were extremely fine examples of the Spanish type, the seed having been sown the first week in February, and twelve bulbs pulled and topped on August the 24th weighed 17½ lbs., while twelve others pulled and topped on September the 8th weighed 18 lbs. It is said that the ground had been well dressed with Clay's fertiliser.

— THE FRUIT TRADE OF JAMAICA, Dr. Morris states in the *Colonies and India*, has now become an established industry, which is rapidly being taken up by both European and negro settlers. Nearly the whole of the fruit is shipped to the United States, to the ports of New York, Philadelphia, and Baltimore. Some of the trade is, however, in course of being diverted to New Orleans, which is only within three days of Jamaica, and in close communication with all large centres of industries in the western States. The fruit trade of Jamaica, inasmuch as it fosters and strengthens other and more permanent industries, is deserving of every encouragement; and it is no doubt with this view the Government has promoted facilities for the employment of contract steamers between Jamaica and the United States, so as to find a ready and expeditious market for the produce. As shown when discussing the prospects of Cacao cultivation in Jamaica, the profits arising from the sales of Bananas, for instance, enable planters to establish the land in Cacao, and similarly the same facilities are offered for the cultivation of Liberian Coffee, spices, Indiarubber, and numerous other plants, which would otherwise be beyond the reach of persons possessing small means. The present position of the fruit trade in Jamaica will appear from the following table of exports for the year 1862:—

Bananas	887,370 bunches	£88,737	Value.
Oranges	35,456,978 "	33,684	"
Cocoa Nuts	2,763,655 "	10,225	"
Lime Juice	78,820 gals.	3941	"
Pine Apples.....	8886 doz.	1111	"
Limes	890 bls.	348	"
Mangoes	150,671 "	146	"
Tamarinds	7696 lbs.	96	"
Plantain	20,412 "	57	"
Shaddock	36 bls.	14	"
Total ..	—	£138,359	

The great increase in the value of this trade during the last ten years may be gathered from the fact that in 1873 the export value of fruit shipped from Jamaica was only £8750. That it will still continue to increase, and that ultimately numerous other industries will be pro-

noted by it, is proved by the fact that greater attention is continually being paid to it, and by the increased demand which is arising in the United States and the Dominion of Canada for tropical fruit. These countries possess a prosperous population, nearly double of that of the United Kingdom, and fruit of all kinds forms an important element in their daily food.

— THE same writer observes that the CULTIVATION OF SPICES, such as Nutmegs, Cinnamon, Cloves, black Pepper, and Vanilla, has also been taken up, not only in Jamaica, but also in Trinidad, Grenada, and St. Vincent. Nutmegs especially do well at Grenada; and with regard to other spices, if they are so successfully and so energetically carried on throughout the West Indies as in the islands above mentioned, we shall have them known in the future, not as the sugar islands, but as the spice islands of the west. With regard to the yield from Nutmeg trees in Jamaica, trees at six years old give a return of about 1500 to 2000 nutmegs per annum. With trees, say, 30 feet apart, and allowing one-third to be male or barren trees, this will give a return of 45,000 nutmegs per acre. Taking an average of ninety nutmegs to the pound, the return in cash value would be 500 lbs. of nutmegs at, say, 2s. per lb., equal to £50 per acre. In the Botanic Gardens, Trinidad, the yield per tree, nett, in the market has been over 20 lbs. (at ninety to the pound this would be 1800 nutmegs) with an average price of 2s. 2d. per lb. during the year. The value here per acre is at the rate of £60 per annum. In both the above instances it is only fair to mention that the calculations have been based on a comparatively small number of trees. The average yield over a large area of, say, forty, fifty, or a hundred acres would be correspondingly lower; but even under any circumstances it is evident that where suitable and favourable circumstances exist, as I believe they do in the West Indies, a nutmeg plantation is likely to be a very successful and remunerative undertaking. The Cardamom, a valuable East Indian spice, has lately been introduced to the West Indies with satisfactory results. It is adapted for cultivation in moist shady situations, at elevations ranging from 200 to 3500 feet. The plants have much of the appearance of the "wild Ginger" of the West Indies, and require little cultivation beyond keeping the ground clear of rank-growing weeds. The return per acre is estimated, at the end of three years, at about 170 lbs. of Cardamoms, worth 3s. to 4s. per lb.

— MESSRS. STUART & MEIN, Kelso, have sent us blooms of their strain of STRIPED FRENCH MARIGOLD, which are extensively grown in Scotland and the north of England for exhibition purposes at this season of the year, and command great admiration for their lustrous colours and correct markings. They are very clear and bright.

— GARDENING APPOINTMENTS.—Mr. J. W. Silver succeeds Mr. Clarke as head gardener to Lord Hill Trevor, Brynkinalt, Chirk, Denbighshire. MR. T. Grant, late gardener to W. S. Gillett, Esq., Harefield, Bitterne, Southampton, has been appointed gardener to Major Murray, Ossemsley Manor, Christchurch, Hants.

PEAS AND MILDEW.

WITH respect to the Peas sent to you I ought to say that it was not until the crop was nearly finished that we had a chance of comparing the variety with our latest crops here. On cooking Laxton's Omega we find the latter much more mealy and the colour darker, and the general verdict "not so good" as the old favourite. It is good on the soil here—it is better on a relative's good land. There was no trace of mildew until the last picking took place, and then very little.

President Garfield (from Sutton) sown late in the same plot, is badly mildewed and grows moderately, but the pods are good.

Telephone (from Carter) also mildews here very badly, but both these cases are doubtless aggravated by the lateness of sowing. They are both ripening seed; not a dish has been picked.

Omega, sown between these two, does not mildew except in small patches.

Latest of All (from Sutton) also sown between them, does not mildew, but is now bearing splendidly, the third picking now being ready, and the row showing signs of bearing for another fortnight at least.

Oxford Tom or *British Queen* (from Daniels, Norwich) now over 7 feet high, shows a slight attack of mildew, the first lot of pods being very small, short, curly, and blackened as if cankered. The pods now swelling are clear, although not so large as I remember on good soil fifteen years ago.

Owing to the dry situation I thought it advisable to make narrow trenches for all the Peas, to dig in a little manure, and to give a sprinkling of dissolved bones; the latter may have affected the pods of *Oxford Tom*.

For some unknown reason two rows of *Ne Plus Ultra* were an utter failure, and were dug up. Some seed out of the same packet given to a relative whose ground is good, grew well, and bore a good crop. As you have kindly suggested growing some of our favourites, I mention the above cases to show how Peas do with us.—COLVILLE BROWN, *Swaffham*.

ORNAMENTAL-FOLIAGE PLANTS.

FLOWERS are never so beautiful as when among foliage; indeed, a great glare of colour unrelieved by green, and solid masses of flowers alone, lack that refinement which constitutes the chief charm of nature as seen in the wilds. Glowing Pelargoniums, Azaleas, Fuchsias, and the other plants employed to make the greenhouse gay, lack half their charm unless intermixed with Palms, Dracenas, and Ferns. Owners of great gardens have long recognised this, but amateurs with limited means have too much ignored the fact. Believing that the merits of such plants as have been named need only to be pointed out to be recognised, I seek to say a word in their favour, and to enumerate a very few of the choicer forms which are amenable to ordinary garden treatment.

AGAVE.—There are large numbers of Agaves in cultivation, but one of the best, and that most generally grown, is *A. americana*. Some of the variegated kinds are very beautiful, and as they are of a very distinct habit and will thrive very well out of doors in summer, one or two should be possessed by every owner of a greenhouse. For filling-in vases few plants surpass these for centres. They will thrive in a mixture of loam, and peat, and sand, good drainage, and enough sharp sand to keep the soil porous. It should be repotted in spring, and it may then be propagated by division.

ADIANTUM CUNEATUM.—There are hundreds of beautiful Ferns which thrive in a greenhouse temperature which cannot be mentioned here, but the one named at the head of this is so beautiful and so indispensable that it cannot be passed. For cutting from to enhance the beauty of flowers in glasses or bouquets this is the best Fern ever introduced, and it will grow fairly well in an ordinary greenhouse. The best soil for it is half fibry loam and half fibry peat, with a good dash of sharp sand. If there is a shady corner in the greenhouse, that is the place for it and for any other Ferns which may be possessed; indeed, it may be as well to procure other Ferns than this one for the shadiest part of the house, or if the house is very much shaded Ferns should predominate. Great numbers of Ferns will grow with exactly the same treatment as recommended for this plant.

CHAMEROPS.—This is a genus of Palms which are for the most part very hardy and well fitted for ordinary greenhouse culture. They are very ornamental, and a few in a house improve the appearance greatly. Good fibry loam, and bits of charcoal mixed with it, suit them all. They are very easily cultivated. *C. Fortunei*, *C. humilis*, *C. exeelsa*, and *C. Martiana* are all good.

COLEUS.—Coleuses are tender plants, which will not live in winter in a greenhouse, but which grow satisfactorily there in summer. Cuttings or plants obtained in spring will make fine specimens in a short time. Cuttings may be very easily struck on a dung bed; all that they want is heat and water, with a moderate amount of root space and any light rich soil.

DRACENAS.—No greenhouse is complete without one or two Dracenas. The stove kinds boast colours not possessed by the hardier greenhouse kinds; but under gaslight, surrounded with white cloths, coloured crockery, and sparkling crystal, the green-leaved hardier varieties appear to greater advantage than the more highly coloured tender forms. Those named below are all very easily cultivated, and all make first-rate dinner-table-decoration plants. Loam, leaf soil, and a dash of sharp sand through it suits them as regards soil. Too large pots should not be given. The young tuberous-like knobs which form at the roots, if separated at potting time, placed in small pots, and started on a hotbed, will soon form young plants. The tops may also be removed from the plants and rooted, but this requires appliances which amateurs generally do not possess. Pieces of the stem will form plants if placed into a good bottom heat. It is better to exchange old plants for young ones with a nurseryman or neighbouring gardener, to whom the old stems may be of some value, than to try to propagate them without proper appliances. Given a fair command of bottom and top heat their propagation is an easy and rapid process, otherwise it is unsatisfactory. Sponging the leaves is necessary to keep them clean and free from insects. *D. rubra* is the best for an amateur, and *D. congesta* is next. *D. australis* soon grows to an imposing specimen. *D. Draco*, *D. indivisa*, *D. indivisa Veitchii*, and *D. lineata* are also worth a place.

FICUS ELASTICA.—A very handsome and an indispensable plant. It thrives well in ordinary loam, leaf mould, and sand. The leaves should be occasionally sponged to keep them clean. The tops taken

as cuttings, and treated as such in a good bottom heat such as a dung bed affords, soon make good plants, as indeed will bits of the stems with a leaf attached. The old plants will, if cut to near the pot, spring and form good plants.

FIGUS REPENS.—A very neat little plant, and very valuable for covering the backs or ends of greenhouses. To save trouble it should be planted out beside any bare wall, which it will cover with its miniature Ivy-like growths. It needs no training nor securing. Wherever there is an unsightly damp wall inside a greenhouse this plant should be employed, and it will cover it in a short time with an ornamental coat of green.

LATANIA BORBONICA.—One of the noblest Palms we have, and it will grow and thrive in a greenhouse, although not so well as in the stove. Fibry loam, fibry peat, and some charcoal mixed together will suit it. Overpotting should be avoided. Occasional sponging may be necessary to keep down insects.

PHENIX DACTYLIFERA.—The Date Palm is well worth growing as a greenhouse ornament. Those who have patience may raise it from ordinary Date stones; these should be sown in a good heat in spring, when they will soon start into growth. Stove heat will forward them on into good plants more rapidly than will the heat of a greenhouse, but even in the greenhouse they will soon form handsome plants. Plants of all sizes can be procured from most nurserymen. Ordinary soil and ordinary greenhouse treatment will suit it admirably. *P. reclinata* is similar, and will thrive under the same treatment.

PHORMIUM.—The New Zealand Flax plants are noble-looking, soon making fine specimens in any ordinary greenhouse. If they have a fault at all it is that they soon become unduly large for small greenhouses. *Phormium tenax* is the commonest, but, unless where there is plenty of room, only the variegated form should be grown. *P. Colensoi variegatum* is also very handsome and finer than *P. tenax*. *P. atro-purpureum* and *P. Veitchii* are also worth growing where room exists for their accommodation. Good loam, and sharp gritty sand to keep it open, is all they need in the way of soil. Sponging may be necessary to destroy white scale, which is often rather troublesome. In dry summers red spider is apt to attack them, but syringing will keep it down or dispose of it. A moderate supply of water is necessary at all seasons.

SEAFORTHIA ELEGANS.—This grand Palm is not very well adapted for small greenhouses, but where a few feet of head room can be given a nobler plant cannot be had for the centre. It thrives in an ordinary greenhouse, and is very easily cultivated. Fibry loam and fibry peat in equal parts, with sharp sand, fits it admirably.

THRINAX ELEGANS.—An elegant Palm, which thrives in a greenhouse, and does not take up so much room as many of the others of the order. Loam and peat and a little sharp sand, with good drainage and ordinary greenhouse treatment, suit it well. Scale is apt to attack it, but can be removed with a sponge and soapy water.

YUCCAS.—These are well worth growing by the amateur, because they are ornamental at all times of the year. Those named may either be grown inside or outside during summer, and of course inside during winter. Open gritty soil—say loam and peat, half and half, and broken sandstone a sixth of the whole—will suit them.—
A GARDENER.

THE ROYAL POTTERY, WESTON-SUPER-MARE.

BEING recently at Weston-super-Mare I availed myself of the opportunity of visiting this far-famed pottery, and, though anticipating something of the sort, was yet surprised at the extent and completeness of the manufactory now for years carried on by Mr. John Matthews. There are few horticulturists who have not heard of this pottery, but all are not aware of the extent of the trade there conducted. Immense quantities of pots, vases, &c., are packed almost daily and sent in all directions. This will be better understood when it is stated that within three weeks of the time of my visit nineteen large cratefuls were sent to Australia, thirty-seven to the West Indies, and ten to New Zealand. The foreign trade appears to be increasing rapidly, but this does not interfere with the work of meeting the large demands of noblemen's and gentlemen's establishments, parks, and nurserymen. In spite of the frequent heavy distributions there were yet to be seen immense heaps of pots of all sizes, ranging from 1½ inch to 30 inches in diameter, and many more are being made and burnt.

The whole process of making and burning the pots, as explained to me, was most interesting. The clay, of which Mr. Matthews has an ample supply, is generally dug in the winter, exposed to atmospheric changes, and is subsequently tempered and ground by powerful machinery. It is then passed forward to the "throwing" shops, where the "potters" mould to the required sizes. The pots are then carried to the drying sheds, these being contiguous to burning kilns, which are thus doubly utilised. When sufficiently dry they are "nested"—that is to say, the small are put in the larger pots and turned upside down to burn, so that each pot stands separate, and yet all the space is utilised. In addition,

"bunches" or piles of smaller pots are placed between the larger ones. The closer the pots are packed the better the kiln holds the fire. Besides the ordinary plain pots there are several specialities largely manufactured, such as Orchid pots, Alpine plant pots, "Long Toms" in great demand among nurserymen, the Oxford pot for specimen plants, insect and snail guards, bulb pots, Rhubarb and Seakale pots, pans for propagating, pans and baskets for Orchids, Strawberry tiles, border tiles, and other useful and ornamental articles.

For years the Royal Pottery has been justly noted for the beauty of the various and innumerable works of art which it has produced in terracotta. These comprise a wonderful variety of figures, fountains, vases, pedestals, garden seats, flower and Fern stands, window boxes, rustic pots, stands, and vases. Many of the new designs are of great merit, are perfectly executed, and quite distinct from anything of the sort previously attempted; while the old classical designs are and always will be in great demand, and therefore largely manufactured. Being informed that an elaborate book of designs is to be issued shortly, I shall make no attempt to further describe the new and beautiful specimens I saw at Weston-super-Mare.—W. IGGULDEN.

GLASGOW AUTUMN SHOW.

THE annual autumn flower Show of the Glasgow and West of Scotland Horticultural Society, which was held in the City Hall, Glasgow, on the 5th inst., was one of the most successful held for many years. Although nothing was present of extraordinary merit many excellent exhibits were staged. Many of the rare plants that used to grace the Glasgow Exhibition are no longer seen, but of ordinary plants very creditable examples continue to be shown, and lately in increasing numbers. We note also a great improvement both in quantity and quality of the fruit. Vegetables are hardly what we are accustomed to in the west of Scotland, but the show of cut flowers was never surpassed.

In addition to the trade collections, which, as usual, fill the greater part of the main hall, from Messrs. Thynne and Smith & Simon, Glasgow; John Lamont & Son, Musselburgh; John Craig, Stirling; Messrs. J. & A. P. Currie showed an attractive stand of garden crockery; Mr. Thomson of Spring Grove Gardens, Kilbarchan, exhibited a most ornamental Leek, which, if its progeny come equally good, would make a beautiful decorative plant. Among the more noteworthy exhibits we must class the twenty-four spikes of *Gladiolus*, with which Mr. A. E. Campbell of Cove Gardens, Gourich, gained the first prize in the class for nurserymen. These were quite equal to anything staged in what may be called the palmy days of the *Gladiolus*, which we fear are past in Scotland. The varieties were *Abricote*, *Apollon*, *Dido*, *Dumont d'Urville*, *Elizabeth*, *Horace Vernet*, *Ida*, *Leviathan*, *L'Unique Violet*, *Million*, *Mr. Derry*, *Mrs. Laxton*, *Murillo*, *Ninon de l'Enclos*, *Opale*, *Penelope*, *Pictura*, *President*, *Queen Mary*, *Rossina*, *Shakespeare*, *Tour de Mond*, and a fine salmon seedling. Judging from Messrs. R. B. Laird and Son's of Edinburgh first-prize stand of twenty-four Dahlias one would think that the day of the decline of the double Dahlia is yet far distant, although the new love—the single form, was strong and attracted much attention. The varieties were similar to those exhibited so often in the south and repeatedly named in the Journal. Mr. Sutherland of Lenzie gained first honours for twelve table plants, rather small but very neat and clean. The twelve were *Pandanus Veitchii*; *Dracænas nigro-rubra*, *Goldiana*, *ignea*, and *gracilis*; *Crotons undulatum* and *Chelsoni*, *Aralias Veitchii* and *leptophylla*; *Palms Cocos Weddelliana*, *Geonoma gracilis*, and *Calamus ciliata*. A beautiful and extensive lot were staged in the gardeners' division, the first being gained by Mr. J. Mitchell, The Gardens, Newmains. For four exotic Ferns Mr. Thos. Hogg, Aitkenhead, Cathcart, easily took first with four fine *Gleichenias*—*dichotoma*, *semi-vestita*, *spelunca*, and *Mendeli*, well furnished and over a yard across and high. The three *Ericas* with which Mr. Boyce, Burn Park, Uddingstone, gained first in that class, and also first for the most meritorious-grown plant in the Exhibition—*E. Marnockiana*, were particularly fine, and well deserved their honours.

For twelve dishes of fruit Mr. Robertson, Rossdhu, Luss, and for six Mr. Boyd, Callender Park, Falkirk, were awarded first with fairly good collections, especially Mr. Boyd's, though hardly equal to the collection shown by the same grower a week previously at Falkirk. Grapes were more than ordinarily good, Mr. Boyd's two bunches of *Alicante* especially so. For two bunches of Black Hamburg Mr. George Thomson, Spring Grove, Kilbarchan, gained first with two handsome bunches, fine in bunch and berry, but a little rusty, as were all the Hamburgs staged. Muscats were not quite equal to those of former years, Mr. Mackonichie keeping his ground here as usual. Apples were very numerous represented, few being full-grown, however.

Three collections of vegetables were put up for an equal number of prizes. By some strange judgment Mr. Thomas Hogg was placed first, Mr. N. Glass second, and Mr. D. MacBean, Craigends, third. Mr. Glass's collection was undoubtedly the most, and Mr. Hogg's the least meritorious, of the three. Mr. Glass's Leeks were the finest ever staged perhaps. Among amateur exhibitors Mr. Kilgour of Blair Drummond showed *Gladioli* well, and Mr. Stewart, of Campsie, Pansies; indeed, cut flowers were shown in enormous quantities and of super-excellent quality.

For some reason Glasgow shows have been falling back of late years. Wednesday's Show showed that the old Society has life in it yet. We hope it may go on improving and take the position which such should in "the second city of the Empire."

CEPHALOTAXUS FORTUNEI.

AMONGST the very distinct Chinese and Japanese Conifers which are now cultivated in our gardens the genus *Cephalotaxus* is very notable as the principal and best-known species composing it are distinguished by noble habit of growth, handsome foliage, and often by a profusion of Fig-like fruits. Three species are at present in cultivation—viz., *C. drupacea*, *C. Fortunei*, the subject of the accompanying illus-

tration, and *C. pedunculata*, a variety of the latter of fastigate habit being also known. The two first were both introduced by Mr. Fortune in 1849; but the last-mentioned species has been in this country about twelve years longer, and is now common in many gardens; but the variety *fastigiata* is a great favourite, and is often seen under the names *Podocarpus koraianus* and *Taxus japonica*. *C. Fortunei* has leaves about 3 inches long, very dark green, and handsome in appearance, and

they are exceedingly handsome and useful in imparting a diversity to shrubberies.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 11TH.

DAHLIAS were shown in such numbers and of such good quality generally at this meeting that a visitor might have supposed it was an Exhibition

Fig. 42.—*CEPHALOTAXUS FORTUNEI*.

Fig. 1 Female plant with its fleshy drupes. Fig. 2, Section of fruit. Fig. 3, Male plant with its inflorescence in the axils of the leaves. Fig. 4, Male catkin magnified.

they are arranged in a close two-ranked manner on each side of the branches. The fruits when mature have a purplish hue, and as they are produced in great numbers where the plants succeed well they have a most pleasing effect. A moderate shelter is requisite to insure the satisfactory growth of these Conifers, as in exposed positions they frequently lose their leaves and assume a very miserable aspect. The soil, too, should be thoroughly drained, but not too dry, or that will produce a similar undesirable result. When in their best condition

specially devoted to these flowers. Most of the firms that are famed for their Dahlias were represented, and as in several cases much taste was displayed in the arrangement a charming effect was produced. Other exhibits before both Committees also added much to the interest of the meeting.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. The following were present:—Dr. Robert Hogg and Messrs. P. Crawley, G. Goldsmith, J. Burnett, J. Willard, G. Paul, L. A. Killick, J. Smith, R. D. Blackburn, Henry Webb, J. E. Lane, J. Roberts, and W. Paul. Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, sent two very handsome Queen Pines, one

weighing 6 lbs. and the other 6 lbs. 2 ozs. They received a cultural commendation. Mr. Horley of Toddington, Beds, sent a seedling Apple and a seedling Pear, neither of which was considered of any merit. Mr. H. Golding of Romford sent a seedling Apple, which proved to be Cellini. Mr. G. Freeman, gardener to W. B. Greenfield, Esq., Beechwood Park, Herts, sent a very large Melon called "The Kaiser, which the Committee could form no judgment of, as it was not to be cut. The Early Milan Turnip from the garden at Chiswick was exhibited along with the Early Munich, both from seed supplied by Messrs. Vilmorin of Paris, and the former was far superior in size and quality to the latter, though both were sown on the same day. A first-class certificate was awarded it last June. Mr. Laxton of Bedford sent an ornamental Crab of high colour, called Dartmouth Crab.

Mr. Ross, The Gardens, Welford Park, Newbury, sent a seedling Melon raised between William Tillery and Dell's Hybrid. It is a large, smooth-skinned, green fruit, with a few traces of netting and a pale flesh. It was over-ripe and had no flavour. Mr. Ross also sent a seedling Grape raised from Black Monukka, being one of five raised from the same source, two being white and three with black fruit. It had suffered much from bad packing, and the berries were all more or less damaged. There were traces of merit in the flavour. The berries are oblong. Mr. Robert Holland of Stanmore Hall sent three bunches of Black Alicante Grapes, admirably grown and carefully finished. They were awarded a cultural commendation.

Messrs. James Carter & Co. sent plants in fruit of a yellow sweet Capsicum called Golden Dawn, for which a letter of thanks was awarded. Mr. King, Aylesbury, sent a seedling Tomato called King's Prolific. Mr. Killick of Langley, near Maidstone, exhibited Duchess of Gloucester and Premier Apples. Mr. Henry Deverill of Banbury sent some dishes of Onions called Rousham Park Hero, a fine large Onion of the White Spanish variety, to which a cultural commendation was awarded. Mr. John Ashby, The Gardens, Boredown, Whitchurch, Oxon, sent what he supposed was a new Celery, but which really was very well-grown Celeri Turc, or Incomparable Dwarf. Mr. John E. Lane of Berkhamstead exhibited a collection of Apples and a great variety of Nuts. Messrs. Veitch & Sons showed a collection of Tomatoes grown out of doors, both exhibitors receiving a letter of thanks.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. The following were present:—J. McIntosh, J. Wills, W. Bealby, S. Hibberd, J. Hudson, H. Ballantine, J. Dominy, W. B. Kellock, J. Cutbush, H. Turner, H. Cannell, and John Fraser.

Mr. C. Turner, Slough, had quite an exhibition of Dahlias, Show, Fancy, Pompon, and single varieties, very tastefully arranged, and constituting the great feature of the meeting. The Show and Fancy varieties, of which about 250 blooms were staged, were arranged on stands in the front of the group, the Pompons and singles being placed in boxes surfaced with moss, and having an informal row of Palms and Aralias behind, and a few small plants between the stands. A charming effect was thus produced, and proved what tasteful displays can be produced with a little care. The most distinct of the Show and Fancy varieties were the following:—J. Green, rich scarlet; Mrs. Harris, white, tipped purple; G. Barnes, bright purple, neat; Muriel, clear bright yellow; J. Standish, dark scarlet; J. Stephen, salmon-scarlet; Lady Gladys Herbert, blush, tipped dark crimson; Flag of Truce, white; Lady Wimborne, bright rosy-pink; Hope, lilac; Prince of Denmark, deep maroon; G. Smith, rich crimson; Grand Sultan, yellow, streaked scarlet; James O'Brien, yellow, numerous scarlet streaks; Mrs. Saunders, sulphur, tipped white; G. Barnes, soft purplish-crimson; W. H. Williams, bright scarlet; and Julia Wyatt, white. Noteworthy amongst the Pompons were White Aster; Lady Blanche, white; Isabel, scarlet; Favourite, deep crimson; Gem, warm scarlet; and Nemesis, maroon, pink centre.

Of the singles the brightest and most distinct were the following:—Helen McGregor, blush pink, yellow centre; Yellow Queen, bright yellow; Alba, white; Mauve Queen, purplish mauve; Beauty of Cambridge, dark scarlet; Firefly, bright scarlet; Duke of Teck, clear purple; and Paragon. The award of a gold medal signified the Council's appreciation of this fine exhibit.

A silver-gilt medal was awarded to Messrs. H. Cannell & Sons, Swanley, who contributed a very handsome collection of Dahlia blooms, representing all the sections, Show, Fancy, Pompons, and singles being shown in large numbers. Very notable were the free-flowering bedding varieties Glare of the Garden, bright scarlet, and Constance, of similar character but pure white. The Show and Fancy varieties were very fine, many being the same as those already named. Amongst the Pompons the following were notable:—Little Dear, white, tipped purple; Rigoletto, maroon; Hindoo, orange buff; Toby, scarlet; Sensation, yellow; Lady Bird, blush, shaded red; Louisa Richter, mauve; Countess Von Sternberg, pale canary yellow; Garnet, scarlet; Little Beauty, dark scarlet; Little Nigger, maroon. Some beautiful singles were also shown, the most noteworthy being Distinction, orange scarlet; Flavia, yellow; Concinna, scarlet, free; Althæa, rich crimson; Brightness, dazzling scarlet; blooms of the white Juarezi and striped Juarezi, the latter orange with a few scarlet streaks. Several stands of fine Zinnia blooms were also staged. A silver Banksian medal was adjudged to Messrs. Keynes & Co., Salisbury, for a number of Show and Fancy Dahlias, representing many fine varieties; the blooms were also of good substance, even, clean, and neat. Messrs. Paul & Son, Cheshunt, contributed a large collection of Dahlias, representing all the chief varieties in the different sections.

A silver-gilt Banksian medal was awarded to Mr. T. S. Ware, Tottenham, for a very handsome collection of single Dahlias, including many new and beautiful varieties. Messrs. Rawlings Bros., Romford, showed about seventy Show and Fancy Dahlia blooms of good size and substance, for which a vote of thanks was accorded. Mr. G. S. P. Harris, Orpington, Kent, showed a stand of Dahlias Baroness (yellow) and Ruby Gem (deep scarlet). A vote of thanks was also accorded to Mr. Glasscock, Bishop's Stortford, for a good collection of Dahlias, comprising many varieties.

A silver-gilt Banksian medal was awarded to Mr. B. S. Williams, Upper Holloway, for a group of healthy Nepenthes bearing a large number of fine pitchers. N. Rafflesiana, N. Hookeriana, N. Henryana, N. Williamsii, N. compacta, N. splendida, N. Mastersiana, N. Dormanniana, N. intermedia, N. superba, N. Khasyana, N. robusta, N. Excelsior, were the chief forms represented, some having pitchers of great size. Mr. T. S. Ware showed

several choice and rare hardy plants, the small but profuse and charming Rose Persian White being very notable. *Milla biflora*, with large white flowers, was also attractive, with the yellow *Cyclobothra flava*, the variegated *Lilium longiflorum*, and flowers of *Lilium speciosum*, roseum, and *Melpomene*. A vote of thanks was accorded.

Mr. C. Bennett, Shepperton, was adjudged a vote of thanks for richly coloured and handsome blooms of seedling Gloxinias. A vote of thanks was accorded to Mr. S. Ford, Crescent Nursery, Brentwood, for blooms of single Dahlias, also to Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, for flowers of *Batemannia Burtii*, *Oncidium plagianthum*, *Miltonia Clowesi grandiflora*, *M. spectabilis lilacina*, and *Cattleya Wallisi*. A cultural commendation was awarded to Mr. Cummins, gardener to A. Smee, Esq., The Grange, Wallington, for a plant of *Miltonia Regnelli superba* with two spikes of about a dozen flowers, a plant of *Warceswiczella Wendlandi* with greenish sepals and petals, and a white violet-blotched lip. Messrs. J. Veitch & Son, Chelsea, exhibited several novelties, including *Pelargonium Archduke Rudolph*, a dwarf free-flowering double zonal variety of a peculiar rosy-scarlet colour, *Torenia rubens*, with deep purplish-blue flowers, and several plants, for which certificates were awarded. Messrs. Hooper & Co., Covent Garden, were adjudged a vote of thanks for a tastefully arranged group of *Næglias*, *Tydæas*, *Gesnerias*, and *Gloxinias*, with Ferns, a central plant of *Nægelia Antinous*—with large velvety purple leaves being very striking.

First-class certificates were awarded for the following plants:—

Vanda insignis var. *Schradleriana* (Ballantyne).—A charmingly distinct variety, the sepals and petals yellow, with rather darker dots, the lip pure white. The plant shown had one spike of five flowers, and was much admired. This is unquestionably one of the finest varieties in cultivation, and is valued very highly.

Miltonia bicolor (Salter).—A pretty Orchid, the flowers of good size; sepals and petals narrow, white, the lip also white, but blotched in the centre with deep purplish crimson. The flowers are borne singly on peduncles arising from the base of the pseudo-bulbs.

Selaginella canaliculata (Veitch).—One of the Indian caulescent species with graceful and finely divided fronds.

Rhododendron Brilliant (Veitch).—One of the greenhouse varieties. Flowers of great size, $2\frac{1}{2}$ to $2\frac{3}{4}$ inches in diameter; the lobes large and round; colour rich scarlet. Head very dense, about fourteen flowers.

Begonia Novelty (Veitch).—A hybrid raised between *B. lineata* and *B. Davisii*, the latter being the seed parent. The leaves are 2 to 3 inches in diameter, dark green, with numerous silvery dots and blotches. Flowers small, bright rose.

Anguloa eburnea (W. White, gardener to C. Dorman, Esq., The Firs, Laurie Park).—A distinct species with large white flowers, very powerfully fragrant.

Dahlia Cetawayo (Ware).—A single variety, very dark maroon, rounded petals, bright yellow centre.

Dahlia Dr. Moffat (Ware).—One of the Paragon type. Flowers large, rich maroon, edged with scarlet. Handsome and effective.

Dahlia Mrs. W. E. Gladstone (Turner).—A handsome flower of the Show type, white, very faintly tinged with pink. Most delicate and beautiful.

Dahlia Duchess of Westminster (Turner).—A single variety; pure white; florets broad and rounded, slightly reflexed at the points.

Pentstemon Cerise Queen (V. Lemoine, Nancy).—Bright reddish scarlet with a white throat.

Pentstemon Purple Queen (V. Lemoine).—Flowers of great size, rich purple; throat white with a few purple streaks.

Begonia The Queen (E. Edwards, Holmside, Leighton Buzzard).—One of the Tuberous section, with enormous double globular flowers; the petals very numerous, white, and yellowish at the base. Very distinct.

THE HERBACEOUS BORDER.

ANEMONE JAPONICA.—Deservedly popular as one of our best autumn-flowering plants. The flowers are a dull red or rose, and are very useful for cutting. It does best in moist soil free from stagnant water, and soon forms a handsome specimen. *A. japonica hybrida*.—This has larger flowers, and the colour is rose, but I have some that are neither *A. japonica* nor *A. japonica alba*, some of the flowers being a very soft rose and others a dull white.

A. JAPONICA ALBA.—One of the best of autumn flowers, especially where large quantities of cut flowers are required. The flowers are pure white inside with a yellow disc, and are very beautiful. It will grow in any soil and open situation, provided water is not stagnant in the subsoil; yet it succeeds best in light rich soil, in which it forms very beautiful specimens, and in the mass few late summer and autumn flowers can equal it. All are readily increased by division or suckers, and should find place in every garden. They started flowering about the middle of August.

FUCHSIA GRACILIS.—Fine in late summer, its graceful habit and depending drops of scarlet and purple are very beautiful, but not so attractive as *F. microphylla*, which has small but lovely magenta flowers, with white pistil and anthers—ruby set in pearl, and is of neat and compact habit. Any light soil suits Fuchsias, and a little mulching over the stools of leaves or litter will make all safe for the winter. Propagation is effected by cuttings under a handlight.

HYACINTHUS CANDICANS.—A bulbous plant with long lanceolate leaves, having a stout erect stem, often 4 feet in height, bearing a score in good examples of large, drooping, bell-shaped, pure white flowers, which open in succession; and

as the flowers are good for cutting, and when mounted useful for bouquets, it is specially valuable, as it blooms in August onwards. Planted 4 to 6 inches deep it is quite hardy with a little mulching over the bulbs in severe weather. It seeds freely, and the seedlings have much more vigour than the parents. The seedlings flower in the second year. A light soil is most suitable.

VERONICA LONGIFOLIA VAR. *SUB-SESSILIS*.—Probably the finest of all the hardy Veronicas. The foliage is ample, and of a deep green colour. It grows about 2 feet in height, bearing its flowers in erect spikes a foot in length, and of a deep blue colour. It is a comparatively recent introduction from Japan, and apparently perfectly hardy.

ACONITUM NAPELLUS BICOLOR.—This flowered at the close of July into August, and were very conspicuous from its blue and white flowers on an erect spike over 3 feet high, the flowers being numerous. Any light and rather moist soil suits it.

ERYNGIUM PANDANIFOLIUM.—This has the appearance of a Pandanus, having leaves fully 3 feet long, beautifully arched, the leaves very spiny, the spines at the base of the leaves being truly formidable, as they are over half an inch in length. In the herbaceous border it has a very distinct appearance, and as a lawn plant is quite equal to any Yucca, whilst for vases in connection with terraces it rivals Agaves. Its flower stems rise to a height of 6 to 10 feet, having a branching head of reddish purple flowers. *E. bromeliæfolium* is smaller in all its parts, the flowers are white on a stem seldom over 4 to 5 feet in height. *E. amethystinum* is also very handsome, having spiny lacinated leaves, and the heads of flowers are of a lovely blue. It is necessary that the soil for these be light or gravelly and well drained. On rockwork they do admirably, and form conspicuous objects.

CHRYSANTHEMUM MAXIMUM.—A vigorous-growing perennial, forming a bush a yard in height, and from August onwards produces an abundance of large flowers about 3 inches across, white with a yellow centre, and may be described as a gigantic Marguerite or Daisy. It does well in any good soil. Cuttings or division.

CHELONE OBLIQUA.—The flowers are rosy purple borne in terminal heads or spikes on erect stems, the plant being free in growth, and attaining to a height of 2½ to 3 feet. Any good soil suits it.

SOLIDAGO VIRGAUREA NANA.—Although the Golden Rods are mostly coarse and only fit for the wild garden or shrubbery, this is fit to take rank with the choicest in the herbaceous border, it having a very large head of bright golden yellow flowers borne on erect stems about 18 inches high, and is very effective. It flowered at the close of August. Division.

SENECIO PULCHER.—Strong in growth and erect, having fleshy and deep green leaves nearly a foot in length, unevenly lobed, the flower stems rising to a height of 3 feet or more, and are terminated by a branching cyme of bright crimson-purple flowers 3 inches or more in diameter, of great substance and endurance. The flowers having a bright yellow disc are very effective. It unquestionably is one of the finest of late summer and autumn flowering plants, and is very vigorous in growth, doing best in a well-drained soil, as it is not one of the hardiest.

RUDBECKIA NEWMANNI.—Free alike in growth and flowering in any open situation, its golden-yellow flowers with a black disc are very showy, and is very useful for cutting, the flowers being produced from August up to a late period, and is one of the best of late summer and autumn flowering plants. Where flowers are in request for filling large vases it should be grown in quantity, and certainly ought to have place in every garden.

SALVIA PATENS.—A well-known half-hardy plant, but in a warm situation and in well-drained soil, with the tubers 4 to 6 inches deep, is quite hardy. Its lovely deep blue flowers from such are produced in late summer up to frost, and is very effective.

LOBELIA FULGENS.—In a moist, yet well-drained border, this yields to none in the brilliancy of its flowers, vermilion scarlet, in late summer, and with a mulch over the crowns in severe weather is perfectly hardy. It attains to a height of 3 feet or more, and is very striking.

SPIGELIA MARYLANDICA.—This is best in moist soil, but it must be well drained. It forms tufts of erect somewhat slender stems, 15 to 18 inches high, terminated by about half a dozen more or less tubular flowers nearly 2 inches in length, crimson externally, and pale yellow inside. It is a very distinct and interesting plant and well worth growing.

PITTYROSPERMUM ACERINUM.—It forms an effective mass from its deep green Accr-like foliage, from which spring in late summer (August onwards) erect stems about 3 feet high, bearing terminal spikes of feathery white Spiræa-like flowers, which form

very effective specimens, and are particularly fine for cutting. It prefers a moist soil. Division.

PENTSTEMON BARBATUS TORREYI.—This attains to a height of 4 feet, bears in panicles very brilliant scarlet flowers, and is very beautiful, and ought to be grown by everyone. A light and not too rich soil suits it best, but reserve plants should be raised each year and wintered in frames, as the Pentstemons are not very hardy.

The herbaceous Phloxes are now very beautiful, and so are Gladioli, and more particularly Carnations, with *Lilium tigrinum*, &c., which along with Sweet Peas, *Tropæolums*, Cornflowers, Sweet Sultan, Dwarf Scabious, Asters, Stocks, and others make a very effective display along with the indispensable single Dahlias.

WALL PLANT—LONICERA HALLI.—This produces its flowers very freely from the axils of the leaves on the current year's growth, clear white, changing to buff, and are deliciously fragrant. It is a desirable climber, and grows freely.—G. ABBEY.

BRIGHTON SHOW.

SEPTEMBER 5TH AND 6TH.

THE Brighton and Sussex Horticultural Society has, during its thirty-one years' existence, done much valuable service in the district, and it is to be hoped will continue to contribute to the improvement of horticulture for many years to come. If, however, the Show is to maintain its prestige in the southern counties it must be better supported by exhibitors than was the case at that held last week, which in paucity of exhibits was one of the least satisfactory held by the Society in recent years. It is difficult to understand the cause of this falling-off, as the prizes in the leading classes are fairly liberal, and the railway companies offer special facilities in the shape of free carriage for exhibits to and from Brighton to any station on their line. This alone might be expected to be sufficient inducement to ensure an extensive display; but such does not appear to be the case, and it is very regrettable that so excellent an Exhibition should be permitted to decline in attractiveness. The general management of the Society's affairs under the care of the Secretary, Mr. Edward Carpenter, continues satisfactory, and the arrangement of the exhibits under the superintendence of Mr. E. Spary of the Queen's Vineries is all that could be desired; and if the Committee is practical and energetic success should be ensured. Much, however, depends upon the last-named gentlemen, and if there is any want of whole-heartedness and willing co-operation it is quite sufficient to account for the deficiency so unpleasantly apparent.

The Royal Pavilion was, as usual, the favoured site, and a more suitable one could not be selected, as the magnificent apartments which are devoted to the fruit, cut flowers, and choicer exhibits generally, are in themselves no inconsiderable attraction both to the townsfolk and strangers. In the garden adjoining a large marquee was devoted to the large specimen plants and groups; but, as in other classes, the competition was weak there, and some difficulty was experienced in avoiding the thinness that would have been too noticeable had not a skilful and judicious arrangement been adopted. The groups of miscellaneous plants and the Ferns were, however, superb, and, as noted below, they constituted the great features of the Show, and afforded an example in style and taste that it is desirable should be followed at many other exhibitions.

PLANTS.

The most important open class in this section was that for a group of twelve plants—six Ferns and six fine-foliage plants—the first prize being the Ashbury cup, value ten guineas, which is presented by the Vice-President, James Ashbury, Esq., and the second and third prizes are £5 and £2 respectively. Only one collection, however, was staged—namely, that from Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, Sussex, for which the cup was deservedly awarded; and though won thus easily, any competitor would have had a most difficult task to show a dozen finer and more healthy specimens. The Handcross plants have so frequently figured conspicuously at exhibitions in the south of England that they have gained considerable fame for the vigorous health usually distinguishing them, proving how well their requirements are understood by Mr. Rann and his able foreman Mr. Sjoquist. On several previous occasions the Ashbury cup has been won by Mr. Warren's valuable specimens, but each time the honour has been well merited. At the Show under notice the most remarkable plants were *Crotons Andreanus*, *undulatus*, and *Hendersoni* beautifully coloured; *Latania borbonica*, very large and finely proportioned; *Areca sapida*, a majestic specimen; *Davallia Mooreana*, fresh and healthy; *Cycas revoluta* of great size, and *Cyathea Smithi* very handsome. In the county class for four fine-foliage plants Mr. Rann was again in the first position with good examples of *Crotons albicans* and *Warneri*, but the latter was especially well coloured. The other prizes were obtained by Mr. Turner, gardener to Major Wray, Wick Hall, and Mr. Meachen, gardener to C. Armstrong, Esq., Withdeane, who both showed plants of moderate size but well grown. Mr. Meachen was the premier exhibitor of eight stove and greenhouse plants in the open class, having a beautiful profusely flowered specimen of *Erica cernithoides*, *Rondeletia speciosa* large and fairly well flowered; a *Stephanotis*, *Bougainvillea*, *Allamanda*, and *Pimelea decussata* were similarly noteworthy. In the county class for four stove and greenhouse plants Mr. Meachen scored another triumph, taking the lead with *Erica Eweriana* 5 feet in diameter and flowering freely, *Rondeletia speciosa* major, *Statice imbricata*, and *Allamanda nobilis*. Mr. Rann was an extremely close second with *Allamanda Wardleyana* over 5 feet in diameter, *Erica Faireana*, *E. ampullacea elegans*, and *Stephanotis floribunda*, all evenly trained, healthy, and well-flowered specimens. Mr. Townshend, gardener to Captain Thompson, Withdeane, followed; but several of his plants were extremely weak.

The entries in the above classes were arranged to form a central bank in the marquee, at each end being placed the Zonal Pelargoniums and Fuchsias

contributed by Messrs. Balchin, Townshend, Gilbert, Meachen, Fluck, gardener to J. O. Smith, Esq., Richmond Villa, and others. The Pelargoniums were particularly bright, and furnished some much-needed colour. The groups of Fuchsias arranged for effect were good, but a similar group of Colenses with which Mr. T. Martin, gardener to J. G. Langham, Esq., Eastbourne, secured the premier award, was even more meritorious, the plants being admirably coloured and tastefully arranged.

GROUPS.

Foremost amongst these were the groups of Ferns arranged for effect in a space not exceeding 200 square feet, this class being open to all exhibitors. Two groups were staged, which in taste of design and beauty of effect we have never seen surpassed, and if a similar class could be introduced into some of the schedules of the metropolitan horticultural societies it would prove a most welcome novelty to many visitors. There was, indeed, no portion of the Brighton Show which attracted so much and such well-deserved admiration as this; and though the first and second prizes were £6 and £4 respectively, these were sufficient to adequately compensate the exhibitors for the value of the plants employed, and the time and skill required to arrange them so artistically. The premier award should have been £10 at least. Mr. W. Miles, West Brighton, secured the leading position with a most elaborate, well-finished, and tasteful arrangement, in which the chief features were as follows:—The ground consisted of small Ferns, principally Adiantums, *A. cuneatum* predominating; at the back was a mound covered with *A. cuneatum*, from which arose taller plants of *Gymnogrammas*, *A. farleyense*, and *A. macrophyllum*. This mound formed a small arch in the centre with a recess, at the base of which were some fine *Todeas*, a constant dripping of water from the mound keeping them bright and fresh. Towards the fore part of the group were columnar mounds of Ferns 2 or 3 feet high, also covered with Adiantums, and having a large central specimen at the top, an example of *Neprolepis davallioides furcans* being very fine. The margin of the group was well rounded, small boxes of seedling Adiantums being employed, so that the plants sloped most gradually to the turf. The group was practically perfect, and reflects the greatest credit upon Mr. George Miles, who arranged it. Mr. Vincent, gardener to J. Hart, Esq., Keymer, was placed second with a charming group, containing a number of very handsome Adiantums and other Ferns, the ground being formed similar to the other, but with a back mound that had a bad centre—a plant of *Neottopteris*, which was rather too deeply bedded amongst the other Ferns, and was quite unsuited for its position. There were other points in which the group was slightly defective—namely, in the want of finish, especially near the margin, where the pots were unpleasantly prominent, but, taking its general effect, it was highly praiseworthy. A similar county class was also provided, the groups not to exceed 75 square feet. Mr. Turner and Mr. Meachen were the prizetakers with neat and graceful arrangements, but much less elaborate than the preceding.

Groups of miscellaneous plants were well represented in the open class, in which a space of 150 square feet was allowed. Mr. W. Miles was again the most successful competitor, and contributed not only by far the best group there, but certainly one of the most distinct, tasteful, and effective arrangements ever shown in public. In the centre at the back was an informal mound composed of fine-foliage plants, Crotons, Palms, Ferns, and variegated Zeas. The last-named were, however, a little too rigidly placed, and would have had a better effect projecting slightly towards the front of the group. The foundation was composed of Adiantum, from which arose a few taller Palms, such as *Areca lutescens* and several Ferns. To break the uniformity a number of Eucharises and *Lilium speciosum* were arranged in irregular bands next the mound, whilst a most decidedly telling feature was formed by the plants of *Lobelia cardinalis*, appropriately introduced with Disas, Ericas, Begonias, Bouvardias, Diplacis, Asparagus, &c. The margin consisted of small Crotons, Gloxinias, Coleuses, *Panicum variegatum*, and the dwarf well-berried examples of *Solanum the Gem*. This, like the Fern group, was also arranged by Mr. George Miles. Mr. Vincent and Mr. Meachen followed, the first-named with a very formal group, but containing plants of excellent quality. In the county class Mr. Turner was the chief exhibitor, taking first place with a collection of Coleuses, Crotons, Begonias, Palms, and similar plants.

CUT FLOWERS.

A large number of collections in the various classes devoted to these imparted much interest to the Exhibition. Dahlias, Gladioli, Roses, Asters, and miscellaneous stove and greenhouse flowers were all staged in good condition. Messrs. Keynes & Co., Salisbury, were the premier exhibitors of Dahlias, having superb blooms in their stands of forty-eight and twenty-four, in both of which classes they obtained the chief prizes. Messrs. Scale and Cheal were the other principal competitors in the open classes, while amongst the amateurs Mr. Boothroyd, Rev. C. Hale, and E. Mawley, Esq., were the prizetakers. Two beautiful boxes of single Dahlias were shown by Messrs. Keynes & Co. and Cheal, who were placed equal first, the collections in both cases containing brightly coloured and varied blooms. Asters were also well shown, French tasselled and German quilled especially so: the blooms fine, and exhibiting a refinement that is too seldom seen in these flowers. The principal stands were from Messrs. Fowler, Morgan, gardener to Major Scott, Reigate, and W. Archer, gardener to Mrs. Gibson, Saffron Walden. Gladioluses were well shown by Messrs. Balchin and Rann; Roses by Rev. R. C. Hales, A. Slaughter, Esq., Steyning, Messrs. Balchin, Scale, and Mrs. Woolard. The competition was good in the class for a collection of miscellaneous cut flowers, some handsome examples being staged. Mr. Balchin took the lead, followed closely by Messrs. Archer, Gilbert of Hastings, and Morse of Epsom, while in a smaller class Mr. Ford was the chief exhibitor.

Table decorations, bouquets, wreaths, and buttonholes occupied considerable space, and some tasteful designs and combinations were contributed. For three stands of flowers and for a table set for dessert Mr. W. Miles won premier honours. Bouquets and buttonholes were well shown by Mr. Brown of Richmond, and Mr. Chard of Clapham Common.

FRUIT.

Strangely enough there was no entry in the class for twelve dishes of fruits, and in the majority of the other classes the exhibits were not nearly

so creditable as is usually the case at this Show. Grapes were, however, shown in good numbers and fair condition, the black Grapes being particularly good. For three bunches of Black Hamburg Mr. Jordan, gardener to Birket Foster, Esq., Witley, took the lead in a class of nine exhibitors, showing large and well-coloured bunches. Mr. Moorhouse, gardener to J. W. Temple, Esq., Tyswood, Groomsbridge, was second, the berries being rather smaller than in the first; Mr. Warren, gardener to Mrs. Hankey, Balcombe Park, taking the third position. Eight lots of three bunches of Muscat of Alexandria were staged, Mr. Herridge, Havant, winning chief honours with bunches of good size and excellent colour. Mr. Johnston, The Gardens, Bayham Abbey, Tunbridge Wells, followed very closely with well-ripened samples, and Mr. Cbatfield, The Gardens, East Houthley, was third. Five collections of six bunches of black were entered, Mr. Moorhouse leading with admirably coloured bunches; Mr. Knight, Adelaide Lodge, Keymer, and Messrs. A. & D. Hart, Dyke Road, being respectively second and third. For the same number of bunches of Muscats there were six lots, Mr. Johnston securing the chief position with large and handsome bunches finely coloured. Mr. Herridge followed closely, the berries being of great size. Mr. Chatfield was third, and an extra prize was adjudged to Messrs. Webster & Co., Worthing. Peaches and Nectarines were well shown by Messrs. Inglis, gardener to T. Lester, Esq., Cuckfield; Dixon, gardener to Sir S. Wilson, Bart., Hitchin; and Hyde, gardener to R. Bacon, Esq., Keymer. Pears and Apples were chiefly shown by Messrs. W. & A. Apter, Broadwater, Ford, McLeod, Townshend, and Jupp; Plums and Figs being also fairly represented. In the county classes most of the above competed, together with Messrs. Spottiswood, Jenner, Butler, and Meachen.

MISCELLANEOUS.

As usual these not-for-competition collections were numerous and attractive, extra prizes being awarded to the following exhibitors:—Mr. W. Balchin, for collections of Apples, Grapes, plants, and flowers; Mr. C. Forbes, gardener to E. B. Foster, Esq., Trumpington, for examples of Lady Downe's and Alicante Grapes; Messrs. J. Cheal & Son, Crawley, for collections of hardy flowers, Dahlias, Pears, Apples, and Melons; Messrs. W. Wood & Son, Maresfield, for Roses; Mrs. Woolard, Cooksbridge, for Roses; and to Messrs. J. Laing & Co., Forest Hill, for Tuberos Begonias. A first-class certificate was awarded to Messrs. Cheal & Son for

Dahlia Lady of the Lake.—A single variety with fine flowers, the petals broad and rounded, white at the base, and tipped with rosy purple.

THE BEECH AT NEWBATTLE ABBEY, &c.

REFERENCE was recently made in the *Journal of Horticulture* to the gigantic Beech at Newbattle Abbey, the residence of the Marquis of Lothian in Midlothian, near Dalkeith, and about eight miles east from Edinburgh. The tree is the largest of its kind in "the land o'cakes," aye, and far beyond its borders. I had the pleasure of inspecting this remarkable Beech upwards of forty years ago. It was then in autumn. The branches of the tree reached all round to the ground, with the exception of an opening being left at one place for an entrance under its leafy shade. Under its majestic arms a dim light only peered through the leaves, and in this natural umbrageous saloon suitable rustic furniture was provided—tables, chairs, &c., to accommodate a small party. At the time I visited Newbattle Abbey Mr. Goodall, the raiser of two Dahlias that long held prominent positions in the floral world, was the head gardener. The Dahlias I refer to were "The Marquis of Lothian" and "The Marchioness of Lothian," the former a red and the latter a light-coloured variety. Both, but particularly the former, were champions in all prize stands in their days. Many old florists must remember of these, and in the lists of nurserymen in days gone by they stood prominently forward. During one of her visits to Scotland Queen Victoria visited this venerable Beech, which I learn is still in a healthy state, although it must be many hundred years old.—THOMAS NICOL, *Balgownie*.

A VILLAGE SHOW.

WHETHER the establishment of annual exhibitions of garden produce at which cottagers are encouraged to exhibit have all the success that is claimed for them in the way of making better citizens many doubt, but there cannot be a doubt of the fact that better cultivated gardens and much finer produce is the result, if the great improvement in cottagers' vegetables apparent at this year's annual Show in Bonnybridge over the two preceding ones may be taken as a fair example of others through the country. This Society was only started in 1881; and though the first exhibition was encouraging, the produce which then carried off the prizes would not now be tabled. In the matter of Leeks, for instance, a valued vegetable in Scotland, anyone present at the last Show would have more than made all the first-prize six at the first. Indeed, many of the vegetables, especially in the collections, would have done credit to exhibitors of twenty years' standing, and in more favourable climates than the exposed Stirlingshire village. Specially worthy of note were the Leeks of Messrs. Cram and Gifford, and the former's collection of vegetables. Mr. J. S. Ritchie, Denny, showed Pansies in the best form, and monstrous stems of Stott's Monarch Rhubarb, but he is a veteran, and can hold his own at the large shows. Mr. D. Cram's Victoria Rhubarb was also very fine.

Among the gardeners' exhibits a beautifully fresh plant of *Begonia semperiflora grandiflora* (illustrated some time ago in the *Journal*) from seed kindly furnished by Mr. Iggulden to the then gardener at Hope Park gained the first prize for greenhouse plants, and was admired by the visitors very much for the denseness of flowering and spotless white of its flowers. The plant was about 3 feet high and as much in diameter, and was exhibited by Mr. P. Walker, gardener to G. R. Ure, Esq. The same exhibitor showed a pair of Mrs. Marshall Fuchsias in a form very seldom seen. The plants, though hardly so good as last year, were over 8 feet high, well flowered, and furnished. Mr. Walker also showed bouquets much better made up than they usually are in the north, and the same may be said of those exhibited

by Mr. Charles Reid, who, though only a working man cottager, beat the gardeners on their own ground.

A GLANCE AT THE RED ROSE VINERIES.

A WELL-KNOWN scientific agriculturist in this district says that no farming, however good, is complete unless it pays. The mere fact of having heavy crops and highly cultivated land does not, according to our authority, constitute the alpha and omega of good farming; it must pay to be an unqualified success. So with fruit-growing; where it is gone into as a commercial enterprise, quantity and quality, however essential they may be towards attaining the desired end, do not necessarily constitute everything. There must be a sound business system underlying the management of the concern, and there must also be a thorough practical knowledge of the subjects which are treated; and in the case of Red Rose Vineries it can scarcely be denied that the proprietor, Mr. Joseph Witherspoon, has mastered both the essential principles of success. He is a thoroughly practical business man, and has evidently mastered whatever secrets may exist in the cultivation of Grapes.

Having an hour to spare when at Chester-le-Street on the 3rd of September, I spent it in a hurried glance over Mr. Witherspoon's vineries and orchard. The place has so often been described here, that it would be a work of supererogation on my part to go over the ground again. Suffice it to say that all the Vines are carrying a heavier crop than ever, the prophecies of failure notwithstanding. The quality of the Grapes is equal to the quantity, and betokens the consummation of the great desideratum, "pay." In such a hasty look as I had it was impossible to take in more than generalities, but I saw sufficient to justify me in saying that Alnwick Seedling is a perfect success here, an impregnated bunch hanging unthinned a perfect cluster of berries. Gros Colman is evidently the favourite market Grape, its noble and commanding appearance dwarfing all other varieties into insignificance, the only exception, perhaps, being Gros Maroc, which is quite unique as a black Grape. This variety, if it can be generally grown as it is at Red Rose, has a great future in store for it. Lady Downe's, as I mentioned in these pages some years since, is not a success here in the same sense as such Grapes as Gros Colman and Gros Maroc, and is being weeded out. In a house of Tomatoes Conqueror is the best variety, President Garfield the worst. Cucumbers are grown best alongside the Tomato, and both as luxuriant and fruitful as can be wished for.

At the starting of the place Mr. Witherspoon planted an almost endless variety of Pears and Apples. He is now reaping the success of his experiment by being able after a term of probation to select some sorts that are admirably suited to his soil and situation. Among Apples he prefers Lord Suffield, Pott's Seedling, Ecklinville Seedling, Melon, and Early Harvest as being amongst the most reliable. In Pears he adheres to his first love, Marie Louise d'Uccle. A favourite Strawberry is Duke of Edinburgh, of which he is very proud.

A new boiler is also under consideration here, and may possibly be heard of to advantage at some future, and not very distant, date. Many other things of interest to the horticulturist may be seen and heard of at Red Rose, and no gardener who can should miss seeing the place. The crop of Grapes must be seen to be understood and appreciated. No descriptive writing can show them as they are.—PETER FERGUSON, *Mere Knolls, Monk Wearmouth.*

NOTES AT THE DUBLIN AUTUMN FLOWER SHOW.

THE weather, although not so warm and genial as could be desired, was fine, and an unusually large number of visitors was present when His Excellency the Lord Lieutenant and Countess Spencer were announced. The Show was held in the spacious gardens attached to the residence of Cecil Guinness, Esq., D.L., and the exhibits were principally staged in a number of large marquees. There is a number of Orchid collections around Dublin, but none had entered. This may be due to the risk of transit and to the limited number of showy Orchids now in bloom, but more especially to the dangers from the unavoidable exposure and draughts. Dahlias, Show and Fancy, were really fine; but the bouquet section was not equally good, and the first prize was withheld. As on last year, F. W. Leland, Esq. (Mr. Short, gardener), Drogheda, was first for both the two dozen and one of distinct varieties; Rev. F. Tymons, M.A., being second, and with splendid blooms. These Shows are noted for Dahlias. Crowds were all day gathered around the stands of single Dahlias, and to many Avalanche, Paragon, Harlequin, and Lutea were quite new. An adjoining stand of the Cactus Dahlia was much admired. As in several other instances, the Rev. Mr. Tymons was first for single Dahlias, and Major Fitzgerald of the Phoenix Park Military School second. The best herbaceous collection was also staged by the former. Here I would draw attention to the difficulty of effectively staging and keeping for any length of time in a presentable condition hardy perennial and border herbaceous plants—for instance, Colonel Nugent, D.L., Killucan, had first prize for a stand of herbaceous Phloxes, all different, yet they had flagged and lost their beauty before the Judges had concluded. Mr. Tymons also had a collection of good hardy flowers.

Those of your readers who have been at former flower shows here will remember the splendid specimens of British Ferns shown by Phineas Riall, D.L., Bray; exotic Ferns by L. G. Watson, Esq., Blackrock; Palms and Cycads by His Excellency the Lord Lieutenant and Chief Secretary, Viscount Powerscourt, and Mr. Jameson Montrose, Mr. Watson already referred to, and others, need only be told that their efficient gardeners have once again maintained their reputations, while a few like Mr. Bracken seemed missed, their places being taken by other aspirants to gardening fame. Well-coloured and brilliant specimens of the newer Coleuses were

shown by Henry McComas, Esq., Dundrum (Mr. Toole, gardener), who deservedly obtained first place. Admirable specimen Zonal Pelargoniums came from Mrs. R. Millner, Phineas Riall, D.L., Alexander Comyns, and George McMaster, Esqs. There were some fine Roses for the time of year, but, on the whole, inferior to last year's, though Mr. Ennis, from Lord Portarlington's, Emo Park, won first prize with many beauties brought from near Tullamore.

The fruit was decidedly good, especially Grapes and Peaches, among the rest those shown by Lady Emily Bury, His Excellency the Lord Lieutenant, and Mr. Pollock, a new exhibitor from Lismany, Ballinasloe. The Veitch memorial medal went to the former lady.

The vegetable exhibits were not what one might expect at Dublin, and certainly behind what I have noticed before, though, of course, many were well grown. As to Gladioli, the cup, as on last year, went to J. F. Lombard, Esq., South Hill, Rathmins, for a stand of thirty-six, of great excellence, being hard pressed by the Rev. F. Tymons; while in the stand of twelve Mr. S. H. Bolton, Grove House, Rathmins, took precedence of Mr. Lombard. The winning cup stand were from almost exclusively English-raised, and were procured from Mr. Kelway, Langport. For contrast there was beside them a large stand sent from France by Vilmorin, Andrieux, and Co., and exhibited by Messrs. Drummond of this city. They could certainly not compare in size or beauty to either Messrs. Tymon's or Lombard's. Some seedlings raised and shown by the Rev. Mr. Tymons were as good as any exhibited. Very fine were Penelope and Mr. George Rundle. In the stand from Southill conspicuous were Henry Irving; Rhaumes, excellent; Mrs. J. Eyton, fine white; Captain Boyton, Samuel Jennings, and Mrs. Burley. One of Souchet's, the best of the yellows of French origin, was Reine d'Or. I have little space left to refer to the several stands of Begonias, tuberous-rooted, around which crowds gathered all day. The feature of those were a stand of twenty-four doubles from W. E. Gumbleton, Esq., Belgrove, Queenstown, which I saw a few days ago, grown in the open air, injured in the travelling, but still grand, not for competition. In size the singles of the Rev. Mr. Tymons and Captain Riall left little to be desired. These I hope to refer to another time.—W. J. MURPHY.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

No. 7.

FEW of those who are frequently in gardens, small or large, will have failed to notice that there are some insects, occurring every season, which seem as if they had acquired a right to remain almost unmolested. This may be because they are generally distributed upon plants, shrubs, and trees, or because they are very difficult to deal with, rather than from the circumstance that the gardener does not object to their presence, for some to which we are referring are at least annoying, if not excessively injurious. The cuckoo spit, *Cercopis*, or *Aphrophora spumaria* (fig. 43), is one of those pests that is seldom

Fig. 43.—Cuckoo-spit insect, *Cercopis spumaria*. a, Mature insect. b, Larva in froth. c, Larva exposed.

assailed by any of the cunningly devised compounds, which have proved so fatal to insect life and so serviceable to horticulture; and its removal by picking off infected leaves is only a partial remedy, since the insect often gets into positions where it cannot be laid hold of. It is not merely the harm done by the insect to vegetation that is matter of complaint, it is very unpleasant in passing along the paths to receive portions of its secretion upon one's clothes. To that, however, we are exposed in a country ramble as well as in a garden, for the species is common everywhere during May and June. This *Aphrophora spumaria* is nearly related to our aphid foes; it belongs, as they do, to the order Hemiptera, but unlike them, in the perfect state the insect has the power of leaping, possessed also by some others in the bug tribe, hence it is popularly called the "frog-hopper;" and many of those who know it by that name as a summer or autumn insect fail to connect it with the "cuckoo-spit" they had noticed early in the season. Warburton, commenting upon a line of Alexander Pope's, which he thinks is an allusion to this species, remarks that he found the country folk called these patches of froth "toadspits," the toad being popularly believed to spit a sort of venom. Such a name was even more absurd than that which gave the cuckoo the repute of producing them, for they are often to be seen where no toad could possibly climb.

The froth is given forth so plentifully by these pests in some states of the weather that it may be seen to fall drop by drop from the leaves upon which the insects are resting; and as this exudation is first drawn from the plant, it is evident that when they are numerous their attacks upon the juices must have an exhausting or weakening effect. De Geer, the Swedish naturalist, watching these little creatures

many years ago, noticed with what rapidity they pump up the sap by means of the rostrum or sucker, and then eject it at the abdomen. Abundance of moisture is as essential to their existence as it is to the well-being of a frog, and the secretion serves to protect them from the sun's warmth; also, we may reasonably infer, it guards them from other insects that are predatory, and from spiders. If we remove this froth carefully we discover under it a soft-bodied grub, green above and yellow beneath, with conspicuous, but minute, black eyes. The same covering serves *A. spumaria* for a protection when it enters upon the pupal stage of life. By some means the full-grown grub forms a hollow under a thickish film of the exudation, which dries in the air, and hides the insect till it is ready to emerge as a "frog-hopper." It is now brown or greenish, dotted over with fine spots, and having two oblong white spots on the wing cases. For the species in its mature state possesses wings though it seldom flies, preferring to run or leap; the males, indeed, are able to spring through the air a distance of several feet, the females are less agile. Fig. 44, shows the insects magnified.

Fig. 44.—Cuckoo-spit insect, magnified.

We have introduced *A. spumaria* here because the Raspberry, whose insect enemies we are about to enumerate, is one of those plants that are frequently disfigured by its frothy envelope; it is also common upon other species of *Rubus* wild and cultivated. In the case of some young shoots of various plants the mischief done by "cuckoo-spit" is so marked that it is advisable to operate upon it. Syringing with plain water does good, but more beneficial results are obtained by the use of a solution of softsoap flavoured with tobacco, or a decoction of quassia; and of course all "frog-hoppers" that can be caught in summer and autumn should be killed.

The Raspberry is visited by more than one species of those weevils that infest our fruit trees, both in the open air and under glass. Of these its principal enemy appears to be the clay-coloured weevil, *Otiorhynchus picipes* (fig. 45), which has been called the Raspberry

Fig. 45.—*Otiorhynchus picipes*, magnified.

Fig. 46.—*Byturus tomentosus*.

weevil, and also the Vine weevil, since it attacks that plant in hot-houses; but *O. sulcatus* is a greater enemy to the Vine than is its relative. These weevils give trouble in two ways. The mature beetles swarm upon leaves and buds, or they will even gnaw the bark of shoots and branches; while the grubs or larvæ by burrowing at the roots weaken shrubs, and so infest young plants as to stop their growth. *O. picipes* resembles others of the group in having a beak that is developed on each side into a kind of ear; the thorax is rounded and granulated, the wing cases light brown covered densely with scales, under which are a series of circular markings and dots; it is, however, unable to fly. During May the Raspberry weevil is usually observed in greatest abundance, the insects emerging about that time from the pupæ, which lie underground through the winter. It is the habit of the species to conceal itself in the daylight. They creep just beneath the earth, or hide in parties amongst the crevices of walls and under loose bark, and come forth in the shades of evening. Even then they drop from the plants at the least sound or the approach of a light. The approved method, therefore, of catching them by cloths spread at night under the bushes and boughs, and shaking briskly, requires much care or many of them escape. Where they attack trees against walls it has been found they enter the soil close to the base of the wall, hence there is advantage in clearing off the top of this, or in applying to it a weak solution of petroleum. Miss Ormerod

suggests that if a band of a mixture of tar and oil were to be run round the stem of standards at a suitable height the beetles could not possibly ascend the trees. As yet the larvæ of *O. picipes* has not been much noticed in gardens, but it feeds, like others of its genus, upon the roots of fruit trees and vegetables through the autumn and winter months. This might be dealt with by any of those remedies commonly applied to check the ravages of the wireworm, the crane-fly maggot, and other subterranean feeders.

Another beetle that is associated with the Raspberry is of a different family, rather less in size than the weevil just described. *Byturus tomentosus* (fig. 46) is a slim little creature, with wing cases of yellowish brown and short antennæ; it is often to be seen in the corollas of various flowers, seeking them presumably for the honey they contain. Kirby and Spence, in their work on entomology, accused this species of biting through the flower stalks of the Raspberry, but I have not had recent proofs that such is its propensity. We suffer most from the larvæ, which is too commonly found in the fruit during July. It is rather slender for a beetle larva, with a flattened head, and two dark spots at the tail, and it lives and grows in its snug concealment, being generally picked with the fruit; if undisturbed it descends from this to the earth when it is adult, I believe, to enter the pupa state. Few suggestions have been made of any value as to methods of preventing the deposition of the eggs.

A small caterpillar of a scarlet colour spotted with black, and having a black head, does some damage to the buds of the Raspberry. This insect, which produces the moth called *Tinea corticella* or *variella*, is found lurking in the buds from the middle of April to the end of May. About the beginning of June the caterpillar spins a web among the leaves it has damaged, and the moth soon emerges. It is a pretty little creature, with glossy brownish fore wings, upon which are some gold-coloured spots; the hind wings are a darker brown. That the caterpillars are hatched in autumn is certain, but we do not know at present where they hide during the winter months. Birds can discover them in the spring quicker than we can, hence their researches amongst the buds of the Raspberry.

Blotches are occasionally observable upon Raspberry leaves about July, which, if opened, are seen to be tenanted by a dingy green grub or pseudo-caterpillar with numerous minute legs. At the beginning of August this is transformed into a four-winged fly, one of the sawflies, and named *Fenusa pumila*. It is a quarter of an inch across the wings, which are black; the body is also black, the legs are pale brown. The Raspberry does not entirely escape aphid visitations; its special enemy is *Siphonophora Chelidonii*, also found frequently on the Celandine, and which somewhat resembles the common aphid of the Cabbage.—ENTOMOLOGIST.

GARDEN CHEMISTRY.

VALUE OF MANURES.

FEW know how to value manures. We pay £80, or, in some instances, as much as £200 per ton for manure which we know to be effective; but whether the same effect could be gained for less, or what materials are necessary, hardly any of us know anything. Every manure in the market depends for its value, first on the nitrogen it contains, and secondly for its phosphates. Some few contain the nitrogen in the form of nitrate of potash, which is more valuable than nitrate of soda, especially for pot plants; but if we allow for the nitrogen and the potash both, it matters not in what form either are if both are immediately available. The value of a manure, then, depends first on what is in the manure, and secondly the state in which it is in. For instance, nitrogen in the form of ammonia or nitrates is available almost at once for the use of the plant; but in the form of rape dust, bones, horn shavings, or farmyard manure it is not immediately available, and is therefore allowed a lower value. Phosphoric acid, again, when soluble is worth more than in the form of bone dust, and in bone dust than in ground coprolites.

In order to know what the value of a manure is we must know of what it is composed. If wholly of sulphate of ammonia it may be worth £25 a ton, if of sal-ammoniac £31 at least. These are the most valuable manures in the market. If of phosphates, for soluble bone phosphate nearly £20 would be allowed for a ton for the soluble and £12 for the insoluble; for soluble mineral phosphate £15, and insoluble mineral £7 10s at the manufactory. Standard values have been fixed upon for each of the necessary elements or compounds in manure, which of course vary from time to time as the market price rises or falls, but which form a guide whereby an analyst can state the approximate value of any manure after ascertaining its composition. Thus, if nitrogen be worth £100 per ton, sulphate of ammonia containing 20 per cent. of nitrogen would be allowed £20 as its value; nitrate of soda yielding 15.5 per cent. would

be worth £15 10s.; sal-ammoniac (ammonic chloride) with 31.7 per cent. worth £31 17s. 6d.; bones with 3.6 per cent. over £3 for that one item in addition to what would be allowed for the phosphate.

Phosphates are valued according to their source and solubility. Soluble bone phosphate was recently allowed a money value of £19 5s. per ton, but that from bone ash only £15, and from mineral phosphates £14 4s. There is something arbitrary in this, as soluble—that is, monocalcic, phosphate is of equal value, no matter whence its source. There is more meaning in allowing £11 10s. for the insoluble phosphate in bonemeal, £8 15s. for those in bone ash, and £7 10s. for insoluble phosphates derived from mineral sources; but even in such instances the values are only approximate, as a good deal depends on the mechanical division of the particles. Potash as sulphate is allowed a money value of 2s. 6d. per unit.

To make the subject quite clear we will take a sample of ordinary manure and calculate its value according to the unit system.

Farmyard Manure.

Water	71.0
* Organic Matters	24.6
† Ash	4.4
* Containing Nitrogen equal to Ammonia	0.54
† Containing Potash	0.52
" Phosphate (monocalcic)	0.50

As nothing else is valued, but yet are of value in farmyard manure, full value should be allowed for those that are calculated, even although much of them may not be immediately available. Valued in this way the above may be summed up thus—

Nitrogen	£	s.	d.
Phosphate	0	9	6
Potash	0	1	11
	0	1	3
	£0 12 8		

which is more than is usually given or allowed by chemists for similar samples. Farmyard manure is, however, not often so rich as the above, especially when straw is very plentifully used. As seaweed often contains as much nitrogen and phosphoric acid as farmyard manure and often four times as much potash, its real value is seen to be greater. Urine which contains

Urea	3.1
Potash	1.2

is certainly worth £2 per ton. Only pure horse urine is as rich as that, however. It is generally largely diluted, but even though containing an addition of three parts of pure water to one of the liquid, it still equals in value ordinary manure. Cow urine is worth about the half of that from the horse.

Perhaps we cannot illustrate this part of our subject better than by reproducing a table submitted to the Scottish Horticultural Association in 1879 by W. Ivison Macadam, F.C.S., Edinburgh, when reading an essay on the food of plants.

ASSOCIATION STANDARDS FOR THE VALUATION OF MANURES—
SEASON 1879.

	Per Ton.	Per Unit.
	£ s. d.	£ s. d.
<i>Genuine Vitriolated Bones—</i>

There is a manure in the market, and it is only one of a class, "for Roses, Vines, and orchard trees." The following is its composition—

Moisture	5.56
Organic Matter and Ammonia Salts	41.33
(containing Nitrogen equal to Ammonia)	(9.96)
Soluble Phosphoric Acid	1.02
(equal to Phosphate of Lime)	(2.23)
Insoluble Phosphoric Acid	13.03
(equal to Phosphate of Lime)	(28.44)
Lime	16.54
Potash	0.56
Nitrate of Soda	11.98
Sand, &c.	6.98
	100.00

As sold this costs retail about £88 per ton. Of course tins have to be paid for; wholesale and retail dealers have each to get profit after paying assistants' wages and storage, carriage, &c., while the "inventor" expects something. Yet what is this manure? A mixture of ammonia salts, nitrate of soda, phosphates, and some other articles of little value. When once gardeners, amateur and professional, know exactly what plants want, the forms of food best suited to them, and the sources, much more artificial manure will be used than now, yet much less money spent.—SINGLE-HANDED.

TOMATOES v. WASPS.—Is it true that wasps will not enter a vinery or fruit house if a few Tomato plants are grown in it? I am informed that this is the case, and it accords with my own experience of this year. We were greatly troubled outside, but have very few inside the houses.—J. P., *Dublin.*

KITCHEN GARDEN.

Autumn Cabbage.—The seed sown some time ago has now produced plants large enough to transfer from the beds to the main quarters, and as this crop is a very important one, the best attention should be given it. Good Cabbages are never produced at any season on poor land, and to grow them of the highest excellence they must be very liberally treated. Where a piece of ground was heavily manured for a previous crop more need not be added before planting Cabbages, but otherwise a good dressing should be dug in before planting. The situation selected should be very open. Plants tenderly reared in autumn never pass through a severe winter well. Drills about 3 inches deep and 18 inches apart should be drawn, and into these the plants should be dibbled 18 inches apart. These drills help greatly to protect the young plants while small, and by-and-by the soil can be levelled up to their stems, when they will remain secure for the winter. For planting now only the largest should be drawn out of the seed rows, and the smaller may be left to remain throughout the winter, or be planted out as a succession in a fortnight's time.

Winter Cucumbers.—These are now making satisfactory progress, and they cannot be too much exposed to the light or robustly grown. The best way of training them is to take the main stem up 4 feet or so before stopping, then train a few shoots from each side. These must not on any account be crowded, as success all depends on their making free, clean, and robust growth, and this they never will do if too much crowded. Liquid manure should not be given until after they are in full bearing. Old plants now showing signs of decaying should have the dying leaves removed, all superfluous fruits cut off, and a little extra bottom beat and liquid manure applied, when the result will be a stimulus to the crop, which will maintain the supply until November or longer.

Tomatoes.—This season has not been one of the best for outdoor Tomatoes. Some of our plants in the most sunny positions have formed large quantities of fruit and ripened a few, but we have not gathered

them by the bushel or hundredweight, as we have done in some years. The cold nights we are now experiencing are not favourable to their developing or maturing, and in many instances the fruit may show signs of decay. When this is the case the best way to save them is to cut the best off and hang them up in bundles in a warm room or glass house to ripen. When treated in this way they are not so good for salad, but they do very well for cooking or sauce.

Mustard and Cress.—Throughout the summer and until now these have grown very well in the open, but now to insure a supply it is best to sow the seed in a frame and under handlights.

Harvesting Onions.—All spring-sown Onions are showing signs of ripening, and the whole of them should be lifted from the ground. Dry weather is always best for this, but the most has often to be made of them in the wet. The first operation should be to draw them out of the soil and lay them down on the surface of the ground. Here they may remain for a week or so to dry a little, and then they should be taken away and spread out in an open airy shed or on a dry pathway, and remain there until the stems are quite withered, when they may be cleaned and stored. In cleaning them the greater part of the stem should be twisted off, and the rough skins which may be quite loose about them may also be rubbed away. The soundest of the bulbs should be put together for keeping, and the others may be kept hack for present and immediate use.

Asparagus Plants.—Recent storms have blown these plants about very much, and this is always injurious to them, as it breaks many of the growths off by the bottom and damages the crowns. Where the stems have run up to a height of 8 feet or so they take a long time to mature in autumn, and to give them every advantage they should be kept staked and tied. Cleaning the surface over the roots should have every attention at this time, as when the ground is overgrown with weeds it is impossible that the crowns can ripen. The present work should be to prevent all stems from being damaged by the wind and making the surface as clean and open as possible.

Sowing Cauliflower.—The seed of Early London and Veitch's Autumn Giant Cauliflowers should be sown at once to produce plants which will be wintered in frames and planted out in spring to head before the spring-sown plants. The seed should be sown on a south border where the soil is good, and the rows may be from 9 inches to 1 foot apart. Care must be taken that the snails do not destroy the young plants just when they are coming through the soil, as they are very apt to do this with young plants at this season.

Wet-weather Work.—Rainy days are now prevalent, and when they occur indoor work should be pushed forward. At such times seed Peas, Beans, &c., may be examined, cleaned, and stored in boxes or bags. Look over Potatoes to remove decaying tubers, and have sheds cleaned out and leaf soil or sand prepared to cover over Carrots, Beetroots, &c., when they are brought in.

FRUIT-FORCING.

VINES.—Pruning and Top-dressing.—The Vines which are to be started in November should be pruned without delay. Vines in good condition may be spurred-in to a couple of buds, as the breaks from these usually show medium-sized compact bunches, which set and swell off finer berries than bunches on shoots starting from strong young wood, which often gives loose bunches and an undesirable number of stoneless berries. If, however, young wood has been encouraged to displace spurs that have become weak and elongated, such should be cut back to plump eyes on well-ripened wood, and the breaks from these will be satisfactory providing means be adopted to insure the breaking of the eyes at the base of such growth by depressing the upper part when forcing is commenced. The Vines should only have the loose bark removed, and should then be washed with soapy water, 8 ozs. soft soap to a gallon of water, and the woodwork washed with soap and water, and the glass thoroughly cleansed with water both inside and out. If painting be necessary it should be done at once—not upon a dirty but a clean-washed surface; and if there has been any scale or mealy bug, thoroughly syringe the Vines and all woodwork and walls with paraffin, a wineglassful to 3 gallons of water, adding the same quantity in bulk of soft soap previously dissolved in hot water. Keep it thoroughly mixed by sharp stirring with a stick whilst the petroleum solution is being applied, and repeat as soon as the Vines become dry. The Vines should have the solution applied to them with a brush so as to reach every crevice, the solution being kept stirred constantly whilst it is being applied. If the house has long been infested with mealy bug have the whole of the woodwork painted with spirits of turpentine, applying it well to every angle and crevice. The trellis should also be dressed with the same, and the walls also. Remove the surface soil, supplying fresh. If the roots do not require more than an ordinary top-dressing all loose mulchings should be removed after pruning, using in its place rich compost with a liberal admixture of bonedust pressed firmly, and complete with a couple of inches thickness of fresh horse droppings. Keep the house cool and dry until the time arrives for starting.

Covering Outside Borders.—Those hitherto exposed to the influence of the weather should now be protected from heavy rain by covering with lights if they are obtainable, or shutters raised a foot or so above the surface, with a good fall to the front to throw off water.

Vines in Pots for Early Forcing.—Cut these back to plump eyes on well-ripened growth, and dress the cuts with Thomson's styptic or patent knotting, keeping in a cool dry place until wanted for forcing. If

wanted to produce ripe Grapes in March or early April they should be started not later than the 1st November—better a fortnight earlier, as they thrive best when brought on gently in the early stages of growth.

Midseason or Succession Houses.—Any alterations or additions to the borders in these houses should be concluded as soon as possible. If the roots required lifting it should be done whilst the leaves are on the Vines, leaving any spray a little longer as an incentive to root-action; but where lifting is not necessary remove every particle of young growths as a means of plumping the buds and insuring the thorough maturation of the wood. Prune as soon as the leaves part freely from the wood, as a complete and long rest is highly beneficial. Later houses should have laterals and extensions shortened back to effect the plumping of the pruning buds, and to admit of the free admission of light and air. Free ventilation is essential on fine days with a little fire heat, if there be any doubt about the maturity of the wood, using it in the daytime only. It is no use expecting first-class Grapes from unripened wood.

Late Grapes.—Grapes intended to keep through the winter must be ripe by the end of the month, or they will certainly shrivel in a short time after the fall of the leaves. If there be any doubt as to this employ fire heat steadily in the daytime, applying most on fine days, and shut it off on all but cold nights, when a little heat may be needed to keep the temperature from falling below 60°. A high night temperature weakens the Vines, as they require as much rest as can possibly be given them. Admit a little air constantly, and ventilate freely on all favourable occasions. Late houses of Hamburgs will colour well even in October; but the Grapes, ripened as they must be by a greater extent of fire heat than is necessary if at all in September, do not keep nearly so well as those ripened when the sun has more power, as the skins are not only thinner, but the saccharine matter is not so highly developed.

Young Vines.—Those that were planted in the spring or early summer months may be allowed to make all the growth they are disposed with a view to extend the root-action and increase the vigour of the canes for some time longer; but any that are intended to fruit next season, and have been allowed to make long rambling shoots, should have these gradually shortened with a view to plump the eyes on the canes, and conduce to the ripening of the wood by a free admission of light and air. If the wood is not ripening kindly apply fire heat by day, with a free circulation of air. Keep the large or principal leaves free from insects, as it is essential that they be preserved in health until they fall naturally.

STRAWBERRIES IN POTS.—Autumn Fruiters.—Plants that are intended to fruit early next month will have set their fruit, and should now have them thinned and the plants placed near the glass or shelves, and be fed liberally with liquid manure. Plants to come in later ought now or soon to be in flower. The chief thing to aim at is to get the fruit set whilst the weather is favourable, after which they can be advanced as they are required.

Spring-fruiting Plants.—Remove all runners as they show, keeping the pots free from weeds and worms. Afford more space as the foliage expands, and keep a sharp look-out for the Strawberry maggot, which hides on the under side of the leaves, and ought to be destroyed, as it not only perforates the leaves now, but later on will perforate and feed on the flower buds, and render the plants blind.

PLANT HOUSES.

Hyacinths.—Where these are wanted to flower early they should be ordered at once, if not already done, potted as soon as they arrive, and treated as directed in a former issue. To maintain a succession a number of bulbs should be potted at intervals of a few weeks. Pots 5 and 6 inches in diameter are ample for single bulbs, but they can be grown very successfully in a smaller size. Where larger pots are in request place three bulbs in 7-inch pots. For purposes of decoration many of the cheaper varieties are the best. In addition to Homerus, single red, and La Tour d'Auvergne, double white, recommended for early forcing, the following will be found good, cheap, and useful. Single whites—Albertine, Grande Vidette, Alba Maxima, Madame Van der Hoop, and Mont Blanc. The two first are admirable for early forcing, and can be brought into flower easier and earlier than any other single white varieties. Grande Vidette is remarkably dwarf, has a grand pyramidal spike which possesses very large pure white bells. Blush whites—Lord Wellington, Gigantea, and Grandeur à Merveille will be found three very good varieties. The first-named is the earliest, and can be brought into flower a few days before the two whites recommended above if potted at the same time. Amongst single reds Von Schiller, Robert Steiger, and Macaulay are good, but none of these is so early as Homerus. To succeed, or even to flower with the second hatch of that variety, a few bulbs of L'Ami du Cœur may be grown. It is early and bright, but the spike is small and puny in comparison to others. Light blues—Charles Dickens, Grand Lilas, and Grande Vidette are amongst the most serviceable. The former is the earliest of the Hyacinths, and one of the best and most useful that can be grown. It scarcely ever fails to produce an immense spike, and often as many as three. The last-named of the three is in the style of Grand Lilas, but has larger bells. Amongst dark blues Argus is the earliest, followed by that free and best of all Hyacinths for decorative purposes, Baron Van Tuyl. General Havelock, deep purple shaded black, is also good, and well worth a place. The yellow varieties are not very serviceable, and a few bulbs only should be grown in comparison to other varieties enumerated. Bird of Paradise and Duc de

Malakoff are two of the best. Double kinds we do not advise to be grown in large numbers, the singles are much more useful. In addition to the white variety mentioned, Lord Wellington and Waterloo, the former blush and the latter deep red, are very good.

Tulips.—In addition to the few varieties mentioned on page 148 for early forcing others should be potted as early as they can be obtained to succeed them, as Tulips are amongst the cheapest of bulbs, and are capable of making a most brilliant display over a lengthened period of time. All intended to be forced into bloom from the middle of January to the end of the season should be potted in 5 or 6-inch pots, placing five bulbs in each pot. In potting the bulbs should be entirely covered with soil, and then placed under ashes outside, the same as the Hyacinths, until the pots are full of roots. The following are good:—Chrysolora, yellow; Vermillion Brilliant, scarlet; Cottage Maid, rose pink shaded white, not good for early forcing, but flowers freely and well after February 1st; Keizers Kroon, scarlet and yellow, a very bold and showy kind; Proserpine, dark rose; Wouverman, purplish-violet. The only white we grow is White Pottebakker. Double varieties are very useful and showy, and do equally as well as the single varieties in pots. A few bulbs of Duc Van Thol may be grown for early flowering in 4-inch pots. Duke of York, Emperor Rubrorum, La Candeur, Gloria Solis, Tournesol (red and yellow), and the yellow variety are amongst the kinds most worthy of pot cultivation; the last two being superb, last well, and are amongst the most striking double Tulips.

Narcissus.—In addition to the Polyanthus Narcissus for pot cultivation, some of the border varieties, when well grown in pots, are most conspicuous in the conservatory amongst other flowering plants. The Hoop Petticoat Narciss (Bulbocodium) is charming when well grown in 4-inch pots, but undue forcing must not be resorted to, or failure is sure to follow. *N. moschatus* does well in 5 or 6-inch pots, and if growing in the open borders should be lifted and potted without delay; place about five strong bulbs in the size pots mentioned. *N. Horsfieldi* and *Emperor* are grand, especially the former, which is very dwarf and flowers freely. The most successful plan with these varieties is to lift them early, before they commence to root afresh if possible, and then pot them moderately deep, and place them in a cold frame, and then cover them with coconut fibre or coal ashes, having about 1 inch over the pots. They should be left in this condition until they grow through the plunging material, and afterwards be brought forward in gentle heat as required.

THE BEE-KEEPER.

THE STINGS OF BEES.

SEVERAL deaths—I think four—from the stings of bees and wasps have been reported in the newspapers this season; a number unusually large and sufficient to excite attention if not alarm. The death of a person from bee or wasp-stinging has been heard of every few years, but the record of four fatalities in a few months from the same cause is not pleasant reading, and may cause unnecessary alarm. A medical practitioner has, I believe, lately and publicly stated that the sting of a bee—meaning thereby the venom of the sting, cannot kill anybody, that when death results it is from an excess of fright. I did not see the doctor's letter, but I believe his views and statements are correct. The record of the deaths which happened lately states that a lady in her kitchen was stung by a wasp on the neck, "swooned away and died in twenty minutes." Another is that of a lady near Harlow, who died within half an hour of a wasp stinging the little finger of her right hand. She had been stung several times before, and was very nervous about it. The pain of a sting in most cases is very severe for a short time, but soon passes away without doing injury if borne in the absence of fear. Neither the venom nor the pain of a sting could destroy life in a person who is not alarmed. We have seen many persons frightened nearly to death on being stung, but on being assured that no fatal consequences would follow bore their sufferings with composure. Though I have been stung thousands of times, probably oftener than any other living person, I am frequently told that bees know me, and therefore do not sting me. The question of bees knowing their masters is a difficult one to discuss, but we may take it up at a future time. At present I wish readers generally to know that I am not exempt from stinging. But stings do not cause swelling on me, or any inconvenience beyond the pain which does not last a minute. I could bear twenty stings in a minute without fear of injury, beyond the momentary pain. This statement is not made in bravado, but to lessen the fear of timid people. I keep many hives, or have done so for many years. I move amongst them gently without fear, turn them up and examine them, put them through all possible and known manipulations, and the bees through all possible exercises without fear; and in all this work I have

never used a protecting veil of any kind for hand or face. Bees can be made accustomed to all such work and practices. If gently handled they will bear a great deal; if kept among the haunts of men or in busy places they become domesticated, and bees once domesticated do not readily become savage or ill-natured again. Bees that are born in unfrequented places are in a sense untamed and untrained, and when visited by human beings and cattle they naturally dread molestation and defend their hives, or mean to do so, by first attacking the unwelcome visitors.

The venom of a bee sting is so instantaneous in its action that we think no cure for it can ever be applied in time. The sting of the honey bee is well barbed, and when inserted in the skin it draws the venom bag with it, which is connected with a self-acting machinery which has the power of injecting venom through the sting into the flesh for some time after separation from the body of the bee. Instantaneous withdrawal from the part stung is in our opinion the best cure for a bee sting. I have not been often stung by wasps, and know little about them, but I believe their stings are as painful as those of bees. The sting of a wasp is not barbed, and therefore is not lost to the insect on being used, but can be used again and again, and is therefore more formidable than that of the honey bee, which sticks wherever inserted, and the loss of the sting is death to the bee.

Wasps' nests are unusually plentiful this season, and as every nest contains many queens they should be destroyed before the queens find warm corners for the winter.—A. PETTIGREW.

GREAT HONEY CROP.—The honey flow here has been unprecedented and unlooked for. My best colony has given over 600 lbs. of honey, up to date—over 100 lbs. being comb honey, and I expect to get upwards of 700 lbs. from it. The colony spoken of carried in from 20 to 28 lbs. of honey per day for nearly a week. I think there are upwards of 100,000 bees in the hive; it is a two-storey one.—E. F. SMITH, *Smyrna, N.Y.* (in *American Bee Journal*).

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

List of Colonial Seedsmen (*J. C.*).—You will find the names of the principal seedsmen at the places mentioned in the "Horticultural Directory," published at this office, price 1s.

Exhibiting Flowers (*Major B.*).—We could have decided the question you submit to us more readily if the names of the "four sorts of stove flowers" show by T had been given, and in the absence of that information

it is impossible to determine whether the awards were in accordance with the terms of the schedule. The wording ("best collection of cut flowers, twelve bunches, distinct varieties") is clear enough—that is, any collection in that class must consist of twelve bunches of flowers and twelve varieties, and if the "four sorts" shown by T were species and not varieties, his collection, according to the strictly botanical meaning of the word "variety," could not be admitted. On the other hand, if they were varieties of one or more species, and in other respects the collection was superior to those staged by B and E, he was undoubtedly entitled to the first prize. Employing the word "varieties" has evidently been misleading, and it might have been advantageously omitted. B, again, had more than twelve varieties, and would therefore not be within the terms of the schedule, while E seems to be the only one who has exactly complied with the stipulation.

Fuchsia procumbens (H. J. G.).—This pretty species grows, flowers, and usually fruits freely enough in a cool house, and as you do not state where the plant is growing we can only conclude that you have it in an unsuitable position. Undoubtedly the fact of fruit not setting is due to inefficient fertilisation, but in the absence of definite particulars it is difficult to assign a reason for this defect. Perhaps the plants have been kept too warm or too damp.

Gardener Leaving his Situation (J. S.).—We are not aware that the precise question you submit has been decided in a court of law. Under the circumstances you name the gardener would act wisely by giving a month's notice; but whether he could be legally dismissed with less notice is a point on which a solicitor should be consulted if necessary.

Vines Unsatisfactory (G. E.).—It is not at all unlikely that the inside border has been too dry, and that, in connection with a moist and rather close atmosphere and low temperature, would have a tendency to cause the leaves to shrivel under the bright sun of the past month. It is certain, too, considering the condition of the foliage, that the Muscat Vine is overcropped, and probably the others are also. You had better examine the border and roots. If the soil is at all dry water it thoroughly, and if active surface roots are not plentiful remove a portion of the old and add fresh soil, making it moderately firm and keeping it constantly moist.

Roses for Wall (N. P.).—As you name Lamarque we presume your situation is favourable, but many districts are too cold for this Rose. Where it will flourish so also will Maréchal Niel and Climbing Devonensis. To these we should add Reine Marie Henriette, Cheshunt Hybrid, and Gloire de Dijon. Those we have named will flourish in a position even more shaded than that indicated in your letter.

Potato Disease Records (Pen and Ink).—We doubt if you will find anything more suitable for your purpose than the illustrated articles in the back numbers of this Journal—namely, Nos. 603, 604, and 747, the issues of October 17th and 24th, 1872, and July 22nd, 1875. These numbers can be had from the publisher for 3½d. each. You might also with advantage procure Mr. Bravender's work, "The Potato Disease, and how to Prevent It," published at 81, Great Queen Street, London. We do not remember the price, but it is not more than two or three shillings.

Judging Culinary Apples (Dublin Subscriber).—All the Apples you name are equally eligible for competition, and none of them could properly be disqualified on the plea of their not being ripe, unless ripeness is especially enjoined in the schedule, which is not usual in connection with culinary fruit.

Hexagonal Netting (A. F. M.).—The netting of which you have sent a sample is obviously of no use for excluding wasps, being too coarse. An article of much closer manufacture is essential, and most good nurserymen, seed merchants, or dealers in horticultural requisites can send samples of different sizes, and these are usually obtained before a quantity is purchased. There is plenty of this netting manufactured through which wasps cannot pass, and it is only by using such and fixing it securely that the pests can be excluded. Ask the firm that supplied you if they cannot send you finer—that is, much more closely woven samples.

Twin Dahlia (Mrs. V.).—Such monstrosities as that you sent frequently occur in Dahlias and other plants, but it is impossible to determine the cause where it does not arise from injury to the flower-bud when young. In the case of the flower sent it appears more like fasciation than absolute deformity, as the two peduncles can be distinctly traced up to the point where they separate and form two heads. It would seem as if two flower-buds were so closely placed together that as they advanced in growth the tissue united and continued to develop in that way until the flowering stage was reached, when the growth of the heads forced them asunder again.

Liliums not Expanding (H. N.).—We have grown Liliums both with peat and without it, and have found it a valuable addition to some soils, while others it has not materially improved. Whether it is required in your soil we have no means of judging; but with good turfy loam not too heavy, decayed vegetable refuse, gritty matter, such as coarse sand or crushed charcoal, Liliums ought to grow and flower well if they are properly treated. Many failures occur from late potting or planting, as if the bulbs are too much dried they are apt to produce stem roots only, few or none issuing from the bulb. In this case, unless the stem roots are top-dressed and the plants are carefully watered, neither the growth nor flowers would be satisfactory. You do not say whether your plants are in pots or planted out, or whether the bulbs were newly imported or grown in your garden. Late-imported and much-dried bulbs often fail.

"Black Blight" on Plants (George Pether).—The "black blight" on the leaves of your plants is caused by the excretion of insects, of which a fungus takes possession. The insects most likely to cause the "black" on the leaves of such plants as Pelargoniums, Heliotropes, and Fuchsias are aphides, and these are best destroyed by fumigation with tobacco paper, the foliage to be afterwards cleansed with water. When the cause is removed the black will not appear. The Fern is no doubt infested with scale, than for which we know of no better cure than syringing with a solution of petroleum—a wineglassful to three gallons of water. The oil should be kept thoroughly mixed by filling the syringe and forcing it sharply a few times into the watering pot, and then applying every alternate squirt into the liquid and the other over the plant, which should be laid on its side and

turned round, so as to keep the petroleum from the roots and insure the wetting of the plant in every part.

Stephanotis Fruiting (Idem).—It is not by any means a rare occurrence for Stephanotis to set and have fruit pods in this country. The pod will become ripe in due course, when the seeds should be separated from the pulp. They may be sown in sandy peat and placed in a stove temperature; if there be bottom heat it will more speedily effect the germination of the seeds. When the plants appear place them near the glass, pot off when large enough, and shift into larger pots as required. In about three years the plants will be strong enough to flower.

Size of Vine and Fruit Borders (R. C.).—As a rule a border of the same width of the house is more than ample, and this may be made in sections, adding a width of 2 or 3 feet yearly. With good soil and management excellent fruit, such as Peaches, Nectarines, Apricots, and Pears, may be grown in borders half the width that the trees are in height; or, in other words, if a wall is 10 feet high, a border 5 feet wide properly made and attended to is quite large enough for the trees in question. There is no Primula of the name you quote; have you not made a mistake in reading the label?

Sub-laterals of Vines Bearing (Sigma).—This is a good sign rather than otherwise, as the fruit denotes healthy Vines and matured wood. You had, however, better remove the bunches, as they will be of no use, yet exhaust the Vines needlessly. We are glad to hear of the great improvement in your Vines. It is a good plan to permit a free extension of lateral growth, but the principal leaves should not be shaded. It will be well probably to top the laterals where the Grapes are ripe, not, however, removing any great quantity of growth, as the chief point to attend to now is the maturation of the wood.

Alicante Grapes Shankd (J. W. Hill).—The berries you sent us are much shanked. Shankd is a result of defective root-action, which may be caused by the roots being in a cold, wet, and consequently badly constructed or constituted border, or from defective drainage; but it very often arises from a deficiency of foliage, and the deprecatory practice of allowing so much to be made in the early stages as to necessitate the removal of a large quantity when the Grapes are in the last stages of swelling. It also sometimes results from the want of calcareous matter in the soil, which may be rectified by giving a good dressing of quicklime and forking it into the border—a bushel per rod not being too much. If it arise from a badly constructed and imperfectly drained border the best remedy would be to lift the Vines and make the drainage efficient. The proper time to do this is so soon as the leaves give indications of being mature. If the Grapes are as badly coloured as those sent they certainly will not keep for any length of time, and are probably in their present defective colour from overcropping. See our remarks on late Grapes in this week's "Work."

Mentha Pulegium gibraltarica (X.).—This valuable green carpet-bedding plant is hardy, yet it not infrequently suffers by excessive wet during winter and spring, especially if it is planted in large masses. A good mode of wintering it is to plant very small tufts of it now on a dry south border, placing two or three rooted sprays together and about 3 inches apart in rows 6 inches asunder, or at such other distance that a small hoe can be run through the ground between them as required. The tufts should not be more than half an inch across in November. If much larger many of the plants are almost certain to damp off. In very wet soils and districts the plants should be conveniently disposed for receiving the shelter of spare sashes, frame lights, or handlights.

Winter's Bark (W. W. L.).—This is the produce of a small tree (*Drymis Winteri*) allied to the *Maguolias*, and is occasionally seen in botanic gardens or choice collections of plants in this country. The bark is a stimulant aromatic tonic, and may be used for similar purposes as cinnamon and *Canella alba*, for the latter of which it is sometimes substituted. Its odour is that of pepper and basil, and its flavour of a burning acidity adhering to the throat. It is said to be good in scurvy, vomiting, and paralysis, and it is also used for tanning. It was first brought to England from the Straits of Magellan in 1579 by Captain Winter, who went out with Sir Francis Drake in his voyage round the world. He found it very useful to his ship's crew both as a substitute for other spices and as a cure for scurvy. The leaves with other herbs are said to have been used successfully in fomentations, and half a drachm of the bark boiled with some carminative seeds promoted perspiration and relieved those suffering from scurvy. Other species of *Drymis*, as *granatensis* and *axillaris*, possess the same properties, and the fruit of *Tasmania aromatica* is used as pepper by the settlers of Australia.

The Pear Tree Slug (G. P.).—The best remedy for this troublesome pest is to dust the trees frequently with quicklime; perhaps the cause of your non-success is not using sufficient at a dressing. You will find figures of the larvæ and perfect insect in the Journal, page 22, July 6th, 1882. In reference to this insect, Curtis—under the head of "*Tenthredo adumbrata*"—says, "Arboriculturists are familiar with a slimy black larva like a little leech which appears as if glued to the leaves of Pear trees, and which is of very common occurrence in fruit gardens in September and October. From its form and appearance Réaumur called it the slug-worm. At the end of autumn, when it has attained its full size, it somewhat resembles a small tadpole. It has twenty feet, which, however, cannot be seen without dislodging it from the leaf. It does not begin at the edges of the Pear leaf, but gnaws away the parenchyma in the middle, leaving the smallest veins and the epidermis of the under side untouched, so that the leaves attacked are left like the finest lace. After four times casting its skin it changes to an orange-yellow colour, comes down from the tree, and forms a cocoon from particles of soil bound together by a few silken threads. The perfect insect, according to Hartig, is 2½ lines long, smooth, black, and shining, with the horns almost as long as the abdomen; the legs are black, the joints and thighs reddish-brown, the wings obscure." The grub is frequently very destructive to wall trees. It appears on Pear trees when the fruit are from one-half to two-thirds of their full size, and by destroying the parenchyma of the leaves it prevents the elaboration of the sap, brings growth to a standstill, and the Pears, instead of swelling, drop. Some authors consider that the slug-worm of Réaumur produces the *Tenthredo Cerasi* of Linnæus; others consider it to belong to the *Tenthredo Æthiops* of Fabricius. The

investigations of Gorsky, Westwood, and M. Delacour have set the question at rest. They have shown that there are several slug-like grubs which are developed into insects belonging to distinct species, and that the *T. Cerasi* of Linnæus does not form its cocoon in the ground, but amongst the leaves of the Cherry.

Ivies for Wall (S. S.).—We doubt if there is a better and quicker-growing form better suited to your high wall than the old Irish Ivy, *Hedera helix hibernica*, sometimes also called *canariensis* and *grandifolia*; but if you covet something less common plant *H. Rægneriana*, which has beautiful dark, glossy, heart-shaped leaves, but the growths do not cling to the wall quite so closely as the other. *H. dentata* is the largest-leaved Ivy in cultivation, its huge foliage being very effective; this you may have a suitable place for somewhere. *H. latifolia maculata* is free-growing and effective, having marbled foliage. Good smaller-leaved sorts are the following:—*H. pedata*.—Leaves hastate, small, sharply lobed, green with distinct silvery-grey veins; a good grower and climber; suitable for walls, pots, and almost all purposes of decoration. One of the most useful. *H. lobata major*.—Leaves medium-sized, bluntly lobed; a cheerful green with clearly marked veins. A very useful free-growing variety. *H. minor maculata*.—Leaves very small, perfectly mottled; habit close; plant of free growth. *H. sublutea*.—Leaves small, irregular, not lobed; centre green, edged and flaked with white and yellow. Distinct but not vigorous. *H. rhomboidea*.—Leaves medium, almost oval; very rich green with clear veins. A good grower, very distinct, and effective. *H. marginata grandis*.—Leaves medium-sized, rich green, broadly margined with ivory white. A very free grower, and valuable for pots, walls, or edgings. *H. marginata rubra*.—Leaves small, two shades of green, broadly edged with white and flaked with pink. *H. marginata major*.—Leaves slightly lobed, deep green, mottled with light green and margined with creamy white; veins clear. Effective and a good grower. *H. chrysophylla*.—Medium grower; leaves green, some of them mottled with yellow, others entirely yellow. Very distinct and effective.

Names of Fruits (E. M.).—1, Barrington; 2, Royal George; 3, specimen not sufficiently matured. The Apricot is Moorpark and the Nectarine Stanwick Elruge. (*J. M., Chester*).—Minehall Crab. (*J. W.*).—Searlet Nonpareil. (*R. I. L.*).—1, Cellini; 2, Irish Peach. (*C. & Co.*).—1, Small's Admirable; 2, Bedfordshire Foundling; 3, Sugarloaf Pippin. (*T. Kennedy & Co.*).—1 and 2, Ecklinville; 3, Keswick Codlin. (*Colville Brown*).—1, Golden Winter Pearmain; 2, Chaptal, a stewing Pear; 4, Orange Bergamot; 5, Early Nonpareil. (*R. P. Williams*).—1, Lemon Pippin; 3, Devonshire Quarrenden.

Names of Plants (T. M. G.).—*Tradescantia zebrina*. (*J. H. C.*).—1, *Lysimachia vulgaris*; 2, *Dracocephalum Ruyschianum*; 3, *Abutilon vitifolium*. (*Dr. S.*).—The specimen is insufficient; cannot you send one with flowers? (*W. N.*).—The *Spiræas* have been mislaid; other samples shall, however, receive our prompt attention. (*R. T.*).—1, *Adiantum macrophyllum*; 2, *Pteris serrulata cristata*; 3, *Davallia Mooreana*.

COVENT GARDEN MARKET.—SEPTEMBER 12TH.

THE state of trade is still dull. A good supply of home-grown Apples arriving, but realising low prices.

as the sheep of the higher mountains, and the other as the soft-woolled sheep. The former breed is a very small animal, seldom weighing more than 5 lbs. per quarter. Both sexes possess horns resembling the goat as to their length and position, and whose habits in various respects it much resembles. The tail is of the ordinary length, and there is a hair-like ridge on the back, throat, and dewlap, the fleece being of varied colours—black, grey, and brown. These animals are very wild and active, preferring the highest spots and the aromatic plants growing thereon to richer herbage. They are more frequently found in South Wales. It is stated with doubtful authority that, like those of Orkney and Zetland, the rams often attack the ewes when in lamb, and thereby diminish their numbers as if for the object of repressing their too great increase. They have black hair on the face and legs, a peculiarity which continues even when they are transferred to the richer valleys for better feeding, and in some respects resemble the Radnor sheep, a superior variety of the same race, but enlarged by feeding on the better pasturage. We think these sheep may be much improved; in fact, this idea is beginning to be recognised by various owners by crossing with either South Downs or the Cheviot; probably their hardier characteristics would render the latter the most suitable to the purpose.

The soft-woolled sheep may be fairly considered as the most general and distinct breed of Wales, and are distinguished from other varieties by the whiteness of the nose and face. The fabric known as Welsh flannel is derived from the wool of these sheep, and the carcass is quite celebrated in the estimation of purveyors and consumers under the well-known term of Welsh mutton. Animals of this breed are small, seldom exceeding 8 lbs. per quarter when fat. They are to be found throughout the whole of Wales, but they delight in lofty situations. Like nearly every class of mountain sheep their habits are exceedingly active, and if attempt is made to enclose them few fences can confine them, and frequently make their escape and regain their native mountains when required to feed enclosed pastures. Their form in some measure corresponds with their habits, being slender throughout, and their hind quarters long like those of the deer. The males have their horns curved backwards, but the females do not possess any. The neck is thin, and arched backwards like the deer in a greater degree than any other sheep. Their fleece contains a certain mixture of hair, though less than other mountain breeds, and this is particularly noticeable on the throat, where it appears like a beard. The fleece seldom exceeds 1 or 2 lbs., but partakes of the long-woolled character, and is well adapted for flannels or hose, but not for cloths. It is often the custom to clip off the wool of the neck and face before winter, for if left it frequently comes off and is lost. These sheep, however, are often found in the island of Anglesea, where they from having better pasturage generally become larger and of better form.

Another breed of sheep found in Wales is called the Radnor sheep, of which there are two specimens, one possessing some of the characteristics of the long-woolled variety, but still resemble to some extent the higher mountain sheep, but of a larger size and better form, fattening to 8 or 9 lbs. per quarter. The others have been more recently crossed with the Shropshire and other breeds with favourable results.

The mountain sheep of Ireland are of various breeds, the chief of which are the Wicklow and the Kerry. The Wicklow, the more valuable but less numerous, are chiefly confined to the Wicklow mountains on the east coast of Ireland, an elevated district, but possessing a moist atmosphere. These sheep resemble in various respects those of the Welsh mountains. They are very wild and small animals, without horns, and with white faces and legs. There is, however, a tendency to become black, which is proved by the number of black lambs that are yeaned. They are larger animals when bred nearer the base of the mountains where pasturage is more nutritious. Towards the summit of the mountains, the ground being boggy and the pasturage scanty, the sheep are smaller, the wool is less fine and more mixed with hair, which appears in ridges along the spine and neck, thus causing the rain to shoot off the back; and this provision against the evils of their position is still further secured by the lambs having a kind of hairy covering on those parts which come in contact with the damp ground. The proximity of the city of Dublin occasions a great demand for early lambs, and these sheep are adapted for this object to a great extent. The mountain sheep are purchased by the farmers of lower and better soils, and the rams put to the ewes in June, the lambs fall about December. They are frequently brought up in pens, somewhat similar to the house lambs raised for the metropolitan market from the Dorset ewes, being separated from the dams in the course of a fortnight, and are much forced by

MOUNTAIN BREEDS OF SHEEP.

(Continued from page 219.)

THE sheep of Wales are of two distinct varieties, the one

sucking those ewes whose lambs have died or have been killed, as well as their own dams. To this afterwards is added cow's milk, so that they are fit for market in the course of about six or seven weeks. The disposition to take the ram so early, the quality of the mutton, and the circumstance of the ewes being very good nurses, gives a special value to this breed, and by thoughtful men it is much regretted that it has not been still more improved by judicious selection and management.

The Kerry breed may be considered as the type of the various mountain breeds which are found chiefly in the west of Ireland. They are something larger than the sheep of the Wicklow and Welsh mountains. They are, however, a hardy, but at the same time an unthrifty race, feeding slowly, and a long while arriving at maturity. Their fat accumulates in the inside, and the animals exhibit no rotundity of form externally. They have small crooked horns, which are usually wanting in the female. They much resemble in their general appearance the antelope races. They pick up their subsistence amidst the peat bogs, occasionally taking provender clandestinely from the neighbouring farms. The only redeeming point in this class of sheep is the excellence of the mutton.

The forest and mountain breeds of sheep in the west of England are the Exmoor and Dartmoor varieties. These are located in the higher situations of Devonshire and Cornwall, and are a hardy race adapted to the poverty of the pasturage which the forests of Dartmoor and Exmoor afford. The Exmoors are rather smaller sheep than the Dartmoor, and are spread over the purely hill districts, but since the "Commons Enclosure Act" many farmers have crossed them with the Leicester, and larger sheep has been secured, but at the expense of stamina and numbers. The original Exmoors are better nurses than the improved or crossed stock, and bring a large proportion of doublets at lambing time. The ewes are always brought down to the vale lands to lamb and get a few roots and oats. The ewes are put to the ram at two years old, and are drafted for sale after three crops of lambs. The best points in the breed are a very strong constitution, which will bear being buried in a snowdrift for several days, with a fine curly horn, a broad square loin, round ribs, drum-like and not a square carcass on short legs, and close set fleece, with wool well up to the cheeks. Wether lambs are usually kept on the hills and feed on the Heather except in the winter months, and are retained until they are three or four years old. Dealers buy the wethers at the farms and send them by rail on to Bristol, Salisbury, Southampton, and other south-coast towns. We have noticed splendid specimens taking the prize at the Christmas Cattle Show in London, particularly those exhibited by Mr. Merson years ago, also those bred by Messrs. Quartly, which have averaged 29 lbs. per quarter as four-year-olds off the hill. Frequently this breed has done wonders; Mr. Tapps' prize pen at Christmas have reached 42 lbs. per quarter. This, of course, only applies to very well fed flocks in an exceptional season, but for their size there are no sheep go the scale so well, nor more perfect in form. In referring to the Dartmoor breed, although they have derived their name from a certain district, they are very small, having soft wool, white faces and legs. They thrive slowly, averaging when fat about 10 lbs. per quarter. Though bred on the heath they are fattened in the plains, and their mutton is considered excellent by the epicure as well as the purveyor, and it commands a ready sale. Wethers of this breed at four years old have been occasionally, by high feeding made to weigh from 25 lbs. to 30 lbs. per quarter, with a large proportion of lean flesh, which makes them very much in request by the metropolitan and coast-town purveyors.

WORK ON THE HOME FARM.

Horse Labour in most districts is still partially or entirely employed in work connected with the harvest. In some of the early counties many farmers have completed the corn and second-growth hay harvest, the remaining work being only the Beans and pulse crops. It is now a good time to employ steam power for cultivating the corn stubbles, as in many cases they are foul with couch and weeds owing to the wet seasons which have prevailed, but especially this is found to be the case on the mixed soils farmed under the four-course rotation. The steam power should be hired where it does not form part of the implements of the farm; the work may then be contracted for. We like to cultivate about as deep as the plough goes, but not deeper, and if this is done both lengthways and crossways the land will be well stirred and lie rough if the work has been carefully done and no spaces missed by the tackle. The horses may after a few days or a week be set to work on the steam-cultivated land by dragging with Howard's self-lifting drag or harrow, as it is the best implement for the purpose; and the longer the couch can be kept on the surface exposed to the weather the better, as the land not only becomes aerated, but also mellow and kind for working fine enough to remove the couch, after which the land will be ready for the seeding of catch crops,

such as Rye, winter Tares, winter Barley, and Trifolium. The latter should be first seeded for, because as the nights get longer and the dews heavier the small white slugs, the greatest enemy to Trifolium, are sure to be busily engaged in feeding on the first leaves of the young plant, therefore early seeding is the surest way of obtaining a full plant. Sowing a full quantity of seed when rather late is, however, important, and from this time not less than 25 lbs. per acre should be sown. Horses will still be required on those fallows which are not finished for every opportunity when the land is dry. Working the land fine and removing any remaining couch and weed should be completed, so that the land may get stale on the surface before the last or ridge-ploughing takes place, which on strong land should not be later than the 1st of October. With regard to the question of manuring land for Wheat with farmyard manure, we recommend that on strong soil situated at some considerable distance may be dressed with artificial manures, applying 4 cwt. of bone superphosphate at the time of sowing, and using nitrate of soda in the spring, as much as may be required according to the season and appearance of the young Wheat plants the first week in April. The farmyard dung, however, may be applied upon lea ground lying nearest to the homestead, and in a busy time the laying it out may be deferred until October, and then spread and ploughed in and sown as fast as ploughed. This plan is, however, only recommended in case of pressure of work on the farm, for as a rule it is better to lay the dung out early in September and plough early, so that the land may have time to settle and get stale and mellow before the seed time.

Hand Labour.—The hedges and borders should now be trimmed close, and the border growth of coarse grass may be retained for use in the covering of Mangolds and other roots, for which it answers a good purpose when stored in heaps. The men will now be required in filling and spreading yard manure as fast as laid out. There are, however, such jobs as turning the dung in the farmyard for the purpose of mixing and equalising the value of it before laying out to be attended to. Any earth heaps also which may have been turned in the summer will again require to be turned over, taking care to bury any weeds or other vegetation which will decay and enhance its value for application on pasture land.

Live Stock.—The grazing bullocks will now require to be looked over, and those which are fit for the butcher sold before the ruck of cattle usually thrown on the market in October takes place; those not now fit for the shambles may be fed with a little extra cake and meal, mixed with a few early Turnips cut with Gardner's cutter, and placed in troughs or skeps on their pasture in order that they may become accustomed to root and meal feeding before they enter the boxes for the fattening, commencing in October. The dairy cows should now be allowed some few pounds of cotton cake per day at the stalls night and morning at milking time. As, however, those in full milk cannot be too well fed, yet those in calf and gone dry should be herded or fed separately and not fed so highly, otherwise it may be found that they have laid on fat internally, which may seriously injure their well-doing at calving time. Young stock cattle may well replace the fattening bullocks when sold, and if required to be sold at an early period, the sooner they get a fair allowance of cake the better, as the days are shortening. The early-lambing Dorset and Somerset horned ewes will now be forward in lamb, and instead of the ewes being sent to fairs for sale, we prefer to buy them of their breeders and send them direct by road to their new home. We dislike very much the practice of sending these ewes heavy in lamb either to fairs or to the farm of the purchaser by railway, as we have known serious losses of lambs occur through being overcrowded into trucks on the railroad. When driven by short stages on the high roads they seldom suffer injury or losses at lambing time. Having kept this kind of stock for more than thirty years, rearing lambs for the metropolitan or other markets, we have found them more advantageous than other stock where the soil and climate is favourable, for foreign importations do not affect the lamb sales at the earliest period.

REMARKS.

2nd.—Strong S.W. gale all night, very stormy day with rain.
 3rd.—Gale in night, fine day with gusty wind, calm in evening.
 4th.—Fine, slight showers latter part of day.
 5th.—Wet early, fine bright day.
 6th.—Fog early; overcast, dull day, and cold.
 7th.—Fine, but dull.
 8th.—Wet morning, clear about 11 A.M., rest of day remarkably clear and bright.
 A remarkably strong gale for the time of year occurred on Sunday September 2nd, after which the temperature fell considerably, so that the week has been colder than the average.—G. J. SYMONS.

HISTORY OF THE POTATO.

THE annual International Potato Exhibition at the Crystal Palace which was held last week invariably attracts much public attention to the familiar tuber; and as the memories of the abundant and diverse varieties there shown are still fresh in the minds of visitors, the present time is not unsuitable to briefly review the history of this indispensable vegetable. Very gradual has been its progress in public favour, and never until within the last ten or twelve years has so much attention been given to the production of new varieties or the improvement of previously existing forms. The Potato trade is now, however, one of the most important departments of many large seed-houses, while some firms devote themselves specially to it. Varieties of standard excellence are being continually added to those of which the merits have been already proved, and it is generally admitted that this is the only way in which the constitution of the Potato can be preserved. That some of the "novelties" fail to satisfy the requirements of experienced horticulturists must be expected; but the general benefit due to these persevering raisers is undeniably great, and it is to be hoped that they will continue their efforts in the same direction.

There is every reason to believe that Chili, and especially the neighbourhood of Quito, is the native country of the Potato. It is there now found in a wild state; its slightly bitter tubers have been thence imported of late years; and cultivation has gradually raised from those tubers plants now producing crops of excellent Potatoes. We learn, also, from Peter Cieca and Molina that when the Spanish navigators first visited Chili and Peru, their inhabitants cultivated and ate a tuberous-rooted plant which they called *papas*. Molina says there are two kinds—the wild, having small bitter tubers, and the other, improved by culture, so as to have tubers grateful to the palate.

The Spaniards first visited South America in the year 1492, and there is no rational doubt of this being the earliest period in which the Potato became known to Europeans. Clusius and some others have surmised that the *arachidna* described by Theophrastus was the same plant, although the suggestion does not appear with a single reason to sustain it; but it seems to us that the *arachidna* is identical with the *aracidna* of Pliny ("Hist." lib. xxi., cap. 20), and this appears to have been synonymous with our Truffle. Pliny says it was a root having no leaf, or stem, or any other part above ground. Cortucius had a similarly groundless opinion as to the identity of the Potato with the *picnocomus* of Dioscorides. This certainly was not the Potato, for it is described as growing wild in southern Europe in stony places, as having acrid leaves, and seeds narcotic, producing heavy disturbed sleep.

The Spaniards imported the Potato into Spain, where it was called *battata*, from the resemblance the tubers bore to those of the Sweet Potato (*Convolvulus battata*), and from thence it was communicated to Italy. This was at the close of the fifteenth or early in the sixteenth century; yet at the

latter period the Potato was so little known, even to botanists, that Lobel, in his "Plantarum seu Stirpium Historia," published at Antwerp in 1576, has no mention of it, though he describes and figures the Sweet Potato. Gerarde in England, however, and Caspar Bauhin at Basel, both in the year 1526, gave notices of their acquaintance with it, yet still evidently as a rarity.

Caspar Bauhin, in his "Phytopinax seu Enumeratio Plantarum," published at Basel in 1596, first bestowed upon it the botanical names it still retains—*Solanum tuberosum*; and his description is also the first occurring that is full as well as accurate. Some of the particulars intimate a knowledge of the consequences of certain modes of treatment that we have been lately and, it would seem, mistakenly, considering of recent discovery. The root, he says, is round, but not completely so, of a tawny or dark reddish colour, and is usually dug out of the earth in the winter, being replanted in the spring. "Nevertheless, if left in the soil it will again vegetate in the spring. Very often the root becomes rotten after it has put forth the stem." It was known as the Spanish or Indian pappar, and endured without difficulty the climate of Europe, for he had seen it in the open gardens of some physicians in the Netherlands.

In his "Prodromus," published in 1671, Bauhin gives a drawing of the Potato, showing the tubers as both round and oblong, and enters still more fully into its description. He says it was first brought from Virginia to England, was thence exported to France, and from the latter country was distributed to other parts of Europe. In Virginia it is called *openawek*, as is stated by Peter Cieca, and in Gomara's History of the Indies. About Quito it was called *papas*, and thence it was sometimes called the Indian or Spanish *papas*, and in Germany *grubblingbaum*—that is, the tuber-bearing shrub. Bauhin says that he first delineated it in 1590 from a specimen in the garden of Dr. Scholtz, who probably received it from Clusius.

Peter de Sivry, Lord of Walhain, had the Potato in 1587 from a friend of the Pope's legate in Flanders. It was brought from Italy under the name of *tortufole*, a name applied to all underground tubers by the Italians. The Lord of Walhain gave two of the tubers to Clusius in 1588.—("Clusius Historia Plant.")

Our countryman, Gerarde, in 1596, specifies the Potato under the title of *Papus hispanicus*, in the catalogue of plants cultivated by him in his garden in Holborn. In his "Herball," published the year following, he describes the Potato accurately. After particularising the Sweet Potato, which he calls "Sisarum Peruvianum, sine Batata Hispanarum, Potatus or Potatoes," he proceeds to the consideration of the common Potato, under the title of "Potatoes of Virginia, Battata Virginiana sive Virginianorum et Pappus." The woodcut and the description demonstrate that the plant he had before him was our common Potato; and he proceeds to observe that "it groweth naturally in America, where it was discovered, as reporteth C. Clusius; since which time I have received roots thereof from Virginia, otherwise called Norembega, which grow and prosper in my garden as in their own native country." At the end of the preface is a portrait of Gerarde, and it deserves notice that he holds in his hand a sprig of the Potato—leaves, flowers, and fruit—as if he considered it one of the most remarkable novelties of his time. After stating the time of its blooming, &c., Gerarde adds, "The Indians call it *papus* (meaning the roots), by which name the common Potatoes (Sweet) are known to them. We have the name proper unto it mentioned in the title, because it hath not only the shape and proportion of Potatoes, but also the pleasant taste and virtues of the same; so we may call it in English Potatoes of America or Virginia. Being likewise a food, as also a meat for pleasure, either roasted in the embers, or boiled, and eaten with oil, vinegar, and pepper, or dressed any other way by the hand of some cunning in cookery."

In 1633 "Thomas Johnson, citizen and apothecary,"

published a new edition of Gerarde's Herbal, and it is very apparent that the Potato had then improved under cultivation, for the tubers there represented by him are large, and in form resembling the Julys now cultivated; whereas those portrayed by Gerarde are small and globular, like those produced by the plant in its wild state.

The positive testimony of Gerarde proves that the Potato was forwarded to him from Virginia; and how they reached that province of North America will be made to appear probable by the suggestions of Humboldt, which we will presently mention. Gerarde, we may conclude, received the tubers from some of the settlers in Virginia, who emigrated thither about twelve years previously, in 1584, under a patent granted by Queen Elizabeth to Sir Walter Raleigh. And thus much is certain, that in 1693 Sir Robert Southwell, President of the Royal Society, communicated to that learned body the fact that his grandfather first cultivated the Potato in Ireland, and that he obtained it from Raleigh. Tradition states further that Sir Walter himself also had the root planted on his estate near Youghall in the south of Ireland, and that he gave them to his gardener as a desirable fruit from America. When the berries were ripe in September the gardener brought them to his master, with the inquiry of disappointment, "Sir, are these the fine American fruit?" Sir Walter, either really or pretendingly ignorant of the Potato's habit, desired them to be dug up as weeds, and thrown away; but in doing this the tubers were revealed, and found to be the available produce.

Humboldt rationally concludes that the Virginian colonists obtained the Potato from the Spanish settlements, for it is quite clear that it is not a native of Virginia, nor even of intervening Mexico, and that it was cultivated in Spain and Italy before it was made known in England from Virginia.

Although the Potato was known to English botanists in 1596, yet horticulture was too ignorantly practised in this country to permit its rapid introduction among our cultivated crops. In 1619 Potatoes were here a desired yet expensive luxury; for in that year of James I.'s reign a small dish of them provided for his Queen's table cost 1s. per lb., when money was at least twice as valuable as it is now.

Potato cultivation spreads rapidly in Ireland, and it became established, it is said, in Lancashire and that portion of our northern coast still celebrated for its culture, owing to some being on board a vessel wrecked upon its shore. Yet the value of the root was not generally known at a still later period; for in a time of scarcity—namely, in the March of 1663—it required to be recommended as a crop of national importance in a letter addressed to the Royal Society. The writer of this letter was Mr. Buckland, a Somersetshire gentleman, and the recommendation was referred for consideration to a Committee of the Society. The report of that Committee was favourable, and the Society not only urged its cultivation to landed proprietors, but requested Mr. Evelyn to enforce the Society's opinions in his "Sylva," then publishing under its auspices, although it was no favourite with him, for in 1664 in his "Kalendarium Hortense," he says, "Plant Potatoes in February in your worst ground." Before the "Sylva" appeared—namely, in 1664—was published a pamphlet, the first devoted to the subject of cultivating the Potato, and bearing this prolix title—"England's happiness increased, or a sure and easy remedy against all succeeding dear years, by a plantation of the roots called Potatoes, whereof (with the addition of wheat flour) excellent, good, and wholesome bread may be made every year, eight or nine months together, for half the charges as formerly. Also, by the planting of these roots, 10,000 men in England and Wales who know not how to live, or what to do to get a maintenance for their families, may of one acre of ground make £30 per annum. Invented and published for the good of the poorer sorts by John Forster, Gent., of Harslop, in Buckinghamshire."

He says that the Potatoes he recommends for general cultivation "are the Irish Potatoes, little differing from those

of Virginia, save only in the colour of their white flowers. These roots, although they came at first from the Indies, yet prosper well in Ireland, where there are whole fields of them, from whence they have been brought into Wales and the north parts of England, where they likewise prosper and increase exceedingly." He recommends a dry well-drained soil for them, to be enriched with dung if necessary. Planting in March, with tubers cut into quarters or halves, to be buried 6 inches deep and 8 inches asunder. The roots, he says, may be begun to be taken up in September, and as wanted until March; so that even then it was known to the cultivators that the colds of winter would not destroy the tubers; and Mr. Forster further adds that the very small roots must be left in the ground to produce a crop the next year. In conclusion, he gives directions for making Potato bread, Potato biscuits, Potato pudding, Potato custards, and Potato cheese-cakes. The produce from good ground was three or four heaped bushels per rod. No one, he says, will grudge for them a shilling per bushel. Mr. Forster then considers the growth of Potatoes as a political question, and recommends the King (Charles II.) to order an importation of the root from Ireland; and that every man in every parish shall grow an acre or two; and that out of every £30 worth grown in a parish £5 shall be paid to the King! He concludes by stating how the Potato may be raised from seed instead of from the root.

Notwithstanding the widely disseminated opinions of the Royal Society, and these published appeals to the public, the introduction of the Potato as an object of cultivation was extremely slow.

Worldidge, in 1687, although he remarked that the Potato was then common in some parts of the Continent, merely suggests that they may be useful for swine or other cattle.

Houghton, writing in 1699, says they were then very common in Lancashire, being introduced from Ireland, and that they begin to spread over England. The roots were boiled or roasted, and eaten with butter and sugar!—"Collections" ii., 468.)

Sharrock, Ray, Lisle, Bradley, Mortimer, &c., writing at the close of the seventeenth, and early in the eighteenth century, make most slighting mention of the Potato; and even Miller in the 4th edition of his Dictionary, published as late as 1771, only mentions the same two varieties, the red and the white tubered, which had been noticed by writers a century his predecessors.

Salmon, who wrote in 1711, speaks of the Virginian and the English or Irish Potato as distinct kinds, though his description shows their identity—the only difference being that the colour of the skin of the tubers of the first was dirty white, and of the second red. "They are only nursed up in gardens in England and Ireland, where they flourish and come to perfection, prodigiously increasing to a vast plenty. The roots are boiled, baked, or roasted."—(*Salmon's Herbal*, 905.)

London and Wise, in the seventh edition of their "Compleat Gardener," published in 1719, do not even mention the Potato; but it must be remembered that this is only an abridged translation of M. Quintinye's work, published some years previously. However, even as late as about 1770, the Potato was not known generally in the south-western counties. Knight, writing in 1831, when he was seventy-two years of age, says—"I can just recollect the time when the Potato was unknown to the peasantry of Herefordshire, whose gardens were then almost exclusively occupied by different varieties of the Cabbage. Their food, at that period, chiefly consisted of bread and cheese, with the produce of their garden, and tea was unknown to them. About sixty years ago, before the Potato was introduced into their gardens, agues had been so extremely prevalent that the periods in which they or their families had been afflicted with that disorder were the eras to which I usually heard them refer in speaking of past events; and I recollect being cautioned by them frequently not to stand exposed to the sun in May lest I should get an ague.

“The Potato was then cultivated in small quantities in the gardens of gentlemen, but it was not thought to afford wholesome nutriment, and was supposed by many to possess deleterious qualities.

“The prejudices of all parties, however, disappeared so rapidly, that within ten years the Potato had almost wholly driven the Cabbage from the garden of the cottagers.”

Mortimer’s “Whole Art of Husbandry” was published in 1707, and a sixth edition in 1761, and in these the Potato is dismissed after a brief notice of ten lines, about half of which are occupied with these observations:—“The root is very near the nature of the Jerusalem Artichoke, but not so good or wholesome. These are planted either of roots or seeds, and may probably be propagated in great quantities, and prove good food for swine!”

One reason certainly that the plant remained so long in disrepute was the defective mode of its culture. This and ignorance of the proper mode of cooking the tubers would make them certainly anything but a tempting article of food. The following anecdote illustrates this:—“A person who had been invited to taste the first Potato planted in his own county of Forfar, N.B., about the year 1730, related that the roots had been merely heated, and that they adhered to the teeth like glue, while their flavour was far from agreeable. The food was thus about to be condemned, when the accidental arrival of a gentleman who had tasted a Potato in Lancashire caused the rejected roots to be remanded back to the hot turf ashes till they became as dainty as they had before been nauseous.”

According to the old statistical account of Scotland Potatoes were first cultivated in the field there in the year 1739 in the county of Stirling, and Dr. Walker assures us that they were not known in the Highlands and Isles till 1743. It is stated in the General Report of Scotland (vol. ii., p. 3) as a well-ascertained fact that in the years 1725-6 the few Potato plants then existing in gardens about Edinburgh were left in the same spot of ground from year to year as recommended by Evelyn; a few tubers were perhaps removed for use in the autumn, and the parent plants well covered with litter to save them from the winter’s frost. Notwithstanding the success that after this period attended the culture of the Potato among the cottagers, its progress among the higher classes in Scotland was retarded by the opinions of different writers on agricultural subjects already mentioned, and also, what is not a little singular, a mistaken zeal in religious matters made some of the Scotch folks hostile to the innovation. “Potatoes,” said they, “are not mentioned in the Bible!” and this was deemed a quite sufficient reason for rejecting them. Famine at last gave the great impulse to the cultivation of this root, and during the latter part of the eighteenth century its excellent qualities became generally understood.”

Such is the early history of the Potato—the most important of all root crops, and it is most gratifying to observe that the efforts that have been made in raising new varieties have been markedly successful. The degenerating theory is vanishing, and varieties are now raised that are better able to resist the attacks of the disease than at any time during the past thirty-five years.

SHOW AND FANCY DAHLIAS AT THE NATIONAL DAHLIA SHOW.

WITH a view to ascertain what are considered by the best growers to be the most reliable Show and Fancy Dahlias for exhibition purposes, I took down, with the kind assistance of a friend, the names of all the double flowers shown at the recent Exhibition of the National Dahlia Society. After tabulating the results thus obtained I found that about 700 Show and 300 Fancy Dahlias had been altogether exhibited, the former in 163 and the latter in seventy varieties.

Taking first the leading Show Dahlias, it will appear from the following list how many times out of a possible forty-two they were to be seen in the Exhibition stands. And to show how satisfactory, so far as they go, are the figures which precede the different names, it may be mentioned that although my friend and I wrote down the

names in alternate boxes throughout the Exhibition, yet we found on comparing results that in nearly every case we had entered each variety in our note books either the same or a very similar number of times:—

No. of times shown.	Name.	When sent out.	Raiser's Name.	Colour.
21	Hon. Mrs. P. Wyndham	1881	Keynes & Co.	yellow and purple
19	Henry Walton.....	1873	Keynes	yellow and scarlet
18	James Cocker	1871	Keynes	purple
18	James Vick	1881	Keynes & Co.	maroon
16	Goldfinder.....	1881	Fellowes ...	yellow and red
16	Prince Bismarck	1879	Fellowes	puce
15	Joseph Ashby	1879	Turner	orange
15	William Rawlings	1881	Rawlings	purple
14	Alexander Cramond ...	1872	Keynes	maroon
14	Ethel Britten	1880	Keynes & Co.	white and purple
13	Shirley Hibberd	1881	Rawlings ...	crimson
12	John W. Lord	1877	Keynes	buff
12	Mrs. Harris	1873	Harris	white and lilac
12	Vicc-President.....	—	Keynes	orange
11	John N. Keynes	1871	Keynes	yellow
10	Flag of Truce	1868	Wheeler	white and lilac
10	John Bennett	1875	Rawlings ...	yellow and scarlet
10	Julia Wyatt.....	—	Keynes	white
10	Royal Queen.....	—	Eekford	cream and crimson
9	George Smith	1879	Rawlings ...	magenta
9	Mrs. Dodds	1881	Keynes & Co.	white and lilac
9	Prince of Denmark.....	1881	Fellowes	maroon & crimson
8	Emily Edwards	1879	Keynes	white
8	Pioneer	1882	Fellowes	black
8	Walter H. Williams ...	1881	Keynes & Co.	scarlet
7	George Rawlings.....	1882	Rawlings ..	maroon
7	Annie Neville	—	Keynes	white
7	Clara	1879	Rawlings ...	peach
7	Duke of Connaught.....	1879	Keynes	crimson
7	Mrs. Shirley Hibberd..	1877	Rawlings ...	cream and pink
7	Ovid	1874	Turner.....	purple
7	Rev. J. Goodday	1879	Rawlings ...	maroon & purple
6	Burgundy	1877	Turner.....	puce and purple
6	Criterion	—	Edwards	rose
6	John Wyatt	1877	Keynes	scarlet
6	Joseph Green	1881	Keynes & Co.	crimson
6	Lord Chelmsford	1880	Keynes & Co.	maroon
6	Thomas Goodwin	—	Goodwin	maroon
5	George Dickson	1882	Keynes & Co.	chestnut
5	Joseph B. Service	1882	Keynes & Co.	yellow
5	Artiste	1877	Fellowes	yellow & carmine
5	Champion Rollo	1881	Keynes & Co.	orange
5	Constancy	1878	Harris	yellow and lake
5	H. W. Ward	1881	Keynes & Co.	yellow & crimson
5	John Standish	—	Turner.....	crimson
5	Modesty.....	1881	Fellowes	blush
5	Mr. Harris.....	1881	Rawlings ...	scarlet
5	Revival	1881	Fellowes	crimson
5	Rosy Morn	1879	Keynes	rose

Turning now to the Fancy Dahlias and treating them in the same way as the “Shows,” the principal varieties come out as follows. It should, however, be stated that in this case the greatest number of times which any one variety could be exhibited was twenty-one:—

No. of times shown.	Name	When sent out.	Raiser's Name.	Colour.
16	Gaiety	1879	Keynes	yellow, red, & white
15	Mrs. Saunders	—	Turner	yellow and white
14	George Barnes	1878	Keynes	lilac and crimson
12	John Forbes	1882	Keynes & Co.	fawn and maroon
11	Fanny Start	—	Pope.....	red and white
11	Oracle	1877	Fellowes	yellow & crimson
11	Henry Glasscock.....	1875	Keynes	buff and crimson
10	Jessie McIntosh	1880	Keynes & Co.	red and white
10	Miss Browning.....	1880	Keynes & Co.	yellow and white
10	Mrs. N. Halls	1881	Rawlings.....	scarlet and white
9	Rev. J. B. M. Canm ...	—	Keynes	yellow and red
8	Professor Fawcett	1881	Keynes & Co.	lilac and brown
7	Chorister	1881	Keynes & Co.	fawn and crimson
7	Egyptian Prince	—	Keynes	orange and red
7	Hercules	1877	Keynes	yellow & crimson
6	Flora Wyatt.....	—	Keynes	orange and red
6	Parrott	1873	Keynes	yellow & crimson
5	Annie Pritchard	1881	Keynes & Co.	white and lilac
5	Florence Stark.....	1879	Keynes	white and purple
5	Hugh Austin	1881	Keynes & Co.	orange and red
5	Miss Lilly Large	1876	Keynes	yellow & crimson

Messrs. Keynes & Co., to whom I am indebted for nearly all the dates given above, recommend the addition of the following—viz., to the Show varieties, 4, Canary; 4, Herbert Turner; 3, Henry Bond; 2, Lizzie Leicester; 3, Miss Cannell; 3, Mrs. Stancombe; 3, Mr. J. C. Reid; 2, Mr. Spofforth; and 2, Triumphant. And to the Fancies, 3, James O'Brien.

When glancing down the dates one cannot help being struck with the prominent position occupied by Dahlias of recent introduction, more than half the varieties named in the two lists having been sent out during the last four years, thus showing how rapidly both the Show and Fancy flowers are being improved. If we may judge by this one Exhibition alone the least constant of the best Fancy Dahlias appear to be—

Charles Wyatt, exhibited	four times as a Show	and	four as a Fancy.
Flora Wyatt	six	"	six
Frederick Smith	three	"	once
George Barnes	eleven	"	nine
Hugh Austin	five	"	five
James O'Brien	five	"	three

As many as thirty-eight Fancy flowers were in all staged in the Show classes against seventeen Show varieties in the Fancy division.

It is by no means claimed that the precise position given to the different varieties in the above lists is such as they would occupy in an extensive *Dahlia* election. In the absence, however, of any such election I have thought that the foregoing particulars, imperfect in some respects though they necessarily be, may at least prove of service to those of your readers who, like myself (and that principally through the lead given us by the National Dahlia Society), are beginning to take an interest in the cultivation of this grand autumn flower.—E. M., *Croydon*.

MR. GLADSTONE APPLE.

I HAVE been from home for some weeks, and in looking back over the Journal have met with an inquiry as to the origin of the Mr. Gladstone Apple. I had mine from a nurseryman named Jackson, of, I think, the Blakedown Nurseries, Kidderminster. I am not sure about the address, but I know his name was Jackson. I must have had mine about 1869, and I am not sure about the price at which the trees were advertised, but 10s. to 15s. each, or some such a price. I know it was very high because I hesitated about giving so much. Mr. Bunyard says it is weak-growing, yet it is a most healthy grower with me.—GEORGE LEE, *Clevedon*.

THE PHYLLOXERA.

HAVING had to battle with the phylloxera on a large scale two years in succession in a new range of vineries in these gardens a few years since, I heartily sympathise with Mr. Austen or any other gardener who may have to contend with this formidable Vine pest, knowing, as I do, the labour, thought, and anxiety as to the ultimate result of the treatment necessarily attending such an important and laborious proceeding. My experience of the phylloxera goes to show that it is in scores of vineries in this country unknown to the gardeners in charge of them, and, who, if asked if they had the phylloxera, would at once answer in the negative, as I have done more than once, in blissful ignorance of it being at the time in the vineries under my charge; and I may state that the ninety-two one-year-old Vines planted in the four new vineries here in the spring of 1879 were home-grown. A few days after making the discovery of the phylloxera being in all my new vineries, and in one of the old ones too, I paid a visit to a large neighbouring garden; and so convinced was I by the appearance of the Vines in some of the many vineries there of their being affected with the dreaded disease, that when I returned I communicated with the gardener, who happened to be from home that day. The result was his visit to me in the course of a day or two, and was made acquainted, not only with my fears respecting his Vines being attacked with the phylloxera, but also with the personal appearance of the insect itself in various stages of development. My friend was horrified with what he had seen—viz., thousands of the Vine-louse busy with the work of destruction on small pieces of fleshy Vine roots under a small microscope. The same autumn—a few weeks after his visit to me—he had to destroy the Vines in several of his houses in consequence of phylloxera being discovered on them. I mention these facts merely to show that gardeners who are unfortunate enough to get phylloxera in their vineries should, as soon as they make the discovery, disclose the fact to their employers and neighbouring gardeners, giving both microscopic views of the insects at work on the Vine roots with a view to the latter being able to recognise the disease should the condition of their Vines be such as to render an investigation of the roots for a cause necessary,

and to enable the former the better to understand the nature and magnitude of the work involved in the process of eradicating the most formidable insect enemy that Vine-growers at home and abroad have to contend with.

Notwithstanding my Vines being affected with phylloxera in 1879-80, they made good growth in the new borders and houses, but their habit of flagging in the presence of sunshine, together with the circumstance of yellow blotches appearing on the leaves, puzzled me not a little, until I made the discovery four or five months after planting, August 27th, that they had phylloxera. And here it may be interesting to note that the disease, in the gall as well as in the tubercle form, first showed itself on the only American (Strawberry) variety which we then had on the place, a fact which proves conclusively that the American varieties are not phylloxera-proof. Having tried various experiments and recorded the results with the Vine louse, my experience goes to prove that the only safe method of eradicating the phylloxera is the "stamping-out system"—viz., burning the Vines, removing the soil, and thoroughly disinfecting the house by washing the woodwork with soft soap and warm water, the brickwork several times with hot lime, and placing over the drainage (keeping close to the walls and piers) an inch thick of common garden salt, which will kill any affected or other roots existing among the latter. This operation should be proceeded with as soon as the phylloxera has been detected and permission obtained. Vine eyes having been secured from some good Grape-growing establishment, and heeled-in out of doors until the following January, they should be washed in warm water and then inserted singly in the ordinary way in 3-inch pots. The young Vines will be ready for planting in the newly-made borders in April, they having been transferred to larger pots during the interval, their roots and general condition being keenly and suspiciously observed during the process of potting and transplanting.

Experience also goes to show that if Vine borders could be completely submerged for a couple of weeks together in July, August, or the early part of September, when the phylloxera is in various stages of development—the young ones just hatched, full of activity and life—the extirpation of the pest would be effected. I am led to this conclusion by experiments made with the insects by immersing pieces of roots badly affected with the following results:—The insects which had been immersed for two days in clean water disappeared altogether, whereas those which had been placed in saucers of soot water (except the young ones) though drowned, had not vanished, but were rendered more transparent, from a yellow brown to a transparent and viscid colour, showing their lines and spots more plainly than before they were immersed and viewed through the same microscope. Experiments with Vines in pots also show that whatever liquid may be applied to a Vine border with the object of killing the phylloxera must have instantaneous effect—that is to say, it must be strong enough to kill the insects in passing through the soil without at the same time producing a similar effect on the Vines; and, in my opinion, that which shall succeed in doing the former will also accomplish the latter. Having in August, 1880, obtained that which I was refused the previous year—viz., permission to adopt the "stamping-out system," I immediately set to work as above described, striking and planting my Vines in 1881, and fruiting them the following year, their condition then and now being such as to justify the assumption of our having dissolved partnership, for ever, let us hope, with the phylloxera, which for two years had been to us an extra source of deep thought, labour, and anxiety.—H. W. WARD.

NOTES ON THE CHRYSANTHEMUM.

"A GROWER AND EXHIBITOR'S" seasonable note on the Chrysanthemum reminds me of a promise I made some time ago to note the result of Chrysanthemums cut down the last week in June and first week in July, as recommended by you on page 538, last volume. This was strange news, no doubt, to many who believed it impossible to obtain exhibition blooms from dwarf plants, the general idea being never to check the plants. Those who had the courage to adopt your advice will, if the plants have received attention, be rewarded with sturdy specimens from 3 to 4 feet high. They who have not as yet obtained the flower buds must not blame the system, but attribute their failure to starvation. Far north the buds will be now showing. I was doubtful at the time about cutting down some varieties, fearing that the buds would not form or be very late, but I am perfectly satisfied with the result up to the present time; for plants so treated began to show buds, the earliest varieties the second week in August, the remainder up to the first week in the present month. It is impossible to say yet what the flowers will be, but if stout wood and plump buds afford any criterion to judge by they ought to be fine. The only varieties that did not break well with me this

season are Prince of Wales, Nil Desperandum, and Jardin des Plantes.
—C. WARING.

MONTBRETIAS.

THE genus *Montbretia*, though small, consists of very showy bulbous plants, which are oftener placed in the greenhouse or bulb pit than out of doors; yet most of them are hardy, and with a little care in choosing a sunny situation, with light soil, they will stand our severest winters. The following are a few of the best.

Montbretia Pottsii, Baker.—The subject of the woodcut (fig. 47),

Fig. 47.—*Montbretia Pottsii*.

was introduced by Mr. G. H. Potts of Lasswade, Edinburgh, and is one of the most valuable additions of late years to our hardy Cape bulbs. It possesses the habit of *Irids* with a combination of the small scariose spathe valves of *Ixia*, and the irregular funnel-shaped perianth and parallel unilateral stamens of the *Gladiolus*. It is unusually large for a *Montbretia*, being between 3 and 4 feet high; leaves four, in a rosette at the base of the stem. The flowers, of which there are from twelve to twenty on each of the five or six spikes, being of a very bright reddish crimson, give the plant a very pleasing effect, especially when in clumps. It flowers from August to September, and should find a place in every collection of hardy bulbs.

M. rosea, Baker.—Similar in habit to above, but having bright rose-coloured flowers with longer tube and larger segments. Very desirable.

M. crocosmaeflora (Belg. Hort. t. 14, 1881) is a hybrid between *Tritonia aurea*, which it much resembles, and *M. Pottsii*, raised by

M. Victor Lemoine. It has the habit of a *Gladiolus*, with an erect many-flowered panicle arranged in a zigzag fashion. Flowers large, orange scarlet, funnel-shaped, tube slightly curved, with three deflexed stamens. A plant that should have a place in every garden.

M. securigera, D.C.—Named from a supposed resemblance of the three projecting lamina or thin plates contained in the flower to a hatchet. Introduced more than a century ago by Mr. Masson. The flowers are of a beautiful copper colour borne on a more or less branched stalk; outer valve of spathe three-toothed; leaves smooth. Flowers in May and June.

M. flava, Klatt.—Introduced first by Colonel Paterson in 1780, is closely allied to the above, but differing in having the bracts acuminate, the whole corolla intensely yellow, and broader leaves. The spots from which the three prominences of the corolla arise have been designated "nectarostigmata." This is a very pretty dwarf species, with large flowers and flat lanceolate leaves. Flowers March and April.

M. lineata, Baker.—Larger than any of the preceding. The flowers, which are of a delicate straw colour, are curiously pencilled with dark lines, which make it as much an object of admiration as brilliancy of colour does in the others. It grows about 2 feet high; leaves well marked by a prominent midrib. A very desirable plant.—D.

PROPOSED INTERNATIONAL EXHIBITION OF VEGETABLE PRODUCTS.

AN announcement having been made, and apparently official, that an International Horticultural and Forestry Exhibition would be held at South Kensington next year, letters on the subject have appeared in the press appealing for support in the undertaking. These letters have been followed by other announcements; and when we see two in the same issue of one journal, one asserting that the Exhibition will undoubtedly be held next year, the other that it has been postponed till 1885, it is at the least conceivable that the public mind is becoming somewhat perplexed on the subject. Although we do not pretend to speak with an authority that cannot be questioned relative to what will be done in the matter of an International Horticultural and Forestry Exhibition, we think we may venture to predict that no such Show will be held next year, and that when an Exhibition is held it will be on a much larger scale and be much wider in its scope, far more varied, interesting, and instructive than any mere display of flowers could be, even if supplemented with everything that pertains to horticulture and forestry.

There has been a lingering feeling for some years past throughout the country that there ought to be a repetition of the Great International Horticultural Show which was held at South Kensington in 1866. The success which attended that undertaking was so great that many felt assured that there wanted but the needful effort to secure an equally successful result; but those who were engaged in the former knew too well the risks that were run, and the narrow escape from its being a failure, to run heedlessly into such another adventure. There is no question that the resources of this country are sufficient to produce a grand exhibition, but whether a display of plants and flowers on a scale of great magnitude can be maintained for six months is quite another matter. Past experience on this point is not encouraging. We cannot forget, nor would it be prudent to endeavour to do so, the extreme difficulty that was experienced in inducing exhibitors at the great Show just alluded to, to permit their valuable productions to remain for a few days beyond the prescribed time to avert a crushing financial failure. If there was a nearly insuperable difficulty, as there undoubtedly was, in maintaining a magnificent show for a fortnight, would the difficulty not be increased in supporting an exhibition worthy of the nation over a period of half a year? A protracted horticultural exhibition on a large scale cannot be held without an enormous outlay of money and great risk of loss. The public of this country have been familiar with flower shows of every extent and variety for many years, and to expect that one on a scale however extensive would be an attraction for any length of time would, we fear, be disappointing. If, however, a horticultural exhibition on an extended scale were to be associated with some kindred objects we see no reason why it might not be carried out to a successful issue.

For examples of exhibitions of plants and flowers stretching over a season we must go to the European continent and to America. Has any one such exhibition been maintained in anything approaching the manner that would meet the expectations of horticulturists and the public in this country? Has there been any one of those efforts that in itself would have been even half self-sustaining? From time to time we willingly concede an imposing spectacle has been produced at home and abroad, but it was transient in comparison with the project alluded to. On the occasions referred to horticulture was represented with other arts, not independent of them. It may be said that the Exhibition announced is to be held in conjunction with forestry. Great as the result might be, we are convinced it would fall short of public expectations, and it would not be worthy of the opportunity that is now presented of having, what has never yet been seen, an exhibition of the vegetable products of all the world. The Fisheries Exhibition is great and wonderful in its

diversity, but far greater and even more wonderful and important would be an exhibition of vegetable products, with illustrations as far as practicable of the methods of preparation and manufacture. We cannot conceive of any combination that would make a more interesting, instructive, and a more attractive exhibition. The buildings that are now at South Kensington would be admirably adapted for such a purpose, and if the Committee of the Fisheries were to undertake it with the same energy and intelligence with which they have worked the Fisheries Exhibition, there can be no doubt whatever that it would be a grand success.

What we propose, then, is that there should be an exhibition of horticulture, forestry, and vegetable products. The main body of the exhibition would consist of the two latter. In forestry we should have not only illustrations of the subject as it is practised in this country and the other countries of Europe for the supply of timber for commercial purposes, but that it should embrace representations of all the woods of the natural forests of the United States of America, our own colonies, India, China, Japan, and of the governments of South America; specimens of the timber cut and polished, and transverse sections of the trees. Living trees of the forests of temperate regions might be planted in the open grounds of the garden, the seeds and fruits could be shown in the galleries along with the woods, and the living plants of tropical trees could be shown in a house specially set apart for them. Every manufactured product of these trees might also be illustrated.

Then there are the plants cultivated for their fibre—Hemp, Flax, Cotton, Jute, China Grass. There might be not only illustrations of the plants in all their stages, but also of the industrial element. What more interesting than to see an Indian at his loom weaving Dacca muslins; the various processes for the preparation of cotton from the pod to the spinning jenny; the hemp industry; a rope walk, and the making of twine; straw plaiting, and the employment of straw, esparto, and other fibres in the great paper-making industry; food products, such as cereals, and their methods of preparation from the mill to the oven; pulse, and their products of herbage and forage; plants for supplying beverages, and methods of preparation—tea, coffee, cocoa, wines, hops, beer; starch, and its preparation from Rice, Potatoes, Wheat, &c.; also arrowroot, cornflour, and articles of this nature in use by the million, but of their origin and preparation the million are practically ignorant; plants furnishing the materia medica, with specimens of the drugs, and information relative to the sources from which they are drawn and how obtained; tobacco—the manufacture of cigars in operation; sugar—with examples where practicable of preparation from Cane and Beetroot; preserves and pickles—the various methods of preparing fruits and vegetables could be fully represented, and the magnitude of this industry exemplified; plants cultivated for their uses in the arts—caoutchouc, gutta percha, with the manufacture of water-proofs represented; also plants cultivated for their oils, dyes, perfumes, and tanning, with examples of obtaining and applying their products.

This is a hurried outline sketch of our project, but we believe it is sufficient to show that it will form a strong and sure basis for an exhibition of far-reaching interest and importance. Add to this the appliances in connection with forestry and horticulture, tools, machinery, structures, methods of heating, and every adjunct in connection with woods and gardens, models of roots and fruits, cones, seeds, also zoological museums of beasts, birds, and insects as friends or enemies of the cultivator. Nor would we overlook the curiosities of vegetation. From the museums in this country, and with examples from foreign lands, we feel sure that a collection of objects of a very extraordinary nature could be arranged that would be a source of great attraction to visitors.

With the same agency that has worked so effectively in producing the present Exhibition at South Kensington, at least equally great results might be achieved in carrying out this project. Through the Colonial and Foreign Offices every country would be reached, and every country would be ready to represent its staple industry obtained from vegetable products, while each having its court and native workers, would powerfully attract attention to its own industry, the vast area of buildings would be filled without difficulty, and an exhibition of extraordinary interest and irresistible attractiveness would be produced.

Nor would all this in the slightest degree detract from the extent or beauty of the exhibition or exhibitions of plants and flowers already proposed. We can see no obstacle whatever to holding, say, monthly exhibitions throughout the year, and one of them, say in May, to be as rich and on as large a scale as that of 1866, provided sufficient inducements are provided to bring the best examples of culture together at a given time. Besides and between these shows nurserymen might presumably occupy space with Clematises, Pelargoniums, Rhododendrons, Roses, fruit, &c., and thus in some measure a continuous display would be produced to brighten, what if well carried out, would be the most complete exemplification of the resources and importance of the vegetable kingdom ever seen in any country.

As at the present Exhibition, where cheap fish dinners are provided for the masses, so in the one contemplated the Vegetarian Society would no doubt be glad to provide at the least equally cheap dinners, nutritious and toothsome, composed wholly of vegetable food; and it will be conceded that instruction on the best methods of preparing vegetables and fruit for culinary purposes is as much needed as the popularisation of fish as an article of diet. This aspect of the case demands, and will no doubt receive, particular consideration.

It will be manifest, however, to most who fully consider the matter, that such an exhibition as the one indicated could not possibly be carried out next year. Even a purely horticultural and forestry

exhibition, especially the latter, could not be satisfactorily arranged so soon; and we have reason to believe that the more comprehensive and immeasurably more important project having been favourably entertained by the official authorities of the "Fisheries," has led to the announcement that a great Exhibition will be held in 1885, this having been decided at a preliminary meeting of the authorities held at South Kensington on the 12th inst. There is good hope that the greater Exhibition contemplated will be held, and we have only to add that the sooner a decision is arrived at, and the necessary machinery is put in motion, the better. The undertaking will be a gigantic one, but the same energy that has been displayed in preparing for and providing the great Exhibition of the present year will be fully equal to the task of providing another exhibition, essentially different, equally great, and certainly of not less public importance in 1885.

[Since the above was in type we have received a letter written by Mr. E. Cunliffe Owen, by request of Mr. Birkbeck, to Mr. Wills, requesting him "to use his influence to notify that an International Horticultural and Forestry Exhibition will be held in the spring, summer, and autumn of 1885," and desiring that the trade should be informed of the fact as early as possible.]

NARCISSI.

THE pleasure derivable from these plants is very great, and it will be increased as fresh additions are made to those already known, mainly, perhaps, through the selection of seedlings and cross-breeding. Perhaps there will not be a much larger accession of species or natural varieties made to the already large series under cultivation. The large number of varietal forms now within reach of all fanciers materially assist to render a collection of Narcissi even more attractive. Undoubtedly there is a sameness about many of the incomparable section under various names, the authors of which would most likely experience some difficulty in defining the points of difference between some of them. Under my care is a collection of these bulbs, numbering about 220 forms, and after closely comparing several alluded to last season these were reasonably reduced, or some discarded as named kinds, and planted in the borders as mixtures because they are all beautiful. We may not expect much additional merit from the Peerless section of Narcissi, but without doubt many fresh and improved forms will be obtained from the Trumpet section, and in my opinion these are the most desirable, being more effective as garden ornaments and more graceful. My desire is to get all the Trumpet forms available and make the most of them.

But my object in making these remarks is not to discuss their merits, for they are already determined, but to draw attention to the fact that it is time the bulbs were planted for next spring's display. Nothing is more prejudicial to good flowering than late planting; therefore those who intend growing them should without any delay make their selection and plant, or, if the bulbs require raising and dividing, this should also be effected, as they are now, or will be speedily, in full root-action again, which it is, of course, unreasonable to disturb. I never allow bulbs to remain in the same position more than three or four years. Thus some were raised last season which had been planted four years, and another batch has been lifted this season. A large number of small bulbs we found by that period, which form a dense mass, and as a result smaller flowers are produced than is the case when the bulbs have ample space for development. Well, now, as the arrangement to be followed wherever practicable, it is best to have all the kinds planted in one bed or border, so as to have the entire collection together—an advantage which will be appreciated, as it not only affords facilities for comparing the varieties, but the effect is much better. This plan is objected to by many for the reason that there is a bare bed during the greater part of the summer months; but this need not be, for it can be furnished with a host of annuals or bedders—*e.g.*, one of my beds is now well covered with Mignonette, which is invaluable for cutting as well as affording rich perfume. Numerous annuals may be planted between the lines of Daffodils without injuring them in the least, and thus a longer succession of flower may be had than if no bulbs were planted. Many growers arrange them in clumps in the mixed border—a plan, too, which has its advantages, especially if the collection is limited, as the flowers are extremely beautiful interspersed with a multitude of other spring flowers. Wherever this plan is adopted each patch should be labelled or marked in some way, or the chances are they will be very much disturbed, if not destroyed, by someone, who could not even be blamed for doing so; besides, in all successful garden operations there must be a thorough system of working.

There are two points of culture, the observance of which I find materially beneficial—*viz.*, deep digging, and a copious supply of good manure. The bulbs send roots straight down into the soil, so to be of special good the manure should be buried deeply in the first planting; and every year after the first planting it is advisable to give them a mulching of manure in early autumn, which is best effected by removing the soil nearly to the bulbs, put the manure in

the opening, and cover again with the soil; the maximum of advantage is thus secured. This method of planting is easily accomplished if all the varieties are arranged in one bed or border, but in the mixed border it is different. It will be necessary to dig holes a foot or more deep, arrange the manure in the bottom, placing some soil over it, upon which plant the bulbs—say about 4 inches below the surface. A few species are benefited if some sand is placed about the bulbs, especially if the latter are inclined to decay at the base; this effects drainage, and is helpful in other ways, but the majority do not require such attention. It is remarkable the length of time some kinds will lay dormant after being imported; especially is this the case with the North African species—*e.g.*, bulbs of the rare *N. Broussonettii* were spotted three years before they showed signs of foliar development, and during the spring and early this year it produced leaves 30 inches long, and I hope to see flowers of it next year; and the little bulbs of *N. monophyllus* remain dormant for a year or two, or even longer sometimes after being imported. This little gem does well in a few places outside, but in most it requires the protection of a frame or handlight.

Below is a list of species and varieties all worthy the space in however select a garden they may be planted, and to which many might be added, but these will serve as a good nucleus to a more extended collection:—

SECTION 1.—THE TRUMPET DAFFODILS.

N. bicolor.—The typical form is later in flowering than most of the varieties here enumerated—very desirable on that account. I noticed they flowered with me in the following order:—Horsfieldi, Empress, Albidus, Sulphurescens, Major, and the type. Such a series lasting a considerable time; indeed, they formed the most attractive group during the season. Horsfieldi is dwarf and very free, with white perianth and deep golden yellow trumpet. Empress is very similar in flower, but there are points of distinction, but is a more vigorous grower, and one of the finest of all Daffodils. Albidus and Sulphurescens are two very desirable kinds, the trumpets yellow and the perianths sulphur, very large bold flowers. Major is in the same way, but with very fine stout flowers, extremely vigorous, and late flowering. I have also J. B. M. Camm, and one named in honour of Mrs. Camm, but as my bulbs were small they only produced moderate flowers this year, but they are very promising varieties, and will most likely hold their own.

The *Silver Daffodils* (*N. cernuus* and *moschatus*) are both very charming kinds, the perianths and trumpets of a pale straw colour, very silvery in *cernuus*, and they are sweetly scented, especially *moschatus*. *Cernuus pulcher* is a very handsome form, with a larger trumpet than the type, while the double variety is charming but unfortunately very rare. I know of one place where a good bed of it has existed for years undisturbed.

N. lorifolius is a free and showy species; perianth sulphur, trumpet yellow; but a variety of it under the name of Emperor is vastly superior as a decorative kind. The flowers are larger and with more substance in them—a fitting companion for Empress.

N. pseudo-Narcissus (the common Lent Lily) is by no means a despicable plant—on the other hand, very desirable. The variety *pallidus* is extremely pretty, the perianth and trumpet pale sulphur, flowering early. *Plenus* is extremely pretty and scarce, the segments bright yellow and sulphur, evenly arranged and sweetly scented. I prefer this to any other double Daffodil under cultivation.

N. minor.—The true variety is very distinct from *nanus*; it is deep yellow, whereas *nanus* is much paler, and the trumpet is longer and more deeply frilled round the margin. *N. minimus* is a minute fac-simile of *minor*, the flowers little more than half an inch across and not much longer. It is very rare.

N. princeps.—A very noble Daffodil; the perianth pale sulphur, trumpet deep yellow, very long and heavily frilled, rather late in flowering, and certainly one of the finest though not much known—more is the pity, as it can be purchased at a low price.

N. maximus.—Undoubtedly the finest yellow Trumpet. What a sea of gold is a large bed of it! The perianth and trumpet are intense golden yellow, the latter dilated and deeply frilled at the mouth. Indispensable in every collection. Major, a less double kind, is frequently palmed off for it, but it is not nearly so good.

The *Tenby Daffodil* (*N. obvallaris*).—A deep yellow, almost a self; one of the best. A form of it named *maximus* is also good.

N. lobularis.—A grand Daffodil, dwarfish, with a sulphur perianth and yellow trumpet. A duplex variety of this named *grandiplenus* produces dwarf very double flowers, very showy, and is frequently sent out under the name *nanus plenus*, but a double form of *nanus* does not exist, as far as I know.

SECTION 2.—N. POETICUS.

The *Poet's Narcissus* (*N. poeticus*).—Well known and admired, with large, flat, pure white perianth and small orange-coloured

corona; highly esteemed for its purity of colour and perfume. There are several varieties of *poeticus*, which are so far distinct that they flower at different periods, without considering the slight floral differentiations, thus forming a beautiful successional series—flowering, if my notes do not misguide me, in the following order:—*angustifolius*, flowers rather smaller than those of the type; perianth flat, segments narrower, light red cup. *Ornatus*, flowers larger than the last; cup lemon edge with orange-red; very fine. *Flore-plenus*, flowers large, very double, and—Gardenia-like—sweetly scented; one of the most valuable for cutting. *Grandiflorus*, flowers larger than all, flat, pure white with crimson cup; a very fine form. *Recurvus*, perianth white with the divisions recurved, with a pale orange-red cup.

N. gracilis.—A slender-growing charming species with umbels of flowers; perianth about 1½ inch across, yellow; the cup small, rather lighter in colour; flowering with the Poet's Narciss. *N. biflorus*, the common Twin-flowering Narciss, very free-growing and hardy, increasing rapidly, forming dense clusters of umbels; the flowers white and yellow. This is a native species, and can be purchased very cheaply.

N. Burbidgei.—This is but a sub-species, originated among Mr. Barr's great collection, and I class it with this series. What may be regarded as the type of this group produces flowers with flat white perianth and cinnabar-red cups, the latter small but rather larger than those of *poeticus*. From the numerous forms of *Burbidgei* I select the following as being the best:—*Delicatus*, large flowers; perianth light sulphur, cup yellow, very clear; a very charming variety. *Grandiflorus*, perianth white, cup deep red edged with orange; flowers large and very showy. *Marginatus*, perianth white, cup lemon margined with deep orange. This is extremely pretty, and, in my opinion, the best of the series. *Primulinus*, perianth light primrose, cup deep cinnabar red; a very attractive variety. But I must not occupy more space in describing other varieties, but it is really difficult to stop where all are good, and we must not forget that the sub-species is named in honour of Mr. F. W. Burbidge, the "Daffodil's artist."

SECTION 3.—MEDIUM-CROWNED, INCLUDING THE PEERLESS, MONARCH, AND MOCK NARCISSUS.

The *Peerless Narcissus* (*N. incomparabile*) produces umbels of yellow and sulphur-coloured flowers, with large flat perianths. There are now, however, such a multitude of varieties that it is difficult to select the best without taking into consideration all the sub-species which have been made, and these appear ever to be on the increase. But how slight are the variations upon which they are based! Thus we have *Barri*, *Leedsi*, *Nelsoni*, and *Vincenti*, and around these are arranged a series of varieties, but I am at a loss to discover the points of difference between the types, saying nothing of the distinctions between many of the forms. Of the *incomparabilis* section proper I may mention the following:—*Albidus*, perianth pale sulphur, very large and regular, cup clear yellow; *aurantius*, perianth sulphur, cup deep orange red, very showy; *albus*, perianth white, cup deep yellow; *albus aureo-tinctus*, perianth white, cup lemon-coloured, margined and tinged with orange; *Crawfordi*, perianth white, cup large, clear yellow; *magnificus*, perianth pale sulphur-white, cup very large, deep yellow, very showy; *plenus aurantius* (Orange Phoenix, "Butter and Eggs"), large double flowers, primrose and deep orange; *pl. sulphureus* (Sulphur Kroon, "Codlings and Cream"), very large double flowers, white and primrose, very showy; *sulphureus*, perianth sulphur, cup large, deep yellow.

N. Barri, perianth pale primrose, cup clear yellow, very pretty; *albidus*, perianth nearly pure white, flat, large, cup deep lemon; *aurantium grandiflorus*, perianth very large, pure white, cup deep orange crimson; this I considered the showiest of all this section. *Stellatus albus*, perianth white, the divisions slightly stellate, cup sulphur; *sulphureus*, perianth pale sulphur, cup deep yellow; this is, perhaps the second best of the series.

N. Leedsi, perianth white, very ample, cup of nearly the same colour or very pale lemon; *amabilis*, perianth pale yellow, cup lemon, very delicate and beautiful; *Gem*, perianth large, pure white, cup lemon; this is one of the best of this group. *Superbus*, perianth silvery white, very even, cup very pale straw colour or quite white; truly a superb variety.

THE JONQUILS.—*N. odoratus*.—These belong to this section, and are almost indispensable for the borders or pot culture. The common single and Campenelle varieties are much esteemed for the deep yellow sweetly scented flowers; minor produces very small rich-coloured flowers. The Silver Jonquil is *N. tenuior*, and a charming little kind it is with its small silvery white flowers. The double form of this is called "Queen Anne's Double Jonquil." The flowers are very double, creamy white, sweetly scented. All these are very easily grown, and none are expensive, so there is no reason why they should not be much more abundant in our gardens than they now are.

N. triandrus.—A very charming species; the perianth primrose, with the segments sharply reflexed like a Cyclamen; cup small, rather paler in colour. A variety of it exists under the name of *albus*, the perianth of which is creamy white. Both are peculiarly handsome and very distinct, requiring a cool damp situation in which to flourish.

N. juncifolius.—A pretty dwarf-growing species with narrow Rush-like foliage and umbels of small Jonquil-like flowers of a deep-yellow colour, quite hardy, and a little gem in its way.—DAFFODIL.

POTATOES.

I HAVE often wondered if other people's experiences in the matter of Potato-growing were anything like mine. I think mine must be peculiar, though they come to me every year as regularly as lifting time comes—nay, indeed I begin to taste some of the bitterness of them by mid-summer, and I go on tasting, the bitterness getting more bitter, even to nausea, until by the time the Potatoes are ready for lifting I am disgusted. These experiences nearly always result in the following conclusions and resolutions—never to grow a long-topped Potato in the garden again, and never to grow an American variety in the garden, let it be ever so much praised, and never to indulge in more than one novelty in a season. If I could only keep that last resolution I should do, but I am afflicted with the Potato fever every spring time, and of course I get all the catalogues of Potato people, and I swallow every word they say about their new and "improved" varieties, and I order some of them, and devote some of the best ground of my garden to them, with the annual result that I have grown a crop of no use except for the pigs; the ground that they occupied is therefore wasted, because the Potatoes grown there are worthless to me for eating purposes, while the after, or winter crop, that must occupy all my Potato land, has been murdered by the sprawling tops of these new and improved varieties of Potatoes. But why cannot I learn sense and have done with novelties for ever? I do seriously wish that I could form and keep such a resolution firmly.

Let us start a company of gardeners (this is the age of companies, you know), shares nothing, expenses ditto, but profits tremendous, the principle of which shall be that no member of this company shall try more than one novelty (in anything connected with gardening) in one season; the penalty for non-observance of the principle of the company being that the member so offending shall the next season try and prove, and report upon all and every novelty in seed or plant or root that is sent out. But seriously, it is very unwise for a gardener to use his land in growing something new, and which may prove worthless, and neglect to grow those things which he knows will probably yield him solid and satisfying produce. I am afraid, however, that many do it, and often get themselves into difficulties by so doing. It is much wiser to grow those sorts of Potatoes, and those only, that experience has taught each gardener do the best on his land and suit his after crops. You will see that I am trying to build myself up in a good resolution. I trust I may succeed. I wish some other gardener would say that he has done the same as I have done, but that he does not intend to do so any more. It would be a great comfort to me; and, by the way, we two would form the nucleus of the company that I have hinted at.—H.

GAILLARDIA PICTA VAR. LORENZIANA.

FROM the reports of this I expected great things, and am somewhat disappointed. Some few plants which were raised late last winter were kept through and propagated by cuttings, which is an easy matter, and these we have grown on as pot plants. Certainly so grown and secured to stakes they are neat and floriferous, but it was as a border plant I expected it to excel. This it has not done, and is not nearly so showy as the old *G. picta*. Neither in pots nor in the borders does it open properly, not one in 200 plants being properly double and worth saving. It varies a little, and with us comes under three varietal divisions—namely, red florets with yellow tips, purple florets with yellow tips, and pure yellow, which latter I think the most valuable. Whether attention in selecting seedlings will ever give us a fully double flower or not is a matter for the future to prove; but if ever success be attained one great drawback seems inevitable, and that is the tendency, during the long process of development, for the outer florets to wither and fall before the inner ones have nearly become developed. The new variety, to my thinking, is not nearly so valuable in any way, for cutting or otherwise, and does not come nearly equal to the old one for brightness.—M. B.

CALIFORNIA LILIES.—Dr. Kellogg, of San Francisco, who has given much attention to raising the California Lilies, finds *L. Washingtonianum* to be the most difficult to raise successfully. "The last time I was out," he writes in the *Pacific Rural Press*, "I took a thermometer to find the temperature where it thrived best in a wild state, also to consult the conditions under which it grew. There is one fact connected with the subject that if followed up might throw great light upon the culture of California bulbs. It is one which I have intended to investigate myself, and the only reason I have not is the distance and mountain-climbing necessary to accomplish it. It was a case of the Washington Lily growing in the basin of a rock. The remarkable feature of this was, the bulb was as large as the top of one's head, and lying upon the ground

were stalks 12 feet in length, carrying from fifty to one hundred flowers. Now, if anyone could investigate the condition under which this growth was made, it seems to me that it would throw great light on the subject. This Lily, nor a great many other bulbs in California, will not grow in sand. I have seen a great variety of bulbs grow in these rocks where, in rainy seasons, they get a great deal of moisture. *Lilium Humboldtii* will grow in California. These seem to require the morning sun. Down below Santa Barbara one may go up a ravine, and if the ravine runs east and west, the Lily will always be on the northern slope, and perhaps on the other side not one will be found. Where the sun strikes when past the meridian you will not find a solitary one growing—that is, where there is no timber; but if the ravine is shaded, trees growing over it, protecting it from the afternoon sun, it will grow on one side as well as on the other. As regards soil, a strong loam for *L. Humboldtii* would be better than leaf mould."

IT has been already announced that an INTERNATIONAL FORESTRY EXHIBITION is to be held in Edinburgh next year, and we learn that the Queen had accorded her consent and patronage to the project.

— THE Brighton Corporation has recently purchased PRESTON PARK for £55,000, and it was opened last week, but a formal presentation to the public will not take place until the grounds have been laid out.

— MR. T. S. WARE, Hale Farm Nurseries, Tottenham, has now a very extensive display of SINGLE DAHLIAS, comprising a great number of varieties, representing many fine shades of colour from pure white, through yellow, orange-scarlet, crimson, maroon, rose, and blush.

— THE Reading Horticultural Society announce their intention to hold an EXHIBITION OF CHRYSANTHEMUMS on November 22nd of the present year.

— GARDENING APPOINTMENT.—MR. W. POPE has been engaged by the Earl of Carnarvon as gardener at Highclere Castle, Newbury, Berks, and enters upon his duties in October.

— A VERY handsome PRESENTATION TO MR. WILLIAM TAYLOR has been made by the Marchioness of Bath. It consists of a valuable and very beautiful drawing-room clock. A letter from her ladyship to her late gardener has enhanced the value of the gift. It is one of those frank, friendly, and appreciative communications which the truly great can afford to write to those who have served them faithfully and well. This letter and the present alluded to are deservedly prized by Mr. Taylor and his family, who are now residing near Bath.

— WE are requested to state that Mr. T. H. Hill, gardener to Mr. A. W. Ruggles Brise, of Durwards Hall, has lifted a root of the "Mr. Bresee Potato," grown with native guano, containing thirty-seven potatoes. The six largest weighed 2 lbs. 1 oz.; 1 lb. 2 oz.; 13 oz.; 12½ oz.; 9 oz.; 8 oz. The whole root weighed 13 lbs. 3 oz. This prolific crop has been sent by the grower to be exhibited at the Native Guano Company's stand at the Fisheries Exhibition.

— MR. J. F. MOULD, nurseryman, Pewsey, draws our attention to two mistakes in our report of Bath Flower Show on page 226. The third prize for nine stove and greenhouse plants in bloom was awarded to him and not to Miss E. Browne; the second prize for six Heaths was also awarded to him, not to Mrs. General Studd. Mr. Mould was also awarded the third prize for sixteen foliage plants. This was not the fault of our reporter, but of the system of attaching the prize cards.

— IN the centre of the transept at the Crystal Palace an improvement of considerable importance has been recently effected—namely, the construction of a circular FERN DELL AND FOUNTAIN, which affords a most pleasing break in the hitherto unoccupied space between the organ and the theatre. The sides are covered with ornamental cork and planted with Ferns, at the base being some rougher pieces of rock; and from these the jets arise—one in the centre, which ejects the water to a considerable height, and five or six smaller ones around it. On the upper margin is a narrow border planted with Ferns and Sela-

ginellas, graceful Palms in pots being employed to add to the effect. It is perhaps doubtful if the Ferns around the sides will endure the constant and rather heavy fall of water from the jets, but in any case the fountain must be considered a decidedly attractive feature.

— "D." sends the following note respecting PRIMULA FLORIBUNDA—"This little-known plant is a native of the Himalayas, and is found as low as 2500 feet. It belongs to the small section with the leaves folded down the middle on the upper face. Leaves spreading, ovate, or obovate crenated, about a foot high, thickly studded with golden-yellow flowers having a long tube. It requires rather a sheltered place on the rockery, otherwise it will prove rather troublesome to get established. It flowers all through the summer. A figure is given in the 'Botanical Magazine,' t. 6712."

— THE plants in the PALM HOUSE AT KEW are being very carefully rearranged, and, judging by what has been already effected, a most valuable improvement in the appearance of the house will result from the alterations. There are numbers of grand specimen Palms and other plants, the beauty of which has been hitherto in a great measure concealed, but efforts are now being made to place these in more conspicuous positions, and in several cases this has been most satisfactorily accomplished. The rods for climbers from the path to the roof have been removed, as it was found they interfered too much with the view of the central beds, while the climbers on the roof itself have been also thinned with advantage to the plants on the shelves. This magnificent house well merits the attention it is receiving at the hands of the officials.

— IN the succulent house of the above establishment the Stapelias are now in excellent condition, a very large and complete collection having been formed. Several are flowering, but the most striking of all is STAPELIA DE SMETIANA, which has flowers 6 inches in diameter, of a peculiar purplish hue, and thickly covered with hairs. The pretty and well-known striped *S. bufonia* is also flowering, and with others similarly foetid proves very alluring to numbers of insects.

— "G. N." writes—"It is a matter of surprise to me that contributions of novelties or rarities at the Royal Gardens, Kew, are not occasionally sent to the meetings of the Royal Horticultural Society at Kensington, as small collections of very great interest both to horticulturists and botanists might frequently be exhibited with very little trouble or expense. The Kew collections shown at the Linnean Society's rooms on various occasions prove what a store of valuable, beautiful, and curious plants they have to draw from."

— THE acquisition of the extensive grounds of the ALEXANDRA PALACE by the London Corporation as a public park is at present under consideration, and is said to be favourably regarded—Lord Shaftesbury and other influential persons having urged the expediency of the purchase in the interest of the public at large, and especially in that of the great suburban district of the north of London, now being covered with houses at so rapid a rate. Some demur has arisen in regard to the Palace itself, for which it was apprehended no remunerative use could be found, as it has failed as a place of amusement in successive hands. Mr. Bourne, C.E., the Principal of the new College of Practical Engineering at Muswell Hill, suggests that a portion of the Palace building should be converted into a great sanatorium, the residue being devoted to popular amusement and instruction as heretofore; and he considers that by the introduction of this new feature the total receipts will be so much increased that the scale will be turned in the right direction.

— A CORRESPONDENT writes as follows concerning ROBBERIES AT FLORAL EXHIBITIONS:—"We read of such robberies as occurred at the Sandy Flower Show with much displeasure; but from an occurrence that was brought under my notice at the Show lately held in Edinburgh it seems as if the operators have gone northwards. A gentleman being suspicious of the movements of a gaudily dressed pair resolved to watch them. Passing to the table where Mr. Ware's single Dahlias had attracted a crush of ladies, he was not long in having his suspicions confirmed by seeing an attempt made on a lady's purse. At once the police were informed, but the pair had beat a retreat. This is merely mentioned so that members of committees may be on their guard and ready to act as amateur detectives if need be, for if once flower shows become 'happy hunting grounds' for thieves much damage will result to the societies."

— THE fourth annual CRYPTOGAMIC MEETING OF THE ESSEX FIELD CLUB will be held in Epping Forest on Saturday, September 29th.

A large number of botanists have promised to attend and act as referees. In the evening a meeting will be held in the assembly rooms at the "Roebuck" Inn, Buckhurst Hill, for the exhibition of botanical specimens, when also the following papers will be read:—"Recent Additions to the Fungus Flora of Epping Forest," by Dr. M. C. Cooke, M.A., F.L.S.; "The 'Lower Orders' of Fungi," by Mr. Worthington G. Smith, F.L.S.; "Fungi as Poisons," by Dr. Wharton, M.A., F.L.S. Botanists wishing to attend or willing to aid in the exhibition of specimens, &c., should communicate with the Hon. Secretary, Mr. W. Cole, Buckhurst Hill, Essex. The members of the party are requested to assemble at half-past three o'clock by High Beach Church. Good maps of the forest may be had at the railway stations, price 2d. and 6d. Tea will be taken at the "Roebuck" Inn about six o'clock. Tickets may be obtained of Mr. B. G. Cole, Laurel Cottage, Buckhurst Hill, up to Thursday, Sept. 27th, price 3s. (for "high tea" and incidental expenses). Early notification of intention to be present at the meeting is urgently requested in order that proper arrangements may be made. Members are informed that the ordinary meeting announced on the card for September 22nd will not be held, the above meeting taking its place.

— "A NORTHERNER" writes respecting the CROPS AND WEATHER IN SCOTLAND:—"Better autumn weather could not be experienced in Scotland than we are now enjoying. There is seldom a cloud seen in the sky, and light breezes dry the corn and fan the reapers, for in addition to being dry the weather is hot for September. In one week more it will be only in late places where a sheaf will remain in the fields. It is quite true that lately there have been rains; otherwise, what a moaning there would have been about the pasture and Turnips! The crops are really very good—where they had a chance. Where they are not, other than meteorological causes have been at fault. The land is full of Potatoes—larger crops of better produce than has been seen for years. Of course they will be cheap. Farmers may—will grumble at this, but the community will have reason to rejoice. Apples are exceedingly plentiful, and those who live near orchards have no difficulty in filling their shelves and jars at 1d. per pound. Already Americans are in the market, and are, perhaps, the best for eating; but for thrifty housewives there is nothing the matter with the less handsome but very much cheaper home-grown fruit."

— THE *Journal des Roses* for September gives a coloured plate of the old ROSE COMTESSE DE BARBANTANNE, which is of globular form, and a delicate blush white in colour. It is one of the Bourbon type, and was raised by M. Guillot at Lyons, and sent out in 1858. It is not, however, very well known in England.

— DR. R. SCHOMBURGK'S report of the progress and condition of the BOTANIC GARDEN AND GOVERNMENT PLANTATIONS IN SOUTH AUSTRALIA during the year 1882 is just to hand. It contains particulars concerning plants and crops that have succeeded or failed in the colony, a general review of the year's work and improvements in the Adelaide Botanic Garden, with lists of the plants added to the collection, all the Orchideæ and Aroidæ in the gardens, of which the collections are large, some interesting facts about plants introduced into Australia, and several photographic views of the gardens.

— REFERRING to the FRUITS GROWN IN SOUTH AUSTRALIA, the above report has the following:—"Of intertropical fruits only a few kinds prosper with us—viz., the Loquat (*Eriobotrya japonica*, Lindl.), Guavas (*Psidium pyrifera*, Linn., and *pomiferum*), and Bananas partially. Even the Pine Apple must be grown under glass. Most of the fruits from other parts of the globe thrive luxuriantly in South Australia, and come to such perfection in size, and frequently in flavour, as is hardly known in other countries, and many fruits are found to improve materially by the change, the climatic conditions being manifestly favourable to them. On the plains grow Apples, Pears, Apricots, Peaches, Nectarines, Medlars, Oranges, Citrons, Lemons, Plums, Cherries, Figs, Quinces, Mulberries, Almonds, Olives, and Grapes; while in the hills and gullies are also grown Strawberries, Gooseberries, Currants, Raspberries, Walnuts, Chestnuts, and Filberts to great perfection. The Apples grow to a great size, but do not always possess the same fine flavour as at home, and contain more acidity. The Apple trees suffer much from the attack of the American blight, for which no radical remedy is at present known. The trees which grow in the hills or in very rich soil suffer most, and at last succumb to this scourge. The Pears grow to perfection and maintain the same flavour as in the old country. The fruits of the Peaches, Apricots, and Plums reach to a large size, and possess a good

flavour. The Cherries do not attain the perfection and flavour of those at home. All the stone-fruit-producing trees are short-lived, especially those of the Peach, Plum, and Apricot, which scarcely live fourteen to sixteen years. This early decline may be owing to the quick luxuriant growth and early excessive bearing of fruit, circumstances which produce over-stimulation and early exhaustion. The finest Grapes are grown in the plains and the slopes of the Mount Lofty range facing the plains. Here they grow to a great size, and the summer months ripen them to the greatest perfection. The wine produced often contains 25 to 30 per cent. alcohol. No doubt the South Australian wine must obtain a character in foreign markets. For the last nine years the oïdium has made its appearance in our vineyards, but not with such damaging results as in Europe. Also the phylloxera has appeared in the vineyards of our neighbour colony, Victoria, to an alarming way, and a good many vineyards have already been destroyed. From this it will be seen that the Australian vignerons, like the European, have to contend against the two greatest scourges which can invade a Vine-growing country. The cultivation of the Olive is a great success, and the oil is considered perfect."

A PEEP AT APPLES AND FIGS IN SUSSEX.

I OPENED my Journal of August 30th on the sunny shore of Worthing. Happily this season we have had some sun, and also, happily, we have many Apples. My attention was immediately directed to the first article, not only because of its subject, but also because of the well-known letters and name at the end—"L. A. K., Maidstone." Mr. Killick always speaks with authority about Apples, and I watch varieties and results with much interest. At the same time there happened to take place at Worthing a good, though only one-tent show, where fruits were in a prominent position; then, of course, I took constant peeps into the fruit shops, made inquiries, and made excursions, as seaside visitors usually do.

Everywhere there are plenty of Apples. I have seen in different parts of England the same sight—heavy crops of fruit, often so bearing down the trees that props were necessary. At the Worthing Show I was surprised to see almost all the Apples were of the green-coloured varieties, not a single Emperor Alexander or Yorkshire Beauty or Worcester Pearmain; plenty of Keswick Codlins, more of Lord Suffields, some Ecklinville Seedlings rightly named and some wrongly named, and a large unpleasing-shaped Apple, very popular in Sussex, called Nelson's Glory, which does not appear in the "Fruit Manual," though it is in Messrs. R. Smith's catalogue. One dish of Red Astrachan indeed showed their red cheeks, but they had been some time gathered, and had none of the beautiful bloom on them peculiar to that variety. "Why do you not show better-coloured fruit?" said I to an exhibitor; "why not Alexanders?" "Because we cannot grow them," was the reply. I saw two fruit gardens near Brighton, both excellent, and one of them most excellent, belonging to a gentleman on whom I cannot say fourscore years have laid their burden, because though of that age he was as upright as a youth of twenty and almost as active. In his fruit garden I saw Cox's Pomona, Lord Suffield, Beauty of Kent, Cellini, and others of a larger size and richer colour than I can grow them in Wiltshire.

Next as to my own personal experience. My especial pet this year is Yorkshire Beauty, which I regard as a "great find" for pomologists. It is healthy as a tree, productive, and the fruit in size, colouring, and flavour is excellent. Of another comparatively new variety no words can be too favourable. I allude to Ecklinville Seedling. It is healthy, vigorous, excellent as a cropper of magnificently sized Apples, and of good flavour. Mr. Killick speaks of Red Joaneting, or, as I prefer to call it, Margaret; although, casting off the White Joaneting, I intend to hold by Margaret. Colour, flavour, shape, earliness, and size are in its favour. Worcester Pearmain has very much in its favour, but its flavour is scarcely equal to its other qualities, though better than Quarrenden, which, like nuts, always seems to me to require something to drink after it.

Why, I would ask, has the Summer Pearmain disappeared from catalogues? It is as handsome as any Apple grown, and its flavour better than most of our present favourites, Irish Peach, of course, always excepted, which is at the head of all summer dessert Apples. In reply to Mr. Killick I will add that with me it is the healthiest of trees, never cankering, though Margaret close by does canker slightly. Duchess of Oldenburg is a charming fruit to the eye and of fair flavour. Stirling Castle, "a very gem of Apples," to quote the "Herefordshire Pomona," is beyond praise. Loddington is another first-rate fruit, and I find it a better bearer than Gravenstein, which crops with me by no means heavily any year.

Perhaps a few words on the cooking of Apples may not be out of place. The best are often utterly spoiled in two ways by the cook—first, by being cooked, especially boiled, too fast; second, by that foolish plan of putting, even by grand cooks in grand houses, any number of Cloves into the pudding or tart, or large pieces of Lemon; the result is Clove tart and Lemon tart, not Apple tart. No flavouring should be put in either pudding or tart until the new year begins, and then a very little only. If you are cooking Dumelow's Seedling not at all, even in April, as it is as fresh in flavour as other Apples when taken from the tree. Cook slowly, and the pudding will be, if the Apples are good ones, like cream. As to flavouring, the less the better. Six Cloves may be allowed, but I once picked twenty-five out of my piece of tart. Each good Apple has a distinct flavour and aroma. Oh, ruthless cook! destroy them not.

At Worthing an Apple named Beauty of Hants was shown, but it was an Ecklinville Seedling, as Beauty of Hants is in shape conical and highly coloured, and was a seedling from Blenheim Pippin. May I beg makers of catalogues to enter New Hawthornden as Winter Hawthornden without an alias? as Winter best describes it, and keeps it clear from the other fruit of that name, which should be called Summer Hawthornden.

A FIG GARDEN.

While at Worthing I was driven to see the famous Fig garden at West Tarring, about a mile and a half inland. Its size is about an acre. You enter, and a dense mass of Fig trees, all standards, are above you; Fig aroma and Fig foliage envelope you, the sweet scent is in the air, the dark green is before your eyes. There is a central path and side paths, all narrow, and so the garden is dim with branches of trees, for the trees all touch each other and join over your head. To one who had never seen a Fig garden it was not only new but strange. Truth is not told, I fear, in that garden, for I came upon a board leaning against a tree, which stated that this is the oldest Fig tree in England, being 800 years old, and was planted by Thomas à Becket! No doubt it was an old tree, probably more than 100 years old, but not 800. One peculiarity in regard to this garden, the continental little bird, the beccafigo, or Fig-eater, visits this garden, and one other at Sompting not far off. How does the little fellow know that he shall find out that he will be repaid for a fly across the Channel by finding a Fig garden at Tarring? Verily instinct is wonderful. However it may be, he does know, and does come, but to no other places save the two named.—WILTSHIRE RECTOR

P.S.—Since writing the above "L. A. K.'s" second article, "Main Crop Apples," has come to hand. Singular to say, I had before me specimens of Red Hawthornden and Yorkshire Beauty for comparison before I read it. I have narrowly examined them, and believe that though much alike—indeed, I may say, wonderfully alike, yet they are not identical. The reasons I give are these—in Yorkshire Beauty there is a vermilion tint lacking in the other; also, though the eyes are not quite alike, nor are the stalks inserted in cavities of exactly the same shape, neither is the yellow colour of exactly the same shade. Both are excellent Apples, but I prefer Yorkshire Beauty.

CATTLEYA MARGINATA.

AMONGST the smaller Cattleyas the species represented in the woodcut (fig. 48) is one of the most handsome, and its beauty has rendered it a favourite with Orchid growers generally. It is also one of the few Cattleyas that succeed best on blocks, and in this respect it forms a charming companion for the fragrant *C. citrina*, *C. Walkeriana*, and a few others. These, unlike the majority of species, do not produce good results when in pots, and the peculiar downward-growing habit of *C. citrina* especially unfits it for that mode of culture. *C. marginata* is a Brazilian Orchid, and was introduced by those celebrated orchidists Messrs. Loddiges rather more than forty years ago. It is now included in most large collections of Orchids, and fairly good plants can be purchased for half a guinea. One reason why it is a favourite is because it thrives in a cooler temperature than the majority of the Cattleyas, a recommendation of great value where highly heated houses are objected to, as they are in many establishments. The cool end of an ordinary plant stove or an intermediate house will suit it, and if attention be particularly paid to the supplying water frequently little difficulty will be experienced with the plant.

The flowers are of moderate size; the petals much broader than the sepals, but, like them in colour, usually a soft rosy purple, the lip being intensely rich crimson, with a narrow margin of white, and a white throat,

which contrasts very markedly with the rich-coloured portion. These tints, however, vary considerably in depth, brightness, and clearness, and the value of the plant varies proportionally to its merits in these respects. The flowers are usually borne singly from the top of the small bulbs, but occasionally two may be produced, though this is comparatively rare. In many collections it is now flowering freely, and a quality of inestimable value at this time of year when Orchid flowers are so scarce is the great time they last in beauty. Under favourable conditions flowers will remain upon the plants for six weeks, continuing attractive from September till the beginning of November.

GARDEN CHEMISTRY.

HYDRO-AËRIAL ELEMENTS.

PLANTS, like animals, find a large portion of their sustenance in air and water. Water pure and simple—that is to say, uncombined,

contains about half its weight of water. Then the *dry* matter of organic beings is largely made up of the elements of water. Water is composed of hydrogen and oxygen (H_2O); and starch, sugar, gum, fat, wood are all composed of these elements, to which carbon has been added. Gluten, fibrin of Wheat and of flesh, and other so-called nitrogenous matters are also composed of these with a further addition—15 or 16 per cent.—of nitrogen with a little sulphur and phosphorus. Even when every part of water is expelled these elements, hydrogen, oxygen, carbon, and nitrogen, form not less than 95 per cent. of garden plants, and oftener over 98. The rest is the mineral matter which is left as ash when plants are burnt. We have seen that the most valuable part of this ash is phosphoric acid, potash, lime, magnesia, &c., and that it is not only absolutely necessary but very scarce in most soils and even manures. Hence their high money value.

These substances come from the soil only, and, when deficient, fertility fails unless these are added. Hence their paramount im-

FIG. 48—CATTLEYA MARGINATA.

forms the greater part of all vegetable substances and all flesh. An average man weighs about 140 lbs., and of that no less than 101 lbs. are pure water. Many animals are even more watery. Cucumbers grown on the "express" system have the appearance of solids, but in reality are very nearly all water. Many fruits contain over 90 per cent; rapidly grown Water and other Melons and berries often as much as 95. When one thinks of this the fact of old Mehemet Ali consuming his 40-lb. Melon after dinner becomes understandable, and we can also understand that the huge Water Melons consumed in Spain and in the warmer regions of America are in reality not solids but liquids, and are evaporated accordingly. Then "dry" bread

portance despite their small proportion in soils and in plants. They have been called soil-elements. The carbon, hydrogen, and oxygen have been called hydro-aërial elements, because these the plants find in air or soil in the form of carbonic dioxide and water. At another place we will consider how these compounds, water and carbonic dioxide, are changed. At present we will consider the source of them—where they are found. That familiar substance water we may at once dismiss in so far as regards its being the source of the hydrogen and oxygen in carbo-hydrates. Its composition has already been given.

Something more must be said about carbonic dioxide. As its

name implies, it is composed of carbon and oxygen, $C O_2$. Take a piece of charcoal and ignite it. It burns. What is this burning? Simply, in chemical language, it is an oxidisation of the charcoal (carbon). The process is purely chemical. Two atoms of oxygen unite with one (this is scarcely correct, but as an explanation must do here) of carbon, and a new compound is formed. This new compound is a gas—it is carbonic dioxide, and it escapes in the air. The same process occurs in the human body. We eat carbo-hydrates—sugar, starch—and digest them. Then by our lungs we take in oxygen from the air. This oxygen by the blood finds its way all through the body, oxidises the carbon of the body fuel, which in the process gives out heat, and is expelled by the lungs as carbonic dioxide. The decay of all organic matter is just this oxidisation. Plants do exactly the opposite of what animals, fire, and decay do.

This carbonic dioxide in the air is the source of all the carbon in plants. Thence have been drawn all the humus of our soils, the peat of our bogs, and the coal which heats our houses and drives our engines; yet its comparative amount in the atmosphere is very small, though in the aggregate it is enormous. Its per-centage in the air is 0.035, or 35 in 100,000. But it is everywhere present, and amounts in the aggregate to over two billion tons, a quantity that quite baffles human conception. When we come to consider the functions of the leaf and the diffusion of gases we will see that the supply of this is never short unless in unventilated, too closely glazed houses.

Although, by growing them in calcined sand, it has been proved that plants can find all their carbon in the air and flourish without its presence in the soil, much is supplied from decaying animal and vegetable matter in the soil to plants by the roots, and without doubt materially assists a rapid growth; and although 0.035 per cent. in the air is sufficient to maintain a vigorous growth, it has been shown that plants are greatly benefited when it is largely increased. When too much is present it is destructive even to plants; but it may be present to an extent poisonous to animals and yet prove of great benefit to plants. Bohn conducted numerous experiments to ascertain the effects of carbonic acid on plants, and found it beneficial up to the extent of 2 per cent., over that it was injurious, and when 20 per cent. was present it killed. On the other hand Godlewski asserts that *Glyceria* was benefited when as much as 8 or 10 per cent. was present. It is supposed that the huge stature of the Club Mosses and Marestails, and the exuberance of vegetation in general at the time our coal beds were formed, was largely due to the much greater percentage of the carbon in the air. Much was also due, doubtless, to the moistness and heat of the climate, as these when combined in our age never fail to induce rapid growth. Those who have read Loudon's account of the poison valley of Java, where carbonic acid issues from the ground, will recall the fact that there vegetation is absent.

Though an increase of carbonic dioxide in the atmosphere be impractical, doubtless its abundant presence in the soil will have a similar effect on plants to what its supply in the air would. Hence manures which supply this, as those from leaves, straw, green manurings, animal dung, &c., certainly possess an advantage over equivalent amounts of purely chemical ones. But a question arises: Is not this fact one of the causes of unfruitfulness in fruit trees in heavily manured garden soils? All the elements of fertility otherwise may be present in abundance, but an excess of carbonic dioxide causes a mere excess of vegetation and unfruitfulness. So far as we are aware, no plants capable of furnishing food to the higher animals have been found in the strata of the carboniferous era. Everything vegetable was too carboniferous. A large per-centage of phosphorus and potash exist in the ash of all nutritious vegetable substances. In the ash of these ancient plants they are singularly deficient, as they always are in plants deficient in animal nutrients, and in consequence the fauna was composed of either Herbivora with huge digestive systems, or Carnivora preying on them. The Frugivora and Graminivora are singularly absent. There was no place for men.

We grow what may here be divided into two classes of plants. The one class may be called foliage and the other flowering, including in the latter those grown for fruit. For the former class we are pretty unanimous in giving quantities of manure of the carbonaceous kind and much nitrogen. Experience has taught the observant to avoid such for flowering and fruiting plants in general; hence there has been a great demand for loam—virgin, brown, or hazel loam—for fruit trees and for flowering plants in pots; and just because of this loam not being always forthcoming, or because of the injudicious enriching of it, not always the best results have been forthcoming. The main virtues of virgin loam are owing to the fact that in it is to be found a good deal of plant food not of the carbonaceous kind. The fault of worn-out—that is, too heavily manured loam, is not that it wants mineral food, but that it contains too much carbonaceous; not that it is deficient in all the elements calculated to produce growth of the most fertile kind, but in addition that which so dilutes it as to run it out, not into fruit and flowers, but into carbonaceous leafiness—unfruitful luxuriance.

We are not aware of the theory being before submitted by any other writer, but we are certainly of opinion that too much organic matter in the form of carbonic dioxide or of nitrogen is against the production of wood of a floriferous or fruitful character, because it encourages a growth that is not solid enough, contains not mineral enough, but is watery, carbonaceous, lax, and contains only enough to support itself or growth of similar character. Flowers attract matter from the body of plants to form fruit, and in that is stored the essence of plant-growth. Seeds are the magazines of future existence; but growth grown lax by reason of highly nitrogenous food, or carbonaceous because of the gas absorbed too largely by leaf or by root, has not this essence to spare—all it finds is spent on itself.

Yet at certain periods fruit-bearing plants demand much carbon. This is always the case when heavy crops are swelling or maturing. Is not this the time to give carbon? Not in the air. This is not only impracticable, but would be attended with danger to animal life, but by the root. Decaying manure yields carbonic dioxide largely, water dissolves its own bulk of it. A thick coat of such over a vinery border at certain seasons, through which the necessary water was passed, would not fail to convey abundance of carbon to the plants just when the plants demanded it, and yet enable us to keep our loams in that hazelly state which alone secures lengthened fertility, because it does not over-supply carbon when not wanted, and therefore enables the cultivator to secure a real maturity of wood in room of that undue extension of cells which, while it furthers enlargement, prevents storage.

To the farmer such questions as these are only of secondary importance; hence nothing has been done by agricultural experimenters in this direction. To gardeners they are of the first, if they are ever to advance and be sure of the road along which advancement is made. If science were to clear up such questions as these gardening advance would not be merely personal and isolated—would not die with the individual and ever slip half steps backward, but move forward in general, and the advance of every individual be the advancement of the whole, because every advance would be understood. Such work would ennoble the doings of the R.H.S.; but Society work, like Government work, though often useful, seldom advances either science or practice.

To what extent nitrogen is derived from the air is an unsolved problem. We know how much ammonia is washed into the soil; we have reason to believe that the soil absorbs some more of itself, and that it is separated by the leaves from air, but to what extent we know not. The amount of ammonia and nitric acid in the air is very small, but because of its diffusibility it is always in contact with the leaves of plants. Hence we are inclined to think that more is separated than is generally believed. Ville's theory that some plants—the Leguminosæ—have the power of using the free nitrogen of the air is not supported by scientific evidence. His experiments and those of his supporters were too loosely conducted to prove anything.

Certain it is that nitrogen must be applied to the soil. Possibly good might follow its use in the air. These points all require investigation, and will probably be placed on a proper footing one day.
—SINGLE-HANDED.

NATIONAL APPLE CONGRESS, 1883.

THE following circular has been issued on this important subject, and we would ask the co-operation of all Apple cultivators towards rendering the collection as complete and as widely representative as possible. We would also recommend that those having Apples which they desire to have named, should send them to this Congress for that purpose, with stamped directed envelopes for replies in each case *accompanying the fruit*. Through no other source can the names be supplied with equal authority.

“At a meeting of fruit-growers, held at South Kensington in conjunction with the Fruit Committee of the Royal Horticultural Society on the 11th September, it was decided to hold a conference on Apples, in the great conservatory of the Society at Chiswick, from the 4th to the 18th October next.

“The unusually abundant crop of this year affords a favourable opportunity for examining the numerous varieties cultivated throughout the country, to correct their nomenclature, and to compare their merits. For this purpose the Council of the Royal Horticultural Society have given the use of their great conservatory, and the collection of Apples grown in the garden, which contains many typical varieties, will be available for comparison.

“This Conference will not take the form of an ordinary exhibition, as there will be no competition and no prizes, the sole object being to seize so favourable an opportunity of gaining information, and making the meeting instructive and educational.

“All fruit-growers are invited to send, and the more widely the collections are procured the greater will be the interest the Exhibition will create. It is very desirable, therefore, that every collection should be accompanied with as much information as can be furnished with

regard to soil, exposure, and physical conditions of the districts from which they are gathered. No limit will be put upon the number which anyone may see fit to send, and it is not at all necessary that they should be the product of his own grounds. The Committee desire that an effort be made to procure representatives of all the varieties that are grown in the various districts, and that all *should be distinctly labelled with the name or names under which they may be known in their respective localities.*

"As the specimens sent are strictly for examination, they must necessarily be at the disposal of the Committee where required.

"All packages addressed to the Secretary must be delivered on or before the 3rd of October. Exhibitors staging their own fruit may do so on the 3rd or morning of the 4th, to be ready for the inspection of the Committee. Notice of intention to exhibit must be given to Mr. Barron not later than the 29th September, stating the number of varieties to be exhibited, or the amount of space that will be required.

"All exhibitors will be admitted to the gardens free, and they will receive a certain number of tickets, according to the extent of their exhibits, for the admission of friends.

"The public are admitted to the gardens on payment of 6d.

"Growers of fruit will have in this Exhibition an opportunity of correcting or verifying the nomenclature of their fruits, by bringing specimens with them, and making a personal comparison.

"The following have been appointed a Committee to carry out the objects of the Congress in various parts of the country:—

Blackmore, R. D., Teddington.
 Britcher, G., Tunbridge.
 Brotherston, R. P., Tynninghame.
 Bunyard & Co., Nurseries, Maidstone.
 Burcott, J., The Gardens, The Deepdene, Dorking.
 Cheal & Sons, Nurserymen, Crawley, Sussex.
 Cranston, & Co., Nurserymen, Hereford.
 Dancer, F. N., Little Sutton, Chiswick.
 Diekson, F. & A., 106, Eastgate Street, Chester.
 Diekson, James, 108, Eastgate Street, Chester.
 Diekson, A. & Sons, Newtownards, Belfast.
 Dunn, M., The Gardens, Dalkeith Palace, N.B.
 Fisher, Son, & Sibray, Nurserymen, Sheffield.
 Garland, John, The Gardens, Killerton, Exeter.
 Gilbert, R., The Gardens, Burghley, Stamford.
 Goldsmith, G., The Gardens, Hollenden, Tonbridge.
 Graham, John, Cranford, Hounslow.
 Grieve, Peter, Bury St. Edmunds.
 Harrison & Sons, Nurserymen, Leicester.
 Haycock, Chas., The Gardens, Barham Court, Maidstone.
 Hibberd, Shirley, Brownswood Park, Stoke Newington.
 Hogg, Dr. Robert, 171, Fleet Street, E.C.
 Jefferies, John, & Sons, Nurserymen, Cirencester.
 Jefferies & Sons, Nurserymen, Oxford.
 Jones, T., The Royal Gardens, Frogmore.
 Killiek, Lewis A., Langley, Maidstone.
 Lane, H., & Son, Nurserymen, Berkhamstead.

Laxton, T., Bedford.
 Lee, Chas., & Son, The Nurseries, Hammersmith.
 Lee, John, 78, Warwick Gardens, S.W.

 Veitch & Sons, Nurserymen, Chelsea.
 Wheeler & Son, Nurserymen, Gloucester.
 Woodbridge, John, The Gardens, Syon House, Brentford.

"Any further information that may be required may be obtained on application to the Secretary, Mr. A. F. Barron, Royal Horticultural Gardens, Chiswick; or to Mr. L. Killiek, Langley, Maidstone."

N.B.—At a meeting of the Sub-committee held at Chiswick on September 18th, John Lee, Esq., in the chair, it was decided that exhibitors be requested to send not less than two fruits of a kind, or more than six, for the purpose of examination.

All packages should be addressed to the Secretary, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick; the charges for carriage of the same will be defrayed by the Society.

Admission to the public will be 1s. on the 4th, and 6d. on other days.

INTERNATIONAL POTATO SHOW.

SEPTEMBER 13TH AND 14TH.

"THE finest exhibition of Potatoes ever seen in England" was the general verdict of horticulturists who visited the Crystal Palace last Thursday and Friday, and the officials connected with this scheme had every reason to be satisfied with the results of their untiring efforts; for never since the Show was commenced some ten years since have the exhibits been so numerous and clean, even, and devoid of coarseness. A table about 150 yards long in the north nave was filled with the entries in the principal classes, the centre of the table between the different classes being filled with small specimen Palms, Ferns, and miscellaneous plants that served to break the monotony considerably. On each side of the chief table were others slightly shorter, and devoted to the exhibits not in competition, which were similarly abundant and interesting. Some idea of the extent of the Show can be gathered from the following numbers, which far exceed those of any previous year. In the twenty-one classes enumerated in the schedule 375 collections were staged, the entries being about 30 per cent. in advance of last year. These included nearly 2000 dishes, or a total of over 19,000 tubers, and in the non-competing exhibits there would probably be 10,000 more. In the leading classes, too, the competition was extraordinarily

keen, no less than seventeen collections of twenty-four dishes, which were so nearly equal in exhibition merits that the Judges had a most difficult task in selecting the premier. Mr. Gribble's fine examples were, however, worthily adjudged chief honours, and in the opinion of many experienced Potato exhibitors such a perfect collection had never been staged before. In the eighteen-dishes class, again, there were twenty entries, similar numbers staging in classes L and N, while in S there were twenty-three, J and F twenty-one, H and D twenty-five; but in E, for six dishes, no less than thirty lots were contributed.

The Show was opened at noon by Mr. Alderman de Keyser in the absence of the Lord Mayor, and the former gentleman also presided at the luncheon subsequently held in the Marble Hall, when he was supported by Mr. Alderman Hadley and Mr. McGeorge, Chairman of the Crystal Palace Company; Mr. P. McKinlay and Mr. Shirley Hibberd taking the vice chairs.

Class A, twenty-four dishes of Potatoes, distinct varieties, nine tubers of each (open). First prize, £10 10s.; second, £7 7s.; third, £5 5s.; fourth, £3 3s.; fifth, £2 2s.; sixth, £1 1s. The first prize was given by Mr. Alderman de Keyser, Sheriff of London and Middlesex; the second, Mr. Alderman Hadley; the third, James McIntosh, Esq., Weybridge; the fourth, R. Russell, Esq., Mayor of Derby; the fifth, L. Fawell, Esq., 4, St. Paul's Churchyard, London; and the sixth, Wm. Holloway, Esq., 6, St. Paul's Churchyard, London. This formed the most important class of the Exhibition, seventeen collections being staged, all of remarkable evenness, and so nearly equal in merit that the Judges had a most difficult task in determining the relative positions of the exhibits, and nearly an hour had elapsed before their decisions were made known. Mr. Gribble, Canon Hill, Maidenhead, was awarded the premier prize for a beautiful even collection, the tubers of moderate size, but distinguished by their symmetry and cleanness. The varieties were Vicar of Laleham, International, Matchless, Fillbasket, Prizetaker Kidney, Covent Garden Perfection, Improved Peach Blow, Bedford Prolific, American Purple, Magnum Bonum, Beauty of Kent, Reading Hero, Adirondack, Woodstock, Mr. Bresee, King of Potatoes, Heather Bell, Porter's Excelsior, Extra Early Vermont, Cosmopolitan, Reading Russet, Schoolmaster, Beauty of Hebron, and Early Regent. Mr. J. Hughes, gardener to Col. Cartwright, Eydon Hall, Northamptonshire, was awarded second honours with a collection of very similar merit, handsome dishes of Mr. Bresee, Edgcott Seedling, Suttons' Prizetaker, Porter's Excelsior, International, and Advance. Mr. W. Kerr, Dargavel, Dumfriesshire, secured the third position. Mr. Robins, gardener to E. D. Lee, Esq., Aylesbury, was fourth. Mr. W. Ellington, West Row Gardens, Mildenhall, was fifth; and Mr. T. Pickworth, Loughborough, sixth.

Class B, eighteen dishes of Potatoes, distinct varieties, nine tubers of each. Open to noblemen's and gentlemen's gardeners only, and the awards to be made by three gentlemen's gardeners, not competitors. First prize, £7 7s.; second, £5 5s.; third, £3 3s.; fourth, £2 2s.; fifth, £1 1s. All the prizes were given (in cash or plate) by Messrs. Sutton & Sons, Reading. In this class also the competition was extraordinarily keen, twenty exhibitors entering and staging a total of 360 dishes, which required almost as much careful consideration as those in the previous class, for there were few faulty examples in any of the collections. Mr. Hughes won premier honours with a very handsome collection of moderate size tubers of the following varieties:—Adirondack, Jackson's Improved, Suttons' Reading Russet, Porter's Excelsior, Radstock Beauty, Suttons' Fillbasket, Beauty of Hebron, Woodstock Kidney, Mr. Bresee, White Emperor, Vicar of Laleham, Snowdrop, Queen of the Valley, Myatt's Ashleaf, Suttons' Prizetaker, Lady Truscott, Red Fluke, and Edgcott Seedling. Mr. H. Clarke, Woodstock, was placed second with neat tubers of Porter's Excelsior, Grampian, Farren's Kidney, Manhattan, Edgcott Seedling, Blanchard, Early Border, Model, Salmon Kidney, International, Beauty of Hebron, Woodstock Kidney, Triumph, Magnum Bonum, Radstock Beauty, Webbs' Surprise, Vicar of Laleham, and Bedford Prolific. Mr. E. S. Wills was placed third with good samples, Mr. W. Robins fourth, Mr. G. Akhurst was fifth.

Class C, twelve dishes of Potatoes, distinct varieties, nine tubers of each (open). First prize, £5 5s.; second, £4 4s.; third, £3 3s.; fourth, £2 2s.; fifth, £1 1s. The first prize was given by Mr. Alderman Cotton, M.P.; the second by Messrs. Daniels Brothers, The Royal Norfolk Establishment, Norwich; the third by Vice-President George Urc, Esq., Wheatlands, Bonnybridge, N.B.; the fourth by Vice-President J. T. Thomas, Esq., 138, Queen Victoria Street, London; and the fifth by Thomas Price, Esq., Lymore, Beckenham. Nineteen collections, containing 228 dishes, were entered in this class, and were throughout of great merit, though perhaps there were more weak and irregular samples in this than in the preceding. The premier awards were secured by Mr. J. Miller, The Gardens, Hamstead Park, Newbury, Berks, for fine examples of Magnum Bonum, Radstock Beauty, Woodstock Kidney, Superior, Pride of America, Vicar of Laleham, Reading Hero, Red Fluke, Myatt's Prolific, Triumph, Porter's Excelsior, and Reading Russet. Mr. J. Hughes was placed second, his best dishes being Queen of the Valley, International, Adirondack, Mr. Bresee, and Reading Russet. Mr. T. Pickworth was third, Mr. W. Ellington fourth, and Mr. W. Kerr fifth.

Class D, nine dishes of Potatoes, distinct varieties, nine tubers of each (open). All the prizes in this class were given by Mr. C. Fidler, Potato grower and merchant, Reading. Of the twenty-five competitors Mr. T. Tooley, Banbury, was placed first with a beautiful collection, comprising dishes of Prizetaker, Woodstock Kidney, Reading Russet, American Purple, International, Queen of the Valley, Schoolmaster, Mr. Bresee, and Radstock Beauty, all very even and clean. Mr. R. Dean was a good second—International, Mr. Bresee, Reading Russet, and Schoolmaster being very fine. Mr. W. Kerr was third with smaller tubers; Mr. L. Stanton, Maidford, Towcester, fourth; and Mr. T. Pickworth fifth.

Class E, six dishes of Potatoes, distinct varieties, nine tubers of each (open). The first prize was given by Messrs. Webb & Sons, Wordsley, Stourbridge; the second by Messrs. Barr & Son, seedsmen, King Street, Covent Garden; the third by T. J. Burrell, Esq., Knight-riding Street, London; and the fourth by Mr. William Earley, Ilford. Thirty collections were staged, and in this keen competition Mr. T. Tooley again secured the first position with tubers of moderate size, very even, clean, and good, the varieties being Porter's Excelsior, Reading Russet, Radstock Beauty, Schoolmaster, Woodstock Kidney, and Mr. Bresee. Mr. W. Kerr, Dargavel, was a close second,

also with moderate-sized tubers, Snowflake, International, Adirondack, and Vicar of Laleham being the best. Mr. H. E. Gribble was third; Mr. W. Finlay, Wroxton Abbey, Banbury, Oxon, fourth; and an extra prize was adjudged to Mr. E. S. Wiles, Edgcott Gardens, Banbury.

Class F, four dishes, distinct varieties, the largest and handsomest, six tubers of each. All the prizes were offered by Messrs. Harrison & Son, seedsmen, Leicester. Twenty-one fine collections were contributed, some very large and beautiful tubers being included in some of them. Mr. J. Hughes took the lead with good samples of International, Mr. Bresee, Suttons' Favourite, and Queen of the Valley, large but even. Mr. W. Ellerton followed with International, Queen of the Valley, Magnum Bonum, Lord Beaconsfield, all of great size. Mr. Bloxham, gardener to Sir P. Duncombe, Bart., Brickhill Manor, was third with Adirondack, Schoolmaster, International, and Trophy; Mr. H. E. Gribble being fourth.

Class G, three dishes of white round Potatoes, distinct varieties, nine tubers of each (open). The first prize in this class was given by James Wright, Esq., Falkirk, N.B.; the second by F. P. Alliston, Esq., The Ferns, Beckenham; the third by Martin Cornell, Esq., 15, St. Paul's Churchyard, London. Amongst seventeen competitors Mr. R. Dean, Ranelagh Road, Ealing, was adjudged first honours for excellent tubers of Schoolmaster, First and Best, and Early Bird. Mr. W. Kerr was second with Bedford Prolific, Schoolmaster, and Mammoth Pearl. Mr. R. West, gardener to J. R. Wigram, Esq., Salisbury, third with Bedford Prolific, Schoolmaster, and Porter's Prolific. Mr. G. Pickworth fourth with Advance, First and Best, and Climax. An extra prize was awarded to Mr. G. Allen, The Gardens, Rainbury Manor, Wilts.

Class H, three dishes of coloured round Potatoes, distinct varieties, nine tubers of each (open). The first prize was given by Mr. Richard Dean, Ealing and Bedford, London; the second by H. M. Pollett, Esq., Fernside, Bickley; and the remainder of the prizes were given by Shirley Hibberd, Esq. In a class of twenty-five collections Mr. R. Dean was again to the fore with even tubers of Vicar of Laleham, Radstock Beauty, and Reading Russet; Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, second with Reading Russet, Vicar of Laleham, and Red Emperor; Mr. C. Akhurst, gardener to Rev. J. W. Bramah, Faversham, was third with Beauty of Kent, Vicar of Laleham, and Adirondack. Mr. Bloxham, gardener to Sir P. Duncombe, Bart., Brickhill Manor, was fourth with Grampian, Radstock Beauty, and Adirondack.

Class I, three dishes white kidney Potatoes, distinct varieties, nine tubers of each (open). The first prize was given by Alfred Lyon, Esq., Stone Villas, Tottenham, the remainder by P. McKinlay, Esq., Headley Lodge, Penge. Eighteen collections were entered, and Mr. J. Pickworth was placed in the chief position with International, Woodstock Kidney, and Royal Ashleaf, extremely even and handsome. Mr. W. Kerr followed closely with Myatt's Ashleaf, International, and Snowflake, smaller but clean. Mr. R. Dean was third with Edgcott Seedling, Cosmopolitan, and Woodstock Kidney; and Mr. Bloxham was a good fourth.

Class J, three dishes of coloured kidney Potatoes, distinct varieties, nine tubers of each (open). All the prizes in this class were given by Mr. John K. King, Coggleshall, Essex. There were twenty-one entries, and Mr. R. Dean secured first honours with Mr. Bresee, Prizetaker, and Bountiful, even, clean, and good. Mr. W. Kerr took the second position with Wonderful, Red Kidney, Defiance, and Sir Garnet Wolseley. Mr. H. E. Gribble was third with Prizetaker, Mr. Bresee, and Defiance; and Mr. Ross fourth.

Class K.—Messrs. Sutton & Sons offered four prizes for eighteen tubers of each of the following eight varieties of Potatoes, open to noblemen's and gentlemen's gardeners only, and the awards to be made by three gentlemen's gardeners not competitors:—Magnum Bonum, First and Best, Reading Russet, Reading Hero, Early Border, Prizetaker, Early Regent, and Fillbasket. There were six exhibitors, Mr. C. Ross taking the lead with very even, clean, and praiseworthy samples. Mr. G. Allen was a close second, Mr. J. Matthews third, and Mr. C. Osman, Sutton, Surrey, fourth. In the four following classes Messrs. Sutton & Sons also contributed all the prizes, the dishes in each containing eighteen tubers instead of nine, as in the majority of other classes.

Class L, for the best dish of any white round Potato of English origin. Twenty exhibitors. Mr. W. Kerr was first with Schoolmaster; Mr. P. McKinlay second with White Emperor; Mr. C. Turner, Slough, third with Schoolmaster; and an extra prize was awarded to Mr. J. Matthews, gardener to E. Twopenny, Esq., Woodstock Park, Sittingbourne, for Suttons' First and Best.

Class M, for the best dish of any coloured round Potato of English origin. Seventeen exhibitors. Mr. T. Creed, Kenesdale, Faversham, was first with Reading Russet; Mr. P. McKinlay second with the same variety; and Mr. Pragnell, Banstead, was third with Suttons' Redskin Flourball.

Class N, one dish of any white English-raised Kidney. There was good competition of nineteen dishes, but the Judges could have had no difficulty in awarding the premier prize to Mr. Pearson, Chilwell Nurseries, Notts, for a remarkable dish of Sanday's Seedling; tubers of good size, pure white, of faultless shape, and said to be early and of the finest quality. It would be interesting to know the origin of this attractive Potato; it appears to be of the Lapstone type, but is less pointed than that variety. There was no more beautiful dish of kidney Potatoes in the Show than this. The second prize was awarded to Mr. B. West, Nuneham, Oxford, for admirable examples of Magnum Bonum. Third honours going to Mr. Kerr for a superior dish of International.

Class O, for the best dish of any coloured kidney of English origin. Nine dishes were staged, Mr. W. Kerr being first with fine tubers of Defiance; Mr. F. Fellowes, Kidderminster, second with Prizetaker; and Mr. T. Pickworth third with the same variety.

Class P, for the best dish of any white-skinned Potato, new variety, in commerce, but not offered to the public before 1882. All the prizes were given by Mr. C. Fidler. Nineteen dishes were staged. Mr. P. McKinlay, Headley Lodge, Croydon Road, was first with Lady Truscott (Suttons'), a white round, very even and handsome in appearance. The second prize was awarded to Mr. G. Allen for rather rougher samples of the same variety; and Mr. R. Dean was third with Alderman (Dean), a large, white, round variety.

Class Q, for the best dish of any coloured Potato in commerce, but not offered before 1883. All the prizes were given by Mr. C. Turner, Slough.

Seven dishes were entered. Mr. T. H. Hills, The Gardens, Durward, Essex, was awarded the first prize for a dish of The Belle (Daniels'), a pale red round variety of moderate size and even form. Mr. W. Kerr was second with Kerr's Sir Garnet Wolseley, a neat-shaped kidney, deep red, blotched with white, of moderate size. Mr. J. Butt, 17, Ruby Street, Wisbech, was third with Red Lion, an oblong red kidney with white eyes.

CLASSES FOR SEEDLINGS.

These were very well filled, a total of forty-five dishes being entered in the four classes. Each class was for a single dish of nine tubers of any seedling variety not in commerce. The greatest competition was in Class S for white kidney varieties, twenty-three dishes being entered, and the following were selected for certificates. A prize of one guinea was also offered by Messrs. Hooper & Co., Covent Garden, for the best dish or variety in each class. The granting of certificates was conditional upon the parentage being fully stated, and the provision of a dish of additional tubers of each variety for cooking. It was also required that tubers should have been sent to Chiswick for planting in the Royal Horticultural Society's gardens for trial.

Welford Park Kidney (C. Ross).—Tubers of moderate size, but very even and regular in form. This was also awarded the prize in the class.

Beauty of Eydon (R. Dean).—A seedling from Beauty of Hebron crossed with Myatt's Prolific; excellent as regards evenness and general appearance.

Hughes' Prolific (Hughes).—This is of the same parentage as the preceding, and is somewhat similar in character but smaller.

Midsummer Kidney (Dean).—A seedling from a cross between Success and Woodstock Kidney, described by the raiser as very early, a good cropper, and of fine quality.

In Class T, for coloured kidney varieties, there were eight entries, the following being awarded certificates:—

Edgcott Purple Seedling (E. S. Wiles).—A long, smooth, deep purple kidney, an exact counterpart of its white namesake in form. This was awarded the prize in the class.

Cardinal (Dean).—A second early kidney from a cross between Early Rose and Bountiful, rich red in colour, even in form, and said to be a good cropper and of first-rate quality.

In Class U for a single dish of a white round variety there were seven entries. Only one certificate and prize were awarded—namely, to

Prime Minister (Dean).—A cross between Magnum Bonum and Woodstock Kidney, a Potato of fine appearance, described as late, strong grower, prolific, and of good quality.

In Class V, for coloured round Potatoes, there were also seven exhibits, the prize and certificate being adjudged to

The Dean (R. Dean).—A dark purple round variety from a cross between Vicar of Laleham and Woodstock Kidney, and really an improved type of the former, said to be of good quality for the table.

MISCELLANEOUS.

The exhibits not for competition were very numerous, and occupied nearly as much space as the collections staged in the classes. Two tables on each side of the central table were devoted to these, very prominent amongst them being Messrs. Sutton & Sons' contribution, in which 165 varieties were represented, comprising twenty-five American, twenty-two sent out by Messrs. Sutton & Sons, sixty-four seedlings not in commerce, and fifty-two other English-raised Potatoes. Very notable also were large heaps of the standard varieties, Reading Russet, Reading Hero, Early Regent, Prizetaker, Fiftyfold, and the new Lady Truscott.

Messrs. J. Carter & Co., High Holborn, exhibited a large quantity of Potatoes, either in dishes or heaps, some being shown as lifted from the ground. A great number of varieties were represented, including most of the generally approved forms in cultivation, together with many specialities of their own. Some noteworthy varieties were First Crop, Eight Weeks, Improved Magnum Bonum, Ashtop Flake, Cosmopolitan, White Elephant, Hero, and Beauty of Hebron. Messrs. Daniels Bros., Norwich, contributed about sixty dishes, mostly distinct varieties, very notable being a heap of White Elephant weighing 115 lbs., the produce of one tuber cut into single eyes and grown without artificial manure. The tubers were rather smaller than those of this variety sometimes shown, and the eyes less deep. Some tubers of this weighing 2 lbs. 11 ozs. were also shown. About thirty seedlings white and coloured round and kidney Potatoes were also shown, some appearing very promising. Messrs. Hooper & Co., Covent Garden, exhibited twenty-four baskets of Potatoes, distinct varieties; Adirondack, Round Blue, Brownell's Beauty, Covent Garden Perfection, Belle, Pride of America, Early Border, and others being notable. The tubers were all shown as lifted from the ground. Mr. C. Fidler, 104 and 105, Friar Street, Reading, had about sixty dishes of Potatoes, with large heaps of Vicar of Laleham, Magnum Bonum, and White Elephant. Messrs. Harrison & Sons, Leicester, exhibited over sixty dishes of Potatoes, mostly distinct varieties, the tubers even and clean. Messrs. Charles Lee & Son, Hammersmith, showed about seventy-eight dishes of good tubers; Lee's Hammersmith, Early Kidney, and Lee's Defiance Purple Kidney being very notable. A collection of thirty-three dishes was shown from the Royal Horticultural Society's gardens, Chiswick, all the tubers being distinguished by the clear even appearance.

As may be readily imagined the work incurred in the necessary arrangements for such an Exhibition is enormous, and the energetic Hon. Secretary, Mr. P. McKinlay, who has for the past ten years so ably performed the task, deserves every praise. His official duties indeed have now become so numerous that he has expressed a desire to be relieved of a portion of the work by a paid Secretary, and the Committee would be acting wisely and well in selecting a competent man for the post. The readiness with which friends of the movement contribute money prizes gives every hope that a substantial salary could be raised without much difficulty.

MASTERPIECE MELON.—I notice in your report of the Bath Floral Fête you say "In the Green-fleshed Melon Class Mr. Iggulden was first with Masterpiece," which I presume to be a mistake in some way, as Masterpiece is a scarlet-flesh variety, and a very good one too. I have grown three batches of it this year, it being so good that my employer

made special inquiries as to what variety it was.—S. MORTIMER, *Purley Park, Reading.*

[The Melon in question is a new variety, and perhaps because of its external resemblance to the original Masterpiece the exhibitor intended to attach the name "Green Masterpiece," but another name would be better if the variety is to be perpetuated.]

CENOTHERA RIPARIA.

It would be well if the name of the plant figured on page 227 could be definitely settled. It is commonly sold, I admit, as *C. riparia*, and it is probably true that the name of *prostrata* is incorrect, but "T." does not give his authority for the name *riparia*, and if he will send the plant to Kew, perhaps he will find that *linearis* is the accepted name; at least, it was so labelled in the Kew herbaceous garden last year, whilst the name *riparia* was given to a very distinct plant of less merit, a garden plant having undivided upright stems 2 feet high, more in the way of a dwarf *C. biennis*. The *Cenotheras* are a difficult genus to get rightly named, and from their shortlived habit in this climate appear in cultivation from time to time and again disappear, changing their name as often as they come out again.—C. WOLLEY DOD.

THE LONDON PARKS.

HAMPTON COURT.

THOUGH out of the metropolitan district the park attached to the interesting old palace at Hampton enjoys an equally large share of popularity with the best in London itself, and very deservedly, for under the experienced care of the Superintendent (Mr. Graham) it has attained great fame for the carpet and other bedding so well carried out there. Examples of all the favourite styles of planting can, however, be seen, from the herbaceous border to the most delicate and intricate carpet design, the only style which is not largely practised being the subtropical. In front of the Palace next the long walk which leads to the river is a series of beds planted in the carpet, mixed, or conventional styles. The beds near the walks at right angles to these, and one forming a semi-circular sweep round the fine Yews, are devoted to Pelargoniums, with some varied and appropriate margin. These are very handsome, and the richness of colour they supply seems particularly appropriate and in accordance with the surroundings. They prove, indeed, how valuable beds of Zonal Pelargoniums are in suitable positions, for no style of bedding would look so well in contrast with the sombre Yews as the brilliant colouring furnished by these. Scarlet and pink shades are especially strongly represented, and the plants are notable throughout for their bushy habit and great floriferousness. The colours, too, are brighter, clearer, and richer than they are in less favoured localities. The carpet designs are distinguished by marked originality, and in most cases by great effectiveness and taste in design, combination of colours, and planting, and in several the beautiful *Echeveria Peacocki* is most effectively employed. This fine species, which is distinguished alike by its neat symmetrical form and slight purplish tint, has for some years been admirably grown at Hampton Court, and it is strange that it has not been employed more extensively in other parks. Possibly, however, the stock is at present rather limited, and it continues too expensive to bed out on a large scale. Unquestionably it will ultimately become a great favourite for all delicate carpet designs. The mixed beds constitute a decided charm, for examples of several beautiful combinations are given, and suggest others of a similar nature. The herbaceous borders have been grand, but their most striking feature has faded, for the scores of vigorous white Lilies that have flowered most profusely during the early summer months are now past their best. They have been magnificent, with grand heads of large pure white flowers, and produced an unrivalled effect. Lilliums are great favourites with Mr. Graham, and a large stock of *L. speciosum* and *L. auratum* is being raised that will one day add considerable charms to this portion of the garden.

In particularising a few of the most striking beds we may commence with those planted in the mixed style, as these are unusually good. One of the first to attract attention is filled with the brightly variegated *Abutilon niveum maculatum*, *Iresine Lindeni*, and *Verbena venosa*, margined with a band of the second-named plant. This affords a pretty contrast of colours, is really very effective. Another excellent combination is furnished by small plants of the silver variegated *Acer Negundo*, *Iresine Lindeni*, and *Verbena Hampton Court Crimson*, a most beautiful variety of rich colour and good habit. A third bed of great merit is composed of the old but useful variegated Pelargonium *Manglesi*, with *Iresine Lindeni* and *Viola Favourite*. Perhaps the most distinct of all is, however, one carpeted with *Verbena Hampton Court Crimson*, with which is planted *Veronica Andersoni variegata*, and edged with *Iresine Herbstii*. This *Veronica* has become a great favourite in many of the parks lately, and as it is readily propagated by cutting, a stock can soon be obtained from a few old plants. Several other mixed beds are devoted to various plants; such, for example, as standard Roses with a carpet of *Cineraria maritima* and *Heliotrope President Garfield*, or *Centaurea candidissima* with the same *Heliotrope*, others of *Chrysanthemum Madame Desgranges* and *Pentstemon Mrs. Sutherland*, and some of a similar style. These imparted much diversity to the general effect, and served to materially relieve the monotonous appearance that usually characterises a great number of beds planted in a similar manner.

Of the ordinary Pelargonium beds the most pleasing were the following, the central plants in each bed being named first:—Pel. Henry

Jacoby edged with *Centaurea candidissima*, a fine contrast being afforded between the very dark scarlet flowers of the former and silvery white foliage of the latter; Pel. Crystal Palace Gem carpeted with *Viola Favourite* (blue), margined with *Iresine Wallsi*; *Ageratum Imperial Dwarf*, a fine variety, of compact habit, most floriferous, and rich colour, edged with *Iresine Herbstii*. This was a simple but handsome bed. Pel. Flower of Spring, carpeted with *Viola Tory*, margined with *Iresine Herbstii*, and edged with *Alyssum saxatile variegatum*. Pel. Mrs. Pollock, carpeted with *Viola Blue King*, and edged with *Ageratum Cannell's Dwarf*, formed a pretty and distinct bed. Pel. Henry Jacoby is used in several other beds with excellent effect edged with Pel. Golden Harry Hieover; Pel. Mrs. Pollock and *Euonymus radicans variegatus*, all of which are noticeable, and prove how valuable this Pelargonium is for bedding purposes. Pel. Amaranth is freely employed, and in one very notable case it is margined with a new dark-foliaged *Coleus* named Taylor's Pet, which is said to have originated at Chelsea, and appears likely to become a favourite, as it is very dwarf, compact, and almost black. In other beds the same Pelargonium is edged with Pel. *Manglesi variegata* and *Ageratum Cannell's Dwarf*. Pel. Rose of Allandale, a good pink variety, is also a favourite, and deservedly, for it is useful and brightly coloured; in one bed margined with *Coleus Verschaffeltii* and *Euonymus radicans* is striking. Pel. Surprise is not often bedded out on a large scale, but at Hampton Court it is one of the standard varieties, and being of a very distinct salmon tint it is very effective, especially when margined with Pel. Flower of Spring, as it is in several cases with admirable results. Many other good examples might be described, for amongst the ninety beds devoted to the Pelargonium and mixed styles, few can be considered faulty even by the most critical.

The carpet beds, it need scarcely be said, fully maintain the fame Mr. Graham has already won for neatness and novelty of design. Soft tints prevail as a groundwork; *Veronica incana*, *Antennaria tomentosa*, and *Leucophyton Browni*, with bold panels of *Alternanthera amoena*, *versicolor*, *paronychioides aurea*, and *Echeveria Peacocki* furnish the chief features. They are all marked by that finish which invariably characterises the best work of any kind, and the excellent condition in which they are kept will preserve their beauty until the frosts commence.

These remarks have been chiefly confined to the beds in front of the Palace, but it may be added that the gardens generally are in similarly excellent condition; turf, shrubberies, walks, and all the minutiae of garden management, evidently receiving careful attention from the courteous Superintendent.—L. C.

SELECTING AND STORING VEGETABLE ROOTS.

THE present is the time when these must have attention, and where there are many roots to lift this work will form the most important in the kitchen garden for some weeks to come. Fine weather should always be selected for the operation, and this is the main secret of successful preservation, and the weather just now prevailing is most suitable.

Potatoes.—The stems have mostly died, and lifting the roots is being carried on, the tubers being spread on a dry pathway. Those spread out here one day are perfectly dry by the next day afternoon, and they are at once transferred to a dark shed, where they remain until wanted. The good tubers are saved, the large ones being taken in first for eating, then the smaller are put in another place for seed, and the smallest as well as the diseased are given to the pigs. This plan of storing Potatoes answers admirably.

Onions.—Next to Potatoes probably these follow in importance. In many places Onions have to be sent into the kitchen every day in the year, and when this is the case cultivators soon begin to find the advantages of careful harvesting. Our main-crop Onions always grow on a large square in the kitchen garden, and include several varieties; but these are not all put together at harvesting time. Those of the White Spanish type are kept by themselves for autumn and winter; then such capital keeping sorts as James's Keeping are stored separately until spring. This is the best way of securing a constant supply and long succession of useful Onions. In beginning to harvest the bulbs they are drawn up and laid down on their sides on the place they were growing, and there they remain for upwards of a week, when they are lifted and laid out again on a gravel path in the vegetable garden. They are allowed to remain there for a week or so, and by this time they are well dried, the stems being withered, and then they are ready for housing. Should wet weather prevail during the time they are newly drawn it is a great advantage to take them into some open shed and dry them there, as they never keep well when subjected to several soakings whilst being prepared for storing. When quite dry the bulbs should have a portion of the rough stem twisted off. We generally leave the stem from 3 inches to 4 inches long on each; and although they are now put down in heaps in the sheds, by-and-by some of them may be made into ropes to hang up, and it is necessary to have a piece of stem to each to do this.

Beetroot.—This should always be taken in before severe

weather commences. Some seasons and in some localities we have had to lift our Beets by the end of September, and in other cases we have left them out until November; but when grown to a good size there is nothing gained by risking them out, and they may as well be taken in as long as the weather is fine. They should be lifted from the soil with a fork, so that none of the rootlets are broken, as this causes them to bleed and spoils them. For the same reason the leaves should never be cut close to the crown. The roots should be dried for a day or two in the open before storing in a cool shed or cellar; and to preserve them properly and prevent them shrivelling they should be stacked and covered with moderately moist leaf soil or sand.

Carrots are treated in all respects like the Beet, and we always manage to keep both until the young crops are ready the following year.

Parsnips, Salsafy, and such-like roots are much better left in their growing quarters until spring, and a quantity may always be lifted for use before severe frosty weather.—A KITCHEN GARDENER.

ROYAL CALEDONIAN SOCIETY'S AUTUMN SHOW.

THE annual Exhibition of the above Society was held as usual in the spacious Waverley Market, Edinburgh, on Wednesday and Thursday last, under the most favourable meteorological influences. Although the entries were in excess of any previous year, internationals excepted, the display was hardly as good as we have seen it. In the larger classes competition was anything but spirited, fewer exhibitors entering than there were prizes offered in some instances.

THE FRUIT CLASSES.

As is usual at the autumn meetings in Edinburgh heavy prizes were offered in these in order to tempt growers to make as great a display as possible, and although some good fruit was shown the display was by no means what might have been expected, with the exception of the Apples, which were both extremely numerous and good.

The competition for three prizes of £5, £2 10s., and £1 10s., offered for a collection of fruit, twelve distinct sorts, only two collections were staged. Both were very nearly equal, but after carefully examining both exhibits the Judge awarded Mr. Johnston, gardener to the Earl of Strathmore, Glamis, Forfar, the first prize. Mr. Johnston's dishes of Black Alicante and Muscat of Alexandria Grapes, Smooth Cayenne and Charlotte Rothschild Pines, Late Admirable and Royal George Peaches were particularly good, while Bananas, Melons, Plums, and Figs were fair. Mr. McIndoe, gardener to Sir Joseph Pease, Hutton Hall, Guisborough, was placed second with a collection but a few points behind the first; indeed, we imagine that but for his Grapes being not quite equal to Mr. Johnston's the first card might have been won by him. He staged Black Hamburg and Golden Queen Grapes in fair condition, Princess of Wales and Royal George Peaches very fine, a good dish of Durondeau Pears, a fine Queen Pine, two very handsome Best of All Melons, and good Figs, Apricots, Plums, and Nectarines. The competition in the class for eight sorts was more spirited, and some fine fruit was staged in this class. The prizes were awarded to Mr. D. Murray, Maybole; Mr. W. McKelvie, gardener to the Dowager Duchess of Roxburgh, Broxmouth; and Mr. James Mackonichie, gardener to P. B. Smollet, Esq., Cameron House, Alexandria, in the order of their names. Mr. Fairgrieve, gardener, Dunkeld, exhibited a good collection in this class, but evidently reserved his strength for the collection of ten sorts of hardy fruits (must all be grown out of doors), in which he was successful in gaining first with Royal George and Early York Peaches in marvellous condition so early as the beginning of September, considering that Dunkeld is situated in Tayside. The Royal Georges especially proved that the expense of glass is not needed, even in the north of Scotland, in order to secure the finest Peaches. The Orange Apricot, Victoria, Jefferson, and Goliath Plums were fine, and the French Bergamot Pears especially so. Mr. MacIndoe was second, his collection containing good dishes of Souvenir du Congrès Pear and Worcester Pearmain Apple. Mr. J. Day, gardener to Mr. Broadhurst, Garlieston, Wigtonshire, third.

For Grapes seventeen classes were provided, and liberal prizes ranging from £6 to 10s. offered. For three prizes of £6, £4, and £2 only two competitors tried their strength in the class for twelve bunches, six white, six black. Mr. McIndoe staged large bunches of Gros Guillaume, Trebbiano, and Gros Colman, and fairly good bunches of Golden Queen, Foster's Seedling, and Black Hamburg. As a whole these were in anything but good condition, not being fully ripe. Mr. McKelvie staged much smaller bunches of Madresfield Court, Muscat of Alexandria, Black Hamburg, and Buckland Sweetwater very well finished, and the Judges placed them equal first. For eight bunches, at least six sorts, the competition was more spirited. Mr. McKelvie was first in this class with fine examples of Black Hamburg, Muscat of Alexandria, Abercainey Seedling, Alnwick Seedling, Madresfield Court, and Buckland Sweetwater. Mr. A. Kirk, gardener to J. T. Paton, Esq., Norwood, Alloa, was a close second, a notable dish; very good Dukes, Alnwick, and Muscat. Mr. McIndoe was third. For four sorts Mr. Kirk was first with well-finished fruit, Mr. Day second, and Mr. W. Lees, Hillborough Castle, Co. Down, who showed a splendidly finished bunch of Cooper's Late Black. For two bunches of Muscats Mr. Ramsey was first with two moderate-sized bunches fairly finished, Mr. Day being second. Mr. Johnston showed two very fine bunches in this class, but hardly ripe. Black Hamburgs were fairly good; the second prize was best, only the bloom was tarnished. Mr. A. Smith, Spiddock, Dumfries, was first; Mr. Mackie, Darlington, second. In the one-bunch classes the first-prize Black Hamburgs were good, Alicantes very fine, Gros Colman not coloured. The best of any black not named in the schedule was a Cooper's Late Black—a splendidly finished bunch. In the class for finest-flavoured black,

Madresfield Court, dead ripe and shrivelling, won the day, and a small bunch of Muscat of Alexandria that for the best-flavoured white. For the finest bloom Mr. Lees' bunch of Cooper's Black was simply perfect. Mr. Dewar, gardener to Captain Archibald, Beechwood, Tillicoultry, staged the Duke of Buccleuch in excellent condition, securing the first prize in the any variety white class. The Vines in pots were not remarkably good, though the crop on the first-prize lot was heavy. Space forbids us further noticing the exhibits in the Grape classes from No. 6 to 17, beyond publishing the names of the principal prizetakers, who are as under:—Messrs. G. Mackinnon, Melville Castle; James Jeffrey, Langholm; William Spence, Loanhead; D. Murray, Maybole; S. Castle, Norfolk; William Lees, Co. Down; and Alexander Lowe, Coltbridge Hall.

Pines were not numerous shown, but were in fine condition. There was a great display of Melons, and these were judged according to quality, although Mr. McIndoe's Best of All, which carried off the prize for green-fleshed, was handsomest as well. Only one bunch of Bananas was shown, but these were very fine. Space forbids us particularly noticing the other fruit classes, but we may say that the Apples were extra good and very numerous, although the naming was very faulty. Some of the most successful exhibitors in the minor classes were Messrs. A. Young, gardener to the Earl of Breadalbane, Taymouth Castle; N. Black, Darlington; M. McIntyre, Innerleithen; D. Murray; J. McIndoe; A. Bremner, Tranent; D. McFarlane, Peebles; John Brunton; J. Souza, Stirling; George McKinnon; G. Dewar, Fife; J. M'Intyre, Woodside, Darlington; George Maclure, Trinity, Gove; Alexander Dalgleish, Eskbank; J. Brunton, Gilmerton.

PLANTS.

Although three prizes of £5, £3, and £2 were offered for tables of plants 20 feet by 8 feet, only two competitors appeared. Both tables, however, were very good, especially the first-prize one, which excelled in graceful arrangement; the second was in the good old-fashioned style. In the classes for specimens were some grand examples of Heaths, Clerodendrons, and Eucharises. In the classes for Orchids, which were but poorly filled, Mr. Curror, Eskbank, had fine specimens of *Miltonia spectabilis* and *Cattleya gigas*, Mr. Paul of Odontoglossum grande and *Phalænopsis amabilis*; Mr. Grossart staging a fine piece of *Vanda tricolor*. The Ferns were mostly good, especially the *Adiantums*, *Filmy Ferns*, and dwarf British species. Among the latter we noticed delightful potfuls in the prize collection—*Woodsia hyperborea*, *Trichomanes radicans*, *Asplenium Trichomanes confluens*, *A. septentrionale*, *A. incisum*, *A. germanicum*, *A. fontanum*, *Polypodium elegantissimum*, *Blechnum spicant cristatum*, *Polypodium vulgare cristatum*, *P. cornubiense*, *Scolopendrium vulgare Baxterii*, and *Woodsia ilvensis*. These would form a capital collection for a beginner. Among the *Lycopods* Mr. Henderson's deserve special notice, his *Widenovii* being a remarkable specimen. *Crotons* were fairly good, *Eucharis* very much so in one or two instances, while *Zonal Pelargoniums* were only moderate, and *Fuchsias* below the average. *Tuberous-rooted Begonias* made a grand show, and the *Vallotas* were well bloomed. *Cockscombs* were very inferior to what they usually are in the north, where they are generally exceedingly well shown. The premier prizes in the leading classes were awarded to the following exhibitors:—Table of plants, 20 feet by 5 feet, for effect, Mr. R. Grossart. Six stove or greenhouse plants, in flower, distinct sorts (first prize by the Corporation of the City of Edinburgh), Mr. J. Paterson, Millbank. Three stove or greenhouse plants, in flower, distinct, Mr. J. Fowler, gardener to Mr. R. Paterson, Grange Road. One stove or greenhouse plant, in flower, distinct, Mr. J. Paterson, Millbank. Four Orchids, distinct sorts, Mr. A. Paul. Two Orchids, distinct sorts, Mr. J. Curror, gardener to Mr. G. Douglas, Eskbank, Dalkeith. Six Exotic Ferns, distinct sorts, not more than one each *Gleichenias*, *Adiantum*, or *Tree Fern*, Mr. Samuel Graham, gardener to Mr. Hugh Rose, jun., Kilravock Lodge. Four *Adiantums*, distinct sorts, excluding *farleyense*, Mr. D. Lawson, gardener to Mr. R. Croall, Craigmackay.

CUT FLOWERS.

In the gardeners' classes for cut flowers some very good examples were shown, *Gladioli*, *Hollyhocks* (in spite of disease), and *Dahlias* being especially fine. For twelve *Gladioli* Mr. Gray, gardener to W. Finnie, Esq., Newfield, Kilmarnock, was first with the following:—*Shakespeare*, *Sir Joseph Paxton*, *Camille*, *Amathée*, *Dunnet d'Urville*, *Fatima*, *Didon*, one unnamed seedling very fine, and two named *Miss Hill* and *Mrs. Finnie*, the latter having already had two first-class certificates. These, though fine, were hardly so good as Mr. Gray usually shows them, his strength being put out in the West on the same day. For the six Mr. Kilgour of Blair Drummond had remarkably strong spikes of *Ondine*, *Horace Vernet*, *Mrs. Finnie* (Gray), *Archduchess M. Christine*, *L'Unique Violet*, and *Shakespeare*. These were in magnificent condition and were greatly admired. *Hollyhocks* were in their way equally fine, especially the spikes and blooms which won the prizes for Mr. Kerr, gardener to W. Scott Kerr, Esq., Sunlaws. Among the spikes *Gem of the Yellows*, *Lord Middleton*, *Cygnets*, *Mrs. Boston*, and *Dr. Mackeyse* were truly superb. *Roses* were wonderfully good, but other cut flowers were far behind those shown the week previously in Glasgow.

Vegetables were shown in goodly quantity and very fine quality. The Leeks from Mr. Cairns, The Hirsell, of the Coldstream variety, were very large, those from Mr. Glass, Carbrook, being not far behind. *Potatoes* were in strong force and made a capital show. Some of the exhibitors seemed to think that a covering of dirt might help them, but it would not do; the brightest and cleanest won the day.

NURSERYMEN'S CLASSES.

As usual much of the success of the Exhibition as a show was owing to the efforts of the trade growers, although we have seen them in better form. Messrs. Ireland & Thomson's table was deservedly first, being brighter and better arranged than the others. Mr. Campbell of Gourock's thirty *Gladioli* were very fine, and similar to those staged by him in Glasgow last week. The *Roses* from Belfast and Aberdeen were conspicuous and attracted much attention.

Among the miscellaneous exhibits the most attractive was the wonderful display of single *Dahlias* set up in fan-shaped bouquets by Mr. Ware of Tottenham, London. Single *Dahlias* there were in plenty from different sources, generally shown as single blooms or ungainly bunches, but these completely cast all others in the shade. Out of some fifty sorts we picked

out the following as being certain to please our Scottish friends who may have fallen in love with the reigning beauty:—Union Jack, H. W. Pettitt, Rosalind, Pantaloon, Wanderer, Baron, Paragon, White Queen, Dr. Moffat, Emerald, and Juarezii of course. Mr. Robert Urc, of 70, Leith Street, had a most notable display of wreaths, crosses—partly artificial, partly natural. The Liverpool Horticultural Company exhibited a new *Adiantum* in the way of *concinnum latum*, but denser. The Lawson Seed and Nursery Company showed a table of miscellaneous plants and some good hand and breast bouquets, two of the latter made of Rowans, Snowberry, and *Salisburia adiantifolia* pleased us particularly. Messrs. Methven & Sons, Edinburgh; Smith, Stranraer; and Montgomery, Cardross, also exhibited interesting collections.

Cut Flowers.—Messrs. R. P. Laird & Sons staged collections of bouquet Dahlias and single Dahlias in bunches, Hollyhock and Dahlia flowers; from Messrs. Lamont & Sons, Joppa, came single Dahlias, one flaked crimson being fine; two pots of *Hyacinthus candicans* were shown by the same firm; Mr. Forbes, Hawick, showed boxes of border Carnations, pretty and useful for cutting, and single Dahlias, also very fine Pentstemons and Verbenas; Messrs. Cocker & Son, Aberdeen, had collections of Show Carnations and Picotees and a box of handsome Tea Roses. We understand the attendance of visitors was fully equal to the average, owing to the fine weather, and the Show was a decided success.

HARDY HERBACEOUS PLANTS.

Anaphalis triplinervia.—Probably one of the most handsome and interesting of the hardy herbaceous Everlastings when well grown. It came into cultivation in this country about the year 1823, but, like many more good old plants, it has become comparatively forgotten, though it has much to recommend it for the rock garden or the flower border. It loves a moist cool soil, and has proved one of the hardiest plants I am acquainted with. It has safely passed through the late three severe winters, a test for many hitherto hardy plants. It is of very neat habit, making dense tufts 8 to 12 inches in height, and is readily increased by division. Leaves about 3 inches in length, oblong, entire, and slightly decurrent; the upper smaller ones narrow, heart-shaped; branches and under side of leaves cottony, upper side dark green. Flower heads silvery white, in dense corymbs, afterwards loose and about 3 inches across. It comes into bloom about the end of July and continues throughout August, but its beauty lasts much longer owing to the persistent character of the flower heads, which remain until injured by autumn winds and rain. It is a native of Northern India, and grows at an altitude of 8000 to 9000 feet.

Tommasinia verticillaris (Koch).—Out of the 1300 species of Umbelliferous plants only a very small percentage are cultivated for their decorative character, the vast majority being useless for ornamental purposes. The plant in question, which is rarely seen in gardens, is one worthy of some consideration. In small gardens small-growing neat-habited plants only should be employed, but in large garden still growing noble foliage plants can be employed with marked effect. The old *Heracleum giganteum* has long held its own as a plant most suitable in relieving the monotonous appearance of many large shrubberies and borders. *T. verticillaris*, on account of its strikingly different foliage, would make a pleasing feature if associated with the *Heracleum*. It has much the appearance of the wild *Angelica*, but taller, more robust in foliage, and more floriferous, with its compound umbels of flowers on long peduncles in whorls along its stout purple stems, which reach to the height of 7 to 9 feet. It seeds freely, by which means it is increased. Native of Piedmont in Italy.

Polygonum affine.—This is better known as *P. brunonis*, but the first name is probably the oldest, and is the one now kept up in establishments of authority. It is still uncommon in gardens, though it could be easily procured from any respectable grower of herbaceous plants; but it is only when the garden becomes destitute of floral beauty that many plants can get credited for the good qualities they possess, and the plant now under notice is one of these. *P. affine* is now at its best, and ought to be liberally grown in gardens where a constant succession of hardy flowers is desired. We intend to make better use of it

Fig. 49.

here another season. One good mass in the garden is 2½ feet through, quite round, a beautiful flat green flake of foliage bearing a hundred of its beautiful spikes of flowers, which are a rosy-red colour, changing to a true red as they become older. A brief description of the plant may be of use to those unacquainted with it. The stems, which are rather woody and prostrate, are furnished with copious, alternate, finely serrated leaves, slightly acuminate, 6 inches in length, and barely 1 inch in the widest part, with a gradual tapering to the base, and stand erect. The flower stems, which spring from the previous year's growth, are 10 to 12 inches in length, furnished with small remote scarcely spreading leaves, and terminating in a dense spike of flowers 2½ to 3 inches in length. It is a native of the Himalayas, and commences flowering with us in August, and continues gay till stopped by autumn storms and frost. It is well adapted for planting in damp or wet places; indeed it is much more at home when growing under such conditions.—T. ENTWISTLE *Wood Lawn, Didsbury.*

SUBSOIL EXAMINATION.

IN answer to the query of "F. J." on page 208 about an instrument for examining the subsoil of gardens, I send you a sketch of a simple and efficient boring tool, which I had made several years ago when searching for stone for road-making, and which is admirably adapted for his purpose. The stem is three-quarters of an inch square solid iron above the union A, below it is 1 inch, and thickens slightly downwards to the top of gouge-like scoop, which is 2 inches in diameter and 16 inches long. The handle is in two pieces similar to C, each 20 inches long, which are screwed together with a couple of stout screws with eyelets like D, and the handle is screwed together very tight to keep it from shifting by a small iron bar passed through the eyelets. This kind of handle is very convenient for shifting up or down as may be necessary. The connection at A (fig. 49) is by means of a male and female screw, and the stem may be lengthened indefinitely for deep boring by adding more lengths with a male screw at one end and a female screw at the other.—EDWARD LUCKHURST.

WASPS DEVOURING UNRIPE PEARS.—Would some kind correspondent inform me if it is usual in other parts of England to find wasps attacking the late, hard, unripe Pears, devouring them so fast each year that I am obliged to pick crops long before the fruit is ripe? This day I have three fine fruits destroyed of a fine winter Pear. Next to it is an early very sweet fruit I shall gather to-morrow; this and my Bon Chrétien Pears are never attacked by wasps. In this garden for three consecutive years this has been the case—viz., all my finest unripe winter fruit is devoured if not gathered; the early-ripening Pears are not touched. We cannot put bottles to trap them on 200 or 300 trees as we do on a wall.—SAXORING.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Making Borders.*—Where it is deemed expedient to plant in early houses or to furnish new ones the borders must be prepared without delay, so that the trees may be planted at the close of this month or at the beginning of October. The border should be 36 inches deep, and the bottom incline to a drain, having proper fall and outlet, and 9 to 12 inches depth of drainage provided, placing the roughest at the bottom and smallest on the top, securing it with a layer of turves grass side downwards. The soil should be in a moderately dry condition and firmly. Good rather heavy loam four parts, one part burnt surface, and a part lime rubble thoroughly mixed together, form a suitable compost for all stone fruits. No manure should be added, as the trees will grow quite strong enough for the first half dozen years; and when a stimulant is required it is best given as a mulching, and the employment of liquid manure when the trees are swelling off their fruit.

Selecting Trees and Varieties.—An early selection of trees is advisable, making choice of those that are well furnished and that have not made a strong growth, but have firm short-jointed wood. The trees should be lifted carefully, preserving all their fibres, and kept moist until they are planted in the borders prepared to receive them. For an early house select Peaches Alexander, Hale's Early, Large Early Mignonne, and A Bec. The second house should comprise such standard varieties as Royal

George, Grossc Mignonne, Violette Hâtive, Belle Bauce, and Nohlessc. Late houses should have Bellegarde, Barrington, Stirling Castle, and Late Admirable. Of Nectarines for an early house Lord Napier and Hunt's Tawny; second house, Elruge, Violette Hâtive, Pitmaston Orange; and later houses, Pine Apple, Stanwick Elruge, Albert Victor, and Victoria.

Lifting Trees.—No trees pay better for lifting than the Peach. Operations of this kind in early and midseason varieties should be commenced without delay, the first consideration being thorough drainage, through which the water can pass freely. Commencing at the point of the border most distant from the tree stem, and working from the extremities of the roots inwards, all long and strong bare roots will be the better shortened back before laying in the fresh compost, which should be used in a moderately moist condition, so as to allow of its being firmly rammed to induce a fibry root-formation, and consequently the feeders.

Late Houses.—When the trees in late houses are cleared of the fruit, every lateral and shoot that will not be required for extending the trees or fruiting next season should be removed, so that the young shoots now swelling their buds may have the benefit of the increased light and air. The foliage must be kept clean and healthy by an occasional syringing and the prompt application of an insecticide, if there be any trace of red spider or brown aphid. The inside borders must be kept moist, as dryness at any time is prejudicial to the health of the trees and the retention of the buds.

CUCUMBERS.—*Plants in Bearing.*—These will now be considerably benefited by a top-dressing of three parts fibrous loam, preferably light, with one part of thoroughly decomposed manure, having previously removed the loose surface soil, but without injuring the roots. If the plants are dry at the roots they should be given a good watering, the water being tepid. Liquid manure should not be given until the roots are working freely into the fresh material, which they will soon do, and then it may be applied with advantage. Maintain a genial temperature during the day of 70° to 80°, and 85° from sun heat. Close early—from two to three o'clock—according to the weather, allowing an advance after closing to 90°. The night temperature should be kept at 60° to 65°. Ventilate freely in favourable weather, especially during the early part of the day, which will do much to keep the growth stout and the foliage leathery. Syringe the plants twice a day when the days are bright, but let damping suffice when the weather is dull.

Winter Fruiters.—Young plants which some little time ago were put into their fruiting quarters will be the better of a little fresh compost being added to the ridges or hillocks in such quantity as to cover the protruding roots. Similar remarks apply to those put out in pots or boxes. The plants have now reached the third or fourth wire, and being stopped, the laterals resulting therefrom should be trained evenly over the trellis. The treatment in other respects advised for fruiting plants is applicable to these.

Plants in Dung-heated Pits.—In order to keep the plants in a healthy and fruitful condition some time longer the linings will need to be attended to weekly or fortnightly as the condition of the fermenting materials and the state of the weather may determine. The plants should be examined weekly for stopping and regulating the growths, keeping it moderately thin, and removing had leaves and exhausted growth, as also knob fruit, which shows itself pretty abundantly on plants that have been some time in bearing, especially at this time of year, and seed-bearing exhausts the energy of the plants considerably more than anything else. When the plants require water let it be given sufficiently early in the day for the foliage to become dry before night. If mildew appear dust the affected parts with flowers of sulphur. Place a covering of mats on the lights at night.

HARDY FRUIT GARDEN.

Gathering and Storing Fruit.—The fruit of Apples and Pears should be frequently looked over and gathered as soon as it parts easily from the tree and the pips are brown—not sooner, for fruit gathered prematurely becomes shrivelled and flavourless. If left too long upon the trees early Pears are spoiled, and both Apples and Pears may then be swept from the trees by the first puff of wind. Much fruit is being spoiled by wasps, which are so numerous that they attack every exposed fruit. When gathering a heavy crop of Wormsley Pippin Apples on the 15th inst., we found several decidedly sour fruits half eaten by wasps driven from the more tempting wall fruit by Haythorn's hexagon netting, which is the best for the purpose, letting in air and light, yet excluding all winged insects. It must not be forgotten that wasps can crawl as well as fly, and they will make their way through any loose place along the top or bottom of the netting. We recently found some two dozen of them feasting upon Peaches, Nectarines, and Figs in our fruit-store, to which they had gained access by crawling through the keyhole. Brunswick Figs are especial favourites with wasps, but the large fruits are easily protected upon the tree by muslin bags. Let no careless person gather fruit—it should be put in the fruit-room without bruise or blemish, or it will not keep, and to that end must be handled carefully. Do not forget that the blossom bud of next year's crop is frequently close to the fruitstalk, and should sustain no injury. The frequent breaking of spurs that it has taken several years to form, which occurs during the fruit-gathering, may easily be avoided by the exercise of due care.

Root-pruning.—All fruit trees, but more particularly Pears and

Apples, that are excessively vigorous and bear little or no fruit should be root-pruned at once before the leaf falls. Mark a circle 4 feet in diameter around the stem, dig a trench close outside it, but only half way round it, deep enough to sever all roots on that side, and then work from the trench well under the tree, so as to prune all strong roots, then fill in the soil, and put a stay to the tree to prevent its being blown over. Enough roots remain in the undisturbed half of the circle to supply sufficient sap to keep the tree healthy. The pruned roots will contribute little or no sap till new rootlets are formed, and then only in moderate quantity for some time to come. Meanwhile fruit buds will appear. Little, if any, wood growth will come upon any of the lower spurs next year; foliage will, however, be sufficiently abundant to elaborate enough sap for the development of plump fruit buds, which will become much more abundant in the second year, and in the third year the tree should be bearing a full crop of fine fruit.

PLANT HOUSES.

Cleaning the Houses.—The season has again come round when the housing of tender plants must be attended to without delay. It is good policy to commence this operation by thoroughly cleaning the houses which the plants are to occupy. The glass inside and out, as well as the woodwork of the house, should be well washed with hot water and soft soap, the walls whitewashed, and the pipes blacked before they are filled with plants. It is important to have the houses clean before the plants are placed in them, so that every ray of light and sunshine possible can reach them during the declining months of the year. Preparation should first be made for those plants that have been occupying cold frames, but will not bear a lower temperature at night than 50° or 55°. This clears cold frames for the accommodation of less tender plants that have been standing fully exposed, and only require for some weeks yet protection at night from early frosts.

Poinsettias and Euphorbias.—These, as well as many other plants, such as Linums, Centropogon Lucianus, Plumhagos, and others of the same or similar character must without delay be removed from cold frames to light positions in houses where an intermediate temperature can be maintained. The two former especially soon show the effects of being starved at this season of the year, more especially if they are injudiciously watered. The leaves soon turn yellow and present a sickly appearance, which arises mainly from inactive root-action, which is very soon the case if these plants are subjected to too low a night temperature. To secure good bracts on dwarf plants of Poinsettias their foliage must be retained, or their heads will be small. Attention is also needed, on the other hand, after housing these plants, not to give them too high a temperature, or they will be excited into growth, and in consequence will be only poorly flowered specimens. Many plants of this description that have been carefully tended through the summer are rendered almost useless by too high a temperature in autumn. After the plants are housed we prefer the application of a little heat, with ventilation at night, in preference to applying it only when there is fear of the temperature falling too low. As soon as these plants commence forming their bracts and flower buds give them a supply of Standen's manure, which assists them wonderfully.

Zonal Pelargoniums.—Plants that have been standing outside all summer in preparation for flowering in the autumn and winter should now be placed under cover. They are now in good condition, but if left out much longer they will undoubtedly commence rapid soft growth through the damp nights and heavy rainfalls, which are frequent in many localities at this season of the year. After these plants are housed, if not wanted to come into flower for some time, keep the atmosphere of the house or pit in which they are placed moderately dry, and give abundance of air during the day; in fact, when very fine the lights may be entirely removed.

A batch of plants housed now and brought forward gradually will come into flower early in November, and will continue to produce trusses freely until Christmas, even if the house in which they are placed is only second-rate, provided it can be kept moderately dry and a temperature of 50° maintained. The double forms, where they are only required for cutting, should be kept by themselves if possible, where a little heat can be given them. These plants are very much benefited by being top-dressed when started to come into flower with a little good loam, in which has been mixed a little Standen's manure.

It is a good plan to strike a batch of cuttings in moderate heat at the present time, both single and double varieties. Place the cuttings singly in 3-inch pots, and when rooted pinch out the points of the plants, and winter them on a shelf close to the glass, where the temperature will not fall below 40°; if it can be kept 5° higher so much the better. These are ready for potting early in the year into 5 and 6-inch pots, and make, if taken care of, an invaluable batch for early flowering.

Bouvardias, Solanums, and Salvias of this description that have been planted out should be lifted without delay. The first-mentioned, after they are placed in pots, should be well watered and placed in cold frames and shaded from strong sun until they commence rooting. The others, as well as Callas and plants of a similar description, establish themselves best when placed outside on the shady side of a wall, where they can have protection if necessary. These plants must not be allowed to flag after they are lifted, and this can readily be avoided when stood out of the sun's rays and kept well supplied with water, and syringed frequently during the day. Do not expose them to the sun until they have commenced rooting, and then only gradually at first.

THE BEE-KEEPER.

WINTERING BEES.

A FORTNIGHT ago the readers of this Journal were advised as to the treatment of skeps in order to prepare them for passing through the winter. They were told to strengthen all weak stocks by joining to them the bees from stocks which were to be taken up, or from those too weak in numbers to be left to pass the winter. We have on former occasions tried to impress the necessity for strong colonies of young bees at the close of the summer season, and whether bees are to winter in skeps or in bar-frame hives the same rule holds good. Have your stocks strong. After the skep has thus been well peopled with bees, and it is seen that sufficient food is stored to give the winter supply, its outer protection should be attended to. Nothing is neater than the ordinary straw hackle well secured by a stout stake, and so made that all drip is carried away well below the floorboard. Entrances should be narrowed and so arranged that mice and other vermin cannot get into the hive.

With bar-frame hives, which are so much more directly under the management of the bee-keeper than skeps, autumn preparations differ somewhat. In Heather districts there will still perhaps be supers on the hives, and finished or unfinished frames of sections on the sides or at the back of the brood nest. The hive must therefore be overhauled, and all honey which can be spared taken away; where zinc separators have been employed these should be now withdrawn and wooden dummy frames put in their place. We purchased some time ago several sheets of Abbott's wooden foundation. These are of course well known to all practical bee-keepers. They are simply sheets of thin wood upon the faces of which have been stamped the ordinary wax foundation. The wood thus forms the midrib of a comb after the bees have worked out the sheet. We have found them to be excellent dividers or dummies for winter use. In order to prevent warping and sagging we have tacked strips of wood along the bottom and sides of the sheet, and let the top into a bar of wood similar to the top bar of our other frames. Strips of list or salvage of flannel fastened down the sides and along the bottom make them fit close, and at the same time easily. The bees have in many instances filled these sheets with honey and pollen, but even where the frames are empty the slugs of stiff comb act as capital dummies superior to the ordinary wooden ones with their hard cold surfaces. With these dummies we are also able to contract the space to be occupied by the bees to a minimum, since the bees can cluster in the cells should they wish to do so.

It will be readily seen that it is of the utmost importance to contract the space to be occupied by the bees in winter. Our modern bar-frame hives are so constructed that the bee-keeper has the means of almost unlimited expansion, and it is this power which enables the bar-framist to obtain such fine harvests of comb or extracted honey when the season is favourable. But when all these store-rooms are not required he must shut them off from the warm living-room where the unemployed workers are to be kept during the winter. The spaces previously occupied by frames or sections can be either left empty during the winter or filled with dry clean oat chaff. Our own hives are mostly constructed so that the frames may run parallel with the entrance during winter, and in these hives we draw the frames to be occupied by the bees towards the centre of the hive, placing a dummy with a slit at the bottom corresponding with the hive entrance in front of the frames, and so arranging a tunnel that the bees may pass in and out, placing over this tunnel and filling the space between the dummy and front of the hive with the dry chaff. Where cork chips are obtainable they are perhaps better than chaff.

We find that a very strong colony can be pressed into the space occupied by seven or eight frames. Over the top bars we place a sheet of ticking, and on this either several quilts of flannel or drugget, or, what is better and clean and handy, a chaff cushion, made by a framework of quarter-inch wood 2 inches broad—thus. Over the bottom of the frame we tack a sheet of canvas, cutting out F. All the compartments excepting F are filled with dry chaff, and another sheet of screen canvas tacked over all. We make a pad to fill up F when feeding is not required. A flap is left removable at pleasure in the ticking to correspond with F. We found that hives over which this cheap and easily constructed quilt was used last winter were perfectly dry and warm,

Fig. 50.

yet superfluous moisture can readily escape through it. When feeding is necessary over the pad is withdrawn, the bottle inserted on a zinc feeding stage, and cotton waste or bits of flannel pressed in round the body of the bottle to keep all warm, the flap in the ticking having been previously lifted. Where hives are kept under cover nothing further will be needed over the hives; but where they are kept in the open now is the time to overhaul the hive covers, to give a good coat of paint, and see that all is watertight from without, with ample accommodation for the escape of the moisture from within. Covers should never be so made that the inner part touches the quilts, otherwise the condensation will drip upon and be reabsorbed by them, and they will in the course of the winter months become a mouldy mass.

Much has been written and spoken against the use of wooden hives, and in favour of skeps as winter receptacles for bees, and undoubtedly the straw skep is better adapted to the welfare of a colony in the hands of one who wishes to give as little attention as possible to his bees; but where the extra care can be given the bar-frame hive (so much more suited for summer use, and for the obtaining of remunerative harvests) can be made as safe and as snug a winter residence as the straw hive. It is the careless and let-alone system adopted by many who have commenced and thrown up in disgust the culture of bees, that, but for the opposite testimony borne in their favour by careful and intelligent bee-keepers, would have brought bar-frame hives into discredit. With ordinary care and attention the bar-frame hive may be put into a condition which will bring the bees safely through the most trying winter. Damp is the great enemy to be combated. No amount of cold will work such havoc as damp or want of proper ventilation, and these are the enemies to be provided against. If the bees are strong, have sufficient food, and the instructions we have tried to give be followed out, then good results are certain to follow. The bees will be healthy and powerful in early spring, and will have a fair start for another working season.—P. H. P.

TRADE CATALOGUES RECEIVED.

- James Smith & Sons, Matlock, Derbyshire.—*Catalogue of Trees and Shrubs.*
 Thomas S. Ware, Tottenham, London.—*Bulb Guide.*
 Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Hyacinths and Tulips.*
 Daniels Bros., Norwich.—*Catalogue of Bulbs.*
 Arthur Jeffries & Co., Westerham, Kent.—*Catalogue of Bulbs.*
 Martin Grashof, Quedlenburg.—*List of New Flowers.*
 Dammann & Co., Portici, Naples.—*Catalogue of Vegetable, Plant, and Flower Seeds.*
 Cranston Nursery and Seed Co., Hereford.—*Catalogue of Bulbs.*
 George Neighbour & Sons, 127, High Holborn, and 149, Regent Street.—*Catalogue of Improved Bee Hives (illustrated).*

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (North Herts).—We know of no book on Roses by the author you name, and if there is one you would derive no more information from it than from those you possess. You might well add to your library the works of Mr. William Paul of Waltham Cross.

Digging, Trenching, and Draining (T. S.).—You will find full particulars concerning the cost of this work in the "Gardeners' Year Book," published at this office, price 1s., post free 1s. 2d.

Cranberries (G. J. B., Netherlands).—The Cranberry most used in England is the fruit of *Oxycoccus palustris*. They are largely imported from Russia for using in tarts, but not for mixing with preserves. The American Cranberry—most esteemed is the large round one produced by *Oxycoccus macrocarpus*, and called in America the Cherry Cranberry.

Sewage Water (F. R.).—It is good for everything, but probably weak

at times, because of the surface water draining into the tank. For all kinds of vegetables and flowers applied in summer it is invaluable. For Vines or plants in pots (but for the latter the water must be clear) there is nothing to surpass it, and hardly anything is so good. The same remarks apply to fruit trees, bushes, as well as other trees and shrubs. To grass land or lawns it may be applied in winter or wherever the ground is poor with nothing but benefit. But could you not lead the surface water into some other drain? then you would know the strength of the sewerage, and how to dilute it.

"Mushrooms for the Million" (J. S.).—The new edition of this work will be ready for publication in the course of a few days, and the price will be 1s. A number of copies of the first edition were sold in paper covers at 6d. each, but as the bound copies published at 1s. have given the greatest satisfaction there will be no further issue of the too fragile form of this treatise.

Root-pruning (S. T.).—The word "hoppers" in the article referred to should have been "loppers," an obvious misprint.

Ground Vinery (H. S.).—In the sketch given of this in "Vines and Vine Culture," the space you mark B is the bottom sill of the frame which rests on the bricks, there is no opening. The points A at the top are of no consequence, and may be cut off close if preferred.

Insects in Old Post (T. W. S., Lee).—Though it would be unwise to speak positively until the insects forwarded have emerged from their pupa state, we consider the Elm post you mention has been mined by the larvæ of a four-winged fly, one of the sawfly group, probably the species known as *Sirex juvenicus*. Their galleries often occur numerous in the wood of Pine and Fir, and occasionally they are found in other trees. Owing to their slow growth they are discovered now and then in wood which has not been suspected of containing living tenants; thus a posse of the flies has been known to appear in a sitting-room, having been hidden within the boards of the flooring, causing surprise or even alarm.

Mushrooms (A. L. T., Notts).—If the spawn is strong and the bed in proper condition Mushrooms usually commence appearing in about six weeks after the beds are cased with soil. Occasionally they appear a little sooner, but two months not unfrequently elapse before they are seen. We have known a bed to be spawned for three months before any Mushroom growth was visible, and the bed proved one of the most continuous bearers we ever had. You had better examine carefully a few of the lumps of spawn, and if the mycelium is spreading you will have Mushrooms in due time; if there is no appearance of the spawn running we should conclude either that it is not good, or the material was not of the right temperature or in the proper condition for its growth.

Mildew on Roses (E. H., Stockport).—Most certainly we do not consider you troublesome. We are ready at all times to give information when it is in our power to do so; but no one can tell you the cause of mildew attacking your Roses. It is mainly due to atmospheric influences that are wholly beyond control. You will, however, find modes of destroying, and, what is better, preventing it, in reply to another correspondent in our present issue. If your plants are dry at the roots water them copiously with liquid manure if needed.

Lifting Vines (S. B.).—You cannot do better than carry out your project of lifting at once, taking especial care that the roots are kept constantly moist during the operation. If you keep the foliage fresh by shading and syringing occasionally as may be needed, and the roots are good, the wood strong and ripens well, you may expect a moderate crop of fruit next year. It would be very unwise to crop heavily. You had better not use too much manure in the soil. If you intend planting young Vines in the inside border to which you allude, a width of 4 feet will be ample the first year.

Pipes in Vinery (G. E., Sussex).—We did not think it necessary to advise your altering the pipes, as we have seen the best of Grapes grown with the pipes even nearer the soil and stems of the Vines than yours are, due attention having been given to watering and mulching. Except for late Grapes it is generally best to allow the roots of the Vines to extend into a good outside border. If you will state the size of the garden under your charge, and the number of men employed, also give your name and address, we will answer your other question.

Making Mushroom Bed (J. W., Leeds).—The material sent by post was necessarily dried in transmission, and in that respect in very different condition from the bulk from which it was taken. It is of the right kind for growing Mushrooms, but whether it is too wet or impure or not it is impossible for us to say. No plainer instructions can be given on the subject than those in the treatise to which you refer. If you carry them out as exactly and intelligently you will, we think, succeed in your object. You have not carried them out exactly so far, as you will perceive if you peruse the chapter on preparing the manure on page 29 attentively.

Vines Unsatisfactory (Inquirer).—Your letter is mislaid, but you will recognise this reply. The examples sent in a small box are similar to many others we have seen, and no one appears to know the cause of the shoots shrinking and leaves shrivelling. One very good gardener is of opinion a too low and damp atmosphere followed by sudden and bright sunshine contributes to the injury, and he has found the Vines to improve by an increase of temperature. We have submitted examples to Mr. W. G. Smith, the eminent fungologist, and he replies as follows:—"I can make nothing satisfactory of these. I can only see that what you say is correct—cellular tissue dead, skin burnt, shoots shrivelled, a little oidium as well as the erineum (fungi), and a number of mites, possibly belonging to the latter."

Celery Fly (H. S. B.).—It is doubtful if there is any remedy when plants are "very much infested" with the grub. Remedial measures should have been adopted sooner. If when the first few blisters are seen the plants are regularly and frequently dusted with soot that will usually save the crop. We can suggest no other course at this late season than crushing the grubs with the finger and thumb. The attacks of the insect will soon cease now. It has been very destructive this year in many places. Early in the season several acres of plants were cut off nearly close to the ground and the tops burnt. These plants produced a fresh growth of leaves and the crop will be

good, but the heads not so large as usual. Also early in the season we saw the grub killed by petroleum; but as we cannot advise its use so late from the fear of its affecting the quality of the stalks we had better not state how it was applied at present. The plants in your herbaceous border have, perhaps, been attacked by the larvæ of the great crane-fly, *Tipula gigantea*. It is most difficult to eradicate. If you have any starlings near cherish them; they are the natural enemies of this garden and field pest.

Grapes not Ripening (H. S.).—It is not unusual for a berry or two at the points of the bunches of Grapes to fail to ripen even when the Vines are in good condition. In thinning Grapes many growers cut off the berries at the extreme point of the bunches when they observe the footstalks smaller than the others and of a lighter green. The non-ripening of a berry here and there is also, as you suggest, often the result of some slight injury to the footstalks. It is not a bad case of shanking, such as was referred to in answer to a correspondent on page 240 last week; still you will not err by perusing the reply in question. We are very glad to hear of your success in Grape-growing, and trust your Vines will go on improving, as the berries are not quite of the first size yet. Black Hamburg Grapes such as yours, if placed in the London market without a particle of bloom rubbed off, might, perhaps, realise 2s. per pound; if rubbed, as so many are in transit, they would sell slowly at 1s. per pound. Muscats are now being sold retail at 2s. to 4s. per pound, according to quality. It is not so much in growing Grapes for market as in packing them that so many persons reap disappointment. Quantities of Grapes arrive in London that can scarcely be sold at all, and certainly not at remunerative prices to the grower, through injury in transit by defective packing.

Mildew on Chrysanthemums (A Grower).—We do not think that the treatment to which your plants have been subjected has caused the "extra bad" attack of mildew. We saw a collection of wonderfully healthy plants last week in another district that had been top-dressed and watered exactly the same as you describe, and richer and cleaner foliage we never saw. The attack is no doubt due to atmospheric causes. Try mixing the sulphur in a solution of soft soap and apply with a syringe; if this fails try Ewing's mildew composition. Mr. Bardney prevents mildew attacking Peach trees and Roses by syringing with a solution of soft soap made as follows:—A lump of soft soap (about 2 lbs. or so) is placed in a saucepan and boiled for twenty minutes; this is placed in a large pot and mixed with five or six gallons of water. About half a pint of this solution is placed in an ordinary large watering-can full of water, and used every time the trees and Roses are syringed. Not a vestige of mildew is seen on the foliage, and the water does not injure the petals of the Roses. It would probably have the same effect if applied in good time to Chrysanthemums; perhaps he will state if he has tried it on these plants.

Soil (North Herts).—The soil sent is very adhesive clay, very unworkable in its present condition, and easily made worse by injudicious cultivation. In such tender-rooted plants do little good, because they cannot root into it. It is for this reason that your Roses fail in colour, and that La France thrives badly. In course of time heavy doses of manure will help the texture somewhat by furnishing it with humus, in which it is deficient; but this is not enough. The best way of permanently improving such soils is to burn part of them, and to mix this part with the staple. We have seen most intractable clays very much improved by this means. Another good way is to collect all the gritty matter possible, such as rakings from off public roads, sandy or gravelly soil, or even coal ashes, and to mix them thoroughly with the soil. Peat is good, not so much as either a soil or as a manure, but as a mechanical opener of the clay. London manure is also good if applied very liberally. It is very doubtful if iron would help your Roses, but the way to apply it is to give very weak solution of copperas in water. There is no danger of quicklime affecting the colour of your Roses on such a soil except for the better, and, failing a liberal application of burnt clay, you cannot do better than give a good dressing of lime. Possibly in trenching you did as the majority do, turned down any good soil you had and the bad up. Never touch such subsoils as yours, unless to dig them over and leave them where they are, and mix gritty opening matter with them. Gritty matter will open them, but if only broken up they will become puddle; better let them alone. In a week or two the amelioration of soils will be discussed by "Single-handed" in his chemistry articles, where you will find more information than can be imparted in a paragraph, but see next answer.

Planting Roses in Clay Soil (Idem).—If you have trenched down any good soil you had and turned up such clay as you have sent us, Roses will do little good if planted in it. The manure you have given is good for the purpose if very thoroughly mixed with the surface soil. If not, this is what we would do. We would gather every stick that would burn, or provide other fuel, and burn as much clay as would cover the beds 3 or 4 inches deep, and we would also provide leaf soil or other vegetable refuse, or screened town manure, or light soil, or peat, or all of them. Meanwhile we would dig the surface of the beds up very roughly, and allow the lumps to dry thoroughly. When dry we would either soften the lumps with water or wait till rain did it, and then would find it easy to knock them to powder with the fork. We would now spread the burnt clay, peat, manure, &c., over the surface, and thoroughly incorporate the whole. Such a soil after this would be worth 500 per cent. more than before, and anything would luxuriate in it; but still, if good light soil could be had we would put a little round the roots at planting time. Then we would make such a thoroughly pulverised soil, not hard, but firm; and we would never attempt to make a very smooth surface with the rake on such soil. Avoid this mistake and keep the surface gritty, cloddy, open. Never work such while adhesive with wet, and never dig in winter or autumn.

Mushroom Spawn (T. S., Notts).—Milltrack Mushroom spawn is that which is found in the accumulated manure of horse or cow stables. It used to be plentiful in the tracks of horses that were employed in working of mills and threshing machines in the olden time, hence its name. It is almost impossible to teach anyone to make Mushroom-spawn bricks except by example, and it is not unlikely you will err if you attempt to make a "large quantity." Try a small quantity first. The following is the plan described in the "Cottage Gardener's Dictionary," and is good when properly carried

out:—Take three parts of horse dung without litter, two of cow dung, one of decayed tanner's bark, one of sheep's dung, and one of good loam; mix to the consistency of mortar, and mould in small frames like those used by brickmakers, 6 inches long, 4 broad, and 2 deep. Three holes to be made half through the bricks an inch apart with a blunt dibble for the reception of the spawn. They should be put on boards for the convenience of moving abroad during fine days, as they must be made perfectly dry, which they often appear to be on the outside when they are far otherwise internally. Before they are perfectly dry they require great care in handling and turning from their aptitude to break; but in about three weeks, if dry weather, when perfectly dried they become quite firm. To pervade them with the spawn, a layer of fresh horse litter which has laid in a heap to sweeten, as for a hotbed, must be formed 6 inches thick in a dry shed. On this a course of the bricks is to be laid and their holes completely filled with spawn, and as the bricks are laid in rows upon each other the upper side of each is to be scattered over with some of the same. The bricks are not placed so as to touch, so that the heat and steam of the dung may circulate equally and freely. The heap is to terminate with a single brick, and when completed covered with a layer 6 inches thick of hot dung, to be reinforced with an additional 3 inches after a lapse of two weeks. The spawn will generally have thoroughly run through the bricks after another fortnight. If, however, upon examination this is not found to be the case they must remain for ten days longer. The bricks being allowed to dry for a few days before they are stored will then keep for many years.

Keeping Black Hamburgh Grapes (C. J.).—The Grapes that have been ripe now for six weeks will not keep so long as those that are ripened about this time, as the sun has much power in late August and early September, and acting on ripe thin-skinned Grapes, such as the Black Hamburgh, prejudicially affects them—not infrequently causing those that were jet black when first ripe to assume a reddish hue. When this takes place the Grapes are not only deteriorated in appearance, but the flavour is impaired and their keeping qualities considerably reduced. In order to insure Black Hamburgh and other thin-skinned Grapes keeping well they should be ripened beneath a good spread of foliage, yet not so crowded as to interfere with the free admission of light and air to the principal leaves. The Grapes not only colour quite as well, but the foliage prevents the sun from rendering them over-ripe, or at least prevents their losing colour—a sure indication of their days for keeping being numbered. As your Grapes have already begun to “mildew,” which we apprehend is to decay and become mouldy, we think they will not under any circumstances keep long, probably not more than a few weeks. We presume you are fastidious in removing decayed berries as they appear, the bunches being examined frequently for the purpose, and every berry in the least decayed removed. This is absolutely necessary. Instead of firing at night, as a rule you should have fires in the daytime, and then ventilate freely, the heat being afforded early in the day and turned off so that the heating medium becomes nearly cold before nightfall. A little air may be given at the top of the house, which will prevent the deposition of moisture through the night; but when the weather is wet the house should be closed day and night, a gentle fire heat being employed to keep the air buoyant, and if moisture accumulates on the inside of the glass admit a little air by the top and bottom ventilators to dispel it. A moderately moist atmosphere is not injurious to Grapes keeping, provided it is not stagnant. The temperature by artificial means ought not to exceed 50° at night, and above this in the daytime air should, whenever the weather is favourable, be freely admitted. It will be advisable to cover the inside border with dry mats to prevent the evaporation of moisture from it, and the outside border should be covered with shutters to throw off the wet. The Grapes will keep better after the foliage begins to fall if they are cut with as much wood as can be spared, and the shoots inserted in bottles containing clear rain water with a few pieces of charcoal in each, the bottles being fixed in an inclined position so that the bunches will hang clear of the bottles. A dry and cool fruit-room is a suitable place, the Grapes, from the more equable temperature, keeping much better than in the variable temperature and moister atmosphere of a vinery. We have cut excellent Black Hamburgh Grapes through December, and occasionally had very good bunches in January, but they were not ripened until towards the end of September.

Names of Fruit (Crockham).—Red Autumn Calville. (G. W. B.).—The Apple is Duchess of Oldenburg. The Pear is not ripe.

Names of Plants (W. M.).—Helianthus multiflorus plenus. (J. R.).—The plant is Siegesbeckia orientalis, a native of India, and introduced to this country about 1730. It is very troublesome in some places, increasing rapidly if not checked. (T. S.).—The specimens reached us in such bad condition that it was quite impossible to recognise them. (M. H. L.).—The Abele, Populus alba.

COVENT GARDEN MARKET.—SEPTEMBER 19TH.

MARKET quiet, with a steady supply of all classes of goods. English Pines in demand.

USE OF GREEN AND FODDER CROPS FOR VARIOUS PURPOSES.

THE value of green and fodder crops, including vegetables, will be determined and accepted under so many and such various circumstances, that it becomes a subject not only of great importance, but of such wide application for agricultural purposes, that it seems at first sight a subject too extensive and comprehensive for the pages of this Journal. But when we consider that many of the vegetables which will come under review have been treated of to some extent under the heading of their cultivation it will render unnecessary in some cases any lengthened observations upon their different uses. The home farmer in his position will, of course, admit of no exception, and therefore various remarks applicable to the case of farmers in general must be accepted by him also; at the same time we hope so to arrange our remarks and observations as to be worth the attention of landowners and their agents. It certainly is high time that all possible benefit which can be derived from the consideration of the agricultural interest should receive the full and ample advantage of any changes calculated practically to improve the cultivation of the land and the particular products included under the heading of our subject.

It is difficult to lay down any rule for cultivation of green crops and vegetables which shall be of general advantage, chiefly on account of the variations of soil, situation, and climate. There is, however, one thing which is beginning to make a strong impression on the agricultural mind, which may be considered the best prelude to beneficial change: it is this, that many of the former practices in farming have broken down, and that the sooner some change is made the better. We are, however, of opinion that corn-farming will, if accompanied with the production of other sale crops suitable to the soil and climate and extended over larger areas, be again made to pay in this country, and the point of rotation of crops, as well as of selection of products, will have to undergo a great change, some of which we have previously alluded to, particularly in this Journal, dating from the 19th of April until the 17th of May last, under the heading of “Ploughing-in or Feeding Green Crops.” It must, however, be accepted that the production of sale crops stand first in the rotation of cropping and cover the largest area, making stock-feeding as refers to sheep a secondary consideration, and that provision for them must under no circumstances be allowed to diminish the extent and acreage of the rent-paying crops in the arrangement or scheme for cultivation of the arable land. A general impression prevails in the minds of some of our largest sheep-farmers, and also of many writers who follow suit, and take it for granted that because many men of ample capital continue extensive sheep-farming, that the cereals and other sale crops are not profitable in cultivation. We must, however, refer to our own experience to support our opinions, whether they are in accordance with those of others or not; for although during a long number of years we continued to keep and feed not only a large flock of sheep, together with a dairy of cows and fattening cattle in the boxes, at the same time we were, perhaps, as fond of stock in connection with our farming pursuits as any farmer or amateur of the present period, yet we never allowed the green and root crops to prevail in extent sufficient to prevent an area of sale crops being produced quite equal to the payment of all the comparatively fixed charges of rent, tithes, and rates. To be able to do this farmers must discard the idea that sheep-farming is a necessity, when, in fact, it is frequently adopted by men of ample capital for

various reasons, which are not always within the reach of men who must farm for profit or lose their position in business, as so many have unfortunately done during the past seven years.

We will commence our observations with those green or fodder crops which are commonly grown after our sale crops, and seeded in the stubbles or eddishes of other productions. A most important green crop is Trifolium, of which there are three varieties, the growth of each being necessary to form a succession of the most valuable of all green fodder crops, but especially for farm horses, from the first week in May until the 20th of July. These consist of the earliest Crimson Blossom, the second early or Pink Blossom, and the last sort of a perfect white blossom; these are each of them when sown in good season very productive even upon inferior or strong soils, especially if 2 or 3 cwt. of bone superphosphate is applied per acre with the seed. This crop is a capital preparation for other and succeeding root crops when grown before Turnips especially, and also upon land which may have previously proved what is called Clover-sick, and when the red Clover has failed; we have, however, grown first-rate broad Clover if seeded for in the Lent corn or Wheat which has succeeded the Turnips, but this point we should certainly have disputed as at all likely if it had not been successful in our own practice. Again, Trifolium will furnish upon strong soils, either hill or vale land, a heavy bulk of green crop, well adapted for ploughing under as manure, and it may also be succeeded by a crop of white Mustard, the seed being sown after as fast as the land can be ploughed and worked down. Upon all outlying land, especially upon the hill strong soils, no manure can be more cheaply or more successfully applied under such circumstances. The two leading points in Trifolium cultivation are early sowing of a large quantity of seed, and we recommend not less than 25 lbs. of seed per acre, sown not later than the first week of September. The only enemy to this plant to be feared is the small white slug. As a green manure for ploughing under, it ranks very high both in bulk and value as a preparation for cereal crops. This Clover is well adapted for conversion into ensilage, and for consumption by dairy cows or fatting bullocks under a well-considered mode of feeding with cake and bean or barley meal combined, will answer a good purpose and prove a valuable substitute for roots, and not likely to injure the quality of milk or butter. When the Trifolium is placed in a well-constructed silo just as it is coming into bloom it will be found much superior in feeding value than when converted into hay, and without the risk of loss from bad weather. Where the land is situated near to towns, Trifolium is of ready sale at a price far beyond any value obtained when converted into hay.

Lucerne next demands attention, and as a forage crop it offers a favourable return for cultivation, and should obtain a place in the list of permanent green forage crops, because it will produce annually a succession of valuable cuttings of the most nutritious cattle food adapted for all kinds of stock. The great benefit derived from the use of this fodder in the green state is the fact of its not only affording a very early produce, but its continuous growth until winter sets in. During the period of growth each cutting comes to maturity for fodder very rapidly, but still in proportion to the warmth of the soil and the climate, but at the same time the most produce or weight per acre will vary according to the natural fertility of the land or manures applied to it, and although heavy crops may be obtained by liberal manuring, yet it delights chiefly in a deep soil.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour in some districts will still be required in connection with harvest operations. Wherever the harvest has been completed the seeding of Trifolium should now be done, the sooner the better; the preparation of the land for the seeding of Rye, Vetches, and winter Beans will now be going on. Where steam power is available it should now be in constant work, cultivating both in preparation for the green catch crops as well as the land to lie as autumn and winter fallow for various purposes in the spring; not only for seeding with Lent corn, but in forwarding the preparation for early seeding of root crops, such as Mangolds, Carrots, Cabbage, and Turnips. After the land has been cultivated lengthways and crossways and has been worked down the couch and weeds may be carted off to heap, there to remain, and when decayed may well be formed into compost for the application to grass land and meadows. Upon various mixed soils, however, which is given to couch and weeds in the month of November before the winter ploughing takes place, women should go over it fork in hand and lift those bunches of couch grass, black bent, and Onion grass and place it in heaps, to be removed by the odd horse as fast as ready. This is especially necessary in all cases where the land is intended for planting with Potatoes at the earliest period in the spring; in fact before ploughing and planting in the spring the women should look over the land again, forking out any lumps of couch which may have grown into notice. As a rule, and in all cases except where there is a rug of couch, women

should during the late autumn and early spring months go over all the fallow surfaces on the farm and remove the lumps of couch. Now this is possible in every season, and may be done except during frost or snow. Whatever the expense may be it is sure to be the cheapest as well as the most effective method of ridding the land of these weeds, which are the greatest enemies the cultivator has to contend with. At the same time it must be remembered that forking out couch is possible in all open weather, and the growth of it may be kept under; but by horse labour only employed in extirpating couch, an open dry time is the only chance for horse labour to be effectually employed in the work of cleaning the land; but in case of a wet spring, such as in our fickle climate often occurs, it is not only impossible, but must still remain a dead weight on the culture of the farm for the future. And further, it will not remain *in statu quo*, but like all ill weeds will grow apace. Laying out farmyard manure upon the Clover leas to be ploughed in for Wheat is going on in every direction on all well-managed farms, and very properly so, especially upon strong and flat-lying loamy land; for by early manuring and ploughing-in the land will be getting mellow and stale, and promising a good tilth at seed time. In some cases where there is fallow land to come in for seeding with Wheat it is often a safer plan to have the ridge-ploughing done as fast as the dung is laid out and spread, leaving the dunging and ploughing the lea ground for a later period, as Clover leas can be ploughed any dry day and sown daily, or the seed may be drilled with a drill attached to the presser, so that the process may be completed as fast as land is ploughed and pressed; and for a late seed time this is the safest plan. The pressers may now have a drill attached to them at little expense by the implement makers, the cost being only £4 10s. for a two-ringed presser, and £7 7s. for a three-ringed implement; and the Wheat when drilled in this way—the seed being buried at the bottom of the groove formed by the ring of the presser—is not likely to be lifted by frost in the winter or spring, and besides this the land can also be horse-hoed should it be required, as the rows of corn will be about 10 inches apart. We well recollect that during the severe frost in January, 1879, that on various farms the Wheat drilled after the presser proved a full plant, while great deficiencies were the result of ordinary shallow drilling of the seed.

Hand Labour.—Spreading yard manure on the fields as fast as laid out both on the lea or fallow will be going on. Hedge-trimming and border-cutting will now be continued until finished; the border grass and weeds if preserved will prove useful in the covering of roots when stored in heap. The home farmer, too, must look to the plantations and woodlands where the grass and weeds often grow and seed with impunity. It is, therefore, desirable to cut and utilise the proceeds in the same way as covering for root heaps. The odd horse or mule, when a strong lad is appointed to go with him, is capable of doing much good work, which becomes valuable in keeping up the decency and appearance not only of the farm homestead and rick yards, but also the constant cartage of couch and other material, each contributing value to the earth or manure heaps as may be required. The odd horse and his attendant may also be employed in carting grass for horses without hindering the teamsmen in a busy time, and the carting of roots, hay for fodder, straw as litter for dairy cows and fatting cattle, should always be done by the odd horse and cart; in fact, on a farm where the labour of men and horses are well and thoughtfully appointed, the odd horse may be said to save the breaking of pairs of horses in their labour, and be reckoned as valuable as the work of any horse on the farm.

OUR LETTER BOX.

Canary Moulting (*Savoring*).—Your bird is moulting now, which is one cause of its losing its feathers. Give it two spots of castor oil into its beak, and feed only on canary seed and a plentiful supply of green food quite fresh every day, lettuce or watercress is the best. Put a bath in its cage, and if it bathes every day it will help the new feathers to come and lessen the irritation. This is the proper time for moulting.

REMARKS.

9th.—Fine bright day, but generally a little hazy.
 10th.—A dull day, with almost continuous slight rain.
 11th.—Wet and misty all day.
 12th.—Dull morning, fine afterwards.
 13th.—Dull early, fine afterwards.
 14th.—Fine, bright, and warm.
 15th.—Fine and warm, hazy towards evening.
 Temperature higher than last week, and rather above the average. The mornings have been very damp and misty.—G. J. SYMONS.

WATER LILIES.

THE summer that is now rapidly closing has been an unusually favourable one for most plants, and especially so for the Water Lilies both indoors and out. The bright warm weather experienced in the spring and early summer caused Nymphaeas to make a vigorous start, instead of the weak, slow, and unpromising beginning they make in a dull and cold spring, such as we too frequently experience now-a-days. If Nymphaeas have been properly wintered and replanted in the early spring in a rich lasting soil in large-enough pots, such a spring as we enjoyed this year is bound to do all that is necessary to make them strong and healthy in foliage and prolific in blossoms, given, of course, the other conditions essential to the welfare of aquatic plants. To many the possession of proper convenience for the cultivation of Nymphaeas, and especially of the tropical species, is denied; and although it is possible to grow some of them and flower them fairly well in tubs, the plants never look at home, nor are they so attractive as when surrounded with something like what we find naturally associated with Water Lilies. It is only in such tanks as Kew, Chatsworth, Oxford, and several other large gardens possess that the indoor cultivation of Nymphaeas on a large scale can be successfully carried out.

Where, however, only a few, or perhaps a solitary plant, can be grown in a stove with other plants, a little difficulty should by no means deter amateurs and others from a trial of their skill, as it furnishes an additional source of interest, and when in flower will vie with the most beautiful occupant of such structures in attractiveness. For this purpose the less vigorous forms are the most suitable.

There is much to be done in the way of establishing Water Lilies in our lakes and streams where they would grow, and especially in establishing some of the exotic species, the hardiness of which is beyond doubt; for in addition to our own white Water Lily we have the North American *N. odorata* and *N. tuberosa*, both robust large-flowered kinds and as sweetly scented as our native one. These would prove perfectly at home wherever the water is deep enough and sweet enough for them, and so would the rose-coloured variety of *N. alba*, of which we know little at present, but which is destined to become a beautiful ornament among hardy aquatic plants. *N. odorata* var. *rosea* is yet another recently introduced Water Lily of the most delicate grace and beauty, and is well adapted for cultivation out of doors in this country. Of all Nymphaeas the last is perhaps the most beautiful, its well-formed flowers, delicate flesh tint, and delicious scent being of the most exceptional excellence even amongst the many beauties of its kind. At present it is so rare that few, if any, of its possessors have ventured to place it out of doors altogether; and yet, judging from its native habitat, there can be no doubt of its hardiness. Lastly there is the yellow-flowered species, *N. flava*, whose *début* at Kew was so complete a success two years

ago, and its distinct colour and well-formed flowers have won for it universal admiration. Hardy enough it is, but so precious that—as is the case with the rose-coloured *odorata*, so it is with this—we like to keep it in a pot under our eyes for fear of an accident. At Kew several plants have been planted in the lake and in the pond, and these are doing very well. Deep planting is necessary for this species, and, in fact, for all Nymphaeas out of doors. The tubers should be safe from the severest frost, and then all fear of death in the winter is at an end.

An interesting fact in connection with these plants, and the readiness with which they adapt themselves to altered conditions as regards temperature and light, may be observed in their thriving well in a tropical tank, and that for year after year, without any apparent debilitating effect. At Oxford the whole of the hardy ones are grown in the warm tank along with the tropical kinds, and at Kew some of the former are perfectly at home along with natives of the Nile and the Ganges regions. A knowledge of this accommodating nature enables us to understand the wide geographical distribution of many of the species of Nymphaea, and although the characters of the species may be slightly modified or altered under different conditions, the general resemblance is always manifest. It is very desirable that the skill of the hybridiser should be brought to bear on these plants with a view to procuring some of the blues, purples, and reds of the tropical kinds into the hardy ones. There seems no reason why by a careful selection such work might not be accomplished, and that it is worth doing will be apparent to those who are acquainted with the bright colours of the tropical Nymphaeas.

Of the species the requirements of which can only be met in a tropical house with specially constructed tanks it would be easy to fill pages in praise of their beauty, and in descriptions of the characters and requirements of each. Few plants reward careful cultivation and observation more fully than these. From the pure white sweetly scented and gigantic flowers of *N. Lotus* var. *dentata* to the blues and deep purples of *N. stellata* and its vars, which include the new *N. zanzibarensis*, down to the small button-like flowers and Frog-bit like leaves of the little Indian *N. pygmaea*, we have almost every shade and form. Some of the forms of *N. Lotus* have been crossed with each other, and have yielded the large flowered, deep-scarlet forms known as *N. devoniensis*, *N. Ortgiesiana*, and *N. Boucheana*—magnificent Water Lilies, large-leaved, strong-growing, and very floriferous. The sturdy character of hybrids is shown in these as in almost all other hybrid plants, and points the way to much greater results from skilful hybridising than any reached hitherto. *N. zanzibarensis* is the latest fine introduction to cultivated Water Lilies. It is beyond question the handsomest of the blue-flowered forms, surpassing the giant blue *N. gigantea* from Australia in its thriving much more satisfactorily under ordinary cultivation than that species.

N. stellata is a very variable species, including those plants known as *cœrulea*, *capensis*, *versicolor*, *cyanea*, *scutifolia*, *micrantha*, and the Zanzibar variety, the prevailing colour in the whole of which is blue in its various shades. It is remarkable that the flowers of the whole of the *N. stellata* forms open wide about noon and close in the evening, whereas the forms of *N. Lotus* open late in the evening and remain fully expanded until noon of the following day. It may be noted that the flowers of the Victoria Water Lily also open in the evening at about six o'clock, and remain open until the evening of the day following.

There is always some difficulty in keeping Nymphaeas through the winter. Some cultivators prefer drying them off in the autumn and preserving the tubers in sand until the following spring. This treatment often results in dry rot, similar to what occurs to Caladiums and other tuberous-rooted plants when treated in this way. My experience leads me to prefer keeping the plants in the water the whole winter through—a much safer method than the former, but

perhaps a little less economical in respect to fuel and space than the drying-off plan. Finally I would recommend abundance of sunlight, plenty of ventilation, and clear and if possible running water for all tropical Water Lilies.—W. WATSON, *Kew*.

GRAPES SHANKING.

NOTWITHSTANDING that one or two persons who have nothing more to learn on the subject of Grape-growing complained some time ago of so much of your space being occupied with matter relating to it, queries come thicker than ever, as may be seen by the answers to correspondents every week. The point which most puzzles both amateurs and professionals is shanking, and although many able articles have been written on its cause and prevention there is still something of a mystery about it, and it probably occurs more or less in ninety-nine vineries out of a hundred in this country.

A correspondent says that, by closely following the advice given in a treatise which lately appeared in these columns, he is now able to colour his Grapes. He has no pink ones, such as he formerly had, but still many of them shank after they are coloured. His border is outside; he has a good depth of soil, which is well drained by a good fall from the house; he has good foliage of a dark green colour and leathery texture, but still his bunches are rather small, and he is annoyed by a considerable amount of shanking.

It so happens that there are two cases very similar to the above which I have been called upon to inspect and give advice on during the present season; but although appearances are alike, I believe both cases are not exactly the same. One border where shanking occurred has been already operated on. It was found to have been very carefully made, but rather too porous, and I have no doubt that at times it has been too dry. It contained a great quantity of what are generally called roots, but which are really, as "Single-handed" puts it, "underground stems" clothed with decayed and decaying bark. Feeding roots with greenish tips and bristling with hairs were scarce; but still there were a few, just sufficient to prove that there was nothing deleterious in the soil, and these were of very recent formation.

The plan adopted was to cut a trench 7 feet from the front wall and 3 feet wide (the border was previously 17 feet wide), severing scores of stems thicker than one's thumb, clear out the drainage and relay it in the bottom of the trench, place a layer of turf over it, then fork down another 2 or 3 inches on the side of the trench nearest the house, and cut all the roots through close to the soil with a sharp knife. The trench is then filled up with some new turf tumbled in roughly and fresh as it was dug up, with some of the best of the surface soil from the part of the border which is cut off to fill up all interstices. A liberal sprinkling of half-inch bones and a still more liberal one of old lime rubbish are given to every 4 or 6 inches of soil, and where the new soil meets the old on the side where the roots are cut with the knife it is trodden very carefully and firmly, so as to prevent the possibility of a crack for the water to escape. Great care will be taken of the foliage, and for a time all growth wherever formed will be encouraged, and as soon as the fruit can be cut the house will be kept rather close and moist, but not so much so as to unduly excite the lower buds which have to produce fruit next season.

The other case which has come under my personal notice is probably a case of the Vines being buried too deep and the border being water-logged. That remains to be proved. But the plan of commencing operations would be very similar; only if I found the soil was sodden and sour, I should after cutting the trench and securing good drainage remove the greater portion of the remaining soil, notch freely the old naked roots, and lay them in something sweet and tempting made very firm—say a mixture of partially decayed loam, lime rubbish, half-inch bones with a little wood ashes or charcoal, and a little road grit or coarse sand, placing rougher and more substantial soil under and above them.

All this sort of work must be done while there is plenty of healthy foliage to induce immediate root-action. If the borders are outside it should be done not later than the middle of October, and September is better still. In some cases where the Vines have not many fibrous roots it may be necessary to shade the foliage for a time from bright sunshine, and if the fruit is cut it is advisable to keep the house well damped down.

I would again urge on all cultivators the necessity of getting their Vines perfectly clean before the foliage falls. Insects and parasites are much easier to kill now than they are when in a semi-dormant state during winter, and spring we know brings plenty to do without insect-hunting; besides at that season, owing to the foliage being tender, such drastic measures cannot be used.

There is, I believe, still nothing so good for the purpose as petroleum, and when the leaves are tolerably hard they will bear two

ounces to the gallon of water used in the way so often described in this Journal—*i.e.*, one syringeful forced violently into the pot, and another in the form of the finest spray on to the plants. The syringe should be used with the tube, not the rose, and the finest possible spray is made by pressing the first finger of the left hand on the end of it.

The petroleum-and-soap mixture is as much used as ever, but not on paint or glass.—WM. TAYLOR.

PROPOSED INTERNATIONAL EXHIBITION OF VEGETABLE PRODUCTS FOR 1885.

I HAVE read with much interest and satisfaction the comments which appear in the *Journal of Horticulture* of this date (September 20th, page 247), and fully concur in most of the suggestions contained therein. Before commenting generally on the article before me, I think it right to explain why the two contradictory announcements appeared in the *Journal* referred to. I had sent a letter to each of the horticultural papers conveying the intelligence that the proposed International Exhibition would be held next year. A few hours after I had dispatched that intelligence I received the letter, a portion of which appears at the end of the article before me. Directly I received Mr. Birkbeck's letter of the 13th I at once telegraphed to each of the *Journals*, but my message only appears to have reached two of them in time to stop the publication of the letter.

The horticultural resources of this country I maintain are amply sufficient to fill all the space now occupied by the Fisheries Exhibition at South Kensington, but I readily admit that if confined to horticultural products alone, the public might tire of the display; but add the vast number of other available exhibits so graphically suggested in the article before me, and the measure is more than full, and contains abundance of subjects to gratify the public, and will contain sources of instruction for all.

I am thoroughly of opinion that a continuous display may be kept up and fully maintained from the middle of April to the end of June, and in that case valuable collections of such plants as Orchids need not remain on exhibition longer than three days; these could be easily replaced by other plants of equal interest, the change inducing visitors to the Exhibition to repeat their visit. The same thing would occur all through the first part of the Exhibition. August might be allowed to pass without any exhibition of tender plants and flowers; it would only be a question of timely arrangement to fill the space with implements and horticultural sundries, and these in turn could be removed to other positions to make room for autumnal flowers and fruits during September and October, to be followed in November by a grand display of Chrysanthemums, fruits from the colonies, and numerous hardy plants suitable for winter decoration, horticultural and agricultural roots, &c. No doubt the numerous Chrysanthemum and other kindred societies would amalgamate if properly treated with, and the prizes they offer severally might, with the prizes the Fisheries Committee should offer, become a common fund for the benefit of all exhibitors. The same reasonable suggestion should apply to all exhibitions held earlier in the year, the Royal Horticultural Society joining in the same way with the amounts they offer every year in prizes for their shows, they alike participating in the benefit that would be gained by the amalgamation. In this way a sufficient fund could be produced to cover all expenses, and so enable the conductors of the Exhibition to organise the finest and most comprehensive and instructive exhibition of horticultural products the world has ever seen. A portion of the proceeds could be applied for the founding of a horticultural college, and institutions for decaying and decayed horticulturists.

The buildings being all ready for the purposes of the proposed series of exhibitions, an enormous expense is saved, and with a continuance of the evening fêtes which have proved such an attraction this season, success will be certain. In succeeding years the fêtes will no doubt be earlier, during the height of the London season.

I have had frequent opportunities of seeing during the past month how much the public appreciate the gardens under the present arrangements. The crowds which nightly go there are of the most orderly character, and I think the fact of not a single police case having been reported since the Exhibition opened speaks volumes in favour of nearly two millions of people as well as the careful management under which they are controlled. All this offers a guarantee for the success of the promised horticultural Exhibition, and proves that no doubt need be entertained of its proving a great success. The great thing needed now is a speedy, formal, and definite announcement by the International Fisheries Committee that the Exhibition shall take place during the year 1885, and that full details shall be furnished with as little delay as possible.—JOHN WILLS.

HARDY HERBACEOUS PLANTS.

GERANIUM TRAVERSII.—Of all the species of Geranium that have as yet come into cultivation *G. Traversii* is probably one of the most remarkable. *G. armenum*, *G. ibericum*, *G. Endressii*, *G. pratense* flore-pleno, and one or two others stand pre-eminent for general decorative purposes, but *G. Traversii* is distinct in its habit of growth, and is most adapted for the rockery. It is perennial, forming a rather dense crown of leaves of a silvery hue, especially in their earlier stage of development. The fully developed leaves are 3 to 4 inches across, round, and cut half way down into seven three-lobed segments, with a petiole 6 or 7 inches in length. The flowering

stems which radiate from its tufted crowns are 12 to 18 inches in length, very slender, and several times branched—dichotomous—are prostrate, and furnished with small reniform leaves under to over 1 inch across, cut in the same fashion as the larger ones, with the petioles varying in length from 1 to 1½ inch. From the axils of the opposite leaves spring the flowers solitary on pedicels 3 inches in length, the colour being light rose and pencilled with purple. It commences to bloom in early summer and continues till autumn. I have lately gathered a few ripe seeds. It is a native of New Zealand, and is almost the only perennial species that has been introduced from that distant region to this country. It bears our English climate admirably, but being a somewhat recent introduction it is as yet practically rare.

ANAGALLIS TENELLA—This modest little denizen has afforded me much pleasure this season, simply from the fact that it has succeeded very well—so well, indeed, that I think it scarcely possible for the plant to be met with even in its wild state in a more luxuriant and floriferous condition than which it is in one of the compartments on the rockery here. It is not a rare British plant, but somewhat local in its distribution. In some districts it is common, in others sparingly represented, and in others quite wanting. It is usually met with on heaths and moors in wet places, growing amongst short grass and other scanty vegetation, on wet banks, borders of streamlets, and in boggy ground. The best example I have seen in a wild state was in County Clare, Ireland, and not very far from the sea, but off the limestone. It grew on a bank from which water was continually dripping, and fully exposed to the sun. It was here in its best form, a glow of rose-coloured bloom, the foliage being almost hidden. It is a low growing plant with creeping slender stems, rooting at every joint, and furnished with small, opposite, shortly stalked leaves, one-quarter of an inch across and between reniform and orbicular in shape. From the axils of the leaves spring the rose-coloured flowers, which are borne on short wiry stems, are bell-shaped and delicate in texture, standing erect, and are about a quarter of an inch in diameter. With regard to our cultivated example, I may add that the flowers were so abundantly produced as to almost correspond with the number of leaves on the plant, and the sight produced was one sufficient to compel the admiration of all who saw it. It was at its best throughout the greater part of July, and it was remarked that it was one of the handsomest plants that had flowered on the rockery. If it came from Labrador, Tasmania, or some other distant region, and was difficult to grow and propagate, it would be highly prized and eagerly sought after by lovers of alpine and rockery plants. Contrary to this, it grows at home, is easily procured, and easy to grow when its requirements are understood. In a garden where a swamp or spring exists its requirements are met at once. It is, however, not absolutely requisite that such conditions should be at hand, as a miniature artificial bog may be contrived for its reception. In our case a saucer not 2 inches deep and filled with loam and sand was employed, peat being objected to on account of its being more liable to turn sour. The saucer was sunk in one of the compartments on the rockery and well supplied with water in hot sunny weather, and the result was that the plant quickly spread over the rim and filled every corner of the compartment allotted to it. Owing to the saucer being shallow, and the roots of the plant being able to reach to the bottom, the soil does not become stagnant, as the moisture passes off by absorption, but is assisted by evaporation.—T. ENTWISTLE, *Wood Lawn, Didsbury.*

POTATOES.

I AM rather amused at "H.'s" experiences in Potato-growing and the unpleasant result which follows his Potato trials. His enthusiasm begins to cool down by midsummer, and by digging-up time is changed to disgust. "These experiences nearly always result in the following conclusions and resolutions—never to grow a long-topped Potato in the garden again, and never to grow an American variety in the garden, let it be ever so much praised, and never to indulge in more than one novelty in the season." If "H." has arrived at these conclusions after a fair trial why does he not keep to them? There is this to be said about the long-topped Potatoes, that they have been more grown lately than others, because the vigorous growers are, as a rule, more free from disease, and the short-topped new varieties have been somewhat neglected, but I hope the necessary attention will be devoted to them. I have a short-topped seedling which I grew for five years entirely without disease, and which ripens before the *Magnum Bonum*, and which I may introduce to general cultivation some day, but I will not say any more in its praise lest "H." should be induced to try it. The long-topped varieties do not run up so high when they are grown without manure, and they require a little more room between the rows. Short-topped varieties, which are also good disease-resisters, will be produced if there is a general demand for them.

With regard to the American varieties, perhaps "H." would do wisely not to grow them if he has a strong soil, which I expect to be the case. They are calculated for warm dry soils. There is a wonderful difference

in the quality of Potatoes made by the soil in which they are grown and surrounding atmospheric circumstances, and those which are good in one place are almost uneatable in another, and that is one cause of the large number of varieties in cultivation, and the disappointment experienced by some people on the trial of a new Potato. There is also a great difference in individual taste about what is a good Potato. Some people like a very dry floury Potato; I do not, but prefer rather a moist floury one such as *Milky White*. Others, again, like a firm eating Potato such as *Magnum Bonum*, and I know one gentleman who likes Potatoes which are commonly called waxy, but I believe he is rather the exception. The American *Early Rose* is not good on some soils, and writers have gone so far as to say that they did not believe one was ever grown in this country which was fit for anything but the pigs; but that was a great mistake, for it is very good on the land here, and we are eating them now every day in preference to others. In speaking of American varieties, it must not be forgotten that without them there would have been no *Magnum Bonum*, for the latter is a seedling partly raised from the former, and without this Potato and the aid of another or two, we should not have been able to supply ourselves with Potatoes of our own growth, instead of sending about three millions of money to foreign countries. I have a seedling of the *Magnum Bonum* which is very promising. It appears to have all the cropping qualities and freedom from disease of the original, but is a little more regular in shape. This will be good news for those who believe in the degeneracy of the tuber, and think the *Magnum Bonum* will inevitably collapse with the disease before long, because there will be another to supply the place of it.

Besides my own seedlings I have grown ten varieties of Potato for the purpose of experiment, and have found the result very interesting and the opposite of that experienced by "H.;" but I go a different way to work. I only plant a peck of each, and do not introduce any to the main crop unless I approve of them. Perhaps some of your readers may be interested in hearing the result of my experiments, which will form the subject of another letter.—AMATEUR, *Cirencester.*

GLADIOLUS COLVILLI THE BRIDE.

WHERE choice flowers are in constant demand for cutting during the spring and early summer months the above should be grown in large quantities and brought into flower in succession as required. The flowers being pure white, they are most useful in a cut state when wired for bouquets, or the whole spikes can also be cut, and are admirably adapted for associating with other cut flowers. Independent of its use and beauty in a cut state, it is invaluable when grown in 5-inch pots for the embellishment of the conservatory or greenhouse. When in flower a number of plants freely associated with other dwarf plants have a choice and conspicuous appearance.

The bulbs of this variety can be obtained any time next month, and should then for early flowering be potted without delay for an early batch. In places where bulbs were forced into flower last spring, have been judiciously treated since, and are strong, potting should be done at once. This will secure a month at the start, which is a great advantage when these flowers are required as early as possible. Drain the pots liberally, and place four or five bulbs in each pot, and if strong they will produce at least seven or eight spikes of bloom. If the flowers are grown solely for cutting, pots of any size can be used. The bulbs should be covered with from half an inch to an inch of soil. If the soil at potting time is moderately moist do not supply water until they commence rooting. Almost any soil will grow them providing it is rich. We have found good loam, a seventh of decayed manure, and coarse sand to suit them well.

After potting place them in a temperature of 50° to 55°, and if possible plunge them in cocoa-nut fibre or other material, merely covering the rim of the pots. Where this can be done no water will be needed until the growths make their appearance through the material in which they are plunged. A good plan is to plunge them until they commence growing in slight bottom heat derived from leaves or other fermenting material. A bed can be made in a cold frame and the plants plunged into it, and the frame kept close until their shoots can be observed, when they should be taken out and given the temperature mentioned above. When allowed to start under cool conditions time is lost and forcing is needed during their latter stages of development. This is a great mistake, as they should be allowed time when fairly well developed, and allowed to expand under as natural conditions as possible. After growth has well advanced they must have a light position, and should be kept as near the glass as possible. While growing abundance of water should be given; in fact they should never be allowed to suffer by the want of it. As soon as they commence showing their flower spikes weak stimulants should be given every time water is needed. After the plants have flowered they must be gradually hardened and then plunged outside, well supplying them with water and stimulants until they ripen naturally. Bulbs treated

as described will be in grand condition for forcing the following season.

It is only necessary to make two pottings of bulbs, as some can be pushed forward and others brought on under cool treatment and retarded to suit the requirements of different cultivators.—SCIENTIA.

ROOT-PRUNING LARGE AND OLD TREES.

I AM very glad to see this subject opened by Mr. G. Bunyard of Maidstone, who, speaking with an extensive practical experience to draw lessons from, may be accepted as a safe guide and counsellor in the matter. Personally, I am quite certain that very many old and comparatively barren trees which are occupying valuable space on walls, and equally valuable space in other parts of the garden, might be made fruitful and satisfying by being subjected to this operation, always provided that that operation is performed with care and judgment. It is annoying in the last degree to have yards, almost miles, of good wall room taken up by old, perhaps time-honoured, but still useless and barren trees, and yet be prevented or afraid to operate upon them fearful of disastrous consequences. I was once in charge of two large trees of Gansel's Bergamot Pear. They were trained to the height of perfection as to the disposition of their branches, but in all the six years I had them in charge did I see more than, perhaps, five or six Pears in any one year, and some years none at all. I suggested to my employer that it would pay to grub them up and plant afresh, and he fell in with the idea, but on referring it to the landlord, or his agent, I forget which, we were forbidden to touch these trees harmfully on pain of something fearful coming to us. They were trees hoary with age and family associations I suppose, and as my then employer was only a yearly tenant we were obliged to let it alone, and endure seeing the barren trees covering some 60 yards of 13-foot garden wall. I should have liked to root-prune both those trees, but, being timid and faint-hearted as to what might be the result, I let them alone.

There are in many old gardens these unserviceable ancients. Since my Gansel's Bergamot experience I have had in my hands, and not long since, a wall of old Pears with stag-horn breast shoots, growing yearly a forest of sticks that would do admirably for training young Fuchsias and Begonias to, but no fruit, or of fruit just one or two at the ends of each of the side main branches. Immediately I took them in hand I reduced these stags-horns down to their lowest dimensions, to the little trusses lying close to the main branches, and then, not caring whether one or two of the trees lived or died, the walls being very full, I root-pruned them, digging the trench at, say, rough measurement, $1\frac{1}{2}$ yard from the bole of the tree, and cutting all roots off, no matter how thick that we encountered in the digging. That was three years ago, and I am glad to report that the trees are full of fruitful wood close to the main branches for the first time in the memory of one of the oldest of my labourers, bearing a fine crop of clean-looking fruit. I am quite sure that we may do more root-pruning than is usual, even amongst some of the oldest of our wall trees, and thereby bring them out of a state of unfruitfulness and vexation to owners into one of profit and usefulness. All that is required is to use judgment in the operation both as to time and manner of doing. As to the time, I think the end of this month (September) is as good as any—nay, better; indeed that is my experience.—H., *Notts.*

THE PHYLLOXERA.

I HAVE no doubt your correspondent Mr. H. W. Ward is perfectly right when he recommends the "stamping-out" system as the only radical one for getting rid of the above-dreaded pest. Had the French nation acted on this advice, which was tendered to it nearly twenty years ago, the insect might have been banished out of Europe, instead of which, in spite of all such nostrums as immersion, which is impracticable, and sulpho-carbons, and such like, the pest is rampant in the length and breadth of their land. Will Mr. Ward lay your readers under an additional obligation by letting them know how and from whence he got the insect at first?—A VINE GROWER.

SENSITIVENESS OF EARTHWORMS.—I am now engaged in extirpating Daisies from the lawn which surrounds my Rose beds, and I have observed how sensitive the earthworm is to vibration. After taking out a patch of Daisies from the soil raised by the Daisy fork, one may notice on replacing the earth and putting it level again a general alarm amongst the worms that may have been raising their bodies through the earth. Possibly the first movements of the fork in lifting the soil may have disturbed the creatures; but certain it is that on tapping the earth down again any that may be within, say, a hand-breadth or

so of the operation retreat or pull themselves in so rapidly and simultaneously that they must have experienced some shock. Has anyone who knows more about the habits of the worm noticed this?—A. M. B

RANUNCULUS IN POTS.

IN many gardens Ranunculus do very unsatisfactorily when planted outside, especially when the ground is light and dry; but they can be successfully grown in pots, and will afford abundance of useful flowers for cutting. When in pots the roots should be secured as early as possible, and about five placed in each 6-inch pot in good rich soil consisting of fibry loam, decayed manure, and a little coarse sand. They should be potted moderately firm, and it is a good plan to place a little sand round each pot. Place the pots containing the roots in a cold frame, and fill the spaces between them with coal ashes, just covering the rim of the pots with the same material. Directly the plants commence growing the ashes must be removed from the surface of the soil, but the pots should still remain plunged. It is a good plan to keep them plunged until they have flowered. When plunged they do not dry so rapidly, which is a great advantage to their successful cultivation in pots. After growth has commenced they must be protected from frosts, and the plants kept as near the glass as possible, with abundance of air both day and night when favourable. They soon draw up weakly in a close confined atmosphere, and will not endure being forced into bloom. To achieve success as natural a system of cultivation as possible must be practised. While growing never allow them to suffer by the want of water at their roots.—LANCASTRIAN.

GRAPES AT THE EDINBURGH SHOW.

HAVING long wished to see Grapes as exhibited at the above Show, I made a point of taking a trip northwards. To say I was gratified does not fully express my feelings, yet I was disappointed in some particulars. As was stated last week, Mr. J. McIndoe, gardener to Sir Joseph W. Pease, Bart., M.P., Hutton Hall, Yorkshire, and Mr. W. McKelvie, gardener to the Dowager Duchess of Roxburgh, Broxmouth Park, Dunbar, were placed equal in the class of twelve bunches of Grapes, six black and six white. All Mr. McIndoe's bunches were large, but the only varieties really good and ripe were Black Hamburg and Golden Queen. Mr. McKelvie had a trio of Muscat of Alexandria, the best in the whole Show; Buckland Sweetwater, good; Black Hamburg, fair; and Madresfield good, much smaller than the others, but ripe. As far as quality went the latter exhibitor decidedly should have had first honours, but the others overweighed them, and it must have been size, and size alone, which the Judges honoured by their verdict. This award gave great dissatisfaction, and to me, a stranger, it was amusing to hear the comments in the northern tongue. I carefully went through the exhibits several times, and failed to see the justice of the awards in this class. This is written in no carping spirit, and doubtless you will find I am not alone in my opinion.

Muscats.—Grand heavy bunches were shown by Mr. McKelvie, excellent produce also being exhibited by other successful exhibitors, notably Messrs. Ramsay, McKinnon, Day, and King, and this valuable Grape was on the whole well represented.

Black Hamburgs.—In the classes for this Grape the exhibits were not on the whole of great merit. The best was a good bunch of nearly 3 lbs. weight, and with fine hammered berries, from Mr. James Jeffrey, Craighleuch Gardens. Some good examples were staged in the collections; the premier bunches in the Show probably being those of Mr. Kirk.

Duke of Buccleuch.—A noble bunch with monstrous berries was exhibited by Mr. McKinnon. Mr. Dewar, Beechwood Gardens, also well won the chief prize in the any white variety class with capital examples of this fine Grape.

Alnwick Seedling.—I expected to see this Grape better represented. Mr. Kirk exhibited it well in a collection; and in the single bunch class Mr. D. Murray, Maybole, won the chief prize with a good bunch, but rather small berries; Mr. Robertson following with a small bunch and grand berries, only five lots being staged.

Gros Colman.—This was still more disappointing, only three bunches being staged in the class, and both the prizetakers—Messrs. D. Murray and Pringle—had good examples, while those shown in the classes were, as a rule, not ripe.

Black Alicantes.—These were generally good without being superior. A few fine examples were shown in the collections, notably by Mr. Day, also in the class of one bunch, in which there were twelve competitors, the prizes going to Messrs. Spencer, Lindsay, and McKay, but they by no means gave general satisfaction; Mr. Ballantyne, Stoneyhill, staging produce equal to any in the class.

Abercainey Seedling.—This was exhibited by Mr. McKelvie, but is too much like the Black Alicante to be considered distinct by me.

Cooper's Black.—This Grape, which is not often seen, was admirably shown by Mr. Lees of Hillsborough, winning him a prize in one of the collections, also first for any black Grape for any variety not in the schedule, and first again in the finest bloom class. It was very good, and appeared to be quite distinct.

Mr. Forbes staged a superb bunch of Madresfield Court weighing about 6 lbs; and Mr. Murray, Park Hall, a beautifully finished example of Gros Maroc.

In the sixteen classes 197 bunches were staged, and there were several in the collections of fruit. The best class of all was that in which fruit was exhibited for the finest bloom. Having given my impression of

the Grapes at Edinburgh, I conclude with the hope that I may not only see the grand city next year, but that I may be again placed in the list of successful exhibitors.—STEPHEN CASTLE, *West Lynn*.

MILDEW ON CHRYSANTHEMUMS.

IN your notes to correspondents, page 262, in giving "A Grower" information you refer to the solution used by me for mildew on Roses and Peach trees, and also wish me to state if I have used it on Chrysanthemums. I have not done so, as I discontinue the use of the syringe on these plants altogether after the approach of heavy dews at night, which commence very early and are continuous in this neighbourhood. When mildew has been allowed to thoroughly establish itself either on Roses, Peaches, or Chrysanthemums the solution advised to be used by me is not sufficiently strong to destroy it, neither are many of the "infallible compositions" recommended for the purpose, unless it is very strong, and not unfrequently then they prove injurious to the foliage of the plants or trees operated upon. If "A Grower" lives in a locality where mildew abounds at this season of the year I feel confident that if he will commence early enough with the softsoap solution, and follow it up regularly, his plants will not be troubled with mildew. If any of my Chrysanthemums are attacked I follow the excellent advice given by you to "A Grower" of mixing a little sulphur in water in which soft soap has been dissolved. The plants are laid upon their sides and thoroughly drenched with it, which is again repeated in a few days if necessary. If the weather prove showery when the operation is performed the plants are placed under cover, so that the sulphur is not washed off them. The soft soap must not be used too strong. After the mildew has been destroyed wash the plants thoroughly with clean water to remove the sulphur. A weak solution of Fir tree oil and a little sulphur will be found useful in destroying mildew.—W. BARDNEY.

THE DESTRUCTION OF PEARS BY WASPS.

YOUR correspondent, "Saxoring" (page 259), in last week's Journal is not alone in his suffering from the wasps. They have attacked the following varieties of Pears here on the walls, espaliers, and bush trees:—Duchesse d'Angoulême, Vicar of Winkfield, Williams' Bon Chrétien, Beurré Clairgeau, and an Easter Beurré. I am of opinion that the small birds, which prefer hard gritty Pears to soft ripe ones, are the beginners of the mischief. The skin of the fruit being pecked by the birds the wasps at once commence operations, which, of course, in a short time cause the complete destruction of the fruit.

In our vinerias as well the wasps are giving us much trouble, especially among Black Hamburgs where not protected. Last year we employed muslin bags with very poor results. The Grapes went mouldy, and the wasps made their way through the bags with the greatest ease. We are now using white paper bags, which can be had from the grocer any size and at a low price. We bore a few small holes at the bottom of the bags, the bag to be slipped upwards over the bunch, but not tied round the mouth, or the Grapes will not keep very long. Strange to say not a wasp has entered any of the bags, though thus quite open at the top. Late Pears intended for exhibition or other particular purposes may be protected in the same way if the material used was waterproof. An invention for the protection of this valuable fruit from the ravages of these troublesome insects would indeed be a boon to the gardening community.—WM. CHISHOLM, *Oxon Heath, Tunbridge*.

IN reply to "Saxoring" as to wasps devouring unripe Pears, I may say that with me, when wasps are numerous, they have done so for several seasons. This season some dozens of the hardest fruits both for stewing and dessert are completely spoiled. But in my case there is another enemy far more destructive, and which precedes the wasp—viz., the tomtit. Many of them can be seen pecking at the Pears on the upper or sunny side and eating the flesh, which makes a hole large enough for half a dozen wasps to enter, as I think the wasp has not the power to break the skin of such hard fruit were it not for that mischievous bird. But all my forward Pears have been more or less eaten.—THOMAS RECORD, *Belmont, Barnet*.

SABBATIAS.

A SMALL genus of North American plants, chiefly biennials or annuals, bearing showy brightly coloured flowers, especially the two described below. They can be readily raised from seeds either sown out of doors in a sheltered border or in pots under glass.

Sabbatia campestris (Nutt.); *S. formosa* (Brickley) in "Prod. Acad. Phil.," 1862.—This is one of the very showiest of our hardy outdoor annuals, and is a native of the open prairies of Arkansas and Red River, where, although not very plentiful, the effect of its deep rose lilac-coloured flowers is quite dazzling when seen through the long grass. It grows from 6 inches to a foot high, with slightly winged stem, branching habit; leaves ovate, amplexicaule, acute, nerved; flowers nearly 2 inches in diameter, each of the variable segments being marked with a five-rayed greenish-yellow star, having an irregular white margin; calyx segments linear-lanceolate, and a trifle shorter than the corolla. It grows well in ordinary garden soil, and, judging from the time the

flowers keep fresh after cutting, is likely to prove useful for purposes of decoration. It was, I believe, first introduced to this country by Mr. James Carter, but was lost until reintroduced by Mr. Thompson of Ipswich through a German correspondent in 1855. *S. campestris* has often been confounded with the *Chironia trinerva* of Ceylon, and, although agreeing in artificial character, the colour of the flower and the ovate leaves distinguish it clearly enough for all practical purposes. There is also a pure white variety, extremely pretty, but unfortunately it is not in cultivation. The species flowers from June to September. The woodcut (fig. 51) represents a spray with several flowers.

Sabbatia chloroides (Pursh).—According to Dr. A. Gray's second edition of the "Flora of the United States" this is one of the handsomest species, but it was probably described before the above was introduced. It has a round stem from 1 to 2 feet high, loosely paniced.

Fig. 51.—*Sabbatia campestris*.

The corolla, which is of a beautiful rose colour, is over an inch broad; leaves oblong-lanceolate; segments of calyx linear, and only half the length of the corolla. It grows round the edges of ponds from Massachusetts to Virginia, and flowers from July to September.—D. D.

AVENUES AND BOULEVARDS IN AMERICA.—The municipalities accept it as part of their duties to adorn and beautify the thoroughfares of the localities over which they have control. The result is that avenues and boulevards are everywhere constructed out of the public funds. Even Brooklyn and New York, which are probably the most ill-governed cities in the American Union, are supplied with abundant trees. When a new city is laid out attention is at once bestowed on those features of urban life which will make it an agreeable abode for all who settle in it. It is a practice in some communities, as in Rochester, to remit part of the taxes if owners of property plant trees along the front of their premises. So much has been done, and is yet being done, towards beautifying the outlying parts of Chicago, that many miles of the loveliest boulevards in the world have already been constructed, while plans have been formed for connecting the whole of the public parks surrounding the city in such a manner that no fewer than forty-eight miles of magnificent drives will eventually come into the possession of

the people. New Haven in Connecticut, known also as the Elm City, is so amply blessed with verdure that the view of the place from East Rock gives one the impression of a town planted in a forest. The same impression is produced when looking down upon the city of Rochester from Power's Block. Cleveland and Detroit are also reputed for comeliness and verdure. Euclid Avenue, in the former city, would certainly be difficult to surpass. To my fancy, however, there is no prettier town in either Europe or America than Milwaukee. Its charming drives, its shady walks, its lawns and flower gardens, none of them enclosed, made it impossible to imagine that one was not strolling through a public park instead of threading the streets of a thriving and industrious community.—(*Our American Cousins.*)

USEFUL APPLES.

It would be interesting to know the best Apple of the year. Ecklinville Seedling has been the best here. The crop as regards number has not been so large as on some other sorts, but taking number with size and bulk when gathered this is our most profitable variety. I have seen it stated that this is not subject to canker in the stem. This is not correct as applied to every garden, as the tree cankers here, but not so badly as some others. It is a variety that requires a good amount of young wood left. Too close pruning is a decided evil. Warner's King is another profitable Apple—not such a heavy cropper as the above, but sure, the fruit large, and a grand keeper. It is very bad with canker. Mère de Ménage is a variety I shall grow more of. It is a certain cropper; the fruits are large, keep well, and are moreover beautifully coloured. The one tree we have is quite free from canker. Cox's Pomona is also a healthy tree. It is well worth growing. Cellini and Hawthornden I am going to clear out. They are good croppers, but the fruits are never large.—B., *East Lothian.*

NOTES FROM A SCOTCH GARDEN.

We experienced so much wet weather throughout the later portion of summer that Pelargoniums have not been at all satisfactory, and proves that it is not well to depend on these exclusively for brightness of effect. By planting many hundreds of *Gladiolus brechleyensis* through the beds and borders we have had plenty of colour for several weeks past. Huge masses of *Tritomas* are now well into bloom, and these will give an effect that no other plant approaches. Well-grown Sunflowers (annual) with eight flowers open at a time are better than anything I know at this season. *Oenothera Lamarkiana* is also a most effective plant. None of these, however, is of much use unless the surroundings are bold and open.

In the race after novelty gardeners are very apt to neglect good things. *Tritomas* are worth more attention than they receive at the hands of gardeners, and another pretty flower is the Japanese Anemone. Anemone japonica is one of the few flowers which are out of place in no position. The flower stems rise from a leafage which is as beautiful in its way as that of any flower. The flowers themselves, pure white, faint lilac, or of a dull rose, are very lovely. Loosely arranged amongst their own foliage with a few half-opened buds they are admirable for vases. I am inclined to think that the lilac form used alone is the most lovely. This variety is, I believe, sold as *A. japonica hybrida*. The present is a good time to propagate these. We cut the roots into pieces, and each of these grows. Of course where only a small stock is wanted good-sized pieces of roots with buds started into growth should be selected. They may either be potted or planted out.

A writer recently recommended surface dressings to be applied to the stock of Chrysanthemums. I have done so for the past two seasons, and believe the practice to be a thoroughly good one. I do not find it necessary to apply the dressing so soon as your correspondent recommends, the end of September being quite early enough for our plants. I do not remember seeing Chrysanthemums look healthier than they are this season, yet they never were subjected to such unusual treatment. We had the plants in 4-inch pots until the middle of July before they could be transferred into their flowering pots. A month after stimulants were commenced, and they have so far thriven admirably. Our stimulants are guano, and latterly sulphate of ammonia once a day. They have twice had a dry dressing of saltpetre, and once a mixture of phosphates, potash, and nitrogen worked into the surface. It is very certain that the Chrysanthemum likes high feeding, and it is equally certain it does not always receive it.

I have our Zonal Pelargoniums in their flowering quarters already. Like the Chrysanthemums they were rather late in being potted, and are not so large as we should like them to be. And another reason: I have not found that it is advantageous to let the plants stand out too long. When the plants are housed the best of the leaves fall in the course of a few days. We escape that by placing them under glass early.—X.

MASTERPIECE MELON.—The fruit I staged under this name at Bath, and which was described as the best Melon in the Show, was received from the Messrs. Sutton & Sons for trial, and was unnamed. It ripened so unexpectedly and quickly that there was not sufficient time to communicate with the Messrs. Suttons unless by telegraph, and as a consequence, a name being necessary, I called it "Masterpiece." I think now I made a mistake in so doing, especially as I now find Messrs. Suttons have a Scarlet Masterpiece; but it was done hurriedly, and after finding its aroma was much better than a fruit of Eastnor Castle I

had intended to stage. The fruit I staged was scarcely ripe, as some we have cut since were much superior to it. It is not of attractive appearance, but that is its only fault.—W. IGGULDEN.

THE ninth Exhibition of the LAMBETH AMATEUR CHRYSANTHEMUM SOCIETY will be held on November 12th, 13th, and 14th, in the Borough Road Lecture Hall. Schedules can be had from the Hon. Sec., Mr. G. Addison, 22, Peckham Grove.

— THE dedication for the public use for ever of BURNHAM BEECHES will take place on Wednesday, October 3rd, when it is expected that the Lord Mayor and the Sheriffs of London and Middlesex will attend in state and perform the ceremony, after which a grand *dejeuner* will be given in the large hall at Eton College in honour of the event.

— "G. N." writes—"One of the noblest of the tall Compositæ employed in gardens is *BOLTONIA GLASTIFOLIA*, which attains the height of 6 to 7 feet, and has pink Aster-like flowers produced in considerable numbers. The leaves are lanceolate, 3 to 6 inches long, and about 1 inch broad. It grows freely in any ordinary garden soil, and large clumps have a good effect at the back portion or in prominent positions in the herbaceous border."

— WE observe that the Yellow Ingestrie Apple is becoming a great favourite in the markets and on the costermongers' trucks. Its neat symmetrical shape, clean clear colour and convenient size, adapting it readily, for "three a penny" no doubt commend it both to producer and consumer. To those of the former who find it a profitable Apple to grow we would commend BRINGWOOD PIPPIN, which is about the same size, of richer colour, better flavour, and a much later keeper. It comes well in succession to Yellow Ingestrie, and keeps till January, when it would pass well for "Golden Pippin" where nomenclature is not much cared for. Besides, it is an excellent dessert Apple, and also one of Mr. Knight's seedlings.

— WE learn that there are GREAT POTATO CROPS IN CHESHIRE. At Chester market last week very fine Magnum Bonum Potatoes were sold at 2s. 9d. per hamper of 126 lbs., or a little over one farthing per pound. Reports from all parts of the country show that the present crop is the largest on record.

— A GRACEFUL plant for a stove or intermediate house is *PHYLLANTHUS SUB-EMARGINATUS*, though it is known in comparatively few gardens. It is of tall elegant habit with small leaves, about a quarter of an inch in diameter, and arranged on slender branches in pinnate manner. A compost of light loam and peat suits the plant, which is not at all difficult of cultivation, and might be added to many collections with advantage.

— THE Glory of the Snow, *Chionodoxa Luciliae*, has become a general favourite; and now another species, *CHIONODOXA SARDENSIS*, has been introduced to notice. The collector who found the bulbs, it is said, near the ruins of Sardis, at an elevation exceeding 4000 feet, describes the flowers as "larger and more numerous than those of *C. Luciliae*, and with the exception of a very small white eye are of a uniform intense Nemophila-blue." If this description proves correct the plant will undoubtedly soon share the popularity of its better-known beautiful relative.

— A CORRESPONDENT writing in reference to DUKE OF BUCCLEUCH GRAPES AT BEECHWOOD, TILlicOUNTRY, N.B., observes that "Mr. Dewar, gardener to Captain Archibald at the above garden, exhibited some fine examples of this Grape at the recent Show in Edinburgh, and was deservedly awarded the first prize in the any white variety class. This variety has received particular attention from Mr. Dewar with very good results, as the fruit shown and at home has been greatly admired. In a warm vinery he has a Vine of the Duke inarched upon Rivers' Sweetwater, but another in a cool house, from which the bunches exhibited were cut, is inarched on West's St. Peter's, and he had twelve bunches on one rod, the lightest weighing

2 lbs. $8\frac{1}{2}$ ozs., and the heaviest $4\frac{1}{2}$ lbs. From one bunch four berries without the stalks weighed $2\frac{1}{2}$ ozs. As with other practitioners, Mr. Dewar considers the extension system the best for this variety, allowing the main laterals to run 2 to 3 feet before stopping them."

— MR. W. WATERFIELD, The Quarries, Exeter, writes:—"In your number of August 30th, page 196, you notice that the root and stem of DATURA STRAMONIUM are smoked like tobacco for the relief of asthma, but are followed by disagreeable effects. A much milder, yet very efficacious remedy, is to dry the leaves, powder and bottle them like sweet herbs, and for use to sprinkle some of the powder upon a square of touch paper (brown paper soaked in a solution of nitre or saltpetre till it will smoulder without bursting into flame), then light the paper and inhale the fumes."

— A USEFUL plant for covering a division or wall in a house is BEGONIA ULMIFOLIA, a species of climbing habit not in general cultivation, but included in a few botanic gardens. The leaves are of moderate size, and, as the name indicates, bear some resemblance to Elm leaves. The stems are furnished on the under side with small suckers or rootlets, which adhere closely to any substance with which they are in contact, climbing and gradually covering it with rich green foliage. Wood seems to suit it best for this purpose, as the rootlets more readily obtain a secure hold, and the plant thrives better. Another excellent wall-covering plant is Pothos celatocaulis, which, however, requires a higher temperature than the former, succeeding well with Nepenthes. It has a beautiful effect, the leaves being quite flat on the wall, like some of the Marcgravias.

— MR. RIVERS of Sawbridgeworth has sent us specimens of SOUVENIR DU CONGRÈS PEAR, which are marvellous examples of good cultivation. One of them weighed $17\frac{1}{2}$ ozs., and the other 15 ozs. Accompanying them were specimens of GOLDEN EAGLE PEACH weighing $9\frac{1}{2}$ ozs., and measuring $3\frac{1}{2}$ inches in diameter; and of GLADSTONE PEACH weighing 9 ozs., and also measuring $3\frac{1}{2}$ inches. The flavour of all of them was very fine, and we longed to have the opportunity of producing on our own account such examples. Golden Eagle Peach is of the deep yellow-skin and yellow-fleshed varieties, and Gladstone is a new variety with a pale skin like Noblesse, and with the faintest tinge of mottled red on the side next the sun. Both are freestones.

— "D. D." writes—"The robust habit generally possessed by the more common species of Rudbeckia, such as R. laciniata, R. maxima, and others, better fit them for the shrubbery than the herbaceous border. RUDBECKIA HIRTA, however, is of less robust habit, seldom attaining more than 2 feet in height at its best. It is very susceptible of damp, and in such situations is apt to be destroyed; when planted in a light dry soil it grows luxuriantly, and will continue increasing for a number of years without division. The flower stalk is naked, about a foot high, terminating with a large pretty yellow flower; ray florets very stiff, slightly indented at their points with a very prominent dark purple disc. A succession of flowers continues from July until they are destroyed by frost. Leaves undivided, oval-shaped, three-nerved, with serrated edges covered with rough hairs."

— THE ROCKERY AT KEW has throughout the present season been steadily increasing in beauty, and has now become one of the permanent attractions of the gardens. The air of newness is leaving it, as the plants are covering the more exposed portions of stone; and as planting has been continued with much judgment and taste, it has now assumed a furnished appearance that is very pleasing. When first constructed this rockery was subjected to rather severe criticism by some, and almost equally undeserved praise by others. It undoubtedly had faults, as a work of such a kind must have, but they were few, and not of fundamental importance—such, indeed, as admitted of being gradually removed or counterbalanced. This continued attention and readiness to remedy defects has resulted in the greatly improved character above noted, which will, undoubtedly, be still further advanced another season. The waterfall and marsh are quite successful, and the recesses devoted respectively to peat-loving plants, seashore plants, and others requiring particular habitats, possess much interest. The old rockery near the Economic house is, we understand, to be devoted solely to Himalayan plants, which appear to thrive particularly well there. This will render it highly interesting if consistently carried out.

— MESSRS. H. CANNELL & SONS, Swanley, send a collection of

DAHLIA FLOWERS representing some useful and brilliant bedding varieties. Foremost in distinctness and richness of colouring is the Cactus Dahlia, D. Juarezii, some of the blooms of which are 6 inches in diameter, with broad pointed rich scarlet florets, which impart a most striking character to the blooms, proving the appropriateness of the popular name. Next is the remarkably floriferous Glare of the Garden, both scarlet and crimson forms, neat blooms, which are produced in great profusion. We recently saw this producing such a striking effect in a nobleman's garden that the gardener suggested it ought to be called the "Blazer." The white Cactus Dahlia Constance is also useful and good, but the blooms are smaller than the scarlet type, the florets broad but less pointed; it is, however, very free. A white variety, unnamed, we take to be Camelliæflora, an old form that is not very often seen in gardens, though it merits attention, as the bloom certainly bears some resemblance to a white Camellia. A pink variety, also included, is very pretty, the florets being broad but with the margins infolded, giving a quilled appearance, and the upper portion being cut still further adds to the distinctness.

— IN describing the VEGETATION and SCENERY near the RIVER CONGO in CENTRAL AFRICA, the correspondent of a daily contemporary gives the following:—"The vegetation that clothes the precipitous shores on the south side of Stanley Pool, near the entrance from the Upper River, is one of the most magnificent spectacles that the Congo offers. Rising nearly perpendicularly from the water the forest climbs the hillsides higher than the eye can reach without a single break in its luxuriance. The variety of colours, too, at this season, when most of the trees are in blossom, is particularly striking. One tree-top will be covered with scarlet flowers scattered with a liberal hand, another has pendulous flowers of a pinky white hanging gracefully by their long stalks amid the sombre masses of foliage, while errant creepers in exuberant growth trail their yellow blossoms over the victims they entwine. There is every note struck in the gamut of green, and the trees that form this mass of foliage may vary in tone from blue-green to greenish-yellow, and from greenish-white to russet-red, and they will differ equally in form and aspect. While some are compactly massed in their leafage, others grow erratically and in disordered tufts. Beautiful Mimosas dominate their fellows, clothed in foliage of dark green velvet; Dracænas raise their spiky heads here and there from out of the soft verdant mass. The large flat leaves of a Fig alternate with the feathery Palm fronds, while many stems are completely disguised by the network of graceful creepers which mask them like a vegetable cobweb. A climbing Palm makes a sort of latticework fence, rising straight up from the water's edge, and seems effectually to forbid trespassing in these fairy forests, while along the river's brim lines of white Lilies stand like sentinels to see the barrier is not passed."

— DOUBTLESS not a few of our readers have seen and admired, or at all events read of, the LARGE BLACK HAMBURGH VINE which some years ago was the glory of the fine range of vineries in the Vice-regal gardens, Phoenix Park, Dublin, and entirely filled one of them, producing annually a quarter of a ton or more of splendid Grapes, and which when seen at this season, with its extended horizontally trained rods almost mathematically strung on either side with their sable pendants, was a sight to wonder at and admire. It was not merely an example of a large Vine, but, what was more important, a grand example of successful Grape culture. It was a source of regret when some three or four years since this noble Vine (whose life history was somewhat peculiar) came to grief from a peculiar affection of the bark and wood, and ultimately died. The defunct will, however, soon have its place filled and its glories surpassed by a worthy successor in the shape of what promises to be a more than equally imposing Black Alicante, which the clever head of the department, Mr. Smith, has already educated to fill a third of the space occupied by its predecessor, and is just now heavily laden with beautiful bunches. By reason of the greater size of its bunches, the greater depth of colour and thickness of bloom, and the much greater length over which the season of the Alicante extends, the aspect of the house, when the young giant fills it, will be finer and more imposing than it was when its predecessor, the famous Black Hamburgh, won the admiration of all.—(*Irish Farmers' Gazette.*)

— A WRITER in the *American Gardeners' Monthly* has the following notes on the EFFECTS OF CROSS-FERTILISATION ON FRUIT:—"An opinion seems to be gaining converts among some careful observers of facts that cross-fertilisation not only modifies the characteristics of the

progeny resulting therefrom, but that the size, appearance, and other qualities of the fruit produced during the season of impregnation must and will, in a greater or less degree, exhibit some of the qualities of the staminate parent, as well as those of the one bearing the fruit. For example, the fruit of a Strawberry of a pistillate variety growing near a given staminate one—by the aid of which the greater portion of the crop is produced and perfected—will show a marked difference in size, appearance, and quality from that of the same variety of plant growing near and impregnated by another staminate variety. A little reflection upon one or two of the primary and well-known laws governing the matter of reproduction by seed will convince any unprejudiced mind, not only of the possibility of such collateral effects of impregnation, but of their extreme probability. These laws are—first, that the fertilisation of the seed is a necessary condition to the formation of the fruit; secondly, that the seed, after impregnation, excites and stimulates by the power of the reproductive principle of life imparted to it by that impregnation the development and growth of a matrix of fruit to suit its own requirements. In view of these indisputable facts is the conclusion not irresistible that, taking for example a bed of a strongly pistillate variety of Strawberry—that portion of the bed lying near to and consequently largely influenced by impregnation from a staminate variety bearing large, fine, highly coloured or high-flavoured berries, will bear fruit partaking to a marked degree more of those qualities than another portion of the same field coming under a like influence from staminate plants bearing smaller meaner fruit?"

— THE "BOTANICAL MAGAZINE" for the present month contains figures of the following plants—*Crinum Hildebrandtii*, a species related to *C. americanum* and *C. crubescens*, from the mountains of Johanna Island, where it was discovered in 1875 by Dr. Hildebrandt. Bulbs were sent to England in 1878. The flowers are in loose heads, the petals very narrow, white, the filaments purple. The leaves are 1½ foot to 2 feet long. *Tulipa Kolpakowskyana* is represented in a faithful figure. This is a fine species, with dark scarlet elliptical spreading petals and purple anthers. It is a native of Turkestan, and was introduced to St. Petersburg by Dr. Albert Regel in 1877. *Leucoium hyemale* is "one of the rarest of European plants. It is confined to a small strip of rocky shore reaching from Nice to two miles east of Mentone." The flowers are small, neat in form, and pure white. *Primula floribunda*, a distinct species from the western Himalayas, with small yellow flowers produced in terminal umbels and from the axils of smaller bract-like leaves. *Senecio concolor*, a South African species, related to *S. speciosus*, and was discovered by Drege at Tulbaghe about fifty years ago. The flower-heads are purplish-rose, and are borne in loose corymbs.

A NEW GARDEN.

THE KITCHEN GARDEN.

PASSING in review numerous gardens which have come under the writer's notice in different parts of the country, the favourite position, and undoubtedly the best, is moderately elevated and gently sloping to the south. Occasionally gardens in a valley are met with, and also high up upon a wind-swept plateau, but it is only dire necessity—that place or none—that should ever sanction the selection of either place for such a purpose. In the valley early and late frosts often do much harm, the mean temperature of winter is lower and the frosts more severe by several degrees than on higher ground; winds, too, are a source of mischief, which may, however, be turned aside by judicious planting. All that can be said in favour of a valley garden is that there we find a deep, cool, and frequently, but not always, rich soil, and plenty of water. It cannot be denied that excellent fruit and vegetables are produced abundantly in such gardens; but summer vegetables, such as Vegetable Marrows, Peas, Scarlet Runner and Kidney Beans, are usually destroyed in autumn by early frosts much sooner than in gardens in more elevated positions. It is not uncommon for the entire crop of Broccoli and Greens to perish from cold in winter, and in spring frost again assails the blossom of fruit trees and frequently destroys it. In some respects an elevated bleak position is worse than a valley. A poor thin soil, scarcity of water, and exposure to winds are the principal evils, all which it must be admitted are to be overcome—quickly, as regards the water supply; slowly, but nevertheless surely, in soil-improvement, and in imparting shelter by planting. Soil-treatment and shelter will both be discussed fully in subsequent papers, but due provision for an abundant supply of water is so

clearly a preliminary matter in the making of a new garden that another useful method of obtaining it must be explained here.

Montgolfier's clever invention, the hydraulic ram, since its introduction has been modified in various ways, but its principle of self-action, or rather of action by means of the water and air passing through it, was wrested from Nature by Montgolfier, and remains unaltered. By means of it a steady flow of water may be sent from the base of a hill to its summit, from a valley to any part of its slopes. Once in position and fairly at work, it embodies the nearest and certainly most useful approach to perpetual motion that I know, for so long as enough water flows into it, on it goes day and night, requiring no attention, sustaining so little damage from wear and tear, that after the first outlay the cost of new valves is very trifling. It is so simple in construction, so efficient in action, and so comparatively inexpensive, that its speedy universal adoption would appear to be a certainty. Such, however, is not the case. I have met with many rams, large and small, by different makers in various

Fig. 52.

 F.—Supply pipe from ram to garden, 1 inch in diameter.

parts of the country, all working well, but it is still by no means uncommon to see manual labour and horse power employed where every facility exists for the use of a ram. Several instances of such wasted power occur to me which might, if necessary, be enumerated. Ignorance of its simplicity, durability and cost, and how and where it is possible to use it, must be the reason why it is not turned to account everywhere; and knowing from experience how much ways and means are discussed when a new garden is made, I have called attention here to one of our best means of obtaining an abundant supply of water economically, and will now proceed to explain sufficiently for general guidance its use and cost.

For an hydraulic ram with a 2-inch supply pipe to work reliably and well, the source of water should be 100 feet from it and 10 feet above it. Fed by twelve gallons of water per minute, the most ample allowance for waste leaves us 1300 gallons forced vertically to a height of 200 feet, and any

Fig. 53.

 C.—Valve.

distance horizontally. In a price list recently sent me by a respectable firm of hydraulic engineers, a machine of this capacity is offered for £6 10s., smaller and larger machines being also offered at proportionate prices. This will afford sufficient data whereon to base calculations; but lest anyone with a small garden should suppose that much less water than the quantity given is not available for our purpose, I may add

that of a list of rams actually at work in my hands, one very small one has a fall of only 9 inches from the source to the machine, another of 13 inches forcing the water to a height of 34 feet, both of them requiring only a few quarts of water per minute. To convey a tolerably clear idea of the construction of a ram, let us now turn our attention to fig. 52, which represents a transverse section of a useful form of it. The water enters at A and escapes at B. In doing this it forces the valve C upwards and closes it temporarily. This sudden check of the rushing current forces it backwards up to the other valve D, which it lifts, and a certain quantity of water enters the air chamber E, and is retained there by the falling of D. As soon as D closes C opens again, and the first process of rushing water and opening and closing of valves is constantly repeated. So much water accumulates in E that the compressed air forces the water up F to the garden. Fig. 53 is a section of the snipe valve, which is of brass, and is screwed into G, fig. 52. Its use is described by Mr. Buchan in his valuable manual on plumbing as "somewhat analogous to the use of a man's nostrils to him. The man may speak, although his nostrils are stopped up, as when he has a cold, but he will speak all the better when they are clear."—EDWARD LUCKHURST.

(To be continued.)

THE LONDON PARKS.

FINSBURY PARK.

OCCUPYING an elevated and beautiful position in the north-east of the metropolis, and commanding extensive views in the direction of Highgate, Muswell Hill, and towards the valley of the Lea, Finsbury Park has gradually advanced in the favour of the residents of that part of London, and is now as popular in the north as Battersea Park is in the south. Its site, it is true, unfits it for the diversity of landscape effect which is the great charm at Battersea; but to counterbalance that the visitor enjoys a more bracing atmosphere, greater boldness of character, and a pleasing prospect. Shrubberies, too, have been judiciously planted with hardy and vigorous-growing plants, which are slowly but sturdily filling up previously vacant places, imparting a much-needed variety in the appearance of the Park, and serving, moreover, as a shelter to beds of choice flowers. Indeed, without this protection flower gardening would be very unsatisfactory there, as the exposure to winds would be destructive of ordinary Pelargoniums, Calceolarias, and similar orthodox bedding plants. With the aid of these shrubberies, however, a flower garden of considerable beauty is ensured; and other sheltered walks assume a subtropical character, with numerous beds of Ficus, Solanums, Abutilons, and similar tender favourites for such beds. Tree-planting has not been largely practised, but there is one of the finest avenues to be seen in London of Black Italian Poplars, which are fast attaining considerable proportions; and though the stems have been much bent in one direction by the wind in their earlier stages of growth, they are now recovering from that and developing into handsome specimens. This avenue extends from the entrance near the Finsbury Park station to the opposite extremity of the Park, and runs parallel with the road, rising slightly to the centre from both ends. The same Poplar is also employed as isolated specimens in other portions of the Park, chiefly because from its hardness it seems the best fitted to resist the keen winds frequently experienced there during winter and spring. Rhododendrons have been planted in several beds, and though some appear to be fairly prosperous the majority look as if a more sheltered site would suit them better. Hollies of the common green varieties and Laurels thrive the best of the shrubs, and form a good foundation and protection for others that are less hardy.

The principal portion of the ordinary bedding is on the highest portion of the Park, near the lake, a walk with a broad belt of shrubs on each side passing through the centre of a large oval expanse of turf also bordered by shrubs, and in this are cut a series of beds in four or five rows, large circles at the back, and smaller ellipses, ovals, oblongs, and circles in front. The beds on each side of the path are similar in shape, and planted alike, with a few exceptions that will be noted. The beds nearest the walk are devoted chiefly to carpet designs, and though nothing very elaborate is attempted, a bold effect being the principal object; yet so well are they planted, so clear and distinct are the designs, that they may claim the visitor's attention and admiration. The beds of Pelargoniums and other plants are similarly distinguished by their freshness and brightness, the plants being well developed before they are placed out, so that compact handsome beds are quickly formed. For several years this has been one of the marked characteristics of the Finsbury bedding, the result of employing such sturdy plants being a proportionately abundant and lengthened display of richly or delicately coloured flowers. In these respects and in general neatness this Park has deservedly obtained considerable fame under Mr. Cochrane's careful management, and with the assistance of his able foreman, Mr. Mardlin.

But to denote particularly the composition of the beds the chief features will be briefly described, commencing with the beds nearest the path. This consists of circular and oblong beds margined with *Echeveria secunda glauca* and *Mesembryanthemum cordifolium variegatum*; the oblongs, which are devoted to Pelargoniums, having an additional inner marginal band of *Lobelia Finsbury Park Blue*, an excellent dark blue variety, which originated in this Park several years ago, and has since

been annually employed in bedding with great advantage, being of good sturdy habit and very floriferous. The Pelargoniums in these beds contain the silver variegated *Princess Alexandra*; *Marshal MacMahon*, a vigorous bronze variety of rich colour; and *Macbeth*, a beautiful golden tricolor that appears to succeed very well in the Park. The circular beds are appropriated to *Alternantheras*, the centre one containing the richly coloured *A. versicolor*, those on each side the golden *A. paronychioides aurea*, and the third pair *A. magnifica*. All these have done exceedingly well, and afford a very striking contrast of colours. The next row of beds comprises four circles and the same number of irregular rhomboidal beds, the former being occupied with *Coleus Verschaffelti* margined with *Pelargonium Robert Fish* and *Echeverias*; the others have *Pelargonium Mrs. Holden*, a compact, strong, and floriferous pink Zonal variety, edged with *Ageratum Cupid* and *Golden Feather*. Following these is a row of quadrangular beds and circles, the latter being of great size and devoted to well-grown Cannas, with marginal bands of Pelargoniums *Rose of Allendale* and *Vesuvius*, with the white *Lobelia The Bride*. The first-mentioned beds contain *Pelargonium Henry Jacoby* edged with *Flower of Spring* and *Lobelia Omen*. Behind these are some very large beds of *Cineraria maritima var. candidissima* and *Verbena venosa* in lines margined with *Iresine Lindeni*. These beds are extremely effective, the contrast between the colours being most striking. On the opposite side of the path the beds are, as already mentioned, similar in form and design to those noted, but a few different Pelargoniums are observable, notably *Mrs. Turner*, a good pink Zonal; *John Gibbons*, a rich crimson variety; and *Cleopatra*, a useful pink Zonal. These also, with *Lobelia pumila magnifica*, form a border next the shrubs, and nearly surrounding the main portion of the bedding.

Several of the walks in other portions of the Park have beds on each side, which are effectively planted with Pelargoniums and miscellaneous plants of a similar character. Some large clumps of Dahlias have also been very showy, and, together with the subtropical beds, impart abundant attractions to the Park during the summer months. Another grand attraction, too, will be provided in about a month's time—viz., the grand collection of *Chrysanthemums* which during the past two seasons have drawn so many horticultural and other visitors to the northern Park during the dull November. The plants are all in excellent condition, and giving abundant promise of fine blooms.

VICTORIA PARK.

The inhabitants of no district of London so much needed a bright and pleasant recreation ground as those residing in the neighbourhood of what is now familiar to all as Victoria Park; and when the open waste formerly termed *Bishop Bonner's Fields* was converted into the present well-kept park a great boon was bestowed upon hundreds of thousands of weary toilers whose occupations retain them east of the city. There during leisure hours in the evening, but especially on Sundays, they can enjoy the brightness of a rich floral display, tasteful carpet designs, luxuriant subtropical plants, and fresh green turf. Or, if during the week they desire a more active form of recreation, there is a gymnasium and swings, a lake for swimming, and abundant space for cricket or other sports. It is not surprising that the Park is so highly appreciated, for it brings pleasure and health to thousands of those that on fine days throng the walks in all the principal portions, or cover the turf with their wickets or goals. In an educational point of view it is also most valuable, as Mr. McIntyre has paid close attention to providing tasteful combinations of colours, either of flowers or foliage, and with a large measure of success, for the bedding at Victoria Park has gained considerable fame in the horticultural world. There are several ways of reaching this Park—by tram or rail to Cambridge Heath station, or by the North London line to Victoria Park station, which is at the extreme east side, and then the visitor can proceed across the Park, taking the chief features, and quitting by the west side near the station first named. When time is an object, however, the former is the most convenient mode of reaching the bedding, as it is all near that side. Entering from this road, a path to the right leads down to the lake and thence through the subtropical ground to the chief carpet beds, and as this is a very convenient route we will briefly refer to the characters distinguishing it. The subtropical plants employed are principally of the orthodox kinds, *Castor Oils*, *Cannas*, *Wigandias*, *Ficus*, a few *Palms*, &c., with margins of richly-coloured *Chilian Beet* that impart a most welcome warmth to the effect. Prominent amongst the *Cannas* is *C. nigricans*, a telling form with exceedingly dark foliage, which has a very good effect in contrast with plants possessing lighter green leaves. *Acacia lophantha* is also freely employed, large clumps being very graceful. Some of these beds are bordered with *Golden Treasure Fuchsia* and *Echeverias*, which form an agreeable finish to the beds. The *Wigandias* have a noble effect, and are indispensable plants for this style of bedding, the *Castor Oil Plants* being similarly useful, especially when vigorously grown as they are there. The rockery, which is near the lake, is an unpretentious structure, principally occupied with succulent plants; but it has a certain degree of freedom, or what may be termed naturalness, in its design that pleases, because it is rarely a character of such adjuncts to the garden.

Leaving the lake, the carpet beds attract attention, and here, as elsewhere, *Alternantheras* form the main portion of the display, furnishing the colour on a groundwork of *Herniaria glabra* or *Mentha*. The first seems, however, to be preferred, and it is surprising how generally it has grown in favour this season; the foliage possesses such a rich deep velvety green hue, and the habit is so dwarf and compact, that it has much to recommend it for this purpose. There are many beautiful designs, but two may be selected as samples of neatness and

beauty, one a circle and the other an oblong. The circle has a large central ornamental cross of *Alternanthera aurea* and *A. amoena*, defined with rows of Golden Feather and *Echeverias*. In the centre of the cross is a fine clump of *Echeveria metallica*, and in the centre of each space between the arms of the cross is a plant of *Sempervivum tabulaeforme* surrounded by a band of *Alternanthera versicolor grandis*. The main groundwork is *Mentha Pulegium gibraltariaea*, on which are triplet chains of small diamonds and ellipses of *Alternanthera aurea*. There is a simple finish in the appearance of this bed that is very pleasing, and furnishes a good example of really effective carpet bedding. The oblong bed is more complicated in design, but fewer kinds of plants are employed. The *Mentha* forms the groundwork, with a margin of Golden Feather and *Echeverias*, with numerous small panels of *Alternantheras versicolor, aurea, amoena, &c.*, which have a diversified and pretty effect, though perhaps the panels are in some cases rather too small—a defect that is often noticeable where very complicated geometrical patterns are attempted. The designs that generally prove most satisfactory are those with bold clumps or panels of colour neatly defined by some neutral tint upon a good green ground, or, if the neutral colour is employed as a foundation, the defining lines are not needed, and this is even more simple.

The Prince of Wales's Feather beds are, as usual, aglow with *Pelargoniums* and ordinary bedding plants, and have produced a most brilliant display during the summer. The series of small beds near the walk skirting the Park on that side are also occupied with similar showy plants, while the large borders near the shrubberies are filled with an excellent assortment of herbaceous plants that keep up a display from early spring until late autumn, far exceeding the standard bedding in length of time, but never producing the same brilliancy of colour, though constantly possessing much interest.—L. C.

THE NATIONAL APPLE CONGRESS AT CHISWICK.

OCTOBER 4TH-18TH.

A VERY extensive and remarkably fine display of Apples is anticipated on this occasion, the applications for space being numerous. Amongst others large collections will be exhibited by Messrs. Rivers and Son, Sawbridgeworth; The Cranston Nursery Company, Hereford; Saltmarsh & Sons, Chelmsford; Harrison & Sons, Leicester; Lee & Son, Hammersmith; Scott, Merriott; Wheeler & Son, Gloucester; Bunyard, Maidstone; Killick, Maidstone; Haycock, Barham Court; Britcher, Tonbridge; Veitch & Sons, Chelsea; Lane & Son, Great Berkhamstead; Dickson, Chester; Poynter, Taunton; Dunn, Dalkeith; Gilbert, Burghley; Stevens, Trentham; Selwood, Eaton Hall and district; Miles, Wycombe Abbey; Clayton, Grimston Park, &c. Extensive collections are also expected from Tweedside.

There will be a meeting of the General Committee on October 4th at 2 P.M. Certificates will be awarded to approved new varieties, the Sub-Committee being entrusted with the preparation of a detailed report, &c

THE National Apple Congress will doubtless be interesting to those who can attend; but what about the far greater numbers who cannot? Will an official tabulated report of the collections be published? if not the Congress will be of limited use.—NORTH BRITON.

In view of this gathering next month, which it is to be hoped will bring together a large variety of Apples, it would, I think, be much appreciated by many of your readers if you would state through the medium of your columns the best way of getting there to see the Gardens. Chiswick is some distance from South Kensington, and as many visitors to London avail themselves of the day trips or excursions organised by the railway companies to the Fisheries and other "sights," and as all gardeners are not acquainted with the quickest and cheapest route to Chiswick from London, a few lines respecting it in your columns would be of great service to those contemplating a visit. Which is the best route by rail from the Fisheries Exhibition at the Horticultural Gardens at South Kensington?—A. HARDING.

[There are three or four trains hourly from the Mansion House *via* the District Railway to Richmond, Hounslow, Harrow, and Ealing, all of which stop at Turnham Green, and some of them at Acton Green stations, the former fifteen minutes' and the latter eight minutes' walk from the Garden. These trains can be met at South Kensington station by visitors to the Fisheries Exhibition.]

LONGFORD CASTLE.

IN the lower portion of a beautiful park fringed with fine timber, with bold masses of trees in the distance, and noble individual specimens in the open central space, Longford Castle, the baronial seat of the Earl of Radnor, is situated. It is three and a half miles east of Salisbury, and was built in the early part of the fifteenth century, but has been much enlarged and beautified by the present owner. Late in 1644 the King demanded its surrender as a garrison. After the battle of Naseby, Oliver Cromwell during his triumphal march, taking Basing House and Winchester Castle on his way, thought fit to summon Longford, and it surrendered to him in 1645. Queen Elizabeth, too, paid a friendly visit of some duration to Longford Castle, which is of great size and remarkable for the beauty of its architecture. The general figure of the building is triangular, is built of Bath stone and small pieces of flint in squares at short and regular intervals between the stone. This is very effective, and the large

circular towers at each angle, and a small staircase tower at each of the inner angles, give to the pile an imposing appearance. In the centre is an open court; at the western front—the carriage entrance—is a recessed vestibule or piazza and a large hall. This façade is profusely adorned with rustic pilasters, with balustrades and a gallery or portico on the first storey. About 30 yards east of the Castle is situate the Manor House, a picturesque building in the Tudor style, having as its prominent feature a central clock tower. The river Avon flows through the park on the east side, and within a few dozen yards of the Castle, in the clear waters of which this noble pile of buildings, with its towers and minarets, is sharply reflected.

THE FLOWER GARDEN.

The Italian flower garden opposite the south front of the Castle is sunk below the general level. It is a parallelogram of considerable size, having a broad central walk, in the centre of which, at the south end, stands an elaborate temple to the Goddess Flora, with steps ascending thereto. It is supported by circular columns having capitals and cornice of the Corinthian order, the temple being surmounted by an urn. On each side of this temple, in a recess to the rear, are large Orange trees with rich foliage and laden with golden fruit; beds of Roses on their own roots, pegged down and growing freely, while between the walks and the grassy slopes are several mythological figures of great age. In the central squares, of which there are four, consisting of twelve beds each on each side the central walk, are large urns supported on pedestals, also vases; several of which, together with large specimens of scarlet and pink *Pelargoniums*, are on and in close proximity to the terraces. Irish upright Yews, with standard and climbing Roses trained to rustic posts, occupy central positions in several of the flower beds, imparting diversity to a beautiful garden. Twenty-four of these beds, eight oblong and sixteen hexagon-shaped, are filled with a select variety of carpet-bedding plants, the remaining beds being planted in masses with *Pelargoniums*, the bicolor, tricolor, and silver-leaved sections being mixed with Blue Perfection and Golden Gem Violas. *Ageratums*, a superior variety of the Tom Thumb, we never saw finer. *Lobelia pumila magnifica* was also highly effective, as was the best bed of the distinct *Calceolaria amplexicaulis* we have seen for years, while *Heliotropes* were very good. After the summer occupants are removed from the beds they are filled with spring-flowering plants, and when these are in beauty the effect must be charming. On the centre of the terrace at the south end of the garden is a sundial, and from this elevated position there is a fine view of the Castle northward; westward, in the undulating park, fine glades, clumps, and single specimens of Beech, Elms, and spreading Chestnuts, with the spire of Salisbury Cathedral cutting the sky-line; eastward, also, the park dotted with handsome trees, having in the background beautifully wooded slopes, behind which is the village of Alderbury, with the tapering spire of its church towering above the tree tops, and in every direction rich masses of foliage just developing its autumnal tints. A view more fair than this—a quiet view of pastoral beauty, it would be difficult to find, as there were so many features to command attention.

A characteristic feature of the flower garden is its broad encircling Yew hedge, through which a series of arches have been cut with mathematical precision, and the whole is enclosed by ornamental stone balustrading, with piers surmounted by stone balls at regular intervals, the lower part of the wall being covered with Ivy and Yew. The garden in question is a model one of its kind, everything—statuary, flowers, Yews—being so admirably balanced and in keeping, it may truthfully be pronounced faultless; lawns, walks, flower beds, everything being in the most admirable condition. Many hardy plants are employed in the beds, and form a sort of permanent carpet as suitable for spring as for summer effect, such low-growing plants as *Veronica repens* and the golden-tipped form of *Sedum acre* being extensively employed. Very striking, and not often seen now, were some beds and large specimens of the true old Tom Thumb *Pelargonium*—sheets of velvety scarlet of its own peculiar glossy hue, and the innumerable small trusses appear to great effect rising from its light green zoneless foliage. For effect late in the season Mr. Ward finds this excels all others, but *Vesuvius* is the most effective in early summer. Some beds of Beaton's distinct old Indian Yellow were also highly effective; but we were especially pleased to see Tom Thumb in his rich autumn garb of long ago, yet fresh and bright as ever, and holding his own bravely among his modern rivals. We leave this garden with the remark that in neatness and finish it ranks with Drumlanrig and Heckfield, and more need not be said.

Immediately outside the flower garden is a large expanse of lawn, bounded on the east by the rapid-flowing Avon, in which fishes by the million are disporting in the clear water, and west and south by fine belts of *Rhododendrons*. In the front of these a line of *Lilium auratum* in flower showed to great advantage, the plants being remarkable by their sturdy habit, and the flowers were seen to great advantage against the dense background of green. The bulbs, we were informed, were planted in June in a border 2½ feet deep of sandy peat. On the lawn are several fine specimen *Beeches*, including a grand example of the purple variety. *Magnolia grandiflora* also diffuses its fragrance, and a huge bush of the common *Barberry* in all aglow with its coral-like fruits. For relief and effect in winter are a few thriving *Conifers*, including a very fine specimen of the dense *Abies Clanbrasiliana*, *Thuja borealis*, *Pinus insignis*, *Juniperus sabina*, and some others.

Noteworthy here are what are called the "Clematis Temples." There are two of them; one covered with *Clematis montana*. These are paved with pebbles like mosaic work. The larger one has a small circular bed in the centre, and mosaic walk round it; eight others, about 2½ feet wide, radiating from it to an outer circle 60 feet in diameter. Between

these radiating walks are eight beds edged with ornamental tiles, and filled with gold and silver Pelargoniums, mixed with purple and yellow Violas. The wirework of this temple is also covered principally with varieties of Clematises. Large oval-shaped beds, in which single Dahlias are the prominent autumn flowers, are appropriately placed; and there are beds of Roses, the plants raised from cuttings and the growths pegged down. Nothing could be more satisfactory than the condition of these, and they must produce a wealth of fine blooms throughout the summer. There is also a row of standard Roses on raised grass mounds outside, and parallel with the low wall of the flower garden; this method of arranging having probably been adopted with the object of rendering the Roses visible from the windows of the Castle. The dressed grounds now under notice are as admirably kept as the flower garden, and form an agreeable link between that beautiful enclosure and the part next to be referred to.

THE PLEASURE GROUNDS.

Southward from the flower garden and Castle these are most pleasantly situated. They resemble a wilderness of vegetation traversed by sound and excellently kept walks, over which the arching branches form a canopy of foliage. Under the dense shade of the deciduous trees it is noticeable how well the common Box thrives; there are bushes of all sizes of it, also large masses of Yews, Portugal Laurels, and other

THE KITCHEN GARDENS.

We say "gardens" advisedly, for there are several enclosures; indeed, we never saw such a great extent of walls on the same space of ground, nearly a mile in length being covered with fruit trees. Prominent among these are Fig trees, which cover more than 100 yards run of wall, clothing it from base to summit, excellent in health and laden with fruit, the varieties being Brown Turkey, Castle Kennedy, and Brunswick; and on another wall near the gardener's cottage a fine tree of the latter covers a length of 60 or 70 feet of wall. The walks are neatly edged with Box, and the borders fringed with Parsley—splendid rows of Lec's Matchless, which would gladden the many gardeners, especially near towns, who experience such great difficulty in maintaining a supply of this indispensable herb. Well-formed pyramid fruit trees and well-furnished quarters of vegetables also arrest attention in this department, as do some rows of Scarlet Runners about 20 feet high, necessitating the use of tall garden steps to gather the abundant produce; and in striking contrast is a lowly bed, not often seen in gardens, of Cranberries. As might be expected, these are in a cool moist position, and growing in a compost of peat and vegetable matter. They are bearing freely, and the fruit is much appreciated in the Castle.

GLASS STRUCTURES.

These are rather numerous, there being upwards of twenty of them,

FIG. 54.—LONGFORD CASTLE.

evergreens. This is a delightful retreat on a sultry day, and the more so since a trout stream winds through it alive with fish and spanned by appropriate bridges. This stream unites at its exit with the rushing waters of the Avon. These pleasure grounds are extensive, and at one part there is a "clearance"—an open expanse of turf known as the "old garden." Here is a very fine example of the Judas Tree, *Cercis Siliquastrum*, a still finer bush 20 feet in diameter of *Chimonanthus præcox*, and a specimen of *Catalpa syringæfolia*. The Deciduous Cypress also thrives well here, one specimen standing alone on the turf; but another a short distance from it among the trees being about 100 feet high, and the stem 8 feet in circumference 4 feet from the ground. Seats and summer-houses here and there render this part of the grounds additionally enjoyable. The walks are edged with flints, and between them and the shrubs are continuous lines of Snowdrops and Daffodils associated with Periwinkles, and the effect in their season must be very attractive; these and other bulbous plants, also the Periwinkle, thriving, like Ivy, in the densest shade. There is little that is gardenesque in these pleasure grounds—their charm lies in their semi-wildness; yet it is very apparent they are not neglected, but in their cleanliness receive the same attentive care on the part of the gardener as every other department does that is in his charge, and form a conspicuous feature of this fine demesne.

some small, others large, but all useful and well stocked throughout. Near the gardener's cottage a square of sloping ground is occupied with a series of pits and houses running east and west. First are two Melon and Pine-sucker pits, then a lean-to Pine pit in two divisions, next following in the order named a three-quarter span range, comprising early Peach and Pine stove, the latter containing good fruiting plants of Smooth Cayenne, Charlotte Rothschild, Black Jamaica, and Queen; an Orange and Camellia house 24 feet wide, with large specimens in the best of health; a pit for the preparation of decorative plants of the usual popular kinds, all admirably grown; a Melon, Cucumber, and Strawberry house in three divisions, the late Melons being of the most promising character, and the Strawberries (now, of course, outside and 3000 in number) being in a thoroughly satisfactory state. Other plant pits follow, one division containing Gardenias planted out, and others accommodating healthy stocks of Eucharises, Tree Carnations, Callas, *Echeveria retusa*—in fact, all kinds of plants for house and conservatory embellishment.

In another enclosure we find a range of vineries in two divisions, with Lord Napier Nectarine and *Passiflora edulis* fruiting on the back wall. The Vines in one, being struck and planted out in 1882, will carry a few bunches next year; the other, a mixed house of Alicante, Black Ham-burgh, Madresfield Court, Mrs. Pince, and Gros Colman, affording

useful bunches for present use. Passing through another archway we find a long Peach house 100 feet long in two divisions, the varieties in the second early house being Grosse Mignonne, Goshawk, and Dr. Hogg, with Pine Apple and Lord Napier Nectarines. The other or late house contains Bellegarde (midseason var.), Prince of Wales, Late Admirable, Lord Palmerston, Barrington, and Rivers' Orange Nectarine. The back wall is covered as well as the trellis, all the trees being remarkably clean and in the best bearing condition.

The last and chief range to be noticed consists of a series of vineries with a conservatory in the centre. This is a well-proportioned and very excellent three-quarter span range 200 feet long, and nearly new; erected by Messrs. Weeks & Co. of Chelsea. This new range consists of a fine central greenhouse or conservatory with two central stages, together with side stages and a tank underneath the tessellated floor capable of holding 7000 gallons of water, and having several inlets for conveying the water to it from the roofs. On each side of this house are two vineries, the Vines in which were rooted and planted in 1881 in an inside border 17 feet wide and an outside border not yet being made. Good drainage was afforded, and the soil consisted of loam, lime rubble, and horse droppings. The first house at the east end is planted with Muscats and one (central) permanent Vine of Roberts' Gros Guillaume, a few of the same, with Foster's Seedling being planted temporarily between the Muscats. The second is a house of mixed late varieties—Gros Colman, Gros Guillaume, Trebbiano, Raisin de Calabria, Alicante, Syrian, Madresfield Court, Lady Downe's, and Muscat of Alexandria. The third, an early house, contains Black Hamburgh, Trentham Black, Black Prince, Buckland Sweetwater, Foster's Seedling, Gros Maroc, Mill Hill Hamburgh, Muscat of Alexandria, White Frontignan, and the Strawberry. The remaining house at the west end is occupied with Gros Colman, Lady Downe's, Mrs. Pince, Gros Guillaume, Black Alicante, Alwick Seedling, and Syrian. The rods of Gros Guillaume in girth average 5 inches and the other rods about 4 inches. The lateral-bearing bunches of Gros Guillaume, many of them measure 2½ inches round, and are bearing Grapes worth going a journey to see, three excellently formed bunches close together on one Vine weighing 30 lbs., well-shaped and regularly furnished with fine berries. The other varieties are also excellently represented. In a short time a very fine collection of superior Grapes may be expected in the houses referred to, and which we trust will give Mr. Ward such a return for his labour as will compensate him for the grievous disappointment he has had to endure in consequence of the virulent attack of the phylloxera, which he has combated so successfully by the stamping-out process. The Vines are clean now, and fine Grapes may be expected at Longford.

The gardens are well appointed in the working departments, good offices, Grape-room, bothy, Mushroom house, and useful shedding being provided, and needed, for the demands are great, produce having to be packed four times a week during the London season. The noble owner, who is the Lord-Lieutenant of the county of Wilts, is highly esteemed as a landlord and employer. He appears to cherish his garden, and provides all that is necessary for its efficient management, water only needing to be "laid on" to render it complete, and this valuable addition will doubtless be made eventually, especially as it would not be a work of great magnitude.

Such an establishment as this is worthy of a competent manager, and such it undoubtedly has in Mr. Ward, for good work is seen in every department, and the admirable order that is observant throughout, and the extreme neatness that prevails everywhere, are prominent features of the surroundings of Longford Castle.

THE OUTDOOR CULTIVATION OF MUSHROOMS.

[Abstract of a paper read before the members of the Sheffield and Hallamshire Gardeners' Mutual Improvement Society, by Mr. W. K. Woodcock, gardener to Mrs. Firth, Oakbrook.]

WHILST residing in London in May, 1882, I had the opportunity of visiting and inspecting the grounds of Mr. J. F. Barter, Mushroom grower and spawn manufacturer, Lancefield Street, Harrow Road, London, and from him I gathered much useful information, the value of which I have fully proved in practice, and I can commend his system to all who wish to grow Mushrooms largely.

SHELTER FOR MANURE.

In the case of a large grower like Mr. Barter, who has large quantities of manure under preparation at one time, no cover is found necessary for it whilst it is under such preparation; but for a gardener who has to collect manure daily from what is made in the stables on the establishment, I believe it to be necessary that some kind of shelter should be found for throwing off the rainfall, as it takes a considerable time to collect a sufficient quantity of manure for making up a bed of proper size. At Oakbrook I have found what answers the purpose admirably in a number of lengths of corrugated iron roofing, each 5 feet by 2 feet. These I set up with their base about 5 feet apart, the tops resting against each other so as to form a span roof with open ends, and as the heap of manure enlarges I add additional lengths of roofing. We give the manure so collected a turn over about twice a week to prevent it becoming very hot and drying mouldy, which would be fatal to Mushroom-growing; this does not take up much time, as the lengths of roofing are easily set aside and replaced when the work is done. By the time sufficient manure is collected, which takes five or six weeks, it is in capital condition for use without further preparation. If by repeated turnings and keeping the covers over it is likely to get too dry, I take off the covers for a few days and leave it open to showers until it is sufficiently damped, when the covers are replaced. I have been particular in explaining my mode of preparing the material, as the greatest of all difficulties which gardeners often experience in their endeavours to grow Mush-

rooms is finding a suitable place in which to prepare the manure, but I have found none to equal for efficiency and simplicity this plan of portable covers, by which any out-of-the-way corner may be used; and if corrugated roofing is not available some old boards nailed together and used in the same way would be equally serviceable, and failing either of these, some stout stakes driven into the ground and old canvas or garden mats stretched tightly over them to form a span roof would answer the purpose.

MAKING THE BEDS.

In commencing to make up my beds I first measure off and mark out by a small stake driven in at each outside corner the ground it is to cover; this is 2 feet 6 inches wide, and of length in proportion to the material I have ready. A cartload of manure will make about 3 yards in length of bed, which, when completed, should be 2 feet 6 inches in diameter at its base, and the same in height from the ground-line to the apex of any length, though it should not be less than 5 or 6 yards, as a less quantity would scarcely maintain a sufficiently lasting heat to cause the spawn to work satisfactorily. The sides should be equal, and sloped up, so as to meet in a sharp ridge at the height mentioned. Mr. Wright in his book suggests that for those inexperienced in the work, guide sticks are useful for getting the correct form and dimensions of the bed, which sticks are made as follows:—Two sticks are cut, each a yard long, which are driven into the ground 6 inches, at a distance of 2 feet 6 inches asunder; the tops are then pulled together until they nearly meet and fastened there, when they give the outline of the bed. When we have marked out the base of the bed by the four corner pegs, a layer of manure is spread over the space to a depth of about 18 inches, which is then trodden and beaten until it is as firm as we can make it, when another layer is put on and treated similarly, drawing the sides in as the work proceeds until the required height is reached; and as the top layer cannot be trodden, it must be made as firm as possible by beating with the fork and spade; when finished the sides should be quite straight, even, and smooth, and as firm as they can be made. I next insert a thermometer well into the bed, and my portable covers come in useful again, set up against each other over the bed to throw off any heavy rains until the heat has sufficiently subsided to be safe for spawning.

SPAWNING AND COVERING THE BED.

I find that in a day or two after making up the bed the thermometer shows a temperature of from 120° to 130°. I wait until that has subsided to just below 100°, when it is safe to insert the spawn. In doing this I do not dibble holes into the bed with a peg, as is often done, but raise up with my hand a small flake of manure, put in a lump of spawn about the size of a hen's egg, and beat down the manure again.

All the portable roofing is at once removed, which is done with so far as this bed is concerned, and is ready to be used again in the preparation of more material. I next cover up the bed as lightly as possible with a thin layer of long litter, taking care to watch the thermometer, and if the heat rises again to over 100° I open the covering along the top to let it escape. In a fortnight to three weeks after spawning it will, if all has gone satisfactorily, be ready for covering with earth; before doing which I like to see that the spawn has permeated thoroughly through the bed, which is easily ascertained by taking out a handful of the material from different places in which the mycelium in the form of fine white threads ought to be plainly visible. For earthing I use maiden loam taken from the fields, well broken up and sufficiently moist to be easily beaten with a spade to a smooth hard face. Our plan of procuring this loam is to take off the turf and lay it aside, then take out a sufficient quantity of loam and replace it with the same quantity of any ordinary garden soil, afterwards replacing the turf. If the loam is too dry when procured it should be broken up small, and well watered a day before being used. If such loam is not procurable, any good garden soil may be used, providing it is not too light and sandy.

The thickness of the casing of soil as given in Mr. Wright's work, and as carried out in my practice, is 1 inch when beaten quite firm if of a heavy texture, 1½ inch for medium, and 2 inches for light soils. As soon as earthed the bed is re-covered with long litter, but the covering will now require to be thicker and closer than that put on after spawning. The length of time which will now elapse before Mushrooms may be expected will vary with the season of the year and the temperature of the external air. If in the summer or autumn months Mushrooms may be looked for in a fortnight to three weeks from earthing; if in the winter months thrice that time may probably elapse before they appear. My bed was made up at the end of last year, and was earthed about the end of January in this year. Mushrooms commenced to show themselves early in March, and I gathered a few off the bed all through that month, although the weather was exceptionally cold nearly the whole of the month. They, however, came but slowly and in small numbers during that month, but as soon as April came, and with it more genial weather, they began to show themselves all over the bed in large clusters. From thence until now, a period of four months, Mushrooms have continually been gathered off that bed in large quantities. If I had kept an account of the number or weight of what has been taken from this bed from the first gathering till now it would have been startling, and probably almost incredible. But it has not been less than three bushels. I gathered more than a bushel at one time in the middle of May.

I do not believe that such quantities are, or can be, produced on indoor beds, nor will the indoor beds continue in bearing for so long a period as those out of doors. I have had as good beds this season in our Mushroom house as I have ever seen or known; but my outdoor bed has, for weight and continuity of crop, surpassed them all. From early in November of last year up to the present date there has not been a day on which I have been unable to gather Mushrooms.

GATHERING THE MUSHROOMS.

In lifting the crop care is required in removing the covering so as not to disturb the young and half-grown Mushrooms, and it is essential that the covering be immediately replaced so as to conserve not only the warmth, but what is of more importance in the summer months, the moisture contained in the bed. It is well to avoid watering the bed unless absolutely necessary, which it sometimes will be in very hot drying weather. I follow Mr. Barter's practice of not watering the bed directly, but of putting it over the litter covering. I put salt in the water in the proportion of about a quarter of a

pound to three gallons of water. If the bed is nearly exhausted a little stable drainage added to the water in the proportion of about a pint to the gallon will materially benefit the bed.

The system of gathering the crop adopted by the London market growers differs somewhat from that where a gardener is expected to send in a daily supply for his employer's table. The London grower uncovers his bed only once a week, and he then gathers nearly all, big and little, that are grown. The gatherer has with him two baskets, into one of which the large Mushrooms are placed, and the small ones, or buttons, in the other. They also attach much importance to the manner of gathering. They say it is especially important that they be all pulled, not cut; and not only do they pull them up by the roots, rubbing the soil off the stem as they go on before putting them in the basket, but each man has in his hand whilst gathering an old table knife, and when any break off on the surface of the bed, leaving a portion of the base of the stem in the ground, he at once with his knife digs it out, making a hole in the face of the bed as big as a walnut, the edges of which hole he then scrapes clean and smooth with his knife. His reason for this is that the stumps of the old Mushrooms if left will produce a mass of fluffy stuff, a kind of mould or fungus, spreading out like a plate all round these old stumps, and that no more Mushrooms will come on the space covered by this mould, whereas if the stumps are scooped clean out small Mushrooms are formed almost immediately again around these holes.

I said it was advisable in private practice to differ in the mode of gathering from the market growers, but I did not mean in respect of this pulling the crop and scooping clean out the base of any requiring it, as I have tried and proved to my satisfaction this theory to be correct. I meant that it is not advisable to gather the whole crop, big and little, as they do. It answers their purpose, as there is a large demand for buttons, which fetch a much higher price than the full-grown Mushrooms. Also as they, as a general rule, uncover but once a week, those buttons if left till next gathering would be too old for market purposes. In gathering the crop only a small portion of the bed should be uncovered at once, and that again covered before uncovering any further, as it is especially important to conserve as far as possible the warmth and moisture contained in the bed, both of which will evaporate considerably if the bed remains long uncovered.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

A SHORT time ago a letter appeared in this Journal from a gardener, who was prepared to subscribe £10 to the funds of this Society provided he could see his way to do so justifiably to himself. To this end he asked a very pertinent question, which the Secretary was invited to answer, and which, without doubt, many others besides your correspondent would be glad to see answered. Hitherto no notice has been taken of that letter; and although it is not likely the question referred to could be answered in the affirmative, an excellent opportunity was and is afforded for the claims of the Institution for support, and the advantages it offers to subscribers to be placed before those whom it is intended to benefit, in a popular manner.

Dry, formal, stilted rules, though essential, are not sufficient for gardeners to thoroughly understand the working of the Institution. And, besides, hundreds of persons who either are, or ought to be, interested in it, have never seen the rules, nor do they know where to apply for them. An advertisement of the Institution is rarely seen, and persons are only reminded of its existence by an allusion to the annual dinner, or sending round the hat occasionally. I am one of those gardeners who are prepared to subscribe, but it has never been made sufficiently clear to me whether by doing so I should in the hour of need have a distinct claim on the funds over those who have never subscribed. I can understand if I had subscribed for a number of years—say twenty—that it would not be easy to pass over my name if I were an applicant for a pension; but suppose I had subscribed for five years only, or had paid a life subscription of £10, and needed aid, is there not a chance that some non-subscriber with powerful friends on the Committee would not have a prior claim to myself when a pension was allocated?

The truth is the working of this Institution is not well understood, and this being so, it necessarily fails to enjoy the full confidence of gardeners who support it, if they join at all, hesitatingly, and as if they were not sure they were doing right or wrong. Possibly the Secretary of the Institution has been enjoying his holidays, but now that the holiday season is over he might perhaps do worse than attend to the letter on page 175, and also to this if it happens to be worthy of his notice. One thing is clear, a benefit society is needed by gardeners, and if the "Royal Benevolent" does not, or cannot, be made to meet the requirements no one need be surprised if an institution is not started on a more popular basis, with the object of benefiting its members in the hour of adversity.—A COUNTRY GARDENER.

FRUIT TREES IN POTS.

ANYTHING that is inexpensive and likely to give satisfaction in the shape of culture I think should be brought before the readers of your widely read Journal. Last year, after having read a work on fruit culture in pots, I procured a few maiden trees of Apples, Pears, and Plums, and had them placed in 10-inch pots. I tended them carefully with water last summer and winter, and this spring kept them protected when in bloom till the fruit was fairly set; then in May I set them out upon the gravel walk (did not plunge them), every day supplying them with plenty of rain water which I kept in store for the purpose, giving them also about once a month a draught of liquid manure made with soot and hen-pen refuse. I send you a sample of the fruit herewith, and the quantity upon each tree:—Victoria Plum, fifty-five; Jefferson Plum, two trees each, forty-five and fifty; Stirling Castle Apple, twelve; Lord Suffield, seven; Pears various up to twenty, the

name of these latter I did not get. I have found the greatest pleasure in looking after these trees. First, we have the most lovely bloom, which in my way of thinking, nothing is so beautiful, then the prospect of splendid fruit instead of a decayed tree after the attention. If this is thought worthy of a place in your Journal, and this method of fruit culture is practised by any of your readers and they find as much pleasure in it as I have done, I shall not have written in vain.—JEDBURGH.

[We congratulate our correspondent on his success, which is both satisfactory and encouraging. The fruit sent was highly creditable to the cultivator.]

GARDEN CHEMISTRY.

THE CARE OF MANURES.

IN the majority of gardens farmyard manure will continue to be regarded as manure *par excellence* and indispensable. It is undoubtedly a good article when properly cared for and applied. Often enough it is neither. Bearing in mind that the chief value of manure of any kind depends on the nitrogen, phosphorus, potash, magnesia, and other mineral matters which it affords, in addition to the effects of humus, it may not be out of place here to give a typical analysis of ordinary farmyard manure. Of course no two samples will be exactly the same, but ordinary mixed manure will approximate to the following:—

COMPOSITION OF FARMYARD MANURE.

	Fresh.	Decayed.
Water	71.0	79.0
*Organic matters	24.6	14.5
†Ash	4.4	6.5
	<u>100.0</u>	<u>100.0</u>
	Fresh.	Decayed.
*Containing nitrogen	0.45	0.58
Equal to ammonia	0.54	0.70
†Containing potash	0.52	0.50
" soda	0.15	0.13
" lime	0.57	0.8
" magnesia	0.14	0.13
" phosphoric acid	0.21	0.30
" sulphuric acid	0.12	0.13
" chlorine	0.15	0.16
" silica	1.25	1.70

In the preparation of ordinary manure great mistakes are made. The manure from stables where hunters and carriage horses exclusively are kept and hard fed is, chiefly owing to its dryness and the careless manner in which it is thrown into heaps, generally reduced in value by one-half or even more. Gardeners are all familiar with the pungent odour that arises from such heaps, but it does not seem to be known generally that the pungency is owing to the carbonate of ammonia which the excessive heat is driving into the air. Nevertheless such is the fact, and no greater mistake can be made than to suppose that turning and damping such until it is wet and greasy will make matters all right. The heating has driven off the best part of the manure, which is, not the moisture, but the nitrogen.

If stable waste were put up into heaps, properly moistened and trodden down as hard as possible, and turned and damped again and again if need be whenever the heat threatened to rise too high, this would not occur. But another danger here presents itself. If too much water be given it will filter through and carry with it the ammonia dissolved in the water; for in the various forms it assume (as in the ulmate, humate, carbonate, &c.), it is easily washed away. Any urca in the manure is thus easily carried. Because of this all gardens should be provided with manure yards with cemented bottoms so inclined that all moisture shall run into a sunk space whence it can be drawn to baste the heap or be otherwise economically used, instead of being allowed to drain away. The littery mass is, weight for weight, far from being equal to this liquid. Failing a waterproof bottom, much may be done by placing a layer of loam or even ordinary garden soil under each heap. This will absorb much of the escaping liquid and filter from it its virtues—becoming itself, when sweetened by exposure, the very best thing to be found for top-dressing Melons just as they are setting, covering roots of any kind of trees that have been enticed to the surface by good treatment, or, indeed, anything.

Manure is seldom half made. The common idea is that when by fermenting and turning a ton of farmyard manure is reduced to 15 cwt., that 5 cwt. has been lost. Unless through carelessness nitrogen, phosphates, &c., have been allowed to escape the very reverse is the case. When fresh manure is applied to soil it is not prepared for the first year's crop, and in consequence the following winter's rains wash much away. This is lost. When very thoroughly

prepared and properly applied the crops get the food they want, and benefit accordingly. As such grow strongly and send roots through every particle of soil little escapes them, and hardly anything is left for the rains of winter to dissipate.

We think manure is seldom applied economically unless it is nearly a year old. But when kept for that length of time in our climate, unless it is protected, much is sure to be washed out, and at any rate the resulting manure is a soddened mass that "cuts like cheese," which, though an ideal state with many, is bad, for it is sour and cold, and will not spread easily. One of the main conditions which should be aimed at in preparing manure should be to have it in an easily pulverised state—something like what manure which has served the purpose of a hotbed and been protected by frames or pits usually is; otherwise it cannot be properly applied without great trouble, and the proper application of manure makes a great difference in the crop.

In order to keep off rain and allow of the proper manipulation of manure when the weather prevents open-air work, it would be a real saving to have roofed-in sheds for the purpose. Here in wet or snowy weather manure could be turned and prepared without injury either to men or manure. Then enough moisture could be given to prevent firing, and yet the manure kept dry enough to be easily pulverised. To pulverise it properly we would even for many purposes put it through a gravel screen. The reason for this we hope to make apparent by-and-by.

Fresh manure, no matter how carefully put up, gives out an unpleasant smell. This can be very much prevented by the use of earth. Old potting soil thrown over a dungheap will deodorise any escaping gas and become enriched in the process. When heaps must perforce be formed in the open air the escape of foul gases may be prevented and the rain thrown off by the same operation if the manure is laid up ridge fashion and covered with soil. It pays.

All garden refuse should be carefully gathered into a heap and rotted down. Such makes more valuable manure than that from the stables. Some garden vegetables, such as Cabbage and Onion stalks, smell offensively when decaying. To prevent this such should be mixed with earth. Such things as Cabbage stumps which rot slowly should be kept in a place by themselves.

It is wrong to mix quicklime with ordinary manure or vegetable refuse—it dissipates the ammonia; but road scrapings, turf from hedges, and such material as the turfy clearings of open drains and ditches, are all the better for being mixed with hot lime. It causes not only the rapid decay of any vegetation, but sweetens and pulverises the soil. Often such material so prepared is the best that can be got for mixing with the staple for planting fruit trees in.

Hotbeds are generally made of leaves and ordinary manure, but tan from the leather manufactories serves the same purpose, perhaps better. In some places the cleanings of flax or "pob" is used, and excellent hotbeds for certain purposes it makes. Then horse-droppings are used for Mushroom-growing. All these materials are valuable fertilisers after use, and because of the care taken of them are generally in first-rate condition for applying to soils.

Old hotbed manure, which has neither been so wet as to sour nor so dry as to fire, constitutes not only a good manure but is suitable as the basis of a soil for many purposes. For mixing with loam and sand it is the best article for rapidly forwarding most bedding plants and many vegetables early in spring. It is also good for mixing with soil for rapid-growing plants in pots, the existence of which does not extend over a few months, such as Balsams, Celosias, and annuals generally. As a matter of fact it is used for by no means ephemeral subjects, but is not the best for such.

Leaf soil is what its name indicates. As Mr. Wright has shown, there is leaf soil and leaf soil. He has shown that that formed in the usual way is very inferior. This he attributes to the fact of its being the product of fermentation; another reason is that when leaves are laid in large heaps too much water is held, and the whole becomes sour; another, and perhaps the main cause of its hurtful qualities, is the fact that heaps of leaves which lie for many months in a wet state are sure to be worked into a puddle by worms; and although these humble creatures certainly perform much useful work in the making of mould, leaf soil made by their agency is very bad. Plants grown in it do not thrive, not even such robust nurslings as Celery or even Cabbage. When the roots of such are examined it will seem as if they were rusted; they are corroded—poisoned. Such leaf soil is rich, but not wholesome. The kind Mr. Wright recommends, and the recommendation we can endorse from experience, is not rich, but it is wholesome. It is that found where it has accumulated of itself—in woods and neglected spots under trees. Never in heaps big enough to heat. Too dry to entice worms to take up their abode in it, thin enough to allow rain to pass through and air to penetrate, it can hardly be called a manure; it is soil that particularly suits very many plants that love "peat." We need hardly add that soil formed from Oak or Beech leaves is much preferable to

that from Planes and Elms. For many purposes, especially for growing Ferns, we have found the decayed fronds of *Pteris aquilina* by no means to be despised; flaky, porous, sweet, it makes a capital rooting medium.

Charred refuse of all kinds, old pea sticks, prunings, and everything that will burn, is of value as a manure, as we have already shown. But we wish to point out that these should be stored dry, for when left to bleaching rains for months they are of little more value than dry dust.

Of the care of artificial manures nothing need be said beyond urging the necessity for keeping such very thoroughly dry. Many mixtures have the property of taking in moisture from the air and becoming lumpy. This should be guarded against, for the value of such depends to a great extent on their friability. When scattered in pieces even as small Peas or even Onion seed they are half lost.

No farm and no garden is complete without a liquid-manure tank. The farmer wants one to save every drop of liquid manure, the gardener to have a supply always to hand, so that he with the least delay and expense possible may be able to give help when help is exactly needed. Not only so, such a tank might be the means of saving much expenditure in addition to securing enhanced crops. There is not a dwelling in the country but is capable of furnishing a constant supply, and this is far too often lost or worse. Water from closets stored in tanks becomes equal to any guano water, and in many cases no other is wanted. If tanks to collect such were placed in such positions that the water from them could run by gravitation to the garden and be distributed by hose, the difference in many gardens would be very apparent. But it will pay to pump it and convey it in swing barrows. Where it cannot be carried by gravitation hose and a force pump is the next best method for distributing it.

In impervious subsoils ordinary brick tanks well puddled outside the brickwork will be perfectly sufficient; but where the subsoil is very open, and especially if the tank is at all near any well, in addition to the puddling the inside should be carefully cemented. It is not a good plan to make tanks very deep, rather make them longer. Their width should not be more than 6 or 7 feet, as that breadth can easily be arched over. Wood rots and iron rusts in time, and so arched brick covers are best; but good large manholes should be left through which pails could be easily passed when the sediment needs removal. Only glazed pipes with faucet joints very carefully cemented should be used. Porous pipes or pipes with faulty joints allow the water to dribble away into the subsoil, while the sediment remains in the pipe. Open joints, too, encourage the admission of tree roots, which revel in the manure and soon choke the drains.

Hides, horns, hoofs, hair, and feathers are similar in composition, and contain nitrogen equal to 20 per cent. of ammonia, which is the only valuable matter in them. They are not of much value to the gardener for producing immediate effect, for they decay very slowly. Horn shavings and dust are the best form in which they are applied. Hair, wool waste, and feathers should be mixed with ordinary manure and thoroughly decayed. As they are not often to be had in any but trifling quantities nothing further need be here said about them. Blood is best prepared by saturating earth with it. Fish is best made into a compost with earth. Seaweed is often of more value than farmyard manure. It needs no preparation.

Earth closet, pigeon dung, hen dung, and all similar manures are best prepared by mixing them freely with earth, and keeping them where the rain cannot reach them till they become mould; at the same time they may be used at once under certain conditions. Tree leaves are generally used for making hotbeds mixed with manure, or thrown into heaps by themselves. They should be treated as directed for ordinary manure. When it is intended to have them reduced to mould, it is well to turn and re-turn repeatedly, so that air may constantly penetrate, and it should be seen to that they never get too wet. Tan mixed with manure to form hotbeds adds very little to the value of the manure, but the mixture contains no evil qualities. Tan itself is not of much use as manure, but as a mulch for shrubs or even Strawberries, and, when decayed, for flower beds, is a very useful article.—SINGLE-HANDED.

TRINITY COLLEGE BOTANIC GARDENS, DUBLIN.

THERE is no time of the year in which this fine old garden is not attractive, and at all times a walk around with the Curator, Mr. F. W. Burbidge, is of great interest. There are few plants in the extensive borders, beds, or houses without a history that even the uninitiated or the most casual visitor would wish not to hear. Whenever I go to our Irish metropolis on business or otherwise I look forward with much zest to a run round with Mr. Burbidge. In winter the warm houses are brilliant with Orchids and many stove and greenhouse plants and some of the newer and best plants just introduced, while the cooler houses are gay with Chrysanthemums and cool Orchids. If tastes lean to spring flowers, through the whole of that period there will be a host of the various bulbs smiling from cosy nooks or occupying long borders—as do the Narcissi—

to greet you out of doors. I have been told there is one of the most complete collections of Narcissi in the world here. Anyone can see, as I often did, that ministering to the wants and studying them of his various *protégés* is a labour of love to the Curator. The place is large, and a mere casual look round gives no idea of its floral wealth. I spent part of two days recently there, and left abundantly satisfied. The few following were either new or striking:—*Æschynanthus javanicus*, a handsome basket plant introduced, if I remember rightly, by Mr. Burbidge from Java, with curious *Salvia*-like orange flowers, and rarely to be met with. *Gloriosa superba*—there was a well-trained floriferous specimen of this climber, very striking with its Lily-like blooms, and a remarkable contrast with the adjacent *Asparagus consanguinea*, as their foliage commingled. For cutting or bouquets imagination could hardly picture anything finer than the graceful Fern-like fronds on arching stems of this *Asparagus*. Mr. Burbidge, for the purpose named, prefers it to *A. plumosus* or *A. tenuissimus*. As finely cut as is its feathery foliage, and apparently so tender, it has more staying power in water when cut than the hardest Fern frond, which evidently points to its more extended culture. *Impatiens Sultani* was very striking in the Orchid house, the brilliant rosy scarlet blooms, as large as a florin, produced from the axils of the leaves and in continuous profusion. Although only introduced into commerce in the present year I was rather surprised to find it in several gardens in Cork and Dublin recently visited, and a prime favourite. *Anthurium Andreanum*—there is here a most promising young specimen of this coveted Aroid, and having just now two well-developed spathes. Of many showy plants it first catches the eye from the moist stove vestibule. Very beautiful is the white tint of the spadix as contrasted with the soft yellow of the tip and the shining, varnished, glowing scarlet of the spathe.

The collections of *Nepenthes* here and in Glasnevin embrace all that have been recently introduced. One of the most conspicuous, and still one of the rarest and most expensive, is *N. Rajah*, introduced by Mr. Burbidge from Borneo and sent out by Messrs. Veitch of Chelsea. It has two curiously recurved fimbriated lips or wings, and studded with hairs or glands within. The lid, I understand, in older specimens often reach nearly a foot long, and the pitcher being nearly half that through. Probably one of the most highly coloured, and which many prefer, is *N. sanguinea*. It is scarce and beyond the reach of most people. I must not pass from the *Nepenthes* without referring to *N. Mastersiana*, certificated last year and raised from *N. sanguinea* and *N. distillatoria*, or what is commonly called the Glasnevin variety. At this time of the year the number of Orchids flowering is limited; still there are some fine varieties among *Masdevallias*, *Miltonias*, a number of *Cypripediums*, *Oncidium*s, *Epidendrum*s, *Zygopetalum*s, *Dendrobis*, and *Lælias*. In the very select, showy, and well-stocked herbaceous beds and borders I cannot pass that welcome beauty of this year's introduction, *Tigridia conchiflora alba*, or, as some call it, *T. pavonia alba*. This and many other plants of doubtful hardness or capricious flowering propensities have a place in front of the long range. There is probably the largest and most select collection of *Chrysanthemum*s in the country; also of single *Dahlia*s. Conspicuously good in beds and borders are many members of the Composite order, which seem to like the warm sheltered positions. Nowhere do you see finer *Helenium*s and *Rudbeckia*s.—
W. J. MURPHY, *Clonmel*.

HISTORICAL JOTTINGS ON VEGETABLES.—No. 8 THE GARLIC AND LEEK.

OUR heading indicates two vegetables of high antiquity once in general favour, yet which are now held in no great estimation amongst the natives of Britain. We are more refined or more squeamish, or, perhaps, less sagacious than our ancestors were who loved these strong-flavoured allies of the Onion. Garlic, however, does not seem at any period to have had quite as much repute in our island as on the adjacent continent, in various parts of which the plant is frequently employed even now in mixed dishes, to the annoyance of sundry tourists who are somewhat fine of nose. These, like other plants of the genus *Allium*, contain both sulphur and phosphorus, hence in the processes of cooking and of digestion their bulbs evolve gases which are undeniably disagreeable, but to which habit reconciles many persons.

To the lovers of word-studies the Latin name of the Leek has afforded amusement and occupation. It is very probable that Bryant is right in his notion that *porrus* is the name, slightly altered, of an Egyptian deity, "Pi-orus," a God identical with the Bel or Baal of other nations. But some uphold the theory that it has an early Keltic root—*pori*, meaning simply to eat, hence porridge, a dish that contained Leeks with various articles beside to form a vegetable soup. This is certain, that the Leek figures not unfrequently in Egyptian hieroglyphics; it was well known to that ancient and singular people, presumably revered by them. A majority of botanists think the garden Leek (*Allium Porrum*) is hardly a distinct species, but a variation from *A. Ampeloprasum*, found wild both in the east and west. The plant may have been brought into England from Germany as some conjecture, but as Leeks are mentioned in Welsh history before there occurs a notice of them in our English annals, it

rather looks as if the species was indigenous in the principality. It is one of the peculiarities of this species of *Allium* that it adapts itself readily to any climate, though the pungency increases if grown in a low temperature.

That the Leek should have been taken as the emblem of Wales is not surprising, the simplest explanation being that it was the usual practice of the small farmers, who helped each other with their ploughs in the olden time, to bring Leeks for their midday repast. "Now-a-days," says one tourist, "in spite of the proverb, 'Common as Leeks in Wales,' few of them appear to be eaten by the Welshmen, but a peasant may often be seen munching an Onion with his bread and cheese." Of course the story has been passed from author to author that the Leek is worn on St. David's day to commemorate a victory achieved by the Welsh over the Anglo-Saxons in the seventh century, when the conquerors had placed Leeks in their hats by way of distinction. Its truth must be considered doubtful. That anonymous writer was probably a Welshman, who, in some rather barbarous lines, praised the green and white of the Leek, taking one as a symbol of courage, the other of excellence.

Gerard the herbalist speaks well of the Leek, which by his time had been introduced into most of the gardens about London, but he gives no directions about its cookery or its culture. Tasser observes that the farmers throughout England were acquainted with it and allowed it a place in their fields, as well as Onions and Garlic, to supply themselves and their neighbours. In one of his quaint verses he remarks:—

"In March Leeks are in season, for pottage full good;
And spareth the milch cow, and purgeth the blood."

King James J., when he arrived in the south of England, was doubtless pleased to find his favourite Leek was not unknown to his new subjects, for he is said to have had a particular liking for the "cock-a-leekie," a dish owing its distinctive flavour to this savoury vegetable; and the Scotch Leek, which differs somewhat from the English kind, having narrower leaves, has also an extra pungency grateful to northern stomachs.

The Shalot or Eschalot (*A. ascalonicum*) is another pungent species, but less offensive than the Garlic. It is named from the town of Ascalon in Syria, which is supposed to have furnished the first samples of it that were sent into Europe. The Crusades, which certainly brought us many Asiatic plants, may have been instrumental in making us acquainted with the Shalot, still called by some folks the Scallion, a form of the name that has not come through France, as has the common appellation. In a book published about 1548 Turner mentions this species, and its small membrane-cased bulbs or cloves clustered together; but in the Tudor times this vegetable seems to have had less patronage than others belonging to the same group.

We need not question the identity of the Garlic referred to in two of the oldest works extant—viz., the Old Testament and the Iliad of Homer; this is plainly the *A. sativum* of modern authors, still occasionally cultivated in gardens; a plant growing apparently wild in some parts of South Europe, perhaps only a true native of the East and of North Africa. By many of the ancients Garlic was regarded as both food and physic. The Romans held it in high estimation, believing it had such restorative properties that it would give strength to the exhausted, and even inspire the timid with courage. Pliny commended Garlic as a specific for a variety of maladies, and several of the old physicians during the period when England had visitations of the plague advised the use of a drink made from Garlic steeped in milk by way of antidote against the infection. Old Fuller averred that the plant was "sovereign" for men, and for beasts also, and in several of the south countries, until very recently, a clove of Garlic was carried upon the person as a remedy for ague and "chin-cough." An oriental superstition ascribes to it the power of driving away evil spirits! The reverence shown by the Egyptians, or supposed to be shown, to the Onion and Garlic was ridiculed by Juvenal:—

"Tis mortal sin an Onion to devour,
Each clove of Garlic has a sacred power.
Religious nations sure, and blest abodes,
Where every garden is o'er-run with gods!"

Before *A. sativum* was cultivated by our ancestors they were well acquainted with some native varieties of the Garlic. It is thought the name is an Anglo-Saxon one, having allusion to the spear-like growth of the leaves in some species. The Isle of Ramsay, so Ray suggests, was probably named from the abundance there growing of the broad-leaved Garlic or Ramson, which would make itself conspicuous by its snow-white flowers, and also apprise the nose of its presence should the by-passer step upon it heavily. The leaves, however, were gathered about

May, cooked in broths, or eaten raw after they had been soaked in water. Even now some folks, it is said, gather for salad the leaves of another British species, *A. vineale*. We have no proof that the Garlic of warmer climes was planted in England before the reign of Henry VIII., but it may have been, although unchronicled. Of its early history as a London vegetable a reminiscence is discoverable in a locality on the banks of the Thames. There was a landing place at a little bay or bend by the city, which was called Garlickhithe, because on the rising ground just above Garlic was commonly sold. This historic fact suggests that the vegetable thus vended may have been grown on the Surrey fields across the river and brought to town by boats. One of the numerous little hills in the vicinity of London has the old name of Plowgarlic or Ploughgarlic Hill, pointing back to a former cultivation of the plant thereabout. The earlier books upon gardening advise the setting of Garlic during February or March. Tusser, however, expresses a different opinion; he recommends November, near or at the anniversary of St. Edmund the King.—J. R. S. C.

DALKEITH.

ON my visit northwards I spent a very enjoyable day at this noble place. The Palace itself, with its Ivy-covered walls, is worth a journey to see, with its clean-shaven wide expanse of lawn. It is very pleasantly situated, and surrounded with fine timber, some trees being apparently 150 feet high. The grounds are well kept, and must afford great pleasure to the public, who are admitted free two days weekly when the family is not residing there. The chapel—St. Mary's—adds to the homeliness of the estate, and, though inside the park walls and private property, is also thrown open to the public, and is well attended. After a tour through the grounds with Mr. Dunn I went through the houses. In the first vinery I found a good useful crop of various Grapes, the best being Gros Colman well coloured.

Camellias were clean and well set with buds. In this house were several plants of the double *Tropæolum Hermine* Grashof, good. Cucumbers were healthy, bearing a useful crop; and growing in the same house were some good specimens of High Cross Hybrid Melon, also good fruit of Colston Basset. James Veitch Strawberry is valued for its productiveness and large fruit for second forcing. A very good lot of stout-crowned plants were growing in pots. Chrysanthemums looked very promising half plunged in ashes. Pines were very strong and healthy, especially Smooth Cayenne. Good handsome fruits were ripening from suckers less than one year old, and they seemed no trouble as grown here. In a small stove I found a very fine plant of *Anthurium Andreanum* with eight handsome spathes, very fine and bright.

Muscat Grapes were a good crop, quite heavy enough to colour well. Next was a good old-fashioned span house of greenhouse flowers. The Statice is very profuse in flowering here. The various old scented Pelargoniums were also in variety, not forgetting Lady Plymouth and Rollisson's Unique. Among Zonal Pelargoniums Henry Jacoby was particularly good, as also Lady Bailey, a good fine-flowered pink. Good fruiting specimens of the *Musa Cavendishii* were noticeable in the stove. Excellent fruit of Peaches and Nectarines were ripening in unheated houses, and Plums were particularly fine. Among the latter Transparent Gage stands very prominent.

I must not forget the fine ribbon borders, which are now at their best. The only irregularity is the back row of single Dahlias. These are grown from seed, and are generally good, some few extra fine, but they vary so much in height and constitution that they are really out of place. In reply to my question of raising by cuttings from selected roots, I was told this will not do, as they fail to make plants, being stunted in growth and not flowering freely.

The Apple crop was good, and my attention was called to a fine tree of at least fifty years' growth of the Ecklinville Seedling. There was no doubt about it, as young trees obtained of this variety and planted all bear the same fruit. Pears were a fair crop.

The kitchen garden was in good cultivation, and Peas growing very strong. The whole of the garden and grounds, together with the various houses, are admirably kept. I have made no attempt at giving a full description of the Palace and its domain, simply jotting down a few items which most took my attention.—STEPHEN CASTLE.

AN EXHIBITION IN CEYLON.

A LARGE Exhibition of plants, flowers, fruits, vegetables, and other products was held last month in Ceylon, and it may be interesting to English readers to note a few of the chief features of the Show as affording an example of tropical horticulture. A number of classes were provided in which money prizes or medals were awarded according to the relative merit of the exhibits, all that possessed in good qualities receiving some recognition. The first class was for "exotic garden perennials in pots," in which collections of Roses and Begonias were the principal shown. For "exotic garden annuals in pots" a fine collection of double Zinnias and other plants was staged. "Ferns in pots" brought a number of entries, Gold and Silver Ferns being the favourites. In "foliage plants" Crotons and Dracænas were shown by several exhibitors, but

strangely enough there was no entry in the class for "native wild plants in pots" when the Ceylon Flora includes so many beautiful plants. The cut-flower class contained Roses, Dahlias, wild flowers, bouquets, and table decorations. The class for vegetables grown in Ceylon by the exhibitor was a strong one, the following being represented—Potatoes, Carrots, Turnips, Peas, French Beans, Cabbages, Beetroot, Lettuces, Tomatoes, Vegetable Marrow, Onions, Yams, Jerusalem Artichokes, Gourds, Cucumbers, Ceylon native vegetables, Leeks, Rhubarb, Turnips, Bandakays, Breadfruits, Brinjals, Capsicums, and Sweet Potatoes. A class was also devoted to fruit grown in Ceylon by the exhibitor, and in this the contributions were numerous, including Plantains, Oranges, Pomegranates, Custard Apples, Pine Apples, Figs, Limes, Mangosteens, Rambutans, Peaches, Lovi-lovies, Papaws, general collection of fruits, and Seville Oranges. The largest class of all was, however, that for general food products grown in Ceylon, in which Tea, Coffee, and Cinchona formed very large and important features. Cocoa, Cinnamon, Arrowroot, Cane Sugar, Cardamoms, Pepper, Nutmegs, Cloves, Ginger, Tobacco, Cotton, oils, and native woods were all shown on a large scale, while classes appropriated to arts and manufactures were similarly well filled.

Referring to the general arrangement of this Show the *Ceylon Weekly Observer* remarks—"Never was the natural genius of the Sinhalese for the erection of ornamental temporary buildings more effectively displayed. Given a sufficient number of Areka and Bamboo poles, and with abundance of young delicate Cocoa-nut Palm leaves, Ferns, Cocoa nuts of different colours from emerald green to rich orange, Palmyra fruits, Pine Apples, and Screw Pine fruits, and the Sinhalese architects and artists will produce designs the most elegant and combinations of colour the most beautiful, such as, while they last, vie with the Gothic arches and pillars and the 'dim religious light' admitted through richly hued windows of the most celebrated cathedrals. The contents of the buildings were quite worthy of them; and although this is not the best season for fruits and flowers, we have rarely if ever seen the tropical wealth of Ceylon so well represented. The Ferns were especially luxuriant, the flowers were beautiful, and the Yams, Pumpkins, Cucumbers, and Gourds prodigious."

THE KILNS, FALKIRK.

FALKIRK is rather a famous place. The great northern Roman well passed through where it now stands in years long gone. Long after that it was the scene of what is called the battle of Falkirk, but what in reality was only the massacre of a small band of West Highlanders, headed by the ancestor of the present Marquis of Bute, by a powerful English army. Again after some more centuries armed hosts encountered hosts a little to the west of Falkirk, where the highlanders under "Bonnie Prince Charlie" encountered on foot and routed in an incredibly short space of time the best mounted troops the south could muster. As if to keep up its connection with warlike work, when Scots and Englishmen had joined hands in a union treaty and marched shoulder to shoulder against the combined foes of the Continent, it was to the sound of caronades cast at Carron a mile or two to the north of Falkirk. Later still, when shot and shell were hurled against the embattlements of Sebastopol, the shot originally came from the Falkirk Iron Works. Today no warlike material is made in the district that we are aware of, but if the Falkirk people have not exactly beaten their swords to ploughshares and their spears to pruning hooks, they now cast the best of grates and supply the world with sewing machines (for in the neighbourhood the Singer is made) and stoves, and I cannot tell what more; but horticulture is indebted to it for hot-water pipes, boilers, and coils.

But trees, Vines, and Orchids are what attract gardeners, and in Falkirk or near by are gardens well known for all these. At Mayfield there once was, and indeed yet is, though its arboreal glories are scattered, a unique collection of the finer trees and shrubs. Those who have seen Mr. Boyd's, of Callendar, exquisitely finished Muscat Humburghs at Manchester and elsewhere may be interested in knowing that they were grown within sight of "Carron blazes," and within one mile of the ancient town of Falkirk. At one time, too, and that not very distant, many pilgrimages were made to the seat of the late Provost Russell to see his famous collection of Orchids. That collection is now no more, yet Falkirk still boasts of one in many respects not the least in the kingdom. Within the last few years John Gair, Esq., of The Kilns, has been gathering together a goodly collection, and these, under the fostering care of Mr. Fairbairn, who was pronounced by one well able to judge, "the best Orchid grower in Great Britain," are rapidly assuming dimensions, as they already are in condition, that will cause them to be more heard of. My visit was but short, and time for taking notes was limited, so few names were noted. But indeed to note the names of all that are worthy in such a collection as this would be to compile a catalogue. I spent the time more profitably by sitting, metaphorically, at the feet of Mr. Fairbairn and learning all I could.

On entering the cool house the Masdevallias first attract attention. These are in magnificent health and growing like Leeks. Next follow *Odontoglossums*, and such *Odontoglossums*! Orchid growers will have an idea of their vigour from the fact that from the top of the bulb of *O. Alexandræ* spikes of flowers were issuing in various instances, while most were throwing spikes that were branched. Individual flowers $5\frac{1}{2}$ inches across have been measured of pure white flowers. "Grand variety!" the reader may exclaim. Decidedly, but good cultivation has a wonderful effect in changing varieties of Orchids. Flowers from a plant in poor health may look like an inferior variety. The same plant when in robust health will turn out a grand variety.

By-the-by, what a fine plant *O. Andersonianum lobatum* as grown here is!

Passing out of the *Odontoglossum* house we enter a very long one cram full from basement to apex with Orchids that will be overcrowded a year hence if they just do as they are doing. It is not a question of holding the ground here, with the aid of an occasional subsidy in the shape of imported plants. The question is, Where is room to be found for all these plants by-and-by? Yet Mr. Gair, with that enthusiasm that marks the true flower lover, cannot help adding more and more always. The first plant in bloom that attracts attention is *Cattleya guttata Leopoldii*, and beside it *Lælia elegans Schilleriana* and *superba*, with *Cattleya crispa superba*. In passing we notice *Dendrobium Walkerianum* with growths 3 feet high, and a *D. Wardianum* with 4-foot stems, which was brought to the place in a match-box only three seasons ago. Last time I called at the same place there were a few unpromising *Saccolabiums*, *Aerides*, and *Vandas* newly imported, now they are beautiful plants that anyone would be proud to own. One *Saccolabium Blumei Dayanum* has a spike at least 15 inches long, and one of *S. B. majus* we note as particularly fine. *Cattleya Dowiana* is in splendid condition, and a row of *C. gigas* all different and all fine. *C. Wallisii* was in bloom, some novel and very fine forms being among them; one almost pure white, with a beautiful rose blotch at the point of the lip, and lovely rose shading at the base of the segments of the perianth. It is to be sent to the recognised Orchid authority, who will doubtless consider it worthy to bear the name of the happy owner. Some very fine forms of *C. Eldorado* are also in bloom. There is also one plant here that nobody else has, and is prized accordingly. It is one of the best, if not quite the best, of the *Pescatoreas*, and is named *Gairiana*. It is in luxuriant health.

Some orchidists grow *Dendrobiums* well and only succeed moderately with others, *Odontoglossums* or *Cattleyas* are the forte of others. Few places can show everything thoroughly good, but The Kilns can. Hundreds upon hundreds are here, every one in luxuriant health such as we all like to see, but only a few seem able to secure. There is a secret or secrets in their cultivation. Part of the secret is that here the plants are thoroughly loved, and this by master and man alike. The consequence is that the one spares no expense necessary to secure their well-being, and the other grudges no labour spent. These are the secrets in all successful cultivation everywhere and in everything.

Mr. Fairbairn was, I believe, the first to use Fern roots instead of peat, and the first to demonstrate its superiority for that purpose. Mr. Brotherston advocates its use, and has referred to Mr. Fairbairn's success with it. Mr. Fairbairn showed us what his ripe experience has taught him to regard as the best kind of fibre to use. He procured it from a distance. It is the surface from off ground where in the woods *Lastrea dilatata* grows to the exclusion of everything else. This is cut just like common turf into tough mat-like squares, and after the soil is shaken from it there is left the best, sweetest, and most lasting fibre it is possible to secure. Better than peat, better than sphagnum, it may often be obtained by those who can secure neither. Mr. Fairbairn states that *Dendrobiums* and other Orchids which require to be kept dry at certain periods, and which are apt to shrivel when grown in sphagnum alone, remain plump when Fern fibre is used. He said he thought that the dried sphagnum had the effect of sucking the juice out of the plants by the roots. The opinion was hazarded that possibly the bulbs were better conditioned, got more material out of the fibre, and therefore had more substance and less pure water, and therefore did not so readily shrivel. He said that might be the explanation, but the fact remained the same.

Besides the *Odontoglossum* house and the large one where the bulk of the *Vandas*, *Cypripediums*, &c., are grown, other two houses are devoted to Orchids. There is also a fine collection of Ferns under glass, a stove, a greenhouse, and two vineries. The latter have considerably improved of late. Mr. Fairbairn has been using lime and also Thomson's manure. Doubtless both have had something to do with the improvement. Some very fine bunches of Abercainey Black were ripening at the time of our visit. In flavour and in the appearance of the wood this very much resembles Black Alicante, but the bunches are much more Black Hamburgh-like in appearance, are handsomer, and is found there to be a better keeper. By some Black Alicante and this are considered one and the same. Seen here the difference is decided, and Mr. M. Temple, who is at present in the district, and is no mean pomologist, considers them distinct, and the Abercainey superior. It seems to be the case of *Vicomtesse Hericart de Thury* and *Garibaldi Strawberry* over again—both very much alike, but one superior; but the same thing often grown under both names are so misleading.

Though the Orchids have been especially noted it must not be supposed that there are nothing but Orchids about The Kilns. Supposing the glass houses were removed and the indoor plants scattered it would still remain a notable place. Leading from the house to the garden where the glass houses are, and which, by the way, was once a bog, the walk passes through a grand *Rhododendron* garden. The grounds are rich in splendid shrubs and trees; even the hedges are uncommon. To screen off part of the lawn is a hedge of Golden Queen Hollies 8 feet high and 30 yards long, densely furnished to the very base, and in luxuriant health. The Yew hedges are kept in the best style possible, and in such a way as is only seen here and there. The flower gardening is not carried out on an extensive scale, but what is done is well done. Where once a gravel pit was is now a shady rockwork covered with luxuriant Ferns, and a goodly Rose garden nestles in a sheltered nook. The lawns are in a model condition, and altogether The Kilns is one of

those model places that are not of common occurrence. The influence of such places upon young men who visit such is to determine them towards the accomplishing of something deserving the name of gardening.—A. H.

FRUIT-FORCING.

FIGS.—Early Pot Trees.—These are now sufficiently advanced to admit of the essential operation of root-pruning and potting being attended to, which should be proceeded with at once. The trees having been plunged will have rooted abundantly into the material, and the surface mulching is full of fibres. If the trees are in 18 or 20-inch pots it will not be necessary to repot, but all the top-dressing should be removed from among the roots with a hand fork, and the strongest roots cut back. The drainage of the pots should be examined, the soil being then top-dressed with a compost of turfy loam three parts, and half part each old mortar and rubbish thoroughly incorporated and rammed firmly into the pots, giving a little water to settle the compost about the roots. Every particle of the fermenting material should be removed from the pit, and the pots stood on the open brick pedestals which it is advisable to have in order to keep the pots well up to the light and prevent displacement by the sinking of the fermenting materials. Trees treated in this way are less liable to cast their first crop of fruit than those shifted into larger pots; yet where it is thought advisable to increase the root space a good shift may now be given, employing the compost above named, and well moistening the balls before potting, ramming the compost well down so as to prevent the water passing through it without wetting the ball. The house should be kept cool, dry, and well ventilated until the time arrives for starting the trees early in December. Any trees in pots outside should be brought under cover without delay and treated similarly.

Trees Ripening a Second Crop.—Trees in succession houses ripening the second crop of fruit ought to be kept drier as the days become moister and shorter, a little fire heat being needed to expel damp, with free ventilation on all favourable occasions, as a dry and warm atmosphere is essential to insure well-ripened full-flavoured fruit.

Ripening the Wood.—Particular attention must be given to the exposure of the wood to sun and air, allowing the points of the shoots to stand out or find their way to the glass. Remove all useless wood, and thin out all soft wood now, removing decaying leaves as soon as they part freely from the trees. Watering trees in permanent borders should be discontinued after this, they having been well mulched and watered up to the present time.

Trees Growing too Vigorously.—Fig trees are gross feeders, and in rich borders make too strong growth, in which case preparations should be made for root-pruning or lifting as soon as the second crop is gathered. The drainage should be thorough, so as to allow of the free passage of the water needed in large supplies through the growing season.

MELONS.—Plants swelling their fruits should be encouraged by closing the house early, maintaining a day temperature of 70° to 75° from fire heat and running up to 85° or 90° with sun, night temperature 65° to 70°. Keep the growths well stopped, and thin so as to expose the fruits fully to sun and air. Water carefully, and when supplies are needed give them thoroughly in preference to little and often. Plants with the fruit ripening should be kept rather dry at the roots, and have a warm, dry, freely ventilated atmosphere.

PINES.—Young Growing Stock.—Take advantage of every opportunity to well ventilate these plants, so that any present tenderness of growth may have the full benefit of favourable weather for hardening it before dull weather commences. With a further view to this object it will be necessary to keep the glass clean both inside and out, so as to allow of the sun's rays not being obstructed. The temperature for these plants should be still continued at 60° at night, or a few degrees less in cold weather, 65° to 70° artificially in the daytime, and 80° with sun, with 80° at the roots. As the days decrease in length reduce the atmospheric moisture proportionately; but a dry atmosphere is extremely pernicious for these plants such as that of large houses, which for these plants, if they must be accommodated in such, can hardly be kept too moist, but pits or small houses with fermenting beds are decidedly preferable. Plants that have already made a good growth and need to be kept gently moving preparatory to their being started into fruit should have the full benefit of all the sun and light possible at the present time. If such plants are at a distance from the glass they should be brought up to it and given plenty of room.

Fruiting Plants.—In order to obtain a genial condition of the atmosphere water should be freely sprinkled on the paths and walls to encourage growth in the fruit. Let the temperature range at night from 70° to 75°, and from 80° to 90° during the day, ventilating from 80° slightly, and close at 85° when the sun is declining. Watering will require to be seen to once a week. Supply plants requiring it with tepid water, to which has been added a little guano or some other stimulant.

STRAWBERRIES IN POTS.—*Autumn Fruiters.*—Plants that are ripening their fruits should have a warm sunny aspect, standing them on boards or slates in a "plant-protector" or span-roofed frame, with sufficient space between them to admit of a free circulation of air, which is essential to prevent damping and enhance the flavour of the fruit. Water should be given the plants when necessary early in the forenoon, so as to allow of the moisture drying up before nightfall. If the weather be dull the plants must have a light airy position in a house where artificial heat can be applied to cause a circulation of air, as a stagnant atmosphere is almost certain to result in the fruit damping off. All the plants intended to fruit in November and continue the supply to Christmas must be housed, and have the fruits thinned, feeding with clear liquid manure.

Plants for Early Forcing.—The early plants of such kinds as Black Prince, Vicomtesse Hericart de Thury, and La Grosse Sucrée to be started in November should, if the weather prove very wet, be protected with lights; but there must not be any attempt at closeness, as warmth and moisture when the pots are full of roots, the foliage ripened, and the crowns fully developed, are likely to cause a premature starting of the plants into growth. Under no circumstances must the soil be allowed to become dry.

PLANT HOUSES.

Show and Fancy Pelargoniums.—These plants, in whatever stage they may be, must from this time have a position in a light airy house as close to the glass as possible, where the night temperature will not fall below 45°. The early batch, if young plants and well established in 3-inch pots, should without delay be placed in others 2 or 3 inches larger. If done at once they will be well established again before winter, and can in consequence be kept in better condition when the days are short and dark than if they had a mass of soil about them in which their roots had not penetrated. In potting drain the pots liberally, and make the soil as firm as possible, which insures dwarf sturdy specimens. If the points of the plants have not been pinched out do it at once. The late batch of old plants have been retained and have only just commenced growth, shake them out and repot them, placing them again in as small pots as possible. Intermediate batches if they need it should be shifted from the small pots in which they have been rooted. These plants must not be syringed after this date except on very fine days, and then early, so that the foliage will be thoroughly dry before night. In order to have good clean unspotted foliage careful watering must be practised.

Mignonette.—Plants trained upon trellises must have a light airy position from the present time, where they can be kept safe from early frosts. If these plants have been well attended to the early ones will have covered their trellises. Give them a little Standen's manure at intervals of about a month, and occasionally clear soot water. Keep their growths well tied down as they advance, and remove all flowers directly they are seen. If a few plants are required to come into bloom remove the flowers from the points of all the shoots, or pinch them, and then allow them to come forward; by this means a regular head of bloom is produced, and the plants will be much appreciated in the conservatory towards the end of November. Those growing in 6-inch pots and still outside must be placed in a cold frame, which will be all the protection needed for some time. The lights should be well tilted at night when mild, and drawn off during the day when favourable. Watering must be carefully regulated in whatever stage the plants may be. The soil must not be saturated, and, on the other hand, should never be allowed to suffer by the want of it, or the foliage soon turns yellow and the growths become hard. If a frame can be spared place it without delay over the batch sown on the open border and just commencing to show bloom. This batch gives but little trouble, and will yield abundance of flowers for cutting this autumn. Not only do they require protection from frost, but from heavy rains, or they soon grow weak and straggling.

Cinerarias and Calceolarias.—If these plants require potting it must be done at once. The latest batches should now be out of pans and placed in pots, so that they become well established before they require to be moved from cold frames. The earliest of the former will have their flower stems advancing rapidly, and will be found most serviceable during November and up to Christmas, especially blue varieties, a colour which is comparatively scarce during those months. Give weak liquid manure and clear soot water alternately every time water is needed. The earliest batches of the latter must not suffer by the want of root-room, or their growth will soon be brought to a standstill and the plants be attacked by aphides. Dispense with shading, and give them a lighter position than they have needed up to the present time.

East Lothian and Intermediate Stocks.—Young plants, either pricked out of the seed pans or boxes into others a further distance apart, or placed in small pots and stood outside, will now be ready for 4-inch pots. Place one good crock at the base of the pot for drainage, and over it a little decayed manure, and then pot the plants firmly in good loam, a little manure, and sand. They can be stood outside again after potting for a few weeks longer. We have ours arranged where a mat or other protecting material can be thrown over them in case of frost. They are not injured by a slight frost, but it is preferable not to subject them to it. Where cold frames are plentiful they can be placed in them ready for protection, but the lights should remain off. Plants of this description should not be "coddled," at the same time they deserve every care.

THE BEE-KEEPER.

HIVE-CONSTRUCTION, HONEY-PRODUCING, AND PRACTICAL MANAGEMENT OF BEES.—No. 3.

A WELL-CONSTRUCTED bee hive to fulfil all the requirements of the present day must be a very different article to the frame hive of our early experience. When we commenced bee-keeping the Woodbury hive was generally accepted as the best for all purposes, and our first stock of bees was put into a home-made one constructed after the well-known description in "Manuals for the Many." Of course it had the defects of the time—rabbits, notches, space above the frames, floor board projecting up into the hive body, wood n crown board, and the inevitable window at the back, with a rebate of a quarter-inch between the hive sides and the glass. This latter feature was an improvement (?) of our own, and formed a beautiful space 8 inches by 4½ deep, which was each year filled with comb and honey, to be admired by friends and blessed (?) by our unfortunate selves when it came to removing the frames and cutting away the superfluous comb from between the ends and the glass. We had no "smokers" in those days, and manipulating with bees was a very different affair from what it now is. We, however, endeavoured to keep pace with the times, and as each step in the improvement of bee hives was made public we took advantage of it, till at last our original hive had its faults gradually "improved" away, and held an honourable place in our apiary for many years, with distance pins, quilts, and all the rest of it.

When Mr. Pettigrew's book first appeared we were much impressed with his method of management as therein described, and being always open to conviction gave it, as we think, a fair trial side by side with bar-frame hives for about six years; the result was that our straw skeps were eventually discarded.

The apiarian whose mind is bent on improvement and who has plenty of opportunities for practice is bound to find out the shortcomings in any hive he is in the habit of working. We have kept bees as a home pastime for seventeen years, usually working from twenty to forty stocks, and have endeavoured during that time to make our hobby a profitable one. We have realised in one year over £5 from one stock, so we know all about that phase of the subject. Our views on the folly of attempting to make a living out of bee-farming for honey in this country have already been stated, but we have managed all through to make our bees pay and leave a fair return for the labour. Our place of business has been for many years a sort of rendezvous for numerous bee-keeping friends, and to the best of our ability we have acted as general adviser to all comers in matters relating to bee culture. These personal details may savour of egotism, but they are recorded here simply to show that our experience has been wide and varied—not confined to our own apiary, but it has enabled us to see how things are managed by the ordinary amateur, and thus, we hope, adding some little weight to anything we have to say on the subject.

So much is written now-a-days on bee-keeping by young enthusiasts of perhaps two or three years' experience who are "going to do" such wonders, or by scientific bee-keepers who teach others how to obtain results never achieved by themselves, that it is misleading to a degree sometimes for those who read, and then tack their faith on words written by gentlemen, who, as W. S. Gilbert says, "mean well, but they don't know."

We have kept our bees in skeps large and small, have used frame hives with large frames and small ones, and the result of all we could learn concerning the merits and demerits of such is that the skep system is to the advanced bee-keeper a thing of the past, that the bar-frame hive is the ne plus ultra of apiculture, and that large frames have so many disadvantages in practice in comparison with small ones that we have been for some time gradually weeding out all large-frame hives and substituting shallow frames.

About ten years ago we first tried the Carr-Stewarton hive, and were much pleased with it in some respects, but the double boxes of which the stock hive consists were a great drawback to its general usefulness. If the bees were wintered in both boxes the combs in the lower one were always more or less mouldy before the winter was over in spite of every care in ventilation. They were also very favourable receptacles for moths, because as the bees clustered in the upper box a great portion of the time, the lower frames were at the mercy of every insect pest which chose to take possession. We afterwards tried the plan of wintering them in one box only, and this was a

great improvement; but the objection against it was that in spring, when breeding was going on and it became necessary to give additional room, this could only be done by adding the second box, so that the hive at one moment was made double its winter size, and this sudden enlargement of the brood nest, lowering the temperature too much, was too great a check in the uncertain weather of early spring. We need hardly say all this trial and experimenting was not likely to go for nothing, and convinced us that the shallow frame had advantages not to be denied, only requiring to be worked on right principles to make it better for all purposes than any other. It need not be stated here how many alterations and changes were made before finally fixing upon the form of hive which we intend to bring before our readers; so we shall, as shortly as we can consistently with making all clear for those who choose to make a hive on our principle, give a general description of the advantages we claim for it. In claiming these advantages we would specially emphasise the fact that it is after several years' trial with it in our own apiary to test its working in what may be called expert hands. It has been tried in the hands of novices, including lady bee-keepers, with equally satisfactory results. It has also worked just as well with the timid bee-keeper who fears his bees, as with the active apiarian who has no dread of them.

In describing the details it will not be necessary to give external measurements with mathematical correctness, because they are of comparatively small consequence so long as perfect accuracy is secured in the internal dimensions. In general appearance the hive resembles a double or twin hive, and the first impression is that it is too large. This can be accounted for by the peculiar arrangement of the wedge front for the floor-board. The latter forms an alighting board 4 inches deep for the bees in winter, and one of the objects we had in forming it so was to avoid an appearance of unshapeliness, which it certainly had without it. This will be readily seen when we say the body box is only 6 inches deep and 2 feet 5½ inches long. With the wedge front inserted the hive appears 11 inches deep, so the appearance, as we may say, is that of a much larger hive than it really is.

The amount of breeding space in the full hive is, on measurement, somewhat over that of eleven frames of the Association standard size. Here, however, the comparison ends, for we contend that the amount of breeding space is vastly increased by the adoption of shallow frames when the hive is properly used. This will be explained later, and we will give seriatim the full particulars of each part of the hive.—W. B. C., *Higher Bebington*.

THE STING OF BEES.

WITH reference to an article which appeared in your last week's issue I enclose you a paragraph taken from the *Christian Globe*, in which the writer mentions a very simple remedy for the sting of wasps, and thinks that the application of this remedy might also prove efficacious in preventing any ill effects from the sting of a bee. As I have not had occasion to apply a remedy of this nature I am not in a position to verify its infallibility. Should you, however, think it worthy of the attention of the readers of your Journal, some of whom may be unfortunate enough to require its application, you are welcome to insert the paragraph, with what I trust will prove to be beneficial results.—W. B. YOUNG, *Alnwick*.

"It will be in the recollection of our readers that two cases of death from wasp stings within a fortnight were recently reported in the papers. Noticing this fact a correspondent has communicated to *The Times* a remedy which, if it be as successful as it is simple, and he vouches, especially those who reside in the country will thank us for reproducing it. Immediately on being stung place the hollow barrel of a key round the sting and press it until it begins to hurt. On removing the key the sting will be found lying outside the puncture it has made, and inside the ring formed by the pressure of the key barrel. I do not recollect whence I first had this homely surgical operation, but it is effective. All pain disappears at once, no swelling takes place, and in a few minutes it is difficult to find again where one has been stung. The sting, in fact, is extracted before its venom has had time to get absorbed into the tissues. This remedy is simplicity itself, and if it applies equally, as most likely it does, to the sting of a bee, it is well worth remembering."

[This is a very ancient remedy, and not, we think, equally efficacious in cases of bee stings, as these are barbed, while the stings of wasps are not.]

THE HONEY HARVEST.—Reports from various parts of the south of Scotland concur in representing the honey harvest to be the most meagre that has been gathered for many years. The late spring necessitated feeding the bees, which, however, bred well and swarmed largely. During the summer the wet and dull weather which was experienced

proved unfavourable for the storing of honey, and, in addition to this, the bee-keepers cannot hope to make up the summer deficiency this season from the autumn Heather, as that has been found to yield very little.

TRADE CATALOGUES RECEIVED.

Kane, Kells, Co. Meath.—*List of Bulbs*.
 Barr & Son, 12, King Street, Covent Garden.—*Catalogue of Daffodils and Bulbs (Illustrated)*.
 Compagnie Continentale d'Horticulture.—*List of Palms, Orchids, and Stove Plants*.
 W. Lovel & Son, Driffield, Yorkshire.—*List of Strawberry Plants*.
 Ralph Crossling, Penarth Nurseries, South Wales.—*List of Bulbs, Flowering Roots, &c.*
 James Yates, Stockport.—*Catalogue of Bulbs (Illustrated)*.
 H. Cannell & Sons, Swanley, Kent.—*Catalogue of Softwooded Florist Flowers, Roses, and Bulbs*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (*A. J. B.*).—We are obliged by your letter, also for your address with the particulars you have sent, and your request will be readily complied with. The qualifications, of which we had no knowledge before, are quite sufficient for the purpose in question.

Sowing Lawn Seeds (*A. M. B.*).—Occasionally when the seeds are sown in the autumn the young plants perish in the winter, but not always—not, perhaps, usually where the soil is well drained and the lawn is not swept during wet or frosty weather. As you only appear to need a small quantity of seed we should sow now, and then if it fails you can sprinkle on a little more in the spring. It sometimes happens that a term of bright weather in the spring prevents the quick germination of the seed and the rapid growth of the Grasses.

Filmy Ferns (*A. H.*).—It is quite impossible for us to say whether you can dispose of them advantageously or not, nor are we able to suggest any better course than advertising them with the object of ascertaining whether a great demand exists for these Ferns or not amongst cultivators.

Waterfowl (*A Dublin Subscriber*).—There is no doubt that many of our readers keep several varieties of waterfowl, but very few of them would undertake to estimate the "average prices" at which birds may be purchased. Your question involving a purely trade matter, the best advice we can give you is to write to Mr. Baily, Mount Street, Grosvenor Square, who will, we think, be able to supply you with the information you need.

Marketing Garden Produce (*C. E. S.*).—It is quite beyond our province to recommend either vendors of garden requisites or purchasers of garden produce; nor do we ever incur the responsibility of advising anyone what crops he should grow. Some persons find winter Cucumbers fairly profitable, others fail in cultivating them remuneratively; and we cannot advise anyone to attempt their culture for market who has not had previous experience in the work.

Worms in Soil (*J. W.*).—Worms in the soil which you are intending to use for Mushroom beds are an indication of its good quality rather than otherwise. In turning over the soil and applying it the greater number can be picked out, and the few small ones that remain will probably make their escape from the thin covering, and do no injury to the bed.

Lawn Patchy (*A. D.*).—You have no doubt indicated the cause of the patchiness of your new lawn—namely, shaving it too closely, and it may be the machine has dragged the grass somewhat in places instead of cutting it cleanly. The remedy is to scratch up the brown parts with a sharp-toothed rake, sow fresh lawn seed of the same kind as before, sprinkling on it a little sifted soil, and run a light roller over it. You may do this at once, and your lawn will soon have a green appearance. After the young Grasses appear you had better cease using the lawn mower for the season, using instead, if needed, a very sharp scythe, and not cutting too close to the ground. It is a mistake to shave lawns so closely as is customary in many places, both during dry weather in summer and on the approach of winter.

Heating Greenhouse (*Idem*).—The temperature that will be suitable for the bulbs, 45° to 55°, will also be of benefit to your Palms, Ferns, and Lycopods. Pelargoniums of the Zonal type, if healthy, and have

active roots, will grow and flower freely during the winter in the same temperature provided they have a very light position. Old plants that are not required to flower in winter may be kept tolerably dry, divested of a number of their leaves, and stored in the coolest position of the house. They will not be safe in frames. Plants that are getting too tall and taking up more room than can be afforded may be cut down, as they can then be placed more closely together on the stages or on shelves suspended from the roof; such shelves, however, will be of the greatest value during the early stages of the growth of your bulbs. Show and Fancy Pelargoniums should be wintered close to the glass; they cannot be safely preserved in a frame. You may cut down the shrubs and trees at any time from now till March, but the sooner you do the work the longer will be the time that must necessarily elapse before they start into growth again and assume a fresh appearance.

Cherry Plum (W. M. B.).—This is not the Mirabelle Petite, which is a small yellow Plum, useful for preserving and all culinary purposes. The Cherry Plum is quite different, and we cite the following description of it from the "Fruit Manual." "CHERRY (*Early Scarlet; Miser Plum; Myrobalan; Virginian Cherry*).—Fruit medium sized, cordate, somewhat flattened at the stalk, and terminated at the apex by a small nipple, which bears upon it the remnant of the style like a small bristle. Skin very thick and pale red, covered with small greyish white dots. Stalk three-quarters of an inch long, slender, and inserted in a small cavity. Flesh yellow, sweet, juicy, and sub-acid, adhering to the stone. It may be used in the dessert more as an ornamental variety than for its flavour, but it makes excellent tarts. Ripe in the beginning and middle of August. The young shoots are smooth, slender, and thickly set with buds. This is the *Prunus myrobalana* of Linnæus. It is frequently grown in shrubberies and clumps as an ornamental tree, where in spring its profusion of white flowers render it an attractive object." Fruit is occasionally seen in the market, but only in small quantities.

Tall Scarlet Pelargonium (*Idem*).—The plant to which you refer as growing in Brittany is *P. inquinans*. There are several strong-growing varieties employed for covering walls and trelliswork under glass. The strongest we know is the old Giant Scarlet, but we seldom see it now. Smith's Defiance is similarly robust in growth, but this also, we think, is scarce. This was followed by Punch, a variety raised by the late Mr. Beaton, and is useful for the purpose you name. We are unable to say which is the best variety for covering rockwork, as so much depends on the size and position of a rockery. Those we have named will cover space quickly, and in a suitable position flower freely.

Chrysanthemums for Exhibition (E. Y.).—If your plants finish well and are neatly trained they will be quite worthy of exhibiting at your local show, but you must secure the crown buds at once by removing the surrounding breaks promptly. You will thus have one good flower on each shoot, and this will be far better than three imperfect blooms; besides, the terminal buds would be too late, and the blooms from the crown buds, although your show is late, could, if rather early, be retarded, as large well-formed flowers continue fresh much longer than small flat examples. If you "take" the crown buds and manage the plants well, we think they will be in condition at the time of your show; but it is important to notice whether the crown buds are not weakened by the too great extension of the surrounding growths appropriating the support from the central buds and practically spoiling them. If this is so, then there is no option but to push on the growths and take the terminal buds as quickly as possible.

Pears (S. S.).—We should expect the varieties to answer on the aspect you name, but during a hot dry season Williams' Bon Chrétien might ripen prematurely, and would not probably be of the best quality. But if your soil is rather heavy and rich as well as deep that will be a distinct advantage. Souvenir du Congrès is a very fine Pear, and Clapp's Favourite appears to be increasing in popularity.

Violets (W. N.).—Many persons cut all the runners off Violets as if they were trimming Strawberries, and they undoubtedly obtain a profusion of fine blooms; but in the case of a new variety, or any variety of which it is desirable to increase the stock, we should certainly allow at the least a number of runners to extend and form plantlets, as we should not perceptibly weaken the old plants, while those from the young would produce a succession of flowers. You will not err by allowing some of the stoutest runners to extend and take root in the bed.

List of Useful Orchids (W. G.).—You will find the majority of the following easy to grow, moderately cheap, free, and handsome:—*Ada aurantiaca*, *Aerides odoratum*, *Brassia verrucosa*, *Calanthes Veitchii* and *vestita*; *Cattleya crispata*, *labiata*, *Mossiae*, and *Trianae*; *Cœlogyne cristata*, *Cypripedium barbatum*, *C. insigne*, *C. Sedeni*, and *C. villosum*; *Dendrobium crassinode*, *densiflorum*, *nobile*, and *Wardianum*; *Epidendrum vitellinum*; *Laelias anceps*, *autumnalis*, and *elegans*: *Lycaste Skinneri*; *Masdevallias Harryana*, *igneae*, *Lindeni*, *Veitchiana*, and *Shuttleworthii*; *Odontoglossums Alexandræ*, *cirrhosum*, *maculatum*, and *Pescatorei*; *Oncidium concolor*, *O. cucullatum*, *Pleione humilis*, *Sophronitis grandiflora*, and *Zygopetalum Mackayii*. The "Orchid-Grower's Manual," published by Mr. B. S. Williams, Upper Holloway, price 7s. 6d., post free 8s., will no doubt suit you.

Boiler Power (J. C.).—A terminal saddle boiler of the dimensions you give will heat close upon 2000 feet of 4-inch piping; but as a large margin must be allowed for the deposition of soot on the surface of the boiler, we should calculate the heating power of the boiler at 1500 feet of 4-inch piping. It would heat over 2000 feet, but the expense in fuel would not compensate for the working of the boiler to its utmost capacity, and is not only uneconomical, but from the heat generated from a highly heating radiating surface injurious to plant life.

Making Soot Water (L. W. S.).—If you place sufficient soot in a coarse canvas bag and immerse it in a tub of water, allowing it to remain long enough, it is bound to change the colour of the water and afford you useful liquid manure for your plants. Another plan is to first form the soot into mortar or paste, then place it in the tub, which fill up with water, stirring occasionally for a day or two, then allowing the soot to settle. A peck of soot will suffice for about thirty gallons of water. If a few lumps of fresh unslaked lime as large as your hand are placed in the tub this will clear the water, and all that will be requisite will be to clear the scum from the

surface before using. If your greenhouse is damp the tub of water would be better removed in the winter. What little water you need then can easily be made tepid in another manner.

Sub-laterals on Vines (East of Berwickshire).—It is usual to remove the sub-laterals from fruit-bearing Vines, nipping them off at one leaf as soon as that leaf is as large as a shilling, and stopping all succeeding growths at the first leaf that forms afterwards, keeping to that leaf throughout the season. It is a simple process of finger-and-thumb work, and is commenced even before the bunches expand their flowers. In the case of young Vines that have not produced fruit it is customary to allow the laterals to extend considerably with the object of encouraging the production of roots; and also in the case of fruiting Vines, if the principal foliage is injured by insects, scorching, or fumigation, it is highly advisable to encourage the growth of sub-laterals, but not to the extent of crushing and crowding the foliage to the extent of depriving the leaves of light and air. An extension of lateral growth on the part of weakly Vines with defective root-action is often advisable at this season of the year.

Lavatera arborea variegata (W. F., Knaresborough).—Although we have a plant that has passed two winters safely in the open air, it is in a sheltered position in the south of England. Young plants grown quickly from seed are thus made tender, and you would act imprudently by entrusting them in the open air in your district. It is only when they assume a ligneous character that they can be considered really hardy. We are glad you have found the plants so handsome. Those you have "3 feet high and beautifully variegated" will be attractive in the conservatory; and as you observe, the young leaves keep fresh a long time in water, they will be valuable to mix with cut flowers for room-decoration.

Gardeners' Dictionary—Seedling Pelargoniums (Young Gardener).—In addition to the "Cottage Gardener's Dictionary" there is Paxton's "Botanical Dictionary," which can be obtained through a bookseller. Its price, we think, is 25s. You cannot have a more useful work of the kind than the one you possess, but by all means have both if you can conveniently do so. The term you mention is an abbreviation of the word "inoculate," the meaning of which you can find in a dictionary. Although several of the seedlings you name would be similar to the parents, there is no certainty that all, or even a majority of them, would be identical.

Heating a Frame (R. P. K., Surrey).—Although some persons have succeeded in excluding frost from frames with the aid of petroleum lamps, other persons have injured the plants by that method of heating. Necessity being the mother of invention, we advise you to consult a tinworker, and together you may be able to devise a small boiler that can be heated by a lamp, this being placed on the outside of the frame. A small pipe passing from the top of the boiler round the frame and back into the lower part of the apparatus will insure a circulation of hot water through the pipes. These may be of tin or metal gas pipes, whichever are the cheaper. This would be the safest plan of preserving your plants, and such a small home-made apparatus would not be costly. A simple, efficient, and inexpensive method of excluding frost from frames and miniature greenhouses is much wanted, and if produced and made extensively known would meet with a good sale.

Leeks (J. Hood).—Cutting back or "topping" the leaves of your Leeks would only lessen the crop by paralysing the growth. If you had given us any particulars about the way you have treated the crop we might have been able to give you a more satisfactory answer; but if, as we imagine, your Leeks have not been transplanted as they should have been, in July at latest, they will be of no great value, as the stems will be all exposed, and therefore next to useless. If the whole are lifted at once and laid in so deeply that these stems are quite covered, they will be well blanched before spring. In doing so dig over the ground, making it smooth, and as you go along, every 18 inches or so lay the line along the dug ground and beat it smooth where the line is laid. Then cut a nearly perpendicular rut 6 inches or more deep, and in this rut lay the Leeks pretty much as you would plant Box or put in cuttings, and level up the earth against them, making it firm. Then dig another 18 inches and repeat the process. If, while the plants were still small, you had dibbled them in deeply, leaving the hole open, the process will not be necessary, and all that is necessary will be to draw earth to the stems.

Heating Pits (J. T. S.).—It is quite impossible that we can keep in our memory the nature and exact dimensions of structures that have formed the subject of past inquiries. We can only say that the top pipe should be the flow, the lower the return. The quantity of piping to be used depends on whether early forcing is needed; if so, two rows of 3-inch pipes would be advisable, but for having Melons ripe in July and August one flow and return 4-inch pipe would suffice. We are now writing on the assumption that your pit is low, in which case ventilators a foot wide would suffice. Ordinary deal is used for the framework of pits, but oak sills give them greater durability. The wires may be 9 inches apart, and a foot from the glass. If you desire to heat one division and not the other, you will need three valves, one each on the flow and return, and one in the waterway connecting the two pipes. You had better procure the services of a practical man to see the boiler and arrange the pipes. This would certainly be the safest course, and in all probability the most economical. A saddle boiler 2 feet long will suffice.

Late Grapes (H. S.).—Lady Downe's Seedling is generally conceded to be the best keeper of all late Grapes, and when well ripened and preserved is of very good quality. It does not usually produce large bunches, and the berries are more liable to scald than the majority of Grapes. The Black Alicante is a stronger grower, producing larger bunches and finer berries than the preceding, but in our opinion is not equal to it in quality. It is a very easy variety to grow. As regards quality of fruit, and also of appearance when well grown and finished, there is no late Grape to surpass, if to equal, Mrs. Pince's Muscat; but many persons fail to produce it in the best condition. In the vineyard at Longleat it is grown in the same division as Lady Downe's and Alicante, and surpasses them both in appearance and quality, though it may not keep perhaps quite so long as the former. It will succeed with Hamburgs as well as either of the others will, but none of the varieties mentioned might give you the same amount of satisfaction as the Hamburgs in the same house. We neither advise you nor dissuade

you on the matter, as occasionally we have seen every one of the varieties succeed with Black Hamburgs, while we have known all of them fail to give satisfaction. Very much depends on the house, the treatment that is given, and the skill of the cultivator. We answered your question on the ground vinery last week, on the same page on which the reply to your other question appears. The latter you have read, but appear to have overlooked the former. Examine the page again.

Cyclamens (*A New Subscriber*).—Cyclamens raised from seed now should be treated as stove plants. The seedlings should first be pricked out an inch apart in boxes of light gritty soil—leaf soil, peat, light loam, crushed charcoal, and sand being suitable—and placed close to the glass in a moist stove or Cucumber house having a night temperature of 65°. Eventually they should be transferred to small pots, using a rather heavier compost, still porous. At all times keep them moist, yet never saturated, as drought is fatal to them. Before the small pots are crowded with roots give them larger, the soil to be still heavier, a little dry flakes of cowdung crushed being a good addition. Apply water cautiously at first until the roots take possession of the fresh soil, then copiously. As the spring advances let them stand on a moist base if possible, syringe them according to the weather, and always keep them moist. When fairly established a night temperature of 60° will be suitable, and when growing vigorously 55° will suffice. With active roots, good soil, and plenty of moisture in both air and soil, with judicious ventilation, your plants will have no "limp" leaves, but stout leathery foliage, which is the certain forerunner of the best flowers the varieties are capable of producing. Defective root-action, the result of some check your plants received, was the cause of their unsatisfactory condition.

Herbaceous Calceolarias (*Idem*).—Prick out the seedlings in the same manner and compost as above advised for Cyclamens, but place the boxes or pans on moist ashes in a cool frame, taking particular care there are no slugs in it, or there will not be long any Calceolarias. Keep the plants regularly moist, and when they touch each other pot them carefully, using a little heavier and richer soil than before. They will still be better in a frame or pit from which frost is excluded, as these plants seldom thrive well on a dry open stage. As the roots protrude through the pots give them more room. This must always be done before the pots are crowded, and when the plants attain strength they will enjoy strong loam, yet open, and enriched with decayed manure. The pots should always stand on a moist base, a dry air being very unsuitable for the plants and very favourable to the increase of insects. These must be prevented, not allowed to appear and then destroyed, but must never be seen. This can be accomplished by very light fumigations at weekly or fortnightly intervals, so that there is always a smell of tobacco in the frame. Strong fumigations are dangerous, costly, and ought never to be required. The plants do not require heat, and will be quite safe if a night temperature of 40° can be maintained.

Names of Fruits (*I. A. C. S.*).—Your Apple is Duchess of Oldenburg (*Rev. E. Bertram*).—1, Nonesuch; 2, Gravenstein. (*G. C. E.*).—2, Loddington; 3, Hambledon Deux Ans; 5, Cornish Aromatic; 8, Fearn's Pippin; 11, Aromatic Russet; 12, Cockle's Pippin. (*W. A. M.*).—1, Margil; 2, Golden Pearmain; 3, Blenheim Pippin; 6, Cellini; 7, Fearn's Pippin; 11, Wyken Pippin. (*W. H. Divers*).—1, Duke of Gloucester; 2, Penny Loaf; 3, Sugarloaf Pippin; 4, Old Golden Pippin. (*Colville Browne*).—Early Violet Fig. (*H. H.*).—Duchess of Gloucester Apple; Peach, probably Barrington. (*J. F. L.*).—Figs: No. 1, Brown Turkey; No. 3, Brunswick. We are sorry we cannot name with certainty Nos. 2 and 4 without the fruit, but judging by the leaves we should say they are Brunswick. (*W. Laird*).—Dumelow's Seedling. (*W. Crowder*).—1, Yorkshire Beauty; 2, Duchess of Oldenburg. (*J. G. Trotter*).—2, Drap d'Or; 3, Coe's Golden Drop; 5, La Fameuse. A Blenheim Pippin Apple or Hesse Pear will suit you.

Names of Plants (*R. C.*).—We cannot determine the name of your Primula from roots alone. (*R. G. M.*).—The variegated leaf is Tussilago Farfara, the long one Chlorogalum pomeridianum. The Parsley would not be worth sending to London, as the supply is large. (*Monmouth*).—Sedum azoideum. (*W. W.*).—The specimens arrived in very bad condition, but we have identified them as follows:—1, Chrysanthemum maximum; 2, Helianthus trachelifolius var.; 3, Chrysanthemum carinatum; 4, Chrysanthemum tricolor; 5, Aster vimineus; 6, Abelia rupestris. The Impatiens is probably a variety of I. glandulifera, *Royle*, with which I. Roylei is synonymous. There are several varieties, varying in colour from white to rose. It is a native of India. (*Winchester*).—1, Gomphocarpus fruticosus; 2, Diplacus glutinosus. (*C. S. R.*).—1, Streptocarpus floribundus; 2, insufficient; 3, Pteris flabellata; 4, a species of Drymoglossum, but it cannot be determined without fruiting fronds; 5, Davallia novæ-zelanica. (*Inquirer*).—Dendrobium serra. (*S. J. W.*).—1, Polypodium vulgare; 2, Lomaria Spicant; 3, Athyrium Filix-femina; 4, Polystichum aculeatum; 5, Nephrodium Filix-mas; 6, N. spinulosum. (*T. S.*).—The long Grass is Alopecurus pratensis, the shorter one Cynosurus cristatus. (*Sambo*).—1, Solanum capsicastrum; 2, cannot be named without flowers; 3, Pteris cretica albo-lineata. (*W. B. S.*).—Mandevilla suaveolens. (*R. C.*).—Rosa bracteata, a native of China. (*J. R.*).—Nicotiana glauca, a South American shrub. The seeds are said to be much relished by humming birds. (*M. H. C.*).—The flower was very much crushed, but it resembles Brassia verrucosa. (*A. M. Grange*).—Specimen very poor, but apparently Peristeria elata. (*A. W.*).—Ulmus campestris variegata, a silver variegated form of the common Elm, there are others with golden foliage. (*W. W.*).—1, Bignonia radicans; 2, Myrtus communis flore-pleno; 3, Leycesteria formosa; 4, Anemone japonica alba.

USE OF GREEN AND FODDER CROPS FOR VARIOUS PURPOSES.

(Continued from page 264.)

IN continuing our remarks upon the growth of Lucerne as a forage crop, dry soils with an open porous subsoil are for the most part well adapted for this plant, which allows the tap root to pierce the soil to a great depth. Deep loam with a chalk subsoil is also good, as well as sandy loams with a mild brick earth under; but in the endeavour to obtain a good tilth so necessary for strengthening the young plants at the earliest period, the land should be deeply cultivated by steam power in the autumn, after which it may be finally laid into stetches for the winter. In the early spring the cultivation must be continued until the soil is perfectly free from any roots of couch grass, black bents, onion grass, or any weeds which are known to be indigenous to the soil under tillage. The application of manure at first may well be artificial or hand manures, such as the bone superphosphate, 4 cwt. per acre of which should be applied just before seeding the land with Barley, of which a moderate bulk of straw is only required, for in case of the Barley crop being laid or lodged a regular plant of Lucerne cannot be expected. Some farmers apply all the manure before seeding the land for Lucerne, especially if drilled on a fallow surface; but we do not recommend this, for it entails an enormous amount of labour the first year with the horse-hoe and hand-hoe without any adequate return from the produce of fodder. When the seed is drilled at the distance of 14 inches across the drills of a Barley crop no extra cultivation is required the first year, yet the plants are gradually strengthening and preparing for the yield of a full crop the following season. It is in the early spring that we would apply the ammoniacal top-dressings, such as 1½ cwt. of nitrate per acre—in fact, 1 cwt. of the same may be applied immediately after each cutting, which will largely increase the produce and give one or more extra cuttings during the year. In the second winter a good dressing of stable or farmyard manure will have the effect of nourishing the plants and preserving them from the ill effects of frost and snow to some extent. If it is found that weeds prevail, horse-hoeing the first dry weather in the spring will be advisable, but generally under liberal manuring the successive crops will overwhelm all weeds.

Lucerne will yield valuable forage for a number of years. Some persons limit the produce to seven or eight years, but we believe if this occurred it would be in consequence of insufficient manuring, or horse and hand-hoeing, or the fact of sheep or horses being allowed to eat out the crowns of the plants. Where liquid manure is obtainable the plants may be preserved for many years if it is applied with liberality and regularity in the spring of the year.

The growth of Sainfoin must next engage our attention, and a most valuable plant it is, and deserves for general culture the highest position in our estimation, especially on the chalk or limestone formation; for although the surface soil may vary, as it often does even on a single farm, yet the fact of the subsoil being suitable to the growth of the plant will have the most important effect on its successful growth under any circumstances. We have for choice the use of two varieties of Sainfoin, the common or old sort and the Giant, the latter being a strong

vigorous-growing plant, yielding a heavy weight per acre, but of a coarser description, especially when made into hay, but as it yields a second crop for cutting it is important. It is also found to thrive upon a variety of soils other than chalk or limestone, and it is also frequently used in admixture with Red Clover instead of Rye Grass, but more especially where any probability exists as to the failure of the Clover plant; but in any case it keeps pace in growth with Red Clover both in the first and second crop. It also acts like Rye Grass in opening the Clover in the swathe whilst the hay is in process of making, enabling the hay to be carried to the stack at least two days earlier than when Clover is grown alone; a very important object is, therefore, obtained without depreciating the value of the hay either for sale or for consumption.

The common or old variety of Sainfoin is usually grown upon the hill farms where the chief object is that of farming upon the poorest and coldest hill, whether of chalk or limestone, as this plant is much more hardy than the Giant variety, but the old variety only yields one good cutting of excellent quality; whilst the after growth is much valued for grazing with the in-lamb ewes, it being generally esteemed as the best green food they can receive, for it has never been known to produce abortion when fed off by pregnant stock. There is, however, a drawback even in this system of feeding, for the stock when feeding are apt to eat out the crowns and crown buds of the plant, and thus injuring the succession for another year; in fact, when thus fed the plants are usually ploughed up at the end of four years or so, many of them having died off and decayed in the soil. It is, however, a plan adopted by some of the most careful farmers when grazing the after-growth to feed it only by a shifting fold and not allowing the animals to gnaw it down too close, which they are sure to do if not folded but allowed the range of the whole field in the early winter months. We notice that some seedsmen make no allusion to the Giant sort in their catalogues. Now this is an omission calculated to induce the belief in young men and beginners that there is but one sort. But to show the distinction and use of the variety, we a few days ago in the railway carriage met with a farmer from a southern county, who said he had just put together the second growth of 34 acres of Giant Sainfoin for hay, but he had 20 acres of after-growth of the common sort, which he said he did not like to feed with sheep in the autumn as it frequently destroyed the plants, and asked what he could best do with it. Our reply was, that although he could not safely feed it off with sheep or horses, he may, however, if the land was well fenced, feed off the grass by young cow stock, or otherwise leave it without feeding at all. Of this latter idea he said he knew nothing, and feared it would injure the successional growth of next year. We explained that it would be just the reverse, for the early frosts would cast the leaves, some falling on the crowns of the plants and others falling on the soil. The former would, however, protect the plants during winter and cause an earlier growth in spring, while the latter, as dead and decaying vegetable matter, would be drawn into the soil by worms, and thus manure the land for another crop. There is no doubt a misconception held by many as to how long this plant can be retained in growing and profitable condition, for if required, and the plants are treated like Lucerne by wider drilling, horse or hand-hoeing, and liberal manuring, in that case it would last for an undefined number of years, as the cause of its not being generally a profitable crop, if retained more than four or five years, was on account of its not being fairly fed by sheep without the land being kept clean and the crop properly manured.

Tares or Vetches demand notice next, as affording one of the oldest and most useful green forage crops, and much valued by farmers for growth on nearly every variety of soil as adapted for feeding cattle, sheep, and horses during the summer months. The varieties in general use are called Winter and Summer Tares. This, however, refers more particularly to the seed time, the winter sort being sown in the autumn and the summer variety in the spring. There is also a variety named the Scotch Goa, which is a stronger growing sort than either the ordinary winter or spring Vetches, and where the seed can be obtained easily and not too high in price they are much esteemed on account of their luxuriant growth, which almost resembles that of the late field Peas of the Maple variety, the bulk of food being very great and succulent, and therefore well adapted for cattle and sheep; but for the latter stock they should be in admixture with Oats, a half bushel of which sown with the Vetches per acre serve to hold the haulm up off the ground, and often renders the entire crop available for food without waste. The same mixture of Oats or Rye is advisable for all species of Vetches, but especially for Winter Vetches. It not only answers the purpose we have just described, but the leaves of any cereal crop will protect

the Vetches against injury by frost in the winter months—a matter of considerable importance in the chalk hill districts, especially on the north and north-eastern sides of the hills. The seed, however, on such situations should be sown not later than the second week in September.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are now assisted most advantageously upon the best managed farms by steam power. We have during the middle of the present month double-cultivated some of the Wheat stubbles which had been left in a foul state by the late tenant, and have also cultivated a long summer fallow after last cross-ploughing, which will complete the work together with rolling and harrowing in very satisfactory condition. As the work was done by steam power during fine weather, and the land in a dry state, the effect will be greater and more beneficial than ordinary horse labour, for the work is not only done without treading by the horses, but so much work is executed in so short a time that it becomes invaluable as an agricultural operation. In the Wheat stubbles which were foul with couch and weeds, a large quantity will be on the surface connected to some extent with the mould, it then becomes a question as to the most beneficial mode of reducing the clods and lumps of grass, and the disposal of them. The ordinary way of proceeding is to continue harrowing and rolling until the couch is freed entirely, or almost so, from the earth, and burn it as fast as it accumulates in small heaps about the field. We have a strong objection, based upon a long experience, to this mode of dealing with couch, but much prefer to do about half the usual labour in rolling and harrowing, and as fast as the accumulations or heaps are got together by the chain harrow, to cart them away to a large heap, and after being turned over once we have a quantity of valuable material for dressing pastures or parkland. We still hold to the idea that we never should burn any materials which can be converted into manure. It is often objected that the seeds of couch and weeds are still alive in the earthy materials, but we care not whether they are or not, for being always applied to grass land they cannot produce weeds, for on pasture land they could not compete with the living grass. We have never found even live couch grass when laid on pasture land would or could grow thereon, for the worms immediately set to work and draw everything applied into the soil, and turn it to good account as manure for the pasture. These are very favourable results compared with the attempt to burn the couch on the land, for even after very much labour in our fickle climate rains frequently occur and prevent the burning, and the couch has still to be dealt with and disposed of in the same or some other way, and in doing this more labour is often expended than when disposed of by heaping for manuring purposes as in the first instance.

Hand Labour.—Both women and men can now be fully employed in various ways. Hedge-trimming must be completed, and common decency requires the women to rake up the proceeds of the trimmings as well as border-cuttings, and for which there is always a use on the farm. Some threshing of Wheat and Oats must now be done for sale and for use; the former will be required for sale and for seeding, and the latter for feeding horses. This will employ men and women too, not only for winnowing the corn, but also in carefully stacking the straw, which is this year valuable for sale, fodder, and litter, and as soon as a stack is made thatching should be done immediately without a day's delay. Men and women will be employed also in connection with cutting and making into hay the after-growth of grass in the meadows, and if it cannot be made into hay through adverse weather, still the grass is valuable if laid and spread on the poorest pasture for manure to be pulled in by the worms, which are our friends frequently when some farmers only give them credit for doing mischief.

REMARKS.

16th.—Thick fog at first; bright warm day; clear moonlight night.
 17th.—Fog early, morning fine; very heavy rain with lightning and thunder 3.30 P.M. to 4.15 P.M.; misty evening.
 18th.—Fine, but rather close and warm.
 19th.—Hazy at first, fine warm day; lunar halo 9.30 P.M.
 20th.—Very dull and damp; rain during morning, finer after 4 P.M.
 21st.—Hazy and dull at first, rain after 10 A.M.; fine latter part of day.
 22nd.—Fine, but not very bright.
 A rather unsettled week, generally foggy or misty in the mornings and evenings, but frequently bright and pleasant during part of the day. Temperature remarkably similar to that of the preceding week and about 5° above the average.—G. J. SYMONS.

RENOVATING GRAPE VINES.

RENOVATING worn-out Vine borders, or re-invigorating exhausted Vines, is work in which many either will or should be engaged at the present time. There are numbers of Vines which, though apparently in excellent condition, yet require extraordinary assistance, or otherwise their decadence will soon commence. By extraordinary assistance I mean liberal supplies of liquid manure, top-dressings with fresh soil, or a renewal of much of the border. The two former measures may be sufficient for some comparatively new borders, but there are some which require the whole. No matter how well a border may have been originally formed, it must eventually become exhausted of several of the properties which rendered it suitable in the first place, and unless these be renewed it is very evident the quality and weight of the crops will soon be visibly effected. As I have recently had to deal with Vines in the worst possible condition I will first describe the renovating process adopted, and then suggest what I consider necessary in the case of Vines in fairly good condition.

When I first took charge of these gardens my employer not only gave me permission to, but suggested a wholesale clearance of two vineries. Having, however, previously taken an active part in the work of renovating a range of five large vineries, and noted the highly satisfactory results, I hesitated to destroy Vines that I thought could be reinvigorated, and I do not regret having preserved those I found here. It is true I to a certain extent marred my work by simply overcropping, yet on the whole I am satisfied with the results. One house was planted entirely with Black Hamburgs, and the other principally with Muscat of Alexandria. The latter were in much the worst state, and perhaps these should have been cleared out, but then a wholesale clearance of a vinery entails much work and expense in forming a new border and raising or buying new Vines. No crop would be obtained the first year, and in my case, owing to the peculiar construction of the house and other uses to which it has to be put, there would only be a partial crop the second season after planting; whereas by renovating we secure a partial crop the following season, and a full crop the second year, with less than half the labour and expense. It is in the autumn when the men can best be spared for extra work, and it is in the autumn when the Vine borders should be renewed, this being when the root-action is most brisk.

I entered upon my duties here early in the spring of 1881, and naturally soon turned my attention to the Vines. On inquiry I found that the borders (outside only) had been made upwards of thirty years, and also for the last seven years had received no solid or liquid manure of any kind, but a very small quantity of guano had been annually dusted over. As a consequence no healthy roots were to be found anywhere near the surface. My first proceeding was to bare the stems down to the main roots, and these were nicked and surrounded by a mixture composed of leaf soil, wood ashes, or rather "burnt bake," as the ashes from a burnt heap of

prunings and other garden rubbish is locally termed, and old Mushroom-bed refuse. As the result of this several of the Vines, Muscats as well as Hamburgs, formed a quantity of large lively roots. When this was observed a top-dressing of turfy loam, short manure, and a dusting of superphosphate of lime was applied. I ought perhaps to mention that the two houses are heated by good flues, these warming the border near the front of the house, and by covering the soil with light litter this heat was preserved. Had the houses been differently constructed and heated I should have formed a light hotbed along the front, as we must not expect old Vine stems and roots to emit early fresh rootlets when the surroundings are cold. The fresh soil was soon taken partial possession of, and a further mulching of leaf soil, than which no better root-enticer exists, was given, and the soil was kept moist.

As will be shown, we had a crop of Hamburg Grapes the same season, and these being all cut early in September we commenced to break up the border. Beginning at the front about one-third, or a width of 4 feet, was cut clean away and wheeled to where it was likely to do good. From this point the soil was forked away, every live root being carefully preserved, till we had reached the space previously top-dressed, and now fairly full of brittle white roots. The old roots which had been kept covered as much as possible and moistened frequently had all bruised pieces cut away, and those preserved, cleanly cut in order to assist their heating. The turf employed had been previously cut, but not long enough to be stacked, neither is it necessary. With this was used a considerable quantity of lime rubbish, "burnt bake," short manure, and some of the old soil, all of which were distributed between layers of turf with the grass downwards and about the roots. The whole was built to a width of 4 feet, made firm, and the roots distributed in layers, and as near the surface as their former disposition would admit. The same autumn I found several of the lifted old roots had formed fibres, and still more formed what I might term root buds, from which rootlets started the following season. These with the roots established in the top-dressing were sufficient to perfect a crop the season following, and now we have, in the case of the Hamburgs at least, a border crowded with roots, especially where I like to have them—viz., on the surface.

Not only were the roots in a bad plight, but the Vines also were in a bad condition. In the first place they had long been too much crowded, a blunder by no means confined to our case. For many years they had been infested with mealy bug and other pests, and this, too, in spite of various violent remedies applied, these much injuring the rods without affecting a clearance of the insects. When I took charge they had received their annual close pruning, cruel scraping, and dressing with some extraordinary mixture, and taking all things into consideration I saw we must endeavour to form new rods as well as new roots. The Hamburgs broke fairly well and produced a good number of bunches, which, thanks to the slightly improved root-action, finished better than hitherto. Of Muscats we secured only a few bunches; these were retained, but all the other shoots from the middle of the house or rods were kept closely rubbed out, also from near the middle to the front ridges of the house, my plan being to lay-in a young growth from the centre to grow to the top of the house, and another from the bottom to be taken up to and stopped at the starting point of the former. In this manner fairly good canes were obtained, and more than this, owing to the weak state of the Vines, I did not anticipate. While in full leaf the top portion or half of the rods, which it will be seen was destitute of young growth, were cut clean away, and if all had gone on well the remainder of the old rods, with the attached upper portions of young rods, would have been cut away the following season. Unfortunately we cropped too heavily, taking a full crop instead of, say, about two-thirds of an ordinary crop. As a consequence the lower young rods

failed to extend to the top of the house as intended, none of them swelled or strengthened as I expected they would do, and, worse than all, the heavy cropping also greatly interfered with the root-action. During hot weather the foliage flagged and shading had to be resorted to. This flagging was the result of the comparative rootless state of the Vines, but in spite of it we had a good crop, which finished and kept well, but the wood never ripened. This season the roots were much damaged by rats, and altogether we are not surprised at the poorer crop resulting. Next season other measures will be resorted to, but this will not interfere with the full crop we hope to secure.

In the case of the Hamburgs, finding they broke fairly strong, and especially as they were already much crowded, no young rods were laid in, but the spurs, or rather laterals, were freely thinned out by disbudding. The crop, however, shanked rather badly, and after careful examination I concluded it was principally owing to the bad state of the rods, and later events and important advice have convinced me I was correct in my surmises, though not exactly comprehending the way shanking resulted. In the autumn of the same year (1881) the rods were thinned while yet in full leafage, for if this operation is delayed till the winter or spring the wounds bleed seriously. During last year the Vines perfected a full and good crop, and in addition formed the requisite number of young rods. The latter were stopped about half way up the roof, were not shortened at pruning time, and this season broke evenly and well, and have given us much the best Grapes we have yet had, besides which they have perfected strong canes to the full length of the rafters. This autumn, or according as the bunches are cut from the growths preserved only on the upper halves of the rods are cut, the old rods will be sawn off.

The only mistake we have made with the Hamburgs was in cropping too heavily this season, but I do not think we shall suffer for this subsequently as in the case of the Muscats, the Vines being vigorous both at the top and roots. If instead of 130 good-sized bunches in a house 24 feet by 15 feet we had been content with 100 bunches the crop would really have been of greater value and no risks incurred. Is not the case somewhat similar in innumerable vineries? I consider overcropping Grape Vines one of the worst forms of "gardeners' greed."—W. IGGULDEN.

[We saw these Black Hamburgs two years ago, and they were miserable; we have seen them this year, and the Grapes were equal in every way to the Black Hamburgs at Longleat.]

BEGONIAS AS BEDDING PLANTS.

A CORRESPONDENT, on page 270, last week, recognised the fact that the time-honoured Zonal Pelargoniums cannot be relied on for imparting brightness to the flower garden during the showery weather that so commonly prevails about the harvest period of the year; and with the object of making good the defect he had planted somewhat freely the fine old *Gladiolus brenchleyensis*. This is a most effective plant where it thrives, but unfortunately *Gladioli* are, generally speaking, at least as uncertain as bedding Pelargoniums. On these latter plants let me say a word. Are not the newer varieties with huge trusses better adapted for a transient blaze of a few weeks than for continuing attractive over a lengthened period? Have the seasons changed, or were the smaller-trussing forms, such as Tom Thumb, Cooper's Scarlet, Indian Yellow, and Bonfire, more persistent bloomers, and less liable to damage by a rainy day than the modern varieties that have almost driven them out of cultivation? Certain it is the beauty of the beds is of shorter duration now than was customary some twenty years ago. We must, however, make the best of the varieties we have, and if they fail, as they too often do, to give satisfaction on account of their liability to succumb to a few showers, we must try something else.

The adaptability of Tuberous Begonias for bedding purposes has been occasionally alluded to during the past few years, and examples of success have been from time to time recorded; still we must recognise the fact that their employment for the purpose indicated is by no means general, and in fact they have

not made anything like the progress that they ought to have made considering their claims to attention, and the results that have been achieved by those who have been successful in their culture.

That these Begonias are well adapted for bedding purposes is beyond all question. They may not, perhaps, succeed equally well everywhere, but it may be said without hesitation that in nine cases out of ten, when failures occur, they are more the fault of the cultivators than of the plants. For some years past all the beds in a garden north of London (Mr. Law's at Southgate) have been occupied with Begonias, simply because they give more satisfaction than any other flower. I have seen them there growing luxuriantly and laden with flowers, while they entailed little more trouble in management than early Potatoes. "Oh!" but it may be remarked, "what will thrive near London will not succeed a hundred miles away." That may be true of some things, but the observation does not apply with over-powering force to these Begonias. Take a journey 150 miles west of London, and examine the beds in the beautiful flower garden of Sir Henry Scudamore Stanhope at Holme Lacy. From more than one source information has been received of the splendour of the Begonia beds there both last year and this. They have this year particularly been indisputably grand.

Lest that test will not suffice to convince the sceptical as to the suitability of Begonias for outdoor culture because of the presumed salubrity of the climate of Herefordshire, we will go further afield for examples. Instead of 150 miles west of the metropolis we will go 400 miles north. Most persons have heard of Drumlanrig, and its manager, Mr. David Thomson, is supposed to know something about flower gardening. He has written the best work on the subject in the language, but that was before the Begonia epoch, and has produced some of the finest examples of the work in hand—flower-gardening embellishment, that have been seen; both at Archerfield and at Drumlanrig his work made him famous. Would this gardener risk his fame by dabbling in novelties as such, and filling beds with plants that would not thrive? The idea is preposterous. Yet he not only employs these Begonias, but last year he planted the most prominent beds in the garden with them, and they astonished all who saw them by their vigour of growth, richness, and the wonderful way in which they endured the drenching rains of that rainy locality, and by continuing brilliant until the frost destroyed them. Similar results, I am told, are produced at Drummond Castle in Fifeshire; but the Drumlanrig test alone is quite sufficient to satisfy all who are not prejudiced that Tuberous Begonias rightly managed will grow and flower in the most satisfactory manner in the majority of flower gardens in this country.

As their success in the west and north cannot be denied, it may be supposed by some persons who have failed in other districts that the moist air of the localities above instanced must be specially favourable to the plants. Perhaps it may be, and if so let the hint be turned to account in growing the plants in gardens less moist. Let the surface of the beds be mulched and more water given, and then see what Begonias will do. It will, perhaps, be as well to tell what they will do—what, indeed, they were doing in not a naturally moist position in Kent a fortnight ago.

Not unknown in connection with these beautiful flowers is Mr. John Laing of the Stanstead Park Nursery, Forest Hill. His work in improving this splendid type of a great genus of plants is to be seen at home. It is a brilliant result. The houses are ablaze with magnificent varieties, the singles with flowers as large as single Dahlias, and if possible more rich; the doubles as large as Gueldres Roses, and some as pure; while others equal in size, form, and colour Turban Ranunculuses. It is a grand display, but we will step outside to an open quarter in the nursery and see what many persons will scarcely believe—some twenty beds, each about 50 yards long by 4 feet wide, completely filled with Begonias all aglow with their handsome flowers. In this great mass of 30,000 to 40,000, or perhaps 50,000 plants, scarcely a blank is to be seen, and if there is one it is, presumably, the result of some exceptionally fine variety having been taken out for "stock;" but the truth is the beds are practically as blankless as they are brilliant, and the result is an undoubted triumph of Begonias as bedding plants.

All these plants are seedlings, and, what is more, seedlings of the present year. The seed was sown in January, and 150,000 plants were first pricked out closely in very shallow boxes—that is, boxes not more than 2 inches deep, then transplanted more thinly in larger boxes, and from these transferred to the beds. If that does not represent the bedding-out process in its integrity it would be interesting to know what does. There the plants will remain till they are cut by frost, and the tubers will

be taken up and stored. In the meantime their colours are noted and the varieties classified. Although all of them are better than the best of a few years ago, only a few, the *crème de la crème*, will be named. The plants are about 6 inches high, with fat stems, sturdy, bushy, and covered with flowers. So far from these Begonias not being amenable for bedding, experience has proved that they make better tubers when planted out than they do grown in pots, hence the most choice and valuable of both home-raised and continental forms are planted out in rough frames with nothing now to cover them, and they grow like weeds.

It is not to be supposed that the inexperienced, and especially those who have not the best means for growing the seedlings, could succeed like a Laing in growing such plants the first season. It would be unwise to attempt this, or rather to rely on seedlings of the same year for filling the beds. Not one amateur or gardener in a hundred has the requisite conveniences for the work, but then scarcely one out of a hundred need fail, provided there are frames, greenhouses, or the usual conveniences for raising bedding plants that are usually prepared in gardens, if he grows his Begonias from tubers. Those of the size of Cobnuts will make good plants, but if as large as Walnuts they are better. They can be had cheap enough in mixture, the price, of course, varying according to size and the quality of the varieties.

A few of the secrets of success in preparing the plants and growing them successfully in beds—that is, if there are any “secrets” now-a-days, may perhaps be usefully divulged. These are the very essence of simplicity. Where persons fail is in over-preparing, over-nursing, or, to use a well-understood and expressive term, in coddling the plants in their early stages, then starving them afterwards. If we look at the plants and note their fleshy roots, succulent stems, expansive leaves, and large leathery flowers, it becomes apparent that they must have rich, free, generous soil, and abundance of water—that is, when they are in full growth. It is also clear that all plants of this nature from Balsams to Begonias are peculiarly liable to be drawn by excessive heat and insufficient light in their early stages. If anyone wants to see how stout and sturdy Balsams can be grown let him sow some seed in pots in May, and plunge these pots in a heap of fermenting materials in the open air. If he wants stout Begonias for bedding let him start the plants on similar principles of affording them gentle bottom heat, but not starting them so soon that they cannot have abundance of light and air to keep them dwarf and sturdy. The precise time of starting can only be determined by the means of growing the plants afterwards, but, as a rule, early in April would be safe for the majority of cultivators.

When once started the plants must be kept steadily growing. There must be no check, and as a rule they are far better if they are never potted. If Begonias are potted, as they often are, grown nearly a foot high under glass, then placed in a frame to “harden,” their pots at the same crowded firmly with roots, and eventually planted out, they will not flourish. Their owners wonder why they do not start and grow freely, concluding the plants are “not fit for bedding.” It would be a wonder if plants thus “prepared” did thrive. Even Calceolarias will not do so, as most persons have found out, and they adopt a simpler and more rational method of preparation. In order to succeed with Begonias we must go back to simplicities. Start the tubers in boxes, then if the plants when an inch or two high can be planted 4 or 5 inches apart in good soil on a gentle hotbed in a pit, or over which a frame can be placed, there to remain till planted in the beds, there can be no better preparation. Failing this they may be grown thinly in boxes, the compost being light and gritty, resting on a layer of decayed manure. Of this the roots will take possession, and in due time the plants can be quickly yet carefully planted in the beds with roots uninjured, stout, healthy, hungry, and ready to immediately extend into the soil in which they are placed. A root-bound plant cannot do this. It tries to do so, and a few fibres start from the wire-like roots here and there that are curled round the soil, but the growth is never free, and the plant struggles for existence. It may not die all at once, but it cannot make free progress, and then “Begonias are no use for bedding.” Better would it be to plant the corms in the beds on the 1st of May and leave them to take their chance, than to prepare them in this root-bound irrational fashion that more than anything else has brought Begonias into disrepute as plants for the flower garden.

Then the soil in the beds should be rich. At the surface it may be light and free to encourage a free start, but not far below it should be about as rich as for Celery. Then will the plants luxuriate and produce thick stems, large foliage, and clusters of wax-like flowers. But they must be sustained by

water, the necessity for the application of which will be materially lessened by covering the surface of the ground between the plants with a layer 2 inches in thickness of cocoa-fibre refuse. This is cheap enough, conserves the moisture, is an impediment to slugs, and imparts to the beds a neat appearance.

The same material dried is one of the best preservatives of the tubers. Mix it with sawdust, or use it without, and a layer of this and of tubers alternately in large pots or boxes will be found to answer the purpose of preserving the latter in a fresh sound state, and the packing medium may advantageously be dug into the beds, and, especially where the soil is strong, will be found highly beneficial; and what a convenience this method of wintering is to those whose glass accommodation is limited, for the stages and shelves are at liberty for other plants through the winter, the Begonias resting meanwhile like so many choice Potatoes.—EXPERIENTIA DOCET.

SOUVENIR DU CONGRÈS PEAR.

IN your last issue you mention two splendid Pears of this variety sent to you by Mr. Rivers. I purchased some trees in pots from that gentleman about nine or ten months ago, and among them was a Souvenir du Congrès, and the fruit has been splendid, not only for size but for flavour also—one Pear weighed $1\frac{1}{4}$ lb., and another was 1 lb. Beurré d'Amanlis grew very large, but the flavour was not rich. I consider Souvenir du Congrès by far the best flavoured large Pear I know.—J. W., *Liverpool*.

THIS is undoubtedly one of the grandest of autumn Pears, and as its merits become fully known it will be grown in most gardens where handsome fruit of high quality is cherished. It would be interesting to know whether the specimens alluded to last week had been gathered from trees grown in pots, and if so this would prove how satisfactory the system is. Pears so grown need no heated structures, but only want shelter from frost during the blossoming and setting period, the trees at all other times being stood in the open air. Such trees laden with fruit are handsome ornaments; and if such noble specimens as those alluded to can be produced the method would appear to be worthy of adoption. Still this fine Pear can be grown most satisfactorily against walls, and a tree will usually be found worthy of the space it occupies.—A FRUIT-GROWER.

THE HERBACEOUS BORDER.

COREOPSIS TRIPTERIS.—This is valuable for producing its flowers from September until stopped by frost, its large corymbs of bright yellow flowers with blackish-brown disc rendering it highly ornamental. It is 4 feet or more in height, having long, narrow, divided leaves, which give it a very distinct appearance.

ACONITUM JAPONICUM.—The deep purplish-blue flowers, borne in stout spikes, and its large, deep green, glossy leaves, render this very effective, and especially valuable from its late flowering, from the middle of September onwards. It attains to a height of $2\frac{1}{2}$ to 3 feet, doing well in any soil, but, like all the Aconites, it prefers a moist one. A. autumnale has spikes of light or lavender-blue flowers, and though similar to, is quite distinct from, A. japonicum. It grows 3 feet high, and is one of the best autumn-flowering plants.

TRITOMA UVARIA GLAUDESCENS.—One of the best, if not the best, of the genus, being very free flowering, with bright orange and scarlet flowers. T. grandis has truly noble spikes, 4 to 5 feet in height, but the spikes of T. nobilis are the largest, and it has the advantage of producing them very freely. T. pumila is dwarf in growth, and the spikes are dark red, not having the glow of the others.

GYPSOPHILA PANICULATA.—This forms a beautiful bush 2 feet high, and is simply smothered with its countless white flowers. It is not only a very effective border plant, but has a very elegant appearance in a cut state. It does best in light soil, and is best continued by seed.

STOKESIA CYANEA.—This commenced flowering at the middle of September, and bears a profusion of palish blue flowers, nearly 3 inches across, which are very effective on the plant and useful when cut. It grows about 30 inches high, and is one of the very finest of autumn-flowering plants. It requires a light well-drained soil, as it is not very hardy, but in a warm situation does admirably.

PYRETHRUM ULIGINOSUM.—A strong stool of this forming a bush 4 feet and more in diameter, covered with its large pure white flowers, 3 inches across, is a stately and beautiful object, and the flowers surpass all the Marguerites for cutting. It attains a height of about 4 feet. It is unrivalled as a late summer-flowering perennial, and does well in any soil, preferably in rich friable loam.

FRANCOA RAMOSA.—The long branching spikes of this are very effective, being borne profusely from September to frost. The flowers are pure white and useful for cutting. It requires a warm situation and a light soil, as it is somewhat tender, and does not succeed in an ordinary border unless well drained, and is best given

the protection of a frame in winter, being readily increased by division and seed.

ASTER VERSICOLOR.—The flowers are only small or medium-sized for a Michaelmas Daisy, white chiefly, changing to rose, some flowers being of that colour when expanded. The flowers are borne in dense clusters or masses, and are very numerous. It grows 4 feet in height, and commenced flowering early in September.

ASTER POLYPHYLLUS.—The flowers of this are only of medium size, white, and very abundantly produced. It commenced flowering early in September, and is a tall grower, 4 to 5 feet high.

ASTER AMELLUS has large purplish-blue flowers, with yellow centres. It is very free flowering and dwarf, not, or rarely, exceeding 2 feet in height. Fine as this is, it is not nearly so fine as *A. Amellus bessarabicus*, with its rich bluish-purple flowers and orange centres, it being unquestionably one of the finest, and is dwarf in habit, attaining to a height of about 2 feet. It is larger and finer than the species. It flowers in the middle of September.

ASTER DUMOSUS.—This grows about a yard high, and has bright purple flowers, produced abundantly at the close of September, and is one of the very best. All the Michaelmas Daisies do best in friable loam, and are readily increased by division.

The **COLCHICUMS** are flowering profusely, imparting quite a cheery appearance to the borders, giving hope of the autumn Crocuses, which are also appearing, and once seen are sure to be appreciated.

WALL PLANT—CLEMATIS COCCINEA.—This proves to be a slender grower, attaining only to a height of 6 feet, and is evidently herbaceous. The flowers are bell-shaped (not drooping), borne or supported by somewhat long footstalks. The flowers are bright scarlet, and the plant when covered with flowers is very beautiful. The sepals are four, but the flower opens very little, the segments being reflexed at the tip and black, the interior of the flower orange. The flowers proceed from the axils of the leaves, and at the extremities of the growths, and singly. It appears to do well in any light rich soil, and commenced flowering early in September.—G. ABBEY.

RENOVATING PEACHES AND NECTARINES— LARGE VERSUS SMALL TREES.

THE present is the time for renovating these trees indoors, and the season for planting is rapidly approaching; in fact, alterations in early and second early houses could have been completed before now where cultivators are not afraid of lifting their trees when in full leaf. It is surprising what beneficial results frequently follow the lifting of old trees. I think, however, it is even more general to find trees that should be in the prime of life brought into an unhealthy and unfertile state through negligent management. Experience has taught us that old as well as middle-aged specimens can be wonderfully improved, and will, after the work of renovation, if not delayed too late, and a season's careful cultivation, regain a healthy condition, and continue bearing good crops of fruit for a number of years. I have seen old trees which a few years ago were considered only fit to be burned, but after being lifted and given new soil are now grand specimens, that for fruitfulness, health, or vigour could not be surpassed by young trees; but how seldom, when young enthusiastic men take charge of houses in which are a number of old trees in a critical condition, do they decide to restore them, if possible, to their former health and vigour? The decision to root them out and plant young trees is often too hastily formed. There are many things to be considered before the work of destruction commences, for old trees can be restored with comparatively little trouble or loss of fruit. The last is an important consideration, and the primary object in the majority of establishments, and what can be expected from young trees before the third season? They can, of course, be fruited earlier, but when the object is to cover the trellis as early as possible with bearing wood, the development of the tree would take considerably longer if they were fruited in their early stage. The best system to adopt when fruit is wanted and the house must be established with young trees at the same time, is to plant the young ones after patching up the old ones to fruit, while the former fill the trellis. The old trees in this case must be cut away annually until the permanent trees are capable of bearing a crop.

Old neglected trees that have been undisturbed for years have roots that are generally almost destitute of fibres, and it is difficult to keep any fruit that may set upon them until after the stoning period. They not unfrequently swell irregularly after they are set, or they fall in stoning. If they can be retained to this stage success afterwards may be anticipated, as fibry roots will have formed along the bare woody stems and have taken possession of the new soil. After lifting, the crop if heavy should be well thinned, but cultivators must be guided in this matter entirely by the health and condition of the trees. Considerable care must be exercised to preserve every fibre possible. The roots in most cases will be found knotty and brittle, and break readily; but it is surprising how rapidly fibres are

produced by these woody stems after they are brought near the surface and laid amongst fresh soil.

Five years ago when renovating a range of Peach houses 260 feet long, two old trees were purposely retained for experiment, one in the early and the other in the second early house. From appearance these trees were of the same age and the same variety, differing only in one being larger than the other. These, as well as some of the other trees in the same houses, had been planted upon a stage formed of 10 or 12-inch pots, with very large slates laid over them, the roots as far as the stage extended being only covered with about 8 inches of soil. The tree in the early house was the largest, and was thoroughly lifted; the other had merely the contents of the stage beneath it removed, and the space filled up with the soil removed from the first-mentioned tree. The experiment ended last autumn, when it would have been difficult to draw a comparison between the two. The one that had been lifted thoroughly and rapidly recruited itself, and was in grand condition, with clean fibry roots, while the other had declined yearly in vigour. Early last autumn the latter was subject to lifting, and the tree shows already a marked improvement in strength and condition of its wood. It was allowed to carry a fair crop of fruit, which was superior both in size and quality to the fruit ripened the two or three seasons previous. This is merely referred to for the purpose of showing how rapid is the work of improvement even with old trees, for few, indeed, could be in a much worse state. I do not doubt that the tree in question would, if we wished to retain it, continue improving and produce crops of excellent fruit for many years.

The question arises, and is of vast importance at this season of the year, Whether large trees are preferable to small ones, or *vice versa*? Until very recently I had a great admiration for large trees, and was inclined to ridicule the idea of growing pignies. In houses say 60 feet long, I could not see the advantage of having five or six trees to fill the space, but thought three much better, or even two. In order to put these ideas into practice I planted three trees to fill the houses of 60 feet. In the second house I resolved that a healthy young tree of Royal George should fill the whole house. Its branches extended rapidly, and soon filled 30 feet of the trellis, and before now would have filled the whole house; but I discovered it was already too large, and instead of proving any advantage results had been quite opposite, not that I entertained any doubt that anything might happen to it, and thus leave the whole house vacant. The principal reason was that the enormous quantity of fruit that it was already carrying ripened too much at one time, and that if it was allowed to fill the house the supply would soon be over. It is clearly evident that to maintain a succession of fruit a number of trees are preferable to one, as varieties can be selected to ripen at different times. I still have a fancy for large well-developed trees, and am inclined to believe they do better on the whole than small ones, but for purposes of succession I believe that four trees in a space of 60 feet would be preferable to three, although I have only three in each of my houses. What say others on this subject?—WM. BARDNEY.

POTATOES.

LIKE your correspondent "H.," I am every spring seized by what he aptly terms an attack of "Potato fever." It is so very interesting to read the descriptions of the new varieties, to mark off a few of the most promising, and so pleasant to chuckle over the prospect of having a few dishes of Potatoes at the local flower show which will fairly distance all competitors. Results are indeed often disappointing, but I would warn "H." against being satisfied with the first year's trial. I gave 2s. 6d. for a pound of Mr. Bresee. On lifting I found a poor crop of small Potatoes, and was disgusted, so the following season I had this variety planted in a spare corner where the ground was poor and full of twitch. As the summer advanced I was much surprised to see the tops look so healthy and well, but on lifting a few roots early in July of that year I was astonished to find my despised Potatoes turn out the finest in the garden, and from that day Mr. Bresee has been one of my favourites. "H." would not complain about the tops, for although branching they are not tall. *Experientia docet*, and I have now about forty varieties which I have tried in my garden with good cultivation and in a field of very poor soil with poor cultivation, so that I shall be pleased to give others the results of my trials. In response to "H.," I would rather suggest that we start a company of gardeners, of which each member shall try one or more novelties, and give the result of his trial to his fellow members. All raisers of new Potatoes, &c., are apt to think their introductions of more merit than they actually are, and a seedling Potato of my own raising I think is about the best ever grown, but no doubt I shall learn that others think exactly the reverse.—H. S. E.

SENSITIVENESS OF EARTHWORMS.—In reference to the inquiries of "A. M. B." relative to the sensitiveness of earthworms, I may say that I have often noticed the same thing; for instance, when employed in moving plants in large pots or tubs, if there are worms in the soil they will sometimes come to the surface as if alarmed by the rattle of the

sticks and chains, used for carrying the tubs, against their sides. We had a gentleman staying here a little time ago who was a great angler, and when in want of worms for bait he would take a pointed rod of iron and insert it in the ground to a considerable depth, and then rapidly twirl it about in the subsoil, when the worms would immediately come to the surface all around. The fisherman on the Thames also tells me that in dry weather when he cannot get worms he has many sent from the neighbourhood of Nottingham, which are procured in the same way.—S. MORTIMER, *Purley Park, Reading.*

CARNATIONS AND PICOTEEES IN BEDS.

As the time is now drawing near for planting Carnations and Picotees in beds, I propose to give a description of the process, also naming the best varieties for that purpose. In the north generally they plant in beds, with the result that the flowers are very fine. If new ground is used a crop of Potatoes is taken off it, which brings out the wireworm in the Potatoes—one of the greatest pests the Carnation grower has to contend with, and which must be thoroughly eradicated before planting. The best time to plant is October and November if the plants are well rooted, whilst those which have not good roots can be placed in small pots 3 inches in diameter, a pair in a pot, wintering them in cold frames and planting out in the beds from the middle to the end of February, following with those of weaker constitution in 7 to 9-inch pots, a pair in a pot, using plenty of drainage to them. They want placing either on a bed of ashes or a wooden stage, so as to keep earthworms out of them. It is a good plan to dig the ground deeply, mixing in some good manure with the soil—that which has been used for a hotbed the same season. I plant my beds with pairs of plants in rows a foot apart and the stools a foot from each other. The beds consist of two rows, with a path between the outside rows of each bed, which are 2 feet apart. This leaves plenty of room to get amongst the plants for weeding and layering.

I do not layer many of the plants the first autumn after planting, as generally the finest blooms are obtained from the plants the second year. Of course, where the plants are very thick it is wise to layer a portion of them, which can be taken off for other beds. The second year after planting it is a good plan to layer all the plants, and lift them when ready, making new beds.

The following list includes a few varieties in each class most suitable for planting in beds:—

WHITE ELEPHANT POTATO.

AS I had read so much about the Potato White Elephant being an enormous cropper and a disease-resister, we procured one peck from Messrs. Harrison & Sons of Leicester last February, and on the 31st of March planted them in heavy clayey soil, for which we understood they were suitable. They were cut into as many sets as possible, which were planted 2 feet apart and 3 feet between the rows. A slight trench was made, and a layer of light manure, strawy material, placed over them to a depth of 2 inches, each row following another as we dug and planted

as we went on. No more was done to them until they were earthed up early in June. The weeds were kept down, and on the 31st of August a monstrous crop was lifted. In all 37 stones of useful Potatoes, for there were no small ones, and not one diseased among them all. Many were of a great size, weighing above 2 lbs. each. We determined to try them as to their quality, and we found them to possess everything that is requisite for a good Potato, being light and floury, with a good flavour. No more was used, and we have reserved them all for seed next year should they keep during the winter. I looked at them yesterday and found them sound and good. I have no doubt that as soon as the variety is well known it will be much grown, as I think almost everything is in its favour.—H. HARRISON, *York.*

FRITILLARIAS.

THE Fritillarias belong to the section Tulipæ, including some of the showiest and most popular of our early spring-flowering bulbs, and from their botanical interest it is cause for regret that so few make a speciality of them. The Fritillaria is one of the few bulbous plants that readily suits itself to nearly any position, and requires no attention whatever other than staking when planted in exposed situations. They will not bear, however, being disturbed when once established, and to this very practice may be traced many failures that have from time to time been recorded. They are distributed over the greater part of the northern hemisphere, and number between fifty and sixty species with endless

Fig. 55.—Fritillaria armena.

varieties, and although not more than one-half are in cultivation, a few only of these can be recommended for general ornamental purposes.

Fritillaria armena, Boiss.—This is comparatively new to cultivation, having been found only within the last few years, and is not admitted as a species in Mr. Baker's monograph of the genus. In general appearance it closely resembles and falls between *F. tulipifolia* and *F. græca*, and is full of interest, from the fact of its forming a connecting link between the sections with entire and trifid styles. It is rather dwarf, seldom attaining more than a foot in height, and the flowers, which are of a lurid purple without any tessellation or chequering, make a beautiful contrast with the bright green lanceolate leaves. Grown in pots for the greenhouse it is very desirable, giving a colour much appreciated at this early season. It was first found about Erzeroum, at an elevation of 7 to 8000 feet; and a yellow variety was also found in the neighbourhood of Smyrna by Mr. Maw, which deserves a distinct name. It is being distributed by Mr. T. S. Ware under the name of the species, and is represented in the woodcut, fig. 55. Flowers early in April and May.

F. recurva, Benth.—The most beautiful of all the Fritillarias. It grows from 1 to 2 feet high, with spear-shaped leaves clasping the stem, and the bright red of the numerous drooping, recurved, bell-shaped flowers, interspersed all over the inside with cream-yellow blotches, far surpassing that of a Lily. It is a native of California, and belong

to the small section with Lily-like bulbs, from the small scales of which it is easily propagated, as it seldom ripens seed in this country. Flowers the latter end of April and May.

F. Hookeri, Baker, forms with *F. macrophylla* a group between Lillies and Fritillarias. They have both been referred to the former, although leaning considerably in favour, and now put into the latter. It grows from 1 to 2 feet high, bearing from eight to twelve large pale lilac Lillium-like flowers, covering more than a third of the whole stem. Found at from 9 to 10,000 feet, and is restricted to the Laching Valley, Sikkim. Flowers in May.

F. pallidiflora, Schrenck.—This, from its vigorous constitution and floriferous character, is one of the most remarkable of the group to which it belongs. The flowers are very large and numerous, of a dull creamy colour, with beautiful purple spots all over the inside. The leaves are broad, oval, and of a glaucous green colour. If taken in hand by some experienced hybridiser and worked with some of the finer varieties of *F. imperialis* the probability is that a plant intermediate between the two would be the result, and which would be very desirable for ornamental purposes. Native of Siberia. It was first introduced to France, and from thence to this country. Flowers March and April.

F. persica, L.—This grows from 2 to 3 feet high, bearing a spike with from ten to forty flowers, varying from dark purple to lilac, without tessellation, Campanula-like, and closely packed together on the stems. It is supposed to be originally a native of Persia, and to have been introduced into this country about 1573. It was cultivated in Gerarde's garden 1596, and at that time, he says, was a denizen of many of the London gardens. Parkinson informs us that "it was sent into us by the means of divers Turkey merchants from Constantinople." Flowers in May. Worthy of a place in every garden from its free habit.

F. imperialis, L.—The Crown Imperial, sent to this country about 1590 from the Royal Gardens, Berlin, is one of the earliest tall flowers of the spring, and makes a fine appearance in the flower border at a season when such flowers are much wanted for decorative purposes. It is said to emit a rank fox-like odour, although I have failed to perceive it; but the beauty of the plant, however, and the splendid magnificence of its various and richly coloured flowers, will ever secure it a place in the garden. The singularity of the nectary, too, in the form of a glandular cavity at the base of each segment, and which contains a drop of nectareous matter when the plant is in full vigour, cannot but engage the attention of the most casual observer. Another of the wonders of Nature, and which is by no means peculiar to this plant, may be observed in peduncles, which bend down when the plant is in flower, becoming upright as the seeds begin to ripen, lest they should fall too soon. There are over a dozen really distinct and desirable varieties, single and double, embracing a great variety of colours; but the most valuable for decorative purposes has three, sometimes four, whorls of pure yellow flowers above each other. Flowers in May. *F. Meleagris* is so well known that it does not need description.—D. D.

AMERICAN VINES AND THE PHYLLOXERA.

MR. WARD has stated that the Strawberry Grape was the first to be attacked with the phylloxera at Longford Castle, and hence concluded that American Vines are not phylloxera-proof. Without wishing to suggest that they are, may I ask what evidence your correspondent can adduce in proof of the Strawberry Grape being an American variety? It may be grown in America, and Vines may have been sent from there to this country. But is this Grape of American origin? I know it is somewhat commonly regarded as an American Grape, but I am of opinion that the Vine in question is not an American variety at all. I know the Grape very well, and its growth and foliage bear some resemblance to those of American Vines, but this is not sufficient evidence of its identity as an American Grape. It is well to know that it is not phylloxera-proof, and Mr. Ward has done good service in recording his experience on that point, as it will prevent persons using the Vine as a stock under the assumption that it is an American variety, and hence less liable than European Grapes are to be attacked by that destructive insect.—AN OLD GRAPE-GROWER.

[If the history of this Grape is examined we suspect it will be found to be of Italian origin.]

MR. WARD at page 446 mentions the fact of an American Vine (the Strawberry) being the first to be attacked by the phylloxera in his vineries, which he says is conclusive proof that American Vines are not phylloxera-proof. Before assuming this we must first know if the variety mentioned belongs to any of those species reputed to withstand the attacks of this insect. Many of what are termed as "American varieties" have much of the blood of *Vitis vinifera* in them. For instance, Mr. Haskell of Massachusetts raised a batch of varieties by crossing *V. riparia* with *V. vinifera*. Now, though these varieties should be attacked by the pest no wonder need be indulged, and neither is it logical to take it as proof that varieties of *V. labrusca*, *V. vulpina*, or any other of the nine species, all differing in constitution, are also liable to attack. Besides being successfully crossed with *V. riparia*, *V. labrusca* and *V. cordifolia* have also been successfully employed for crossing the ordinary Grape Vine. Though varieties from such parentage should fail it does not follow that any, far less all, of the pure species should do so.—A. HONEYMAN.

[In Dr. Schomburgk's report of the Adelaide Botanic Gardens, South

Australia, it is stated that "the Californian phylloxera-proof Vine (*Vitis californica*) has been found to succeed there, the growth being very luxuriant, the Grape making a palatable claret wine. It is found grown in the vineyards of California where other Vines have been destroyed by the phylloxera, but this species remains uninjured. Experiments seem to prove that it is too robust for the phylloxera to fasten upon it. The French Vine-growers are much interested, and are experimenting with it. Professor Hillyard of the Californian State University and others have reported favourably upon its merits."]

BEECH LEAVES AND FUNGUS.

I PERCEIVE that your able correspondent "Single-handed," in his most valuable paper on the care of manures, endorses what Mr. Wright had stated in his equally interesting article on leaf soil, that "soil formed from Oak or Beech leaves is much preferable to that from Planes or Elms." I had always understood that leaf soil from Beeches produced an influence in the soil harmful to most plants, a mycelium which attacked the roots. I have generally found leaf soil, made in the ordinary way of Beech leaves, full of this mycelium, with a strong Mushroom smell. In the case of standard Roses, where the stake has decayed and broken off at the surface and the rotting lower part suffered to remain in the ground, I have generally found that the Rose tree has gradually died, and on taking it up I have found the roots covered with mycelium, originating apparently from the decaying stump.

I now lever up all such stumps, and am careful in planting that no pieces of dead wood get in the soil among Rose roots; and when I found that what seems to be the same mycelium is produced apparently by decaying Beech leaves, I came to the conclusion that this was the cause of their being popularly considered harmful, and even wondered if this was the reason why the ground under Beech trees is, as a rule, barer of all vegetable growth than that under other trees.

Beech trees seem to me to be of a harder and more woody nature than others. They take much longer to decay. On this light soil I have seen them ploughed up again, after being buried a year, nearly as fresh as when they fell. In fact, the poor people here collect them to stuff pillows and cushions, which shows how tough they must be.

I think the old nut cases produce the mycelium more readily and abundantly than the leaves do, but it would be difficult to separate them, and I think the leaves, with their hard woody fibres, produce it also.

There are many Beeches in the neighbourhood of my garden. The dry winds of March bring the leaves from a distance and heap them in drifts all over the place. I have generally burnt them as much as possible, but I shall be glad to learn that I have been wrong in attributing harm to their use as leaf soil.—A. F. M.

CULTURE OF THE CHOROZEMA.

CHOROZEMAS are amongst the most useful and beautiful of winter-blooming plants, being also well adapted for house decoration; but when used for this latter work should not be allowed to remain too long in the house, or the plants would be permanently injured. Although of the hardwooded type it grows very freely, being of a rambling habit. It can also be grown into a good-sized specimen very quickly, and they will last for years if well attended to. Propagation may be effected either by cuttings or seed, but the best and cheapest way is to procure young plants from a nursery at the present time. The plants should be wintered in a rather warm greenhouse, but it is best to grow the plants in a well-ventilated greenhouse when they have attained a good size, as they will last longer in health. Plants procured now and kept in a warm greenhouse until March will then require a shift into pots 2 or 3 inches larger, using well-drained pots, as these plants, like all other hardwooded plants, will not succeed if the pots are not thoroughly drained. The compost should consist of lumpy fibrous peat, with a liberal addition of sand. Pot firmly, and keep the plants close until well established. On bright days and as the season advances syringe the plants lightly on warm afternoons, and shade from bright sun. Being a very loose grower it will require stopping rather frequently. The shoots should also be kept tied out. After the plants are well rooted and have grown so as to require another shift they should be repotted and kept growing as freely as possible until the middle of September, when they should be exposed to air and sunshine, but avoid cold draughts. If all has gone well they will bloom freely during the winter, after which they should be placed in a light position and repotted just as growth commences. Give the same liberal treatment as they received the preceding summer, when they will be good-sized specimens by the time their blooming stage arrives. After this season I do not think it is of any benefit to grow them in a warm house during the summer, but they should be kept under glass and syringed lightly on warm afternoons, and after blooming to be pruned slightly. They will last for several years if their requirements are well attended to, but a few young plants are always acceptable.—A. Y.

WASPS ATTACKING FRUIT.—I have no tomtits, and yet the wasps have nearly stripped my Pear trees, which bear very hard, round, green fruits. I have now tied long strips from old muslin curtains round the branches, and have made muslin bags for Pears on the standard trees, and so far have kept off the wasps, but I fear the covering will interfere with

the ripening. We have for many years protected out-of-door Peaches with thin muslin. It should be of a thinner kind than window curtains. We used to cut up old tarlatan ball dresses for the purpose.—F. R.

NEW PEAS.

ANYTHING that Mr. Muir writes, especially regarding Peas, must be read with great attention by all, and his opinion of Culverwell's Paragon and Giant Marrow coincides so well with what I wrote a few weeks back, that "Peas in 1883" was extra good reading to me. The fault that Mr. Muir finds with Day's Sunrise is one which will prevent this Pea from becoming a favourite with growers for market. I found the pods fill very slowly, and they had to be picked over several times, but it is a good cropping Pea. I quite agree in it being really cheaper in the long run to purchase new and good varieties when they first come out. For instance, I purchased a 3s. 6d. packet (a quarter pint) of Culverwell's Paragon. I sowed them very thinly, and the Peas grew 6 feet high and very branching, with a profusion of pods. A few only were picked for trial, and the other day I gathered the sere pods and shelled out the seed, which measured up three-quarters of a peck—a gratifying result. This Pea will probably be very little cheaper next year, when I shall be able to plant a good many rows and also part with a portion of my stock. Surely this is better than waiting until next year to purchase a packet at perhaps a shilling less cost than this year. The results from my sowing of Culverwell's Giant Marrow, although very satisfactory, are hardly so good as with Paragon, and I consider the latter one of the best and most prolific Peas grown, being satisfactory in size, appearance, and to the palate.

May I ask Mr. Muir whether the Canadian Pea is procurable in England, for I should much like to try it?

EARLY MARKET PEAS.—May I inquire from your readers what Pea they consider best to grow for an early field crop for market? What is required is a hardy very early Pea, of medium height, with fairly large pods, of good colour, well filled with peas of good table quality. If the pods fill all together so much the better. I have tried several kinds, but all have proved unsatisfactory in one way or other. Kentish Invicta, pods are too small; Early Champion, ditto; Ringleader, ditto, and in addition too long in podding; Sunrise, too long in filling, and then not many at the same time; William I. is rather tender with me. The kind called Sickleback hereabouts (otherwise White Scimitar) is the favourite with most of my neighbours, but although satisfactory in other respects the peas are small and of poor quality.—H. S. E., *Great Totham*.

TO-DAY (Thursday) an interesting sale of HYBRID SARRACENIAS will take place at Mr. Stevens' Rooms, Covent Garden. These are from the collection of O. O. Wrigley, Esq., of Bury, who has become famed for his success with these plants, both in a cultural point of view, and in raising distinct and beautiful hybrids. The entire stock was, it appears, purchased by Mr. G. Toll, and by him they are now about to be dispersed. They comprise the results of crosses between variolaris and purpurea, purpurea and flava, Drummondii alba and flava, variolaris and psittacina, flava picta and Stevensonii, and many others. The principal named hybrids are Swaniana, Atkinsoniana, Tolliana, Wilsoniana, Maddisoniana, and Mitchelliana.

— A CORRESPONDENT, "T. S.," asks, "What will prevent sheep GNAWING THE ROOTS in Ash, Oak, and some other trees in winter, also occasionally in summer? Since the hard winters of 1879, 1880, and 1881 every nauseous dressing that can be thought of has been tried without effect." We shall be glad if those of our readers who may have prevented animals breaking fruit or other trees will state what pigment they used successfully.

— "J. B. H." writes—"Would your correspondent 'A Scotsman,' who has so severely criticised the EDINBURGH GARDENS, kindly inform me how the fifteen lines of plants filled in the ribbon border style should be placed so as to produce the best contrast, and also the most pleasing harmony? Of course red or white cannot in every case be the first line. What should then occupy that place?"

— WE have received from Messrs. J. Laing & Co., Stanstead Park Nurseries, Forest Hill, a box of TUBEROUS BEGONIA flowers remarkable for their substance and diversified colours, but especially noteworthy as having been cut from plants growing in the open air after the cold night of Monday last. This would suggest that these plants are as hardy as

Dahlias, and such brilliant, chaste, and pure clusters as those before us must be an ornament to any garden in which they are grown. The adaptability of these Begonias for culture in the open air with a method of preparing and growing them successfully will be found in another column.

— "C. S. R.," Redhills, Cavan, writes, by way of answer to "Saxoring," page 259, concerning WASPS DEVOURING UNRIPE PEARS:—"I would say that when in Derbyshire in 1879 I was plagued in the same way. This year we have suffered similarly in Cavan, as the Plums and early Pears are gathered the wasps have taken up their abode on the late trees."

— IN the intermediate compartment of the new range at Kew an interesting and pretty plant is now flowering. It has been provisionally named BEGONIA PICTA, but there is a little uncertainty about it at present. One peculiarity is that there are two very distinct forms, one with light green rough heart-shaped leaves, the other with very much darker leaves of similar shape, but heavily blotched with a deep shade of green approaching black. The flowers on both are alike—a soft clear pink, the petals broad, and the outline neat. They are also dwarf and compact in habit.

— THE Cape house, which adjoins that above mentioned, now contains several pretty plants in flower, and amongst them very notable is COBURGHIA INCARNATA, which was well figured in Sweet's "Flower Garden" some years ago, and is not, therefore, a novelty, though rarely seen. It is similar in habit to other Coburghias with broad strap-shaped leaves, and bears heads of three or four flowers. The corolla tube is 6 inches long, narrowly funnel-shape, very bright scarlet, lighter at the base, and the outer surface of the lobes is blotched with dark green. Like others of the genus it succeeds well in a cool temperature and an ordinary compost of loam, sand, and leaf soil.

— WE receive many CURIOUSLY ADDRESSED LETTERS during the year, and often wonder how many of them reach their destination. The Post-office officials deserve credit for delivering letters addressed as follows:—"Lexton's Fillbasset Beis, High Holborn, W.C., F.G., Cuens Sessman, Cartress, London, England." Which being interpreted means Messrs. Carters, Queen's Seedsmen, High Holborn, London, and was sent, presumably, in answer to an advertisement of Laxton's Fillbasket Peas.

— "B." writes as follows in reference to EXHIBITS BEFORE THE FLORAL COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY.—"It is regrettable that some exhibitors of flowers take such little trouble to send or stage them in a suitable manner. It is by no means uncommon to see sprays of plants with no names attached, either carelessly placed on the tables half hidden by other exhibits, or in some obscure corner. Occasionally, too, exhibits brought by members of the Committee are shown at the table and removed when their duties are concluded; while some liberal exhibitors give any choice flowers away hours before the stated time of removing them, so that visitors who arrive late have no opportunity of seeing them."

— IT appears that HIGH PRICES FOR RARE ORCHIDS are still obtainable, for we are informed that recently at a sale at Mr. Stevens' Rooms, Covent Garden, a plant of a new Aerides, offered by Messrs. Sanders & Son, was purchased by Sir Trevor Lawrence, M.P., after a spirited competition at £246 15s. This is an extraordinary price, and appears to have attracted the attention of a daily contemporary, which compared the present demand for Orchids to the Tulip mania, and recommends speculators to turn their attention to the matter.

— M. E. ANDRE, in "Le Tour du Monde," writes as follows on GATHERING CAOUTCHOUC IN EQUATORIAL AMERICA.—"The tapping of the trees they had discovered was being actively carried on. The adventurers, clad in ragged pantaloons, the body naked, were behaving like demons under the supervision of their chief round the gigantic Figs (Ficus), whose bark they were tearing off by slashing it with their hatchets. The operation reminded me of the process of gathering resin in the Landes of Gascony. But here, instead of zinc cups to receive the resinous juice, the caucheros placed Heliconia leaves, on which the precious latex flowed white as milk. The liquid was collected and poured into calabashes (totumas), where it soon coagulated and formed caoutchouc, ready to be packed and exported."

— MR. G. HAWKINS, Ewenny Priory Gardens, Bridgend, sends us the following note on CUCUMBERS:—"I have grown Wheeler's

Empress of India since it came out, and many others alongside it including nine varieties, this summer. It is a model for a long Cucumber, and I cannot find any to excel it for exhibition work and flavour. The other two best for general use are Pettigrew's Cardiff Castle and Garraway's Clifton Perfection. Those three ought to be grown by everyone who has not tried them."

— PART 7 OF THE TRANSACTIONS OF THE ESSEX FIELD CLUB has been forwarded to us, and proves by its completeness how thoroughly this Society is doing its work. The Club was instituted four years ago, and has been so well conducted that it is now in a most flourishing condition with over 400 members, and additions are being continually made. It has become of more than local importance, and the members now include a large number of distinguished naturalists in many other districts. The Transactions are edited by Mr. W. Cole, the Honorary Secretary, and the part now referred to contains "The Ancient Fauna of Essex," by Dr. H. Woodward; "The Macro-Lepidoptera around Maldou," by G. H. Raynor, M.A.; "On Deneholes," by T. V. Holmes, F.G.S.; the Address of the ex-President, Raphael Meldola, F.R.A.S.; "Primæval Man in the Valley of the Lea," by W. G. Smith, and several other smaller papers on various interesting subjects. Some of the above are illustrated with woodcuts. Lists of the officers and members are also given, with the rules and objects of the Club. It is under the patronage of the Duke of Connaught, Ranger of Epping Forest, and the President is Professor G. S. Boulger, F.L.S.

— MESSRS. CASSELL & Co. send us copies of the following monthlies. Part 56 "Familiar Garden Flowers," containing coloured plates of *Geranimum sanguinum* and *Potentilla alpestris*, the latter with descriptive matter, also including references to the principal allied species. Part 79 of "Familiar Wild Flowers" gives plates of the Woodruff (*Asperula odorata*), and the Kidney Vetch (*Anthyllis vulneraria*), both well-known plants. Part 38 of "Paxton's Flower Garden" has fine plates of *Amaryllis blanda* and *Grammatophyllum speciosum*, together with illustrated gleanings and memoranda concerning several rare or interesting plants.

— WE have received the schedule of the LIVERPOOL CHRYSANTHEMUM AND FRUIT SHOW, which is announced to be held in St. George's Hall on November 27th and 28th. A grand collection of blooms may be confidently anticipated, and good fruit and winter-flowering plants are sure to be staged. The prize of the widest import is a silver cup, value 10 guineas, given by Messrs. J. Williams & Co., manure dealers, for eighteen cut blooms of Incurved, and eighteen of Japanese varieties of *Chrysanthemums* distinct, the competition open to all England. The cup is now on view at the silversmiths', Messrs. Thomas Blundell & Sons, Great George Street, Liverpool. The conditions are stated in the schedule, which may be had from the Secretary, Mr. Joseph Gore, 34, Ullett Road, Liverpool.

— WE are informed that at the INTERNATIONAL EXHIBITION to be held at NICE from the 1st of December, 1883, to 1st of June, 1884, the two following grand special prizes will be offered in the horticultural section. First, the medal of the Minister of Agriculture and a thousand francs for the exhibitor who has contributed most to the splendour of the Exhibition by a continuous display of plants, and, secondly, the medal of the City of Nice with five hundred francs for the exhibitor who has contributed to the success of the Exhibition by maintaining the best supply of cut flowers; and similar prizes are offered by the Principality of Monaco for the best collections of fruits and vegetables, and by the administration of the Exhibition for the best display of garden structures and accessories to horticulture. Owing to numerous applications for space the time for entries has been extended until the 20th of October.

— MESSRS. J. J. THOMAS & Co., 362, Edgware Road, have recently had on view some extremely beautiful ROSE TEMPLES AND ORNAMENTAL WIREWORK, intended for the Calcutta International Exhibition in December next, and they will undoubtedly constitute an important feature there, for we have never seen better samples of such work. Eight temples will be sent, six of these being of the ordinary type, which have been frequently shown at London and provincial exhibitions, but two are much larger and more elaborate in construction. One, designated a pavilion, is 21 feet high, the roof being dome-shaped, of handsome proportions, the open wirework being of a delicate mauve tint, the uprights and main framework

coloured chocolate and gold. The other is 18 feet high, with an octagonal centre and four elegant porches; this is coloured in two shades of green, light and dark. The most remarkable piece of work is, however, a magnificent aviary for small birds, which is valued at 100 guineas, and is probably the finest example of the kind ever produced. It is 6 or 7 feet high, somewhat in the style of an oriental palace with three domes, the centre one circular and the others long, and the whole of it is constructed of polished brass. In addition to these a variety of flower stands, bird cages, mosquito helmets, and numerous other useful or ornamental articles will be sent to represent the general work of the firm.

— GARDENING APPOINTMENT.—Mr. George Miles, foreman to Mr. W. J. Clarke, Spring Grove, Bewdley, has been engaged as gardener to W. H. Anderson, Esq., The Firs, Kidderminster.

— PART 6 OF HARDY PERENNIALS AND OLD-FASHIONED FLOWERS (170, Strand) gives a continuation of descriptive and cultural particulars of various plants of more or less interest, from *Ourisia coccinea* to *Saxifraga ccratophylla*, several illustrations accompanying the letter-press, some being fairly good, and others, as of *Phlox frondosa*, being very indifferent. Capital initial letters are still employed for the specific names in the cross-headings, but in the body small letters are mostly used, even where by established custom capitals are the rule. The latter, however, are employed for the names of places, such as *Primula Carniolica*, *P. Tirolensis*, where small letters are now used, and in two places "*Primula Cashmirianum*" occurs.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

"A COUNTRY GARDENER'S" letter on page 277 says what I desired to say, but did not, and he says that very much better and clearer than I could hope to do. I can quite understand that the tone of my letter would sound so greedy and selfish to the Secretary of the Gardeners' Royal Benevolent Institution that he would consider it a waste of time to argue the matter with so grasping a person. It was very far from my feelings was this avariciousness of spirit. What I desired to know is just what "Country Gardener" very fairly and clearly asks, and that is, What guarantee has a subscriber of ten guineas or a subscriber for ten years, that he will be elected when his life trials come upon him? If it depends, as it appears to do now, on the accident of his possessing sufficient patronage to recommend him for a pension, that does not appear to be a very desirable or encouraging state of things, and certainly one not full of stimulation to anyone to contribute. This is what we country gardeners desire to know before we can be expected to either give special donations or subscribe to the Institution either annually or with a life membership.—P.

I WAS very pleased to observe in the Journal of last week (page 277), that "Country Gardener" has called attention to this Institution. I have been looking for an answer to the first letter on page 175, and I trust now there is a second that the Secretary will answer both fully. I entirely agree with your correspondent that a benefit society is really necessary for gardeners. I for one would be pleased to join it. I, like your correspondent, would contribute to the "Royal" if I knew the benefits to be received by doing so. I trust some of our leading men will take the question up, and not let it drop until something is settled.—ANOTHER COUNTRY GARDENER, *Hants*.

BROAD BEANS.

THESE are favourites with many, and they are easily grown and useful. The varieties are now very numerous, but really good ones are not plentiful. The best of all is the Aquadulce. The first season I had this variety, now some years ago, the pods were long and handsome, but it was not so prolific as could be desired; but by selecting seed year after year I have now a strain which is wonderfully prolific. This year these commenced podding when 9 inches high, and some of them which were stopped when 18 inches high matured eight, ten, and twelve pods from 9 to 15 inches in length. The lower pods were resting on the ground, and they were much admired. I have seen nothing in the way of Broad Beans to equal the crop, and shall take care to perpetuate the stock. Some of the pods were 16 inches in length, and the average length was a foot.

Biddle's Monstrous Longpod was spoken highly of, but with us the pods though numerous were too short, the longest not exceeding 6 inches; and considering its recommendation I was disappointed with it. Nettle-ship's Prize Bean, which I had from a seedsman in the west of Scotland as being the most extraordinary variety ever seen, failed altogether to equal what was said of it. It is short-podded, and has been placed far down our list.

Seville Longpod would be found very much superior to the majority of Broad Beans we find specially recommended. Leviathan is a fine one to produce long pods, but it lacks in prolificness. The Windsors, although having a pedigree, are far behind several sorts. Mackie's Monarch Long-

pod is an impressive name and a fertile Bean, but it is very short as Beans grow now-a-days.—A KITCHEN GARDENER.

GRAPES AT CLOVENFORDS.

MUCH has been written respecting the Grapes grown at this noted establishment, so when northwards I availed myself of the privilege freely accorded me by Mr. Thomson to visit and note for myself what is being done. Briefly, then, will I describe as fairly as I can the condition of the varieties.

LADY DOWNE'S.—This valuable Grape, which is highly esteemed by Mr. Thomson, was first examined. The crop looks noble. Fancy span houses 200 feet long, proportionately wide, and very high pitched, the roofs covered as regularly as can be imagined with bunches of Grapes. The Vines are 9 feet apart, each carrying three rods, and there are twenty or more bunches of a good size for keeping on each rod. To my mind medium bunches of 1½ lb. or 1¼ lb. are prettier than the larger ones. The Grapes were colouring well. I did not observe many laterals with two bunches, but where those were present I could see but little difference in quality or size of bunch or berries. Really this Grape when thus excellently grown has a very superior appearance. I particularly noted that the majority of large bunches were grown on young rods run up last year. Some bunches would turn the scale at 4 lbs. and had no shoulders. Again, some bunches were so broad across the top as to resemble Alicantes. Mr. Thomson assured me that he intended bottling about 1000 bunches. The laterals were strong and not at all close, and the foliage was good. Houses of this variety presented a sight not soon to be forgotten. Attention is required when the bunches are in flower to get them to set evenly. There is little scalding, as might be expected in such lofty well-ventilated houses. Doubtless plenty of fire heat has somewhat to do with the success attained, there being, I believe, six rows of 4-inch pipes on each side of the houses. There are three houses of this Grape, and the crops represent something considerable, especially when it is remembered they are not used until the other var. Grapes are cut. This Grape will keep well on Vine until March.

BLACK ALICANTE.—So good are the crops of this Grape I really fail to see why rods were cut out to make way for the preceding. The bunches are noble, some I think weighing 6 lbs., and all of good colour, though the berries might have been larger by a little more thinning. The bunches being large were of course less numerous than those of Lady Downe's, yet I feel sure some of the Alicante rods carried nearly double weight of the other. Alicante is of little use for keeping after Christmas, the fruit being so watery, though good cultivation improves them in the latter respect. I left these (being rather interested in this variety) with a very favourable opinion of it. This a very hardy Grape, and sets very freely—too freely for some persons.

MUSCAT OF ALEXANDRIA.—Of this I consider the crop too heavy to finish well; the rods, being only 3 feet apart, have not sufficient space for the fruit to ripen and colour early. These, though grown extensively, do not pay for growing in proportion to Alicante. Some fine pieces were hanging with good berries, still they gave me the idea of not being quite happy. This, however, only confirms the opinion of good Muscat growers that this Grape requires very special treatment to grow it well. Then the question arises, Will this special treatment pay for market purposes?

DUKE OF BUCCLEUCH.—I had seen this Grape exhibited at the Edinburgh Show the day previous in grand form, and expected to see it growing extensively at home, but I was too late, as the bulk of the crop was cut. However, sufficient was left to exhibit the high character of this noble Grape. Tasting is always considered a test for quality, and I had the pleasure of tasting in liberal quantity, and very superb the quality was. The berries are so large that one is a mouthful, and the skin thin. This Grape must command attention, and whoever has it once will certainly want it again. No doubt it is a great success here, and there is no spot which occurs in some places. This is a very early variety, and I do not suppose will keep long with any certainty.

GROS COLMAN.—This is the Grape at Clovenfords, and of itself worth a journey of 400 miles to see. The two spans, 200 feet long, were a picture. I do not wish unduly to flatter Mr. Thomson respecting this the grandest of all market Grapes, but must say the crop is very encouraging to a small grower like myself. Invariably the bunches were without shoulders. The reason is not far to seek. First, for keeping we know such bunches are far the best, but the most important point is the ripening, a bunch without shoulder being comparatively easy to finish, and when finished can be packed safely and securely. The owner of these grand Grapes speaks with experience when he says the Gros Colman takes two months longer to finish than Alicante. Plenty of fire is required for this. I did not expect find this quite so late, still there is no doubt about it being

right, as my experience tells me it will colour and finish very late in October. In lean-to houses this variety was ready for cutting, but then the crop was lighter than in the span houses. I should not advise the planting of Gros Colman extensively in lean-to or in mixed houses. I brought home sample berries measuring fully 4 inches in circumference. The flavour I know is faulty, still the noble appearance will always command special attention. The Vines were planted 8 feet apart, but the rods were about 3 only asunder; foliage good, but presenting the usual characteristic of this kind—namely, curled edges, slightly coloured, with the usual touch of red spider. This, though slight, requires attention, and Mr. Thomson thinks sulphur on the pipes helps to keep it in check. No other Vines take this pest so freely, so growers should be on guard. I took particular note of the general crop all through, and observed that no matter how light the crop, which of course colours quickest, the bunches do not come any larger. I have left, say, from six to ten bunches on one rod and twice that number on the next, yet there was no great difference in size of bunches; the berries are, however, the largest on the light-cropped rod. I do not think it wise, therefore, for cultivators generally to attempt very heavy cropping, as a rod bearing from, say, 18 lbs. to 20 lbs. will give more satisfaction than a crop will of twice that weight. I came away with the impression that Gros Colman with three or more rods is better than when limited to a single cane. I note, however, that Mr. Thomson is averse to a very rapid extension for this variety. Astonishing growths of young cut-backs of Gros Colman planted in other houses will doubtless create a sensation some time.

GROS MAROC.—I saw one Vine of this Grape well cropped, berries very good, and covered with fine bloom. I believe Mr. Thomson is only waiting to test its keeping qualities before deciding on the merits of this variety for market. I may have something to say respecting it later on.

I make no attempt at fully describing all that is to be seen at this large establishment. The Orchid growers, however, would have a treat, for these plants are grown very largely. I have purposely avoided the manure question, but ere I finish let me give a word of praise to the Vine manure as made by Mr. Thomson. It is a Vine manure, yet so harmless and withal beneficial that every Orchid, Fern, or plant for which it is employed can be detected. Naturally Mr. Thomson is proud of this, and the conclusion I came to after examining the borders, both inside and out, was that the soil itself is but a poor sample of stiff hungry loam, such as is soon worn out. All the houses were as clean and orderly as in a nobleman's garden, which is not always the case in commercial establishments. My thanks are due to both Mr. W. Thomson and his son for their very hospitable treatment of a stranger, and I trust this first visit may be the beginning of a series of future enjoyable visits.—STEPHEN CASTLE, *West Lynn*.

TEA ROSES IN WINTER.

CHARMING unfolding buds of these Roses are always welcome, and appear to be especially valued in the late autumn and early winter months. In the spring they can easily be had by forcing by all who have the necessary means for producing them. During the closing months of the year flowers can be had with little forcing, provided healthy plants are established in pots. Such plants that have been outside for some time past will have their wood thoroughly ripe, while others have broken back, producing new growth which will in a few weeks yield abundance of useful buds. These, if housed in a light position where the night temperature can range from 50° to 55°, with a rise of 10° during the day, and the house closed early while the sun is upon it, will give some very useful flowers after those in the outside borders are past. Those that have not commenced growth should have the thin weak wood removed and the stronger shoots partially shortened before they are started. Those that have already started can, if too early, have the buds removed at once, and they will quickly make short growths and produce buds in quantity. With strong plants, and these given careful and judicious treatment, the supply of useful buds need not fail between now and Christmas.

If any of the plants are much rootbound they may with safety be transferred into a little larger pots. Others should be well top-dressed or given a little Standen's or Crown manure, which acts quickly and beneficially upon Roses whether in pots or planted out. Young plants in 6-inch pots that were rooted from cuttings last spring should be removed from the cold house in which they have been growing, and placed in the same genial temperature above mentioned, and they will well repay the care that has been devoted to them. Be careful that red spider does not exist upon the plants when removed indoors; but the moment it is seen wash them thoroughly with soft soap, in which has been mixed a little sulphur.—CULTIVATOR.

ANCIENT BRIDAL WREATHS.—It appears that the Roman bridal wreath was of Verbena, plucked by the bride herself. Holly wreaths were sent as tokens of congratulations, and wreaths of Parsley and Rue

were given under a belief that they were effectual preservatives against evil spirits. The Hawthorn was the flower which formed the wreath of Athenian brides. At the present day, in our own country, the bridal wreath is almost entirely composed of Orange blossoms on a background of Maidenhair Fern, a sprig here and there of *Stephanotis* blending its exquisite fragrance. Much uncertainty exists as to why this blossom has been so much worn by brides, but the general opinion seems to be that it was adopted as an emblem of fruitfulness. According to a correspondent of *Notes and Queries* the practice has been derived from the Saracens, amongst whom the Orange blossom was regarded as a symbol of a prosperous marriage—a circumstance which is partly to be accounted for by the fact that in the East the Orange tree bears ripe fruit and blossom at the same time. It has also been suggested that this flower was introduced into our wedding customs by French milliners, having been selected for its beauty rather than for any symbolical reason.—**THISTLETON DYER** (in *Cassell's Family Magazine*).

THE ESSEX FIELD CLUB.

FOURTH ANNUAL CRYPTOGAMIC MEETING, SEPTEMBER 29TH.

ENTHUSIASM of more than ordinary strength seems to be one of the especial characteristics of the members of the above fast-growing and admirable Club, as, though the afternoon fixed for the annual Fungus foray in Epping Forest proved as unfavourable as possible, yet the gathering at the rendezvous, High Beach church, was very large. They commenced their explorations undeterred by the heavy rains, which soon rendered the Forest more suitable for amphibious animals than human beings, and a stranger unfamiliar with the objects of the Club and the self-denying spirit produced by a devoted study of botany, might have been reasonably surprised at seeing such a party assemble. Macintoshes, leggings, ulsters, cloaks, and various other protective articles were in strong force; baskets, bags, and satchels of all shapes and sizes being similarly numerous to contain the spoil that was so eagerly sought. Fungologists of world-wide fame were there duly armed, and soon plunged into the moist fastness of the Forest, undismayed by possible rheumatism or influenza. Ladies, too, delicate and fair, most bravely faced the dangers and discomforts, imparting the sunshine of their presence to the expedition, and served in no mean degree to lighten the gloom, especially as regarded the younger and more susceptible gentlemen members of the party. Fully equipped they commenced their explorations shortly after half-past three, and for a period of two hours and a half, during the greater portion of which time rain was descending in torrents, the recesses, nooks, and glades were diligently searched for choice, rare, and peculiar Fungi. The leading members proved very successful, Drs. Cooke and Wharton conveying to the head-quarters, "The Roebuck," at Buckhurst Hill, a good representative collection of the principal species found in the district. Others also contributed, and considerable space was covered with the interesting but unsavoury exhibits.

Nearly one hundred members and friends assembled at the Roebuck, and after a substantial tea had been partaken of, with the keen relish which only hungry naturalists experience, they adjourned to the exhibition room to discuss the finds of the day and the numerous miscellaneous contributions. The room is a large one, and four tables extending nearly the whole length were devoted to botanical and other specimens of considerable interest. One of the principal exhibitors was the President of the Society, Professor Boulger, who showed some complete collections of Essex Cryptogams, including *Jungermanniaceæ*, and Fresh-water Algæ, in addition to about twenty species of British Orchids, representatives of the family *Rhizocarpaceæ*, including *Marsilea*, *Azolla* and *Salvinia*, and a collection of British Ferns, all well preserved and carefully named. Another very remarkable exhibit was a collection of Epping Forest Fungi from Mr. J. English, prepared and preserved in the excellent method described in his little manual upon the subject. By this process the form, colour, and characteristics of the species are admirably preserved, and, being mounted upon small square blocks of wood, they have a life-like appearance that is very striking. Some recently collected living Fungi were also shown, and a species (*Polyporus umbellatus*) previously unknown in Great Britain, but found by Mr. English in Epping Forest, July 19th of the present year, attracted much attention. It is of very distinct appearance, a number of small brown or blackish cups being borne on small whitish stipes arising from a common stem. Mosses were also shown by the same exhibitor. G. P. Hope, E-q., Havering Chase, sent a complete collection of Essex Algæ; Mr. H. Bennett, eleven cases of British Characeæ; an album of British Ferns beautifully mounted by Miss Marion S. Ridley; Epping Forest Mosses from Mr. E. Forster, and eighteen cases of British flowering plants from the Club museum, prepared in Mr. English's method. A grand collection of Lepidoptera, in fifty-seven glass cases, was also shown by Messrs. W. B. G. & H. A. Cole, representing a large number of British and foreign species, some extremely rare, and all in a fine state of preservation. Plans and sections of the Loughton Camp, very cleverly executed by Mr. D. Cole, occupied one end of the room, together with cases of pottery, flint flakes, flint axe, and other curiosities found during the excavations at that camp. Several members also kindly brought microscopes, with specimens of Cryptogams prepared to show the peculiarities of their structure. Upon the walls were hung a series of diagrams and drawings illustrating the fructification of Cryptogamic plants. These were remarkably good, being distinguished by the clearness of definition distinguishing Mr. David Houston's work.

Dr. R. Hogg sent specimens of the so-called Ginger-beer Plant, which somewhat resembles large irregular grains of boiled sago. They were shown to several of the leading botanists and fungologists present, but very little appears to be known about it. Dr. Cooke states that he has frequently examined specimens sent him to be named, but he could only determine it to be a cellular vegetable body similar to some other low forms of Fungi such as the Yeast and Vinegar Plants, but apparently distinct from them. He regards it as an immature form of some species which, when placed in the sugar-and-water mixture usually employed in the manufacture of the "ginger-beer," is under unnatural conditions, and cannot develop its normal characters. The best plan, he considers, would be to endeavour to grow it comparatively dry, as then probably it would assume its proper form. Mr. W. G. Smith stated that the Fungus was well known in several districts, and that it is occasionally sold in small bottles as a curiosity, but from a cursory examination he had given it he concluded it was a form of Yeast. Mr. Jackson, Curator of the Museums at Kew, has had samples submitted to him, and is now trying it under various conditions. Dr. Silvester is also investigating its characters, and has found, as other experimenters also have, that ground ginger seems beneficial to the growth of the Fungus, which then decomposes the sugar more rapidly.

An ordinary meeting of the Club (Professor Boulger presiding) was held when the visitors had inspected the exhibits, and several new members were proposed and elected, and after some other official business had been disposed of, Dr. M. C. Cooke gave a few remarks upon "Recent Additions to the Fungus Flora of Epping Forest." He stated that since the last issued by the Club had been compiled over forty species new to the district had been observed, and several were also new to Britain. He especially referred to the *Polyporus umbellatus*, shown by Mr. English, which had been found in various parts of Europe, but not previously in England. Several others found by Mr. W. G. Smith and Dr. Cooke were also noted. Some Fresh-water Algæ were also mentioned, several of which had been discovered by the lecturer during recent researches amongst those minute plants. Mr. W. G. Smith followed with an interesting paper upon "The Lower Orders of Fungi," which will be published next week in these pages. Dr. H. T. Wharton read an elaborate paper upon "Fungi as Poisons," which was listened to with great attention. He stated that no hard-and-fast line can be drawn to distinguish eatable from poisonous Fungi, and the only method is, as with flowering plants, to obtain an accurate knowledge of the species themselves. The principal are readily recognised, and with close observation no difficulty will be experienced in detecting the noxious members of the family. He briefly enumerated the most remarkable of the injurious forms, but observed that there is much difference of opinion respecting the innocent or poisonous Fungi, some being described under the one head and some under the other even by eminent fungologists, and he advised all to abstain from testing species respecting which there is the slightest doubt. Even ordinary Mushrooms in moderate quantities affect some persons injuriously, and one man he knew always had a number of strange symptoms after partaking of a very small portion. He thought much depended upon the constitution of the individual, and also upon the state of their health at the time of eating the Fungus. Careful and thorough cooking is most essential, employing salt and pepper liberally, and possibly by this means some slightly poisonous species might be rendered safely eatable. In cases of poisoning by Fungi death may occur from a few hours to several days, but prompt remedies are important; an emetic administered immediately, followed by a strong dose of castor oil, is the safest antidote that could be recommended.

Mr. R. Meldola, Ex-President of the Club, and the delegate at the meeting of the British Association at Southport, read a report respecting the regulations of this Association concerning the appointment of delegates of local naturalists' societies and field clubs throughout the kingdom, by which it appeared that the privilege would be restricted to those of sufficient social status, and which publish their transactions in a printed form. Mr. W. Cole read portions of a lengthy report of the Committee appointed to investigate the pre-Roman camp at Loughton, and explained the diagrams and plants previously alluded to, but the complete report will be published in the "Transactions" of the Club.

Shortly after 9 P.M. the meeting was brought to a close, and the members and visitors dispersed damp, but not depressed, unanimously wishing that the next gathering may be more favoured by the weather.

MR. JOHN HOLLINGWORTH.

I AM sure that there are no lovers of the Rose who have ever come in contact with this veteran amateur but will rejoice to hear of his recovery from a long and painful illness, that at one time made his recovery very uncertain. He is the "doyen" of amateur Rose-growers. Of the exhibitors of the days when Mr. Hedge and a few others were the small phalanx he only remains. Ever ready to encourage the culture of his favourite flower, he still retains his ardent love for it, and rejoices to see the numerous competitors who now enter the list, and whom he is ever ready to cheer on in his hearty way, even though at the expense of his own success. In a visit I paid the other day to Maidstone (of which I hope to say something in an early issue of the Journal), I had the pleasure of seeing him. For nearly three months he had been laid by with rheumatic gout, and was two months in bed; but even then he had his beauties brought up for him to inspect, and rejoiced to hear of all that was going on in the Rose world. On leaving him he desired me

to give his kindly greeting to all rosarians. "Tell them," he said, in his cheery way,

"If bullets and the gout
But put the commodore about,

that I hope to meet them again next year." But it is not rosarians alone who will rejoice in his recovery. None know how kind and benevolent he and his good brother are (in Maidstone they are known as the Cheryble Brothers), and many will rejoice to think that, although the hand is still crippled, it is as open as ever, and that neither age nor illness has chilled his warm heart.—D., Deal.

ROOF CLIMBERS.

FUCHSIA PENDULÆFLORA.

MANY species and varieties of Fuchsia are admirably adapted for training to the roofs of conservatories, and the one represented in fig. 56 is especially good for that purpose. Its deep crimson-scarlet flowers are produced in loose pendulous clusters, and these are so numerous and

56.—FUCHSIA PENDULÆFLORA.

continually produced that the plant is beautiful during a greater portion of the summer months. The length of the corolla tube gives a very distinctive character to the flowers, and this Fuchsia is, considering all its characters, exceedingly attractive and useful. It requires no special treatment except that it seems to succeed in a higher temperature than most other species or varieties. Good substantial loam with a little well-decomposed manure, leaf soil, and sand suit it, and pruning will be needed occasionally to remove the weak and unripened wood.

Fuchsia pendulæflora is a native of South America in common with the majority of its allies, and was introduced in 1879. *F. corymbiflora* is related to it, but has smaller flowers, and several other species with long tubular flowers, such as *F. serratifolia*, are handsome plants for the roofs of houses.

LILIUM AURATUM.—Allow me to call the attention of your readers to the successful manner in which I have this year grown a plant of *Lilium auratum* from a bulb procured from Messrs. J. Carter & Co. of High

Holborn, London. I planted it in an 8-inch pot in turfy loam, with one-fourth of drift sand, covering the bulb an inch deep. Up to 15 inches high the stem is round, then it commences to flatten, and at 4 feet is 1½ inch in diameter, with dense foliage; it then divides into three parts, 4 inches higher, and bears a monster truss of thirty-two handsome spotted flowers. I have it in a window adjoining the street, where numbers of passers-by stop to admire it, some thinking it artificial. I have taken five first prizes with it. The bulb cost me 2s. 6d., and it is my intention to purchase half a dozen more with the object of endeavouring to grow them still more successfully.—T. MERRICKS, Stafford.

[Our correspondent has been successful, but the stem of his Lily is fasciated, and he must not expect that all others he may purchase would be of a similar character.]

THE PHYLLOXERA.

"A VINE-GROWER" asks, on page 268, if I will say how and from whence I got the phylloxera at first. In reply, I beg to say that having

had a Vine in a pot of the Strawberry Grape from a private garden some four or five years prior to discovering the insect in our new vineries in 1879, and having traced the progress of the disease during the interval from the house in which that Vine was planted, I therefore may reasonably assume that this was how we got the phylloxera at first. But failing to see in what way my naming the place whence I obtained the supposed infected Vine could possibly assist in furthering the object in view—viz., the extirpation of the destructive pest, I would, for this reason, prefer to be silent on that point.

The idea has just occurred to me, in connection with the stamping-out the phylloxera, of the advisability of appointing as an "Inspector of Vine nurseries," a man practically acquainted with the dreaded insect in its various stages of development, and whose duty it should be to visit all the nurseries in which Vines are grown for sale from about the middle to the end of August, for the purpose of examining the young Vines before being dispatched to various parts of the country, and without his "certificate of health" no firm be allowed to part with a Grape Vine; also, in the event of detecting phylloxera on the Vines in any of the nurseries so visited, he should order and witness the destruction of the whole stock in hand. If this were done, and I see no reason why it should not be, phylloxera in this country would soon become a thing

of the past. Nurserymen and gardeners would alike willingly contribute to a fund for defraying the expenses attending an annual inspection of Vine nurseries. This would not be very great, for if necessary district inspectors might be appointed.

Meantime, I would counsel those who may be contemplating the erection and planting of new vineries to plant in April or May, using Vines struck that spring, and which, previous to being planted, should be inspected by some gardener having experience of the phylloxera. In conclusion, I may be allowed to suggest what, in the first place at any rate, I consider the right plan for any gardener who may happen to have planted a new vinery with Vines obtained from the trade and infected with phylloxera to communicate with the vendors, and get an assurance from them that they will, at any cost, stamp it out, and that would be all that could and should be required of them.—H. W. WARD.

THE HERBACEOUS BORDER IN THE AUTUMN.

YOUR able correspondents, Messrs. G. Abbey, T. Entwistle, and others have been giving very interesting and seasonable articles on some of the best varieties of hardy plants in cultivation, but I will just briefly notice some of those which are most conspicuous in the borders here. For brilliant effect few, if any, equal *Gaillardia grandiflora*, the flowers of which are nearly 3 inches in diameter, and of a bright orange-yellow colour with dark crimson centre. They are produced in great abundance. *Scabiosa caucasica* is a lovely gem of more than ordinary merit; the flowers are large, fully 3 inches in diameter, and of a delicate shade of lilac-blue. *Rudbeckia Newmannii*, a very showy plant; flowers bright golden yellow with a dark centre. *Coreopsis lanceolata* is one of the very best hardy perennials, and is a most profuse bloomer, the flower heads being bright golden yellow. *Achillea Ptarmica* fl.-pl. and *A. serrata* fl.-pl. should have a place in every collection, supplying as they do for nearly two months an almost unlimited quantity of pure white flowers. Too much cannot be said in praise of the useful *Matricaria inodora* fl.-pl., which is now a mass of lovely white flowers. I find the best way to grow this plant is to insert cuttings every autumn, which make large plants about 2 feet through by the autumn of the following year. *Chrysanthemum maximum* is a stately bush fully 2 feet in height, producing an abundance of large white Marguerite-like flowers. *Pyrethrum uliginosum* is a grand back-row plant; flowers large, pure white; very useful. *Bupthalmium salicifolium*, a very free-flowering plant, producing an abundance of orange-yellow flowers. *Anemone japonica* and *A. japonica alba* should be grown in quantity. The singular flowers of *Echinops Ritro* are very interesting, presenting when in full bloom a perfect ball of lilac blue. A beautiful perennial is *Francoa ramosa*, but it is scarcely hardy in this locality, requiring protection throughout the winter, which it well deserves. Its long graceful spikes of pure white flowers are produced in great abundance for nearly two months; it is one of the most beautiful autumnal flowers in cultivation. *Lythrum Salicaria roseum* is resplendent just now with long spikes of lovely rose-coloured flowers.

Perennial Phloxes, Pentstemons, border Carnations, and others are making a grand display just now, while many of the spring and early summer-flowering plants, as if desirous to add a parting tribute to the waning year, are again flowering very freely. Some of the most prolific are *Ranunculus acris* fl.-pl., *Delphiniums* of sorts, *Campanula turbinata* on the rockwork flowering very freely, and *Polyanthuses*. Some plants of *Spiræa japonica* that were forced in the spring and afterwards planted out have on an average six spikes on each, and are very useful. Every attention should be paid to have the borders clean, and all plants that require it should be tied up to stout stakes, as the heavy winds and rains of autumn play sad havoc among the plants if they be neglected.—WM. MARSHALL.

LIFTING AND TRANSPLANTING FRUIT TREES.

THE time for carrying out this operation having arrived, a few remarks respecting the best method of procedure may be acceptable. The success of a fruit tree depends in a great measure upon its having had a good start. The first step to be taken in forming a handsome and fruitful tree without making a new and expensive border, is to determine the distance the trees shall be planted from each other against the wall. For Peaches, Apricots, Plums, and Cherries this should be about 15 feet, and for Pears 20 feet. Then having marked $3\frac{1}{2}$ feet on each side the position chalked on the wall for the trees, and 5 feet therefrom and in a regular curve from point to point, excavate the soil (assuming it to be unsuitable to the growth of the trees) to the depth of 3 feet, and for drainage provide a layer 9 inches thick of brickbats, elinkers, or stones, filling in the ehinks with a barrowful of gravel, and over that place a layer of turf. The soil, consisting of three parts good loam and one of old lime rubble and horse droppings mixed well together, should then be placed in the holes in readiness for the trees. This done, and assuming that wherever space between the permanent trees on the walls admitted of a few young trees from the nursery being planted annually to develop for a year or two—viz., until the extending branches of the permanent trees

render their removal necessary, we shall at once proceed with lifting and transplanting.

The trees should be taken up about the end of September or the beginning of October, to allow time for fresh roots to penetrate the new soil during the interval of planting and the trees shedding their leaves. They should be lifted with as much soil adhering to the roots as possible, so that the tree may experience little check. A trench should be opened around the tree about 3 feet from the stem, keeping a more or less distance from the latter, according to the size of the tree to be lifted, and deep enough to admit of the soil being worked away from underneath the tree with a five-tine fork without injury to the roots. When the ball of earth has been reduced sufficiently to allow of two or three men lifting the tree, place it on a mat, securing it round the ball of earth, and with a hand-barrow carry it to the station made ready for its reception.

In planting, sufficient soil should be used to allow of the tree being in its proper position as regards height from the surface after the soil had subsided 6 or 9 inches. The soil should be worked with the hand among the roots, the latter being spread out in a horizontal and slightly downward direction, and should have the points of any damaged or over-luxuriant shoots cut away. When the tree has been half planted, take hold of the stem with both hands, and give it a few gentle shakes in an upward direction to make sure of there not being any space left between the roots and the soil, then complete the planting, treading the soil, which should be moderately dry, well together. Secure the principal shoots loosely to the wall with nails and shreds to prevent their swaying, and then lay on 3 inches thick of short dung as a surface mulching. Trees thus planted, providing the after treatment and other circumstances be congenial to their requirements, cannot fail to give a good account of themselves in due time.—H. W. WARD.

A VEGETABLE KINGDOM EXHIBITION.

PERMIT me to adopt my own heading in referring to what is termed "the Proposed International Exhibition of Vegetable Products." That is not sufficiently concise for me, as it will not be for the public, however properly it may express the nature of the wonderful gathering that has been proposed to be held at South Kensington in 1885. Such an exhibition, fully representative of the industries that arise from the cultivation of plants in all parts of the world, would completely eclipse in magnitude and variety the present extraordinary display pertaining to matters in connection with the sea.

No doubt the "horticultural resources of the country are sufficient to fill all the space occupied by the present Fisheries Exhibition." But a very important question arises—namely, Would the whole, or half, or even a tenth part, be represented there? It is generally conceded that the great display of 1866 was the largest that has ever been seen, and many persons competent to judge are of opinion that a finer would not be produced now whatever inducements were offered. Yet the exhibits referred to would not occupy one-fourth the space that is now provided by the substantial erections in the Horticultural Gardens. And then that Show was only for a limited time, and it is a practical impossibility that by no amount of removing and "replacing" could its high character be maintained throughout the season. If Mr. Wills were master of all the gardens in the land there is no doubt the buildings would be filled to overflowing; but we must recognise the fact that owners of gardens are in the habit of refusing to empty them for the purpose of making a great public display. Very fine exhibitions of plants and flowers can no doubt be held periodically; but as to maintaining an unbroken exhibition of the magnitude contemplated, it is a question if it can be done satisfactorily.

To commence with, let us consider the resources for producing a spring show. The measure of such a show may be taken from what has been done in the past. Even if the spring shows of the Royal Horticultural and the Royal Botanic Societies could be joined together they would not occupy half the space of the entrance gallery alone. But these shows cannot be joined, for the simple reason that the bulk of the exhibits at one are removed and occupy by far the greater portion of the space at the other. But then it may be said the Dutch cultivators would bring Hyacinths, Tulips, and all kinds of bulbous plants which they grow so largely. They might bring some, but judging from their exhibits at the great shows which have been held in Belgium, they would not add materially to the magnitude of the Exhibition, however interesting their contributions might be. If they could bring their bulb farms there would be something to rely on; but the fact must be admitted that their exhibits of plants in pots would not half equal in magnitude, while they would be inferior in quality, to the best of our home productions. A great show could be provided unquestionably, and with permanent vegetable products and cultural and manufacturing appliances by this and other countries, there would be sufficient to attract the million. But to rely only on plants at one time, then "remove them and fill the space with implements and sundries" at another, would not meet the expectations of the public, and hence would end in disappointment.

To ensure success there must be a great permanent exhibition of vege-

table products and cultural appliances permanently arranged. Then periodical, national, or international displays of plants, flowers, and fruit on the largest possible scale, and these would induce the million to "repeat their visits" much more frequently and satisfyingly than by a mere interchange of plants and implements as suggested on page 266. The permanent exhibits must be on such a scale and of such a character as in themselves would attract world-wide attention, and the field is amply large enough to ensure this. The flower shows, like the musical *fêtes* of the present year, to be grand special attractions at intervals during the season.

The National Auricula Show might form the centre of a grand display in April. A magnificent exhibition of Azaleas, Rhododendrons, and Roses in pots could be provided in early May; then a gigantic miscellaneous exhibition might be opened on the 1st of June, with an international jury of adjudicators. The National Pelargonium and National Rose Shows would follow in July; in August the National Carnation with a second miscellaneous plant and early fruit show on an extensive scale would command attention, as would the succeeding National Dahlia and General Cut Flower Show in September. A National Potato and Root Show would be a success in October. Then the campaign might be brilliantly closed with a National Chrysanthemum and Hardy Fruit Show in November. In this way horticulture would be more fully represented than by any other means, and an ever new and ever widening panorama of attractiveness would be unfolded.

But can even all this be done? It would not be effected by a stroke of the pen. The Committees of these Shows would have to be satisfied, and the Crystal Palace and the Royal Botanic Society to be reckoned with; yet all this would be easier than maintaining one unbroken exhibition on a sufficiently imposing scale as to command public attention. There must be a series of distinct shows each to form a new element of interest, and the inhabitants of the metropolis would attend again and again.

As to the "proceeds for founding a horticultural college," &c., that subject is scarcely ripe for discussion; and to enter seriously on it now would savour somewhat of "counting chickens before they are hatched." Of more immediate importance is it to summon a preliminary committee of horticulturists and ascertain the views of the members: it is just possible that all these individuals may not be endowed with the same sanguine temperament as your correspondent of last week. Yet the time proposed is opportune and the means greater than ever they were before, and perhaps than will ever be afforded again, for providing an exhibition of vegetable products representing horticulture, forestry, agriculture and the cognate industries on such a scale as has never been attempted, and which adequately carried out could scarcely fail to prove a grand success.—EX-EXHIBITOR.

BORDER PLANTS IN IRELAND.

SEVERAL of these very useful and essential flowers have been mentioned lately by contributors to this Journal, but there are many others worth notice. One particularly deserving attention is *Patrina scabiosæfolia*, which bears effective bright yellow flowers about as large as a pennypiece on stems about 3 feet high. Another good yellow flower is *Helianthus multiflorus flore-pleno*, which is most useful in shrubberies and for cutting from. It lasts a long time in vases. *Coreopsis præcox* and *C. auriculata* are especially bright in large tufts, and can be seen a long distance, producing an abundance of flowers throughout August and September. *Phygelius capensis* is a striking border plant, while *Oenothera Fraserii* forms one of the richest edgings that could be imagined, a change from the close and formal edgings now so much in demand. It does well round beds of American plants, as it thrives well in peat. *Aster longifolius formosus* is a good variety and colour of this old-fashioned, but useful flower—forms a fine contrast mixed with the *Patrina* mentioned above. *Anemone japonica alba* and *hybrida* grow and flower charmingly here, producing large clusters of their valuable blooms.—J. PITHERS, *Summerhill, Co. Meath.*

THE APPLE CROP, WHAT SHALL WE DO WITH IT?

ACCORDING to accounts received from all parts of the country the average of the Apple crop is heavier than it has been for some years, and people are beginning to ask what shall be done with it. Those who have fruit rooms will of course fill those structures, and they will possibly discover that Apples will keep as well, if not rather better, than they do in a half-stocked room. Lofts, cellars, and even corners of bedrooms will be used for storing some out of the abundance of this most important fruit, and possibly it will keep as well in any of these structures as it will in the most elaborately built fruit room.

Two years ago we had a very violent storm in the beginning of October which knocked down most of our Apples. Our fruit room was small, and could only be made to accommodate the best of the fruit. Some was stored away in vegetable hampers for immediate kitchen use, and some five or six sacks of inferior sorts and those which were most bruised, were simply put in a heap on the grass between four sheep hurdles with the idea of speedily using them for cider. It was, however, the middle of

January before the cider could be made, and in taking out the Apples I was astonished to find how few of them had decayed. Scarcely any of them were too far gone for cider-making, and I have no doubt they were all the better for keeping, for the liquor produced was excellent. But the point which most struck me was that the decay was not communicated from one fruit to another; one Apple which was sound would be found embedded in the partially decayed pulp of one or two others, and although they were not choice dessert kinds so that I could not be sure about the flavour, yet as far as could be judged from tasting ordinary culinary Apples they had not deteriorated in this respect.

I have since heard of a number of villagers near by who make Apple-growing and Apple-keeping a speciality, who never move their fruit from the time it is gathered and placed in a heap till they want to sell it. Their theory is that handling the fruit does much more harm than leaving in a few which are decaying. It is generally supposed that exhalations from decaying or even ripening fruit is detrimental to the keeping of that which should ripen later. Here now, in the case of the Apple, is some evidence to the contrary, and it comes at an opportune season.

Those who are in difficulties as to what to do with their large quantities of Apples should do what experience has taught is the best with the choicest fruit. For the rest put them in a heap anywhere so that rats and mice can be kept from them, throw straw or other light covering over them on the approach of severe frost, and leave them otherwise to take care of themselves. If you want to spoil them as quickly as possible put them where they will be warm and dry. But there are many of your readers who know more about keeping Apples than I do, and now is the time when a record of their experience will be received with acclamation. An article on cider-making for amateurs from an experienced hand will also be welcome.—WM. TAYLOR.

NOTES FROM WOOD LAWN.

THE shrubberies here are looking gay, although we are now in the last week of September. A few heads of *Lilium auratum* are still to be seen. *Lilium speciosum* (*lanceifolium* of Paxton, but not the accepted *lanceifolium*, which is not in cultivation) is now at its best, and is well represented here by good clumps with from twelve to twenty stems, which have a noble appearance amongst the shrubs. It is a most valuable Lily in all its forms, on account of its flowering late. In mild genial autumns it continues in bloom for a long time. As a rule, in the north it is caught by frost before it has quite finished blooming, but it only shares the fate of all autumn-blooming plants. When well grown as a pot plant it is highly valuable for the conservatory previous to the Chrysanthemum season. In the border it loves a deep rich friable soil, well drained, and the small amount of shade which the shrubs afford to it seems to meet its requirements.

What a grand and useful shrub is *Hydrangea paniculata grandiflora*. It is liberally diffused in the shrubberies here, where it thrives admirably. No shrubbery ought to be considered complete without it, and the fact of its blooming at the end of summer and throughout the autumn months renders it one of the most valuable of all hardy flowering shrubs. Its great panicles of white flowers are highly useful for large decorations. Every branch terminates with one of these beautiful panicles, and if either gardener or employer wishes to spare the indoor bloom this will be found a most useful plant to cut from for a supply. I have grown this shrub both pruned and unpruned, and I am satisfied that close pruning is best for it, which operation should be attended to about the end of March. Here we have some well-developed specimens, as it has been grown for a number of years; indeed my employer was one of the first to introduce it to cultivation in this neighbourhood.

Kniphofia (*Tritoma*) *Uvaria* is too scantily represented here, nevertheless the few clumps growing in one of the borders have rendered assistance by their spikes of fiery scarlet blooms. Two forms of the double perennial Sunflower are to be met with in gardens about here, one with a very symmetrical-shaped flower, the other comparatively ugly. Both are forms of *Helianthus multiflorus*. The best of the two we grow here. It has been blooming a long time, and in my estimation it puts the now popular *H. rigidus* (*Harpalium*) quite in the background. The erratic habit of this latter plant mars its usefulness for a border of choice plants. To stroll from home 2 or 3 feet in one season is common to it. The flowers are of as bright a golden yellow as can be found among Composites, and are very beautiful, the blackish disk giving considerable relief to the conspicuous ray florets. For two seasons we have grown this in large pots buried in the border, with a view to keeping the stems in a more concentrated space. Last year we experienced good

results from such treatment, but this season it is not quite what it ought to be, and to turn them out of the pots this winter may not be unwise, and pot the strong eyes the following winter.

To revert to the shrubs again. With the exception of the Hydrangeas, various forms of Azalea and Mezereon, deciduous shrubs are absent from the shrubberies proper. Care has been taken in arranging the various kinds of shrubs. For instance, the planting of two deciduous sorts side by side has been avoided. Also on account of the somewhat limited extent of the shrubberies forest trees are absent, and the evergreens employed are such as have been considered most suitable for the purpose. Hollies, both variegated and plain-leaved, are well represented. The same may be said of the Golden Yew (*Taxus baccata elegantissima*); but the most noteworthy feature in the shape of a shrub is *Retinospora plumosa aurea*. This presents itself in its best form, and some striking examples are amongst the number. The type also is made good use of as a relief to the golden form. Rhododendrons are represented by all the best sorts, and the varieties judiciously distributed. The old *R. ponticum* is entirely absent. I can assign several reasons why the ordinary forest trees are absent. In the first place, they grow too large and also too rapidly, their naked appearance in winter is unsightly; in summer their spreading branches shade everything growing near them, and their roots ramify to such an extent as to aid materially in exhausting the soil, which would afford to the innumerable herbaceous plants and bulbs a most pitiable existence. Moreover, if we want to see forest trees, we have only to turn to our little sloping wood, which in the spring is covered with the Bluebell and Campion, and other beautiful wild flowers natural to the place.—T. ENTWISTLE.

THE GREENHOUSE AND ITS INMATES.

(Continued from page 183.)

RHODODENDRONS.

OF late years Rhododendrons have become fashionable for greenhouse and conservatory decoration, and grand plants they make in houses suited to their requirements. Many of our very finest species require greenhouse treatment, but most need plenty of space, and to be planted out in prepared borders. When they are grown in pots they are seldom in the robust health which is necessary to produce a pleasing effect. We have often seen large plants in fine health. Greenhouse Rhododendrons are not quite suitable for beginners, but we advise all amateurs to try and flower a few Rhododendrons of the hardy varieties yearly. Grow the plants outside, and only flower them inside. For this purpose a bed of sandy peat should be made for planting them in. This done, duplicate plants (to flower every alternate year) should be obtained in spring of the following varieties:—*R. Nobleanum* (rose), *Nobleanum album* (white), *caucasicum* (yellowish), *ciliatum* (pinkish white), *præcox* (lilac), *præcox rubrum* (red), and *multiflorum album* (pure white). These will all flower by January or February if treated as described below.

If a few are wanted for March and April the following should be grown:—*Altaclerense* (crimson), *Flambeau* (crimson), *John Waterer* (scarlet), *Lord Clyde* (crimson), *Mrs. John Clutton* (white), *Mrs. John Waterer* (pink), and *The Queen* (white). These should be planted so wide apart that the sun and air may play freely amongst them. Should a dry summer ensue watering and mulching may be necessary. By the end of October one of each variety should be placed into pots large enough to hold all the roots without crushing. Sandy peat should be used to fill in any necessary interstices. Watering should then be cautiously, yet efficiently, done, and the plants stood in a cold frame, which should be kept rather close for a week or two. By Christmas they should be transferred to the greenhouse, where they will soon reward the cultivator with their charming flowers. Of course care must be taken that plants having flower buds are lifted. After flowering is past the plants must be taken care of, and placed out again by the end of May, there to remain for two years to recruit themselves, when they will be again fit for lifting and potting. Next October the others should be lifted and treated in the same way.

SOLANUM CAPSICASTRUM.

This plant is grown for the sake of the profusion of bright scarlet berries with which it is clothed during the autumn and winter months. It is when well furnished most attractive, and it is, moreover, very easily grown. It may be raised from cuttings in spring, but it is better to raise the plants from seeds. Any light soil suits them, and the seed should be sown in the greenhouse, or, better still, in a pot placed on a hotbed. As soon as the plants have four leaves they should be pricked out 3 inches apart in boxes and kept growing. Pinching should be attended to in order to produce bushy specimens. When they become crowded in the boxes it will be time for planting them out. In the sunny south they will do very well outside, but in cold northern localities they will require to be under glass. The plants should be placed not nearer than 20 inches apart, and if they are in frames ventilating will require to be attended to. (When the climate does not suit them outside it is better to try one or two than to bother with them.) It will be necessary to syringe them occasionally with soft soap water or tobacco

water once a week to prevent insects injuring them. They will need to be lifted carefully and potted by October or sooner if frost is expected. After they are lifted they should be placed in a cold frame, and kept close and shaded from strong sunshine for a few days until they have fresh roots. They may be afterwards removed to the greenhouse. They make good table plants, the berries appearing to advantage by artificial light among the dark green foliage.

STATICE.

When well grown *Statice* are very showy plants. An ordinary greenhouse is warm enough in summer, but scarcely so in winter, unless the warmest corner is given to them. Good loam, leaf soil, or decayed manure, and a good dash of sharp sand or pounded charcoal, will suit them as regards soil. Syringing with soapy water to keep down green fly should be attended to. Care should be taken not to allow these plants to flower excessively. A good growth should be made in spring before any flower spikes are allowed to form. *Statice profusa* is the most generally useful variety, but *S. Holfordii* makes a finer exhibition specimen.

TACSONIA VAN-VOLXEMI.

There are several *Tacsonias*, all very good greenhouse climbers, very much resembling *Passifloras*, and requiring the same treatment. *T. Van-Volxemi* is the best, and is a most lovely climbing plant. It is a strong grower and requires plenty of room. No better plant is grown for clothing rafters or large spaces of back and other walls in a conservatory. It may be grown in a pot, but is much better planted out.

TEA ROSES IN POTS.

No matter how little accommodation one may have, room should always be afforded for one or two Tea Roses in pots for the sake of having a bloom or two in the late winter and early spring months. Or for covering a rafter or back wall what could be more suitable than a Tea Rose? The Rose *par excellence* for such a situation is *Maréchal Niel*. To do it justice it should be planted out in a prepared border either outside or inside the house. Proper drainage ought to be provided, for soil soured by stagnant water does not suit Tea Roses. The young shoots which spring from near the base and grow vigorously should be laid in at full length. The year following these will bear fine blooms in profusion. In pruning, all old twiggy wood should be cut out and the young clean shoots retained, for it is always from these shoots that the finest blooms come, although smaller shoots from older wood will bloom freely if it is properly ripened.

Roses require to be potted in good loam, with a little manure and bonemeal. When the soil is well filled with roots liquid manure is of great benefit, and top-dressings of rich manure ought always to be given. The plants should be kept cool through the winter to give them a rest, which is what all plants require. While resting they should be pruned. This, generally speaking, consists in cutting out useless spray and shortening back the good shoots to plump well-developed buds. The beginner should not introduce his plants to the house before the days begin to lengthen visibly, say in February. It is very well for gardeners having skill and proper appliances to force Roses all winter, but the amateur who has not a forcing house to forward his plants in and other structures to nurse them in afterwards should not attempt it unless he is prepared to buy fresh plants for another year, for Roses will not submit to it and remain in health; but Roses will do well for years if only forwarded a month or two each spring. Ordinary greenhouse heat will suit them at the period named. Green fly will be almost sure to attack them, but soapy water applied with the syringe will keep it in check. Should mildew appear, dusting the affected parts with flowers of sulphur is efficacious.

After the plants have flowered—say by May—they should be removed to a sheltered spot out of doors and plunged in ashes. If the pots are well filled with roots at this stage plenty of weak liquid manure should be given them, and the surface of the soil top-dressed with rich manure. Weakly shoots should be removed and strong wood encouraged. The plants may be shifted during summer if they are at all likely to become root-bound. A showery time should be chosen for this operation, so that no check may be suffered by the plants. All flower buds should be removed as fast as they appear. Sometimes the plants show a number of buds late in autumn, and the temptation is then great to remove them to the greenhouse where the buds may expand. If late flowers are more valued than early ones this may be done. In October the plants should be rested by being kept moderately dry and cool but safe from frost, and started gently in February again, after having been pruned.

TROPÆOLUMS.

Tuberous *Tropæolums* are beautiful easily managed plants. They should be purchased in the autumn when at rest. Good drainage must be given and comparatively large pots used, for "shifting-on" is too risky a process in the case of these plants for an amateur to attempt. Fibry loam, leaf soil, and a good sprinkling of charred refuse and sharp sand will suit them well. Potting should be firmly done, and the bulbs covered 2½ inches. Watering must be carefully attended to, just as much being given as will keep the soil moist and no more until growth commences, when it may be gradually increased. The very slender shoots should have a neat trellis to run on, and care should be taken to distribute the growths evenly, as they are apt to form a tangled mass. After the foliage decays water should be gradually withheld, and finally stopped altogether while the plants are resting. When resting they should be placed outside or in a cool shed. The soil must, however, be kept dry. *T. speciosum* and *T. Jarratii* are the best kinds.

VALLOTA PURPUREA.

This plant is indispensable to the amateur and gardener alike. Although an Amaryllis it is evergreen, and must be treated as such. It flowers in August or September. After the flowers have faded it should be freshly potted and kept growing slowly, with a moderate allowance of water all winter. By May it should be placed in a cold frame (or in warm localities outside) for the summer months, and duly attended with water. When the flower spikes show it should again be removed inside.

TULIPS IN POTS.

Tulips in pots require treatment almost similar in every way to Hyacinths, so we need not repeat our instructions. Six bulbs may be placed in a 6-inch pot, and a dozen in a pan 9 inches wide. They may be had very early in bloom. It is only the early Dutch kinds which are grown for greenhouse or window decoration. The following are all good and cheap and fit for any ordinary purposes. *Singles*: Due Van Thol—some half-dozen varieties (these are the earliest)—Joost Van Vondel, Proserpine, Keysers Kroon, Tournesol (two vars.), Queen Victoria, Vermillon Brilliant. *Doubles*: Due Van Thol, Tournesol, Le Candeur, Hereules, and Mariage de ma Fille.—A. H.

ZAUSCHNERIA CALIFORNICA.

DURING the present season this pretty perennial has been very notable on my rockery. It has been flowering all through the summer,

Fig. 57.—Zauschneria californica.

and is even now attractive. It is easily grown provided it is not planted in too damp a situation, and a moderately dry place can be readily found for it upon any rockery. It can be raised from cuttings or seeds, the plants obtained in the latter way flowering in autumn if raised in May.

The first plants were raised from seeds collected by Mr. Hartweg in fields about Santa Cruz in California, and received in England, May 11th, 1847, and plants were raised in the Horticultural Society's Garden. It forms a bushy perennial, about 3 feet high, clothed with ovate, sessile, toothed leaves, resembling those of a Gaura. Every branch emits from the axils of all the upper leaves one horizontal bright scarlet flower, about 1½ inch long. Its general appearance is

not unlike that of a Fuchsia, but the calyx tube has four stout ribs. The petals, which are inversely heart-shaped, spread flat; the eight stamens, with red anthers and a red four-lobed stigma, project beyond the flower.

There is a plant which I take to be a variety of this species very much smaller in growth and bearing smaller flowers, more tubular in form and deeper in colour. When I first examined the flowers I thought they were only pistillate, as the stamens appeared to be undeveloped, but now the stamens have advanced and produced pollen. It is therefore one of those numerous plants in which the pistil is mature before the stamens.—R. B. C.

KITCHEN GARDEN.

Seasonable Work.—A weedy kitchen garden looks bad at all times, and it is never the most profitable. Keeping gardens clean in summer is commendable, as the young crops thrive under such attention; but cleanliness is just as beneficial now and throughout the winter as at any other season, and we would urge everyone to see to this matter. The hoeing season will soon be over, as the ground becomes wet and unsuitable for this operation, but if thoroughly cleaned now it will remain in this desirable condition for some months to come. All old vegetable roots and stumps should be cleared from the ground. Remove decayed Peas, and save and store the freshest of the stakes to be used again next year. Seed of anything now maturing should be gathered before being blown out of the pods by strong winds or spoiled by drenching rains. Superfluous seeding plants should all be thrown away. It is better to have the quarters clear than occupied with useless stuff for which there will never be any demand.

Roots.—Late Potatoes, Carrots, and Beetroot should be lifted and stored for the winter without delay. It is an advantage of the utmost importance to have all roots placed under cover in a dry condition. We are busy storing everything we can for winter use, and when the bad weather comes, as more than likely it will do shortly, it will find us quite independent.

Cauliflowers.—Many of these are now turning in, and as a few degrees of frost may occur any night, care should be taken that the heads are not spoiled by this. The purest and finest flavoured Cauliflower heads are always had when a few of the outer leaves are bent over and broken to cover the heads from the time they are first visible, and the protection these afford prevents a slight frost from doing them any harm. Some cultivators are in the habit of allowing their Cauliflower heads to become from 1 foot to 2 feet in diameter before cutting, but this practice we cannot recommend. The heads should be cut when they are close, firm, white, and in the finest condition for the table. When the supply exceeds the demand the heads may be preserved for some weeks if they are cut with 6 inches or so of stem attached, the bulk of the leaves cut off, and the stems inserted a few inches deep in moist leaf soil or sand in a dark shed or cellar.

Winter Spinach.—Most of this is growing freely now, and as the plants are liable to become crowded, therefore thinning them out must be well attended to if large succulent leaves are desired. At the first thinning the plants should be left about 6 inches apart, and then allow all to remain until they meet again, when every other plant may be drawn out for use, and those remaining will furnish many gatherings throughout the winter and well into spring.

Vegetable Marrows.—These have been unusually fine and prolific this season, and plenty of growth and blooms are still being formed, but little or few fruits will set on those plants bearing many old Marrows. It is a common practice to allow the early fruits when not wanted for the kitchen to hang on until they become yellow and ripe, and they often remain long after this; but where late fruits are desired no fruit must be permitted to become large, and many of the superfluous shoots should be thinned out. Indeed, to grow Marrows properly they should be treated like Cucumbers in stopping and cutting off fruits and shoots. Marrows are much valued by many during the winter, and they are very easily preserved, as if cut just as they begin to grow yellow, and hung in a net in a dry room, they will remain in good condition for many months.

Parsley.—All rank-growing leaves which have assumed a yellow hue should be removed, and only the young green leaves which are chiefly confined to the centre should be allowed to remain to grow for a winter supply. In districts where it is necessary to protect it a number of the best young roots should be lifted now and planted in a cool frame where they will soon begin growing, and they will be found most useful during the winter. It is an advantage to lift the plants with a ball of earth attached to the roots, and they succeed best in a heavy soil.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Early House*.—*Pruning, Cleansing, and Tying-in*.—The trees in the early house that had the fruit ripe in May are now devoid of foliage, and should be pruned. If any shoots

have escaped notice during the season of growth that are now unnecessary, they should be cut out, and beyond cutting back any shoots that have ripened to the extremities to sound well-ripened wood, very little use will be found for the knife. The branches in a well-trained Peach tree should be 12 to 18 inches apart, and the branches upon those not more closely disposed. This will allow of the foliage and fruit having the full benefit of light and air. The trees being loosened from the trellis the woodwork of the house should be well brushed with soap and water, and the trees carefully washed with the same, being careful not to disturb the buds, and when they become dry dressed with some approved insecticide, applied with a painter's brush. The woodwork and trellis should be painted if needed, and the walls limewashed. The border must have the loose surface soil removed, and fresh rich material supplied if it has not been already done in lifting the trees. The lights may remain off the house until wanted for closing the house, having them repaired and painted so as to be in readiness when required; but if they have been replaced to ward off heavy rains the ventilators should remain open constantly, and if the house has fixed roof lights care must be taken to prevent the inside border from becoming dry, or it is likely the trees will cast their buds when they ought to swell for expanding the blossoms.

Root-pruning and Top-dressing.—This should be proceeded with in late houses as soon as the leaves give indications of maturity, and be brought to a close as soon as possible, as operations of this kind are best performed whilst a majority of the leaves are on the trees. Where young trees or those of some years' training have to be taken in from open walls ripening the wood may be facilitated by digging a trench a few feet from the stem and leaving it open.

VINES.—Late Houses.—Where late-keeping Grapes were encouraged in spring with fire heat and through the early summer, and artificial heat when ripening, the fruit will now be well finished, and the foliage showing the beautiful tints of colour peculiar to most of the late kinds, especially the thick-skinned section, which are a good indication of the thorough maturation of the wood. Every lateral should now be taken off down to the main buds. Ventilation as the days decrease in length and increase in moisture will require more careful attention. With the Grapes well in advance free ventilation, with slight fire heat by day is the best course to pursue, turning off the heat when the front ventilators are closed for the day. Should the inside borders become dry before the Grapes have coloured well, a good watering with weak tepid liquid manure should be given in the morning; and as the greatest danger to be guarded against is the condensation of moisture on the berries, it should be overcome by covering the border with dry clean litter or fern, with liberal ventilation at the apex, and a little extra fire heat. This will often cause the Grapes to colour up to the footstalks in a short time.

Houses of Ripe Hamburgs.—These will now require careful management. Keep the house dry and cool, ventilating freely when the external air is dry, and employing fire heat only to expel damp. Examine the Grapes occasionally for decayed berries, which must be promptly removed. Avoid anything likely to raise dust and causing it to settle on the berries, as sweeping and raking borders.

Covering Outside Borders.—All outside borders, especially those of early and late houses, should be covered with a good thickness of dry bracken, and place all available lights or shutters over it for throwing off the wet.

Early Houses.—The Vines in those that are to be started in November or December must be pruned at once, the Vines cleansed as well as every part of the house—woodwork, glass, walls, &c., having everything clean, sweet, and in thorough working order for a new start when the time arrives.

Early Vines in Pots.—Those intended for the earliest crop of Grapes should be placed in their fruiting quarters. Start, if possible, with a gentle bottom heat from fermenting materials, as three parts Oak or Beech leaves with a fourth part stable litter well worked and sweetened before placing in the bed for the Vine, which last should have the pots on pedestals of open brickwork to prevent their being displaced by the sinking of the fermenting materials. The materials should be brought up about the pots, but not to cause the temperature to exceed 70° to 75° about the pots. The ammonia vapour will assist the Vines in breaking; and as the roots will pass from the pots to the bed the berries will swell to a much better size than when the roots are confined to the pots. Sling the rods in a horizontal position over the fermenting materials to insure a good break. Start with a minimum temperature of 55° by artificial means, and 60° to 65° by day from sun heat, and maintain at the last-named by artificial means in the daytime as the buds expand and are expanding into growth.

Young Vines.—Those that were planted in spring or in early summer from eyes struck in spring will yet be growing freely, but means must be adopted to get them thoroughly ripened without delay by keeping the house quite dry and moderately warm by day with free ventilation, keeping the laterals constantly pinched, except it be a few at the extremities, so as not to give too severe a check to the root-action, and a low night temperature with free ventilation will soon make all right.

PLANT HOUSES.

Heliotropes.—Cold nights injure these plants very much, and even the slightest frost will destroy them. The plants we purposely prepared for flowering this autumn are now in frames. This position is becoming too cold for them, and they will be placed where a night temperature of

50° can be maintained. The plants required latest will occupy the coolest end of the house. Unfortunately these flowers do not last long after they are cut and placed in warm rooms, yet they are in constant demand, and appreciated highly for their fragrance. A batch of cuttings may now be rooted and grown gently through the winter for early flowering in spring, when they will be found most useful.

Double Petunias.—Some of the dwarf varieties grown in 5 and 6-inch pots are admirable for the decoration of the conservatory during spring and summer. If cuttings have not been rooted they should be inserted without delay, but for an early display they should now be established in thumb pots, and ready for others 2 inches larger. When in this condition the plants should be grown under cool conditions, but if only just rooted they should be encouraged in an intermediate temperature for a time. They require frequent stopping to insure dwarf sturdy specimens. The winter treatment that suits these plants is so similar to that recommended for French and Fancy Pelargoniums, that those who follow the advice given will be successful. The only difference in cultivation is, the soil should be a little lighter for Petunias than for Pelargoniums. Cuttings should be rooted from time to time for the purpose of forming a succession. Plants rooted about Christmas will follow those required for early flowering, and can be grown rapidly after the new year.

Celosias.—If these plants are in a backward state they should be pushed forward without delay in a little heat. Air must be given when favourable, and the plants arranged as close to the glass as possible, for they are very liable to become tall and weak if kept close and warm. A little heat applied judiciously is very beneficial in their last stages of development, as their plumes are brighter in colour than when developed under cool conditions. These plants require a good supply of water, but it must not be carelessly given, as their roots soon suffer, and the plants in consequence do not last half the usual time. These plants are amongst the most useful that can be grown for winter decoration, for their beautiful heads of gold and crimson will last in good condition from November until February in a temperature of 45° to 50°, provided damp can be kept from them, which is their greatest enemy in winter.

Dielytra spectabilis.—Where this beautiful and useful plant is appreciated for forcing, and grown at home for that purpose, the foliage has died down and the roots may be lifted. When lifting the dormant plants should be sorted, and the smallest replanted for next season's forcing; small pieces planted now in good soil make grand plants for forcing in one year. Roots that can be placed in 5 and 6-inch pots are large enough for the majority of decorative purposes. It is not necessary to lift them for potting with any soil attached; on the contrary, it may be all shaken from them. After potting place them in a cold frame until they are wanted for forcing.

Pyrethrums.—These are very beautiful when forced into flower in spring, and are very useful both for decoration and cutting. Where plants are not established in pots lift at once from the open borders while the foliage is green and fresh, and with soil adhering to the roots. After potting a thorough watering is necessary and a cold frame in which to place the plants, which, if shaded from strong sun and kept close for a fortnight, will have commenced rooting, and can then be subjected to cool treatment until their foliage dies. Do not allow them while at rest to become dry, but keep the soil moderately moist.

THE FLOWER GARDEN AND PLEASURE GROUND.

Preparing for the Winter.—Frosts will soon occur, and any tender bedding plants required for next season's stock should at once be placed under glass. All choice varieties of Pelargoniums, or any of which there may be an insufficiency of cuttings struck, ought to be lifted and potted. No ball of earth can be procured with them, nor is required. Many of the old leaves should be trimmed off, or otherwise they will damp off and perhaps injure the growths; the roots shortened, and the plants potted firmly in as small pots as can conveniently be employed. The more robust sorts may be placed several in 6-inch or 8-inch pots, or in boxes. The greenhouse and vinery shelves are the best places in which to winter the more delicate varieties. If not damaged by frosts more cuttings may yet be inserted, and any that have damped off be replaced. The variegated sorts are best wintered thinly in small pots, being very liable to damp off when placed in boxes. Keep all Pelargoniums on the dry side both before and after they are struck, as the less growth they make the better; and should any of the boxes especially become saturated with moisture large numbers of cuttings will inevitably be lost. It is too late to strike Verbena cuttings, and if there is not sufficient already rooted, a few old plants of each favourite variety should be lifted, taking care to preserve a small ball of earth about the roots. Give them good soil and pots rather larger than the balls, and winter in well-ventilated frames. If a good named variety or varieties of dwarf Lobelias be grown, such as *pumila magnifica*, Brighton, Blue Beard, and the white Princess of Wales, and which are preferable to seedlings, lift a number of old plants, trim off the bloom, and pack them clear of each other in well-drained boxes of good soil. These, if wintered in a greenhouse, pit, or frame, will in the spring divide into a great number of rooted pieces.

The best Ageratums for bedding are Cannell's Dwarf and Swanley Blue, but of these it is very difficult to procure cuttings. A quantity of each or any other preferred sort should be potted and wintered similarly to the Lobelias. Old plants of Heliotropes and Lantanas as a rule lift badly, but should they be required the attempt ought to be made. Preserve a ball of earth if possible, and when potted place them in a pit or frame, keep rather close, and water and shade carefully. During the

winter they will require rather more heat than Verbenas. Cuttings of *Gazania splendens* if dibbled in boxes of sandy soil root readily, and may be wintered in a cold frame. If a considerable number of plants are required it is best to prick the cuttings out on a prepared bed and to cover with a shallow frame, where they may remain till the spring. *Petunias* and *Phlox Drummondii* are much more effective when raised by cuttings; great care must be taken when lifting the old plants. *Abutilons* lift readily, and both the flowering and fine-foliage varieties may be found useful for conservatory decoration; a few strong untopped plants will give a great number of cuttings in the spring. *Cineraria maritima* also lift well, and are more dwarf and even when raised from cuttings in the spring. *Begonias ascotensis* and *weltoniensis*, and the tuberous-rooted varieties will also bear lifting, and providing a moderate-size ball of earth be preserved about the roots will flower for some time longer in a greenhouse. *Salvias* may be similarly treated, and are very bright during the late autumn and early winter months. *Ageratums*, especially the tall growing variety, lifted from the borders are very useful for the same purpose.

Iresines, *Coleuses*, *Alternantheras*, *Mesembryanthemums*, and *Sempervivums* of the arboreum type ought to have been long since struck. Failing this, old uninjured plants may yet be lifted. Small balls of earth, especially if heavy, should be retained, and only comparatively small pots be given them. The back shelves of heated houses are the best positions for all but the *Sempervivums*, the latter doing best in an intermediate temperature. *Kleinia repens* may be lifted, divided, and dibbled in rather thickly in well-drained boxes of light sandy soil. *Echeveria metallica*, *Pachyphitons*, *Aloes*, and other tender succulents ought all to be housed or otherwise protected from frosts. They do not require large pots nor much heat, and should be watered but little. The lower leaves of the flower stems on *Echeveria metallica*, if taken off and either dibbled in pans of light sandy soil or laid on a moist shelf in heat, will eventually form plants.

THE BEE-KEEPER.

HIVE-CONSTRUCTION, HONEY-PRODUCING, AND PRACTICAL MANAGEMENT OF BEES.—No. 4.

THE following are the particulars of the hive referred to last week:—

Internal Dimensions of Stock Hive.—This is 2 feet 5½ inches long, 14½ inches from back to front, and 6 inches deep. It gives accommodation for eighteen frames and two close-fitting dividers 1 inch thick, besides allowing an inch of "play" for the frames. The advantages of this inch are many and obvious. We rarely have occasion to lift out the divider, because lateral space is obtained by pulling it back close to the side of the hive. If we want to insert a broad frame with sections to get them started, we have only to remove one divider; it also does away with all the difficulties which arise when frames are made to fit tight, such as shrinking and swelling in the wood of the top bars, slight irregularities in the combs, the insertion of queen cages, &c. It also secures a very large platform above the brood nest capable of holding two crates or forty-two 1-lb. sections. We do not advise this use to be made of it, unless in exceptional cases; but it gives the great advantage of allowing nine frames, or one-half of the hive, to be manipulated while a crate of sections is worked on the other half.

It frequently happens that a spell of bad honey weather will follow after bees have got well at work in sections, and in such weather at such a time breeding goes on very fast. To lift off crates of sections every time we want to open up a hive is out of the question; but with nine frames of comb come-at-able we keep queens busy ovipositing, can help weak stocks with a few frames of brood, substituting comb foundation for those removed, and above all keeping up the "comb-building impulse," which gives to bees the appetite for work well known to all practical men. Another advantage is that queens are less liable to be lost while frames are being unskillfully handled. Mishaps of this kind are more frequent than is generally supposed; but if a queen is unusually nervous and inclined to run wildly about, as some undoubtedly are when hives are opened, they will generally take refuge at the end of the hive furthest from the operator, and thus be safe out of harm's way while he is examining combs and perhaps shaking the bees from them.

It would take too long to enumerate all the advantages which this large working space over the tops of the frames gives to the apiarian, such as slinging, doubling, &c.; but they will readily suggest themselves to a practical man, and we shall, in explaining the practical working of the hive, have to allude to it again.

Size of Frames.—Until the adoption of the Association standard frame we used the ordinary Carr-Stewarton size for our hive. Since the introduction and general adoption of the first-named frame we

have modified the size a little, and it is now 14 inches by 5½ inch, outside measure, with a top bar 17 inches long—in other words, an Association standard frame cut down 3 inches in depth.

Anyone who has studied the subject, and has worked with large frames, will have noticed that an inch or two of the lower side of the combs are very frequently unused by bees either for brood or honey; at the same time, 2 or 3 inches of the upper side are almost invariably filled with honey. Now, our contention is that the size of frame which will minimise these disadvantages (for disadvantages no one will deny that they are) as much as possible is the one which should commend itself to all.

The body of the hive should be the "brood-nest" in reality as well as in name, and should in the honey season only contain as much food as will supply the daily wants of the bees. All surplus is best stored apart and in such a way that the apiarian can remove it in saleable form. A shallow frame is generally filled with brood down to the bottom bar, and has but little honey stored at the top. We have had hundreds of frames filled with brood from top to bottom, and when giving a crate of sections we remove any outer combs which contain honey only, along with the divider, to the opposite end of the hive, so that the combs under the sections are full of brood. The combs removed are placed outside the dividers, thus crowding up the bees and rendering them more likely to enter the supers. In addition to this, the fact that there are few available cells for storing honey in that part of the hive compels the honey-gatherers, for some time at least, to store all they get in the sections above.

Shallow frames are better than deep ones for the following special reasons:—1, For fixing full sheets of comb foundation. With ordinary care anyone can fix a sheet of foundation 4½ inches deep without fear of its breaking down or sagging. 2, For transferring combs from skeps. Here there is an immense advantage. When cutting the combs to fit frames, pieces 5 inches deep are what we want to fit tightly into the frames; and this allows us to cut away the bottom or worst edge of the comb and just so much of the honey at the top as is best away, while laths under the combs are not needed. *Propos* of transferring, a well-known expert in our hearing was dilating on the evil effects of transferring which had come under his notice. He stated his opinion that foul brood was frequently caused by the bees clustering to the tops of transferred combs, while the brood in the lower parts chilled and perished—to become the forerunner of disease. With a comb about 5 inches deep to cover we need scarcely say there is no fear of the mischief occurring.

Spreading Brood.—This important feature in modern bee-keeping is one of the best that has been made known for many years, yet it has not come into general use. The reason of this is obvious, and is contained in the words of a rather extensive bee-keeper whom we met at a show last year. "After reading Mr. Cowan's book," he said, "I spread my brood once; but never again if I know it. Why, by dividing the brood with a sheet of foundation one part of it was entirely deserted by the bees, and all perished!" We learned afterwards that he used very large frames and had not taken the precautions necessary. Apart from this carelessness there is great risk attending the operation if large frames are used, and amateurs cannot be supposed to tell, as practical apiarians can, when it may be done with safety. The way to reduce the risk to a minimum is to use a shallow frame. If the bees only cover six of these we venture to say no harm will result from inserting a sheet of foundation in the centre at any time when breeding is progressing fairly.—W. B. C., *Higher Bebington, Cheshire.*

BEES SWARMING IN SEPTEMBER.

WOULD any of your able correspondents be so good as to inform me through the medium of the Journal whether it is unusual for bees to swarm so late as the second and last week in September? As we keep bees I am anxious to learn anything of interest concerning them. One morning during the second week in September one of the garden men informed me that there was a swarm of bees on the Elms in the park. I was surprised to hear it, and had the curiosity to go and see them. As our bees were put to rights for the winter I did not trouble to take this swarm, as I did not consider the bees sufficiently numerous to stock a hive of themselves. This evening (September 27th) I had my attention again drawn to a swarm, but as far distant from our own bees as it could be within the garden. This time I determined to give the swarm a chance and have hived it. I should be obliged for any information on the subject, as I consider the honey season ended with the Lime trees here, and our hives got lighter after these had ceased flowering.—C. WARDEN, *Wilts.*

TRADE CATALOGUES RECEIVED.

George Rudd, Bradford, Yorkshire.—*Catalogue of Auriculas, Carnations, and Picotees.*

Nabonnand, Golfe-Juan-Vallauris, Alpes Maritimes.—*Catalogue of Roses and Miscellaneous Plants.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Plums (E. F. B.).—We are obliged by your reminder, and you will perceive the matter has been attended to.

Studies for Young Gardeners (A Foreman).—If you will send us your full postal address a letter will be sent to you on the subject of your communication.

Selling Fruit (A. B.).—We never answer such questions as you have submitted. You may possibly obtain the information by writing to Mr. Webber, Central Avenue, Covent Garden, London, W.C.

Narcissuses for a Graveyard (Mac).—All the stronger-growing varieties are suitable for the purpose, and these you will find enumerated in the principal dealers' catalogues at the lowest prices.

Vine Leaf Blotched (J. L.).—There is not much the matter with the Vine leaf. It is not unusual for the foliage to similarly change on the approach of autumn; still in all probability there has been a little scorching that might have been averted by a different system of ventilation. You do not say a word as to the general condition of the Vines—whether weak or strong, fruitful or the reverse, and it is impossible for anyone to judge of their state by one small leaf crushed into an envelope. Blotches in the leaves are sometimes the result of inferior glass in the roof.

Vine Roots Unhealthy (H. T. H.).—There is no evidence of the presence of the phylloxera on the portions of roots before us; but, as has been previously intimated in this Journal, portions of the fibrous roots should be sent, as it is on them that the insects congregate during the season of growth. Still, we do not think your Vines are attacked by this pest, and the fibreless state of the roots, with their partial decay, is quite sufficient to account for the condition of the Vines. They are much in the same state as the roots of some Vines of which Mr. Iggulden took charge two years ago, and which he changed and improved by the practice he has detailed in our present issue. You cannot do better than to treat your Vines similarly, and produce a mass of healthy surface roots; healthy and fruitful growth will then follow. You had better also note Mr. Iggulden's remarks on overcropping one of his vineries.

Heating Greenhouse (F. J.).—To heat a house of the kind you describe satisfactorily the boiler should be fixed behind the house, and sufficiently low to enable the pipes to be taken below the doorway, which, we presume, is at the end of the house. From beyond the doorway they may be raised a few inches above the floor, the top one for the flow, the lower for the return water, the two to run along the front and further end of the house, or as far as the door (if there be a door at that end also), and there connected by an elbow. By this arrangement 3-inch pipes would do; but if you can only arrange them along the front two rows of 4-inch pipes would be requisite, or three rows of 3-inch, a double flow and single return, and this would enable you to utilise your present piping.

Chrysanthemums (J. J.).—There is a rather small reflexed variety named Cloth of Gold, also a Pompon variety used to be grown under that name; but, so far as we are aware, there is no Cloth of Gold in the Japanese class. Julie Lagravère is not a Pompon, and is not properly eligible for staging in that class. We have occasionally seen small flowers of this variety in a stand of Pompons, but those who stage them run great risk of having their stand disqualified by the judges. Considering that there are so many varieties of Pompons it is not necessary and is unwise to associate with them at an exhibition any flowers of doubtful admissibility.

Grapes not Colouring (Lancaster).—Your Vines appear to have done as well as could be expected under the circumstances, seeing that you have had "good bunches and berries and no shanking as formerly." No more than this could be expected the first season after lifting, especially as you say you were unable to ripen the wood. With the wood matured this season and the increased root-action your Grapes will no doubt colour well next year if the Vines are not overcropped. We presume the soil in which they are growing is free and good; be careful that it does not become dry at any time, and should the laterals not be so strong as is desirable, nor the foliage so stout, an application of liquid manure given now might be of decided advantage. We have given liquid manure to Vines when they were quite at rest with the best results. Your Vines may, however, not need such assistance; of this you will be the best judge, knowing their condition and the composition of the border. We should lift the Alicantes immediately the crop is cut.

Midseason and Late Pears (Reader).—The following will probably answer your requirements:—Beurré Diel, Fondante de Charneu, Zéphirin Grégoire, Huyshe's Victoria, Glou Morceau, Beurré Sterckmans, Easter

Beurré, Josephine de Malines, and Bergamotte Esperen. These are not all large, but are good Pears, and will succeed as pyramids in your district. Assuming you have a bold central crown in your dwarf Hydrangeas you had better remove the side growths and reduce the supply of water. They should now be plunged in ashes in a cold frame, and no more water given than is necessary to keep the foliage fresh.

Warts on Vine Leaves (Abbot).—There is nothing whatever in the appearance of the leaves and wood you have sent us to indicate the presence of the phylloxera, and we feel sure your Vines are quite free from that pest. Your large deep and rich border has invited such vigorous growth as to distend, and in some instances to rupture the cellular tissue; but we do not apprehend that this will have any serious results, as there is plenty of foliage quite healthy or only slightly affected. Your object now must be to mature the wood by maintaining a warm dry atmosphere, with free ventilation; to this end fire heat will be economical, because effectual. Your border would have been better if it had been limited to 6 feet in width until this autumn, and it might probably with advantage have been firmer. It would then have been netted with fibrous roots, whereas now it contains a limited number of such; but the roots are of a luxuriant character, and supplying more sap than the leaves can properly elaborate and assimilate. If the border is light and loose make it firmer when it is dry, and only then, as to firm it when wet would be ruinous; and your Vines should be grown steadily—that is, not forced under a high temperature, while ventilation should be liberal night and day. It is just possible you have not always admitted air early enough in the morning. With care we think you will eventually have fine Grapes.

Vines Flagging (W. J.).—There is no appearance whatever of the attack of the phylloxera on the fibrous roots you have sent, and from the fact of your Vine having made a strong cane 20 feet long this year we do not suppose your Vines are attacked with the pest. Gros Colman though robust is a very tender-foliaged Vine, and unless special care is taken in watering, ventilating, and even lightly shading sometimes on the sudden return of bright sun after a week of dull weather, the leaves are apt to be scorched, turn brown at the edges, and fall prematurely. The Vine is also peculiarly liable to the attack of red spider. We suspect yours has been attacked by this insect, and the injury to the leaves and the premature defoliation of the Vine would necessarily affect the roots, and cause many of the fibres to decay. Do not keep the border too dry, neither must it be saturated now the foliage is falling.

Vine Growths Crooked (J. T., Bristol).—The rod being produced by an old Vine that was cut down some time ago there is no telling where the roots are; but this we know, they are not foraging in the good soil to which you allude, and they are not healthy. We should make no attempt to renovate such a Vine, as in doing so you would necessarily injure the roots of the others that are thriving satisfactorily. We should either dig up the old Vine, take out a few bushels of soil, add fresh, and plant a young Vine, or should train an extra cane from an existing Vine that is in good health. This latter plan would probably be the best, as a Vine will support two or more rods as well as one, and the space would be more quickly covered and a crop of fruit produced than by planting a young Vine. It is no use doing this in any case without adding fresh soil, as a young Vine rarely thrives in an old border.

Leather Parings (J. M. R.).—They are very good for furnishing nitrogen to plants, but nothing more. Of this nitrogen clean samples contain as much as does nitrate of soda; but it does not follow that they are therefore of equal value, as in the one the nitrogen is at once available but in the other it is not. Still, good samples are worth £2 or £3 per ton to manufacturers of manure, and if you could find a market for them the money they might fetch would be better spent by you in the purchase either of manufactured manure or ordinary dung, for by themselves they are not true manure. But if a tenth were added to ordinary manure, and overheating provided against by keeping the heap fairly moist, the value of the manure would be doubled. Allowing them to heat by themselves is almost certain to cause loss of nitrogen, as the sense of smelling would inform anyone; but in the bulky manure the ammonia would be absorbed and preserved. The fact that the farmers in your district will not have the material you mention for the carrying only proves the necessity there is for farmers becoming acquainted with agricultural chemistry. We could name a district where they will not look at sewage, but cheerfully pay for and convey long distances broken bottles, earthenware, tin cans, cinders, and a little town's dust! Tanned refuse, such as bark, is of little use except for mixing with heavy soil to render it lighter. The process of tanning adds no manurial value to anything. Fine leather shavings unmixed with other matter are used for fruit trees in the London market gardens, also for Filberts and Hops.

Seedling Grape (Clifton).—Your Grape very closely resembles the Black Corinth, the dried fruit of which is sold as the Currants of commerce. Though the berries are sweet and the colour good, the variety is not worth keeping except as a curiosity. You cannot have a better Black Grape than the Black Hamburgh for such a house as yours, and it is questionable if you can do better than train up an additional rod or rods from your existing Vine of that variety, and so occupy all available space. You would obtain quite as good fruit from three or four rods as from a solitary cane. If you particularly desire another black variety try the Madresfield Court, or if you prefer a white one plant Foster's Seedling; but the Black Hamburgh is the most useful of all for the position indicated in your letter.

Seedling Alpine Auriculas (E. Clapham).—If your seedlings are not overcrowded now they will not become so during the winter, as in all probability some of the leaves will decay, and these should be carefully removed. Place the box in a frame, but only place on the lights during wet or inclement weather, and at all times admit air in the absence of frost. Only give sufficient water to keep the foliage fresh, and do not apply it over the leaves. The great enemies to guard against in winter are damp and slugs. Immediately growth commences in the spring pot the plants, and eventually plant them out where they are intended to flower. In the event of a very severe winter in the north bank soil or ashes round the sides of the box, and cover the plants with perfectly dry leaves and they will be quite safe.

Tuberose Culture (*T. Mossman*).—The following simple method has been described by a very successful cultivator. Procure sound well-ripened bulbs as soon as you see them advertised. If in quantity divide them into two or three batches for succession. Pot the first at once, either three bulbs in a 32-sized pot, or one good bulb in a 48-pot. In either case use a rich loamy soil, or if the loam is poor add one-third of well-decayed manure that will pass through a quarter-inch sieve, and a little sand. Pot rather firmly, afterwards place them in a cold frame, or under the stage of a greenhouse where there is little or no drip from plants above, and cover them with cocoa-nut fibre refuse, fine coal ashes, or some other material that will run between the pots. This will keep the soil sufficiently moist for rooting to commence, which will begin in a fortnight. As they advance take them out, and for a few days place them in a position where they at first have but a moderate light, such as under the stage of a plant house. It will be seen that the young growth will gradually assume a natural colour, when the plants may have the full light and heat of an intermediate house. A stove heat is more than they need, and to have them in flower quickly a cool greenhouse is not sufficient. After making a little foliage the flower spikes begin to appear, and as they grow to from 2 to 4 feet in height and are very slender, a stake must be placed to each. Each spike if good will produce two dozen blooms in succession, pure white with a most delicious fragrance. When in bloom they are conspicuous if placed in the conservatory with the spike of flowers arising just above other plants, but they would be principally required for cutting. The perfume is strong, therefore for room or any part of house decoration too many must not be employed at one time. During growth the plants are subject to the attacks of green and black aphides, which infest the spikes of flowers. Liquid manure given twice a week will be found to benefit the plants, and by potting in succession they may be had in flower during the greatest part of the year. They are among the most useful for cutting for bouquets, wreaths, and buttonholes, as they are sweet-scented, pretty, and last a long time.

Temporary Structure for Chrysanthemums (*Lambridge*).—A temporary shelter for these plants can be readily constructed of wood and canvas, the dimensions being proportioned to the number of plants you have. Stout posts at the four corners, with connecting pieces at the top and back, form the essential framework, which should be preferably in the form of a lean-to house, and if it can be placed against a wall, the top sloping forward from it, it will be even less trouble. Ordinary rough deal will suffice if the object is to build the shelter as economically as possible, and the canvas may be hung round the sides and over the top at night and in wet weather, but during the day it can be removed from the front. Specially prepared waterproof canvas or calico can be obtained from some dealers, but the following is a simple mode of rendering such substances impervious to wet. Take pale linseed oil, three pints; sugar of lead, 1 oz.; white rosin, 4 ozs. Grind the sugar of lead with a little of the oil, then add the rest and the rosin. Stir the whole well together in a large iron pot over a gentle fire. Tack the calico loosely on the frame, and apply the mixture with a large brush.

Naming Fruit (*Jno R. Peill*).—It is impossible to name any particular day as you considerately suggest; send them at your convenience and they will be attended to as soon as possible. Only six varieties can be named at once, and if more are sent the surplus cannot be preserved.

Names of Fruits (*Reader*).—The Apple is Gloria Mundi, the Pear Marie Louise. (*E. F. Behrens*).—Sops in Wine. (*Rev. A. Fitch*).—Apple Trumpington. The plant is Lycium europæum. (*T. H. Sykes*).—1, Kerry Pippin; 2, Golden Winter Pearmain. (*N. C.*).—1, Longville's Kernel; 2, not known. (*Colville Browne*).—1, Marie Louise; 2, Red Doyenné; 3, Maréchal de Cour; 4, Beurré Bosc; 5, Vicar of Winkfield. (*Warrington*).—Burr Knot. (*E. J. Nicholson*).—1, Doyenné Blanc; 2, White Summer Calville; 3, Ord's; 4, Red Autumn Calville. (*David Smith*). The Pea is no doubt a sport from Laxton's Supreme, and is worth saving. The Apple is not of any merit. (*J. W.*).—Hollandbury. (*Dickson Brown & Tait*).—Warner's King. (*T. Buckerfield*).—2, Beurre d'Arenberg; 5, Chaumontel; 7, Nouveau Poiteau; 9, Glou Morceau; 11, Beurre Diel; 13, Marie Louise. (*C. Spider*).—1, Margil; 2, Golden Noble; 3, Franklin's Golden Pippin; 4, Cox's Orange Pippin; 5, Beurre Clairgeau; 6, Glou Morceau. (*Jas. Fletcher*).—2, Ribston Pippin; 3, Golden Winter Pearmain.

Names of Plants (*C. J. S.*).—1, Lythrum Salicaria; 2, Phygelius capensis; 3, Verbascum nigrum. (*J. W. M.*).—The plant was named Helianthus multiflorus plenus on page 263. (*J. C.*).—Chrysanthemum segetum.

COVENT GARDEN MARKET.—OCTOBER 3RD.

A SOMEWHAT brisker trade doing and prices better, good samples of Peaches being now in demand, as also English Pine Apples. Apple market heavy.

USE OF GREEN AND FODDER CROPS FOR VARIOUS PURPOSES.

(Continued from page 286.)

IN extending our remarks in connection with the use of Vetches it is not our intention to say much relating to their cultivation, because we have in this Journal written upon their cultivation in an article which appeared on the 12th of September, 1878. It is, however, necessary to refer to their value as fodder in their green state just as they come into bloom, as they furnish valuable food for sheep and lambs, but especially for the latter, in June and part of July. It is the custom in Dorset, Wilts, Hants, and various other counties for the lambs to run in advance of the ewes into a fresh fold daily, or, if there is no other change to Sainfoin or Clover, then a fresh fold is given twice a day, and it is in these folds that they get their trough food, such as cake, cracked beans, or peas. The Vetches are considered by practical men to furnish the most nutritive food grown on the arable land at the summer time, for although the winter Vetches will turn off for seeding in the first or second week of July, yet the succession of Vetches for folding is made continuous by the growth of the summer or "Goa" Vetches.

Although the growth of Vetches for sheep in the hill districts, but especially on chalk and limestone, are much approved, yet their strongest advocates are of opinion that they injure and seriously damage the preparation for Turnips, which are usually grown as a successional crop, as it is said to leave the land in a loose and hollow condition, especially of a dry season, when the young Turnip plants are sure to fall a prey to insects, such as wireworm and grub. On one occasion when we were present at a farmers' club meeting these objections were taken, although admitting the value of the crop otherwise by the introducer of the subject, and challenged the members to recommend a substitute, and we advised the growth of Trifolium with Mangolds cut and fed in troughs with some cake or other meal in admixture. The way to obtain the Mangolds for this system is either to pit them in the autumn on the field (where the Trifolium has just been sown) at convenient distances apart, or otherwise when the Mangold crop is removed to pit, and reserve in the field a certain portion of the crop, the remainder being removed for cattle feeding at the homestead. In this system the Trifolium is sown as fast as the Mangolds are pulled, which should be done by an early growth and early removal, thus giving the Trifolium a chance of being seeded in good time. It will be noticed that in either case whether Mangolds are thus used in connection with either Vetches or Trifoliums, that it affords an opportunity of improving the green fodder for the sheep. There is one objection, which will not occur with the lambs unless they are being fed for the butcher—viz., that many of them when near maturity as fat lambs frequently suffer from the stoppage of urine, and are lost in consequence of Mangold feeding. Still, when store sheep or breeding ewes are kept they do not feel any ill effects from this manner of feeding. Upon strong land seeded with winter Vetches as a preparation for Wheat they may be fed off just as they come into bloom with great benefit with any supplementary food which may be required in the troughs, after which the land may be sown with White Mustard, to be fed-off or ploughed-in as may be deemed advisable. In some cases, however, where there is any couch remaining, the land should lie fallow and receive autumn cultivation. Sometimes a late crop of Turnips is taken, but only on light and dry soils, as the Turnips could not be fed off with advantage on flat strong land. Vetches are, however, occasionally used as fodder for horses, and they are well adapted for the purpose, especially when the green pods are formed, for the teammen call them both green and corn food combined.

Vetches are not much approved of for ensilage, nor when used as hay, but if intended to be made into hay it is a good plan in stacking to introduce into the rick whilst building layers of sweet Oat straw, and the straw by the heating of the Vetches becomes impregnated with a pleasant aroma, and when cut into chaff together with the Vetch hay makes good dry fodder for farm horses, especially in the winter months. Buckwheat is frequently grown as food for sheep while it is young and just coming into bloom, and cattle also are fond of it, and young store cattle in the boxes are found to do well when it is used as green fodder. It seems of little importance how poor the land may be, for a good bulk of food may be raised on sandy land in particular, and is much valued if fed off by sheep. It is

frequently, however, considered desirable to plough under the haulm while green, and just about the period of blooming; for it is found that upon the thinnest sandy land it proves a valuable and lasting manure, as it adds to the staple of the land on decay. A kind of humus which not only enriches the soil for Barley-growing but enables even the most burning sands to withstand the effect of our hottest summers.

Buckwheat is neither adapted for ensilage nor hay, as it possesses too large a portion of woody fibre. It may, however, be sown as late as the middle of July for the purposes of green manuring. As an instance of sowing it to remain for seed, we remember seeing a valuable crop of seed produced upon a thin gravelly soil in a southern county in 1880, and a Wheat crop following produced six quarters and one bushel per acre of the Essex rough chaff variety, and a good average bulk of straw. The seed is well adapted for the feeding of any kind of poultry, and the crop is frequently grown by game-preservers for the enticing, feeding, and retaining on the estate where game is preserved, not only of pheasants, but partridges and grouse, affording as it also does excellent cover during the early part of the shooting season.

The Lupin is not so much used in the British Isles as it is on the Continent, especially in Germany, where it is grown and fed off by sheep in the green state at blooming time. There are two sorts or varieties commonly cultivated, one producing a yellow flower and the other a blue blossom, the latter being grown almost entirely, saved for seed and ploughed in; the former is grown principally for green fodder, but also for ploughing-in as manure for the production of cereals, like Barley and Oats especially, as it is seldom grown on our best soils and loamy land adapted for Wheat. Nevertheless, upon thin clay soils when well cultivated, and the haulm properly buried, to do this rolling is the first operation, and followed by the plough fitted with skim coulter, and drag chain with weight attached, a very large bulk of haulm very succulent, and yet containing much woody fibre, may be successfully buried; and when pressed at the same time the preparation for Wheat is first-rate, and will prove a lasting benefit to those poor elays containing but little mould or humus. We must not lose sight of the fact that the chief value of this crop lies in its thriving well on high and very poor sandy districts, usually producing Heather in the unentivated state, and where other forage plants of value can scarcely be grown, except Buckwheat, which may be called its only competitor as a forage crop upon the poorest sands.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This is the most important part of practical agriculture as far as animal power is concerned, but we do not by any means undervalue ox labour. Still both these modes of animal power in cultivation must yield the palm to steam power when at fitting times of the year it can be done with benefit, simply because in our fickle climate it is important that so much can be done in so short a time, with the best effect, if we use our discernment and discretion aright in choosing our season for operations. It may be said that this applies with most truth on large occupations commanding steam power for all purposes to which it can be applied, and these are legion when properly attempted. Yet the farms of moderate size can be greatly improved by the use of steam power hired as a supplement to the horse power of the farm. This preface brings us to the points to be considered at this date, and in doing so let the home farmer remember the great difficulties of our climate, which alone prevent our following the even tenor of our work on the farm, especially at the seed time for Wheat. But do not let the peculiar difficulties of the Wheat season for sowing at certain times be forgotten, although it seldom happens so extremely unpropitious as to give us no real seed time for Wheat on the majority of soils between the 20th of October and the 20th of February, as was the case last year. Several seasons, however, we can recollect as being a near approach to it—viz., those of 1841 and 1872. This fact, however, brings to our mind that although the seasons may have been adverse, yet the farmers of the present day are not so well prepared for them as those of fifty years ago, for we well remember at that time it was common to see upon the chalk hill farms the young Wheat plant high enough to hide a hare as she sat in her form the first week in October; in fact, some of the fairs at that time, held the first week in August, were especially used for the sale and purchase of Wheat, the produce of the previous year, for seeding purposes. There were various reasons stated to justify the practice of this early sowing of Wheat, one of which was to prevent blight on the eve of harvest, and we have in our time seen numerous instances where the early-sown had escaped blight, where the Wheat sown in what is now commonly called the Wheat season suffered serious injury. The important point in our time to be considered, is the difficulty upon all mixed or flat-lying soils to obtain a dry time enough for sowing after the 20th of October. Here, therefore, is the lesson to be learnt, that in our culture and arrangements in preparing the land for seeding for Wheat, the work should be forward enough to finish sowing both fallow and lea ground by the date above mentioned upon any soil or climate.

Hand Labour.—In case of the hedges and fences not being finished, trimming them should be done while the sap is in the wood. Filling dung cart to be laid on the Clover leas where the second growth has not

been ploughed in and spreading it, will now be going on, for the sooner it is spread the better, as it can be ploughed under and buried better. The Turnips now, being large and full of foliage, are just in the best condition for breaking down and ploughing in for Wheat if not required for sheep-feeding. Threshing with the steam machinery will now be going on, and winnowing the same will employ some men as well as women to assist in the work. Finishing and topping the straw ricks as fast as the corn is threshed should be carefully done, and also thatching the same, as the best bright Oat straw for fodder will be valuable, as also the Wheat or Rye straw, and will meet a ready sale in the nearest town, for nearly every tradesman now keeps a horse and van for delivery of goods, as well for advertising, and we suppose it answers both purposes.

Live Stock.—Horses, we find on purchase, are still at rather a high price, especially animals of 16½ hands in height and stout in proportion, and we believe that all farm horses should be equal to deep ploughing in ordinary soils with two to a plough, or in summer time two to a double-furrowed plough. Sheep are still selling at very high figures, too high to promise profit in feeding for the butcher. Some of the best fairs in the south of England are just past, but others are nearing. The great fair at Weyhill in Hampshire offers some of the best Hants downs, as well as the best Dorset and Somerset horned ewes. The latter are sold in great numbers at this fair from the 7th of October to the 10th, on the last date principally the Hampshire down ewes and hoggets are offered. The horned ewes sold here are the very finest animals that can be found in the kingdom for the production of early lambs for sale in the metropolitan market at Christmas and on into January, February, and March, and we believe that it will be found that when sheep are very dear that these early-lambing ewes yield more profit than any other stock, for early lambs meet with no competition from abroad like sheep for mutton. In times like the present, when foot-and-mouth disease prevails so much, and is increasing in many counties of the United Kingdom, it is worth while to take account of the advantage to the home farmer who breeds all the animals he may require, whether of cattle, sheep, or swine. He will not only have the satisfaction of having for his purposes such animals as may be best adapted for the soil and climate of the farm, but will require to make no wholesale purchases of Irish or other cattle, which have lately gone far to spread the disease from one district to another, and, therefore, the farms on which the stock of cattle required are bred thereon, will have the greatest security against contagious diseases of every kind, but more especially if a strict look-out by the shepherd and herdsmen is kept, under the orders of the home farmer using his own caution and intelligence.

OUR LETTER BOX.

Kerry Cattle (R. B.).—The following numbers contain articles upon Kerry cattle. No. 958, August 7th, 1879, page 118; No. 1, July 1st, 1880, page 18; and No. 5, July 29th, 1880, page 105.

Lucerne and Dodder (W. L., Streatham).—The parasitic weed called the Clover Dodder is so named because it usually attacks such plants as Clover and Lucerne, the seed of which vegetates in the soil, but produce spiral shoots, which soon wind round any neighbouring plants, but especially of Leguminous plants, and then becoming disconnected from the earth derives its sustenance from the juices of the living plants of Clover, &c. The seed is generally furnished by foreign seed grown on soils to which it may be indigenous. It is not easy to remove it from the soil by ordinary eradicating appliances, for what would kill the seeds or germs of Dodder in the soil would also probably destroy other succeeding vegetation. We therefore recommend that the soil under the Dodder patches should be dug off clean from 2 to 3 inches deep and stife-burned—that is, charred by fire and smoke, which will destroy the Dodder seeds and germs. We do not do this in ordinary cultivation, for the Clover-cropped land comes up and is ploughed for Wheat; but, in this case, if it is desired to retain the land under Lucerne, the land may be burned where the Dodder has existed the first dry day or two, the ashes spread, and the vacant patches are re-seeded to Lucerne.

REMARKS.

23rd.—Thick mist and cold in early morning; fine bright day.
 24th.—Wet morning; fine afternoon; rain again in evening.
 25th.—Windy morning; fine day; short sharp shower at 1.45 P.M.
 26th.—Wet at first; bright breezy day.
 27th.—Very heavy showers with bright intervals.
 28th.—Fine bright morning; overcast afternoon; slight rain in evening.
 29th.—Fine at first, afterwards showery.

Very unsettled weather during the week.—G. J. SYMONS.

APPLES IN THE ASCENDANT—DOUBLE GRAFTING.

FOR the first time after the lapse of centuries the full value of the Apple has been recognised. At one bound it has risen from almost the lowest position in the schedules of exhibitions into the front rank; is even accorded, as it eminently deserved, a position such as no other fruit has attained at the head quarters of practical horticulture—historic Chiswick. A really national show of any kind of fruit such as the display now on view in the Royal Horticultural Gardens has never been held before, and those who have witnessed the great gathering will concede that not one national show of special garden products, whether of Auriculas, Roses, Pelargoniums, Carnations, Dahlias, Gooseberries, or even Potatoes, has equalled this in either magnitude or interest. Nor has there been equal evidence in any one case that the necessity for these special gatherings has been so great as for the truly national gathering under notice; and it follows, therefore, that from none of them has the benefit been so marked as will result from this remarkable Apple Congress. In stating this it is not intended to in the slightest degree detract from the special shows alluded to. All gatherings of this nature are direct incentives to higher culture, while they widen the interest in the different garden products and extend the industry of horticulture. Let them all flourish, and that they do so shows the more clearly—and this is why they are mentioned—the great, the almost surprising, neglect which the Apple has hitherto been fated to endure. What is best is most common, and perhaps on this account the Apple, like the Potato, has been so long left authoritatively unnoticed until by accident, private fancy, or carelessness the nomenclature of varieties is almost in a state of chaos, errors thereby having been multiplied, and orchards and gardens occupied unprofitably. A change having become urgent and the time opportune, an effort is at last made to do something towards effecting an improvement in the supply of this indispensable fruit, so that raisers and cultivators of trees and consumers of their produce may be mutually benefited.

This is the object of the extraordinary gathering that is more fully referred to in another column—a gathering that has astonished the promoters by its magnitude, and rendered the labours of the scrutineers even more onerous and difficult than was expected. They have, however, faced their task boldly, examined systematically, and a strong mark of recognition is due to one and all for their valuable services in the work in question. The complete results of their labours will not be immediately apparent, but that they will eventually be found of substantial service there cannot be a doubt.

There is much to be learned in connection with this important fruit, and those who have the most intimate acquaintance with it will be the first to admit this. Beyond the classification of varieties, determining the accuracy of their names, and acquiring information relative to adaptability of different Apples to various districts, a wide field for research

is open on the question of stocks. Broadly speaking, and for general purposes, competent nurserymen know as a rule the stocks that are suitable for certain varieties and different forms of culture; but the full importance of double grafting is not yet sufficiently appreciated, nor can it be ascertained except by extensive and carefully conducted experiments.

Working one Apple on another that is itself established on a Crab or Paradise stock has a marked influence on the tree both as regards vigour, productiveness, also the size, and even the colour of the fruit. On these points we have some evidence as the results of trials on a limited scale conducted over a series of years by Mr. Harrison Weir. The record of some of these experiments is before us, and in a few instances are striking and suggestive if not strange, and we may appropriately direct attention to them here.

Duchess of Oldenburg grafted on the Early Strawberry, a tree nearly dead with canker, revived the tree, which now makes vigorous growth, the fruit growing to a very large size, colouring beautifully, and ripening fully three weeks earlier than is usual with this variety.

Duchess of Oldenburg grafted on the Golden Winter Pearmain makes very thin wood, but appears healthy. The fruit is small and of a pale green colour.

Duchess of Oldenburg grafted on Reinette Van Mons makes very little growth, the fruit being hard and much smaller than the above, but very handsome in appearance.

Golden Noble grafted on the Golden Winter Pearmain does remarkably well, the fruit also being very fine.

Golden Noble grafted on the Hollandbury does not do well, the growth being poor and fruit very small. The same variety grafted on the Tower of Glamis succeeds fairly well.

Golden Noble grafted on the Ribston Pippin, a tree almost killed with canker, makes most vigorous and clean healthy growth, the fruit also being clear and fine; but the same variety grafted on the Striped Beefing is useless.

Lord Suffield grafted on Cox's Orange Pippin will not make any growth, neither does it succeed on either Reinette de Canada nor Reinette Van Mons. Neither is it quite satisfactory on the Golden Winter Pearmain, the growth being too weak and the fruit too small; but worked on the Hollandbury it makes clean healthy growth, bearing very fine fruit; while on the Sweet Rymer it makes little growth and fruits very heavily.

Beauty of Kent grafted on Reinette de Canada makes thin but clean growth and bears freely, but the fruit is smaller than usual.

Blenheim Pippin grafted on the Irish Peach does not succeed, being very much inclined to canker; on Omar Pacla it makes poor growth and bears very small fruit; but worked on the Sweet Rymer it thrives well, making clean vigorous growth and fruiting satisfactorily.

Cox's Pomona grafted on the Golden Winter Pearmain does remarkably well, the fruit being very fine indeed, but has no colour even in the sun, being quite green, and does not ripen so early as usual.

Cox's Pomona grafted on Reinette Van Mons does very well; the fruit is under medium size, harder than the above, but very handsomely coloured.

Cox's Pomona grafted on King of the Pippins, trees that were almost dead with canker, makes vigorous growth and produces fine fruit abundantly, but not having quite so much colour as the variety in common. Mr. Weir remarks that King of the Pippins and Golden Winter Pearmain are quite distinct with him both in growth and fruit, though they are classed as synonymous in the "Fruit Manual." Perhaps the trees are on different stocks.

Cox's Pomona grafted on Hawthornden, that does not do well in his garden, takes very freely, and the fruit is fine but very pale in colour. The same variety on Tower of Glamis grows vigorously, but has not yet fruited; on the Alfriston, which does not do well, the growth is healthy and the fruit fine, freely produced and handsome, while on the Reinette de Canada the growth is rather weak but productive,

the fruit, however, being smaller than the average, a few days later in ripening, but very highly coloured.

Those results are very suggestive. If the ripening of an early Apple, such as the Duchess of Oldenburg, can be accelerated by three weeks, the fruit being also large and beautifully coloured, that is an important point gained, and the same stock is worthy of being tried for other early dessert Apples such as Mr. Gladstone, also kitchen Apples, and if the results are equally satisfactory we shall be closely approaching the desideratum of having Apples all the year round.

The vigorous growth of Golden Noble on the Ribston Pippin "almost killed with canker," suggests the desirability of trying the Ribston on the Golden Noble thus established, with the object of ascertaining how far the stock will influence the old favourite in rendering its growth similarly free and cankerless.

That soil and climate influence the colouring of Apples is beyond question. The examples now on view from widely separated districts show this conclusively. From Kent, Middlesex, Monmouthshire, Dorsetshire, and Devonshire we find highly coloured fruit, whereas the same varieties from Lincolnshire, Staffordshire, Yorkshire, and Durham are practically colourless. This is only what might be expected; but few persons would anticipate that Duchess of Oldenburg grafted on the Golden Winter Pearmain should not colour at all, while on the Reinette Van Mons the fruit should be so handsome, nor that exactly the same phenomena should occur with Cox's Pomona worked on the same stocks, especially as Reinette Van Mons is not itself highly coloured. It is quite clear there is something to be learned on the question of stocks, and it is equally certain that much knowledge on varieties can be gained by an inspection of the 8000 dishes or more of fruit in the marvellous collection at Chiswick. It is a grand museum of Apples, and most instructive, especially as the correct and erroneous names are attached to the dishes where corrections were necessary. It affords such an opportunity for the study of the Apple as has never been seen before, and is not likely to occur again. All gardeners, and indeed everybody interested in this fruit, should make an endeavour to spend a few hours at Chiswick during the next week; and, as has been suggested by Mr. Harding, if advantage is taken of excursion trains from various districts to the "Fisheries," two wonderful Exhibitions can be seen in one day, and neither of them will soon be forgotten.

Nor must reference to the contributors to this remarkable display be omitted. There were neither money prizes nor medals to tempt them, yet from nearly every county in England fruit has come, with interesting consignments from Wales and Scotland. Perhaps especially noticeable is the great representative collection of 279 varieties from Tweedside, not only by the excellence of much of the fruit, but by the complete manner in which it was presented by Messrs. Ormiston & Renwick of Melrose. It is the produce of sixteen gardens, and was accompanied by an apparently unlimited supply of printed circulars containing lists of the varieties and notes from the several cultivators explanatory of the conditions under which the fruit was grown, such as altitude, soil, subsoil, and treatment to which the trees had been subjected. This must be regarded as a model consignment. Messrs. Jefferies of Oxford also collected and furnished fruit from several gardens and gave similar information; the Durham Gardeners' Institute also worthily shared in similar work. Other collectors probably assisted, and to them and to individual contributors the thanks of cultivators are due for the generous support thus given in rendering the gathering what it undoubtedly is, a decided success.

Mr. Barron is especially to be complimented on this satisfactory achievement, and the cheerfulness with which his assistants have discharged the extra duties that have devolved upon them merits approval, while Mr. Killick has worked assiduously in naming the fruit, his intimate knowledge of Apples rendering his services valuable.

It will be remembered that the collection remains till the 18th inst., and can be reached in half an hour from South Kensington, both Turnham Green and Acton Green stations on the Metropolitan District Railway, being about ten minutes' walk from the Gardens; Chiswick station on the London and South-western line being also within a mile of the Exhibition. It may be also remarked that the vinery in which the chief display is arranged is the finest in England, and the Grapes above and the Apples below form a spectacle unexampled and unique.

The immediate result of this Congress will be to stimulate the planting of Apples of the best varieties, thus the fruit supply of the future will be insured as better than that of the past, and assuredly there is room for improvement.

ORCHIDS IN AUTUMN.

As some of the most beautiful and useful of these choice plants need special attention now, a brief note on their requirements may, perhaps, be of service to those persons who are "trying their hands" at the culture of the most popular kinds, and are hoping to succeed in growing and flowering them well. At present I will confine my attention to three of the most useful genera—*Dendrobiums*, *Calanthes*, and *Odontoglossums*.

Dendrobiums.—Such kinds as *D. nobile*, *D. Wardianum*, *D. Devonianum*, and others that were started early and allowed to make their growth under the influence of plenty of heat, light, and air, will now be in a well-ripened condition. This condition must be reached before the plants are removed to cooler, drier, and more airy quarters. It is a great mistake to bring these plants to rest prematurely, for such treatment will not insure the best results. They must be carefully and gradually brought to a standstill to enjoy the period of rest so essential to their successful cultivation.

Calanthes.—These, if properly attended to during the summer, will be strong, and their flower spikes now throwing up rapidly. From this time they should enjoy a somewhat drier atmosphere than has been necessary during their growing period. Do not discontinue the use of stimulants until the first flower opens, and maintain the foliage healthy as long as possible. The glass of the house inside and out should be thoroughly washed if needed, so that every ray of light possible will reach the plants. Keep them close to the glass, as the colour of the flowers depends very much upon the light they receive when they are developing. If the early batches are coming forward too rapidly the temperature can now be gradually lowered, and the plants thus retarded.

Odontoglossums.—Many plants that have made strong well-ripened growths will be producing flower spikes. A sharp look-out must be kept for slugs at the present time, for if any are allowed to exist a good number of spikes may be ruined in a night. A little cotton wool placed round the spike is an admirable plan, but the safest is to suspend the plants from the roof until the spikes are firm and thus safe from the ravages of these most troublesome pests. Keep a sharp look-out for aphides, and eradicate them at once, for when they are allowed to establish themselves upon the flower spikes they soon injure and deform the blooms. I am no advocate for fumigating these plants, but remove these insects by means of a soft brush and a little weak tobacco water. Shading is often practised after this date by many growers, but ours is removed for the purpose of allowing those growths not yet fully developed an opportunity of becoming thoroughly matured. The plants must not be allowed to suffer by the want of water either at the roots or in the atmosphere. Keep them close to the glass and admit air freely when favourable, and the flower spikes will be stout and compact instead of weak and slender. Do not allow the night temperature to fall below 55°, and allow a rise of 10° during the day by sun heat.—W. BARDNEY.

THE ROSE ELECTION.

AN election of newer varieties, valuable as it is, necessarily means a small number of voters, and not a few of those who have so kindly assisted in previous years have returned their papers, honestly confessing that their experience of "newer" varieties was not sufficiently extensive to justify their giving an opinion. This is every way satisfactory; it proves that those who have voted in previous elections are for the most part growers who desire to record their own views founded on their own experience, and it is this collective recorded experience that is of value. Some, however, of the returns have had remarks attached to them not altogether complimentary to the general excellence of the newer Roses—for instance, one remark appended was that there were not more than a dozen worth cultivation. This perhaps is a little too sweeping, yet I fear there is a fair amount of

chaff along with one or two Roses that will rank very highly in any election return. It is true that in the general election of 1882 A. K. Williams achieved a most honourable position, and although it did run Marie Baumann very hard for premier position, I apprehend if the two Roses were pitted one against the other, the older variety would win easily, at least as far as my experience goes. In constancy of bloom, in soundness of constitution, and in perpetuality of good blooms late in the season, there can be with me no comparison as to the respective merits, and the gentleman must retire with the best grace he may. Others, perhaps, have formed a more favourable opinion of their respective merits. I only give my own, merely adding that if both were brought together in the highest perfection simply as exhibition blooms it would be a difficult matter to assign the premier position to either.

The returns in the present election show the necessity for a good Rose catalogue, such as we all hope the new edition of the National Rose Society's catalogue will prove to be. The ages of some of the candidates for honours have been put back, and not a few of these I have been compelled to exclude. Some Roses, too, I fear are getting "mixed"—for instance, Constantin Tretiakoff in two catalogues before me has become Fretiakoff.

But I must pass on to the results of the poll. In all there are thirty electors, nineteen amateurs and eleven nurserymen, and the table is given as usual, the first column giving the votes for each Rose as in the best six, the second as in the second best six, and the third as in the next twelve (amateurs). The same columns with an asterisk denote the same votes given by nurserymen.

RESULT OF THE POLLING.

No.	Name of Rose.	Character of Rose.	Year of Introduction.	Raiser's Name.	Amateurs' Votes.			Total.	Nurserymen's Votes.			Total.	Grand Total.

* Sent out by William Paul & Son.
 ** Sent out by G. Paul.
 † In Paul's catalogue, Postans, and William Paul & Son.
 ‡ Sent out by Turner.
 § Sent out by Cranston.

Of the untabulated Roses named, four received five votes; eleven received four votes; and amongst these I ought certainly to note H.T. Lady Mary Fitzwilliam, 1882 (Bennett), for three of these votes are first-class votes; nine others obtained mention three times, thirteen only twice, and twenty-three out of the total number named (ninety-six) have only a single vote—nearly a quarter of the number named! It is quite possible that some few of these ninety-six may have on the score of age no title to their votes, but I think this number is but small, as I have eliminated a large number. And here I may mention how deeply I am indebted to Mr. Ellwanger's book on the Rose for information as to dates and raisers' names. No other catalogue that I have yet seen approaches it in information on these points.

As all doubtless anticipated, A. K. Williams heads the poll, and is the only Rose that has in all of the lists first-class votes only. It is truly a glorious Rose, and, if it obtain greater vigour and strength

of constitution, must be universally allowed to be one of the brightest gems of our national flower. The Teas are not as high as they might be, or, I might add, as they deserve. Some electors have a difficulty in contrasting the two varieties, and they settle the difficulty by omitting the Teas altogether; but for this they must have obtained a better position. It is a difficulty I do not feel, for I should settle it by asking myself this question, "Which should I give up?" if forced so to do.

On the whole revision, one is driven to the conclusion that a few years hence a goodly number of these ninety-six Roses will have disappeared, and even among the three dozen tabulated there will be blanks. As some guide to value, and probable future of many, the first-class votes are valuable. Taking these votes only, the table reads thus—

- | | |
|--|-----|
| 1. A. K. Williams, 30. | } 4 |
| 2. Mad. G. Luizet, 26. | |
| 3. Duchess of Bedford, 21. | |
| { Countess of Rosebery }
{ Madame Lambard } 12. | |
| 6. Duke of Teck, 11. | } 3 |
| 7. Mad. Marie Verdier, 10. | |
| { Charles Darwin } 7
{ Innocente Pirola } | |
| Harrison Weir
Pride of Waltham
Mrs. Jowitt
Etoile de Lyon | } 3 |
| Mad. Eug. Verdier
Lady Sheffield
Merveille de Lyon
May Quennell
Violette Bouyer
and | |
| Lady M. Fitzwilliam. | |

Only nineteen Roses, and six of these receiving but three first-class votes, is not great promise of many "perpetual" varieties.

The following have kindly made returns. *Amateurs*:—Miss Watson Taylor, Headington, Oxford; Revs. C. Bulmer, Credenhill, Hereford; A. Cheales, Brockham, Surrey; H. H. Dombrain, Westwell, Ashford, Kent; and F. Page Roberts, Scole, Norfolk; and Messrs. George Baker, Holmfels, Reigate; James Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate; J. Burrell, Heighington, Darlington; John Choyce, Pinwell Grange, Atherstone; W. J. Grant, Ledbury; Thomas B. Hall, Rock Ferry, Cheshire; Edward Mawley, Addiscombe, Croydon; Wm. Moore, gardener at Caedreglan Park, Cardiff; George Mount, Harbledown, Canterbury; F. C. Pawle, Northcote, Reigate; J. D. Pawle, Wray Park, Reigate; J. Sladden, Badsey, Evesham; and E. R. Whitwell, Barton Hall, Darlington. *Nurserymen*:—Messrs. Bunyard & Co., Maidstone; B. R. Cant, Colchester; E. Claxton, Allerton, Liverpool; G. Cooling & Son, Bath; Cranston & Co., Hereford; Curtis & Co, Torquay; Dickson & Co., Upton, Cheshire; H. Frettingham, Beeston, Notts; Jefferies and Sons, Cirencester; H. Merryweather, Southwell, Notts; W. Rumsey, Joyning's Nursery, Waltham Cross.

To these many others besides myself will feel deeply indebted. One or two returns were useless, the dates taken no note of throughout, and received so late that I could not keep faith as to time of publishing if I had returned them. As it is, I have been sorely tried in doing so.—JOSEPH HINTON, *Warminster*.

P.S.—September 29th.—By this morning's post came Mr. G. Paul's return. It bore the motto "Better late than never;" but, alas! the outcome of the returns was already in the printer's hands. Yet I am sure all the readers of "our Journal" will be glad to see Mr. G. Paul's list, I therefore give it *in toto*; and it is interesting to note how very slightly it differs from the collective opinion of the thirty electors:—

- | | |
|-----------------------|---------------------------|
| 1. A. K. Williams. | 4. Countess of Rosebery. |
| 2. Duke of Teck. | 5. Mad. Lambard. |
| 3. Mad. G. Luizet. | 6. Duchess of Bedford. |
| 7. Merveille de Lyon. | 10. Mrs. Laxton. |
| 8. Charles Darwin. | 11. Marie Verdier. |
| 9. Mad. Eug. Verdier. | 12. Harrison Weir. |
| 13. Innocente Pirola. | 19. Violette Bouyer. |
| 14. Egeria. | 20. Ulrich Brunner, fils. |
| 15. Mad. Cusin. | 21. Madame A. Jacquier. |
| 16. Pride of Waltham. | 22. Madame Welch. |
| 17. White Baroness. | 23. Lady Sheffield. |
| 18. Helen Paul. | 24. George Baker. |

These twenty-four names differ but little from the collected twenty-four, except in position; Mad. Cusin, White Baroness, Mad. A. Jacquier, Mad. Welch, and George Baker being the only differences, and three of these are in the thirty-six.—J. H.

STRAY NOTES.

Eupatorium riparium.—This, although not quite as showy as its congener *E. odoratum*, is nevertheless a very useful plant for affording a supply of cut flowers and for decorative purposes during winter. It possesses

the great merit of being easily grown, and will stand almost any rough treatment, hence its great value. Cuttings taken in early spring, placed in heat until rooted, afterwards potted, and placed in close frame or pit for a few days. Harden them, and in May plant them out in some spare corner of the garden, occasionally pinch them to keep them in shape, and water when necessary. This is all the attention they will require until September, when they may be lifted and potted, afterwards placing them in a close pit until established in their pots, when they may be removed to wherever they are desired to flower. Such is the *modus operandi* whereby this species, also *E. odoratum*, may be grown, with a minimum of trouble and attention, into useful plants.

Impatiens Sultani.—A most useful and accommodating plant. It lives in either a high or medium temperature. Cuttings struck and grown in small pots make admirable little gems for associating with miniature plants of Gloxinias grown by us in small-size pots with two to three flowers on each plant, and small Ferns in the jardinières of the drawing-room.

Salvias.—Such varieties as Pitcheri, rutilans, splendens, gesneræfolia, and patens, are also very useful for winter work. Patens is going out of flower, but the remainder are coming into flower. Splendens and gesneræflora may be planted out where labour power is curtailed, and lifted and treated similar to the Eupatoriums.—J. U. S.

FRUIT-GROWING.

To a gardener who is strongly attached to his calling, especially if he happens to be what is generally termed "an all-round man," there is probably no work connected with his duties that is more interesting, or for which he has a greater fondness, than planting fruit trees. The falling of leaves and the ingathering of fruit announce to us that the season will soon be here for such work to commence. Where it has not already been done no time should be lost in making a close examination of every tree in the garden, at the same time noting all such as are in an unsatisfactory state, and deciding what remedial measures are to be applied in each case. It is seldom indeed that we find every tree in such a satisfactory condition as we desire. Where there is a tendency to over-luxuriance and the production of wood instead of fruit, root-pruning must be resorted to. When it so happens that the trees which are in this condition have been undisturbed for a number of years, it will in some cases take three or four seasons to accomplish the desired result, and the work must be proceeded with gradually—the first season operating on one side of the tree only; this being done by digging out a trench at a reasonable distance from the trunk, and cutting through all roots which come in the way. Work out all the soil from amongst the roots with a four-pronged fork, at the same time severing all the large ones taking a downward course. Afterwards cut off with a sharp knife all jagged ends and those roots which have been bruised during operations. Too much importance cannot be attached to this point. Fill in with the same soil, and tread it down as the work proceeds, finishing off with a mulching of half-decayed stable manure, and in the event of the soil being of a porous nature give a good soaking of water. The following year adopt the same plan with the other half of the tree.

When trees are comparatively young and unproductive they may with safety be entirely lifted and replanted the first season of their being root-pruned; but with old-established trees, especially if they are growing in what are termed strong soils, the treatment recommended above will be found much the best. Although we say this by way of an inducement to keep on the safe side, we have successfully lifted and transplanted old trees in one season; but of course more care and caution is required, otherwise the result might have been the reverse of satisfactory. With Apricots, Apples, Pears, and Plums there are probably more failures due to over-luxuriance than to any other cause. It should therefore at all times be regarded as a matter of the highest importance to adjust where necessary the balance of power between root and branch.

There is another source of disappointment besides the one we have alluded to, and by no means an uncommon one, and with which fruit-growers are well acquainted—viz., "the yellows," as it is termed in gardening phraseology. Peaches and Nectarines, owing, it may be, to their more tender constitutions, are more liable to this disease than any other kind of fruit grown in our climate. The causes of its appearance are various, but may be attributed chiefly to badly drained soils and to those of a hungry poverty-stricken nature. Subsoils of the worst characters are also a fruitful source of the disease. When trees are in this state they are very subject to red spider, the leaves fall prematurely, and the wood fails to ripen. In very bad cases the best plan to adopt is to destroy the trees and plant young ones; but if it is a mild form, or, say, of two or three years' standing, then undoubtedly the best and safest course to take is to lift the roots entirely, bring them nearer to the surface, and plant in fresh soil, which may consist of good turfy loam mixed with charred rubbish and a little well-decomposed stable manure. On Peach walls where the disease we are now dealing with has made

its appearance measures should be taken as soon as the leaves fall to prevent its recurrence for some years to come. This may easily be done, provided there is an ample supply of suitable material at hand when the time arrives for the work to commence.

Presuming that the border which it is contemplated to take in hand is well drained, the work should be begun at one end by taking out a trench 2 feet wide and 18 inches deep, taking a distance from the wall of about 5 feet. The top spit and the loose soil should be worked to the bottom of the trench, mixing along with it and filling up to about 6 inches above the surface with such compost as that recommended above; and in the event of the natural soil of the garden being of a highly calcareous nature a little peat, if it can be obtained, will be found good to add thereto. As the trenching proceeds tread down the soil moderately firm, lifting and replanting the trees at the distance of about 15 feet from each other, not forgetting to finish off with a mulching of stable manure. The branches may be tied up and slung to the wall, securing them in their positions early in the new year.

Concerning young trees received from the nursery we would strongly urge the importance of having the ground for their reception prepared beforehand, so that when they arrive they may be planted with the least possible delay. It is equally important to dispatch orders early; then the trees may be expected to come to hand early, and be planted before winter weather arrives. Neglect and dilatoriness on this point not unfrequently ends in trees arriving with roots very much frozen, and the ground in which they are to be planted frozen also, and altogether in an unworkable state.

Coming now to small fruits the Strawberry is perhaps the most important. The ground where these are to be planted should be trenched and heavily manured to a depth of fully 18 inches if the best results are desired, and such should always be the object in view, for, as the old adage says, "What is worth doing is worth doing well." July and August we have found to be a very good time for making new beds, making use of plants which have been forced. These get well established before winter, and yield a full crop the following season. Of course beds may be planted now, but they will not bear such a good crop next year as those planted earlier. Give them plenty of space, say from 2 to 3 feet each way.

Raspberries next demand attention. They often fail and yield the least satisfactory results from occupying the same quarters for too long a time. They like liberal treatment and rather a moist situation. With us the canes grow from 9 to 10 feet high, and are as thick as one's thumb, producing fruit of a presentable appearance and of good quality. Our *modus operandi* consists of trenching the ground 2 feet deep and giving plenty of strong manure, planting stools with two or three canes to each 6 feet apart each way as soon as the leaves have fallen.

Gooseberries and Currants are all the better for not occupying the same ground for too long a time. Young bushes always produce the finest fruit, but where it is not convenient to incur any extra outlay old ones may with safety be transplanted towards the end of this month. Now is a good time to insert cuttings of the latter, bearing in mind to pick out the buds from the lower part of the cutting, and in three or four years hence they will be large enough to replace the old bushes. In conclusion we would strongly impress upon the minds of those who contemplate planting fruit trees the importance of paying close attention to the following points—viz., avoid deep planting, stake and tie securely all such trees as require it as soon as they are planted, and give a mulching to the surface of 3 or 4 inches of half-decayed manure.—J. HORSEFIELD, *Heytesbury*.

EARLY OR SUMMER-FLOWERING CHRYSANTHEMUMS.

In the *Journal of Horticulture* for July 26th, 1883, a paper appeared by Mr. J. Udale, gardener at Shirecliffe Hall, Sheffield, the concluding paragraph of which, on summer and autumn-flowering Chrysanthemums, reminded me how little seems to be known of the progress made and being made in early-flowering Chrysanthemums. They are not all Pompons. Madame Castex Desgranges, at present the grandest white summer bloomer, is a large Japanese kind, quite as large, when well grown, as Elaine, but with the excellent quality of not growing more than half the height, and not being much more than half the time coming to perfection. Thus cuttings inserted at the beginning of May bloom during October, though if the earliest flowers are desired, the cuttings must be struck in June or July of the year before and wintered in cold frames kept from the frost, then they will bloom as early as the middle or end of May; in fact, from May onwards they may be bloomed any time. This has nothing to fear beside any of the late ones; it is a grand plant, one of the best ever grown. It is not new now. I have grown it four seasons. It is said to have been sent out in 1877, but the trade

in and around London knew little or nothing of it till 1880, when I first grew it and endeavoured to make it known.

Précocité is still, perhaps, the best early yellow, but the new yellow sport of Early Cassy is better in some respects. Chromatella, or Chrome Stella, is not a good plant. The new Frederic Marronet of this season is far before it in habit of plant and form of flower. It is the same colour—orange-yellow, a small Pompon, and came into bloom August 7th; a real little beauty. Frederic Pelé is in some respects the best of the colour, but it is a shy bloomer and has a delicate constitution. My red sport of Madame Piccol (syn. Mr. Piercy) is a much more profuse bloomer. Pompon Toulousain is another red, very early, very free and robust as well as dwarf. Early Cassy is not nearly so good as Madame Piccol, which is the same colour. Golden Button is simply worthless, while Scarlet Gem is of a very tender constitution, and only seems to do well on gravel subsoils. One of the very best new Pompons is Lyon. It is of French origin. Colour, rosy purple, much the tint of Madame Piccol, and makes the latter of little value, only that it is rather later. Lyon blooms in September from spring-struck cuttings, and is a superb Pompon in every respect; an admirable plant.

Nanum, the Sistou of the French, although old, is still in many respects the best early white, it is so dwarf and stout. Besides being the very earliest of all, it will bloom from plants struck the summer before by the middle of May, and under glass is of exquisite whiteness. Another of the best of the early whites is the new Mdle. Jolivart. It is very dwarf, and a profuse bloomer, with a flower of wax-like appearance differing from all others. The new Mrs. Cullingford resembles it a little, and is between it and Nanum, but does not bloom till September, and is a taller plant, but very fine. The little Petite Marie is another pretty white variety; it will bloom at 4 inches high and is very early.

The following are all good, early, and new—Virginia, white; Anastasio, magenta; Inimitable, orange; Curiosity, lilac white; Lavallée, white; St. Crouts (syn. Pollion), pink; Zenobie, orange; Secrétaire Daurel, Tresorier Lacoste, crimson and buff. Besides many others which I cannot mention now, I intend to publish a list of some of the best between now and November, and will write more if I find this is valued. I shall be glad to hear from anyone interested in early-flowering Chrysanthemums, or show my collection to anyone who will send me word when they will call. I have been growing, collecting, and studying them for the last seven years, and probably know something about them others would wish to know, and they are welcome to hear from me what they may wish.—W. PIERCY, *West Road, Forest Hill, S.E.*

NOTES ON PEAS.

PEAS have only succeeded moderately with me this season the earliest crops being by far the best, the midseason fairly good, and late varieties very indifferent. This is only what might have been anticipated, as the soil is a gravelly loam with gravel beneath, and in such soils it is useless expecting fine full late crops without making special preparations, as the growth has to be made when the days are hottest and driest, and the plants become stunted, producing a weakly haulm, whilst the peas are few in the pod, badly swelled, and are soon over, even if they escape attack by mildew. Not only was the above disastrous in its effects, but the caterpillars of the Y moth fed upon the leaves and ate the flower buds, whilst the maggots of a minute fly were most assiduous in their attentions. These between them committed great havoc; and as I have not had the same evil to contend with I shall be grateful for any information that would point to some mitigation of the mischief done by these pests. I think it likely that fir-tree oil syringed over the haulm might prevent the eggs being laid upon them, which I think takes place during the early part of June to early July, but I do not know enough of the life history of these insects to warrant any positive statement. Can any of your entomological correspondents enlighten me?

Happily the sparseness of haulm and the mildew can be successfully combated by strengthening the plant with a deeper soil. This is best done by taking out a trench 2 feet wide and a spade deep, putting in about 6 inches thickness of well decayed manure, forking this well into the soil at the bottom of the trench, and then returning the soil thrown out to its former position. This will form a ridge, and in the centre of these the peas may be sown. When the peas are sown, and by or before they are a foot high, mulch on both sides of the row with about half-decayed manure to the extent of 3 or 4 inches thickness and 18 inches wide, giving previously a thorough soaking of liquid manure if the ground be dry, and from this time forward a thorough watering must be given weekly if there is little or no

rain. This will give very much better results than leaving everything to the weather; indeed the labour and means will be amply repaid by a full supply of delicious peas, whilst the ground is undergoing an enriching process, fitting it for the carrying of almost any crop.

William the First was our best early Pea, and First and Best Early maintained its reputation for earliness, free-bearing, and good quality. Criterion did well, bearing abundantly, and like its prototype, Ne plus Ultra, was of fine quality. It certainly is one of the best second earlies, being a much earlier and dwarfer form of Ne plus Ultra. It grows 5 to 6 feet high.

Gladiator, one I believe, of Mr. Laxton's raising, purchased and sent out by Messrs. Veitch & Sons, proved a marvel of productiveness, having large pods exceedingly well filled with medium-sized deep green peas, which proved of excellent quality. It partakes somewhat after the type of Fillbasket, having a curved pod, but the quality is much superior and the season is longer. It is a Pea of such merit that it cannot fail to become a favourite with growers for market and those that cannot command long sticks, as this only grows 3 feet high and is remarkably prolific.

Marvel is a fine Pea of the Veitch's Perfection type, but comes in earlier and is very productive, the pods being large, as also are the peas, and has ten or more in a pod, which are delicious in flavour. A main crop variety, growing 3 feet high.

Telegraph did very much better than Telephone, filling its pods better and giving fully twice as many of them. The quality, it is needless to say, was excellent, as all the peas of Mr. Culverwell's raising are, size and quality being inseparable. The Giant Marrow gave its magnificent pods abundantly, and as an evidence of quality I may mention that not a pod was gathered 6 feet from either end of row, so much esteemed were they by those ever prone to test the quality of Green Peas. It is one of the very best late Peas, growing full 6 feet in height. I have had it half as much more.

Best of All surpassed Veitch's Perfection, which is saying much, filling its pods better, and is a medium grower (3 feet) of the highest quality, being good for main or late crops. Sturdy was of stout branching habit, and did not mildew nearly so badly as most, bearing an abundance of deep green peas, which keep in season a long time, having in fact the habit and size of pod of Veitch's Perfection, whilst the peas are like those of Ne plus Ultra, excellent in quality. A very desirable late Pea, producing pods successively; height 3 feet.

Ne plus Ultra was the best of the tall-growing late varieties, being, as it almost invariably is, unrivalled, standing the vicissitudes of late summer and autumn as regards climate better than any other, unless it be Emperor of the Marrows, which I may state has almost, if not quite, superseded British Queen.

These have proved the best with me, and I need not trouble anyone with enumerating varieties that have done badly, as another season may alter the estimate; still, those named I feel certain will hold their own. Mr. Laxton sent me some of his new Evolution, and the reputation of the raiser being so great it is certain the name would not have been given without justifiable reason. I expected much and have not been disappointed. It grew very vigorously and was much branched, yet only attained to a height of 3½ to 4 feet. The pods were produced in great abundance, twice the length of those of Omega, which it somewhat resembles in the shape and greenness, the pods containing in some instances a dozen peas, and the quality excellent. Sown at the same time as Omega, it was several days earlier, and from its branching habit afforded the crop successively. I think it will prove a very great advance on many second early and main crop varieties, and become popular in gardens and also for market purposes.—G. ABBEY.

MICHAELMAS DAISIES.

ASTERS have within the last few years made considerable advancement in public favour; and this is not at all surprising seeing they come into flower at a time when few other plants are attractive, together with their adaptability to furnish the necessary supply of cut flowers where the hardy outdoor plants are depended on. Ordinary garden soil is quite good enough to grow them in. They require, however, plenty of room, otherwise from superfluous root-growth they will become very troublesome unless divided every second or third year. They present a great variety both in height and the size and colour of their flowers, are suitable for nearly all purposes—the wild garden, shrubbery, the flower border, or rockery, and when judiciously planted in any or all of the above places have a very telling effect at this dull season.

I have selected from a very large collection a few that can be recommended for general culture, and likely to prove useful in gardens where from lack of space the cultivator is compelled to choose only the very best. The wild garden has been for some time engaging the atten-

tion of most of the leading horticulturists in this country; and a few large establishments, notably Kew, have already made a move in the matter, and from what we have seen are likely to prove successful. In planting the wild garden much care and management are required to successfully imitate Nature, and, before attempting it, it is necessary to have at hand a large and varied collection of plants from which to choose. A few of the stronger-growing Asters are very desirable for isolating; and the following, which grow from 5 to 6 feet high, are useful—

A. Novæ-Angliæ and its varieties; large heads of very showy rose and purple flowers. A. Novi-Belgii, very attractive, purplish. A. cordifolius, large spikes of lavender flowers; effective. A. lævigatus, much-branched, purplish mauve. A. multiflorus, dense spikes of small white; most attractive of this section.

In favour of planting such bold and attractive plants in the shrubbery little need be said. The following will be found suitable, the plants growing from 3½ to 4 feet high. A. amethystinus, rosy. A. polyphyllus, white. A. turbinellus, loose-panicked, large, light purple flowers; very pretty. A. patens, bluish purple; good. A. cricoides, pure white. A. diffusus and its variety horizontalis; very bushy, densely branched, whitish. A. vimineus, white. A. versicolor, various-coloured.

Plants suitable for the flower border, from 2 to 3 feet:—A. punctatus and A. dracunculoides, corymbose heads, blue. A. oblongifolius, dense heads of large pretty blue flowers. A. discolor, one of the most beautiful varied-coloured Asters; we have all shades from rose to pure white. A. lævigatus, var. minimus, fine rose. A. Amellus, large purple. Suitable for rockery, 1 to 2 feet:—A. dumosus, dense head, pinkish. A. spectabilis, purplish. A. cricoides var. Reevesii, pure white. A. linearifolius, purplish; very good. A. sericeus, very beautiful; glaucous leaves, purplish rose flowers.—D. D.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

I AM a country gardener, and wished to subscribe £10 10s. (or £1 1s. annually) to the Gardeners' Royal Benevolent Institution. Before doing so I asked a few questions respecting its benefit to me if wanted, or to my widow if left. The following is a copy of a letter I received at the time, and may possibly help some of my fellow gardeners.

"24th Oct., 1876.

"14, Tavistock Row, Covent Garden, W.C.

"DEAR SIR,—Your note to hand. In reply, I beg to inform you that by a payment of £10 10s. at once you become a life subscriber, and that when your attaining the age of sixty, provided such subscription had been paid for fifteen years, you would in the event of requiring the assistance of the charity have a prior claim over those who had not subscribed so long, or not at all, and that in the event of your death before that time your widow would, upon attaining the same age, stand in the same position, but in either case you would be required to conform to the rules. I am happy to say that our Society is in a very flourishing state, having a nice nest-egg of £10,750* put by in the funds. I shall be happy to hear from you, and would certainly suggest your paying £10 10s. at once, but, of course, you are the better judge of your own means.—Yours faithfully,

"EDW. R. CUTLER, Secy."

* The "nest-egg" on December 31st, 1882, was £14,750.—J., *Sussex*.

[Mr. Cutler writes to say that he never notices anonymous letters, but if any of our correspondents will favour him with their names and addresses he will be pleased to afford them any information in his power. We hope Mr. Cutler will not object to the anonymous letter from "J., *Sussex*," to whom we are obliged for his readiness to afford the information that is undoubtedly sought for in reference to this Institution, and which it appears the Secretary declines to supply in the manner in which it would be the most useful—namely, publicly.]

HOW ARE WE TO KEEP OUR APPLES?

BY doing what Mr. Taylor suggests on page 299. Store them, as I have done for years, in a damp airy cellar. Handle them as lightly as possible, and place in crates, bampers, or old cases with holes bored in the sides, so as to prevent the fruit from heating. On the approach of frost cover as directed by Mr. Taylor. Fruit treated thus will remain plump and good at least two or three months longer than if stored in a high and dry temperature. Before use develop the flavour by placing in a high temperature for twenty-four hours at least.—A. M. B.

PASSING NOTES.

Pansies and Violas.—I think it may be said with much truth that the bulk of English gardeners do not know or do not indulge in the wealth of beauty that our Scotch brothers do in the matter of Pansies and Violas, to say nothing of other plants. The drier climate of the south is against growing these flowers to the fullest development, and they are not sought after to any very great extent. It is a pity that this is so, for there are few hardy plants that can and do give such sweet and abiding satisfaction as do Pansies and Violas. A year or two ago I saw a catalogue of these plants from Messrs. Dickson & Co. of Edinburgh, and was somewhat astounded at the enormous quantity of both Pansies and Violas they were sending out. To know of them was in my case to have; and this year I have had from the plants I had from them, to the great pleasure and satisfaction of my young lady employers, plenty of most rare and beautiful blooms of both Pansies and Violas. I hardly know which of the two kindred families of flowers to give preference to, but this I know, that *Viola alba odorata* was not allowed to carry a flower long. They were picked as fast as they showed, "Because, you see,

gardener, it's the first time we have had a Pansy-like flower with the scent of Violets." That was the explanation to me by one of the young ladies on my observing that they seemed very fond of them. I say, then, to all gardeners who grow special flowers for the ladies of their house, and it is the pleasantest of all duties, Grow plenty of *Viola alba odorata*.

Blue Stone, a Pansy-Viola as it is called, being a hybrid between some of the varieties of *Viola cornuta* and some of the Pansies, I like so well that I have propagated it as largely as I could, and it will figure conspicuously in my spring flower garden next season all being well. Countess of Kintore is a blue with light-coloured edges, a capital grower and most attractive and interesting variety. I need not catalogue them, however; that is better done by vendors in their trade catalogues, which include all the best varieties of hardy border and florists' flowers.

Chou de Burghley.—As I have been cutting splendid heads of this new and most admirable vegetable during the past month I desire to record my testimony in its favour. "It is most excellent." That, however, is the testimony of the cook that I have to serve, and I can safely say that few know what good vegetables are better than she does. "But what is it?" she went on to ask; and before I could reply she added, "It's like a Cabbage and yet it isn't a Cabbage. It's like a Cos Lettuce almost in form, and boils just like a good Broccoli. I am sure it isn't a Cabbage because the water doesn't smell as Cabbage water does. What is it?" Then I said that it was *Chou de Burghley*, a new vegetable raised by Mr. Gilbert, gardener to the Marquis of Exeter of Burghley Park, and was the result of a cross between the Cabbage and a Broccoli, and as I had a lot growing I was glad to hear so good an account of it from her, "But," I said, "how do they like it in the dining-room?" "I have not asked," she said, "but I argue that they like it much, for there was not a scrap came out." So much for *Chou de Burghley*.

Potatoes (vide page 267).—"Amateur, *Cirencester*," is just the correspondent that I hoped would take up this Potato question. His is a very fair letter, the letter of a man with a mind of his own. Mine was not, I am bound to admit that, because, unfortunately, I write as I feel at the time, and being somewhat impetuous of disposition and temperament I rush in helter skelter, reckless of consequences. By this I lay myself open to the pens of such calm thoughtful men as "Amateur, *Cirencester*." I do not mind this when it is resultful of such communications, present and prospective, as his. I shall look out for his promised letter containing the outcome of his Potato experiment with considerable eagerness. I am delighted to hear that he intends to stick to Potatoes; so indeed do I in my way if I can keep my resolutions, and still gladder to know that he is trying to improve our great esculent by the raising of new varieties. I should like to make a personal appeal to him and say, Dear brother Potato lover, please remember we short-top people, we that must have two crops off the same piece of ground the same season, and not give a yard between each row either, we that want our Potatoes to be ready for the table and of first quality the very day they are lifted out of the ground and onwards, we that desire and strive to get a great crop of Potatoes off a small piece of ground. Just keep these ideas in mind, dear brother, and raise new varieties of Potatoes, and we will bless you with a deep and overflowing blessing.—H., *Notts*.

MR. HENRY HOOPER.

A WELL-KNOWN form will be missed, not only from our metropolitan, but from many of our provincial exhibitions, for I have just heard of the death of this well-known florist. Wherever there was an opportunity he was always anxious to display the results of his culture, and to show that in a quiet way he was doing his share in making horticulture popular. He did not pose as one who was doing it all for the good of the public, nor claim credit for disinterested labours; at the same time he was none the less a benefactor to horticulturists, for he has introduced in various classes of flowers, but more especially in Pansies, Picotees, and Pinks, some valuable varieties.

I have never, until this year, had the opportunity of seeing him at home. His nursery was indeed a strange one—rough and untidy, but containing a valuable collection, and the plants he sent out from it were always good and healthy; in fact, the garden was like the man himself, one of the old type of florists, no kid-glove gardener, but plain and bluff and honest—the very embodiment of good nature and kindness, and like his garden there was "good stuff in him;" fair and upright in his dealings; a good husband and father, and respected by the citizens of Bath who were interested in horticulture. His son, whom I saw, is an intelligent young man, and although I know nothing positively, yet I should imagine that the business will be carried on as usual, and the name of Henry Hooper will, I hope, still continue to remind us of his labours and successes.—D., *Deal*.

SINGLE DAHLIAS.

SO numerous have the varieties of single Dahlias now become that it is evident some method of classification is necessary, especially as several very distinct types have been gradually formed. Mr. T. S. Ware, Tottenham, has paid much attention to these popular plants, and has raised some thousands of seedlings during the past three or four years, and after a careful examination of these he has formed four groups, founded on obvious characters. The first of these includes those with "star-shaped flowers," a new section, of which about a dozen varieties have been raised at Tottenham. They are distinguished by neat, pointed,

flat florets, spreading widely from the axis, very slightly overlapping at the base, and as the points are free the flowers have a distinctly star-like form. The majority do not exceed 2 inches in diameter, and their neatness of form combined with their bright colour is fast rendering them great favourites. The woodcut (fig. 58) represents two of these, and show the characters of the type admirably. The shaded form is Magpie, the florets being light in the centre with a crimson margin; the other is an unnamed seedling, brilliant crimson in colour, and very free. A beautiful orange-scarlet-coloured variety, named Bedding Gem, in this group is also noteworthy, as the colour is a peculiarly distinct shade, and it is extremely free. Yellow, maroon, dark scarlet, "crushed straw-

are Sulphur Queen, brilliant yellow; Empress, pure white; Union Jack, white, edged with crimson; and Orangeman, rich orange.

AMERICAN VINES AND THE PHYLLOXERA.

In reply to your correspondents who ask at page 292 what evidence I can adduce in proof of the Strawberry Grape being an American variety, I have only to say that my experience of this Grape and the American Catawba is that they are one and the same variety, and Mr. Barron's description of the latter in "Vines and Vine Culture," page 237, goes to strengthen my opinion on this point, inasmuch as it agrees in every particular with the character of the Grapes grown here under the

Fig. 58.—MAGPIE.

CRIMSON SEEDLING.

berry," and many other shades are represented, but most of these varieties are at present unnamed.

The next group comprises those varieties with "flat florets"—that is, the florets radiate at right angles from the axis, regularly overlapping nearly to the tips, but the margins and apex do not fold or reflex in any degree. This section is readily distinguished, the florets being much broader than the last-mentioned, and the former may be considered as an improvement on the original single Dahlias. The two shown in fig. 59 (p. 317) are typical representatives of the group. Dr. Moffat, a greatly improved Paragon, recently certificated, and resembling the parent in colour, is a beautiful variety, more constant than the older form. The other, Danger, is a rich scarlet variety, wonderfully free and bright, quite unrivalled in its colour. Four other fine varieties in this section

names of the Fox and Strawberry Grape, and of which I send by this post a sample for your opinion. Hence my associating it with the American varieties of Grapes.—H. W. WARD.

[The Strawberry Grape before us is evidently a variety of *Vitis labrusca*, an American species, but was probably raised in Europe, as it was not known in America when M. Planchon made his exhaustive investigation of American Grapes. It is distinct from the Catawba, which, however, is a variety of the same species. The history of the Strawberry Grape is given as follows in Barron's "Vines and Vine Culture," page 229. "This singular Grape is generally assumed to be of American origin, on account, it may be supposed, of the great similarity in the leaves, and in the character of the fruit, to the native American Grapes. It is, however, we believe, of European origin. Lady Cave sent us some fruit from near Montreaux, on the Lake of Geneva, and stated that she found it in the market at Gray, on the Saone, west of Dijon, which almost fixes its nativity to that district."]

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, James McIntosh, Esq., in the chair, the following candidates were unanimously elected Fellows—viz., Geo. W. Clare, J. Hastings Duncan, James William Temple, Reginald Ward, and Mrs. Wilkinson.

— IT is proposed to celebrate the NATIONAL APPLE CONGRESS by having a dinner at Ashley's Hotel, Covent Garden, in the rooms of the Horticultural Club, on Thursday, October 18th, at 6 P.M., Dr. Hogg, F.L.S., in the chair.

— WE have received from Messrs. Jefferies of Oxford a box of blooms of the most beautiful unnamed SINGLE DAHLIAS we have ever seen. The variation of colour is remarkable, and every type of the flower is represented. The selfs range from white to the richest maroon. Some of the varieties have flaked florets, such as maroon streaked with rose, white marked and tinted with lilac, and purple veined with crimson. Others of the flowers have margined florets, one scarlet edged with orange buff being extremely bright, and another purplish puce margined with pale rose, very chaste; while the base of some of the darker florets is orange, forming a bright ring round the disc, which is effective. Several of the blooms before us are quite equal to the best named varieties, and all are good.

— A SHOW of ARTIFICIAL FLOWERS AND FRUITS is now being held at the Royal Aquarium, Westminster, and is in some degree interesting as showing the skill exercised in the imitation of their real prototypes. The flowers are formed of various substances—wax, wool, and a fine material resembling muslin. The Roses modelled in the first-named are very truthful representations, but the best case has suffered in transit; the form and colour of the petals have been more faithfully reproduced than by any other method. In the wool the majority have a very unnatural appearance, but some samples of Pansies are life-like in colouring and form; a plant of Lobelia in a pot is also an excellent sample of skill. The muslin-like material appears to be cut or stamped out, and is not very satisfactory, except in the case of Bonvardias and Stephanotis, which look fairly well. As to the kinds of flowers represented a large number are recognisable, but some are entirely artificial and do not exist except in the artist's imagination. One indeed that appears to be a favourite would be a welcome novelty; it consists of a small tubular corolla with three petals, purplish mauve, shading lighter in the centre, and crowded in dense clusters. The fruit is admirably modelled in wax, Cherries, Peaches, Plums, Apples, and Pears being reproduced with the utmost exactness. Unfortunately this is the smallest portion of the Exhibition. It, however, suggests what an interesting permanent pomological museum could be formed by taking counterparts in wax of all the principal varieties of fruits. How greatly such an institution would add to the attractions of Chiswick, for instance.

— "T. E." writes that "A fine specimen of RENANTHERA LOWII is now flowering at Ferrières, near Paris. Its long leaves, which measure a yard or more in length, appear small if compared with the length of the spikes of buds, which reach a length of 3 yards. Each spike—of which there are at present eleven—numbers 280 buds, all flowering at the same time, which are so different in appearance that side by side they may easily be taken for distinct species. It is reported from Italy that in the garden of the Marquis Corsi-Salviati at Sesto Fiorentino the Renanthera Lowii is also at present in flower, which is the first time that it has ever flowered in Italy."

— MR. THOMAS TWINING, the well-known author of several scientific works and schemes, has issued a description of a BOTANIC STAND, which is claimed to be "a means of agreeable instruction in the knowledge of the natural orders of plants." The plan consists simply of employing a shelf with a protective rail on each side, on the top of iron hurdles, so that a series of plants illustrative of the principal natural orders can be raised to a suitable height for inspection, thus avoiding, as Mr. Twining states, "the inconvenience of having to stoop very low to study

the majority of plants, whereby ladies' clothes are liable to get damp, rheumatism and the like being not unfrequently occasioned by imprudence of this description." It is always well to simplify matters as much as possible, and the Botanic Stand may prove useful in some respects; but those who undertake the study of natural history are generally prepared to face a few difficulties and inconveniences.

— WE learn that the GRAPE HARVEST IN SOUTHERN ITALY AND SICILY is very satisfactory. The first snow has fallen in the most elevated parts of the Abruzzi. Grapes are abundant, but rather later than usual in ripening, in almost all the provinces of Southern Italy. A fair Tobacco harvest is reported from Lecce, but those of Cotton and Figs are less favourable. In Sicily the Grape harvest is not only plentiful in quantity but also of a very superior quality. The Olive crop is very fair in the province of Palermo.

— A CORRESPONDENT writes that Dr. Domingo Freire, of Rio Janeiro, the discoverer of the YELLOW FEVER FUNGUS, has made the experiment of transferring this Fungus into the system of animals by injection, and has obtained satisfactory confirmation of his theory. The inoculated animals, after a very short time, showed all the symptoms of yellow fever, and on dissection their blood was found to be full of the germs of the Fungus.

— RESPECTING the WHITE PINE Professor Sargent says:—"The entire supply growing in the United States and ready for the axe does not to-day greatly, if at all, exceed 80,000,000,000 feet, and this estimate includes the small and inferior trees, which a few years ago would not have been considered worth counting. The annual production of this lumber is not far from 10,000,000,000 feet, and the demand is constantly and rapidly increasing."

— MR. G. HAWKINS observes—"Mr. J. C. Wheeler has sent out a great novelty in his GIANT TEN-WEEK STOCKS. We have garden parties here every week for three months, and the Stocks have been greatly admired by all. Some of the branches are as large as the central spike of ordinary Ten-week Stocks."

— THE HAMPSTEAD, CHILD'S HILL, AND WEST END CHRYSANTHEMUM SOCIETY will hold their third annual Exhibition on November 20th and 21st of the present year. The classes are numerous, three prizes being offered in the majority, ranging in value from 12s. to 2s.

— MR. JOSEPH MALLENDER, The Gardens, Hodsock Priory, Notts, sends the following summary of the WEATHER OF SEPTEMBER:—"The total rainfall was 5.09 inches, being more than has fallen here on any of the previous eight Septembers, and more than in any month since October, 1880. Rain fell on twenty days; 1.03 inch fell on the 10th. The mean temperature of the month was 56.0°; warmest day, 18th, 73.0°; coldest day, 30th, 50.1°; maximum in the sun on the 16th, 123.2°; minimum on the grass on the 9th, 33.9°; mean temperature of air at 9 A.M., 55.6°; mean temperature of soil at 1 foot deep, 57.4°; sunshine during the month, 106.2 hours, or 28 per cent. of possible duration. There were five sunless days. The highest reading of the barometer on the 13th was 30.321°; lowest reading on the 2nd, 28.656°. Wind mostly from northerly points; average velocity, 8.3 miles per hour."

— A NEW American monthly paper devoted to gardening is entitled "THE CONSERVATORY," and which it is said will contain each month "A review of the flower trade, trade news, and essays on floral subjects." The third number for September contains eight pages, the principal article being one on window gardening and sketch of the flora of Jamaica. It is published in New York.

— ANOTHER addition to horticultural literature has been started in the Channel Islands, and bears the title of the "JERSEY GARDENER." The second number is just issued, and though of a very unpretentious character, is somewhat an improvement upon the first; it seems, however, a little behind the times, and is suggestive of some of the earliest attempts at horticultural journalism in England. We hope it will go on improving and do good in its district.

— A PLANT that well repays the cultivator for any extra attention which he may bestow upon it is CODONOPSIS ROTUNDIFOLIA, *Benth.* It belongs to a section of Campanulaceæ, from the majority of which, however, it differs in habit, and is more nearly related to the beautiful and much-admired *Cyananthus lobatus*. It is of a climbing, or, more

properly, of a trailing habit, and is useful when planted to scramble over loose stones on the rock garden, where its large and beautifully marked bell-shaped flowers render it very conspicuous. Its requirements are few, and like most of the Himalayan plants, it grows luxuriantly and flowers profusely in ordinary loam and leaf soil in a rather shady situation. There is also a variety called *C. grandiflorus*, which is more ornamental than the above, the colour of the corolla being more variegated and with a more spreading calyx, the whole plant very much resembling a magnified Deadly Nightshade.

— A VERY novel and interesting industry has been started in the South Seas by an American firm—THE DRYING AND PRESERVATION OF LOCAL-GROWN FRUIT. The process used is called the Alden process, of which we have no details. The firm has 50 acres or more of Bananas under cultivation, and intend also to buy from outside planters. The Bananas are first thrown into boiling syrup, and then subjected to the drying process, the sugar crystallising upon the fruit and imparting a delicious flavour. If this plan of utilising this most nutritive and wholesome of fruits could be introduced into Queensland, thousands of acres might be grown for export, and the industry become most lucrative—(*The Queensland Planter and Farmer.*)

MR. GLADSTONE APPLE.

MR. GLADSTONE Apple was introduced to the trade by my father in 1868. It is a chance seedling, of which there are so many in Worcestershire. The old tree is, I should say, a hundred years old, and is located near here. It is much the finest early Apple we have, a sure bearer, and the old tree, although so ancient, shows no sign of decay. It ripens here about the 20th of July. If I am spared I will send you some fruits next season.—W. JACKSON, *Blakedown Nursery, near Kidderminster.*

GARDEN CHEMISTRY.

SOIL LOSSES.

IF manure be very thoroughly prepared, and be applied very near the surface, where it will be at once appropriated, the loss of plant-food will be reduced to a minimum, but there will still be loss more or less preventible. For generations it has been known that lime disappears from soil to which it is applied, and its periodical application is therefore necessary. How this happens has been explained under the head of "Lime and Liming," and therefore nothing further need be said on that matter. It may, however, be not so well known that applications of ammonia chloride and sulphate determine the loss of an equal amount of lime. In the soil these salts are decomposed, the ammonia is fixed, and the sulphuric acid and the chlorine liberated. These combine with the lime present, and form calcic sulphate and chloride—extremely soluble salts, which may be detected in the drainage water immediately after the first heavy rain following their application. The sulphuric acid and chlorine of potassic salts are lost in the same manner. Indeed, as a rule, while the bases of manurial salts, such as potash and ammonia, are fixed by the soil, the acids are generally lost. Phosphoric acid is an exception to this rule, for either with iron or lime this speedily, however soluble when applied, forms insoluble compounds, which remain in the soil until attacked by the roots of plants and utilised.

Calcic carbonate, sulphate, and chloride losses are not serious, as they can be cheaply supplied in different forms; but nitrogen, not at all subject to loss in the form of organic compounds, such as it occurs in humus for instance, or even as ammonia, is very soluble and easily lost when changed to nitrate. An erroneous idea prevails that clay in soil will hold such, no matter how much rain may pass through the soil. This has been shown to be a mistake by none more clearly than by Sir J. B. Lawes, Dr. Gilbert, and Mr. Warrington at Rothamsted, although to Schloesing and Muntz belongs the credit of discovering the means by which the nitrification of nitrogenous organic matter, ammonia, urea, and similar substances is accomplished.

It would occupy too much space to give the details of the process by which nitrification is accomplished. Suffice it to say that it cannot go on unless organic nitrogenous matter, ammonia, &c., be present, also a salifiable base, such as lime, a certain degree of heat, and a ferment, which is an exceedingly minute organism and classed as a bacterium. These conditions exist in all fertile soils during summer and autumn, and the consequence is that the process goes on almost continually; but it goes on most rapidly when the temperature is highest. We may have nitrogen as it exists in ammonia or in humus; we may have the bacteria which swarm in all surface soils; and

we may have a salifiable base, such as lime; but if the temperature be below or near freezing no action takes place. The oxidisation of the nitrogen in the soil does not proceed rapidly in winter; but as spring advances it begins, it goes on with accelerated pace in summer, and attains its maximum by the early autumn months. At Rothamsted it was found that a solution of proper materials, which took thirty-seven days for complete nitrification when the temperature was 52° Fahr., only required eight days when 86° was maintained. Schloesing and Muntz have shown that at 99° nitrification is ten times more rapid than it is at 37°. Hence the reason why Scotch loam is richer than English, and hence one of the great advantages of bottom heat, for in this country it is only in artificially heated soils that nitrification proceeds rapidly.

Now naturally least nitrates are in the soil just when most wanted, in spring, and most when least wanted, in autumn, for these nitrates are very easily washed away. Hence the very strong reason for applying very near the surface thoroughly prepared manure when seeds are sown or plants put out.

To show when nitrates are naturally most plentiful, and also how they are lost, a quotation may be made from a lecture delivered before the Society of Arts by Mr. Warrington some time ago. On that occasion he produced tables showing the average amount of nitrogen as nitrates in the drainage water from certain gauges constructed for the purpose. The soil was in fallow, and was unmanured. The figures are the averages of five years. I may reproduce part of the table.

	Rainfall.	Amount of drainage.		Nitrogen as nitrates.	
		20-inch gauge.	60-inch gauge.	20-inch gauge.	60-inch gauge.
January to March.....	5.78	4.53	4.31	8.80	9.92
April to June.....	7.81	2.22	2.63	5.06	6.10
July to September	10.07	3.84	3.46	14.24	10.80
October to December	8.84	6.24	5.91	16.72	15.82
Total.....	32.50	16.83	16.34	44.82	42.64

When it is said that 44.8 lbs. of nitrogen is equal to 287 lbs. of commercial nitrate of sodium it will be seen how serious a loss is thus suffered; and if so much nitrates are formed, partly no doubt from the nitrogen washed into the soil by rain, but chiefly, doubtless, from the using-up of the comparatively small store of humus in ordinary agricultural soils, what must it be in the very much richer soils of gardens? Of course heavily cropped land will not thus suffer loss, because very much of the nitrates will be used by the plants, and, as evaporation will be greater, not nearly so much water will appear as drainage. For instance, while 33.7 lbs. of nitrates were found after fallow per acre in the upper 18 inches of the soil, after Wheat only 2.6 lbs. were detected in the month of September.

The main facts are these: in the autumn most nitrates are found in natural soils, and in the late autumn and early winter months most is washed into the drains or the subsoil. Now perhaps at no other season is there so much nitrates left to the mercy of the rains, for then not only is there much soil bare (neither covered with evaporating leaves nor searching roots), but then much manure is wheeled out from pits and spread over the ground or dug in. To show the error of this we need only quote from Mr. Warrington once again. In one instance, when 88 lbs. of nitrogen was given in autumn to Wheat, not less than 66 lbs. had been removed from the soil by drainage in four months and a half. Of course the nitrogen in ordinary manure is not so easily lost as that in the case of chemical salts, but that the loss in wet winters is very serious there can be no question at all. A chain is no stronger than its weakest link; nitrogen is the weakest link in ordinary manure; by allowing nitrates to escape, or even to provide for their escape, is making this link, and thereby the chain, much weaker.

SAVING THE NITRATES.

There can be no doubt that the best way to prevent the loss of nitrates is to keep the land continually under crop. When the soil is well filled with hungry roots, rapid production of soil nitrates only means rapid growth. Not only so, a dense leafage, with the active evaporation leaves effect, reduces, nay, often prevents, any water sinking deeply, even though rains are heavy. But it is not always possible to have ground cropped with growing crops. Potatoes, Cabbages, and a host of other things are removed, often too late for another crop to take their place till spring. In such cases it is customary to dig the soil up roughly and call it winter fallow. A far better plan would be to sow the ground very thickly with grass seeds, especially when the soil is very light or the rainfall great. Perhaps Italian Rye Grass is the best variety to apply for this purpose, as it has

great foraging powers, grows strongly, has a special capacity for assimilating nitrates and attacking insoluble phosphates. Such sown thickly in September would do much to prevent soil losses, by organising soluble matters, and also be helpful in preparing such insoluble salts as iron phosphates for future use. Moreover, such has a sweetening effect on soil long cropped with garden crops, which no fallowing can secure. Vetches will give a greater amount of herbage to dig in, and so will Mustard and Rape. But Vetches have the same effect on soils that Peas and Beans have, and in practice we find that often these have to follow each other too closely. Mustard and Rape have the effect on soils that Turnips and Cabbages have, and we all know that when these follow each other too closely in a rotation, clubbing and other serious evils often result. Many old garden soils would be restored to a great extent if they could be laid down in pasture for a few years. It is seldom practicable to do so, but sowing down all vacant ground in autumn very thickly with grass seeds would partly answer the same purpose. It would sweeten the soil, keep it dry, save the nitrates, and be quite equal to an application of manure equal in amount to the herbage produced. This, when, from mistaken notions of economy, not enough manure is allowed, or when it cannot be got, would be a great advantage, for artificials cannot altogether supply the place of ordinary manure, though with the economising of all vegetable refuse, and the practice of green manuring, as this has been called, it is both possible and practicable.

Many flower gardens lie for the greater part of the year exposed to the impoverishing effects of the weather, besides being blanks and eyesores. Were they levelled down as soon as the summer contents become unsightly, and thickly sown with, in this case, Rape or Mustard, or, if a level surface be desired, with grass, not only would the necessary expenses be lessened—for seeds could be procured from the hayloft good enough for this purpose—but the appearance be much improved.

Much plant food is lost when too heavy applications of lime are given. For want of lime much nitrogenous matter in many garden soils is quite useless, and accumulates. When lime is given this becomes rapidly prepared, and when large doses are given much more nitrates are formed than the crops can utilise. For this reason lime should only be sparingly applied to garden soils rich in black mould, and when given no other manure whatever should be applied at the same time. In very old neglected gardens lime could thus be made to cause the working-up of the accumulated manure, for manure that only accumulates may as much be regarded as lost as when washed away. If it is liberated by lime gradually it may be regarded as so much unrealised wealth turned into available assets.

By digging at the wrong season much actual wealth is thereby thrown away, because it facilitates the escape of much valuable plant food, but this will be more fully discussed under the head of tillage.—SINGLE-HANDED.

THE NATIONAL APPLE CONGRESS.

OCTOBER 4TH TO 18TH.

SUCCESS in an unexpected degree has attended the efforts of the Committee formed to inaugurate a National Apple Congress at the Royal Horticultural Society's Gardens, Chiswick; for the world has never seen so grand an exhibition of these useful fruits as that opened on Thursday last, the 4th inst. Without money prizes or inducement of any kind beyond the desire to advance the cause of pomology and to assist in reducing the nomenclature to a satisfactory standard, exhibitors have come forward in large numbers from nearly every county in England and Scotland. Wales and the Channel Islands, too, have contributed, while distant Sweden is also represented. The unanimity with which the scheme was welcomed is both surprising and gratifying; but is no doubt in a great measure due to the energy displayed by the leading members of the Committee, who have striven hard to render the Congress what it has proved to be—unique in the annals of horticultural exhibitions.

The great vinery in the Chiswick Gardens presents a spectacle of remarkable beauty, the roof being draped with the Vines—the abundant, pendant, golden and black clusters having a charming effect—while beneath are broad tables of brilliantly and diversely tinted Apples, a few graceful plants in the centre of the stands adding much to the general beauty. This magnificent vinery is 180 feet long, and in addition to the two tables in the centre, each 6 feet broad and extending the whole length of the house, the side shelves are also filled with exhibits. The contributions are arranged in counties, those contained in this house, which is the head-quarters of the Congress, being chiefly Kent, Middlesex, Hertfordshire, Essex, Bedfordshire, Sussex, and Surrey. These include the bulk of the finest produce shown, as in only a few other counties, notably Herefordshire, are such large and handsome Apples staged as those in the home counties. In colour, too, the southern exhibits are much superior, and the Kentish Apples in particular excel in this character. Six other smaller houses are also appropriated to contributions, and the chief difficulty experienced has been to find space for them all. In consequence a few exhibits which arrived late could not be arranged under their respective counties. The old Fig house contains the Devonshire, Gloucestershire, Lincolnshire, Welsh, and Swedish Apples, the two divisions of the span-roof

range, usually devoted to Begonias and Pelargoniums, being occupied with Scotch Apples and those from the northern counties, such as Yorkshire and Cheshire. The long range near the boundary wall, which is in three divisions, contains exhibits from Leicestershire, Somersetshire, Northamptonshire, Herefordshire, Oxfordshire, and a few others of less importance.

The total number of dishes is about 8000, and it is estimated that nearly 1000 varieties are represented. Many of these are only of local fame, and amongst the others great confusion exists as to the names, but the Committee are performing an invaluable service both to the exhibitors and the public generally in carefully determining the correct titles. In this respect alone the Congress will do good work, as an authoritative revision of the names and synonyms of Apples grown in various parts of the country could not have been accomplished in any other way.

Some varieties are remarkably well shown throughout all the counties, and particularly noteworthy in this respect is Peasgood's Nonesuch, which is very handsomely represented in all the larger collections. Warner's King, too, is another fine Apple that is good throughout from all districts and every county, while amongst the newer varieties Lord Derby stands pre-eminent as a general favourite. Perhaps the most handsome Apple in the Show is Washington in the Maidstone collection; it is perfect in form and colour, but as the samples were grown under glass they cannot be fairly compared with their less favoured associates. Blenheim Pippin and Annie Elizabeth are admirably shown from scores of gardens; while of the brightly coloured varieties Worcester Pearmain takes the lead in numbers, Duchess of Gloucester being equally rich but not so abundant. Colonel Vaughan is also good. Of small yellow dessert Apples, Yellow Ingestrie is the most generally exhibited, while King of the Pippins is a favourite dessert variety with nearly all contributors.

In the following notes of the exhibits under the several counties only the varieties best represented are named.

BERKSHIRE.

Though moderate in extent the Berkshire contribution contained many handsome specimens, colour and size being well balanced. Mr. T. Jones, gardener to Her Majesty the Queen, Frogmore, has the finest collection, and throughout the Apples staged are distinguished by great merit, handsome kitchen varieties and brightly tinted dessert varieties rendering the exhibit really attractive. As a representative collection from a private garden we give the names of all the varieties shown by Mr. Jones, and it will be seen that it includes all the best Apples grown in the south of England. The total number of varieties is 153, sixty-seven kitchen Apples and the remainder dessert varieties as follows:—

Kitchen Apples.—Alfriston, Annie Elizabeth, Bess Pool Baron Ward, Baldwin, Brown's Codlin, Betty Geeson, Cox's Pomona, Cellini, Calville Blanche, Dr. Harvey, Dumelow's Seedling, Edmund Jupp, Ecklinville, Emperor Alexander, Flower of Herts, Frogmore Prolific, Forge, Flower of Kent, Grenadier, Galloway Pippin, Golden Noble, Hoary Morning, Holland Pippin, Jonathan, Jolly Beggar, Keswick Codlin, Lord Derby, Lord Raglan, Lady Henniker, London Pippin, Lewis' Incomparable, Mère de Ménage, Maltster, Minchall Crab, Mank's Codlin, Nelson Codlin, Norfolk Beefing, Norfolk Bearer, Old Woman, Omar Pasha, Ogles Grove, Peasgood's Nonesuch, Prince of Wales, Queen Victoria (Small's), Rhode Island, Royal Somerset, Rymer, Roundaway Magnum Bonum, Red Hollandbury, Reinette du Canada, Small's Imperial, Small's Admirable, Stirling Castle, Sheep's Nose, St. Savoir, Stamford Pippin, Transparent du Grongell's, Welford Park Nonesuch, Worcester Pearmain, Warner's King, Wadhurst Pippin, Winter Greening, Wormsley Pippin, Wooling's Favourite, Yorkshire Greening, and Yellow Bellefeur.

Dessert Apples.—Adams' Pearmain, American Nonesuch, Aromatic Russet, Beaumaris Red, Baddow's Pippin, Boston Russet, Braddick's Nonpareil, Brownlee's Russet, Beachamwell, Blenheim Pippin Barton's Incomparable, Beaumaris, Cox's Orange Pippin, Cook's Seedling, Cobham, Calville du Dantzig, Cockle Pippin, Cornish Aromatic, Carraway's Russet, Claygate Pearmain, Coe's Golden Drop, Court of Wick, Copmanthorpe Crab, Court-Pendu-Plat, Downton Pippin, Downton Nonpareil, Duke of Devonshire, Dutch Mignonne, Eldon Pippin, Early Nonesuch, Early Nonpareil, Franklin's Golden Pippin, Fairy Apple, Fair Maid of Windsor, Forester, Frogmore Nonpareil, Fearn's Pippin, Forfar Pippin, Graham Apple, Gipsy King, Gipsy Queen, Golden Pippin (Small's), Golden Russet, Golden Winter Pearmain, Golden Harvey, Improved Ashmead's Kernel, Jefferson, King of the Pippin, Keddleston Pippin, Kerry Pippin, Lord Burghley, Lucomb's Pine Apple, Lamb Abbey Pearmain, Lodgemore Nonpareil, Lemon Apple, Melon Apple, Margil, Martin's Nonpareil, Mannington's Pearmain, Newtown Pippin, New Rock Pippin, New Ribston Pippin, Pennington's Seedling, Powell's Russet, Pomme d'Api, Pine Apple Russet, Pearson's Plate, Pine Golden Pippin, Royal Russet, Rosemary Russet, Ribston Pippin, Reinette Ontz, Ross Nonpareil, Reinette du Caux, Ribston Pearmain, Round Winter Nonesuch, Scarlet Nonpareil, Seek no Farther, Scarlet Russet, Sturmer Pippin, Stark, Scarlet Pearmain, Taylor's Seedling, Wyken Pippin, White Paradise, and Winter Peach.

Mr. C. Ross, The Gardens, Welford Park, Newbury, contributed seventy-two varieties, large handsome examples—Kentish Fillbasket, Golden Noble, Loddington, Cox's Pomona, Warner's King, and Lord Derby being notable amongst the largest, while the brightly coloured scarlet and Worcester Pearmain are similarly striking. Mr. Mortimer, The Gardens, Purley Park, sent forty-two varieties, and Mr. W. Riddington, Hungerford, thirty varieties.

BUCKINGHAMSHIRE.

Slough, the home of Roses and Carnations, contributes its share to the productions of this county, Mr. C. Turner's collection of 150 varieties being the principal exhibit, and comprises some creditable examples of well-known and reliable Apples. The leading varieties were Cat's Head, Ecklinville, Golden Noble, Fearn's Pippin large and richly coloured, Duchess of Gloucester very pretty, Tom Putt highly coloured, Yellow Ingestrie, Prince of Wales, New Hawthornden, Ribston Pippin, Lord Suffield large and handsome, King of Pippins, Worcester Pearmain, Peasgood's Nonesuch, Lady Henniker, Lord Derby, Cellini, Mère de Ménage, and Cox's Pomona. Mr. J. Smith, The Gardens, Mentmore, Leighton Buzzard, staged sixty varieties, generally in fine condition, but particularly fine is Queen Caroline, which is shown in many other counties in good form, Worcester Pearmain and Peas-

good's Nonesuch. Mr. G. T. Miles, The Gardens, Wycombe Abbey, High Wycombe, shows twenty varieties from bush trees on the Paradise stock, and they are all distinguished by a clean fresh appearance. Golden Noble, King of Pippins, Ecklinville, Emperor Alexander, Nelson's Glory, Lord Grosvenor, Peasgood's Nonesuch, Beauty of Kent, Lord Suffield, Blenheim Pippin, Fearn's Pippin, and Mère de Ménage taking the lead amongst the varieties. Mr. A. G. Bridgeman, Thames Bank, Marlow, has thirty-five fine varieties, and Mr. H. Cakebread twenty-four varieties.

CHESHIRE.

The two great firms in this county town contribute the chief portion of the exhibits from Cheshire—namely, Messrs. James Dickson & Son and Messrs. F. and A. Dickson & Son. Each of these firms stage a hundred varieties, comprising some very handsome specimens, indeed they are the best shown from the northern counties. The varieties that are most deserving of notice are, in the former's collection, Golden Knob, Hoary Morning, Lady Henniker, Mère de Ménage, Golden Winter Pearmain, Gloria Mundi, Alfriston, Warner's

Apple, almost black; Ecklinville, Wippell's Seedling, Wormsley Pippin, Gravenstein, Maltster, Hollow Core, Smiling Beauty, Fearn's Pippin, Emperor Alexander, Gloria Mundi, and Lemon Pippin. Mr. J. Garland, gardener to Sir T. D. Ackland, Bart., Killerton, Exeter, has sixty varieties, including some uncommonly fine specimens, such as Warner's King, 12½ inches round; Alfriston, 12 inches; Dumelow's Seedling, 11¼ inches; and Emperor Alexander, 11¼ inches, the last-named being very handsome, though we recently saw a fruit of the same variety 13 inches in circumference. Winter Hawthornden, Royal Russet, Tom Putt, Red Autumn Calville, Autumn Pearmain, and Blenheim Pippin are good, together with several prolific cider Apples, such as Fremlett's Bitter and White Cluster from bush trees. Mr. A. P. Rogers, Furzebrook, Axminster, has fifty varieties of fair quality.

DORSETSHIRE.

A collection of 140 varieties from Mr. W. G. Pragnell, gardener to G. D. W. Digby, Esq., Sherborne Castle, constitute the whole of the Dorset exhibits,

Fig. 59.—DR. MOFFATT—DANGER (See page 313).

King, and Emperor Alexander. From the other firm, in addition to the above, Lord Derby, Mère de Ménage, Tower of Glamis, Nelson's Glory, Annie Elizabeth, Pott's Seedling, Queen Caroline, and Cox's Pomona are fine. Mr. Selwood, The Gardens, Eaton Hall, Chester, shows 160 varieties, the finest specimens being those of Annie Elizabeth, Golden Noble, Yorkshire Greening, Mère de Ménage, Ecklinville, and Dumelow's Seedling. Mr. J. Maddocks, The Gardens, Oakfield, Chester, has twenty-seven varieties, including large specimens of Lord Suffield, Nelson's Glory, and Alfriston, most of the others being small, as those are in the collection previously mentioned.

DEVONSHIRE.

Exhibits from the cider county do not occupy very extensive space, but Messrs. R. T. Veitch & Son of Exeter have an important contribution of 100 varieties, which are represented by large and handsome fruits. They comprise New Hawthornden, Lord Suffield, Veitch's Cluster being also referred to the latter variety; Blenheim Pippin, Kingston Black, a very dark red

These are very fine, some exceedingly handsome fruits being shown of the larger varieties. They have all been grown on cordon trees except Blenheim Pippin, Warner's King, and one or two others. The best of the collection are Hollandbury, handsome in size and colour; Cox's Pomona, Peasgood's Nonesuch, Hawthornden, Beauty of Kent, Beauty of Hants, Bellefleur de Brabant, Ecklinville, Golden Noble, Hoary Morning, Royal Somerset, Yellow Lustre, Old and Scarlet Nonpareils, Downton Pippin, and Agremont Russet.

ESSEX.

This county is not largely represented, and with the exception of the Chelmsford collection the examples staged are not of remarkable merit, being mostly small and greatly wanting in colour. Messrs. J. Saltmarsh & Son, Chelmsford, have about 120 varieties, instructively labelled with particulars concerning the soil, situation, and stocks upon which the fruit shown has been grown. Most of the standard sorts are well to the fore. Peasgood's Nonesuch from a standard in a low gravelly position is good, Warner's King

is large and even, Reinette du Canada, also from a standard, is handsome, and Judd's Seedling, from a high exposed position, is of notable quality. Other good Apples are Winter Hawthornden, Ribston Pippin, Fearn's Pippin, Garret's Pippin, Scarlet Nonpareil, Blenheim Pippin, Sops in Wine, and The Queen; of the last some very handsome fruits from the seedling tree grown in loam on gravel well indicate the characters of this fine variety. Mr. W. H. Strangeman, gardener to R. Warner, Esq., Broomfield, Chelmsford, exhibits twenty-one varieties carefully selected from a large collection. Very notable is Lemon Pippin of a full, clear, golden tint. Mr. W. O. Ward, Ramsey, Harwich, has 112 varieties, a few of which, as Warner's King, are large, but the majority are rather small or rough.

GLOUCESTERSHIRE.

As one of the great Apple counties it was expected that a good display would be provided by the Gloucestershire exhibitors, and this has proved the case, although the position the exhibits are arranged in is less suited to an imposing display than the large vinery, which is devoted to the home counties. Messrs. J. C. Wheeler & Son, Gloucester, have a beautiful collection of ninety varieties, the fruits large, clean, and of fair colour, though they do not excel in this character. Notable amongst the best are Worcester Pearmain, King of the Pippins, Mère de Ménage, Brown's Pippin, Alfriston, Blenheim Pippin, Manx Codlin, Golden Noble very large, Royal Russet, Warner's King, Radford Beauty, Dumclow's Seedling, and Spencer's Seedling. Mr. T. Shingles, The Gardens, Tortworth Court, Gloucester, contributes fifty varieties, very neat and fair-sized fruits, conspicuous amongst them being Annie Elizabeth, Manx Codlin, King of the Pippins, Lord Suffield, Reinette de Canada, Northern Greening, Blenheim Pippin, Warner's King, and Mère de Ménage. Messrs. J. Jeffries & Son, Cirencester, show a handsome collection of eighty varieties, all of considerable size, and the coloured sorts very bright. Stirling Castle, Cat's Head, Blenheim Pippin, Annie Elizabeth, Golden Noble, Lord Suffield, Worcester Pearmain, Emperor Alexander, Striped Beefing, and Royal Russet are prominent amongst the finest.

Mr. H. Ritchie, The Gardens, Eardiston, Gloucester, sends 100 varieties, mostly small, but Tom Putt, Forester, Blenheim Pippin, and Red Streak are good.

HEREFORDSHIRE.

A magnificent and extensive collection is exhibited by the Cranston Nursery and Seed Company, Hereford, 250 varieties being represented and the majority in unusually fine condition, some being large and handsome. The varieties shown in the best form and colour are the following:—Cox's Pomona, Colonel Vaughan, Warner's King, Stirling Castle, Loddington, Annie Elizabeth, Nelson's Glory, Fearn's Pippin, Lady's Finger, Sam's Crab, Worcester Pearmain, Winter Peach, Yellow Ingestrie, Sugar Apple, Rymer, Peasgood's Nonesuch, Golden Spire, Ecklinville, Pym Square, Devonshire Nine Square, Lord Derby, Blenheim Pippin, Claygate Pearmain, and Belle Norman. Two very attractive new Apples are Cliffey Seedling, a rich yellow and red-streaked variety of moderate size, very neat in form, and Herefordshire Beefing, a dark red Apple, flat, said to be good for kitchen or dessert, and to keep till June, the habit of the tree being very erect and vigorous. Mr. W. Styles, The Gardens, Brampton Bryan Hall, Hereford, has twenty varieties of Apples, with a few Pears, but they are small. Mr. T. Parker, Moreton Court, Hereford, has several varieties, Colonel Vaughan being very handsomely coloured, and Tyler's Kernel, a dark red Apple of good appearance.

HERTFORDSHIRE.

The exhibits in this county hold a prominent position, four large firms contributing handsome collections, mostly distinguished by the size and regularity of the fruits, though not so high in colour as those from some of the other southern counties. Messrs. T. Rivers & Son, Sawbridgeworth, have a most interesting and extensive collection, comprising about 130 varieties, some very large and well coloured. A few French, American, and Russian varieties are shown separately from the others, and include amongst the first-named fine samples of Mère de Ménage, Belle Dubois very large, and Reinette d'Angleterre. Of the Americans the pretty red-speckled Melon Apple is noteworthy, together with Washington, King of Tomkins County, and Baldwin. The best Russian Apples are Duchess of Oldenburg, Emperor Alexander, and a small yellow Apple named Sevinkia. Of the general collection the kitchen Apples are large and good, the dessert varieties also being of fair colour. The varieties best represented are the following:—Keswick Codlin, Lord Suffield, Cox's Pomona, Peasgood's Nonesuch, Gloria Mundi, Lord Derby, Warner's King, Blenheim Pippin, Bedfordshire Seedling, Worcester Pearmain, Aromatic Russet, Sops in Wine, The Fairy, King of the Pippins richly coloured, Scarlet Golden Pippin, Wyken Pippin, Kerry Pippin, Mannington's Pearmain, and Winter Peach.

Messrs. Paul & Son, Cheshunt, exhibit a fine collection of 150 varieties—very clean, even, brightly coloured samples—all labels attached stating the soil the varieties have been grown in, which is chiefly loam. Selecting the finest we have the most notable in Warner's King, Blenheim Pippin, Transparent de Croussels, a wax-like yellow and attractive Apple; Chesbunt Pippin, fine colour; Melon, Golden Noble, Manx Codlin, Peasgood's Nonesuch, very fine; Tower of Glamis, Mère de Ménage, large and rich colour; Worcester Pearmain, bright; Lord Suffield, American Mother, Stirling Castle, Keswick Codlin, Round Winter Pearmain, Lord Derby, Catshead, Loddington, Betty Geeson, Burr Knot, Summer Strawberry, American Crab, and Fairy Apple.

Messrs. Lane & Son, Great Berkampstead, show 160 varieties, the majority of unusual size and even in form, but a little wanting in colour. Very notable are Kentish Fillbasket, Queen Caroline, Pope's Apple, Wormsley Pippin, Brabant Bellefleur, Warner's King, with similar fine samples of D. T. Fish and Poor Man's Friend, both of which are referred to the first of the three; Nelson's Glory, Lord Derby, Peasgood's Nonesuch, Stirling Castle, New Hawthornden, Lane's Prince Albert, very handsome, of good size, and perfect form; Newtown Pippin, Pott's Seedling, Loddington, Scarlet Admirable, Formosa, Worcester Pearmain, very finely coloured; Glory of the West, Yorkshire Beauty, Red Hawthornden, Golden Spire, Lord Suffield, Grenadier, and Lord Grosvenor.

Messrs. W. Paul & Son, Waltham Cross, sent a most extensive collection representing 200 varieties, all of good size but deficient in brightness. With them, however, are shown two dozen varieties from the firm's seed farm at Framfield, Sussex which are remarkable alike for their regularity of form

and rich colour, very prominent being Mabbot's Pearmain, a well-known useful variety sent out by the firm; Hoary Morning, Worcester Pearmain, Cox's Orange Pippin, and Cox's Pomona, which are shown in the general collection also. Of the Waltham Cross varieties the principal are Warner's King, Beauty of Waltham, Lord Derby, Winter Hawthornden, Baxter's Pearmain, Lewis's Incomparable, Brownlees' Russet, Red Hawthornden, Beauty of Kent, Fearn's Pippin, Peasgood's Nonesuch, and Evagil. Mr. J. C. Mundell, gardener to Lord Ebury, Moor Park, Rickmansworth, contributes forty varieties; Irish Peach, Strawberry, and Julien being the most notable, the others being rather under the average size.

KENT.

The garden of England well maintains its claim to the title at this great Show, for of all the fine collections that occupy the tables in the large vinery none surpasses those from Kent, and very few equal them. In colour the Kentish Apples are matchless, and viewing the collection from one end numerous shades of crimson and yellow with the rich green kitchen varieties has a most pleasing effect. L. A. Killick, Esq., Langley, has a magnificent collection of 140 varieties, without doubt one of the most beautiful in the whole Exhibition, as richly coloured varieties form a large proportion of the total. Very notable amongst these Worcester Pearmain, Premier, Duchess of Gloucester (Duchess's Favourite), Swedish Pearmain, and Cox's Pomona all of which are exceedingly bright. Other fine Apples are Manx Codlin, Golden Noble, Yorkshire Beauty, Lord Suffield, Lord Derby, Warner's King, Mabbot's Pearmain, Duchess of Oldenburg, Beauty of Kent, Hoary Morning, Fairy Apple, and Red Hawthornden. Mr. W. Chisbolm, Oxon Heatb, Tonbridge, has twenty-eight dishes of good specimens. Mr. R. Gardy, Maidstone, shows four varieties, Loddington grafted on old trees on light soil being fine, also Stirling Castle and Yellow Ingestrie. Messrs. T. Frost and Son, Maidstone, have fifty varieties all fairly good.

Mr. C. Haycock, The Gardens, Barham Court, Maidstone, contributes one of the most handsome collections in the county, and, indeed, in the entire Show, the 124 varieties represented being in the majority of cases not only of great size but of extremely rich colour. The varieties best shown in this collection are the following:—Mank's Codlin, Golden Spire, Reinette du Canada, Beauty of Kent, New Hawthornden, Lord Derby, Mère de Ménage, large; Gloria Mundi, Peasgood's Nonesuch, handsome; Warner's King, Emperor Alexander, Loddington, Golden Noble, Royal Russet, Bedfordshire Foundling, Potts' Seedling, and Small's Admirable. All these are of great size, and form the back rows. The front rows contain the following rich-coloured varieties:—Court Pendu Plat, Worcester Pearmain, Reinette Grise, Mother Apple, Nelson's Prolific, Cellini, Orange Pippin, Cox's Pomona, Washington, Mignonne Rouge, and Melon. Other fine varieties are Yorkshire Beauty, Jolly Beggar, Duchess of Oldenburg, Gooseberry Pippin, Summer Golden Pippin, and Pitmaston Pine Apple. Branches of Wilson's Prolific, a small red and very free Apple, are also notable. Several other exhibitors send small collections, the principal being the following:—Mr. W. Herrington, Betteshanger Rectory, Sandwich, nine dishes; Mr. W. B. Langridge, Mereworth, Maidstone, eight dishes; and Mr. S. H. Goodwin, Smartswell, two varieties.

Mr. G. Goldsmith, The Gardens, Hollenden, Tonbridge, shows seventy varieties, brightly coloured and fine in size. Blenheim Pippin from a standard tree is notable for its rich colour, and the variability of this Apple is very notable from different districts. In some cases, as the above, it possesses fine colour, and in others is, even when ripe, very dull. Shepherd's Fame from an espalier tree is admirable, and Castle Major with Cox's Pomona, also from espaliers, are similarly fine. Fearn's Pippin and Colonel Vaughan are superbly coloured, Gloria Mundi and Hollandbury being large and handsome. Mr. C. Langley, Crabble, has thirty varieties; Mr. G. Butcher, Oak Lodge, Tonbridge, the same number, amongst them being fine examples of Harvest Festival, very rich crimson. Mr. G. White, Fairlawn, Maidstone, sends a collection of equal extent; Golden Noble, Blenheim Pippin, and Loddington forming the most prominent varieties.

Messrs. G. Bunyard & Co., Maidstone, contribute greatly to the Kentish exhibits with 150 varieties, very handsome fruits, the majority being from young trees on the Paradise stock; some specimens of Washington form, however, the chief features of this collection, as in form, size, and colour they are all they could be desired. One fruit in particular is as regular as if it had been most carefully moulded, and the crimson streaks as even as if they had been painted. These fruits have been grown in a cool orchard house, and to this in a great measure they owe their fine appearance, for several other samples in other collections from outdoors are much inferior. Another fine dish from Mr. Theodore Moilliet, Hawkburst, included in Messrs. Bunyard's exhibit, and similarly from an orchard house, is notable. That large and handsome Apple The Queen is also represented in fine condition near the Washingtons. Selecting a few of the best Apples in the general collection the following deserve notice:—Cox's Pomona, Lord Derby, Grenadier, Cellini, Tower of Glamis, Yellow Ingestrie, Pott's Seedling, Scarlet Admirable, Winter Hawthornden, Golden Noble, Pitmaston Pine Apple, Manx Codlin, Warner's King, Mère de Ménage, Worcester Pearmain, Gloria Mundi, and Queen Caroline. Mr. J. Neighbour, The Gardens, Bickley Park, has forty-five varieties, and Mr. G. Beaton, Yotes Court, Maidstone, fifty varieties, both of average merit.

MIDDLESEX.

Considerable space is occupied by the Middlesex Apples, and the general quality is very satisfactory; though wanting the brilliant colour of the Kentish contributions, they compensate for this by excellent size, form, and clearness. Very prominent is the collection of 150 varieties from Messrs. J. Veitch & Sons, Chelsea, which includes some superb examples of the leading Apples. Especially fine are Peasgood's Nonesuch, Mère de Ménage, Worcester Pearmain, Flower of Kent, Baumann's Red Reinette, Lord Derby, Red Hollandbury, Alfriston, Warner's King, Winter Hawthornden, Ribston Pippin, Lady Henniker, Emperor Alexander, Annie Elizabeth, Striped Beefing, Dr. Harvey, Calville de Dantzig, red, crimson; Cellini, Lord Suffield, Jefferson, Cobbett's Fall Pippin, Scarlet Pearmain, and Barton's Incomparable. Messrs. C. Lee & Son, Hammersmith, also have a praiseworthy collection of 120 dishes, representing many more varieties, in fine condition and good colour. Peasgood's Nonesuch is represented by several dishes, all the fruits being marked by their size and fine appearance. Other good varieties are

Hollandbury, Hoary Morning, Warner's King, Blenheim Pippin, Lord Derby, Lewis's Incomparable, Emperor Alexander, Mère de Ménage, Lady Henniker, Lord Suffield, Worcester Pearmain, Cockpit, King of the Pippins, Waltham Abbey Seedling, Cox's Pomona, and Gloria Mundi.

Other exhibitors of smaller collections are Mr. J. Roberts, Gunnersbury Park, Acton, who has fifty dishes, the fruit mostly of fine appearance. Mr. R. Bray, Bedford Villa, Bedford, has seven varieties; Mr. Wood, gardener to Mrs. Sanderson, Duke's Avenue, Chiswick, has thirty dishes; Mr. G. Thompson, Croxby House, Hounslow, shows twenty varieties; and Mr. J. Woodbridge, The Gardens, Syon House, Brentford, contributes forty varieties, including some very handsome samples of Lord Derby, Blenheim Pippin, Warner's King, Alfriston, and Loddington.

The collection grown in the Chiswick Gardens is, however, the most remarkable in this county, comprising nearly 300 varieties. As it is thoroughly representative of the leading sorts we give the names of all those shown. Many of the finer kitchen Apples are admirable in size and form, and the dessert varieties are fairly coloured and clean. Several curiosities are included, one of the most notable being a blue streaked Nova Scotian Apple, which bears a bloom resembling that of black Grapes, with a distinct bluish tint, and possesses a good flavour. The names of the varieties are as follows:—

Culinary Apples.—Alexander, Baldwin, Barchard's Seedling, Baumann's Red Winter Reinette, Beauty of Kent, Beauty of Wilts, Bedfordshire Foundling, Belle Bonne, Banwell's Large, Blenheim Pippin, Blue Pearmain, Brabant Bellefleur, Calville's St. Sauveur, Cambusnethan Pippin, Cellini, Cogswell, Cox's Pomona, Cox's Seedling, Cumberland Favourite, D'Eclat, Derbyshire Crab, Devonshire Buckland, Duke of Glo'ster, Duke of Beaufort, Dumelow's Seedling, Dutch Codlin, Dutch Fullwood, Dyer, Edmund Jupp, Empress of Russia, Fair Maid of Kent, Fallwater, Flanders Pippin, Flower of Herts, Freask's, French Codlin, French Crab, Frogmore Prolific, Gascoigne's Seedling, Gestreifer Herbst Suisse Apfel, Gelbe Richard, Gloria Mundi, Glory of England, Golden Noble, Grenadier, Grange's Pearmain, Greig's Harvest Reinette, Gunner Furst-n Apfel, Higg's Seedling, Hoary Morning, Hollandbury, Holland Pippin, Hollow Crown Pippin, Holzer's Herbst Apfel, Hubbardson's Nonesuch, Hunt's Royal Red, Kentish Codlin, Keswick Codlin, Kirke's Schöne Rambour, Knight's No. 1, Landsberger Reinette, London Pippin, Longville's Kernel, Lord Suffield, Lucombe's Seedling, Maiden's Blush, Mammoth Pippin, Mank's Codlin, Mary Greeds, Mère de Ménage, Miller's Glory, Minshall Crab, Muckenham Rother Winter Koenig Apfel, Myatt's George IV., Nelson Codlin, New Hawthornden, New Hawthornden (Paul), New or White Hawthornden, No Core, Nonesuch, Norfolk Bearer, Norfolk Coleman, Norfolk Beaufin, Northend Pippin, Northern Greening, Old Hawthornden, Old English Codlin, Orme, Penny Loaf, Pomme Poire Blanche, Pomme Water, Pattiswick Seedling, Potts' Seedling, Red Bough, Reinette du Greville, Rhode Island Greening, Rosenhager, Rother Eisen, Royal Codlin, Round Winter Nonesuch, Rymer, Sage No. 1, Schlesvig Jordbaersaeblo, Seedling R. Dudley, Shepherd's Newington, Small's Admirable, Somersetshire Deux Ans, Stirling Castle, Stone's Apple, Striped Beaufin, The Queen, Thompson's Seedling, Thoresby Seedling, Tower's Glory, Transparent Codlin, Twenty Ounce, Wadhurst Pippin, Waltham Abbey Seedling, Wagner, Warner's King, Withington Fillbasket, Winter Coleman, Winter Hawthornden, Winter Majetin, Winter Pearmain, Winter Redstreak, Winter Strawberry, Yellow Beaufin, Yellow Bellefleur, Yellow Bough, York Glory, and Yorkshire Greening.

Dessert Varieties.—Adams' Pearmain, Autumn Pearmain, Algarkirk Seedling, Burchard's Reinette, Brickley Seedling, Bradley's Pearmain, Brownlee's Russet, Betsy, Byson Wood Russet, Brown's Imperial Russet, Braddicks' Nonpareil, Barcelona Pearmain, Baddow Pippin, Beachamwell, Barton's Incomparable, Baxter's Pearmain, Braddick's Nonpareil, Burr Knott, Beat's Pippin, Bess Pool, Cox's Orange Pippin, Colonel Vaughan's, Calville rouge précoce, Carnation, Court of Wick, Calville Blanche, Cockle's Pippin, Court Pendu Plat, Cornish Aromatic, Cornish Gilliflower, Claygate Pearmain, Caraway Russet, Cluster Golden Pippin, Coe's Golden Drop, Dundee, Datzler's Gold Reinette, Downton Nonpareil, Downton Pippin, Duchess's Favourite, Dutch Mignonne, Duchess of Oldenburg, Eldon Pippin, Evagil, Early Nonpareil, Englische Koenig Pearmain, Egg or White Paradise, Fish's Pippin, Federal Pearmain, Flat Nonpareil, Formosa Nonpareil, Fenn's Ribston Pippin, Fearn's Pippin, Franklin's Golden Pippin, Grange, Golden Russet, Gravenstein, Gogar, Golden Ball, Golden Nonpareil, Golden Russet, Golden Reinette, Golden Pearmain, Golden Russet Nonpareil, Haffner's Golden Reinette, Hughes' Golden Pippin, Herefordshire Pearmain, John, Isle of Wight Pippin, Kroon Apfel, King of the Pippins, King Harry, Knight's Lemon Pippin, Lippan Wilding, Leathercoat Russet, Loan's Pearmain, Lord Burghley, Lamb Abbey Pearmain, La Fameuse, Malakovna, Morris' Russet, Muskirke Gelbe Reinette, Miller's Luken Hagen, Martin's Nonpareil, Morris's Court of Wick, Margil, Manchester Pippin, Mela Carla, New Rock Pippin, Nonpareil d'Angleterre, New Green Nonpareil, Northern Spy, Ord's, Old Pomeroy, Omar Pasha, Ostogotho, Old Golden Pippin, Parry's Pearmain, Powell's Russet, Pearson's Plate, Princess Royal, Pomme de Neige, Pigeon's Heart, Pitmaston Nonpareil, Pure Golden Pippin, Pitmaston Pine, President Defay, Ponto Pippin, Peach, Quatford Aromatic, Reinette du Canada, Reinette du Caux, Ribston Pippin, Ronalds' Royal Pearmain, Ronalds' Orange Pippin, Ross Nonpareil, Red Winter Reinette of Schmidtbebers, Reinette Kapuziner, Royal Russet, Reinette d'Holland, Sudbury Beauty, Screveton Golden Pippin, Seigende Reinette, Sam Young, Stubton Nonpareil, Sweeney Nonpareil, Sops in Wine, Stadway Pippin, Staten, Scarlet Nonpareil, Spencer's Green Seedling, Summer Nonpareil, Swedish Reinette, Vale Mascal Pearmain, Vineyard Pippin, Victoria, Van Mons Reinette, Wheeler's Russet, White Nonpareil, Wormsley Pippin, Werder's Golden Reinette, White Molascha, and Yellow Ingestrie.

Mr. A. Wyatt, Market Gardens, Hatton, has seven varieties, handsome samples of Hanwell Souring, Alfriston, Blenheim Pippin, Beauty of Kent, Ribston Pippin, Duchess of Gloucester, and King of the Pippins being included.

NORTHAMPTONSHIRE.

Mr. R. Gilbert, The Gardens, Burghley, Stamford, contributes the principal collection from the above county, 100 varieties being staged, including several new and older seedlings, some of which are well known in the district. Some of the more recent are seedlings with such popular names as "The Butcher," "Parcels Post," &c. The former of the two is, if distinct,

a fine Apple—large and of symmetrical form. A small red Apple named Sell's Prolific is also noteworthy. It is said to be good for either cooking or dessert, and keeps until March. It has been known about Stamford for fourteen years, and was raised by Mr. Sells of Uffington. Of the ordinary varieties the following are well represented:—Emperor Alexander, Scarlet Nonpareil, Wyken Pippin, Summer Golden Pippin, Golden Noble, Round Winter Pearmain, Reinette du Canada, Loddington, Peasgood's Nonesuch, New Hawthornden, Warner's King, Claygate Pearmain, Blenheim Pippin, Golden Noble, and Duchess of Gloucester. Mr. J. Harlock, Lilford Hall Gardens, Oundle, shows a dozen varieties, all the fruits being very handsome, especially Emperor Alexander from standard trees, Worcester Pearmain, Beauty of Hants, and Warner's King from espaliers, and Mère de Ménage from a standard.

NOTTINGHAMSHIRE.

Messrs. J. R. Pearson, Chilwell, stage the principal collection from this county, about 100 varieties being shown in very creditable condition. Most of the standard varieties are included, such well-known sorts as the following being the most notable:—Fearn's Apple, Warner's King, Lady Henniker, New Bess Pool, Ecklinville, Golden Reinette, Cox's Pomona, Emperor Alexander, White Russet, Cellini, Spencer's Favourite, Ringer, Eve Apple, Stirling Castle, Ribston Pippin, Cobham, and Reinette du Canada. Mr. H. Bradley, Southwell, exhibits forty-five varieties packed in dried Lycopodium in small boxes. Several of the varieties are remarkable for their high colour, though not above the average size, Dumelow's Seedling, Lord Derby, Ecklinville, King of the Pippins, Lord Lennox, and Worcester Pearmain being the most notable; the last in particular is finely coloured.

OXFORDSHIRE.

Messrs. John Jefferies & Co., Oxford, have the largest collection in the Exhibition, no less than 343 dishes, which probably represent at least fifty more varieties. These have been collected on the same principle as the Tweedside Apples—namely, from a number of gardens in the county, and as the varieties bear labels stating the name, soil, situation, description of the tree, and other particulars, this exhibit is most interesting and instructive. The following have contributed to this collection:—Mr. J. Britain, Southleigh, Witney; Mr. Thomas, gardener to Mrs. Drake, Bicester; Mr. Hope, gardener to the Earl of Jersey, Middleton Park, Bicester; Mr. W. Holloway, Cowley; Mr. Gould, gardener to Mrs. Stone, Stratley; Mr. Pearse, gardener to W. M. F. Melliar, Esq., North Ashton Hall; Mr. G. Thompson, gardener to Sir W. Herschell, Littlemore, Oxford; Mr. Finlay, gardener to Col. North, Banbury; Mr. J. Gee, Oxford; J. Druce, Esq., Eynsham; Miss Watson-Taylor, Headington; and Mr. F. Warland, Kidlington. From so many different districts and soils the Apples vary considerably in all characters, but generally they are of average size and colour, with a few exceptionally fine specimens scattered through the collections. The varieties that are the best shown in the majority are the following:—Fearn's Pippin, King of the Pippins, Warner's King, Golden Pippin, Claygate Pearmain, Ribston Pippin, Herefordshire Pearmain, Blenheim Pippin, Dumelow's Seedling, Ecklinville, Mère de Ménage, Emperor Alexander, and Lord Derby.

SOMERSETSHIRE.

The exhibits from this county are not, as a rule, distinguished by great size or remarkable colour, but they include many curious and interesting varieties. Mr. R. H. Poynter, Taunton, has about eighty varieties, amongst them being Blenheim Pippin, Warner's King, Dunster Codlin, Ribston Pippin, Tom Putt, finely coloured; Royal George, Sweet Morgan, Hawthornden, Curry Codlin, a large Apple, yellow, shaded with red; Lord Suffield, Cellini, New Hawthornden, and the peculiar conical bright red Apple the Sheepsnose, the Sweet Sheepsnose being of similar shape, but a soft green with a tint of red. Mr. J. Scott, Merriott, has 200 varieties, but these also are small, though Beauty of Hants, Cox's Pomona, Golden Winter Pearmain, and Golden Noble are fine.

SURREY.

Several fine collections were arranged under this county, but, strangely no trade collection was staged, all being from gentlemen's and amateurs gardens. The majority of the samples were fine as regards size and form; but, as in several other cases, the colour was rather weak, except in a few instances. Mr. G. W. Cumming, gardener to A. H. Smee, Esq., The Grange, Wallington, contributes 200 varieties, which are grown in a low damp situation, and therefore could not be expected to be of extraordinary merit. Some extremely good samples were, however, shown of Lord Derby, Warner's King, Wadhurst Pippin, Burr Knot, Emperor Alexander, Elsinore, Cornish Gilliflower, Packham Robinson, Golden Reinette, Clove Pippin. Several seedlings and local varieties are included from Mr. Smee's large collection. Mr. J. Burnett, The Gardens, Deepdene, Dorking, contributes 100 varieties of good quality and well labelled, giving the soil and stock upon which they are grown, thus furnishing much useful information. Some of the most notable examples are Sturmer Pippin (Crab stock, clay soil), with Tower of Glamis and Norfolk Beefing on the same stock and soil. King of Pippins (Crab stock, sandy soil) was also good, with Cox's Orange Pippin from an espalier (stock and soil the same as the last), and Welford Park Nonesuch on the Paradise stock and greensand soil.

Mr. T. Taylor, gardener to J. McIntosh, Esq., Duncannon, Oatlands Park, has ten varieties mostly for name; but including two dishes of Landsberger Reinette, one from a tree in a dry sunny position, the fruits being clear wax-like, yellow, very beautiful, and the others from a tree in a moist position, the fruits greenish with a tinge of red round the eye and on one side—quite distinct from the former, except in shape. Mr. J. Dean, Titsey Gardens, Limpsfield, shows sixty varieties; Mr. J. Barclay, The Durdans, Epsom, twenty-four varieties, amongst which a dish of Scarlet Nonpareil from a standard tree are notable for their high colour. Mr. H. Matthews, Betchworth, has twenty-four varieties, Palmer's Glory and Queen Caroline being most handsome. Mr. B. Greaves, Brome Hall Gardens, Holmwood, sends twelve varieties for name; and Mr. Ridout, gardener to T. B. Haywood, Esq., Reigate, has a beautiful collection of thirty-six dishes, representing sixty or seventy varieties mostly in capital condition, and with many instructive notes respecting the soil, situation, and stocks.

SUSSEX.

The leading collection from this county is that from Messrs. Cheal and

Son, Crawley, which comprised 250 varieties, and is throughout distinguished by high quality, the fruit large, even, and in the majority of cases beautifully coloured; they are also carefully labelled with their names, uses, and other particulars, which add much interest to the exhibit. A few of the best varieties are the following:—Cox's Pomona, Blenheim Pippin, New Hawthornden, Gloria Mundi, Royal Russet, Holland Pippin, Carvan's Victoria, Colonel Vaughan, Worcester Pearmain, Dumelow's Seedling, Peasgood's Nonsuch, Pride of the Mill, Glory of Charlwood, Red Muster, King Apple, Jefferson, Golden Noble, and Avalanche, the last a large yellow Apple being very handsome.

Mr. S. Ford, The Gardens, Leonardslee, Horsham, shows 150 varieties, which he states is half the number grown there. The site is 273 feet above sea level, and he finds all the varieties a week to ten days late and weak in colour. Still some of the Apples shown are very handsome and deficient in no qualities of importance. Especially fine are Blenheim Pippin, King Apple, Thomson, Hollandbury, Bedfordshire Foundling, Mère de Ménage, Warner's King, Wax Apple, Flower of Kent, Red Cadbury, Duck's Bill, Forge, Quarrenden, Emperor Alexander, Calville Blanche very large, and Gravenstein, also good. Eight seedlings are included in the above, the most remarkable being one named Marie Henriette, a small deep crimson-coloured and very prolific Apple. Mr. J. Rust, The Gardens, Eridge Castle, Tunbridge Wells, has forty varieties, grown in a very exposed position 400 feet above sea level on a stiff loam. As might be expected, few were unusually fine, but Mère de Ménage, Sops in Wine, Striped Beefing, and Emperor Napoleon were of good size. Mr. R. Mills, Southdown Road, Shoreham, has twenty varieties, and Mr. T. Moorhouse, Lapwood Gardens, Groombridge, about the same number, both fairly good, but not of remarkable merit.

WILTSHIRE.

Several exhibitors have examples of Wiltshire Apples, but the majority are not remarkable for their high quality. Mr. J. Horsefield, The Gardens, Heytesbury, sends a small collection of a dozen varieties, but these include some of the best in the county, Annie Elizabeth and Cox's Orange Pippin being remarkably fine. Mr. C. Warden, The Gardens, Clarendon Park, Salisbury, has forty varieties unnamed and rather small; and Mr. G. Allen, The Gardens, Rainsbury Manor, Hungerford, has thirty varieties, also unnamed and of moderate size.

WORCESTERSHIRE.

Several excellent collections of fine Apples are contributed, being grown in this county; but one of the most noteworthy of all, though certainly few varieties, is that from Messrs. R. Smith & Co., Worcester. This includes two dishes of the celebrated and favourite Worcester Pearmain, of extraordinarily rich colour, a dark glowing crimson. The variety Grand Duke Constantine, a large and handsome Apple tinged with a delicate and soft rosy hue, is similarly beautiful, and Smith's Pippin, a moderate sized Apple, yellow, and very even, is another attractive variety, and the better-known Yorkshire Beauty sent out by this firm is also finely coloured. Worcester Pearmain is shown extremely well in dozens of collections, but the samples above mentioned are unrivalled in richness. Mr. E. Cockbill, Wick House, Pershore, has fifty varieties, including some fine specimens of Lord Suffield, Kentish Fillbasket, Blenheim Pippin, Golden Noble, Nine Square, and Brunswick Codlin. Mr. J. Twinberrow, Walsgrove, Great Witley, Stourport, has samples of Red Dick, a late cider Apple, very dull red on one side and of conical form, and Counsellor, locally known as Walsgrove Wonder, very fine.

YORKSHIRE.

The most noteworthy of the York collections is that from Mr. McIndoe, gardener to Sir Joseph Pease, Bart., M.P., Hutton Hall, Guisborough. This comprises about fifty varieties, and in several cases duplicates are staged to show the difference in quality of the same variety under glass and outside, the former being in every case incomparably superior in size and general appearance. This is particularly the case with Alfriston, Warner's King, Prince Albert, Lord Suffield, and Lady Henniker. Specimens of an Apple from New Zealand, and named Prince Bismarck, are also shown. It is a large green Apple, somewhat in the way of Warner's King, but with a deeper eye. Some of the best of other varieties staged are Peasgood's Nonesuch, Melon, Lewis's Incomparable, Evagil, Annie Elizabeth, Small's Admirable, and Potts' Seedling. Mr. Bourne, gardener to Admiral Chaloner, Longhill, Guisborough, sends nineteen varieties, but none is very remarkable. Mr. W. Chuck, The Gardens, Brodsworth Hall, Doncaster, has seventy-two varieties of fair quality. Mr. G. Summers, The Gardens, Sandbeck Park, Rotherham, contributes forty-nine varieties, including some good fruits of Mère de Ménage, Warner's King, Nelson's Glory, and Fearn's Pippin. Mr. H. J. Clayton, The Gardens, Grimston Hall, Tadcaster, exhibits thirty varieties; and Messrs. J. Slater & Son, New Malton, have about fifty varieties, all grown on the Crab stock. None is large, but they are clean and of even form.

OTHER COUNTIES.

Bedfordshire Apples occupy very little space, only one exhibitor—namely, Mr. Laxton, Bedford, showing. He has some fine examples of the new Schoolmaster Apple, which are large, of good form, and are much admired for their general fine appearance.

Cambridgeshire.—Very poorly represented is this county, Mr. H. Bull, Bernard House, Cottenham, having eleven varieties of little note except one called the Jolly Miller, a dark red Apple of moderate size and said to be very

prolific. It was raised by Mr. H. Smith of Cottenham ten or twelve years ago. Mr. H. Apthorne, Albion Brewery, Cambridge, sends six varieties for name.

Durham has one collection of ninety varieties from the Gardeners' Institute, Darlington (F. C. Ford, Secretary), and there are fairly good samples of Tower of Glamis, Beauty of Kent, Gravenstein, King Apple, Potts' Seedling, Ecklinville, Blenheim Pippin, Bedfordshire Foundling, Emperor Alexander, and Cellini.

Huntingdonshire.—Messrs. Wood & Ingram, Huntingdon, exhibit a fair collection of twenty-four varieties, not very large but even and clean; Murfitt's Seedling, several local varieties such as Greaves' Wonder—also Blenheim Pippin are the best shown. Mr. A. Harding, The Gardens, Orton Hall, Peterborough, also has twenty-four varieties; Cox's Pomona, Potts' Seedling, Alfriston, Ribston Pippin, and Striped Beefing being especially good, though several others are also fine.

Lancashire.—Mr. R. Maries, Meythorpe Nursery, Lytham, is one of the principal exhibitors from Lancashire, for, though only showing fourteen varieties, they are nearly all of fair size and good shape. Lord Derby, Potts' Seedling, Ringer, Court of Wick, and Blenheim Pippin especially. Mr. J. Hathaway, Latham House Gardens, Ormskirk, shows sixty varieties, but all rather small and green; and Mr. F. Winkworth, The Gardens, Childwell Hall near Liverpool, has fourteen varieties of little merit.

Fig 60.—Lord Derby Apple (See page 321).

Lincolnshire is represented by two collections—from Messrs. Rowson Brothers, West Torrington Gardens, of thirty-one varieties, but small and poorly coloured, and the other from Blankney Hall Gardens, of fifty varieties, the best of which is Warner's King.

Monmouthshire is represented by only one small collection—namely, ten varieties from Mr. W. Jenkins, The Willows, Abergavenny, but these are exceedingly richly coloured. Fearn's Pippin, Yorkshire Beauty, and Emperor Alexander are first-rate; Monmouthshire Beauty, a very rich red Apple of moderate size, most attractive, being the finest coloured of all. The latter fruits are from a tree on the Paradise stock.

Norfolk.—Two collections of forty and fifty varieties respectively are staged by Norfolk growers, Mr. E. Burbury, Cossey Park Gardens, Norwich, having the former number, mostly small samples; and Colville Brown, Esq., The Paddocks, Swaffham, has the larger number, similarly small and green.

Shropshire.—Another of the moderately represented counties, two small collections being staged. Mr. H. S. Kemp, Haughton Gardens, Shifnal, has forty varieties, none very fine, but American Catkin, Tower of Glamis, and Lord Suffield are of good size. Mr. G. Mardall, The Gardens, Ashton Hall, sends several unnamed varieties.

Staffordshire.—Mr. Stevens, The Gardens, Trentham, has fourteen varieties of moderate merit, Cox's Orange Pippin being the best.

Westmoreland.—A very moderate display is provided by this county, Mr. C. Crossland, The Gardens, Beechwood, Arnside, being the only exhibitor, staging thirty-four varieties, three fruit of each, and mostly small. A small dark red variety named Duke William is described by the exhibitor as a good kitchen Apple and very prolific.

Leicestershire.—This county is not largely represented, only one collection being staged by Messrs. Harrison & Sons, Leicester—100 varieties, of good colour, even, and of moderate size. The standard varieties are all included, and the large sorts such as Warner's King, Gloria Mundi, Lordy Derby, and others are fairly good.

WALES.

Mr. G. Griffin, The Gardens, Slebeck Park, Haverfordwest, has the chief collection of Apples grown in Wales, eighty varieties being represented. Although, however, the majority of these are distinguished by excellent colour they are rather under the average size, and in some cases very small. There are no unusually large samples. Blenheim Pippin is fairly good, with particularly richly coloured fruits; Cox's Pomona is of fair moderate size, other good varieties being Winter Hawthorden, Kentish Fillbasket, Beauty of Kent, Reinette du Canada, King's Sauce, Alfriston, Royal Russet, King of Pippins, and Rymer. This and the next collection occupy a portion of the stage in the old orchard house, where the American Vines are now being grown. General Benson, Fairy Hill, Swansea, has sixty varieties, including the Forest of Dean Apple, which somewhat resembles Hoary Morning; also a seedling from it, which was named Bevan's Seedling. This somewhat resembles the old Nonesuch, but minus the open eye of that variety.

SCOTLAND.

One of the span-roof houses usually devoted to Tuberous Begonias during the summer months is appropriated to exhibits from Scotland, and a fine display is afforded by these, for though colour is wanting the specimens are mostly distinguished by good size and evenness. By far the most notable are the collections of Tweedside Apples exhibited by Messrs. Ormiston & Reuwick of Melrose, by which they have rendered most valuable aid to the Exhibition. Two hundred and seventy-nine varieties are represented from the following:—Mr. John Cairns, gardener to the Earl of Home, Hirsell; Thomas Hogg, Esq., Hope Park, Coldstream; Mr. James Fairbairn, gardener to Miss Scott Makdougall, Makerstoun; Mr. W. Fowler, gardener to Lord Polwarth, Mertoun; the Rev. M. H. Graham, Maxton House; Mr. George Grey, gardener to Mrs. Merklam, Gladswood; Mr. J. Thomson, gardener to the Earl of Dalkeith, Eildonhall; Mr. W. Sharpe, gardener to Alexander Curle, Esq., Priorwood; Mr. W. Rollo, gardener to James Carle, Esq., Hurleyburn; Mr. H. Scott, gardener to the Hon. J. C. Maxwell Scott, Abbotsford; Mr. J. Jardine, gardener to Lady Brewster, Allerby; A. Ormiston, Esq., Mayfield, Gattonside; Mr. W. Deck, gardener to Lieut.-General Henry, C.B., Pavilion; Mr. E. Farquhar, gardener to Mrs. Dalrymple, Langlee; and Mr. M. McIntyre, gardener to C. Tennant, Esq., The Glen, Innerleithen. Messrs. Ormiston & Reuwick have displayed much energy in forming such a representative collection as this, and to still further increase the advantage pamphlets describing the soil, situation, and other matters in connection with the culture of the trees are furnished to the visitors. The varieties most distinguished by their size and general merit are the following:—Lord Suffield, Alfriston, Kentish Fillbasket, Mère de Ménage, Warner's King, Emperor Alexander, Waltham Abbey, Manx Codlin, Gloria Mundi, Stirling Castle, Striped Beefing, Ecklinville, Dumelow's Seedling, Annie Elizabeth, Cox's Pomona, Cellini, Blenheim Pippin, Betty Geeson, Yorkshire Greening, Dutch Mignonne, Lord Grosvenor, Hawthornden, Golden Noble, Calville Blanche, Keswick Codlin, Claygate Pearmain, Irish Peach, Kerry Pippin, Braddick's Nonpareil, Devonshire Quarrenden, Ribston Pippin, King of the Pippins, Fearn's Pippin, Hollandbury, Syke House Russet, Reinette de Canada, Cockle's, Margil, Queen of the Pippins, Cox's Orange Pippin, and Sturmer Pippin.

Mr. P. W. Fairgrove, gardener to the Dowager Duchess of Athol, Dunkeld, Perthshire, has a collection of forty-six varieties, amongst which Ecklinville, Warner's King, Lady Suffield, and North Briton are the best, the others being small. Mr. J. Clark, The Gardens, Brodie Castle, has fifty varieties also rather small, Emperor Alexander and Gloria Mundi being by far the finest. Mr. R. P. Brotherston, The Gardens, Tynningham, Prestonkirk, N.B., has 100 varieties of fair size. Ecklinville, Warner's King, Irish Peach, Hoary Morning, Gloria Mundi, Northern Greening, and Blenheim Pippin being the most noteworthy. Mr. King, gardener to J. G. C. Hamlin, Esq., Dalzell House, Motherwell, Lanarkshire, shows seventy varieties, and a few of these are the best coloured amongst the northern Apples, some of the Winter Calville being particularly fine. The curious Lady's Finger is also notable in this collection.

Dr. Robertson, Errol, N.B., has thirty-two dishes, comprising about sixty varieties, only one or two fruits being shown of each. Few of these are remarkable for their size, but Dumelow's Seedling, Winter Strawberry, Blood Red, and Lass o' Gowrie are fine, especially as regards colour. Mr. Reid, Ballindean, N.B., has twelve dishes; Mr. D. Doig, Rossie Priory, Inchtute, N.B., about forty varieties; Mr. J. Cameron, The Gardens, Auchterarder House, Perthshire, has thirty varieties for naming; and Mr. J. Brunton, Drem, N.B., has eighty-one varieties, large and good, Lord Suffield, Warner's King, Emperor Alexander, East Lothian Pippin, Ecklinville, Gloria Mundi, and several local varieties being very well shown. Mr. Dunn, The Gardens, Dalkeith, contributes a large collection, comprising about 200 varieties, the fruits being of average size but very green. The best examples are MacDonald's Apple, Golden Noble, Warner's King, Alfriston, Winter Russet, Paradise Pippin, Oslin, and Worcester Pearmain. The Scottish Horticultural Association, Edinburgh, sent seven varieties, amongst which Northern Dumpling is fairly good, the others are poor. One contribution has been received from the Orkney Islands—viz., a dozen varieties from Mr. T. McDonald, The Gardens, Balfour Castle, Kirkwall Orkney. They are grown

in a strong clay soil, and are mostly very small and dull-coloured. Stirling Castle, Brabant Bellefleur, and Gloria Mundi are the only varieties of average merit.

JERSEY.

Mr. C. B. Saunders, The Saviours, Jersey, is the only exhibitor of Channel Island produce, staging sixty varieties of Apples, some of which are very large and handsome, while others are very small compared with specimens from the English counties. Emperor Alexander is beautifully represented. Cox's Pomona is similarly handsome in all points, other fairly good fruits being Lord Lennox, Downton Pippin, Dumelow's Seedling, Tower of Glamis, Golden Noble, Peach Apple, King of the Pippins, Lady Henniker, and Grenadier. A more extensive and imposing display might have been reasonably expected from these favoured Islands.

SWEDEN.

Foreign-grown Apples, excluding those from the Channel Islands, are represented by only one collection—namely, that from Mr. J. Loney, gardener to J. Dickson, Esq., Gottenburg, Sweden, who has about thirty varieties of Pears and fifty of Apples. The fruits in both cases are fine, but have been grown under glass; and, therefore, though very interesting, have not the same practical value as those from the open air. They are certainly examples of good culture, and in that respect are highly satisfactory. The Pears include Souvenir du Congrès, Josephine de Malines, Beurré d'Anjou, Paternoster, Duchess, Maréchal de Cour, Doyenné du Comice, Beurré Bachelier, Duchesse d'Angoulême, Marie Louise, Passe Colmar, Beurré Diel, Bonne d'Ezée, and Doyenné Boussoch. The Apples comprise many bearing local names, and amongst them is one said to be a great favourite in Sweden

ig. 1.—Grenadier Apple.

and known as the Akerø; it is a pretty variety, of moderate size, wax-like or semi-transparent in appearance, tinted with a peculiarly soft crimson hue. It possesses a firm flesh and distinct pleasing flavour. Other noteworthy varieties are Margil, Forge Apple, Cox's Pomona, Citron Apple, Emperor Alexander, King of Pippins, Jolly Beggar, Stirling Castle, Calville Blanche, Lord Grosvenor, Court Pendu Plat, Cellini, and Newtown Pippin.

CONGRESS APPLES.

SUPPLEMENTARY to our report of the great Exhibition at Chiswick, we shall from time to time refer more particularly to some of the fruit of special interest, with the object of affording matter for instruction relative to some of the varieties that are not widely known, or which are known under different names on the one hand, or for showing the distinctness of varieties that are considered identical on the other.

The fruits now figured fairly represent two of the finest varieties at the Congress—namely, fig. 60, Lord Derby, and fig. 61, Grenadier. These are considered by some cultivators as synonymous, and it is not unlikely that one has been sold for the other. They are, however, perfectly distinct, as may be seen by the engravings. Lord Derby, one of the very finest of culinary Apples, is somewhat conical and of a dark shining green colour; Grenadier, inclining to oblate, and more sym-

metrical in outline. It also is a valuable Apple, and both of them may, without hesitation, be included in the same collection.

EXHIBITION ROSES.

IN the Journal for September 20th a correspondent writes, "That with a view to ascertain what are considered by the best growers to be the most reliable Dahlias for exhibition, I took down the names of the flowers shown at the recent Exhibition of the National Dahlia Society." It appears to me that the above is a most sensible and practical course to adopt to attain the end in view, and I would certainly recommend its adoption to the National Rose Society. Suppose every Rose shown at Kensington and the two other shows held by the Society to be noted and the results tabulated, we should get a record that would be more valuable than even the catalogue published by the Society; and as a help to beginners in enabling them to avoid purchasing Roses which never appear at a show, although having a large E before their names in the nurserymen's catalogues, it would be of much service.

I am aware that some excellent show Roses are entirely absent in exceptional years from the show tables, but to remedy this I would suggest that the record extend over three years, so as to give the dry-weather Roses a chance. If this were done I venture to predict that some quite unexpected results would follow; and whilst many an impostor would be found out, many a good, honest, and reliable Rose at present not sufficiently appreciated would receive its due share of honour.—
ASPIRO.

[We understand that the compiler of the list of Dahlias has been for some time engaged upon a similar list of Roses shown at the principal exhibitions, so that "Aspiro's" desire will probably be shortly gratified.]

THE "LOWER ORDERS" OF FUNGI.

[A paper read by Mr. Worthington G. Smith before the annual Cryptogamic Meeting of the Essex Field Club, September 29th.]

A CONSIDERABLE number of the nobler Fungi grow amongst grass in open, upland, breezy plains and pastures. Some grow in delightful glades, some by pleasant grassy roadsides, and others in well-kept gardens and greenhouses. These Fungi belong to the "upper orders," or the "upper ten thousand" amongst Fungi. I now propose to say a few words on the more numerous "lower orders" of Fungi—the outcasts and parasites of fungoid "society"—the "lower" Funguses with perverted, depraved, and seemingly unnatural tastes—the hangers-on, the inebriate, the unclean, the dwellers in nasty places, and those which live parasitically upon each other.

The student who selects the "lower orders" of Fungi for study must be prepared for a certain amount of scoffing and deision from outsiders. He must not be surprised if he hears sarcastic remarks, and he must even be at times prepared for a little self-defence.

I will notice some of the Fungi with depraved tastes first. One of these is *Agaricus nauseosus*, found by Fries growing on the carcase of a defunct wolf. Another is the group of *Agaricus ostreatus*, found by Mr. Ploughwright vegetating on the body of a stranded whale at King's Lynn. It was a curious coincidence that the "Oyster Agaric" should fix itself on a dead marine monster. A very degenerate Fungus, if indeed it be one, is the resident in the human stomach, named *Sarcina ventriculi*. Still viler are the Fungi which fix on the human head and cause ringworm, or on the foot and cause the "Fungus foot" of India. Mr. Berkeley tells us that it is no uncommon thing to find a somewhat large Fungus named *Coprinus* on the dressings of amputated limbs in hospitals. This is a horrible instance of a Fungus, whose natural pabulum is the juice of manure, turning carnivorous and living on the juices of the human body as found on the bandages of wounds. Another objectionable parasite is the Fungus of the salmon disease, named *Saprolegnia ferax*. When this low parasite cannot find noble salmon to prey upon it pays its unwelcome attentions to our common house flies, and fixes them to our window panes in autumn. Some professors insist that this parasite, like *Sarcina*, is an Alga, whilst other professors insist upon its being a Fungus, and the younger the professor happens to be the more furiously he will fight for his favourite name. Some older men, who believe with Mr. Huxley that there is no distinct line of demarcation even between the animal and vegetable kingdoms, consider it just possible that there may be no hard-and-fast line between a Fungus and an Alga, and that *Saprolegnia* may possibly occupy the debateable ground.

Most people will agree with me when I say that the Fungus named *Isaria arachnophila*, which lives on dead spiders, is possessed of a corrupt and vitiated taste. The name means, I suppose, "the Spider-loving *Isaria*," but this can hardly be from the afflicted spiders' point of view. One family of social ants, the *Mermeceidæ*, is preyed upon by an unsocial Fungus, sarcastically named *Torrubia myrmecophila*. Wasps, even in this country, are sometimes attacked whilst still alive by the *Isaria* condition of the Fungus named *Torrubia sphaerocephala*,—this means the "Round-headed *Torrubia*," or, as an anthropologist would say, the "brachycephalic." Some allied Fungi descend to still lower depths, for the pretty little sluggish unobtrusive "American blight" insect is often preyed upon by *Microcera coccophila*, or the "Coccus Lover." Even larvæ and pupæ are not safe, for three species of Fungi named *Torrubia entomorrhiza*, *T. militaris*, and *T. gracilis* attack these stages of a poor moth's life. The Chinese have a species of *Torrubia* peculiar to their own country which grows on large fat pupæ. Not to be behind the Fungus in "botanical enterprise," the Chinese carefully collect the Fungi together with the attached pupæ, and after tying them in neat bundles with silken threads sell them in their markets like small bundles of Asparagus, as choice ingredients for celestial soups and for stuffing turkeys. As Funguses and turkeys' livers go to make the delicious Strasbourg pie, it may reasonably be assumed that the Chinese dish is one of the first order. This very incomplete list of insect, caterpillar, and chrysalis-loving Fungi might be greatly extended, particularly if a lot of "friends from a distance" were included, but I have mentioned a

sufficient number to show how some of the "lower orders" of Fungi eke out a precarious existence.

One British Fungus grows upon leather, but whether it is more common at Northampton than elsewhere I have not yet heard. It does not luxuriate in large curriers' shops, or in stylish boot and shoe establishments, for the Fungus belongs to a low order. Most of the members of its family luxuriate on dung-hills, but this one sticks to leather. I have once or twice seen it on the rotten cast-off shoes of Epping Forest gipsies. A few years ago I accidentally met a grave dignitary of the Church hurrying to the Loughton railway station with a large rotten boot depending from each hand and a bundle of putrid rags under his arm. He had secured these treasures from a ditch side, and boys were making humorous remarks about the clergyman's luggage. It was not necessary for me to ask my friend what he had got, for my fungological eye detected a rich harvest of the rare *Ascobolus saccharinus* (a sweet thing in *Ascoboli*) on both boots and rags. Fungologists should always lovingly examine any old boots or rags, "ditch delivered of a drab," that they may meet with in their sylvan rambles. Old rags, boots, sacking, hampers, rotten matting, flannel, and carpeting are often prolific with cohorts of the "lower orders" of Fungi. Epping Forest was at one time rich in gipsies (properly called vagrants), but as these people gradually get "moved on" by the active verderers, old boots, horse-collars, and rags may gradually get thinned out, and *Ascobolus saccharinus* may have a bad time of it. Still, if new railways are made, and taverns, steam roundabouts, knock-'em-downs, and Aunt Sallies are erected by authority near every station, there will probably still be found plenty of old shoes, dirty rags, basketwork, and rubbish for the Fungus to fix on. On these little-esteemed objects the fungologist may find, if fortunate, the delicate *Coprinus domesticus*, *Macrosporium concinnum*, *Aspergillus roseus*, *Raphalomyces pallidus*, *Onygena piligena*, *Ailographum maculare*, *Thamnomycetes hippotrichioides*, and many other Fungi.

Old rope is often a treasure to a fungologist, therefore swings, such as prevail at Chingford, should not be too much discouraged. I have several times found *Perisporium vulgare* on pieces of decaying rope near Loughton, but *Nectria funicola* has eluded me from paucity of old rope. Everyone who has been Chingford way, especially after a bank holiday, a balloon ascent, fireworks, crackers, and scratch-backs, must have noticed the quantity of well-picked knuckle and shank bones thrown about by excursionists, who out of wise economy bring their own provisions. It is no good to look for Fungi on examples too fresh from the holiday makers' teeth, but I once saw the rare *Onygena apus* growing on an old weather-beaten Essex bone. If one is favoured by fortune a dead horse or a dead donkey may still be lighted on in the Forest, though I am bound to confess that these objects are less common now than before the city conservators commenced draining and beautifying the glades. Should an old defunct example be found let the hoofs be carefully examined, and the enterprising fungologist may be equally fortunate with myself and light on *Onygena equina*.

Before dismissing the unpleasant Fungi I must advert to such as derive their nourishment from manure-heaps and dung. Nearly all the members of some genera of Fungi literally revel in manure. *Coprinus*, *Bolbitius*, *Ascobolus*, and *Pilobolus* are notable examples. The two latter delight in the pabulum afforded by manure, and the members of the latter genus, as the name *Pilobolus* indicates, throw off their hats with rapture at maturity. It is essential for a good knowledge of fungology that the dung of different animals should be conscientiously examined. No less than twelve lovely species of *Ascobolus* grow on cow dung. Some are peculiar to this material, others are less particular, and sometimes roam to dung of the horse, deer, sheep, or rabbit; two beautiful *Pezizas* also grow on cow dung. Leaving the interesting dung-borne genus *Ascobolus*, or "ascus," or "sack-thrower," in reference to the Fungus at maturity discharging into the air innumerable transparent bladders or sacks full of spores or seeds, I may refer to *Poronia punctata*, which grows equally well on horse and cow dung, to *Cœdocephalum laticolor* on sheep's dung, to *Ascophora elegans* on fowls' dung, to *Botrytis Jonesii* (poor Jones!) on the dung of dogs and rabbits, and *Aspergillus dubius* on rabbits' dung. The two vilest Fungi are *Mucor caninus*, found on the dung of dogs (and, strange to say, cats), and the execrable *Isaria felina*, found solely on the dung of cats. Dr. Cooke was the first in his self-sacrificing researches to add this treasure to the British flora, and I well remember being present at a meeting of a London amateur scientific society when this valued possession was tenderly taken from a tin sandwich box for exhibition, to the delight and admiration of the assembled botanists. The choice specimen here referred to was lent to me, with many admonitions for its safe custody, that I might make a water-colour painting of the whole affair. I felt bound in honour to make this painting, although it was done at a little personal inconvenience; but I was ultimately repaid, for the officers of the British Museum bought the drawing for their collection of rare and beautiful objects at South Kensington.

There is, as we all know, a time for everything, and the best time for looking for and gathering *Isaria felina* is before people are up in the morning, or in the dusk of evening when but few people are about, for it must always be remembered that common people do not enter into the feelings and aspirations of fungologists devoted to the "lower orders." If the Fungus is sought for in the locality whence Dr. Cooke's example was derived a few lessons in the art of self-defence before going on the excursion may prove useful.

Leaving these Fungi, a few words may be said about some of the peculiar ones. *Dactylium oogenum* grows only inside eggs, *Dactylium roseum* inside nuts, *Coprinus radians* grows on scullery walls and ceilings, *Ascophora phycomyces* on greasy walls, *Sporotrichum fenestrale* on window glass, a large number grow on our wall papers, whether varnished or unvarnished. A *Peziza* named *P. Pigottii* is said to grow on ceilings, and other species grow in cisterns and water-butts. I once found a novelty in my own cistern, and as I could not identify it (and disliking all new species) I sent it on to Mr. Berkeley for a name. By a curious mistake Mr. Berkeley thought the prodigy had been sent by his friend Dr. Bull of Hereford, so he forthwith published it under the name of *Peziza Bullii*, with the laconic addendum of "Dr. Bull—in a water-butt." This took Dr. Bull by surprise and amused me, for I certainly had no wish for any nasty watery Fungus to be termed *Peziza Smithii*, with the humorous addendum of "Mr. Smith—in a water-butt."

Cannibalism is very common in Fungi. Amongst my drawings in the British Museum is one representing a group of *Agaricus lignatilis* growing

upon *Polyporus annosus* whilst still attached to the tree. I have also seen *Agaricus tuberosus* not only growing from the gills of *Agaricus* and *Russulæ*, but growing out of the tubes of *Polyporus squamosus*. *Agaricus Lovcianus* grows on the top of *Agaricus nebularis* whilst still alive, and a drawing of mine representing a family of the former growing on the top of an example of the latter may be seen in the Bethnal Green Museum. A sort of underground Truffle named *Elaphomyces variegatus* is preyed upon by a comparatively large Fungus named *Torrubia ophioglossoides*, whilst an allied *Elaphomyces*, named *E. granulatus*, supports a still larger parasite named *Torrubia capitata*. A Puff-ball-like Fungus named *Scleroderma vulgare* is often preyed upon by a Fungus bigger than itself named *Boletus parasiticus*. Two Fungi named *Nyctalis astrophora* and *N. parasitica* grow upon *Agaricus* and *Russulæ*. *Peziza saniosa* grows on *Thelephora sebacea*, *Peziza clavariarum* on *Clavarias*, *Peziza erythrostroma* on *Sphærias*, and *Helotium pruinosum* on *Hyxoxylon* and *Diatrype*.

I have only mentioned a few of the larger parasites and cannibals; some live on dead Fungus flesh and others on the living juices. The microscopic species are far more numerous, and these latter parasites often attack other parasites. For instance, the *Boletus* which grows on the living *Scleroderma* is often attacked whilst still alive by a sore pest of *Boleti* named *Hypomyces luteo-virens*; the *Pezizas* which attack *Clavarias* and other Fungi are sometimes eaten up by *Bactridium Helvellæ*. The list of cannibals amongst Fungi might be extended to an almost interminable length, for fungous fungivori are so common that few species are exempt from attacks.

A few of the "lower orders" of Fungi are parasitic on Lichens, as *Dothidea Piggottii*, *Sphinctrina turbinata*, four species of *Illosporium*, and others; but the Lichen subject is difficult to approach, as certain professors have of late somewhat loudly taught us that there are no such things as Lichens, but that Lichens are only Fungi involving and growing parasitically over *Algæ*. If this hypothesis is a correct one the species of *Dothidea*, *Sphinctrina*, and *Illosporium* just mentioned are parasitic on Fungi, which are already parasitic on *Algæ*. It is to be regretted that the members of this Club have few opportunities of testing the truth of the Schwendenerian hypothesis, as although unicellular *Algæ* and small Lichen-like Fungi are both extremely abundant in Epping Forest, yet the very Lichens which are said to be the Fungi of the one class, growing upon the very *Algæ* belonging to the other class, are nowhere to be found. When I printed this statement in a former report of an Essex Field Club meeting, someone, thinking to effectively silence me by proving that Lichens really could grow in London, wrote that Sowerby had once found Lichens growing on the outside of the dome of St. Paul's. This astounding statement in print temporarily paralysed me; but on referring to Sowerby's works I soon discovered that, instead of his finding Lichens growing outside the dome of St. Paul's, what he really did find was a Fungus named a *Myxogaster* growing in a gallery inside the building. I thereupon humbly wrote again, claiming to have my opponent's error corrected, and also to point out that one of the strongest advocates for considering all Lichens to be Fungi had previously taught us that all *Myxogasters* were animals and not Funguses at all. I clearly pointed out that an animal found creeping about (for *Myxogasters* do creep about) inside a church had been made to do duty for a Lichen vegetating outside the Cathedral dome! It unfortunately happened that no room could be found for my rejoinder, so the readers were left in a sort of *limbus fatuorum*. It is not so well known as it should be that there is a sort of "Salvation Army" amongst biologists, with a "General" and other paid officers, and that what these gentlemen cannot effect by argument and reason they try to accomplish by sound and fury, by the banging of the big drum, by the flaunting of banners, and by allowing (when possible) no side but their own to be heard. In conclusion I will refer to some of the Fungi given to drink.

Most Fungi are partial to moisture, but some are followers of Father Matthew, and revel in water; such are *Mitrula paludosa*, *Vibrissæ truncorum*, and some others. Hitherto the more marshy parts of the Forest have been rich in the production of the various *Agaricus* found only in wet and boggy positions. As it seems the Forest is to be gradually drained and unnaturalised, so that London excursionists may never get the polish taken off their boots, all these curious marsh denizens must ultimately disappear. Some Fungi prefer "heavy wet" of a different nature. For instance, there are two Fungi which especially attack corks of wine bottles; they bore through the substance of the cork and then attack the wine; in fact, both these Fungi practise the trick well known to wine merchants, termed "sucking the monkey." I am hardly at liberty to consider the Fungi which grow on the dregs of wine and beer as true toppers; they may be classed with the Fungus found only on spent hops, and named *Peziza theleboides*, or to the degenerate teetotaller named *Agaricus coffeatus*, which is only seen on coffee grounds. A Fungus named *Zasmidium cellare* lives almost solely in wine vaults; fortunately, however, this species has not yet "acquired the habit" of boring corks. Mr. Berkeley mentions a Fungus found in strong Madeira wine; it is a critical species, far too knowing to grow in South African sherry, in which compound it has never yet been detected. We all know how the Yeast Fungus ferments beer, and we have probably all read Sir Joseph Banks' account of the Fungus which attacked the cask of wine. The wine cellar enclosing the cask had been closed for three years; at the end of this period the door of the cellar was opened, and it was then seen that the cask had been attacked and rotted by Fungi, and that the Fungus growths had fattened on the wine as it gradually leaked from the cask. The astounded butler was literally petrified to the spot as he saw the huge wine-fed Fungi on the floor, and the empty wine cask—more than a "little elevated"—pushed up to the cellar roof on the heads of the Fungi.

Cider is sometimes attacked by *Penicillium crustaceum*, and some large and choice specimens of this Fungus, presented by me to the nation, may be seen in the public room of the Department of Botany at the British Museum, South Kensington. The large Fungi grew naturally within a sealed bottle of cider, where they still are. The non-fungological public gaze with wonder at the narrow-necked sealed bottle, and cannot imagine how such large Fungi ever got in-side-her (in cider).

ROYAL HORTICULTURAL SOCIETY.—OCTOBER 9TH.

DAHLIAS again contributed largely to the attractions of the meeting, especially the single varieties. Asters were also shown by several in good

condition, and dwarf Marigolds were exceedingly bright. New plants were represented by some notable novelties, amongst which the celebrated *Vanda Sanderiana* formed the focus of attraction, and a little crowd of Orchid-lovers was gathered round it nearly all the afternoon. Fruits, particularly Apples, were good from Great Berkhamstead, and the Vines in pots from the same firm were much admired; but the superb examples of Charlotte Rothschild Pine Apples from Mr. Nicholas proved a counter-attraction in the Fruit Committee to the *Vanda* in the Floral Committee.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. The members present were Messrs. P. Crowley, G. Goldsmith, A. W. Sutton, L. A. Killick, J. E. Lane, A. Howcroft, W. Denning, H. J. Veitch, G. Bunyard, J. Burnett, and J. Willard. A silver-gilt Knightian medal was awarded to Messrs. Lane and Son, Great Berkhamstead, for four specimens of Vines in pots—two specimens of *Alicantes* with a dozen bunches each, well-coloured Foster's Seedling with about the same number of bunches, and Black Hamburg with rather more, the bunches small and berries also. Bunches were shown of Gros Colman large and well coloured; Barbarossa, also fine in bunch and berry; Muscat of Alexandria well ripened; Black Prince, even and deep colour; Trebbiano, very large bunches; Alicante, fine in bunch and berry and superbly coloured; Black Hamburg and Mrs. Pearson, both in good condition. About 100 varieties of Apples in fine condition were also shown, mostly of good form and colour. Lane's Prince Albert was particularly notable amongst the newer varieties, branches showing the prolific character being also exhibited. Six dishes of Pears were shown, together with Belle de Septembre, Grand Duke, and Wyedale Plums. G. F. Wilson, Esq., Weybridge, sent some berries from a Black Hamburg Vine grown in a cold orchard house. They were large and of good flavour.

A bronze Banksian medal was awarded to Mr. Nicholas, The Gardens Castle Hill, South Molton, Devon, for three very handsome fruits of Charlotte Rothschild Pine Apple, two weighing 8 lbs. each, the other 7½ lbs., magnificent specimens, even and superb in form. A Smooth Cayenne, weighing 8 lbs. 2 ozs., was also shown, similarly handsome in appearance and colour. Mr. E. Nelson, Dunmore House, Staines, sent fruits of Apple Stanwell Reinette, a neat variety, of moderate size, yellow shaded with red on one side. Mr. J. Booker, Chatteris, was awarded a vote of thanks for some fine examples of Warner's King Apple. Mr. J. Walker, Thame, sent three dishes of Apples, Hollandbury and Wall's Seedling being very fine, the last very richly coloured. Mr. W. Fowle, gardener to Sir H. Mildmay, Bart., Dogmersfield, Hants, showed six specimens of King Edward Apples, very large, and high coloured on one side. Mr. J. Perkins, The Gardens, Thornham Hall, Eye, Suffolk, sent fruit of Victory of Bath Melon finely ripened. Mr. E. W. Dance, The Gardens, Gosfield Hall, Halstead, sent samples of a seedling Apple, very attractive, yellow, streaked and spotted with bright red.

Mr. J. Muir, The Gardens, Margam Park, Taibach, South Wales, was awarded a first-class certificate for a new Vegetable Marrow named Muir's Hybrid. It is of moderate size, about 6 inches in diameter, globular, and very prolific. Mr. Goldsmith, Hollands, Tonbridge, sent six dishes of Pears, Doyenné Boussoch being very fine; six fine Onions, Reading Improved, were also shown, for which a cultural commendation was awarded. Mr. R. Dean, Ealing, sent fruits of a fine new yellow Tomato named Dean's Golden Queen, very even; a new red variety, a cross between Stamfordian and Green Gage, named Dean's Red King; it is also an even and richly coloured variety. Mr. Dean also exhibited eleven dishes of new English Potatoes raised at Bedfont, and comprising Sunrise, Alderman, Chancellor, Prime Minister, Cosmopolitan, Standwell, The Dean, Recorder, Cardinal, and Midsummer Kidney. Mr. E. Holmes, Lichfield, sent specimens of a Crab named La Beauté d'Automne. The fruits are about 1 inch long, egg-shaped, and orange-coloured with a tinge of scarlet. Mr. J. O. Cooper, Calcot Gardens, Reading, sent a number of seedling Apples that were not found to be of special merit. Six varieties of Nuts were also shown, one, the Duke of Edinburgh, a very large Filbert, being awarded a first-class certificate. Messrs. J. Veitch & Sons, Chelsea, exhibited a large collection of Endive, comprising Batavian, Improved Curled, Moss Curled, and White Curled; a number of Savoys, and about thirty varieties of Tomatoes, representing all the different types, from the small Currant-fruited to the large President Garfield and Stamfordian.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. The members present were Messrs. T. Moore, J. Laing, H. Bennett, W. Bealy, J. Wills, Shirley Hibberd, H. Eckford, G. Duffield, J. Fraser, H. Ballantine, J. Dominy, H. Turner, J. Douglas, H. Cannell, J. McIntosh, J. James, F. R. Kinghorn, and H. Ebbage.

A bronze Banksian medal was awarded to Messrs. H. Cannell & Sons, Swanley, for a choice collection of Asters—*Amellus major*, purple; *longifolius formosus*, pink; *Formosissima*, deep purple; *novæ-anghæ*, rose; *polyphyllus*, white; and *lævis*, mauve, being the best. A vote of thanks was adjudged for flowers of *Dahlia Ariel*, a free white variety of the Glare of the Garden type. Several plants of *Sempervivum arboreum*, var. *variegatum* were notable. A bronze Banksian medal was awarded to Messrs. Rawlings, Bros., Romford, for a large and beautiful collection of Show, Fancy, and Pompon Dahlias, including a large number of fine varieties. Mr. Woolford, gardener to W. Lee, Esq., Downside, Leatherhead, showed plants of *Trichocentrum orthoplectrum*, with a flower like a *Miltonia*, the sepals and petals brownish and narrow, the lip bright crimson. *Oncidium incurvum album*, with a large panicle of small white flowers, was very attractive; also a plant of *Miltonia Bluntii*, with one flower, the sepals and petals narrow, creamy, with pale purple blotches, and a mauve and purple lip. The grand *Vanda Sanderiana*, from the same garden, was certificated, and is described below. Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, was adjudged a vote of thanks for a collection of Orchids, comprising *Oncidium Forbesi*, flowering very well; *Vanda cærulea*, with two fine spikes; *Cypripedium Spicerianum*, *Oncidium varicosum*, Rogersi, and *Cattleya Gaskelliana*. A plant of *Anætochilus argenteus pictus* was also shown in fine condition. A vote of thanks was accorded to Mr. Turton, The Garden, Maiden Erleigh, Reading, for three well-grown plants of *Celosia pyramidalis coccinea*. Messrs. Cross & Steer, Salisbury, sent plants of a neat double white Perpetual Carnation named Louisa Ashburton. Mr. Wilson, gardener to H. M. Pollett, Esq., Fernside, Bickley, was awarded a vote of thanks for flowers of *Zygopetalum Mackayi* and *Oncidium Forbesi* cut from a spike with thirty-four flowers.

Messrs. Veitch & Sons, Chelsea, exhibited several new plants, for which

certificates were awarded, the most notable being the famous *Nepenthes Northiana*, which was introduced by the firm a short time since. Mr. W. Bull, Chelsea, had some new plants. The elegant white variegated *Panax Victoriae*, the graceful *Calamus ciliaris*, *C. sikkimensis*, *Phoenix rupicola*, and the rich green rugose-leaved *Crithmum spendidum*. *Eucharis Sanderi* was included, but is described with the certificated plants. Mr. Eckford, The Gardens, Boreatton Park, Shrewsbury, sent plants of a white-flowered Zonal Pelargonium, the bright rosy-scarlet *Begonia nitida coccinea*, *Fuchsia atro-purpurea* with dark purple foliage, and two seedling Dahlias, one bright yellow, and the other white streaked with crimson. A cultural commendation was awarded to Mr. Chamberlain, gardener to G. F. Wilson, Esq., Weybridge, for cut spikes of *Odontoglossum tigrinum*, *Oncidium unguiculatum*, and *Odontoglossum Alexandrae*, the flowers in each case being large and of good colour.

Mr. T. S. Ware, Tottenham, was awarded a bronze Banksian medal for a charming collection of seedling Dahlias, very bright and extremely fresh. The best of the varieties shown were the following:—Nora, bright pink; Negress, dark maroon; Lucy Ireland, rich crimson; *lutea grandiflora*, bright yellow; Scarlet Defiance, bright scarlet; Mrs. Burbidge, violet purple, fine; Indian Yellow, distinct shade; Mrs. Castle, rosy scarlet, very distinct shade; Freedom, dark scarlet, star-like; B. Barkaway, scarlet, edged with orange; Beauty of Uplands, scarlet, tipped with bronzy yellow; Victory and The Queen, pure white; and George Clarke, one of the Paragon type, deep maroon, edged with purplish crimson, very beautiful. Mr. R. Dean, Ealing, exhibited a number of plants of dwarf Marigolds *aurea floribunda*, a bright yellow form, and some darker varieties. The strain was commended by the Committee. The plants were dwarf and very free, and were lifted from the ground a few weeks ago. Flowers of the single and double *Chrysanthemum coronarium* were also shown.

First-class certificates were awarded for the following plants:—

Vanda Sanderiana (W. Lee, Esq., Downside, Leatherhead).—This magnificent Orchid formed the great feature of the meeting, the plant shown having five sturdy growths, bearing two spikes, one with two flowers and the other with eight flowers. These are of great size—5 inches across one way, and $3\frac{1}{2}$ to 4 inches in diameter. The two lower sepals are nearly circular, 2 inches in diameter, of a yellowish buff ground colour, veined and reticulated with a reddish purplish hue. The upper sepal and the two petals are similar in shape and colour, smaller than the sepals, more ovate in form, and of a delicate soft pink colour. The lip is small, the tip recurved, of a velvety chocolate hue. This species was introduced by Messrs. Sander and Co. about a year ago, and this plant is, we understand, the first that has produced flowers, and is probably the largest in cultivation.

Crinum ornatum (Bull).—A plant with two spikes, each bearing over a dozen flowers, was shown and much admired. The petals are narrow, white, with a broad stripe of dark rose down the centre of each, and the free-flowering habit of the plant renders it particularly valuable.

Eucharis Sanderi (Bull).—A neat and very distinct species, the flowers pure white and smaller than the common species, but the corona, which is so prominent in that, is quite lost in this, or diminished to a plate adnate to the tube of the corolla. The petals are ovate, and about 1 inch broad.

Medinilla Curtisi (Veitch).—A Sumatran species, very distinct, and resembling the *Rogersias*. The leaves are ovate, sessile, clasping the stem, 3 to 4 inches long and 2 broad. The flowers are white and wax-like, in terminal and axillary clusters, on reddish peduncles.

Nepenthes Northiana (Veitch).—A plant of this celebrated species was shown with six immature pitchers, the largest, however, giving some idea of their beauty when fully grown. The inner surface is beautifully mottled with crimson on a lighter ground, and the outer surface is also distinctly spotted with crimson, the mouth being striped with crimson and green. Dried pitchers nearly a foot long were shown with the plant.

Adiantum Weigandi (Veitch).—A graceful dwarf *Adiantum* of *A. cuneatum* habit, with rather larger pinnules and looser fronds. The pinnules are shorter, so that the fronds have a more narrow appearance.

Chrysanthemum Mons. Dufour (Cannell).—A distinct variety of the Japanese type, with narrow florets, the margin revolute and bright rosy crimson. A plant was shown indicating its free and early habit of flowering.

Begonia Mons. Duvivier (W. Bealby, Roehampton Park).—A dwarf compact tuberous variety of the *B. Veitchii* type, but taller-growing, with globular brilliant scarlet flowers, very full, and $2\frac{1}{2}$ inches in diameter.

HARDY FRUIT GARDEN.

Preparations for Planting.—Push on preparations for planting, so that all may be in readiness by the end of the month. Omit no detail, however trifling. Make stations 6 feet square and 2 feet 6 inches deep, each connected by 2-inch pipes with the nearest drain, 6 inches of rubble at the bottom, 2 feet 6 inches of soil above it, pressed by trampling closely, and raised 6 inches above the surface to allow for settling down. If fresh turfy loam is used examine it closely, and if it is deficient in small stones add a third of charcoal, coal ashes, or mortar rubbish to prevent its settling down into too compact a mass, as it is very liable to do as the grass roots decay. Difficulties often arise in procuring soil for the stations; do not forget, therefore, that soil which will grow good vegetables will grow fruit trees. Poor loam may be rendered suitable by a liberal mixture of old manure or road scrapings. Some of the best soil we ever used for stations was a heap of pond mud mixed with lime. Put a stake for fastening the tree to, and a label for naming in readiness at each station. The operation of planting will be explained fully in our next calendar.

SELECTIONS OF THE BEST FRUIT FOR A SMALL GARDEN.—*Six Apples for Dessert.*—Early Julien, Worcester Pearmain, Irish Peach, Margil, King of Pippins, Cox's Orange Pippin. *Six Apples for Cooking.*—Duchess of Oldenburg, Keswick Codlin, Warner's King, Stirling Castle, Small's Admirable, Tower of Glamis. *Twelve Pears.*—Williams' Bon Chrétien, Fondante d'Automne, Doyenné du Comice, Comte de Lamy, Knight's Monarch, Dana's Hovey, Comte de Flandre, Glou Morceau, Jewess, Winter Nelis, Bezi Vact, Easter Beurré. *Six Dessert Plums.*—Green Gage, MacLaughlin's Gage, Transparent Gage, Reine Claude de Bavay, Coc's Golden Drop, Blue Impératrice. *Four Cooking Plums.*—Early Rivers, Victoria, Belle de Septembre, Cluster Damson. *Six Peaches for Open Walls.*—Early Beatrice, Rivers' Early York, Dr. Hogg, Grosse Mignonne, Belle Bauce, Walburton Admirable. *Six Nectarines for Open Walls.*—Advance, Lord Napier, Stanwick Elruge, Pitmaston Orange, Balgowan, Pine Apple. *Four Cherries.*—Early Purple Gean, May Duke, Kentish, Morello. *Two Apricots.*—Kaisha, Peach. *Two Figs.*—Brown Turkey, Brunswick. *Currants.*—Red Dutch, Victoria, White Dutch, Lee's Prolific Black. *Gooseberries.*—Early Sulphur, Green Gage, Warrington, Champagne Red. *Raspberries.*—Prince of Wales, Yellow Antwerp. *Strawberries.*—Vicomtesse Héricart de Thury, President, Dr. Hogg, Helena Gloede. *Nuts.*—Cosford, Pearson's Prolific. In this selection we include only such sorts as we have proved to be hardy, sure croppers, and of high excellence in size, flavour, and form of fruit.

SELECTION OF THE BEST FRUIT FOR A LARGE GARDEN.—*Dessert Apples.*—Early Julien, Early Strawberry, Red Joanetting, Mr. Gladstone, Kerry Pippin, Worcester Pearmain, Yellow Ingestrie, Margil, King of the Pippins, Hubbard's Pearmain, Pine Golden Pippin, Cox' Orange Pippin, Pine Apple Russet, Golden Russet, Melon Apple, Old Nonpareil, Cornish Gilliflower, Sturmer Pippin. *Kitchen Apples.*—Duchess of Oldenburg, Keswick Codlin, Lord Suffield, Mank's Codlin, Nelson's Codlin, Wormsley Pippin, Cellini, Warner's King, Loddington, Stirling Castle, Ecklinville Seedlings, Small's Admirable, Cox's Pomona, New Hawthornden, Tower of Glamis, Alfriston, Golden Noble, Blenheim Pippin, Northern Greening, Striped Beefing, Dumelow's Seedling, Hanwell Souring, Gooseberry.

PEARS.—Summer Doyenné, Citron des Carmes, Jargonelle, Williams' Bon Chrétien, Summer Beurré d'Aremberg, Beurré de l'Assomption, Beurré d'Amanlis, Colmar d'Été, Desiré Cornelis, Souvenir du Congrès, Fondante d'Automne, Fondante de Charneau, Madame Treyve, Marie Louise d'Uccle, Gratioli of Jersey, Doyenné du Comice, Comte de Lamy, Knight's Monarch, Seckle, Urbaniste, Maréchal de Cour, Général Todtleben, Dana's Hovey, Comte de Flandre, Thompson's, Forelle, Beurré Superfin, Huyshe's Victoria, Glou Morceau, Josephine de Malines, Jewess, Zephirin Gregoire, Bezi Vact, Winter Nelis, Easter Beurré, Madame Millet.

DESSERT PLUMS.—Green Gage, Purple Gage, Mac Laughlin's Gage, Transparent Gage, Reine Claude de Bavay, Bryanston Gage, Washington, Denniston's Superb, Jefferson, Coc's Golden Drop, Blue Imperatrice, Kirk's. *Cooking Plums.*—Early Rivers, Early Orleans, Victoria, Lafayette, Prince Englebert, Diamond, Automne Compôte, Belle de Septembre, Cluster Damson.

CHERRIES.—Early Purple Gean, Early Rivers, Belle d'Orleans, Empress Eugénie, May Duke, Black Tartarian, Governor Wood, Archduke, Reine Hortense, Transparent, Bigarreau, Belle Magnifique, Elton, Late Duke, Kentish, Morello.

PEACHES.—Early Beatrice, Early Alfred, Rivers' Early York, Dr. Hogg, Grosse Mignonne, Royal George, Belle Bauce, Barrington, Walburton Admirable.

NECTARINES.—Advance, Lord Napier, Stanwick Elruge, Downton, Rivers' White, Pitmaston Orange, Balgowan, Pine Apple.

MISCELLANEOUS FRUIT.—*Apricots.*—Kaisha, Large Early. Moorpark, Peach, Orange. *Medlars.*—Dutch, Nottingham. *Nuts.*—Cosford, Pearson's Prolific, Cob, Red Filbert. *Currants.*—The same as for small gardens. *Gooseberries.*—To those named for small gardens add Ironmonger, Keens' Seedling, Yellow Champagne, Pitmaston Gage, Roaring Lion, Crown Bob, and Green Walnut. *Raspberries.*—Prince of Wales, Belle de Fontenay, Carter's Prolific, Yellow Antwerp. *Strawberries.*—Black Prince, Vicomtesse de Thury, Marguerite, Lucas, James Veitch, Sir Charles Napier, Dr. Hogg, Loxford Hall Seedling, Helena Gloede. *Figs.*—Brunswick and Brown Turkey are the only really good sorts on open walls; Grizzly Bourgasotte may be added, as it generally ripens a few of its delicious fruit.

FRUIT-FORCING.

FIGS.—*Trees for Early Forcing.*—Forced Figs early in the season when well ripened are a valuable addition to the dessert. Under certain conditions the management of the Fig is not difficult; it requires heat, moisture, and good living when growing, bears best under restricted root-space, and needs a sound calcareous loam, crushed bones, and decayed manure, and can be forced most satisfactorily in a light well-ventilated house, a span being most suitable. The finest varieties for cultivation under glass are Brown Turkey, Negro Largo, and White Marsilles, as they produce good crops of the largest and best flavoured fruits. Should the trees for starting early in December for a supply of ripe Figs in May have to be purchased, they should be selected from a reliable stock with clear single stems, and well furnished with shoot-jointed side shoots and spurs. It is also necessary that the trees be thoroughly established in pots. When received, place them in a cool house where they can have full ventilation by day, also night, if frost does not prevail. This is far preferable to placing them outdoors to be deluged by heavy

rains and to be acted on injuriously by wind and frost before the large leaves have completed their functions and the growth is well ripened. It is futile expecting a profitable crop of Figs from trees in pots or otherwise not having the wood matured, and for early forcing it is essential that the trees be grown in heat so as to make and perfect an early growth. Water the trees above referred to moderately, but keep them rather dry than too wet until the leaves turn yellow and commence falling, when the pots may be placed close together and protected, if frost is not excluded from the house, with dry fern or litter until the time of their being placed in heat. Fig trees, unlike some other kinds of fruit trees, improve with age, which applies more particularly to trees in pots, and these ought, when forced early, to be plunged in some mild fermenting material into which the roots can run as the growth increases. Oak or Beech leaves, from their mild and durable heat, answer better than either tan or stable litter, and afford a constant supply of nutriment at the most critical stage of growth, when a check from want of water is likely to cause the first crop of fruit to fall.

PINES.—*Re-arranging the Plants.*—Plants which are likely to require similar treatment through the winter months should be brought together without much further delay, and assign those which are fruiting, or likely to do so shortly, a place where a sufficient heat is available under the most adverse weather, and where they will derive the full benefit of sunshine and light. Successional plants should be left to themselves in a house or pit that is not likely to have a very acrid atmosphere, but where moderate moisture is at all times present, with a temperature of about 60°. Young stock are best kept in health through the winter in light pits having fermenting materials in them, as these afford conditions favourable to vegetation, but it is necessary that the watering be judicious.

The Fermenting Beds.—Now, or as soon after this as possible, the beds should be seen to, adding fresh material to those that require it, and only making up fresh beds when absolutely necessary, paying particular attention afterwards to the heat generated in them, as a superabundant amount of it at the roots, now that these are in an active state, would be quickly injurious to the plants, and upset future calculations. Continue the temperature indicated in our last calendar, only in cold weather it may fall a few degrees; and as this may shortly be expected let preparations for covering at night be completed, nothing being so economical in fuel, and the necessity for not heating the pipes so highly is very beneficial to the plants.

CUCUMBERS.—*Treatment in Houses.*—Plants in full bearing, more especially those that have their roots in a somewhat confined space, should receive copious supplies of weak tepid liquid manure. Examine the plants at least once a week in order to stop the shoots one joint beyond the show of fruit, to thin out exhausted growths and where likely to be too crowded, training the growths evenly over the trellis. Maintain a sweet growing atmosphere. Cut the fruit as soon as it attains a suitable size for table, and place them with the neck end in a saucer in which there is about an inch of water in a fruit or other room from which frost is excluded until they are required for use. The plants being freed of the strain upon them for food in the larger fruit will have it concentrated on the smaller fruits, and this should be persisted in during the fruiting period of the plants.

Insects.—Should green or black aphides appear fumigate moderately two or three evenings in succession, having the foliage dry, but the other surfaces in the house must be well damped to maintain a genial atmosphere. Syringe well the following morning, and ventilate freely if the weather permits. Red spider is not often much trouble at this season, but if it be present dress the hot-water pipes thinly with a mixture of flowers of sulphur and skim milk. This is also good against mildew, but the best remedy for the mildew is to dust the affected parts with flowers of sulphur. Canker must be subdued by rubbing quicklime well into the affected parts, repeating as needful.

PLANT HOUSES.

Heaths and Epacris.—Plants that have been standing outside, or have had the protection of cold frames or old lights merely for the sake of shooting off heavy rains, should now be housed. Assign them a light airy position, which will assist to ripen them more thoroughly, and they will bloom better in consequence. Light and air are of the utmost importance, especially with those batches that flowered late and are required for the same purpose again. These plants often flower sparsely, thus causing disappointment because they are not housed soon enough. It is a mistake to leave them in frames until the beginning of winter. Water them carefully, or injury will soon follow; in fact, the plants should never suffer by want of water, and need even more attention in this respect now than has been necessary in the summer, during which period they are not so liable to suffer by being overwatered, as is the case at this season of the year.

Chrysanthemums.—Plants intended for early flowering should be housed without delay, and will even bear gentle forcing if wanted as early as possible. Such varieties as Elaine, James Salter, Early Red Dragon, Sœur Melanie, Mrs. Rutter, and La Coquette are amongst the best for early flowering. If a batch is given a little heat and another lot of plants placed in a cold house a succession of flowers will be maintained. Those grown for late blooming must be kept outside as long as possible; but they must have a sheltered position, for heavy cutting winds do them much injury at this season of the year. Any temporary structure is useful where the plants can be protected from bad weather and early frosts, and then placed outside during the day when fine, and also during mild nights. Eradicate aphides as they make their appearance with tobacco powder, and wash the plants if mildew makes its

appearance with softsoap water in which a little sulphur has been mixed, and protect them from heavy rains after it has been applied until the mildew has been destroyed.

THE BEE-KEEPER.

SEASONABLE NOTES.

Cold wet weather and shortened days assure us that summer has gone, and with it the honey season of 1883. The now completed harvest must be differently characterised for different parts of the United Kingdom. There have been local periods of plenty and local periods of famine. While some parts have yielded an income above the average, some have given the bees hardly sufficient to keep them alive; but taken as a whole, the season may be looked upon as a fairly remunerative one to the bee-master.

After a long absence from home we return to find that our own bees, situated near an abundance of Heather, have evidently made good use of the late fine weather. The condition of the hives proves that their inmates have "improved each shining hour." Although supers put on before we left home are not all finished off as we should have liked to have seen them, still many sections have been completed. Others, well filled with honey, but not sealed completely, will be very nice for present consumption. Nearly every hive has given a surplus, all from the Heather. Some of these hives had already given supers from the early harvest, which was principally gathered from fruit trees, wild flowers, and Bean and Clover blossoms. These supers were filled prior to July 20th. Our best bar-frame hive has yielded altogether 55 lbs. of super honey—i.e., 40 lbs. in sections over the hive, and 15 lbs. of good white comb, taken from the back of the hive, outside a queen-excluding dummy; the best straw skeps gave us a super of 18 lbs. of sections. Every hive had stored more honey than was needed for wintering, some easily sparing frames of sealed honey from 10 lbs. to 20 lbs. weight. These frames of honey often contained pollen also, and were put to a good use.

We have inquired for stocks of bees which were about to be "taken up." Even in the midst of enlightened bee-keepers, after hearing lectures on the humane system, and after attending bee-tents at county shows, there are some who will still burn their bees, unless someone rescues them by driving and gives the bee-owner (we cannot say bee-keeper) a shilling a hive for saving them. We soon heard of some bees which were doomed—the owner did not wish wantonly to put them over the sulphur pit, but he "hadn't time to see to 'em," and was very glad for us to save their lives. So we drove two very strong colonics—strong as to the number of bees but with very little honey. The queen of one we caged and gave to a hive which was queenless, after well scenting the bees and queen. The bees of the driven hives were united, and a bar-frame hive stocked with them upon five of the frames taken from our hives, and an empty comb in the middle. This has made a very good stock, and we have not had to cut up and run down the honey from the brood combs, work we always dislike. Another colony will be made to-morrow with two other stocks of bees otherwise doomed.

We have before pointed out the great mistake made by old-fashioned bee-keepers in allowing their hives to multiply too much in one season. Swarms and casts and virgin swarms and colts are constantly pointed out to us with much pride. A goodly row of skeps, thirteen in number, was yesterday shown us as a grand result of the season's bee-keeping. The owner had only four when we visited his garden in the spring. We were not thanked for our advice when we pointed out that if only the prime swarms had been kept and the rest returned, a better result as to weight of honey would have been realised. No, he did not like to meddle with the bees, they knew best themselves what was the thing to do. The fact is that the whole of the short summer's weather had been taken up in preparing for swarming or in recruiting strength after swarming, and the harvest was lost. This man will "take up" his bees after hopping is over, which means about the 8th of October, and by that time there will not be sufficient honey left in the skeps to pay him for the trouble. So called "swarms" are already heard of in the district, a sure sign that bees are nearly starving, and rushing in dismay from their poverty-stricken homes. A correspondent in the Journal of last week marvels at the sight of a swarm of bees in September. It is indeed a very sad sight, and tells a tale of coming distress among poorly-provided stocks during the hard weather which is fast approaching. It is too late to remedy this state of things now by feeding with syrup with any certainty of success. Nights are cold, and the bees are more inclined to cluster closely for warmth than to mount for syrup. Should any reader have his hives so spread out as to numbers of stocks and thinned down as to strength of individual

colonies, his only chance of carrying any through the winter is to unite the bees of the lightest hives to those of the heaviest, and to feed up to 20 lbs. weight rapidly and at once, if the bees will take it; otherwise to put barleysugar or candy-eake over the feeding hole, with a warm covering over the food early in the new year. There is danger ahead even should weather permit the bees to store sufficient syrup. Should such cold weather set in as to prevent the bees from sealing up the stores, the presenee of a quantity of liquid food in hives is liable through fermentation to cause dysentery later on, when the bees feed on the unwholesome food. But if the weather be mild there is yet time for the syrup to be sealed over. A little of the solution of salyelic acid added to the food will greatly assist in preserving it pure and wholesome. There are some bee-keepers who are advoeating the use of candy-eake or meal-eake alone to carry bees through the winter. We would rather move earefully in this experiment. Our strongest stocks have often been those fed up on syrup the previous autumn, and assisted in spring with farinaeous food. We much doubt whether eandy-eake would remain the whole winter in a sufficiently dry and hard condition to be safe in the hive in close proximity to the elustering bees.—P. H. P.

* * All correspondenee should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (R. M.).—Our "Garden Manual" contains concise instructions on the cultivation of all kinds of hardy fruits in the open air, its price by post being 1s. 9d. Pearson's "Orchard Houses," which will be useful to you, can also be had from this office, price 1s. 7½d. Mr. Rivers publishes useful works of the kind you indicate, and of which particulars can be had by writing to Sawbridgworth, Herts. All the subjects you mention are treated of in the *Journal of Horticulture*.

Heating Melon Pit (J. T. S.).—For a pit 8 feet wide and the same in height at the back two 4-inch pipes will be sufficient for the production of late Melons, the flow pipe to be conducted along the front of the pit for top heat, the return in a chamber below the bed. You would not act unwisely by leaving a couple of sliding shutters in the wall, so that a portion of the heat from the return pipe could pass into the house if needed. The depth of soil depends very much on its texture and the attention given in watering; but a foot in depth in a bed 2 feet or 2½ feet wide we should find ample for supporting the plants and crops. The plants must first be placed on hillocks, adding more soil from time to time as the roots protrude, until the whole is made level and firm.

Fixing Hot-Water Pipes (Idem).—For celerity and simplicity there is no plan to equal that of using indiarubber rings. One of these is placed on the end of a pipe and pushed into the socket of the other. The joint is then watertight; but for insuring stability the joints should be completed with Portland cement—that is, assuming the pipes are to be permanently fixed. Considering their durability the rings are not expensive. You can ascertain the price from an ironmonger.

Vine Wood (Idem).—The portion you have sent is weak but fairly well ripened, and the eyes are prominent. Such wood can only produce small bunches, but the berries may be of good size and quality. You had better not prune too closely. Please send fresh examples of Ferns, and if possible with fructification, and we will endeavour to give the names.

Mildew on Roses (S. Carlisle).—Only three weeks ago we published the following in answer to a correspondent, but you do not appear to have observed it:—"Try mixing the sulphur in a solution of soft soap and apply with a syringe; if this fails try Ewing's mildew composition. Mr. Bardney prevents mildew attacking Peach trees and Roses by syringing with a solution of soft soap made as follows:—A lump of soft soap (about 2 lbs. or so) is placed in a saucepan and boiled for twenty minutes; this is placed in a large pot and mixed with five or six gallons of water. About half a pint of this solution is placed in an ordinary large watering-can full of water, and used every time the trees and Roses are syringed. Not a vestige of mildew is seen on the foliage, and the water does not injure the petals of the Roses. See also what Mr. Bardney says on page 269 in our issue of the 27th ult." Two ounces of soft soap will be sufficient in a gallon of water, and as much sulphur may be added as will make a mixture of the consistency of thin cream.

Heating Small Greenhouse (G. S.).—We have no doubt that the method

shown in your sketch will answer very well, provided the return pipes are nowhere lower than the bottom of the boiler. It will be essential to have an air pipe at the highest point of the pipes, and a feed pipe to enter near the bottom of the boiler. You will find methods of heating small greenhouses in our advertising columns, all of which are good, and we are quite unable to recommend any one of them as the best for your particular case. You can obtain particulars from the makers and judge for yourself, as the question of cost can only be determined by purchasers.

Propagating Evergreens (G. Edwards).—The present is the time for inserting cuttings of evergreens. Select short-jointed and firm growths of the present year, severing them with a hcel of the last year's wood, and after trimming off the leaves insert the cuttings two-thirds of their depth in gritty or sandy soil. The best plan is to dig trenches, as if for Box edging, a foot apart, placing the cuttings in them 6 or 8 inches asunder, levelling in the soil and treading it firmly about them as the work proceeds. The evergreens you name are very liable to be destroyed by rabbits. Common Rhododendrons are better where these animals abound, and seedlings can be purchased cheaply. Hollies are useful, and are raised both by cuttings and from seed. Young succulent growths of evergreens are of no use for the purpose in question, as not one in a hundred of such cuttings will emit roots.

Planting and Manuring Red Currants (Antwerp).—If nothing is to be grown on the land but the Currants, and the plants be small, undoubtedly it will be better only to apply the manure where the roots will find it, adding more as needed; but we should imagine that a better plan would be to manure the whole land, and raise some other crop between the bushes till the latter gained strength and dimensions to fill the whole ground. If your subsoil be free, and water does not stand long after rain, putting in drains will not be necessary; but if the soil is heavy and water does not pass away readily, then by all means drain. If the grass land be worked in the way you mention, and be liberally manured, success with Magnum Bonum Potatoes is not only possible but very probable.

Planting Vines (Idem).—Not knowing the circumstances of your case we are not in a position to give a categorical reply to your questions. If the Vines were planted in a good border and the canes trained thinly to a wall having a southern aspect so that the canes would mature, we can see no objection to your carrying out your project in building a house over them; but if they must be planted in the open, to be afterwards covered with a span-roofed house, they would be liable to so many vicissitudes, such as laceration by the wind and a sunless season preventing the wood ripening, and also to injury in erecting the house, or at least they would obstruct the workmen, and so render the building more costly. Taking all this into consideration there is risk of your losing more than you would gain in carrying out your plan, and under such circumstances we should hesitate in adopting it.

"Spiregeponecia and Francois Abeculator" (H. S. P.).—It is possible that the plants you refer to under the above names may be *Spiræa japonica* and *Francoa appendiculata*. If that be the case the following methods of culture will suit them. The *Spiræa* is best grown in a pot in a cool house or frame, employing substantial loam and leaf soil with a little manure and occasional supplies of liquid manure when growth is advancing. If the plants are stored in a cool frame they can be introduced at intervals to the forcing house and obtained in bloom much earlier than usual, a supply being maintained over a long period by this means. They may also be planted in good soil in the open garden, and taken up and potted as required. The *Francoa* can be either grown in the border or in pots like the former in a cool house, where its flowers prove very useful. Good turfy loam, not too heavy, with sand and leaf soil in moderate proportions, form a suitable compost.

Orange Trees Unhealthy (Inquirer, Ireland).—An application of lime water would not have the good effect you anticipate. Defective root-action is the chief cause of the unsatisfactory condition of the trees, and undoubtedly it would be better if you could prevent the temperature of the house falling so low in the winter. You can do little to them now, but may improve them in the spring, and in the meantime avoid overwatering. As soon as signs of fresh growth are apparent we should dig out the soil from the tubs quite to the bottom, and remove it as near to the stems as possible without materially disturbing, or at least not injuring, the roots. We have seen much more than half the soil thus removed, and by adding fresh, such as turfy loam and a liberal admixture of crushed charcoal, bones and wood ashes, the roots being carefully placed in this, and the whole made as firm as the soil not removed, water being judiciously applied, and old trees were made young again. It does not at all follow if the roots are few and the tubs large that they should be filled at once with soil; but the soil may be supported with a wall of turves several inches from the sides of the tubs, precisely on the principle of making a Vine border in sections. By adopting this plan and keeping the plants as warm as possible in the spring, syringing freely in fine weather, and keeping the foliage scrupulously clean, the trees will improve. The surface soil immediately round the stem should also be removed, and all dead and dying branches cut out; indeed, as soon as roots take possession of the fresh soil rather close pruning would result in stronger and healthier growths.

Vine Manure (Kirby).—With not a word about the kind of soil you have, how and when you made up your border, and the manner of manuring it since, we are not in a position to say whether the mixture you name would be of any benefit or not. In making up Vine borders it is usual to add bone, and it is usual afterwards to feed with liquid manure made from guano. If you have done as other good Grape-growers do it may well be doubted if your mixture would do the slightest good. But if you have never given any bones, never used manure rich in phosphate, and especially if your soil is naturally poor, it might do good. You can hardly go wrong in forking in the lime you name, and, if manure is needed, bone ash and bone meal are among the most valuable phosphates. If lime is plentifully present in the soil, as it will be if you carry out your programme, the "dissolved bones" will no sooner be added than they will cease to be "dissolved," and, as the other phosphates will be cheaper, and, in your case, equally effective, you may save that item. But 42 lbs. of phosphate to 2 lbs. of potash salts is an unequal proportion of ingredients, especially if you consider that Vines want more potash than phosphate. Of course we cannot guess whether your soil is rich or poor in potash, or indeed anything else; but we should mix the

bone material and the potash salts in equal quantities, and give as much once a year as you propose doing four times. 2 lbs. a year of your mixture to the yard is far too much—a quarter of the amount is enough. Neither would we sprinkle such over the surface and attempt to water it in, but fork it into the surface. So far from an application when the fruit is ripe being stored in the Vine and branches, and causing a strong start in spring, not a very great deal of one applied early in spring will get promoted so rapidly. As for the sulphate of ammonia, it may be applied at the time you mention and watered-in with benefit, but in greater quantity than you name. If a thorough drenching be given almost an ounce per yard may be given. But are you sure you know where the roots are? It is not enough to manure the border—the manure must be where the roots can reach it. "Single-handed" will devote a chapter to the explanation of terms.

Grapes Decaying (T. A. D.).—Some of our correspondents take care when seeking for information to state as clearly as they can the circumstances of their case, and narrate briefly the practice they have adopted, and which has resulted in failure. In nine cases out of ten such persons indicate the cause of failure, and we are able to suggest a remedy, if one is known. Other persons merely jot down a result without giving a hint of what may have led to it, and—naturally to them, we suppose, but strangely to us—expect to receive a satisfactory reply. We can only suggest in your case that either the border is too wet or the house too close and damp, and possibly the temperature is allowed to fall too low at night, causing a condensation of moisture on the berries. Maintain a dry buoyant atmosphere by firing in the daytime and affording early and judicious ventilation, keeping a little heat in the pipes at night, and the house nearly closed when the weather is very damp. Remove every decayed berry promptly, and if needed protect the border from heavy rains.

Garden for Vegetables (J. P., Dublin).—A question of this kind obviously cannot be explicitly answered in the absence of knowledge as to the fertility of the soil. If it is very good a vegetable supply for your family may be maintained on one and a half acre, there being no fruit trees to interfere with the crops; but if the land is only moderately fertile two acres would not be excessive.

Celery Leaves Blistered (A. B. C.).—You are right in supposing that they are affected similarly to Parsnips and Mangold Wurtzels sometimes are, but wrong in attributing the injury to "something at the roots." It is caused by the Celery fly, *Tephritis onopordinis*, puncturing the leaves and depositing eggs, the resulting grubs or larvæ eating away the parenchyma, and this causing the parts to wither. When full grown the grubs at this season descend into the earth, and remain in the chrysalis state until spring, when they give birth to the fly. Remove all the withered parts, and the insect will do no more injury this year.

Naming Plants (J. C.).—We have attended to all that we could identify. We receive parcels every week without any letter pertaining to them, and these are necessarily passed over. If you will send good specimens packed so as to arrive in good condition, and enclose a note with them, we will endeavour to determine the names and publish them in the Journal.

Fruits for Name (To Correspondents).—We have several boxes of fruit which do not contain the names of the senders, and letters received by post do not enable us to determine by whom the different parcels were transmitted, consequently the fruit cannot be named. We have attended to all the fruit in our possession, except one parcel, which contains the name of the sender of it. In all cases the names of the owners should accompany the fruit, whether a letter is also sent by post or not, otherwise it is impossible that the fruit can be satisfactorily attended to. We must repeat our rule of not naming more than six specimens at once, and again state our inability to preserve any surplus fruit for naming in a future issue, nor do we undertake to send replies through the post.

Names of Fruits (W. Bentley).—1, Black Prince Grape; 4, Pomme d'Api; 5, Golden Pippin. (Fareham).—1, Cellini; 2, Braddick's Nonpareil; 3, Cobham; 4, Waltham Abbey Seedling; 5, New Hawthornden; 6, Blenheim Pippin. (W. Thornton).—1, Cellini; 2, Sykehouse Russet; 3, Golden Reinette; 4, Royal Russet; 5, Scarlet Nonpareil. (N. W.).—1, Dumelow's Seedling; 2, Scarlet Nonpareil. (G. W. Boothby).—Blenheim Pippin. (J. Gilmore).—4, Greenup's Pippin; 7, Goff; 8, Keswick Codlin; 9, Carlisle Codlin; 11, Catshead; 12, Nonesuch; 13, Fearn's Pippin. (I. H. S.).—1, Golden Winter Pearmain; 2, Small's Admirable; 3, Hollandbury; 4, Carraway Russet; 5, Blenheim Pippin; 6, Golden Noble. (W. W.).—1, Yorkshire Greening; 2, Warner's King; 3, Jolly Beggar; 4, Small's Admirable; 5, Coe's Golden Drop. (R. P. Williams).—2, Gloria Mundi; 3, Hawthornden; 4, Autumn Bergamot. (W. K.).—1, Beurré Diel; 2, Beurré d'Aremberg; 3, Van Mons Léon Leclerc; 4, Swan's Egg; Apple, Small's Admirable. USE OF GREEN OR FODDER CROPS FOR VARIOUS PURPOSES.

(Continued from page 306.)

LUPINS are not often used as forage for cattle or horses, except in admixture with other forage plants, the advantage being, if used as forage at all is to feed off with store sheep folded on the land; for although sheep stock do not sometimes take to it kindly at the first, yet they soon appear to like it, and thrive remarkably well upon it as store animals. We find this crop noticed by a writer in the Journal of the Royal Agricultural Society of England, and in alluding to an experiment the writer states:—"I drilled about 1 bushel of seed per acre on 18 acres of poor land, from which I obtained fifty waggonloads of sheaves. The luxuriance of this crop quite astonished all who were acquainted with the sterility of the soil, and the quantity of grain before harvest was estimated at forty to fifty bushels per acre." For any further information we must refer the reader to our article on the cultivation of Lupins in the number of this Journal dated the 9th September, 1880.

Burnet is a plant seldom grown in this country; it is, however, oftener grown on certain continental States, is used for growing on poor soils not adapted for Clover and Sainfoin, it is, however, used for cattle forage, especially for milch cows. It is principally valued as folding forage for sheep on lands when broken up out of sheep walks or downs on the chalk or limestone hills. The seed may be sown amongst Lent corn in the same way as other grasses. Although it is found useful for sheep when grown alone, yet it is frequently found amongst our samples of Sainfoin seed, and is generally considered a spurious mixture, and only spoken of by the practical farmer as one degree better than some of our troublesome weeds.

Broad or Red Clover is one of the most important fodder plants available for the home farmer, for although it grows in full perfection for one year, yet it is never quite certain to yield a regular plant and full successional crops upon all soils under all circumstances. The most probable method to obtain a full plant is to alternate it with other Grasses, so that it may not be grown upon the same land oftener than once in eight or ten years; but even then some soils fail to maintain a regular plant, although it might have shown well and promising after harvest when grown in either Wheat or Lent corn stubbles. It is therefore well at all times under such uncertain conditions to have some admixture such as Sainfoin or Italian Rye Grass, especially when required to produce in succession two crops for hay. It does answer well to mix White Dutch or Trefoil, as these crops are required in the alternate husbandry. Alsike may be grown with it, but this Clover is also one of the alternate varieties available, and should certainly be retained for that purpose. There is no doubt but the condition of the land, both in fertility and cultivation, is important towards securing a good plant, for we have frequently seen the headlands of a field where the land had been trodden most at the time of culture, which being close and fine on the surface, will produce a full plant when the rest of the field has failed. In consequence of this our own plan was to sow the Wheat in the spring, the ground, of course, being firm, but especially when Wheat followed Potatoes, for then the land would generally work fine on the surface, and in this way we invariably secured a full plant of Clover, and frequently a fine crop in autumn after harvest to cut for the soiling of cattle in their boxes and horses in the stables. When treated in this way the plant was maintained during the winter, whereas whenever we fed the young Clovers with sheep their sharp incisors always injured the plants more or less.

Our recommendation is to grow two crops in succession for hay by cutting them both very young, which not only favours future growth but insures the most nutritious hay. When both crops are cut young we can often get a good third cutting, frequently enough for ploughing-in, which is a matter of great consequence, for when properly done it will insure a good average Wheat crop if the land is clean and otherwise in good condition. It also gives the best result by saving Clover for seed, instead of sheep feeding the second growth as proved by our own practice for many years, and also by Dr. Voelckiron's experiments at Leighton Buzzard in Bedfordshire it was corroborated, and the benefit derived was decided to have been obtained by the increased weight per acre and value of the Clover roots as manure for the Wheat crop. Readers requiring information relating to the culture of Broad Clover should refer to the numbers of this Journal dated December 9th and 16th, 1880.

In referring to Italian Rye Grass we can only say that it has commanded more attention during the past twenty years than formerly, and especially the foreign imported seed; and although much of this has been used, and when saved for seed has been sold for use in this country, the seed which is saved in the British Isles is far inferior to the foreign seed in regard to the production, not only of the earliest grass, but also in its value as a crop of quick succession. It has depreciated in value, and we therefore recommend the home farmer to obtain foreign seed. Caution must, however, be exercised, for it is so often found to be mixed with twitch and other grass seeds, that unless it is carefully examined by those who are perfectly acquainted with the various seeds of grass, as well of spurious as genuine, it cannot be easily detected, hence the seed should be warranted true and genuine and of foreign growth. It is extremely valuable as forming the basis of profitable and continuous growth for land under irrigation by town sewage, or the sewage from dairy cattle in their sheds, and will yield more and greater weight of green fodder than any other variety of grass in cultivation. It is also recommended for the purpose of ensilage, thus giving an opportunity when large crops are produced in summer time, and in excess of immediate requirements of preserving it containing its full value for cows and horses without risk of loss by the weather like hay-made provender, and when the silo is perfect and the grass properly secured it is quite as valuable as newly-cut grass for soiling, and even more so, as it comes to use in the winter months. There is no question of its great feeding power for the production of milk and butter when used with discretion and judgment.

Lentils are not much grown in this country, but may prove useful as green fodder when treated in the same way as Vetches, especially as there are two varieties, one for winter or autumn sowing, and the other for seeding in the spring like summer Tares, and may be used in the same way as food for the same kinds of stock. Some of our cereal crops are valuable as green fodder as well as for the production of grain and straw. We must say that they deserve a share of attention, for in the green state Rye is not only a useful green fodder, but comes early into use, especially for sheep which have a daily or nightly fold of it while feeding in the irrigated meadows. At the same time it is good food for dairy cows, producing abundance of milk. It is also used when cut into chaff with sweet straw for farm horses, and it is well to introduce them to the season of green fodder in that way, for we know practically that a sudden change to green fodder from all dry provender suddenly, frequently injures the health of some animals, or partially disables them for a time. Rye is of two sorts, the common or Giant Rye, the latter being very early and productive, while the common sort is the most hardy in severe winters, and the likeliest to yield a full crop of grain in our English climate. It also produces most valuable straw for thatching stacks and cottages, it being much more wiry and lasting than Wheat straw. It is, however, in some cases sown in April and cut for hay, in imitation of the oat or prairie hay made in America, and proves extremely valuable when used as chaff for hunting and carriage horses, nor is there any doubt but Rye ensilage will be valuable if cut in due season and properly secured in the silo. One of the great benefits to be derived from Rye is, that almost any root crop may be grown in full bulk after the Rye is removed from the land.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are now almost continually employed in the preparation and seeding the land with Wheat, Winter Vetches, Winter Oats and Winter Beans. It is a matter of such great consequence that those sorts of Wheat best suited to the soil and climate should be used in preference, that we will give our experience and recommendation as to

the best sorts for cropping and quality of the grain produced. First in our estimation as adapted for the highest cultivation and best Wheat land is the Dwarf Essex Rough Chaff, for we know that on a very shallow soil near the seacoast in a southern county it has given thirteen sacks per acre of first miller's quality for three years in succession, 1880, 1881, and 1882. And the maximum produce ever attained within our knowledge from this Wheat was nineteen sacks and one bushel per acre in 1870, of splendid quality upon a friable loam out of Clover lea in a southern county. Upon thin or shallow soils in good condition we would advise, if climate is favourable, the sowing of Imperial or velvet chaff white Wheat, such as is sold by seedsmen who give special attention to this branch. We have seen some of this sort grown on dry loamy land last harvest, with immense ears, well chested; we shall certainly sow some this year on our own farm. Upon pale lands on the chalk we have seen fine samples of the white Wheat called Weeb's Challenge, and it is a sort well suited to this soil. Upon low-lying land frequently subject to blight, we prefer the best sorts of red Wheat, like Golden Drop and Browick. Upon the cold chalk hills we also recommend both of these sorts, as well as the old Red Lammas, for they are very hardy and not so soon lifted by frost in the early spring. The time has now arrived when upon all strong, flat-lying land the Wheat should be sown without further delay—look back at last autumn and recollect the great disaster of late sowing, and in various instances none could be sown until the month of March. We sow two bushels per acre on fallow land early, but later on two and a half bushels; on Clover lea we sow two and a half bushels early, but later on three bushels per acre, and we prefer sowing to drilling on lea ground, unless drilled behind the presser with the drill attached; but on all flat-lying strong land which is usually subject to various noxious weeds, we prefer drilling at from 10 to 12 inches apart between the lines, for otherwise in some seasons the land must be horse-hoed in the spring, and unless this is done the weeds become masters of the crop. Again, on such land the Wheat plants will often lose colour; horse-hoeing or hand-hoeing is then the only resource to open the surface of the soil and invigorate the plant and renew a healthy colour, for a sickly fading colour is sure to result in small ears, and if on such land the Wheat is sown broadcast the crop must fail more or less. Again, upon light gravel or sandy land, the red weed or wire weed, and often wild Marigold, are sure to injure the crop when sown broadcast on a fallow surface, and should be drilled wide enough for hoeing, whether sown after Turnips fed off or ploughed in for manure.

Live Stock.—Cattle, except dairy cows and store stock, may now be housed or yard-and-shed-accommodated, as the early frosts are very injurious to all cattle feeding for the butcher, and the sooner they are put into winter quarters and liberally fed with cake or beanmeal, barleymeal, &c., in admixture with cut roots or cabbage, the more benefit they will receive, and wherever boxes can be had, stalling fattening cattle is entirely wrong in every respect as to the making of both meat and manure. Wether sheep feeding for the butcher, too, should now be fed upon roots or cabbage, and not allowed to run out of fold to graze, but receive a full allowance of cake, beanmeal, and good hay, for if ever fattening sheep will pay it must be at the present price of mutton; it is, however, a clever feeder who can make a profit on sheep at the present rate of buying-in and stocking the farm. Still, we must not forget that the early horned Dorset and Somerset ewes are now beginning to lamb, and these, well fed upon dry land so that both the ewes and lambs shall be fattening together, as they will prove more beneficial to feed them fat than the later lambing down ewes or longwools. This goes far to illustrate the fact that a breeding flock will pay best, or lose the least when not profitable, and we would advise the home farmer or young farmer to keep this point steadily in view.

OUR LETTER BOX.

Alderney Cows (G. G.).—By all means keep them in sheds at night now, and also in the daytime when the weather is very inclement, keeping them very clean, and feeding and ventilating judiciously.

REMARKS.

30th.—Wet morning, fine afternoon with sunshine, showery evening.

1st.—Bright morning, afterwards overcast; a cold day.

2nd.—Fine, bright, and cold.

3rd.—Cold wet morning, fine after 3 P.M.

4th.—Very stormy throughout.

5th.—Very fine morning, overcast in the latter part of the day, rain in evening.

6th.—Fine and bright all day.

A cold and unsettled week, frequent showers, but a good deal of bright sunshine. Mean temperature 4° below the average, and about 9° below that of the preceding week.—G. J. SYMONS.

FRUIT TREES IN POTS.

I WAS highly pleased to read of "Jedburgh's" successful culture of fruit trees in pots in the simple manner described on page 277, as I had previously entertained a similar idea and had resolved to carry it into practice this autumn. The method advocated by your correspondent will commend itself to suburban gardeners especially as being a most useful and valuable one; for, unlike many of their country brethren,

they have to battle with smoke, indifferent soil, and circumscribed space, yet, notwithstanding these untoward circumstances, the former are in many instances expected to supply fruit of good quality for their employers' table. I do not mean to infer that if a gardener had to supply Apples and Pears in quantity he would find the method of growing the trees in pots likely to answer, but for securing a moderate supply of them, also of really creditable fruits of Cherries and Plums for the table, the latter system will prove a valuable and profitable one.

Many will argue that the adoption of this system will involve great expense and additional labour by way of watering. This objection may, however, be dismissed on two grounds. Firstly, no elaborately constructed orchard house is needed when trees are grown according to your correspondent's method; and if trees are purchased already established in pots fit for bearing, the difference in price between them and those lifted from the open ground for ordinary planting is not more than a third in excess as a general rule. Secondly, the additional labour involved in potting, protecting, and watering will be amply compensated by the greater amount of finer and better flavoured fruit secured.

A similar plan to this one I saw adopted with half a dozen or more Plums a few years ago. The trees were plunged in an unheated Fig case where plenty of ventilation was given until the fruit had set, after which the trees were removed outside and plunged in a border by the side of one of the kitchen-garden walks. A copious supply of weak liquid manure was given from time to time, and I must confess I have never seen heavier crops or tasted better flavoured fruits than these, and all produced with a minimum of cost and trouble.

In suburban gardens—such, for example, as the one I have charge of—space is considerably restricted, and the soil by no means congenial to the growth of fruit trees generally. We are only too glad to welcome and adopt any really serviceable methods of securing good crops of both fruits and vegetables. Healthy vigorous young trees planted in our soil will not grow and fruit satisfactorily; and to remove the existing soil and supply better would prove a most expensive method, especially, as in our own case, when good soil can only be obtained from a long distance. My employer is anxious to have a reasonable supply of high-class fruits for dessert, such as Apples, Pears, Plums, Cherries, and Peaches in season, and knowing the difficulties already stated, has permitted me to adopt a scheme I have formed having for its

object the means of better production and protection of the foregoing trees in flower and fruit.

Two evils I have to contend with are unsuitable soil and London smoke. Another equally grievous remains, however, one which affects country as well as suburban gardens—viz., spring frosts. To provide a remedy that would prove efficient and yet not too expensive in its application was the task I had for some time set myself to do. First of all it was decided to adopt the late Mr. Rivers' plan and build a cool orchard house, as our object is not to force but to produce crops of good fruit in season. Having a south wall with a 10-foot border measuring upwards of 100 yards in length, it was determined to take advantage of this and build a lean-to house. After a careful estimate of the cost such a structure would involve we found this scheme would prove too expensive; therefore I set to work to devise another method which I am now putting into practice. The plan I am adopting, then, is as follows.

The wall I have mentioned is 12 feet in height, and the border at the base 10 feet wide. Posts of 4-inch deal and 9 feet 6 inches long are placed in sockets 18 inches deep at 10 feet from the wall, and are continued at intervals of 6 feet the length of the border. Pins are driven vertically in the top of each of these posts, and cross beams with corresponding holes to retain the posts in position are placed thereon. Rafters of similar material occur every 6 feet. These receive a framework 3 feet wide, fitted with grooved sashbars for the reception of Hartley's patent rolled plate glass to form a wall coping. The remainder of the roof will be covered with hexagonal netting. The spaces 6 feet by 10 feet in front will be fitted with a light framework of wood and wire netting, as also the ends, with the exception of a door to each, fitted with lock and keys. The use of the wire netting is to protect the crops from the depredations of feathered and human thieves, both of which are unfortunately numerous hereabouts. The 3-foot glass coping will protect and assist the trees in flowering and ripening, and in lieu of the glass roof and sides in the structure I have just described I propose to fix rollers at the base of the glass coping to receive tiffany, which will be let down the roof and sides in cold frosty weather when the trees are in bloom.

Having thus far described the structure I will now say a few words on what I propose doing inside. First, as to the wall, two-thirds of which are occupied with young trees of good varieties of Peaches and Nectarines and "old stagers" of Apricots and Figs. I propose to plant a few more good kinds of Peaches, and the remainder of the space fill up with upright and oblique-trained cordon Pears and Apples. I prefer the cordon as applied to Pears to other systems, one great advantage being they come early into bearing; and if a particular variety does not succeed it can be speedily discarded and replaced with better varieties without much loss of time. This system has been adopted with great success by that able cultivator and your esteemed correspondent Mr. Luckhurst of Oldlands, to whom I am greatly indebted for much information and advice in the selection of the best varieties of Pears likely to succeed with me.

As to Apples on the same plan against walls—French varieties being required—I propose procuring Calville Blanche, Calville Rouge d'Hiver, Calville Malingre, and a few other similar varieties as figured and described by M. Poiteau in his magnificent work the "Pomologie Française," tome iv., for the privilege of consulting which I am indebted to a kind and generous employer. As I have before said, the soil is unsuitable to the growth of fruit trees, therefore I propose overcoming this difficulty by growing pyramid Cherries, Plums, and Apples in pots, and plunging them in the borders. Raspberries will be planted against the posts that support the roof; miniature trees of Champagne Gooseberries and White Currants will be planted at intervals, and finally all the best varieties of Strawberries will be planted in every available space.

Such, then, is an outline of my scheme for supplying a

moderate quantity of what I feel sanguine will prove really creditable fruit, grown in a minimum of space, protected from the injurious effects of spring frosts, and quite under the control of the cultivator. Good loam will be incorporated with the existing soil when planting the wall trees. This will support, with occasional assistance by way of artificial manure, not only these but the Strawberries and Gooseberries too. The trees in pots will be well supported, therefore a heavy crop will be insured in a minimum of space—a great boon to many situated like myself.—A SUBURBAN GARDENER.

CULTURE OF HARDY ORCHIDS.

AFTER considerable experience with hardy Orchids I find there are but few species really capable of multiplying themselves to any extent and increasing in size under cultivation. Most Orchids live more or less when properly cultivated, but as they do not multiply in the long run the individual deaths soon extinguish the collection. I have found after various experiments that the following species multiply by the growth of the roots.

Aceras anthropophora.—The green Man Orchis will, if not disturbed, give a marked increase in the course of two or three years. It thrives best in a shady exposed situation, say on the top of a rockwork facing due north.

Cypripedium Calceolus.—One of our prettiest and most interesting British Orchids. It increases considerably when planted in a dry chalky border under the shade of Pine trees. A gentleman in the south of England tells me that with him it grows like a weed under the above conditions, and becomes so strong that it has to be checked every second or third year as an inducement to flower.

C. pubescens.—This is easily cultivated, growing and increasing in an ordinary shady border, but when planted in a damp situation amongst the coarser-growing hardy Ferns attains a perfection seldom if ever equalled in its native habitats.

C. spectabile.—The prettiest species of the genus, requiring the same treatment as *C. pubescens*. It is also well adapted for forcing, and when better known is likely to be used very much for that purpose.

Epipactis palustris.—The only one of this genus that increases, which, however, it does but slowly, and only under favourable circumstances. It should be grown in a shady corner, where water can be used unsparingly. It is very susceptible to drought, and will often succumb if allowed to become dry.

Goodyera repens.—A pretty little sweet-scented plant, which I find does best on a damp shady border under Pine trees, where it increases and flowers profusely. I have tried it on a bog exposed to the full blaze of the sun, and in less than a month more than half had disappeared.

G. pubescens increases rapidly under the same treatment as given above for *G. repens*. Is perfectly hardy, standing our severest winters with impunity.

Habenaria tridentata may be said to more than hold its own under ordinary circumstances. It does very well when grown in pots, but succeeds much better in a low damp situation planted in peat, and where it will not be subjected to perpetual shade.

H. bifolia, with its numerous white flowers, is perfectly at home on a moist border overshadowed with Ferns, where it increases rapidly, and has already more than filled the place allotted to it.

H. hyperborea.—A small North American species, having nothing in the way of beauty to recommend it, although of considerable interest botanically. It increases slowly in a composition of brick and lime rubbish in a shady border. It must be watered occasionally in very dry weather.

Herminium monorchis.—When grown in a stiff chalky clay will, in the course of a few years, increase considerably.

Orchis foliosa.—Often called Poor Man's Orchid, from the ease with which it can be cultivated, a damp shady spot in a compost of peat, lime rubbish, and decayed leaves being the most suitable for its full development. It increases at the rate of about 50 per cent.

O. latifolia I find increases very slowly, even when carefully attended to. It does best in ordinary garden soil, and requires plenty of water in hot dry weather.

O. maculata.—A very pretty species. It increases when planted under brushwood, partially shaded in ordinary soil. It also grows and flowers freely on rockwork with north aspect.

Ophrys pseudo-sambucina.—In one year increases 25 per cent.—that is, from twenty-four bulbs I collected thirty. It requires to be grown in pots in a cool frame, and will not stand frost.

Ophrys bombylifera is the most productive of any of the hardy Orchids; it never fails to more than double itself. From fifty pseudo-bulbs of this species planted singly in pots, no fewer than forty four had produced two pseudo-bulbs each, whilst six had produced three pseudo-bulbs each, making 106 as the total for the year. They should be placed singly in pots about the beginning of September in good rich soil, with plenty of drainage. The pots may then be embedded in sand in a cool frame, which should be kept open as long as the thermometer is above 40°, unless when raining or during high winds.

The whole can be watered as a bed, but only at two periods of their growth—viz., in September and October, when the roots and leaves grow, and in January and February, when the young pseudo-bulbs grow. Between these two periods little water should be given, and when the flowering is over the water should be gradually decreased, and eventually cease.

Where it is not convenient to have them in pots they may be planted under a hand-glass, taking care after the bulbs are planted to cover them over with good river sand. Here they are liable to the attacks of slugs unless sawdust be laid round the inside edge of the hand-glass. They will stand a little frost, but I find a few Pine branches very useful to throw over them in severe weather. In the case of the pots, when the stem and leaves die, they may be taken out of the frame and placed on their sides in a cool shady place until the beginning of August, when they may be emptied and the new pseudo-bulbs collected.

For those under the hand-glass, as soon as the leaves show signs of decay, the top part of the light should be tilted, so as to admit plenty of air, and at the same time guard against their getting wet. It would also be well to cover the glass with some light shading material. Collect pseudo-bulbs as directed above, and replant the requisite number as soon as they show signs of growth.—D. DEWAR, *Herbaceous Department, Kew*.

SIX MONTHS IN A VINERY.

ALTHOUGH I have very much cause to be gratified with the reception "Vines at Longleat" met at the hands of the public, it has been urged, and with some reason, that not many people have such an admirably constructed house to deal with as that therein described, and indeed comparatively few cultivators have even a chance of forming new borders and planting young Vines; therefore to meet the requirements of a large number of readers I resolved to make a sort of diary of the management and its results of what may be fairly termed a very commonplace sort of vinery, and as the building in question is considerably over half a century old, and its occupant probably but a very little younger, I hope I may be able to make the matter interesting.

The notes I have were made almost daily for the space of five and a half months, commencing last New-year's day, with enlarged notes and remarks made about once a week, consequently they are rather voluminous; but I will promise not to inflict more than a portion of them on your readers, as some of them are rather crude, and although interesting and instructive to myself they must be considerably condensed to suit the present popular taste. I shall, however, as I go on add notes embodying the "wrinkles" picked up during the two seasons which have elapsed since the writing of my treatise, and wherever I have had occasion to alter or modify my views I will endeavour honestly to state the facts plainly.

The description of the house must now of necessity be written from memory, but it will be sufficiently accurate for the purpose. Its dimensions are about 40 by 16 feet, and it has a fall of probably 5 feet in its length. In shape it is hip-roofed, or what is sometimes called three-quarter span. It faces the south, has a rather flat roof, with heavily built sliding lights and panes of old-fashioned glass about 6 inches wide. To lessen the cost of construction at a time when glass was very dear, the part of the roof which faces the north was constructed of lath, plaster, and slate—or at least that is how it is at the present day. The path is under this portion, which of course is of no use for growing Vines, so that the cultivable width is reduced to about 11 or 12 feet.

It has upright front sashes about 18 or 20 inches high; these are available for ventilation, but are not of much use for admitting light, as the mullions, framework, and plate are of such a substantial build that they nearly overshadow them. It has been so far modernised as to have five rows of 4-inch pipes fixed in it, but in other particulars it does not, I think, differ materially from the original plan.

One Vine occupies the house. It is planted close to the front wall inside, and about equidistant from each end. It divides when it reaches the top of the front sashes; a main branch runs to each end

of the house, and other branches springing from them at intervals of 3 to 4 feet are trained up parallel with the rafters.

When I took charge, nearly fifteen years ago, the greater part of its roots were outside, or at least very few could be found inside. It bore Grapes of various colours, various sizes, and various flavours; and I understood it had long been its nature so to do. After a time, when it had been subjected to a little medical and surgical treatment, its character became more fixed, and now it is a veritable Black Hamburgh. It has a magnificent stem of 16 or 18 inches girth; but although one Vine fills the house it cannot be said that it is now grown on the extension system, for having long ago filled its allotted bounds it is kept spurred-in quite closely, and is therefore to all intents and purposes grown on what is called the restrictive mode.

The subject of renovating and rejuvenising Vines having been so lately written about, it is unnecessary now to detail that part of the subject; but where roots have to be cut through I would again urge on all cultivators the importance of getting it done speedily while the foliage is healthy.

Prior to the commencement of my diary all insects had been destroyed by the liberal use of petroleum and water as soon as the fruit was gathered. A top-dressing to the inside border had been given at the same time in the shape of some naturally made leaf soil, a little loamy soil, and some half-inch bones pricked in with a fork 3 or 4 inches deep.

This operation would destroy many small fibry roots, but at this time of year with healthy foliage they start making root again immediately, and utilise to the fullest extent anything fresh and suitable which is given them. Pruning had also been completed at least five weeks in the orthodox fashion of spur-pruning.—WM. TAYLOR.

(To be continued.)

POTATOES.

THIS year I have grown a great many varieties of Potatoes, and have done my utmost to find out the best croppers and least liable to disease. Year by year I add a few new kinds to my stock, but I have determined to do away with many of the varieties I have grown this year. They have had a fair trial planted in my garden in a light soil well dressed with stable manure and old lime rubbish, and in a field with hot gravelly soil moderately manured. Almost all the varieties are of recent introduction, and if I succeed in drawing the attention of your readers to a few really useful Potatoes, and thus prevent their incurring disappointment in growing some belauded but worthless ones, I shall be amply repaid, for I am an ardent admirer and most interested cultivator of the noble tuber. The following are the results of my trials.

Ashleaf (Veitch's).—The best early kidney for the garden, of very good quality, earlier but not so prolific as Myatt's. No disease.

Ashleaf (Myatt's).—Great cropper in the garden and good in the field, the tubers being of good size, quality, and appearance. Best early for market-growing. No disease.

Advancer (Daniels).—A great cropper in the garden, all the tubers being very large, but the eyes rather deep and haulm very robust. This Potato did well in the field also, and was free from disease. A good field variety.

American Purple.—A very useful variety. Grown in the garden only it produced fine clean tubers free from disease. Haulm strong and branching.

Beauty of Hebron.—A great cropper both in the field and garden, of good quality for table, early and of good appearance. One of the best Potatoes for field or garden, and quite free from disease.

Beauty of Kent.—Of first-class table quality, a good cropper in the garden, but bad in the field. Haulm medium and mottled. It is a handsome Potato; and good for garden cultivation. Slightly diseased.

Cosmopolitan (Carter's).—A second early rough-skinned kidney, handsome and good cropper. Grown in the garden only this year for the first time, I can but express a belief that it is a very good variety.

Duke of Albany (Sharpe).—This Potato is very prolific and early, with tubers large and of splendid table quality. It is quite free from disease. This variety will without doubt be very popular with growers for market, and either for garden or field I can very strongly recommend it.

Early White Emperor.—Useless except for exhibition.

Eight-weeks (Carter).—A good cropper both in field and garden, of excellent table quality. The haulm is branching and mottled. Being early, prolific, and of good appearance, it is well suited for field or garden cultivation.

International Kidney.—Useless except for exhibition.

Improved Peachblow.—In the garden a good cropper with large tubers; in the field a bad one, but with large tubers. I keep this Potato for baking. Free from disease. Haulm erect and strong.

Mammoth Pearl.—In garden and field few tubers to the root, but all of good size.

Manhattan.—A fair cropper with large tubers, but badly diseased in both field and garden.

Matchless.—A handsome early variety and prolific. Free from disease, but of poor table quality. Moderate haulm.

Mr. Bresee.—This also goes by the name of Peerless Rose. It is of fair table quality, very prolific in garden and field, and very handsome. Some of the Potatoes grown in the garden were immense. Being early with short haulm it is useful where Savoys, &c., are grown between the rows.

Porter's Excelsior.—Handsome and prolific, but no good except for exhibition.

Pride of Wilts.—Useless except for exhibition.

St. Patrick.—Good cropper in field and garden. A second early kidney, of good quality for table and free from disease. Profitable for field cultivation, producing a good crop of fine tubers on a poor soil.

Schoolmaster.—Handsome and of good quality. An excellent garden variety, but not prolific in the field.

Trophy.—Good cropper, producing large tubers both in field and garden, but of poor table quality. Of good appearance, and nearly free from disease.

Triumph.—Handsome and prolific in field and garden, with plenty of fair-sized tubers, none being very large. It is very early and of dwarf top. Quite free from disease.

Vicar of Lalcham.—Very handsome blue round, a good cropper in the garden, but not in the field. Boils very white. Slightly diseased.

Woodstock Kidney (Sutton).—Prolific, with very robust haulm, producing very clean-looking Potatoes of good quality. Diseased.

Wormleighton's Seedling.—An improved Magnum Bonum, producing, I think, larger and truer-shaped tubers, which are of excellent table quality. A great cropper, and a thoroughly good Potato in every respect. Free from disease.

White Elephant (Daniels).—Great cropper in the garden, but, much to my surprise, a poor one in the field. Not of good table quality.

Wiltshire Snowflake (Lye).—Takes the disease, but is a good cropping Potato of excellent table quality. The tubers are of uniform size.

Other varieties I grow, but I am afraid that I have already written far too much. The above is the result of my experience, and I trust it may be of some use. In conclusion, I may say that for garden cultivation I would choose Veitch's Ashleaf, Duke of Albany, Beauty of Kent, Schoolmaster, Wormleighton's Seedling, Beauty of Hebron, and Eight-weeks. For the field—St. Patrick, Mr. Bresee, Myatt's Ashleaf, Advancer, Beauty of Hebron, Duke of Albany, Eight-weeks, and Wormleighton's Seedling; or in all, twelve Potatoes for both field and garden cultivation.—H. S. E., *Great Totham*.

THE OLD CRIMSON CLOVE CARNATION.

THIS is one of the best of all our border flowers, and I am glad to see it has been brought so much into notice this season, as of all Carnations this is my favourite. Its colour is decided, the flowers never fail to open in profusion, and its fragrance is delightful. We grow scores of it and never have too many. It begins to open its massive blooms in June, and never ceases producing them until late in October, and we can always count on having it in bloom sixteen or seventeen weeks, which is much longer than the majority of Carnations will continue flowering. It is not easily damaged by wet or injured by cold nights, and it will bear any frost or severe weather in winter. If left undisturbed for years it will grow into a large mass many feet or yards in diameter, or it may be layered and rooted like any other Carnation and planted out in beds or borders in spring. Young plants like these generally produce the finest blooms, but for a grand old-fashioned mass the undisturbed plants are unsurpassed. Some years ago I sent a number of plants of this to Mr. F. W. Burbidge in Dublin, and from him I had a quantity of a dwarf-growing double-blooming Sweet William, which in colour exactly resembles the Crimson Clove, and they are both charming.—J. MUIR.

THE EDINBURGH GARDENS.—"J. B. H." asks me to perform a great task, much greater indeed than he seems to be aware of. At page 21 of the present volume is a paper on the subject, to which his attention may be directed. There he will see recommended what Mr. Thomson has to say on the subject in his "Handy Book of the Flower Garden." If your correspondent is in earnest about studying the arrangement of colours in flower gardens this he will do, and he would not be much benefited by all that could be pressed into a paragraph, which is all that time will allow me to write at present. "J. B. H." says white or red cannot always be used as edging. Certainly not. But neither is appropriate next grass, where a yellow is not, and it was the variable use of yellow as an edging in the Edinburgh gardens that was criticised. Next grey stone colour, such as the pavement of the garden over the

Waverley Market presents, yellow or blue (but not the bronze of St. Martin's Blue Lobelia), would look well enough, though green might be best. Often the walks are of white gravel, in which case white would be a bad thing, while yellow would be very good, and blue the very best edging possible. In arranging colours the surroundings have to be taken into consideration, so that the subject is much more complex than may seem at first sight. "Red or white cannot in every case be the first line. What, then, should occupy that place?" In the Scotch fashion that may be answered by asking, "What colour is outside and what inside the edging or front line?" Till that is known no answer can be forthcoming. Green, grey, brown, white, or even black may be outside, and a score of shades inside. What the edging should be depends on the varying circumstances.—A SCOTSMAN.

TWO INSECT FOES OF THE PEA.

IN reply to Mr. Abbey, I may say that the caterpillar of the Y moth (*Plusia Gamma*), which is a tolerably general feeder, does not often attack the Pea, for this reason, I think, that before the chief emergence of the moth the leaves of the plant are beginning to decline somewhat, and its instinct leads it to deposit eggs where the caterpillars will get a better supply of food than from the Pea, or even from the Bean. July, or later, is the time when these moths mostly appear in plenty, but some are out in June, and they would be likely to visit the Pea, but this has only now and then occurred in England. So far back as 1735 it was noticed that the caterpillar of the species was very destructive to both Peas and Beans growing in the market gardens near Paris. The application of any compound of unpleasant odour, containing tobacco or petroleum for instance, would check the moths in their work of egg-laying, but such applications cannot always be used in the case of this plant. It is not difficult to detect the pearly-looking round eggs, which are placed in patches. When young caterpillars have appeared they may be removed by syringing or washing with weak soapsuds or quassia water.

The fly referred to is *Phytomyza nigricornis*, described by Curtis; the eggs are laid in June, and the maggots or larvæ appear in a few days principally infesting the tendrilled leaves. I am afraid there is no effectual mode of warding off the attacks of this insect. All infected leaves when discovered should be picked off and destroyed.—ENTOMOLOGIST.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

I HAVE read with interest the notes that have lately appeared in your columns concerning the above Institution, and I still hope that something good may come of the discussion, but I do not think Mr. Cutler's letter quite satisfactory. Some time ago I wrote on this subject. I have the rules of the above Society to hand, and I fully intended becoming a subscriber, but I have read and re-read the rules, but still I cannot see my way clearly. It seems to me not quite what two-thirds of the gardeners want. I have nothing whatever to say against the Institution; doubtless it is a very good one, but in my opinion a sick and benefit society would better meet the wants of the majority of gardeners at large if properly constructed. Do I hear someone say, "There are plenty of such societies already?" Perhaps so, but I would have this one specially organised to suit its purpose, and I would have no one a member of it who was not connected with horticulture. I think that by so doing we should be helping one another, and in a manner protecting the profession from being imposed upon quite so much. There is not the least doubt that at the present there are more gardeners (or would-be gardeners) than there are places for them, with the result that a good man cannot get good wages (nor fair wages, if we take into consideration what a gardener has to contend against). I trust this matter will be taken up by abler men than myself, and I feel sure that our Editor will, as usual, lend his aid where gardening and gardeners are concerned, and I would invite every gardener to send in his private opinions and suggestions, then we may be able to form a committee to consider the subject.—J. SMITH, *Hampstead*.

I AM sorry to find that on a question so strongly affecting the gardening fraternity, and of such vital importance to the best interests of the Society he represents, the Secretary of the Gardeners' Benevolent Institution should shelter himself from inquirers who are only anxious for the truth, behind the "anonymous writers" flimsy barriers. It gives people who look at facts only, and care nothing for persons, the idea that the cause is a weak one or an unsafe one when the person who is able, and is the only one to defend, because the only one thoroughly conversant with full knowledge, creeps out of the way of inquiry, and that behind that now-exploded protection, the anonymity of the inquirers. Anonymity is good when questions are fairly and reasonably discussed on their merits alone, and not influenced by the social position or personality of the writers. It is then only that the real truth can be arrived at; and, to my thinking, public questions affecting public interests ought to be discussed in a public way; and that they are better so discussed anonymously, from the fact that we are so hemmed around with our personalities, that if these are imported into the discussion only by names, these very names will give a bias to the arguments which otherwise they would not have. The editor of the paper in which the questions are considered may be left to take care that nothing offensive to any man's personality shall be allowed to appear. I am quite sure Mr. Cutler might have safely left himself in the hands of the Editor of the *Journal of Horticulture*. Such a question as refusing to reply to anonymous writers gives an undeserved

rebuke to such writers as "D., Deal," "Wiltshire Rector," and others, who write anonymously, regularly, and who are about the most honoured of the paper's contributors.

It is a curious comment on Mr. Cutler's refusal to reply to anonymous writers, that in the very paper that he refuses us, an anonymous writer, "J., Sussex," supplies us with the information from Mr. Cutler himself that he declines to give. The letter given last week by "J., Sussex," contains nearly everything that I inquired for, but the chief thing that I desired to know is left about where it has always been, and where it is so unsatisfactory to men who desire to have something safe to rely upon. That the getting put upon the pension list depends upon an accident, the accident of having influence enough to make our case prominent. We know that every gardener is not favoured with patrons sufficiently influential to command attention to his case, and, if he had, there appears to be no clearly defined manner of representing cases. These are blots on the system, and had better be faced, and faced publicly too.

I should be sorry beyond anything to think that I had said a single word to annoy or embarrass the officers of a Society with such a nobility of purpose in it as the Gardeners' Benevolent has; but I wanted light, and I want light still—more light to see my way clearly in a matter that not only affects myself but that affects, or may affect, those I love when I am not there to stand by them. Let this matter of appointment be made plain, and there will not be that old cry that gardeners do not support the Gardeners' Benevolent Society as they ought any longer.—P.

WHEN I wrote on the subject before (page 227), I did so in the hope of eliciting authoritative information that I felt might be of service to myself and other gardeners. As no reply was forthcoming to a letter that appeared a fortnight previously, a most proper and important letter, as I conceived, I concluded the Secretary of this Institution was temporarily absent from his duties, enjoying, as I was charitable enough to imagine, a period of well-earned rest. But what are the facts?

Four letters have appeared publicly asking for information on a public Institution, and yet the Secretary of this public Institution has somewhat tardily and just a little curtly stated that he can only attend to letters that are addressed to him and reply to them in a private manner. Fortunately there is someone willing to do what he can to make the position of the Institution and the advantages it offers widely known. I join cordially in thanking "J., Sussex" for his letter, and seeing that he enclosed Mr. Cutler's reply to himself, I cannot now see that it would be of any use for anyone writing to the Secretary for further particulars. I was fully prepared to become a life subscriber, and others of my friends were contemplating joining also, provided after the information that we were confident the Secretary would gladly afford we felt justified in doing so.

How could I or anyone else write to the Secretary when we did not know his address, which was most certainly the case with myself and associates? I was requested to write the letter on behalf of others as well as myself, and I felt in doing so that it would be of advantage to the Institution too to have the opportunity of having its claims for support placed fully and prominently before those it is intended to benefit. Here is a Society with the high-sounding name of the "Gardeners' Royal Benevolent Institution," and yet hundreds of gardeners know practically nothing about it, and are absolutely ignorant of the address of its Secretary. They read about its annual feast once a year, perhaps, and of the pensions granted, but as to the working of the affair, the principle of determining the pensions, and the advantages offered to subscribers, they know nothing, and because they wish to know each must write separately to the Secretary whose address until now was not even vouchsafed. What matters it to Mr. Cutler if I do not choose to let everybody know I have £10 to spare? If he had been a gardener struggling on 22s. a week for years as I have done, and hoping for an extra shilling or two, he would not wonder that I did not let the world know that I could get on without the coveted increase.

But that is a small matter. The main fact to be borne in mind is this. Information of a purely routine character has been sought for repeatedly on a matter of great public importance, and yet the Secretary of a public institution refuses to supply it in a public manner. Is he afraid of the great world of gardeners knowing too much about the Institution which he represents? His simple announcement conveys that idea undoubtedly, and that is scarcely the way to gain public confidence.

It is not conceivable that there is a charitable institution in the land whose Secretary would not have availed himself with alacrity of the opening that was afforded him for placing its advantages before the public, nor a business manager who would have refused such a chance of making his trade known. But then I am told, and the opinion widely prevails, that Mr. Cutler is an Honorary Secretary, and discharges his duties gratuitously. That of course we must appreciate, but such an arrangement is not always the best. It is sufficient to account, however, for his conduct in this case, and which has prevented the Institution from adding at least one more life subscriber to its lists.—A COUNTRY GARDENER, *Yorkshire*.

[Our correspondent is not well informed as to Mr. Cutler's position in the Society, as he has always been a paid official of the Institution.]

SINGLE DAHLIAS.

IN addition to the two groups mentioned last week—namely, the star-shaped blooms and those with flat florets, Mr. Ware has formed two others, including respectively varieties with florets partly reflexed at their points, and those with florets strongly reflexed. Upon careful examina-

tion, however, of some hundreds of seedling named and unnamed varieties, we think it would be preferable to amalgamate these, and form one section to contain all the varieties with reflexed florets. In the woodcut, therefore (fig. 62), only the extreme of the type—namely, two forms with strongly reflexed florets: Lucy Ireland, which is of a rosy crimson hue; and Fairy Pet, a variety with smaller flowers, white, margined with crimson.

The reflexed group, taken in the broad sense we have indicated, includes the chief bulk of Mr. Ware's stock, the moderately reflexed varieties being by far the most numerous. The others may be regarded in a florist's point of view as a higher development of these, and at present there are few more than a dozen named and tried varieties, though these include the finest yet obtained, and additions are being

suffice as an indication of the range of colours:—In Memoriam, crimson-purple, handsome; Mafinc, yellow with white tips, very early; Lutea grandiflora, clear sulphur, free; White Queen, pure white; Buffalo, orange-buff; Francis Fell, rich purple; Christine, pink; and Crimson Beauty, warm crimson.

WORMS AND WALKS.

At this season of the year worms cause great annoyance to the gardener, and give considerable trouble in keeping walks and lawns clear. When the walks are edged with the shears for the last time the gravel should be carefully drawn back with a hoe and the wormcasts drawn into heaps with the same instrument and then removed. If this is done, the gravel returned and well rolled down again, they will not remain clean for a fortnight. Before returning the gravel apply a sprinkling of salt, and

Fig. 62.—FAIRY PET.

LUCY IRELAND.

annually made to them. They have an appearance of great substance, the florets being so grand and regularly overlapping, while the colour comprises some exceedingly rich shades of crimson. A few of the best are as follows:—Mauve Queen Improved, soft shade of mauve; Mrs.

rbidge, rich plum-purple, very distinct; Gambetta, lilac-mauve; Charles Lawes, yellow shaded crimson; Mrs. Castle; rosy scarlet, and Scarlet Defiance, a handsome variety, with large brilliant scarlet flowers.

Amongst the moderately reflexed varieties will be found some that approach very closely to the newer type, and even on one plant all gradations may be occasionally found, and it is owing to this circumstance that we think it is not advisable to separate them. Some dozens of beautiful forms could be named in this section, but the following will

over this the gravel can be spread. This will stop the worms working, and the first light shower will bring the worms to the surface. The majority of these will die, but to be certain they should be gathered up and thrown away. We may frequently apply a few cans of water to the salt as soon as it is applied, and the worms come to the surface at once and are then removed. It will be found that if the trouble is taken to apply a little salt at this season but little annoyance will be given afterwards all winter. That invaluable insecticide paraffin will also answer the same purpose if it be applied with water through a fine-rose can, but I do not think it will keep them back so long as salt, although they quickly come to the surface after it has been applied.—SCIENTIA.

GRAPES AT OLD WARDEN PARK, BIGGLESWADE.—On entering the late vinery in this fine old garden I was struck by the magnificent

appearance of some of Pearson's Golden Queen and Gros Guillaume Grapes. Some of the last-named are exceptionally good both in size of bunch, berry, and finish. I should say as many as half a dozen bunches on one Vine average at least 8 or 9 lbs. each. On a single rod of the Golden Queen are some very useful bunches, well finished, and not a shanked berry among them. Some Black Alicante and Lady Downe's are also very creditably finished. The grounds at Old Warden are at all times worth a visit, but in the spring they must be especially charming. If spared till that time another year I hope to be able to have a look round with Mr. Allis, the head gardener, who would, I think, at all times do his best to entertain—A VISITOR.

WE are glad to hear that the NATIONAL APPLE CONGRESS AND GREAT EXHIBITION OF APPLES is to be prolonged for a week. In consequence of the vast amount of labour involved in the examination of the very numerous examples of Apples exhibited, and the great interest that is being taken in the Exhibition by the general public, it has been decided to continue the Exhibition open until Thursday the 25th inst. Exhibitors who desire to do so may remove their fruit on Friday the 26th inst.

— THE magnificent VANDA SANDERIANA shown by W. Lee, Esq. Downside, Leatherhead, at Kensington last week, was unanimously pronounced to be one of the finest Orchids that has been exhibited for several years. Any addition to the rapidly increasing ranks of handsome Orchids is especially welcome when it combines attractions of an unusual character with a striking novelty of type, as is the case with this Vanda. It is not surprising, therefore, that it caused a sensation amongst Orchid growers, for this is the first plant that has produced flowers in England, and is, we understand, probably the largest in cultivation at present. The specimen is one of Messrs. Low's importation, and now has five sturdy growths, the leaves of moderate length and slightly recurved. The flowers in form are very suggestive of *Odontoglossum vexillarium*, the two larger lower sepals corresponding to the lip in that Orchid, and all the petals and sepals are on the same plane. The colour is also peculiar, in the lower sepals particularly so, the parallel reddish purple veins being very distinctly marked on the yellowish ground, and the secondary veinlets interlace freely, giving quite a netted appearance. The upper petals and sepals being of pinkish hue also contrast strangely with the other portions of the flower. The plant seems to be of vigorous and free-flowering habit, as it was bearing two spikes, one having eight flowers.

— THE INTERNATIONAL FORESTRY EXHIBITION, to be held in Edinburgh next year, is now being fully discussed, and is likely to prove the most extensive show of this character ever held. The Queen has accorded her patronage, and a large number of noblemen and gentlemen are also supporting the project. A guarantee fund of nearly £5000 has been raised, and twice that amount is expected. The General Committee is under the presidency of the Marquis of Lothian, who will be aided by several scientific and practical foresters. The principal classes will be for practical forestry, forest produce, scientific forestry, ornamental forestry, illustrative forestry, forest literature, economic forestry, loan collections, essays, reports, and miscellaneous.

— AROUND the mound near the Cumberland Gate of the Royal Gardens, Kew, efforts are now being made to establish a WILD GARDEN that will undoubtedly prove a great attraction in the early spring months. Great numbers of bulbs are being planted. *Galanthus nivalis* and *Elwesi*, with *Eranthis hyemalis* and *Crocuses*, form a large proportion of those employed, while the common wild Hyacinth has been placed out in thousands. When in flower these will produce a charming effect, and, being near a walk that is much frequented, they will be seen and enjoyed by a large proportion of the visitors. The idea is a good one, and might be still further developed, as there are many positions in the Botanic Garden that could be utilised in this way. Near the lake in front of the Palm house *Colchicums* have been lately flowering beautifully, several of the slopes being quite covered with their purple flowers. At the foot of the mound above mentioned it is intended to plant the

grand specimen of *Polygonum sachalienense*, which now occupies a position near the No. 2 museum. Several other imposing plants will be also introduced.

— ANOTHER consignment of SINGLE DAHLIAS from Messrs. John Jefferies & Co., Oxford, include some beautiful varieties, but are specially notable for the satisfactory condition in which they arrived and for the time the flowers have since lasted. The florets had all been secured by dextrine, a simple means of overcoming the chief defect of these varieties—their fugaciousness. Comparatively few single Dahlias are seen in the florists' shops in Covent Garden Market, owing to this character, the pompons and semi-doubles being the chief favourites.

— A PUBLIC PARK presented to Coventry by Mr. David Spencer, an old citizen, was opened on Monday, the 11th instant. The occasion was also utilised for the performance of two other ceremonies—the unveiling of a statue erected to the memory of Sir Thomas White, a Lord Mayor of London in the sixteenth century and a great local benefactor; and the dedication to the residents of another park, given by the trustees of the Sir Thomas White charities, and planted and laid out by the corporation.

— ON Saturday afternoon last the Hackney Microscopical and Natural History Society held a FUNGUS FORAY. About thirty of the members and their friends, two or three of the best known fungologists in London being among them, met at Chingford, and explored some of the richest ground in Epping Forest. About 100 species of Fungi were found, including one hitherto unknown in Britain, and several rarities. A large number of those collected, after being authoritatively identified, were carried home to be experimented upon gastronomically.

— WE have received the following circular relative to the COMPLETION OF THE "PINETUM BRITANNICUM," which we readily publish:—"In announcing the arrangements for the completion of this work the proprietor desires, in the first place, to express his thanks to the subscribers for the great forbearance and kindness which they have extended to him during its interruption for some time past. The costly nature of the publication and its unremunerative results may perhaps be accepted as some apology for its interruption; but in his desire to keep faith with the subscribers the proprietor feels that it is incumbent on him to proceed with the work, trusting to reap in the future, by the sale of copies of the complete volume, some reward for his labour and expenditure. As originally announced, the present series of the "Pinetum Britannicum" will be completed in fifty parts, thirty-seven of which have already been published. The remainder will be issued as follows:—Parts 38 to 42 on November 1st; parts 43 to 48 on December 1st; parts 49 and 50, with title and index, January 1st. Subscribers who require back parts to complete their sets are requested to make application without delay, as very few remain on hand. There will be a few complete sets for sale after the publication of the last part, orders for which should be at once sent in, price 25 guineas. Communications relative to the work to be addressed to Mr. Edward Ravenscroft, 14, Loudoun Road, St. John's Wood, N.W.; or to Messrs. W. Blackwood & Sons, Publishers, George Street, Edinburgh, and Paternoster Row, London."

— AN address on VARIATIONS IN NATURE, read by Mr. Meehan before the American Association for the Advancement of Science, Montreal, has been published, and contains many interesting facts in reference to this subject. After briefly discussing Darwin's views he gives the following example of variation:—"Near my home in south-eastern Pennsylvania we find the common Virginia Creeper, *Ampelopsis quinquefolia*, with five leaflets. In Texas Mr. Buckley finds it with seven, in northern Pennsylvania it is found sometimes with three. Along the Canadian line it is mostly with five, but sometimes with seven. In south-eastern Pennsylvania the leaflets are usually broadly ovate, slightly serrate, dark green, and the flowers and fruit are borne on rather stout pedicels. In Colorado the leaflets are rather wedge-shaped, deeply lacinate, of a somewhat glaucous green, and the pedicels slender. In south-eastern Pennsylvania the secondary veins are delicate, curved, and diverging from each other as they extend towards the edge of the leaflet; along the shores of Lakes Erie and Ontario, especially on Goat Island, near Niagara, the veins are very prominent, straight, almost parallel, and give the appearance at first sight of Horse-Chestnut leaves. We do not regard these outlying forms as species, we do not even consider them as varieties. But why? Merely because we find in what I will call the central form a tendency to all the characters referred to. If this central one were to disappear I think

Botanists would have no difficulty in regarding the outlying forms as well-marked varieties, if not good species."

— REFERRING further on to so-called WASTE OF NATURE'S FORCES he remarks—"We discover nothing in the behaviour of plants to indicate that they are actuated by individual good further than may be necessary to enable them to fall in with Nature's great aim of preparing for the future. Millions of seeds are produced for every one that grows; millions grow for every one that lives long enough to flower; millions of flowers open for every one that yields seeds, and millions on millions of grains of pollen are produced for every one grain that is of service in fertilisation. But these surplus seeds, surplus plants, surplus pollen are useful, not to the parents which bore them, not in any way to themselves, but as sacrifices to posterity. They serve as food. They die that something else may live. They all work in with Nature's grand aim of developing something for the future. At the present time the eyes of science are turned to the past. We compare the dim view with that which is about us, and we perceive that all things have worked together for the good of the whole. We see that nothing has lived in vain. We know that in the general economy of Nature there is no waste anywhere."

— WE are informed that the usual display of CHRYSANTHEMUMS IN FINSBURY PARK was opened to the public on Sunday last the 14th inst., and the flowers will be at their best from a fortnight to a month afterwards.

— THE HERTFORDSHIRE NATURAL HISTORY SOCIETY will hold a Fungus Foray at Watford on the 27th inst., when several noted fungologists are expected to attend, amongst them being Dr. M. E. Cooke and Mr. W. G. Smith.

— MR. C. HONEY, Stamford, writes:—"I notice in the pages of your Journal an account of CHOU DE BURGHLEY, and can bear testimony to all your correspondent says, and I feel bound to add that after the lead is cut it is the most prolific green I am acquainted with."

— PART V. of "BULBS AND BULB CULTURE" (170, Strand) contains descriptions and culture of Gloxinias, Pancratiums, Tuberoses, Fritillaria, Alstroemeria, Tritoleia, Agapanthus, Muscari, Pæonia, Oxalis, and Amaryllis. Several of these will be scarcely recognised as bulbs, and the title should have been made to include tuberous plants. The cultural particulars are full and generally good, but the woodcuts are too diminutive, and in several cases unfaithful. The names, too, especially as regards the terminations, seem to indicate rather erratic ideas respecting nomenclature.

— GARDENING APPOINTMENTS.—Mr. Arthur Young, late of Holme Lacy, Hereford, has been appointed gardener to S. Barlow, Esq., the eminent Manchester florist, for his new estate Schimdda, at Llandudno. Mr. Noah Coppin, late gardener to F. Pine, Esq., West Tree, Maidstone, has been appointed gardener to C. C. Wyllie, Esq., Walden, Chislehurst, Kent.

— PART VI. of "THE HERTFORDSHIRE POMONA" is now issued, and contains faithfully coloured plates of forty-two culinary and dessert Apples, seven cider Apples, thirty-one Pears, of which nine are perry varieties. Sections and full descriptions of the varieties accompany each plate. The concluding part of the work, with introduction and index, will be published in the autumn of 1884, after the Congress and Exhibition of the Pomological Society of France to be held at Rouen in October.

— MR. DAVIS of Camberwell sends us three handsome blooms of the JAPANESE CHRYSANTHEMUMS JAMES SALTER, ELAINE, AND COMTE DE GERMANY, which we have never seen so fine at such an early date. The blooms are large, clean, and the petals of good substance. James Salter in particular is very beautiful, the soft tint distinguishing it being very clear.

— MR. J. SHORT, Darlington, writes—"In the Journal of October 4th attention is called to an example of successful culture of LILIUM AURATUM. Kindly allow me to add another under rather different circumstances. In the gardens, Heslington Hall, York, a few weeks ago, might have been seen growing in a Rhododendron bed amongst others one stem 9 feet high, having thirty-six flowers, all of them at that time perfectly formed. The bulbs in this bed had received no special treatment, but were planted, I understood, a year or two ago along with the Rhododendrons."

— THE NORTON, MALTON, AND DISTRICT CHRYSANTHEMUM SOCIETY will hold the nineteenth annual Exhibition in the Bower Memorial Schools, Norton, on Tuesday, November 27th. Classes are also provided for fruits, vegetables, agricultural produce, and birds.

— MR. B. COWAN writes:—"Mr. Ford, gardener to Mrs. Pease, Pierremont Hall, has at present a magnificent specimen of LAPAGERIA ROSEA (Fisher Holmes variety) in bloom. It is planted in a span-roofed house on the north side, covers 40 feet by 8. It has flowered principally in clusters of seven and eight each. The flowers were very large, wide in the apex, a deep red or maroon in colour, and almost too numerous to count. This superb plant is in a tub 2 feet square, and is about six years old. It was well worth going a long journey to see, and Mr. Ford told us it was much finer a few weeks since."

— THE "Journal des Roses" for October gives a coloured plate of ROSE ETENDARD DE JEANNE D'ARC, which is said to be a seedling from Gloire de Dijon raised by M. Garçon at Rouen, and sold to M. Jules Margottin, Bourg-la-Reine, in 1878. The stock was nearly lost in 1879 owing to severe frost, but has now been increased sufficiently for distribution. It is of a very delicate pale creamy white, the flower large and full, and resembling its parent in general appearance.

— THE second volume of Messrs. Cassell & Co.'s re-issue of "PAXTON'S FLOWER GARDEN" is now before us, handsomely but neatly bound, and bearing the character of general excellence distinguishing the works of this firm. It contains forty-four coloured plates, the majority very well executed, though a few are a little defective in accuracy of tints. The frontispiece is a representation of the double Bouvardia Alfred Neuner, which is fairly faithful, but the flowers are scarcely so symmetrical as they usually are on the living plant. In the gleanings and original memoranda are many interesting notes respecting rare and curious plants, illustrated with good woodcuts. The book is printed on stout slightly toned paper, and would form a useful and handsome addition to any library.

— THE last issue of the "ILLUSTRATION HORTICOLE" contains valuable coloured plates of Pothos celatocaulis, a distinct Aroid that is fast becoming a great favourite for covering the walls of stoves; Odontoglossum Londesboroughianum, a showy Orchid, with a large two-lobed bright yellow lip and red-barred sepals and petals; and Campylobotrys Ghiesbreghtii variegata, a remarkably handsome-foilage plant, with large acutely elliptical leaves, dark green, with silvery creamy and pink spots and veining, the under surface of the leaves, with the young growths and stems, being of a rosy hue.

PLANTING FRUIT TREES.

It is time to make the requisite preparations for planting fruit trees by draining and trenching the site, adding, if possible, fresh loam. Unquestionably the best of all soils for fruit trees is the top spit of a pasture where the soil is of a calcareous medium-textured loam, and the fresher it is the better. Preparing loam by stacking for months or years may be very convenient for plants in pots, as the growth of the grass of the freshly cut turf is inconvenient, but the decay that takes place is so much loss to the plants. The grit in it would be an advantage rather than otherwise, in rendering the soil more friable, and prevent that grossness of growth which, in many instances, is fatal to the production of profitable crops. Turf being not obtainable, other means must be employed to render the soil suitable. If very heavy, the surface only being loose and ameliorated, with a stiff clay beneath, it would be advisable to burn a quantity of the clay and mix it thoroughly with the surface and some part of the clayey subsoil, which will deepen the soil and be more suitable for fruit trees.

Light and shallow soils would be improved by a good dressing of marly clay, and all soils not naturally calcareous are improved by an admixture of old mortar rubbish. Deep loams are unquestionably the best, yet if they are wet the trees only make indifferent returns, hence the necessity of draining them thoroughly. Close-textured loams are improved by the addition of sand or road scrapings, and there is no doubt of the value of ashes, as well as sand and road scrapings, in improving the texture of clay soil. In the case of soils long subjected to a course of heavy manuring for the production of high-class vegetables, it is patent such will produce a tree quickly, with the certainty of its growths succumbing to gum or canker. An addition of lime, a bushel per rod, would be useful, and a good

firming of such soil highly beneficial in inducing sturdy growth—i.e., short-jointed thoroughly solidified growth.

Manure should be avoided, as the mixing of manure of any kind, leaf soil or other vegetable matter (except it be charred refuse) only tends to force wood, and young trees grow quite fast enough for the laying of the foundation of a healthy and fruitful specimen. In all cases of poorness of soil a top-dressing is the best method of enriching the soil, so that the rain may carry the liberated juices down to the roots, these latter being encouraged to the surface by the mulching of short manure, and this should be kept moist in summer by watering with liquid manure during dry weather.

Soils that are not only light and thin, resting on sand or a gravelly bottom, are the most difficult to deal with, as from the openness of the soil the trees suffer much from drought, making but a poor growth in the summer, and in autumn if it and the late summer be wet, growth takes place, which does not ripen kindly, and the consequence is the trees are much subject to canker, and this is attributed to the roots having passed into the sand or gravel, whereas it is the unripe condition of the wood consequent upon the late growths. There should be a good addition of clay or marl to such soils when the ground is trenched, chopping it into small pieces, and mixing it thoroughly with the lower portion of the soil as the work proceeds. It renders the soil more retentive of moisture in dry weather, and it is remarkable how tenaciously the roots seek and cling to it. Still more apparent is the healthy appearance of the foliage of the trees, and the steady progress of both fruit and foliage in dry periods, whilst those that are not so treated show by their flaccid foliage and checking of the growth the distress they labour under.

The practice of making a bottom for the trees at the stations where they are to be planted of brickbats and old mortar rubbish may answer some purpose. What? If to keep the roots from striking down into the subsoil it must be very inefficient for the purpose, as nothing short of concrete will do so effectually; and if for drainage, it is certainly only a very poor apology for that efficient drainage which consists in removing all water beyond the soil's retentive power within 30 inches of the surface. It is only poverty and drought at the surface that causes the roots to strike down in quest of moisture. Moisture itself is not an evil; it is when it is allowed to become stagnant that the mischief is done. Instead of these receptacles for holding water it is far better to drain thoroughly with tiles, and if the soil be naturally wet, plant on raised mounds; in fact, trees do badly more frequently through deep planting than any other cause, and should be studiously avoided.—G. ABBEY.

WHICH IS THE BEST LATE PEA?

THIS is a good time to ascertain from the multitude of varieties which under the greatest difference of climate, soil, treatment, and circumstances gave the greatest satisfaction. In the absence of a Pea congress or election we look to the gardening journals for information. I have had a wide field of observation lately from Cork to Dublin to gather the views of others, and this seems to be the general conclusion in the majority of cases. Ne Plus Ultra is very generally grown, and holds a well-established reputation among Marrows when sown the first half of the month of May. A few had either heard of or grown Mr. Laxton's new Pea Evolution, Sutton's Latest of All, Kelway's Bruce Findlay, and Carters' Telephone, but none of those was grown as largely or spoken of as highly as Carters' Stratagem. Personally I have found the quality excellent up to the present, and when planted on rich soil and in an exposed position there is no risk of mildew. It requires plenty of room and a deep soil. It is surprising the depth the roots will travel for nutriment; the foliage is rich glossy dark green grown thus, and it has the further great advantage, that when fully exposed and grown robustly it requires little staking. Of wrinkled Peas I found few to excel Bruce Findlay this year.

For latest use I am not sure if Ne Plus Ultra is not still the best. Larger growers may be able to throw light on the point.—W. J. M., *Clonmel*.

LIFTING AND STORING GLADIOLI.

THIS is a matter requiring immediate attention, and upon which the best authorities seem to disagree. That veteran grower "D., Deal," would place each corm in a flower pot to ripen towards the end of this month or the beginning of the next, while Mr. J. Douglas advocates cutting off the plants close to the crown of the bulb at once. I have grown the choicer Gladioli long, and watched the results with considerable keenness, but I must confess I cannot agree with Mr. Douglas's recommendation. I plant from the end of February to the first week in April at intervals, and there is none now ripe or withered but *G. brenchleyensis*, and whether it is lifted or left in the ground that variety lives readily through the winter. I consider that when frost comes towards the end of this month growth has ceased, but maturation, or ripening of the corms, has only commenced. If left in the ground, and

that they are sufficiently deep, with the winter mild and soil porous, a choice variety may escape, but those who grow rare and expensive hybrids will run no such risk. When lifted, how can maturation take place if the stem is cut away quite green? If Mr. Douglas maintains that no injury accrues to the corm by cutting away the stem, our positions will be intelligible. It would be well if there was an expression of opinion on the point, as possibly it may be the explanation of the mystery—the Gladioli failure so many complain of. As often stated in the Journal, my plan is to lift the corms and let the process of ripening or maturation then slowly take place. Leave the labels attached to the stems, no clay usually remains attached, the spawn are undisturbed, plenty of river sand is procured just immediately before it is required, so as to be moist—this is within the reach of most people. I am particular about the sand being moist. The plants as lifted are then placed on a dry loft uprightly, the sand placed around the corms; sand, corms, and stems then slowly dry out, and a month or two after, when examined at leisure, I venture to say every corm will be as hard as a bullet, and not one gone. Everyone may therefore grow Gladioli so far as winter risks are concerned.—W. J. MURPHY.

THE NATIONAL APPLE CONGRESS.

VISITORS to the great Apple Show at Chiswick have found ample material for study and reflection. Those especially who have large collections or who are about to plant extensively have been well rewarded for their journey. No better opportunity could have been afforded of comparing the characters of the numerous varieties, and whether the cultivator requires large and handsome or richly coloured varieties he has had abundant facilities by making a selection. It is true that there is one important quality that could not be ascertained by these exhibits, and that is the freedom with which the several varieties bear; but a means of determining the value is furnished by the number of exhibitors from different districts who stage them in good condition. For example, there are some Apples, such as Peasgood's Nonesuch, which are almost equally good from a great number of widely separated counties, and in these cases it may be safely concluded that the variety is a reliable one in all the important characters. In the official report which is to be ultimately issued under the direction of the Committee, these facts will be probably tabulated, so that it will be seen at a glance which are the most general favourites, and valuable information will thus be furnished to Apple growers. To aid in rendering the official report still more valuable circulars are being issued to all the exhibitors, requesting them to describe the situation on which the varieties shown have been grown, soil, subsoil, stocks, character of tree, best twelve culinary varieties for the district, the same number of dessert varieties, with any general remarks bearing upon the subject. That the majority will fill up and return these forms may be reasonably expected, and as about 130 growers will be consulted a mass of valuable information will be obtained, that when digested and arranged will constitute a compendium of Apple lore never before equalled. It is, however, probable that the public may have some time to wait for this, as the work will necessarily be great, and must be thoroughly done to be of any benefit. In the meantime, therefore, a few selections may be given of the typical varieties, commencing with the

LARGEST AND MOST HANDSOME APPLES.

Two of the largest specimens in the Exhibition are of Gloria Mundi, one in the Middlesex collection, which is nearly 14 inches in circumference, and weighed when cut 1 lb. 2 ozs.; the other is in the Sawbridge-worth collection under the name of Belle Dubois, and is very similar in size, but not quite so deep. Some fine examples of Lord Suffield also equal the dimensions of the first named, Alfriston coming very near, and perhaps in several cases exceeding it in weight, while Loddington is equally notable in a number of collections. The following include all the large and handsome Apples most numerously represented:—Annie Elizabeth, Bedfordshire Foundling, Betty Geeson, Blenheim Pippin, Catshead, Cellini, Claygate's Pearmain, Cox's Pomona, Dumelow's Seedling, Dutch Codlin, Ecklinville, Emperor Alexander, Gloria Mundi (Belle Dubois), Golden Noble, Golden Spire, Gravenstein, Grenadier, Hanwell Souring, Harvey Apple (shown as Dr. Harvey), Hollandbury, Irish Giant, Kentish Fillbasket, Keswick Codlin, Lady Henniker, Landsberger Reinette, Lane's Prince Albert, Lewis's Incomparable, Lord Derby, Lord Grosvenor, Lord Suffield, Manx Codlin, Peasgood's Nonesuch, Queen Caroline, Reinette de Canada, Round Winter Nonesuch, Royal Russet, Scarlet Admirable, Shepherd's Fame, Stirling Castle, Tower of Glamis, Waltham Abbey Seedling, Warner's King, Washington, and Winter Hawthornden. Two very handsome Apples may be added to these, one a new variety that is represented well in a few collections—namely, The Queen, which is particularly good in Messrs. Saltmarsh's and Messrs. Bunyard's stands. The other is Grand Duke Constantine, which we only observed in Messrs. R. Smith's contribution. It is not, however, a new variety, though a very beautiful one, being of great size and finely streaked with rich crimson. It is of Russian origin, but does not appear to be much grown in England, though it is well worthy of attention.

THE RICHEST-COLOURED APPLES.

In no quality is there so great a range of variation as in the colour of the Apples shown, of course taking them generally. The southern exhibits are of the richest tints; but amongst these, samples of the same variety from one county, and even from neighbouring gardens, differ greatly in brightness. Climate and latitude undoubtedly exert the chief effect, but that much is due to soil is observable in many instances. A striking

example of this is included in a collection from Bedford, the variety Manx Codlin being shown of a uniform yellow tint from a standard tree on a clay soil, but the same variety from a gravel soil has a deep red side, the colour also suffusing the other portion of the Apple. The Kentish Apples are supreme in colour, and though several other counties equal these exhibits in size none contains so many finely tinted samples.

The following are the leading coloured varieties, a few being local:—Algarkirk, American Mother, Calville de Dantzig, Colonel Vaughan, Cornish Aromatic, Cox's Pomona, Countess Howe, Court Pendu Plat, Cowarne Red, Devonshire Quarrenden, Emperor Alexander, Fearn's Pippin, Forge, Fameuse, Herefordshire Beefing, Hollandbury, Honeymoon, Imperial, King of the Pippins, Kingston Black, Lord Lennox, Mabbot's Pearmain, Maiden Apple, Margarete Reinette, Marriage Maker, Mignonette Rouge, Nanny Apple, Norfolk Beefing, Premier, Prince's Pippin, Pym Square, Red Autumn Calville, Red Astrachan, Red Cadbury, Red Autumn Calville, Rasenhäger (Sweden), Red Joanetting, Scarlet Admirable, Scarlet Pearmain, Soldier, Swedish Reinette, Sweet Kingston, Tom Putt, Trumpington, Winter Queening, Wilson's Prolific, Winter Reinette, Worcester Pearmain, and Herefordshire Beefing.

STREAKED APPLES.

Though several of these are included in the two preceding lists they may be enumerated together, as they form what might be termed a distinct popular type, and are very attractive:—Beauty of Kent, Burford Red, Citron Apple, Cliffey Seedling, Cowen's Victoria, Devonshire Nine Square, Devonshire Queen, Fameuse, Flower of Kent, Hall Door, Hoary Morning, Jefferson, Margil, Monmouthshire Beauty, Nanny Apple, Pomme de Nieve, Pomroy, Red Rawlings, Redstreak, Ronald's Royal Pearmain, Striped Beefing, Sam's Crab, Sheep's Nose, The Queen, and Webster's Harvest Festival.

VARIETIES CERTIFICATED.

The Fruit Committee held a meeting at Chiswick on Thursday the 11th inst. to examine the numerous seedlings and new varieties submitted, but the result of their labours was not very satisfactory, for only two were considered sufficiently meritorious to deserve a certificate—namely, Grenadier, shown by Messrs. G. Bunyard & Co., Maidstone, which we figured last week, page 321, and Bramley's Seedling, from Mr. H. Merryweather, Southwell, Notts, which is figured in the present issue, page 341. Of the others some were considered fairly good and promising, but further particulars were desired respecting them; one, however, with a grandiloquent title, was rather forcibly denominated "a beast."

I HAVE been much gratified by closely examining the Apples shown at Chiswick. The information elicited and recorded will be very useful, but to trust to this Show alone will be very unwise for intending planters of Apple trees. There should be a Show next Christmas, and also in March, June, and October of 1884. Growers will then have more time to give further details of stock, soil, subsoil, climate, &c.

It has been long known that some sorts succeed well under certain conditions, but are nearly worthless under others. It is quite clear to me that heavy soils with clay subsoils will never be able to compete with Kent in growing Apples for market. Nevertheless, it will be a boon for persons growing for own consumption to know what sorts do best under such adverse circumstances. It is easy enough to improve the top soil, but very difficult to alter the subsoil; and therefore I consider information as to subsoil is most important.

I have a Sturmer Pippin tree which for some years bore good and clean fruit, but lately the produce has been poor in size and specky. This result I attribute to the roots having got down into the subsoil, although as well drained as a water clay subsoil can be.

This season of 1883 has doubtless been in many places (not in mine) a very good one, and thus some sorts have fruited finely which in other years have not done well. Therefore, I think a show in an adverse season would do as much good as the present one; but this will always remain to be the right thing done, as exhibiting the results of a generally good Apple year.

Mr. Harrison Weir's experiments are very interesting. Will he kindly state in your columns the nature of his subsoil, and the sort of stock the Early Strawberry was grafted on that was renovated by Duchess of Oldenburg on it? I have found by grafting Warner's Seedling (a provisional name) on an old cankered Crab-stock Apple tree, that the old stem is less and less cankered every year—indeed, nearly now clean. We must have Plum and Pear shows, and in London, not at Chiswick.—ROBERT WARNER, *Broomfield, near Chelmsford.*

GARDEN CHEMISTRY.

APPLICATION OF MANURES.

BEFORE being able to apply manures to the greatest advantage we must understand how they stand in relation to the soil; but as this will be discussed more fully under another heading it is only necessary to say here, that while the soil fixes and secures part of the manure against loss, other portions, and those the most valuable, are not held by the soil, but are liable to be washed away by the rain. Nitrogen in the organic form, or even as ammonia, is not liable to be thus lost to any serious extent, but these, especially in summer and autumn, are readily converted into nitrates, which the soil does not hold, and which can always be detected in drainage water from fertile fields,

but more especially gardens. This is one reason why manure should always be thoroughly prepared. Fresh manure in spring is not in a condition to yield much food to plants, because it is not prepared. During summer and autumn this preparation goes on in the soil, and often manure is lost because it becomes plant food after the plants it was intended to feed are removed. The general idea is that what is over will be available next season. This is only partly true. So far as regards the best of it the winter rains carry it away in the drainage. When very thoroughly prepared, on the other hand, the plants get the benefit of its virtues at once, grow in the best manner possible, and by autumn there is comparatively little to lose. It has been utilised.

Then much manure is dug in too deeply. Manure should be placed where the roots of plants can find it the moment they push. Too often time is lost by the plants being obliged to stand still till the roots find the manure. Not only does this cause a stunted growth at first when luxuriance is wanted most, but it is also the cause of late luxuriance when luxuriance is an evil. When manure is dug in deeply, or even trenched down as it often enough is, before the roots of many things reach it, the season is half lost and the nitrogen down the drains.

In applying manure for nine purposes out of ten there is no better way of doing so than spreading it over the surface and forking it up with the surface soil; but in order to be able to do so it must be very short and the soil dry, otherwise it should be dug in as near the surface as practicable.

For most crops it is best to apply the manure in spring, and this even in the case of those put in late in autumn. Onions, Spinach, winter Cabbage, spring bedding stuff stand the winter best, and ultimately give superior results when put out in soil moderately rich only, and helped by top-dressings of manure so prepared as to be ready to yield up their goodness at once, or by heavy drenchings of liquid manure.

In the case of fruit trees, unless newly planted, the application of manure is apt to do, not good but evil, should the spring frosts cause the trees to miss fruiting; but when trees, including Raspberries, Gooseberries, Strawberries, are seen to have set a crop, and are not in the best luxuriance, then is the time to give help, not only to secure the finest crops possible, but to prevent the exhaustion that causes future failure. If ordinary manure is used for this purpose as top-dressings it must be thoroughly prepared or it will be of no use. In the case of artificial manures they cannot possibly be too thoroughly diffused, and should, therefore, be carefully sprinkled over the surface and thoroughly mixed in with it.

There are times to give manure and times to withhold it. The time for applying it to nearly all vegetable crops is just exactly when they come into being, for a thoroughly good start in the seedling and at the transplanting stages is more than half the battle. This constitutes one more reason why manure should be very thoroughly prepared and forked into the surface only. To apply it rank and raw, and deeply dug in, is to court failure in every but the best soils in the best condition. For the flower garden surface-manuring in spring secures a vigorous start that lasts, and is supported during summer when dense flowering and hot suns tend to exhaust; and by the time cool nights and autumn rains encourage leafy growth at the expense of floriferousness, instead of this evil being intensified by the discovery on the part of the roots of deeply dug-in manure, the manure is spent and floriferousness secured.

To feed young Vines which are growing with great luxuriance is to run the risk of making—nay, to secure the certainty of causing, growths that may be large, but will surely be full of pith, sap, and not fruitful. To let them starve when a heavy crop is swelling is to attempt to run uphill without steam. The conviction grows on us that all such subjects are best managed with abundance of mineral food. This of itself will not secure the best results, but when it is always present we may be considered to have the steam well up and only requiring to be turned on. Applying nitrogen does this. Nitrogen itself will not secure a response, mineral matter alone will not; but if a plant has at its disposal enough mineral matter, and nitrogen be supplied, the response is immediate. Growth may be, and often is, too luxuriant for fruiting or flowering. Less nitrogen will secure a flowering fruiting habit, but fruit and flowers may be scanty because of stunted growth: then is the time to give more nitrogen. A friend of mine in East Lothian had a fine batch of winter-flowering Pelargoniums. They were fed with mineral matters. To increase their vigour and production of flower sulphate of ammonia was given them. They at once went off into leafy luxuriant flowerlessness. Had the plants been suffering and stunted the effect of a careful application would have been what was desired.

We cannot in the present instance enlarge on this point, but it is without doubt an important one to which not enough attention has been given. One more instance we will give. Some years ago we had a long line of French Marigolds put out in poor soil purposely in order to keep them dwarf. As they usually do under such circum-

Fig. 63.—THE GREAT VINERY AT CHISWICK.

stances, they came very light in the colour. A florist friend told me that nitrate of soda would darken them to any shade desirable. To prove this it was given freely at one end, less so at the other; in fact graduated from nothing at one end to a good dressing repeated at the other. To my surprise it was exactly as my friend had told me. At one end, where most was given, the plants, which at first gave pure yellow flowers, became first striped, then grew darker till they came without a trace of yellow. Those that had none remained yellow, while as the manure was graduated the flowers gradually became deeper and deeper in colour. Not so long ago stinting for want of water was generally practised in order to ripen off Peach trees and even Vines. But this course was not always satisfactory, causing as it did dropping buds and weakly trees. Under glass late and early firing and more moderate growing have been the means adopted to secure thorough ripening, and therefore fruitfulness. I am convinced that by the proper use of mineral food and nitrogen this process can be materially forwarded; luxuriance, hard driving, can be practised with safety when required, when the fruit is swelling or dense floriferousness threatens to break down the energies of the plant; and stinting be practised, not by starving but by judicious and wise feeding.

There is one way manure is given that I must warn against, even at the end of a long chapter. It is giving it to vegetables forced in darkness. Judging from calendars, we should imagine the giving of manure water and rich soil to Rhubarb, Seakale, Asparagus forced in darkness, to be universal in order to feed it or cause greater growth. It does not. It is the matter formed in the green leaf under sunlight that contributes to plant-growth, and it is such matter stored up in stems and roots that is drawn out when forcing in darkness is done. Were there no other evil following except the loss of manure no great harm might result; but giving diluted urine, infusion of animal dung, or guano water to forcing plants to drink is not better than pouring sewage into wells. As found in the plants such are not altered to plant tissues; they remain as poisons filthy and dangerous.

—SINGLE-HANDED.

THE GREAT VINERY AT CHISWICK.

THE National Apple Congress has drawn much attention to the handsome vinery in the Royal Horticultural Society's Gardens at Chiswick, and as it presents one of the most beautiful spectacles that a pomologist could wish to see, we have thought it a good opportunity to give an engraving of it prepared from a photograph taken by Mr. C. Henwood, High Road, Chiswick. The house may be termed the head-quarters of the Exhibition, but does not represent its magnitude. The largest portion of the finest exhibits are contained in it, the contributions from Kent, Middlesex, Hertfordshire, Sussex, Berkshire, and Essex occupying the principal part of the space, four or five smaller houses being also filled with Apples.

An excellent description of this vinery is given in Mr. A. F. Barron's work on "Vines and Vine Culture," which we extract as follows:—

"This noble vinery—probably the largest structure devoted to the cultivation of Grapes in existence—was originally erected as a plant conservatory, forming the first portion of a grand building in the form of a + with a central dome, projected for erection in the Horticultural Gardens at Chiswick, when Chiswick was at its zenith and the leader of horticultural progress. It was built by Messrs. Bailey of London nearly fifty years ago, and, as we were informed by the late Mr. R. Thompson, the cost was something about £4500, a heavy duty then existing on glass. It is a span-roof curvilinear structure of iron and glass, 180 feet in length, 30 feet in width, and 26 feet high, running east and west, and heated by two of Stevenson's patent boilers, fixed by Messrs. Burhidge & Healey. Ventilation is obtained by ventilators on both sides over the piping, and from a ridge lantern; this, although apparently very limited, is very perfect and quite sufficient.

"In the year 1857, the cultivation of plants having been abandoned, it was proposed by the late Mr. G. McEwen, then Superintendent of the Gardens, to plant it with a collection of Vines, and this was accordingly done. Borders on the most limited scale were prepared, both inside and outside; that on the outside was about 5 feet in width, bounded by a broad gravel walk on a raised terrace; and that inside the house was about 9 or 12 inches in depth, and formed on the surface of the stone pavement of the conservatory."

Numerous varieties of Grapes were first tried in the house and afforded an opportunity of determining their relative merits; the worthless sorts were subsequently removed, others being cut down and grafted with proved varieties.

"At the present time the varieties cultivated are chiefly those standard sorts which have been found suited to the house—viz., Black Hamburg or Frankenthal, which is the best of all, Alicante, Gros Guillaume, Madresfield Court, Gros Colman, Lady Downe's Seedling, Black Prince, Black Monukka, West's St. Peter's, Dutch Hamburg, Buckland Sweet-water, Raisin de Calabre, and Muscat of Alexandria.

"The greatest number of bunches produced in one season was four thousand five hundred (4500), their aggregate weight being somewhat over two tons."

It will doubtless be satisfactory to many to learn that the Exhibition is to continue open until the 25th inst., a prolongation of time that will

probably enable some hundreds to visit the Show who have not at present had the opportunity of doing so.

CENTAUREA ARGENTEA.

THIS occurs to me to be one of the most useful of all white-foliaged plants suited for hedging purposes. It is perfectly hardy and easy of propagation, division of the root being the best method, though it strikes freely under handglasses or in a cold frame. It is of a naturally spreading habit, hence easily kept in its place, and it is far whiter than *Cineraria maritima* or *Centaurea ragusina*. I have not seen this plant used much in England, but it is in great favour here. I am propagating all I can obtain of it. This plant would look well mixed with *Verbenas*. I saw a hed of these the other day remarkably bright, and it appears to me that it should be in all gardens where hedging is a speciality.—J. PITHERS.

GARDENERS' BENEFIT SOCIETY.

SEVERAL of your correspondents have been lately advocating the founding of a Gardeners' Benefit Society. They do not seem to be aware that there is such a Society in good working order, and the funds of which are economically managed and husbanded.

About the year 1865 a considerable number of the leading gardeners in the suburbs of London met, and after several meetings brought the subject before the public by holding exhibitions in the City of London. The first was held in the Albion Hotel, Moorgate Street, and figured in the *Illustrated London News* of April 22nd, 1865. The next exhibition was held in Finsbury Circus, and most handsomely assisted by the residents of the Circus. Many will remember the two following exhibitions held in the Guildhall of the City of London, the use of which was kindly and unreservedly granted by the Lord Mayor, the Aldermen, and the Common Council of the City, and resulted in starting the Society with a sum of several hundred pounds. The leading working members of the Committee at that time were the late Mr. Osman Rhodes, who was the original promoter, William Marshall, Esq., James Crute, Esq., and Shirley Hibberd, Esq.

The Society was advertised and made known from time to time in the horticultural papers, and has gone on gradually increasing quietly and unobtrusively since. The funds in hand in January last were—in the Benefit Fund, £1504 16s. 6½d.; Benevolent Fund, £856 11s. 4¼d.; Management Fund, £3 8s. 10d.

I may state here the reason it is not advertised more extensively is from there being no fund for the purpose. The moneys of the Benefit and Benevolent Funds cannot be used for other than their legitimate purposes, and nothing has surprised me more than the lukewarmness displayed by gardeners in supporting such a praiseworthy institution, as our object in founding this Society was not to make it a charity, but to endeavour to make the members provident, and in time of need come upon the funds as a matter of right. Owing to various causes there have been no exhibitions held for its benefit in late years, neither would they be required if gardeners would support it as they ought.

The name of the Society is The United Horticultural Benefit and Provident Society, and the Secretary is Mr. John F. McElroy, The Gardens, Moray Lodge, Campden Hill, Kensington, W., and whose respected employer I notice is an annual subscriber of one guinea. Mr. McElroy makes it a labour of love, working without remuneration at present, and he will be pleased to give any information required. The Trustees, Committee, &c., are all elected according to the rules. The financial part of the Society was vouched for as being safe by A. G. Finlayson, Esq., the Government Actuary. The Society is well named Benefit and Provident, as, unlike any other benefit society, the members' moneys keep accumulating, with interest added each year, each member's account being kept separate; and the rules seem so adequate to reduce the call on the Benefit Fund to a minimum, that they should be carefully read by all wishing to join. There are no entrance fees, and no money fines for non-payment of subscriptions, this being specially provided for in the rules. For instance, my share of the sick pay was for 1877—1s. 9½d.; for 1878, 8½d.; for 1879, 1s. 0½d.; for 1880, 1s. 6d.; for 1881, 1s. 1¼d.; for 1882, 5d.; to January, 1883, 6¼d. The remainder of the members' subscription is placed at interest as before stated. I find I am member No. 1, having been the first Secretary, and joined in 1866, and I have placed to my credit, according to the balance sheet issued in February last, £38 5s. 0½d. There is no burial fund, the member's own money supplying this when required.

The benefits are 16s. per week in sickness, for which the subscription is 9d. per week, and 10s. 6d., for which 6d. per week is paid, and 2s. 6d. to the Management Fund, and 3s. to the Benevolent Fund annually. I trust the publicity now given may induce gardeners to come forward and join a Society founded specially for their benefit.—WILLIAM HEALE, *Lowfield Nurseries, Crawley, Sussex.*

N.B.—The annual meeting is held in February of each year. The sum now invested in 3 per cent. consols is £2485 1s. 10d.

ORANGE FUNGUS ON ROSES, &c.—We have been very much troubled with this of late years. Last year I took up and replanted several hundred Rose trees, which seemed to prevent the fungus coming so soon this year, but it did not cure them, as it appeared again as had as ever last month, and as the fungus is on the lower surface of the leaves it is very difficult to do anything to prevent it. I have seen a fungus much

like it on the Coltsfoot and Marshmallow and the Hollyhock, and also on the common Groundsel. I should like to know if they are alike or of a different kind.—GEO. CLEMENTS.

THE ROSE ELECTION.

GARDEN ROSES.

FROM various causes this election of garden varieties is scarcely satisfactory, at least to myself. Some few among the voters have understood the limitation of age in the newer varieties election to apply also to garden varieties; these returns, having evidently been framed on a misunderstanding, I have set aside. But again, another set I cast aside on first thoughts but afterwards included them, as, although they greatly modify the ultimate result of the poll, yet they are not really misleading in the general total. The returns in question wholly ignore the Tea and Noisette Roses, and in fact appear to have answered the question as though it had been "The best garden varieties among exhibition Roses of Hybrid Perpetual character," instead of "What are the best garden Roses?" To me it appears that this question is open enough to include any variety of Rose, and I am at a loss to understand how some of the Teas cannot be inserted. What, then, it may be asked, are the good qualities of garden Roses? I will try to answer this question according to my light. Firstly, then, it appears to me absolutely necessary that garden Roses should possess vigour of constitution. It is not probable that in ordinary gardens the Roses will be petted and taken care of through the winter; on the contrary, with rare exceptions they will be allowed to take their chance. Here and there one or two, being special favourites, may obtain some extra care, and therefore I should not be surprised at any list of twenty-four varieties containing two or more tender Roses, but I should expect these to be exceptions. Then they need to be free-blooming, and this may be produced either by perpetuality of bloom during the whole season, or by the excessive abundance during a shorter period, as in some of the summer Roses. Yet again, variety of Rose is essential, and as nearly allied to this requisite, distinctness. These qualities I should expect to find in a list of twenty-four varieties, and according to my humble and very fallible judgment, few, very few, of the lists sent appear to be framed on these principles.

I have in this election kept the two classes of voters distinct, not so much because I considered it necessary, but that it renders the return more interesting to compare the opinions of the two different classes of voters. These opinions are curious; for instance, Boule de Neige, Senateur Vaisse, and Mrs. Bosanquet, in all of which, although the nurserymen are only as two to three in proportion, the nurserymen's votes are far in excess of the amateurs'. Bouquet d'Or is a notable instance of the opposite kind, as no nurseryman mentions it.

The columns are the same as in the other election.

Order.	Name of Rose.	Character of Rose.	Date of Introduction.	Raiser's Name.	Amateurs' Votes.			Total.	Nurserymen's Votes.			Total.	Grand Total.
					A	B	C		A*	B*	C*

31	Victor Verdier	H.P.	1852	Lacharme	0	0	1	1	0	1	4	5	6

Of the remainder, eleven Roses obtained five votes; ten varieties reached four votes; eighteen others were mentioned three times; as many as thirty-five had but two votes, and it will scarcely be believed that in the total of 182 Roses named, seventy-seven, very nearly half, were only mentioned once. It seems to me, writing only from memory, that in no previous election have so many Roses had but a

solitary admirer, and yet the number of voters amounts to but twenty-eight. I certainly had made up my mind before the receipt of the lists that the lovely Banksian Roses would have had a few admirers, but they are amongst the solitary. Rose de Meaux again has but two friends, one being our esteemed friend "D., Deal," the other the returning officer. This, too, was most unexpected to me. "D., Deal's," list appears to me to meet my ideas of "garden" varieties more than any other, although that of Mr. J. Sladden is also of a similar character. As they may interest some of our readers, I give these two lists:—

"D., Deal's."	Mr. J. Sladden's.
1. Gloire de Dijon	Gloire de Dijon
2. Céline Forestier	Souvenir de la Malmaison
3. Rêve d'Or	Mrs. Bosanquet
4. Cheshunt Hybrid	Common China
5. Princess L. Victoria	Aimée Vibert
6. Blairii No. 2	John Hopper
7. Common Cabbage	Jules Margottin
8. Rose de Meaux	Queen of the Bourbons
9. Common Moss	Crimson China
10. Rosa Mundi	Céline Forestier
11. Settina	La France
12. William A. Richardson	Belle Lyonnaise
13. Rosa rugosa	Madame Plantier
14. Souvenir de la Malmaison	Felicité Perpetuelle
15. Cramoisie Superieure	Crimson Bedder
16. Lamarque	Fisher Holmes
17. Paul Ricaut	Blairii No. 2
18. Persian Yellow	Baronne Prevost
19. Jean Cherpin	Common Cabbage
20. Stanwell Perpetual	Charles Lawson
21. Crested Moss	Paul Verdier
22. Madame Plantier	Dupuy Jamain
23. Longworth Rambler	Fulgens
24. Paquerette.	Common Moss

Personally I am surprised that La France, one of the freest bloomers and most fragrant varieties, finds no place in the first list, but possibly its habit of declining to open in rough weather may have told against it. Still, either of these lists, containing different varieties as they do, yet seem to my view the fittest returns of "garden" Roses.

It must be confessed that this list of "garden" varieties, as brought out by the returns, has an unmistakeable aroma of the exhibition tent. Indeed it is not until we reach No. 25, the common or old Moss, that we arrive at a variety that has not figured in some exhibition stand during the last five years, whilst from 13 to 18 inclusive we find some of our best exhibition sorts of Rose; and out of the thirty-one tabulated very few indeed would not pass muster where seventy-two varieties were asked for.

Again I thank most heartily those who have assisted me by making returns. We may not absolutely hit the exact truth, and the collective opinion may not always be correct, but it is a sure move in that direction.—JOSEPH HINTON, Warminster.

WHITE ELEPHANT POTATO.

LIKE your correspondent Mr. Harrison, I find that the White Elephant Potato is, on heavy soils, a wonderful cropper, and I can safely say no other Potato grown here can match it for cooking qualities and flavour. I obtained 2 lbs. from Messrs. Daniels Brothers, Norwich, three years ago (to whom, I think, this Potato owes its publicity), from which I had over 80 lbs., many of them weighing 2½ lbs. each, and I have this year an immense crop of large sound Potatoes; but I find that if they are left in the ground too long after showing ripeness they are liable to disease. Therefore take them up in good time and you have the remedy.

The first year I grew them I exhibited a dish of them at our local show, and was told by the judges that they were cattle Potatoes, only fit for pigs. Since then some of these judges have grown them; and to show the fallacy that even judges are liable to fall into, I will just relate that I managed to get a dish of these very Potatoes prepared for the judge that took the greatest objection to them, and upon his being questioned as to the quality he declared it was a good, dry, floury Potato, and no better could be wished for. I have this year grown about eighteen different varieties, and took all the first prizes in our Cottagers' Show. My judgment is, there is no Potato for a poor man to surpass the White Elephant.—LOUIS BISSENDEN.

PANSIES AND VIOLAS.—Your correspondent "H., Notts," has contributed notes on the above flowers. Can any of your correspondents tell us the difference between Pansies and Violas as sold and grown, and I might also say exhibited, at the present time? I once put this

question to the late Mr. H. Hooper of Bath, whose decease I am sure will be lamented by many florists who had the good fortune to know him, but his answer was not at all satisfactory. The same subject has also occupied the attention of more than one Lancashire botanical society with which I am acquainted, and the decision arrived at being—Sow a packet of seed; call the good large flowers Pansies, the poor ones Violas.—WM. PLANT.

CONGRESS APPLES.

BRAMLEY'S SEEDLING.

ABOUT seven years ago fruits of this Apple were sent to us by Mr. H. Merryweather, Southwell, Notts, and we then predicted that it would prove to be a valuable variety. This prediction has been to a great extent verified, for the Apple has increased in public favour, fruits have been highly commended by the Fruit Committee of the Royal Horticultural Society at South Kensington, and at Chiswick last week it was one of the only two varieties honoured with certificates amongst the numerous seedlings submitted. As the woodcut (fig. 64) shows, the fruit is of good size, somewhat like Ecklinville Seedling, but, very dark green in colour; it also varies in shape and size, some being larger and others smaller than the specimen represented, more oblate and angular. It is heavy, the flesh being white, juicy, and melting, with a brisk but not too sharp acidity.

The variety was raised from seed by Mr. Bramley of Southwell some years ago, and was obtained from him by Mr. Merryweather

Fig. 64.—Bramley's Seedling Apple.

who distributed it to his customers in the neighbourhood, giving great satisfaction. The tree is strong in habit, quite free from canker, and is especially noteworthy for the character of bearing freely during bad seasons; in fact it is a very constant and abundant bearer. It is said by the exhibitor to be "ready for use when gathered, but can be kept until the following June, and cannot be surpassed as a kitchen variety."

THE INSECT ENEMIES OF OUR GARDEN CROPS.

No. 8.

THE greatly increased culture of the Strawberry throughout Britain has of late made us better acquainted with its insect foes, although we find that in some important points in their history we have still much to ascertain. As was to be expected, new enemies have appeared, tempted to attack the plant by the circumstance that now it is often cultivated, not in the limited area of the old-fashioned Strawberry beds, but upon extensive tracts of land. Other enemies we notice are doubtless species that have long frequented the plant, which, however, were scarcely observed when Strawberries were less grown, and gardeners perhaps less intelligent than they are in our day. The older writers upon gardening, in fact, hardly allude to any insects occurring upon the Strawberry, though they mention that the fruit is particularly liable to the visitations of snails, slugs, and the like, as it offers attractions to the molluscous tribe. It is likely that

some of the damage charged upon slugs was really the work of an insect managing to keep itself concealed.

The majority of the insects that infest Strawberries are beetles of the order Coleoptera, but rather diverse in size and habit. Before referring to these I have to speak of a species belonging to the Lepidopterous order, which has been briefly mentioned in this Journal by one of its well-known correspondents, Mr. Raitt of Blairgowrie. Having placed in my hands sundry particulars regarding its habit, this gentleman requests me to do what he himself could no doubt have done far better, and also to express his regret that from various causes he has been prevented from giving the account of it which he once promised to the readers of these pages. Mr. Raitt remarks very truly that this has the power to prove itself a serious enemy, the loss caused thereby in the vicinity of Blairgowrie during the last few years amounting to many hundreds of pounds. Fortunately no instance quite as bad has been reported elsewhere, but the insect has been found moderately mischievous in other districts, more in the north than in the south, I think. About May, when the new leaves are expanding, it is perceivable that a proportion of them continue folded, and appear to be spotted also, or pierced. Upon opening these we find generally a single "worm," or small larva, then seldom exceeding one-sixth of an inch in length. (From Mr. Raitt's use of the qualifying word "generally," it would seem that at times more than one larva is found resident in a fold of young leaves.) If these are left undisturbed they grow during some months, becoming adult in August, or possibly rather earlier, depending on the season. The bulk of the larvæ, at least, are fully grown in the summer; some, however, are to be detected upon the plants as late as September or October. The moth appears on the wing towards the end of the summer, and continues out till November. Both the leaf and the flower-buds are objects of attack, no doubt; where the leaves have been greatly checked in their development the plant subsequently puts forth few flower-buds, if any.

The circumstance is specially noted by Mr. Raitt that no moths are seen in spring; it is therefore highly probable, he thinks, that the species passes the winter months in the egg state, the egg being well hidden within the buds of the Strawberry. At the same time it is to be remembered that some of the moths allied to this species are known to hibernate and lay their eggs in the spring, but I hardly think it likely that if these insects did so they would have escaped the observation of this careful naturalist. That we should fail to discover the eggs is not surprising, they must be minute objects and usually scattered. Assuming, therefore, that the eggs are laid upon the plants during the autumn, Mr. Raitt thinks that a hopeful method of prevention is to clear the plants about October or sooner, then cover the crowns with earth to check the deposition of eggs. A less hopeful experiment has been tried, dressing heavily with some solid or fluid that might be supposed to kill the larvæ. But in May, 1882, one patch was well sooted, and another syringed with a solution of soft soap and paraffin, yet the insects survived, owing to their being protected by the wrappings of leaves.

Supplementing what is stated by Mr. Raitt, I may add that the insect in question has no familiar English name, but we might call it the Strawberry Moth; its Latin name is *Peronea comariana*. In Britain it appears only to have been recognised as a distinct species about thirty years ago, previous to which date it had been passed over as a variety of *P. comparana*. That insect is common throughout these islands, the larva feeding upon Sallow and Willow. Like most of the genus, these species are difficult to discriminate, from their markings being apt to vary, and specimens of two or three other species of *Peronea* have been taken for *P. comariana*. The wings are greyish or reddish brown, with a dark patch, sometimes lengthened into a bar; head and thorax also brown, the abdomen paler. The larva or caterpillar has the usual aspect of its brethren in the Tortrix tribe, greenish yellow, transparent, having the outer skin so loose that it overlaps the divisions of the body when the creature contracts itself. It has been taken upon the wild Strawberry as well as upon our garden varieties of these. Some naturalists report that it prefers the white-fruited kinds. Mr. Hodgkinson informs me that he has noticed the larvæ by hundreds in the middle of June, and a few weeks afterwards on examination he found that the sparrows had cleared many away, the marks of their bills upon the leaves being sufficiently visible.

The Strawberry is grown pretty freely in North Kent districts which I frequently visit, but the cultivators have not, to my knowledge, had to complain of this insect. Hence it happens that I am unable to say anything about it from my own observation, not having seen the species in life as yet. My friends who are entomologists do not appear to be satisfied that the deposition of eggs takes place during the autumn; it might even prove to be the case that some of the eggs are laid in autumn and some in spring. Mr. Raitt is positive that the flower-buds are infested as well as the leaf-buds; then, unless the larvæ migrate from one to the other, it is natural to con-

clude the moths place eggs upon the flower-buds at the early part of the season. And it is no uncommon circumstance for a hibernating moth to escape notice amongst the many insects of the spring, though it may be quite conspicuous towards the end of the autumn, when winged insects are few. One entomologist tells me he has seen the moths flying in clouds; if so, a considerable burning of weeds just at the time of their emergence would probably kill many, or check the distribution of eggs.

Leaving till next article some species that require to be noticed, we close with a brief reference to a subterranean enemy called vernacularly St. Mark's Fly (*Bibio Marci*), although I am hardly sure there is a good reason why it is thus placed under the patronage of a saint. Most of the larvæ or grubs in this group are feeders upon decaying substances, therefore not to be accounted injurious in gardens should they appear there; but those of *B. Marci* principally attack roots, and occasionally cluster about a plant in parties of twenty, thirty, or more. The Strawberry is one of the species it prefers, and another is the *Ranunculus*. This grub when adult is a little over half an inch in length, brownish, and studded with stiff short hairs, which serve instead of legs. In the male fly the eyes are remarkably large, almost joining each other; the female has them wide apart and inconspicuous.—ENTOMOLOGIST.

LORD DERBY APPLE.

I AM a great admirer of this fine Apple. We have only one strong bush-shaped tree, but this very rarely fails to carry a heavy crop of fruit, being superior in this respect to several others growing under similar conditions. The whole of the fruit generally grow to a great size, some measuring $13\frac{1}{4}$ inches in circumference, and they have when fewer in number measured 14 inches round. With us the fruit vary in shape considerably, as some are oblate or somewhat similar to the Grenadier Apple figured on page 321, though less symmetrical, while others are conical, as figured on page 320. In my opinion it is essentially a kitchen Apple, as, although juicy and sweet when ripe, they are much too clumsy for dessert purposes. Court Pendû Plat is my ideal dessert Apple, and I wish raisers of dessert varieties would take that for their model instead of going in for large size.—W. IGGULDEN.

FONDANTE DE CHARNEU PEAR.

THE VALUE OF WALL SHELTER.

AT last I have obtained some fruit of this little known but most excellent Pear. I have only one tree of it, a fine pyramid of such robust free growth that I had to resort to root-pruning to induce it to form fruit buds. This was done two years ago, and fruit buds are so abundant as to afford promise of a full crop of fruits next year. This year I have only a few dozens of fruits, some of which are just ripe, and prove so delicious as to induce me to thus prominently call attention to it. When it is better known it will undoubtedly take a leading place among our best dessert Pears, and it can only be from ignorance of its value that it is, and has been so long neglected. I had great difficulty in procuring a tree of it, but by the aid of the late Messrs. William & Thomas Osborn after much inquiry I was at length successful, but it is doubtful if it could be found in any nursery in this country now, for it is not mentioned in any of the fruit catalogues which I have seen.

The fruit answers so exactly to Dr. Hogg's description of it in the "Fruit Manual" that I cannot do better than transcribe it here:—"Fruit large, sometimes very large, the ordinary size being $2\frac{1}{2}$ inches wide, and $3\frac{1}{2}$ inches long; pyriform, uneven in its outline. Skin smooth, pale greenish yellow, with a faint tinge of red on the side next the sun, and thickly strewed with large russet dots. Eye large and open, with erect acute segments, set in a shallow uneven basin. Stalk upwards of an inch long, slender, curved, and inserted without depression by the side of a fleshy lip. Flesh tender, buttery and melting, sugary and richly flavoured. An excellent Pear, ripe in November." I may also add the interesting note of its origin:—"This was discovered as a wildling by M. L'égipont, growing on his property at Charneu, a village between Verviers and Aix-la-Chapelle, in the province of Liège, Belgium, in the beginning of the present century."

The ripening of Pears is so proverbially uncertain that it is difficult to fix the exact time, but November is undoubtedly about the time when this Pear is at its best, most of the fruit now being still firm to the touch, and with that faint tinge of yellow which indicates the beginning of the ripening process. The fruit is only of the ordinary size, notwithstanding the extraordinary vigour of the tree; but this is probably attributable to the tree being a pyramid, and in order to obtain fruit of an extraordinary size a palmette verrier or cordon of it should be trained against a wall. I intend cutting down half

a dozen cordons of Pitmaston Duchess, which is worthless and grafting Fondante de Charneu upon them.

The great difference which wall shelter makes in the size and form of many sorts of Pears is singular and important. One might naturally suppose that the finest and most handsome fruit would be found upon the most vigorous tree, irrespective of situation; but it is not so. So far as my experience goes wall fruit is always superior to that of trees of any form out in the open. I have just now gathered the fruit from a Marie Louise pyramid, growing only about 20 feet away from a west wall. The crop was moderate and the tree vigorous, so that there was nothing wanting so far to promote the full development of the fruit, yet it was little more than half the size, and not nearly so handsome as fruit of the same kind from a palmette verrier against a north wall only a few yards off. Nor is this a solitary instance. The same thing invariably occurs here with the fruit of Beurré Rance, Citron des Carmes, Louise Bonne of Jersey, Doyenné du Comice, Beurré Clairgeau, Williams' Bon Chrétien, Madame Treyve, Huyshe's Victoria Winter Nelis, Bergamotte Esperen, and Fondante d'Automne, all of which I happen to have planted here against walls of various aspects, and also out in the fruit garden. The late Mr. J. R. Pearson said, "Few persons have any idea of the excellence of many Pears when grown on a good wall," to which it might once be replied that few persons had wall space at their disposal for such a purpose. But now that the value of cordons is fully understood almost every garden may have its selection of choice Pears on walls, for twenty cordons only require the space once devoted to the huge horizontal tree with its spread of 30 feet.—EDWARD LUCKHURST.

KITCHEN GARDEN.

Winter Protectors.—These should all be ready and in order before frost or severe weather sets in, and as this may come at any time now it will be well to make preparation. The Bracken Fern is one of the best materials that can be used for placing over Celery, Lettuce, and all young or tender vegetables in winter; and this should be cut now, as when left until quite decayed it crumbles away when dried and is of little use. It should be cut when dry, allowed to lie on the ground for a few days, and then be taken in and stacked or stored in a shed. Frames, handlights, and sashes requiring repairs or paint should be attended to now, as it is a great advantage to have these in good condition when using them as protectors in winter.

Blanching Endive.—All the Endives grow and spread outwards, and to have them delicate, white, and tender in the centre they must be tied up and blanched. It generally takes about three weeks to blanch them after being tied up, and the first should be tied up now and a small batch at intervals throughout the autumn and winter. Any short pieces of matting do to tie them with. All the leaves should be gathered in a cone-like form and then bound rather firmly together.

Open Air Tomatoes.—These have stopped growing, and as a few degrees of frost will spoil the fruit it should all be cut and the plants thrown away. The smallest fruits need not be saved, but all from the size of a pigeon's egg upwards will be useful and should be looked after. The best way to treat them is to tie eight or ten fruits together and hang them in a warm airy place until they ripen. If many fruits can be cut now they will keep up a supply until Christmas.

Rhubarb for Forcing.—Where Rhubarb is wanted as early as possible or about Christmas, the roots often refuse to grow freely, partially through their often being grown in the shade and being not well matured, and also owing to their not being well rested before forcing. In damp soil it takes them a long time to become dormant, but if lifted now and placed in a shed with a few leaves over the roots they will soon be completely to rest, and when introduced to the forcing quarters they will grow readily. Rhubarb which is only being cultivated in the ordinary way in the main quarters should have all the old leaves removed as soon as they decay, and then spread a good coating of manure over the crowns.

Lifting Late Potatoes.—Probably all these have not been dug yet, but they should be placed under cover now quickly, as the weather will not benefit them in any way. Potato-digging should only be done when the weather is fine and dry.

Earthing Celery.—Celery in all stages of growth must have attention in this way. That which had some soil placed to it a month or more ago will have grown more now, and should have a final earthing-up. The utmost care should be taken that none of the soil falls into the centre of the plants; but when each plant is bound with a piece of matting there is not much danger of this happening. In banking the soil against the

plants the outside should be beaten firmly and be made quite perpendicular, so as to throw off the rain.

Young Cabbages.—Snails and caterpillars may have eaten some of these in the quarters lately planted, and the blanks should be filled at once, that the plants may become established before winter.

Kidney Beans.—Under ordinary culture these are almost over, but dwarf varieties still fresh and green may have their period of usefulness prolonged by covering them with frames or other protectors. Late plants grown in frames should have air admitted to them every fine day, and superfluous damp should never be allowed to collect about them, as this will make the tender young fruit decay, and it will also prevent the fruit forming. A large batch of Osborn's Forcing variety should be sown in pots now to bear fruit about Christmas. We like to put six or eight seeds into a 3-inch pot, grow them in these until the plants are 4 inches high, and then place them in 8-inch pots. Other persons grow them satisfactorily without repotting. Good soil and not less than a temperature of 65° is necessary to do them properly.

Winter Cucumbers.—These should now be strong and healthy, and capable of bearing fruit from November onwards. Keep the shoots well thinned out. Never allow the leaves to become dirty. Insects should never obtain a footing at this season. When they do it is most difficult to eradicate them, as the plants have not the same vigour to resist them as they have in spring or summer. Syringe on fine days, and any leaves on which there are insects should be sponged. Where the young fruits are coming in clusters nip them all off but one, as this will be quite enough at each joint now. The temperature at the top and bottom should not be lower than 65° or higher than 75°.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Early House.*—If the trees in the earliest house have not been pruned no time should be lost in finishing this operation, in order that the wood may be properly cleansed and dressed. The trellises and woodwork should also be washed and painted if necessary, and when these operations are completed tie the trees carefully to the trellises. Protect the outside borders with a layer of dry fern to throw off the wet, having all ready for forcing when the time arrives.

Second and Midseason Houses.—The trees in the house that ripened their fruit in June have shed their leaves, and should now be pruned; but if disbudding, thinning the growths where too crowded, and cutting out the bearing wood of the current year as soon as the fruits were gathered, was attended to very little pruning will now be necessary, as the shoots will have ripened to their extremities. If, however, there be too much wood thin out the weak, and only cut back any shoots that have sappy growth, removing also weakly attenuated shoots intended for next year's bearing that have only single bloom buds to firm wood with triple buds, making sure that the pruning eye or joint has a wood bud. The house and trees should then be thoroughly cleansed, and the whole put into thorough-going order ready for a fresh start. The trees in mid-season houses will be parting with the foliage, and should be assisted by brushing them with a light broom. If any rooting or lifting is contemplated it should be performed whilst the leaves are upon the trees, as it is important that root-action be encouraged immediately following the operation.

Late Houses.—The trees in these will be ripening the wood and plumping the buds. They must not lack water at the roots, and should have plenty of air. When the wood is firm root-pruning or lifting when necessary should be performed. Young trees that make vigorous growth and show a proneness to late growth should have a trench taken out about 3 feet from the stem and as deeply as the roots, and cut off all outside the radius, leaving the trench open for ten days or a fortnight, when it may be again filled up firmly, the surface soil being removed down to the roots and fresh material replaced and made firm, a good watering being given, and mulch the surface with short manure.

Weakly Trees.—Trees that have made weakly growth in consequence of heavy cropping may be induced to break strongly another season by having two or three good waterings with liquid manure, which should be applied after the removal of the mulching and hard surface soil down to the roots, afterwards top-dressing with about 3 inches of good loam from an old pasture, adding a little charred refuse and old mortar rubbish, not adding any manure except as a mulch to the surface. Pruning in the case of weakly trees may be more severe than when the trees have made vigorous growth; but the best time to do this, or rather thinning out the past year's wood, is immediately after the crop has been gathered, in order that there may be the free action of light and air on the young growth to ripen it and perfect the buds for next year's crop.

Pruning Young Trees.—Trees that are young and extending should only have the wood thinned out where too crowded, and should only have the growths cut back to originate shoots for filling the vacant space with regularity, and any shoots not ripened to their points may also be cut back to firm wood; but where gross shoots have been stopped during the season of growth little shortening-back or pruning will now be necessary.

The planting season having again come round we may give a selection of varieties, of which many of the recent introductions have size, and in some instance colour, to recommend them; but it must be said of the majority that they are deficient in quality as compared with the older sorts. *Early Peaches*:—Alexander, Hale's Early, Large Early Mignonne, À Bec, Dr. Hogg, and Crimson Galande. *Midseason*:—Grosse Mignonne, Alexander (Noblesse), Royal George, Belle Beauce, Violette Hâtive, Dymond, and Bellegarde. *Late varieties*:—Stirling Castle, Barrington, Late Admirable, Nectarine Peach, and Prince of Wales.

Nectarines:—Advance, Lord Napier, Hunt's Tawny, Elruge, Violette Hâtive, Pitmaston Orange, Pine Apple, Humboldt, and Victoria are good.

Cherry House.—The lights having been removed as advised some time back they should be replaced before severe weather; but before doing so it will be well to have the rafters well scrubbed down with soft-soap and water, and the house thoroughly cleansed; the remaining foliage ought also to be removed, and the trees dressed with an insecticide. The house should be kept well ventilated, except when frost prevails, so as to keep it as cool as possible. If planting fresh trees is contemplated the needful compost should be prepared, so that the work may be expeditiously performed when the trees from outdoors are fit to remove, as they are when the leaves have generally begun falling. The top spit of a pasture where the soil is a medium-textured loam, with a sixth of road scrapings, is the most suitable compost. Trees that have been trained to walls for two or three years are best. In the matter of varieties, Black Tartarian, May Duke, Elton, and Governor Wood are suitable.

MELONS.—The latest crops are now ripening, and should have a somewhat high temperature and dry airy atmosphere, or they will not ripen well or be of good quality. By artificial means a day temperature of 70° to 75° should be maintained in dull weather, with 10° to 15° rise on clear days, and 65° to 70° at night, having a little ventilation constantly. Water will only be required at the roots to prevent flagging.

PLANT HOUSES.

Eucharis amazonica.—Where these plants are grown largely for flowering during the winter months, and have been treated liberally through the summer without allowing them to flower, they should now be in the best condition. Those that have fully matured their growth should have less water at the roots and then removed for two or three weeks into a temperature of 50°. Cold draughts must be avoided, and the plants must only have sufficient water to prevent the foliage flagging. They must also be watered very carefully after they are again brought into warm quarters. After a short rest the plants will quickly produce their flower spikes. If the plants rested are in small pots and full of roots feed them liberally after their spikes are visible. By resting a few well-grown plants at different times or at intervals of a few weeks, a valuable supply of blooms will be maintained. With plenty of plants in small pots and the resting properly carried out, it is by no means difficult to have flowers during the whole winter. *E. candida* is worth growing because it can be flowered in very small pots, and on this account is valuable for room-decoration; its flowers, which are much smaller than those of *E. amazonica*, and will be found invaluable for bouquet-making.

Tabernaemontanas.—The varieties of this useful plant are producing their double white flowers nearly the whole year round. *T. coronaria* fl.-pl. is more adapted for spring and early summer flowering, while *T. camassa* produced its flowers in greatest abundance about August. This has been the character of our large plants, and in order, if possible, to induce the first-named variety to flower during the winter we cut it hard back, and after it had commenced growth we pushed it on rapidly, until a few weeks ago it was placed under a little cooler treatment. It is again in brisk heat, and has commenced showing a fair number of flower buds. Hard cutting-back appears to suit them well, for our plants have made remarkable growth, and we intend to subject them to the cutting-back system annually, especially so if we can make them flower during the dullest months of the year by so doing.

Gardenias.—Where a few old plants were retained and pushed on rapidly to make their growth early in the season, and then subjected to a little cooler treatment, will have, if in any way confined at their roots, abundance of flower buds in various stages of development. These will come forward rapidly if placed in brisk moist heat, especially if they can be accommodated with a little bottom heat. When introducing them give the plants a little Standen's or Crown Manure, both of them being very good for these plants, as the young growing fibry roots soon show on the surface. We have great faith in the application of the manures named, to be applied to the surface of the soil, and the feeding with guano and other stimulants through the water pot that has been in practice so long will soon be obsolete with us, for more harm than good often results from this kind of feeding, especially when the work is left to inexperienced hands.

Ferns.—Those that are grown for cutting, whatever the varieties may be, must have light positions, and where the temperature is not too high and air can be freely admitted when favourable. These conditions must be strictly observed if the fronds are expected to last long after they are cut. These plants are not unfrequently, when grown for these purposes, kept too moist, too much shaded, and too high a temperature. Fronds cut from plants grown under such conditions are almost useless, and often shrivel before they can be arranged in the vases. Plants that have been subject to such conditions may yet be wonderfully improved if they are shifted into another position and the conditions named above carefully carried out. These plants must not suffer from having insufficient water, and feeding must be resorted to if the plants are thoroughly root-bound.

Narcissus and Roman Hyacinths.—If these plants were potted when advised they will be taken from the plunging material and at the present time be in frames. At first light must be admitted to them gradually, or else their foliage will be injured. As soon as the foliage is green they may, if wanted in bloom as early as possible, be placed in a temperature of 55° at first, and then 60° after they have commenced growing. Keep

these plants as close to the glass as possible, and give them abundance of water.

THE FLOWER GARDEN AND PLEASURE GROUNDS.

Propagating Shrubby Calceolarias and Violas.—The present is a good time to insert cuttings of Calceolarias, and it is not yet too late to propagate Violas. Frames, in size according to the number of plants eventually required, should be employed, and if a few only are grown then handlights are suitable. The former to be stood on a hard dry surface, some rough partially decayed manure thrown in and made moderately firm; next, about 6 inches in depth of any fairly good soil available, and on this a thinner layer consisting of equal parts of sifted loam and leaf soil, with a liberal addition of sharp sand or road grit, this being levelled, faced with sand, and lightly smoothed with the back of a spade. The cuttings to be made from rather firm flowerless shoots, these being shortened and trimmed to about 3 inches in length, and dibbled in firmly at from 2 to 3 inches asunder each way. Water them in, put on the lights, keep close and shaded from sunshine during the day, give a little air during warm nights, and when found to be rooted, say in about seven or eight weeks' time, give all air possible. The aim should be to check growth till later on, when it can be encouraged under more favourable circumstances. It is useless to attempt to strike flowering shoots of Violas, those only which are springing from near the stem being suitable for the purpose. Cuttings of Gazania splendens may be inserted and treated similarly to the Calceolarias.

Perennials.—Cuttings of good sorts of Antirrhinums, Pentstemons, Pansies, and Phloxes may yet be dibbled-in in handlights disposed at the back of a north wall or in a cool shady position. Use plenty of leaf soil and sand in the compost. Select cuttings from the least sappy young shoots, dibbling these in firmly. Water them in, keeping them close and shaded as required. New beds of either of the foregoing may be formed during favourable weather, and this will lighten the usual heavy spring work. All are better for frequent divisions and replanting in rich and deeply dug fresh soil. They will need mulching with either leaf soil, short manure, or cocoa-nut fibre refuse, or otherwise may be injured by frost. Well-rooted cuttings or layered plants of Carnations, Picotees, and Pinks ought to be separated from the parent plants, and either potted up or planted out in deeply dug beds, to which has been added a dressing of horse manure, this being especially suitable when collected from the roads, and therefore gritty. Any extra choice or delicate sorts may well be potted off singly in 3-inch pots, wintered in cold frames, and planted out early in spring, this being particularly advisable where slugs are troublesome. Strong well-hardened seedlings may also be planted out; but these in many cases will soon be eaten by slugs unless the beds are surfaced with cocoa-nut fibre or the ashes from a garden "smother." The slugs should also be trapped either with Broccoli leaves or heaps of bran. Choice Dianthus and Pyrethrums are also much preyed upon by slugs, and those very solicitous to preserve them should lift and place them in boxes of good soil, and cover with frames. The Pyrethrums may be divided at the same time.

Flower Beds.—Advantage should be taken of dry weather to clear off Geraniums and other summer bedding plants—no matter how fresh they may be—in order to refill the beds with the spring-flowering plants. If this is delayed till cold wet weather intervenes the work cannot possibly be well performed. Such plants as Silenes, Saponarias, Limnanthes, Forget-me-nots, Wallflowers, and Daisies are all more gross-feeding than the majority of the summer bedding plants, and consequently the beds ought to be enriched with plenty of short partially decayed manure. In dry weather this can be better dug in, and the bed made firm about the plants, so that the latter be less likely to be up-heaved and injured by frosts. In the next calendar reference will be made to suitable combinations of hardy plants and bulbs. The carpet beds, where protected by canvas or even branches of evergreens, are still attractive, and may well be spared a time longer. The choice succulents dotted about the designs can be protected during the nights with inverted flower pots, taking care, however, to stop the holes of the pots. If the designs or groundwork are formed with hardy plants, these will admit of the introduction of other hardy plants, which, if duller in colour than the former delicate occupants, will still preserve the figures, and render the beds ornamental during the winter.

THE BEE-KEEPER.

HIVE-CONSTRUCTION, HONEY-PRODUCING, AND PRACTICAL MANAGEMENT OF BEES.—No. 5.

(Continued from page 303.)

It may be argued against the use of shallow frames that the bees are liable to perish in winter in consequence of their having to change their clustering place more frequently than if they were on large frames of comb containing double the quantity of food. This sounds reasonable enough in theory, but in practice we have found the result entirely opposite, and where stocks in our apiary have perished at one end of the hive while plenty of food was stored at the other end. Such disasters have only occurred in hives with large deep frames, and in no single in-

stance have we known it happen with the shallow frames. The reason is not far to seek. We winter the bees on nine frames, which are about equal to six of the Association standard size. Now if the floorboard of a deep-framed hive is withdrawn in cold weather, and we can look from below up among the combs, we observe the bees clustered to within about 3 inches from the lower edges. When the warm sun plays about a hive on a sunny day in winter it causes the cluster of bees to expand a little, and they feed while this movement is going on. Any tyro in bee-keeping knows that bees do not hibernate like queen wasps or humble bees, but that they require food, probably every day in the coldest weather. When the sun's rays do not help them in the way mentioned, either the act of feeding or the desire for food brings into play the wonderful power bees possess of increasing the temperature of the hive at will, and they spread themselves out to seek food as it were; but they do not expand sufficiently to pass under the bottom of the combs, and hence the necessity for cutting winter passages to assist them in reaching food. These winter passages only lessen the evil, but do not do away with it. Now we contend that a shallow frame does. The bees when the least expansion of the cluster takes place can pass freely under the combs, take up a new position on them, and no winter passages are necessary.

The well-known broad-shouldered top bar of Mr. Abbott has been adopted, and the frames slide on metal runners raised one-eighth of an inch above the back and front of the inner walls. The sides of the body of the hive are level with the top of the frames, the back and front being also level on the outsides, while the cork-packed space between the outer and inner walls is five-eighths of an inch lower, and has a half-round groove along its whole length under the frame ends to allow free finger-room for manipulating. It will be seen that the distance between the ends of the frames and the inner walls of the hive is regulated by the raised outer walls, and when the frames are in position their tops and the walls form a perfectly level platform.

Broad Frame for Sections.—During the last year or two much importance has been attached to the advantage of working sections in the body of the hive. The system does not, so far as we can judge, appear to find so much favour in practice as in theory, for we have found very few bee-keepers indeed who regularly follow the plan of obtaining the bulk of their section honey in this way, though a great many have, like ourselves, tried it and given it up. There can, however, be no doubt about the great advantage of starting sections as well as finishing them off in the body of the hive under certain conditions which generally exist at the beginning and end of each honey season. Our broad frame has a top and bottom bar, each five-eighths of an inch thick, hinged at the side, and holds three 1 lb. sections of the ordinary $4\frac{1}{2}$ by $4\frac{1}{2}$ size, or two $1\frac{1}{2}$ lb. sections $6\frac{1}{2}$ by $4\frac{1}{2}$.

Spare Frame Box.—This very useful adjunct to our hive is $14\frac{5}{8}$ by $13\frac{1}{2}$ inside measure. It holds nine frames, and during a great portion of the year remains on the top of the quilts ready for use. The object for which it was originally devised was to hold the frames which are removed indoors when reducing the number of combs in preparing the bees for winter, and it is of course always used for this purpose; but it is so useful when manipulating for holding frames of comb foundation, section frames, queen-excluding diaphragm, &c., that we always let it remain from March to October on the top of the hive. Sometimes it is filled with frames of comb, and when placed by the side of a rack of sections is used for slinging purposes; we thus have sections at work and slinging going on at one and the same time. Last but not least, in cases of emergency it forms a makeshift hive admirably adapted for second swarms or for accommodating driven lots of bees. We have had as many as half a dozen stocks at one time located in these spare frame boxes till we had time to get hives ready for them.

Entrances.—These are three in number. The centre one is 6 inches long and half an inch high, the side ones are each 3 inches long and are $4\frac{1}{2}$ inches from the larger or centre one. This last has two sliding doors, each $3\frac{1}{2}$ inches long, while the side entrances have each one door the same length. These doors, by means of a sort of dovetail cut in the upper side and a corresponding cut in the slide in which they work, will not fall out when the floorboard is withdrawn. The side entrances are kept closed for a great part of the year.

It is well known that bees are often much distressed in very hot weather in consequence of the great heat in populous stocks at such times. To obviate this it is usually recommended that the floorboard be withdrawn a little, or the hive raised up so as to allow a free current of air underneath, while the bees pass out in front and rear. Our objection to this was the crushing, so horribly grating on the nerves, which in spite of

the greatest care was sure to take place sometimes while replacing the wedges under the floor in the evening. With three entrances, 12 inches long in the aggregate, the air can pass under the whole of the hive without disturbing the floorboard, and we find none of the evil effects of overheating.

When it is desired, half a dozen frames may be used for slinging from the body of the hive while sections are on, and the side entrances render it unnecessary to watch that drones are not imprisoned when inserting the queen-excluding diaphragm. In addition to this there is the advantage of the bees not being compelled to work through the excluder zinc. Another special use for the side entrances is that we are never at a loss for a nucleus hive; the exercise of a little ingenuity in arranging the entrance so that the queen may not mistake it being all that is required, and we can form a nucleus of from two to five frames of the very best size and form for the purpose.

A close-fitting block of wood having a projecting screw in the front side to facilitate its withdrawal, is inserted in each of the side entrances when they are not in use, and are pushed up flush with the inner wall of the hive to prevent the bees passing round the dividers when they happen to be placed across the entrance.—**WM. BROUGHTON CARR.**

LINCOLNSHIRE BEE-KEEPERS' ASSOCIATION.—The eighth annual Exhibition of this Association, which is advertised to be held in the Exchange Hall, Grantham, on the 19th inst., is expected to prove a great success, the entries being numerous, and the competition for the prizes offered will probably be keen in several of the classes. On the following day a honey fair will be held, and 2 tons of honey are anticipated. A correspondent states "the town is beginning to be all of a buzz already," a result, no doubt, mainly due to the zealous and enterprising Honorary Secretary of the Society, Mr. Godfrey.

TRADE CATALOGUES RECEIVED.

- Francis & Arthur Dickson, Chester.—*Catalogue of New and Select Roses.*
 L. Delaville, 2, Quai de la Mégisserie, Paris.—*Catalogue of Bulbs and Tubers.*
 Thomas Rivers & Son, Sawbridgeworth, Herts.—*Catalogues of Fruit Trees and Roses.*
 George Cooling & Son, Bath.—*Catalogue of Roses and Fruit Trees (illustrated).*
 Cranston's Nursery & Seed Company, King's Acre, Hereford.—*Catalogues of Roses, Fruit Trees, and Forest Trees.*
 Thomas Horsman, 102, Godwin Street, Bradford.—*Catalogues of Roses and Bulbs.*
 Joseph Schwartz, Route de Vienne, Lyon.—*List of New Roses.*
 L. Späth, Berlin.—*General Catalogue of Plants.*
 Constant Kerkvoorde, Wetteren, Belgique.—*Catalogue of Fruit Trees and Roses.*
 William Paul & Son, Waltham Cross.—*Catalogues of Roses (illustrated), Fruit Trees, and Shrubs.*
 E. Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Seed Corn (illustrated).*
 William Kerr, Dargavel, Dumfries.—*Catalogue of Seed Potatoes.*
 William Rumsey, Waltham Cross.—*Catalogue of Roses.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Treatment of Water Lily (*Devoniensis*).—There will be no difficulty in preserving the plant if you place it in a large pot or tub, and sink this about 6 inches to a foot beneath the surface of the water. A compost of good loam, leaf soil, and a little well-decayed manure is the best that can be employed, and in it the plant will grow strongly.

Seedling Dahlias (*W. H. C., Kent*).—The blooms sent are not equal to many varieties that are now in cultivation, and if you visit a large

collection, either public or private, you will form a better idea of the improvement which has been effected in recent years.

Yellow Tomato (*F. W., Isle of Wight*).—You can take out the seed if you choose before sending the fruit, but in that case it would probably not reach us in the best condition for estimating its merits. We cannot undertake to comply with your alternative proposition. We think Messrs. Daniels gave you good advice to try the variety another year and compare it with others, as only by that means can its merits and distinctness be satisfactorily determined.

Calceolarias (*Inquirer*).—There is no better place for Calceolarias at this season of the year than a cold frame; but they must be placed on ashes or otherwise arranged so that worms cannot enter the pots. The plants cannot be placed too near the glass, but they will do very well at the distance you name provided the glass is kept clean. The soil must never be dry, and an insect never be seen on the leaves. They may remain in the frame as long as they are safe from frost.

Blinds Decaying (*Cambridge*).—Although we do not think that waterproofing would materially prevent the blind rolling, we are of opinion that as tiffany is so cheap, it would be easier, better, and more economical to cut off the decaying strip and attach a new piece. Waterproofing is a tedious process, and you might not succeed to your expectations, and it would be better to purchase material already waterproofed, if you require it, when making new blinds. A method of waterproofing is published on page 305, our issue of the 4th inst., in answer to a correspondent who required it for covering a temporary structure for protecting Chrysanthemums.

Cypress Unhealthy (*A. B. C.*).—We fear your letter has been overlooked, but as it is not dated we are unable to determine for how long; however, nothing has been lost by the delay. The only method we can suggest for renovating the specimen is to remove the exhausted soil from the roots and cover them with a mixture of fresh loam, wood ashes, and leaf soil, pressing it down firmly, and surfacing it with manure to keep it moist and exclude frost. In all probability young roots would take possession of the fresh material, and healthier growth would then follow. The greater the distance the soil is removed from the stem the better, and no time is more favourable for the work indicated than the present.

Variiegated Currant (*Ludlow Subscriber*).—Variiegated forms of the Black Currant are occasionally met with, but as a rule the leaves are not so distinctly marked as those you have sent, from half to two-thirds of their surface being creamy white. It is rarely these variiegated bushes grow freely, most of them having a stunted appearance, with small wood and malformed leaves. The fruit they produce is also small and inferior in quality. We quite agree that the bush from which you have sent us a spray has a pretty effect; and if some of the strongest growths were used as cuttings and inserted the young trees so raised would be more vigorous than the old, and some of them at least might retain the variiegated character of the parent bush.

Roses in Clay Soil (*J. M.*).—No doubt the application of the road drift (which we presume is gritty) and manure, applied as liberally as you propose, will be of great benefit; but we quite fail to comprehend the circumstances which prevent you taking up and replanting the Roses, since you appear to be able to dig the ground between them. The work would be more quickly done if the ground was first cleared, and certainly better for the Roses after they were replanted, as adding a thickness of 6 inches to the surface would bury the roots too deep, while they would still remain in the strong cold soil, and could not derive the benefit they ought by the more gritty compost above them.

Dividing Vallotas (*Sussex*).—If you wish to increase the number of your plants the small bulbs may be separated from the others and potted just when the plants commence growing in the spring. For producing large brilliant masses of this fine autumn plant dividing is not necessary, but larger pots, or rich top-dressings may be given as required to insure strong healthy growth. Potfuls of bulbs producing from fifty to 100 trusses are highly effective. Two rows of Roses will be ample for your bed, planting 2 feet apart in the rows and quincunx fashion—that is, the plants in each row not opposite each other.

Employment in the Tea Plantations (*W. C. B.*).—If you have no private and influential friends who could obtain you a situation such as you desire, the best course would be to endeavour to enter the Royal Gardens, Kew, stating at the time that you desire to go abroad. There are many situations for which good salaries are paid, and we know several young gardeners who have succeeded extremely well in various parts of India, as well as in the tea plantations. The gardeners taken on the Kew staff are expected to have a general knowledge of indoor and outdoor garden routine, to be fairly educated, and to have good moral characters. If you apply to the Curator, Mr. J. Smith, he will forward you the necessary form, which must be filled up, signed by your employer, and returned to Kew, when, if your credentials are found to be satisfactory, your name will be placed upon the books to await a vacancy if there is not one at the time. Between thirty and forty young men are employed, and some are constantly leaving, so that it is not likely you would have to wait very long.

Peach Flowers Falling (*Lodge*).—Defective root-action, immature wood, dry soil, and a moist and close atmosphere during the flowering period, are all contributory causes of the evil of which you complain. In all probability you would do well to raise the roots of the trees at once, placing them in fresh soil, and keeping the border regularly yet not excessively moist. Read Mr. Bardney's article on page 290, the issue of the 4th inst., and follow the practice there detailed. In the spring when the trees are flowering draw gently a plume of Pampas or Feather Grass over them after it has previously been used on the free-setting variety, and the blossom will probably set freely, but only if the root-action is good, the border moist, and the wood ripe. Your long stringy Peach is probably worthless; why not remove it and plant a good variety?

Working in Hothouses (*B.*).—In some gardens probably a man may have time to take off his coat every time he enters a hothouse, and put it on again when he emerges into the open air; but these are what gardeners know as "easy places," and are not common. In the majority of gardens

where glass structures are numerous and much forcing is done the men are too few in proportion to the work to render such precautions practicable. Much work has to be done in a limited time, especially towards the close of every afternoon, and the men have to move quickly, and possibly this brisk movement is beneficial, for certain it is that young men who are naturally healthy seldom take cold when thus engaged, whatever changes of temperature they have to endure. Men who are not healthy ought not to share in this occupation, nor should slow standing-about men, who are almost certain sooner or later to pay the penalty of their resting habits by receiving a chill that may have serious consequences. At the same time even active men should not be reckless, and pass from a tropical temperature to a cold potting shed, and there remain for half an hour with no more protection than they had in the heated house. If any of our readers can give what you ask—namely, “some directions how to work in houses with a high temperature, and at other times in the open air, with the least injury to health,” we will readily publish the information.

Making a Boiler (H. J. G.).—As you “know nothing about boilers” you had better employ someone who does know something about them to make one for you. We will, however, answer your questions. The boiler should be entirely closed; the flow pipe to be taken from the top of it, and the return entering near the bottom. An aperture should be made for the escape of air at the highest part of the flow pipe, but will seldom require to be open, never so long as the water circulates freely, as it will do if the pipes are properly arranged, and then the boiler will be quite safe. The flow pipe is best taken vertically for a foot, or as much more as you like, then conducted along the house with a slight rise to the further end, the return to have a corresponding fall, but in no case must any part be below the boiler. The feed pipe may enter the return hot-water pipe close to the boiler, the cistern supplying the water to be on a level with the highest part of the pipes in the house. A boiler containing half a gallon of water, or even less, would suffice for your gas pipes; but they are too small, and half the length of twice the size would be better. You had better consult some practical man on this subject, and this, with our reply, may enable you to succeed in your object.

Vines Cropping Indifferently (Rosa).—The mealy bug, though calculated to injure, and, in fact, spoil the crop, would not cause the Vines to crop so badly unless some insecticide were used to destroy the insects and has also proved injurious to the Vines. This we apprehend is the case, as you state the Vines have few spurs. Instead of cutting down the rods, or removing them and replanting, it would be better to take up a cane from the bottom of the rafter of each Vine next season and train them up without stopping until they reach the top of the house. The laterals should be allowed to make as much growth as the space will admit without interfering too much with the light, to which the principal leaves should have full exposure. When the wood of the cane becomes brown and hard the laterals should be shortened by degrees until they are brought in close to the cane, which last, when the leaves have fallen, may be cut back about one-third of its length, and depressed the following season before the eyes start it will break from the base and through its length, showing fruit plentifully. The cane should be disbudded, leaving shoots along both sides at about 18 inches apart. This cane will supplant the old rod, hence when the Grapes are cut the old rod should be removed and the young cane left in its place. This will not cause any loss of crop. As the border has only been half made, by which, we presume, half the space is meant, it would certainly be advisable to increase the width; but if the term be used figuratively, or that the border is a bad one, it certainly would be advisable to lift the Vines and make a proper border, which should be done so soon as the leaves give indications of falling. Even if the border be only “half made” it would, were lifting not resorted to, be advisable to remove the surface soil down to the roots, and if these are deep raising them and laying in fresh compost within a few inches of the surface, or if not lifted cover the roots with fresh loam, to which has been added some crushed bones and a small proportion of charred refuse. See that the drainage is good, as the Vines will not thrive in a water-logged border. Syringing will not bring mildew, nor in any way injure the Grapes, provided the water be clear and used judiciously. The mealy bug may have been brought into the house with the plants. The Grapes will never be satisfactory until the pest is exterminated, for which there is no better remedy than the judicious application of petroleum, the Vines and house being syringed with a solution of it after the leaves have fallen, thoroughly wetting every part, and repeating in the course of a few days, or so soon as the Vines become dry. A wineglassful to three gallons of water is a proper quantity, and when applied should be kept thoroughly mixed by a few sharp squirts into the watering-pot, and afterwards every alternate one on the plants and watering can. This may be repeated just before the Vines are starting into growth, and with careful attention in looking for and destroying any insects that may appear during growth, very little injury will be done to the Grapes next season. The plant must, however, be thoroughly cleaned.

Names of Fruits (Kidder).—*Apple*.—2, Kerry Pippin; its shape is not explainable. *Pears*.—3, Red Doyenné; 4, Easter Beurré. We cannot name the other. (R. J. L.).—3, not known; 4, not known; 5, Doctor Harvey; 11, Keddleston Pippin; 13, Cox's Pomona; 14, Cox's Orange Pippin. (Long-craft).—7, Adams' Pearmain; 8, Reinette de Caux; 9, Dumelow's Seedling; 10, Blenheim Pippin; 11, Petworth Nonpareil; 12, New Hawthornden. (L. B.).—1, Greenup's Pippin; 2, Golden Reinette; 4, Cobham; 6, Flower of Kent. (Fareham).—Maréchal de Cour. The flower appears to be a good variety of *Aster novæ-belgii*. (W. B.).—*Pears*.—1, Gansel's Bergamot; 2, Beurré Sterckmans; 3, Beurré d'Amanlis. *Apples*.—1, Blenheim Pippin; 2, Nelson Codlin; 3, Court Pendu Plat (C. J. Nicholson).—1, Beauty of Kent; 2, Nelson Codlin; 3, not known; 4, Greenup's Pippin or Yorkshire Beauty; 5, Lord Suffield. (Mrs. Shepherd).—1, Court of Wick; 2, Golden Pearmain; 3, Nonpareil; 4, Fearn's Pippin. Warner's King is a large kitchen Apple, and Lord Burghley is a small dessert. (John Larner).—The Apple is no doubt Cox's Orange Pippin, but the other we do not recognise. It is probably a local variety. (W. Thornton).—1, Beauty of Kent; 2, Golden Noble; 3, Boston Russet; 5, Golden Russet; 6, Winter Greening. (W. H. Wakeley).—1, Bedfordshire Foundling; 2, Round Winter Nonesuch; 3, Pennington's Seedling; 5, Wyken Pippin; 7, Sops in Wine; 8, Cox's Pomona. (H. Brevis).—Probably Winter Nelis. Why do you not graft the tree with

some variety that will ripen? (E. Harvey).—The large Apple is Alfriston, the small one French Crab. (W. S.).—2, Sturmer Pippin; 3, Golden Winter Pearmain; 4, Golden Russet; 5, Nonesuch. (E. B.).—No. 2 is Lewis' Incomparable; No. 3 is probably a small specimen of Rymer, and the others are correct.

Names of Plants (Rev. E. F. C.).—Your plant is *Dahlia glabrata*, which is well known in gardens; the colour varies a little in plants obtained from seed, but those sent resemble the common type. It is a graceful and distinct species. It was figured and described in this Journal, page 285, September 29th, 1881. (G. W. B.).—*Pleione humilis*. (J. C.).—Specimens too imperfect and crushed to be determined.

COVENT GARDEN MARKET.—OCTOBER 17TH.

We have no alteration to quote, our market remaining the same, being well supplied and all classes of goods cleared at previous rates. Best samples of Apples somewhat higher.

USE OF GREEN AND FODDER CROPS FOR VARIOUS PURPOSES.

(Continued from page 328.)

AMONGST the seeds sown for fodder or folding for sheep especially, we must not omit White Mustard, for although it is not a particularly fattening food, yet it is well adapted for breeding ewes or any store sheep, and may be taken by sowing twice or thrice during the summer time for folding, if sown in regulated succession. By the same rule it is specially adapted for ploughing under as manure, and in our experience we have found that it not only enriches the land, but it has, to a great extent, a deleterious and poisonous effect upon nearly all our pernicious and weed-like grasses, such as couch or twitch grass, and this effect is particularly noticeable, irrespective of its strong and smothering influence, to all and any growth of weeds.

Although in this Journal we have written upon the cultivation of Maize on the 2nd of December, 1880, yet our present object is to refer chiefly to its use in the green and growing state. We grew this crop, for seed only, soon after the early variety was introduced by Wm. Cobbet, still we have not so much experience as to its value for fodder on the farm. In the Journal of the Royal Agricultural Society of England in 1882, Mr. C. S. Read has referred to it in a letter to Mr. Joseph Darby as follows—"I have grown green Maize the last two years, but the hurricane of October and the frost quite early in this month beat down and half-killed the Maize, but the cart-horses eat it as well in its half-withered as in its green state." It is not generally fit to use before the middle of August, but as it lasts through the autumn when green crops are frequently scarce and cannot be relied upon, it gives it an additional value. We find that in America it is both ploughed in and also converted into ensilage, but it is cut into chaff before placing in the silo, and it is therefore ready for use upon the opening of the silo. Many persons are well pleased with it, and especially when sown after a crop of Vetches cut green in the early part of the summer.

Various opinions exist as to the advantages to be derived from the growth of Maize and also its use as a fodder. These are found in the reports which may be read in the Journal of the Royal Agricultural Society in 1882, from one of which we have quoted. Another statement by a Mr. Sturdy is given from Wareham, Dorset. He says—"For nearly twenty years I have grown Maize here, first in the garden as a vegetable, where it ripens perfectly, and also as a green crop for sheep and to cut for cows. It is only suitable for light sandy soils. I have sown it in the middle of July, but it is rather late, and it is fit to fold sheep on about the middle of September. It seems to exhaust the ground even where it is all fed off by sheep. Green Maize is exceedingly healthy food for lambs. I have grown both round and flat sorts, but prefer the European round. It ought to be tested before sowing, as much of the Maize sold is either so old or has been heated that it will not grow." It is very clear from this statement, as well as our experience, that a crop for feeding on the land or for soiling cattle may be grown by late sowing after such green crops as Trifolium, but still the bulk would not be so great, because it is the early-ripening sorts which come best in late seeding. We have always found the late varieties yield an enormous bulk of green fodder when sown as soon as the young plants may be considered safe from frosts. Mr. C. S. Read tells us that in favourable seasons his crop weighed upon an average 21½ tons per acre, and that he found cows, horses, and pigs all seemed very fond of it, and that he could not see any difference in the growth or quantity of the fodder produced from the seed of round or flat Maize.

Mr. Sturdy has laid great stress upon the growth of Maize on light sands, but we entertain no doubt that the bulk grown would be much in accordance with the fertility of the land, both by its nature and the system of manuring. For the deep soils in the United States, as well as Italy and elsewhere on the Continent, the heavy loams, if dry, give the most abundant crops, and sown as a second green crop at so late a period as midsummer, we have no crop to compare with it in bulk and nutrition as green fodder per acre. There is no question that green Maize may be converted into hay as well as ensilage, but not with the same facility in our fickle climate as in some foreign parts. Green Maize has also been recommended to supply green fodder to the dairy herds with a succession of succulent forage at a period when the pastures in the autumn generally fail or get stale.

In remarking upon Prickly Comfrey as a crop for yielding a succession of green fodder, there are many conflicting opinions as to its profitable growth, and this may be expected while we have so many other varieties of forage crops from which to choose. Upon arable farms one great drawback is that the land becomes foul and filled with small roots of the plant, any of which propagate and grow like the roots of the Artichoke amongst the successional cereal crops, and often prove as bad as weeds. We have various writers upon the subject, both as to its value and abundant produce, but we must in practice look to a comparison of its advantages against other crops; most people, for instance, prefer Lucerne, and we are of the same opinion. Much is put forward by some persons as to the cattle disliking Comfrey. This certainly often occurs at first, but the aversion of the stock to the leaves of this plant may, it seems, be easily overcome by passing them through the chaff-cutter with some dry fodder in admixture like sweet straw, and in this way for feeding cows, especially in a milking dairy where milk is sold, it may be found of some importance. We shall not, however, enlarge our observations, but the reader may obtain full information as to its cultivation in this Journal, dated June 10th, 1880.

Although we have written on the value of Gorse, Furze, or Whin in this Journal on the 18th of September, 1879, yet we consider in these times of agricultural depression it becomes a matter of great importance to the home farmer and land agents as to the growth and use of forage crops, but more especially so upon the hill tops or poorest of soils however situated. We have the idea that more may be done with Gorse for feeding stock than has often been attempted. For instance, we will take the down lands and heath lands of various districts in the kingdom. Now the pasture is very poor upon the former lands, and yet it is used for a sheep walk almost entirely, and, except in a few cases where the proprietor has thought it worth while to plant Larch Firs, it yields next to nothing either to the value of the estate or its capabilities for the feeding of stock. Still we find important instances, one of which we select from the pen of Mr. Joseph Darby as described in the Royal Agricultural Journal of 1882. He says—"Mr. J. Forrester (Lord Portman's manager at Bryanston, Dorset) is accustomed, when the spring

is backward and other green food not plentiful, to have the young shoots of wild Furze bushes gathered by the cartload from the extensive sheep downs belonging to the home farm, and brought to the homestead to be crushed, cut, and mixed up with straw chaff and other food." But we find this hardy wild plant when transferred to field or hill culture frequently becomes quite a treasure to the stock-feeder on poor soils usually destitute of roots or green fodder of any other kinds in the winter months as well as March, April, and May.

We note what Mr. Martin H. Sutton of Reading says of Gorse—"It produces such a large supply of food for such a small expenditure that it deserves the notice of every stockmaster." It is an important point in its value that Gorse when once a plant has been obtained it is like Lucerne and Sainfoin, as it retains possession of the soil and continues to yield valuable produce for a number of years when properly managed. One more point on a sporting estate remains to be noted—that it furnishes excellent cover for game without injuring the produce of folder or spoiling sport, because it comes into use after the conclusion of the shooting season. Horses are particularly fond of crushed furze, and as it comes into use before other fodder crops are ready in the spring it is invaluable for furnishing a glossy coat to the animals in the winter months, not to be obtained when they are fed upon all dry fodder alone, for it is known to contain more nutritive matter than the ordinary roots cultivated on the home farm.

Rape or Cole seed comprises two varieties. The common or dwarf Rape furnishes the most nutritive green food for stock of any plant to be found in our list of fodder plants. It requires great care when folding sheep upon it, for it is so rich and succulent that the animals are often induced to eat it so hastily that they become hoven or blown. Continuous sowing is necessary, for it keeps for use but a very short time when sown thick as usual, for the leaves turn purple, then yellow, and fall, leaving but little food. This, however, may be obviated by hoeing and leaving the plants a good distance apart, or by planting as for Cabbages, when they will throw out a large amount of foliage. The Cole seed is also called the Giant or Tall Rape. We have seen it grow higher than the folding hurdles, and in some districts of the north and north-midland it is found to grow so strong that sheep are left to feed their way into the crop without folding. We have no notes of the weight per acre of this food, but it must be very great in the case of a crop of full bulk. The common Rape or dwarf sort is said to be the most forcing and nutritive fodder. We were asked the question a few days ago if Rape was well adapted for ploughing in as manure. Our reply was, Certainly, for we have no other green crop of the same bulk which yields so much value as manure if ploughed in before the leaves begin to fall. The plan is to cut the crop with the scythe as close to the ground as possible, and below any buds upon the stem of the plants, otherwise, even when buried, they are apt to sprout and require weeding out of the succeeding cereal crops.

[On page 327 last week it was stated that it answers well to mix White Dutch Clover with Italian Rye Grass; it should have been stated, the mixture does not answer well; and on page 323 Dr. Voelckiron was inadvertently written for Dr. Voelcker.]

WORK ON THE HOME FARM.

Horse Labour.—In all districts where Wheat crops will ripen and the climate is otherwise favourable, Wheat-sowing will still be proceeding. Much has been already sown on the cold hill farms, and should soon be concluded, the sooner the better. Farmers who occupy strong flat clay lands have met with some delay, but the weather since the second week commenced has been more favourable, and on such soils it is now a good seed time if the weather continues favourable. A point of great consequence is the laying and size of the ridges for Wheat, for in various counties in the midland districts the large high-backed ridges are approved; but in some of the home and southern counties the five-turn or 8-foot-wide ridges are fashionable; but in some of these districts the very small ridges, which Mr. Mechi used to call dressing the land in corduroy, prevails. However all or any of these may be objected to, still our own experience and observation dispose us to tolerate whatever is customary in ploughing the strong lands for Wheat, because the tenants frequently remove from one district to another, and of course carry with them their experiences as well as prejudices; but it is only fair to say those methods of laying the land for the winter seeding of Wheat which prevail are generally right, with this exception, that strong land when too wet to produce full crops requires more consideration as to the last ploughing than land which has been effectually drained.

We made a full statement last week as to the sorts of Wheat to be sown, and therefore we now only say that Red Wheats will do best upon inferior soils and cold climates, whereas the best varieties of White Wheat require not only warm and dry fertile soils, but also liberal cultivation.

Still we must consider that some of northern counties and Scotland succeed best with spring-sown Wheat; otherwise as a rule it is better to let the land lie over for Oats, drege, or Beans, than to sow late in an almost impossible seed time, like the unfortunate seed time of last year. We believe that large areas last season sown late, say after the middle of November, had far better have remained until the spring and been seeded with early White Oats, for our experience tells us that as many quarters of Oats can be grown as sacks of Wheat, upon land as we cultivate for Wheat with manure. Some horses should now be employed in harrowing and rolling upon the autumn fallows which have been steam-cultivated on every opportunity which occurs of dry days; because if the autumn rains which usually occur soon after this time should occur no more cultivation can be done on the fallows. But the Wheat land will be getting into heavy and in good condition to receive the seed, especially upon Clover leas, but upon fallow surfaces ploughing and seeding daily and simultaneously is the safest plan of proceeding.

Hand Labour.—As fast as the Wheat is sown upon any flat strong land, the surface water furrows should be struck and made out as soon as possible after the work is finished. Taking up Mangolds will require hand labour, also in the case of ploughing-in Turnips for Wheat which have been hoed and obtained good-sized bulbs, will require to be mown over to cut off the greens, the bulbs being picked up and chopped; but the best plan of any, although more expensive, is that the roots should be passed through an old Gardner's cutter and then spread.

Men are now principally employed in filling and spreading dung both on fallow and Clover lea preparation for Wheat. Hedge-clipping should now be finished and borders trimmed, to facilitate scouring of the ditches upon the strong land farms. Upon some arable farms men may be employed in grubbing up fences and draining the ditches where necessary; for it is difficult to understand why live fences should be required to separate the fields upon arable land unless required for shelter; but again, shelter is only of use on pasture lands, because where sheep are fed on arable land they are, or ought to be, folded, in order that their droppings may be applied at the right time and place. The removing of the internal fences enables the home farmer to lay out his land in oblong fields, which is a great saving of horse and hand labour.

Live Stock.—The value of all the best and forward ewes for lambing, both of horns and Downs, is still high, but less by from 5s. to 7s. than last year; the top price for flocks of the finest horned early-lambing ewes in the kingdom has varied from 77s. to 80s. each, while fairly useful stock has made from 60s. to 70s. each, while some of the best early December lambing Down ewes have made as much as the latter figures. At present we may call the price of sheep in general about 5s. per head less than last year. Upon any of the dry well-cultivated soils in the home and southern counties these horned ewes not only yield more return than any other sheep for the food consumed when managed with judgment and liberality, but they will, both ewes and lambs, go to market in good time, enabling the farmer to sow his Lent corn early and in the best condition, a matter of immense importance when we consider that the farmers say they keep sheep to manure the land and bring full crops of grain. Milch cows are doing well yet, there being plenty of grass in most cases where pastures and park lands have been well managed, manured, and carefully fed during the summer months. Bulls now, if not sent to market fat, should be put into the boxes and stalls for further feeding, and may with benefit receive their full allowance of 65 lbs. of Turnips or Cabbage per day, with 4 lbs. of cake, and 2 lbs. of bean meal daily, mixed with the cut roots, and get also good sweet oat straw in their racks, for let it be remembered that hay-feeding cannot be carried out with profit, in fact straw is chiefly required to promote the digestion of other food by ruminating animals.

THE SEED HARVEST OF 1883.—We are now in a position to give some reliable information as to the probable output of the seed crop of the present season. **Red Clover.**—A satisfactory crop is anticipated in all the producing districts, although the bad weather experienced in Europe generally at the time we are writing may prejudice the harvest considerably. The area under red Clover in England is larger than usual. German and French reds are also cultivated liberally, and prospects are very satisfactory. Canadian and American reports anticipate a large crop of red Clover, but as this is considered inferior as compared with European-grown seed, the crop is not important in plentiful home seasons. The markets, however, of all kinds of red Clover being absolutely cleared, values remain moderately firm at present. **Cow Grass.**—A fair average crop of English seed is expected, some being well harvested before the present inclement season set in. We anticipate superior quality of this article to the last two or three years, with lower values. **Alsike and White Clovers.**—Some nice parcels of English Alsike have already reached our hands, and the home crop both of white and Alsike is generally satisfactory. Reports of Swedish and German Alsike are of only a moderate character, and fine samples of German and French white are scarce, commanding full values of last year. **Trefoil** is a plentiful crop both at home and on the Continent; qualities fair average, and prices under last season. **Perennial and Italian Rye Grass.**—The crops of both promise to be abundant, but the samples in some instances bear evidence of damage by rains. We have handled several handsome parcels at favourable rates as compared with last year. **Timothy.**—This crop is plentiful both in Europe and America, and as the home crop seed is always very superior in quality, the American supply does not get attention. **Lucerne.**—A good average crop; samples bold, bright, and

clean. **Broad-leaved English Rape.**—Fine samples are scarce, and last year's values are readily reached. There is an abundance of German seed of moderate quality. **Natural Grasses.**—Fine cleaned samples of Foxtail, Fescues, Sweet Vernal, and Poas are reaching us in only moderate quantities, and command high prices. It should, however, be borne in mind that these qualities possess high germinating properties, in addition to freedom from weeds and rubbish, as opposed to lower grades sometimes quoted. **Swedes and Turnips.**—Undoubtedly the most unsatisfactory crop of the season. The Swede harvest was greatly impeded and the produce reduced by the inclement early summer weather in England, whilst the continental crop, never a large one, is almost nil. **Mustard.**—This is generally a fair average crop, but a brisk autumnal demand has led to firm values for fine English samples. **Hemp and Canary.**—Plentiful crops anticipated, with moderate prices. Summarised, it may be understood that the seed harvest generally is above the average of the past two or three years, and in most cases finer qualities with more moderate values may be expected.—JAMES CARTER & CO., High Holborn, London (and Mark Lane).

ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.—The monthly meeting of the Council of this Society was held at their offices, 26, Charles Street, St. James's, on the 2nd inst. In the unavoidable absence of Lord Carrington, who is now in America, the chair was taken by Mr. Joseph Druce. The Secretary stated that there were at present on the books of the Society 616 pensioners, ten having died during the past three months; and that since the last meeting of the Council £1765 had been received from subscriptions and other sources. Cheques amounting to £3865 for quarterly pensions and current expenses were drawn.

OUR LETTER BOX.

Chickens (B. A. C.)—It is not easy to rear chickens in so confined a run. You would perhaps have done better to coop the hens, and let the chicks run over the whole available space. Do you give them green food and gritty matter, and keep the runs very clean? Minorcas or Houdans of a good laying strain would probably suit you best.

Farming on Poor Soil (Anxious)—The soil being poor and the climate bleak we recommend you to grow Italian Rye Grass from foreign seed, also Lucerne; and as your land is of a dry sandy nature the manure best adapted for both these crops is liquid manure saved at the cow stalls. Before, however, attempting to grow these crops, a good dressing of chalk or lime is necessary. If it has not received any, from 20 to 25 tons per acre of the former would be a fair dressing, and 150 to 200 bushels of lime per acre. With regard to the application of artificial manures, bone superphosphate and nitrate of soda are essential, the former to be applied (when the seed of any grasses are sown) about 4 cwt. per acre, the latter (between every cutting of the grass) 1 cwt. per acre. If you obtain the number of this Journal dated July 24th, 1879, you will find full information as to cultivation, &c., of Italian Rye Grass; and the same information as to Lucerne in this Journal for 22nd of May, 1879. Both can be obtained at this office. If you require to lay down land to grass for constant feeding you will find all the required information in this Journal, also in numbers dated the 5th, 12th, and 19th of February, 1880.

Lucerne (W. W.)—Lucerne will be found too great a risk of being damaged by frost if sown in October; it is best sown in May under the directions as given in this Journal, May 22nd, 1879, page 388. On gravelly soil the land should be broken by the subsoil plough below the depth of ordinary ploughing, otherwise the roots of the plant cannot go down, and will not succeed.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 7th.—A fine day though cloudy.
 8th.—Fine and mild, but not bright.
 9th.—Misty morning, dull day.
 10th.—Foggy dark morning, brighter in afternoon, but generally misty.
 11th.—Misty dark morning, fine mild day.
 12th.—Fine and mild.
 13th.—Fog at first, fine mild day.

A very fine week, calm and dry, with high barometer.—G. J. SYMONS.

25	TH	Last day of Apple Congress at Chiswick. Sale of Vanda Sauderiana [and other Orchids at Mr. Stevens' Rooms, Covent Garden.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

DURING the past few weeks more than ordinary attention has been directed to the subject of gardeners' insurance—that is, of persons who are engaged in gardening operations as a means of livelihood, making, so far as they are able and as facilities are afforded, some provision for themselves when no longer able to work, or to their families who may be left without adequate means of subsistence. No more important question than this can engage the attention of any body of operatives; and it would be a matter of surprise if gardeners were not fully alive to the prudence of making some immediate sacrifice for the accomplishment of an object so worthy of their serious consideration and so deserving of their prompt and united action.

The properly trained and average-educated gardener of the present day is not wanting in intelligence. In this respect he ranks at least on an equality with the skilled mechanic; while not a few who are engaged in the calling with which we are identified have by close study and persevering efforts in self-improvement—both as regards intellectual attainments, high moral qualities, and general deportment—raised themselves distinctly above the level of mere handicraftsmen, and won, as they have merited, the esteem of those of higher social rank than themselves.

All this is matter for congratulation; but then the circumstance must be admitted, and we regret its existence, that the average gardener is not equally remunerated with the average mechanic, and not a few of the best and most accomplished of gardeners cannot, even by the exercise of habits of frugality, do more than maintain themselves and families in a befitting state of respectability. Some, we are glad to know—a few hundreds probably—are so circumstanced that they can provide for the comforts that they have a right to enjoy in the eventide of life; but the vast majority, the thousands of industrious men, are not able by their own efforts to make any adequate provision for the future, even if the blessing of health is vouchsafed to them during the ordinary term of an industrious career. Recognising this fact, for fact it is, it becomes incumbent on all to co-operate with the object of effecting by mutual help that which it is so desirable to attain—a means of livelihood for themselves when they can no longer labour, or for those who are dear to them who may be left helpless in the world.

This is essentially a practical question, and it is better to admit the position at once and make the best of it than to lose time in indulging in speculative theories instigated for raising, in some way or other, the wage rate of gardeners. This cannot be effected by any artificial means whatever. So long as young men are trained as gardeners in the present liberal manner, and in far greater numbers than vacancies can possibly occur for them to fill, so long will, and must, the wage rate of gardeners remain as it is, or fall

lower. It is not the habit of millionaires even to pay more than the market value of anything they may purchase, whether it is skilled or unskilled labour or any material commodity; and gardeners act on exactly the same principle, for none of them will give a shilling for a knife, no matter how good it may be, if he can get one of the same quality for ninepence. Far better, then, will it be to recognise the real position of the craft and act accordingly than to indulge in any golden dreams of the future, and go on dreaming until the time of a sad awakening occurs, and they find themselves worse than before—willing but not able to labour, and with nothing to rely on but the casual charity of others to enable them to live.

The remedy lies in co-operation of a material kind for a substantial purpose—contributing during years of health and activity to a common fund from which the members can claim as a right a share of the benefits which it offers in the time of adversity.

The Gardeners' Royal Benevolent Society, which has lately been the subject of discussion, was established for the benefit of gardeners or the widows of gardeners in their old age. But this "charity," to quote its Secretary's description, is not well understood, and does not enjoy the confidence of those to whom it appeals for support; and as its acting official has distinctly declined to enlighten the public on the administration of the Institution in the only way in which he could do so effectually, we can only conclude that any efforts of ours to that end would not be agreeable to him, and therefore turn to another source, in the hope of finding a means of helping those of our industrial readers who are desirous of helping themselves to do so prudently, safely, and profitably.

We are well aware that a great number of persons engaged in gardening as a vocation are members of some of the great general benefit societies, such as the Foresters, Odd Fellows, and other organisations of that nature. They are to be commended for their endeavours in thus making provision for the adverse contingencies of life; but the Society which we desire to bring as prominently as possible to the notice of our readers offers far greater facilities to its members, while it is not less safe. Our primary object in doing this is to benefit gardeners, and not to advertise the claims of this particular society. If any other institution exists of the same nature that offers greater advantages to its members, and is equally and indisputably safe, we shall be glad to be made acquainted with it, and will not less willingly urge its claims for support.

The United Horticultural Benefit and Provident Society was started by gardeners for gardeners, and its directorate consists wholly of gardeners—the Trustees, Messrs. G. & J. Wheeler and J. George; Treasurer, Mr. J. Hudson; and Secretary, Mr. J. F. M'Elroy, being well-to-do members of the craft, and the Committee shrewd, practical, business men. That they are equal to their duties the flourishing state of the Society demonstrates, and we have no doubt whatever that once its character becomes fully known it will command the support of gardeners generally, and the number of members will rapidly increase.

We have been cognisant of the existence of this Society for some time, and have quietly watched its progress, naturally hesitating in a matter so serious to publicly recommend it until we were abundantly satisfied with the soundness of its principles and of its satisfactory working condition. On neither of these points have we the slightest misgivings, and we do not hesitate to speak of it in unequivocal terms of approval.

Since the publication of Mr. Heale's letter on page 339 last week we have carefully examined the books of the Society, and nothing could exceed the alacrity with which Mr. M'Elroy placed them at our disposal. We were invited to scrutinise every page, examine every item, and point out any fault. We did examine closely, but could find no fault, and the extremely clear and accurate manner in which

all the transactions are recorded is a credit to the Society and its Secretary.

Established in 1866, it made comparatively small progress during the first few years, and on the present Secretary commencing his duties twelve years ago only numbered forty members. Since then there has been a constant and steady increase, and, what is particularly important, a vastly greater proportionate increase of funds, the balance sheet of 1882 showing £2485 1s. 10d. invested in consols, and ninety-six subscribing members. The increase of the sick fund over the preceding year was £182 17s. 6½d., and of the benefit fund £54 10s. 8d., or a total of £237 8s. 2d.; and against this what were the disbursements?—the extraordinarily small sum of £21 18s. 5l., this including cost of management, sick pay, and moiety, according to rule, to the Benevolent Fund, thus showing a balance on the year in favour of the Society of £215 9s. 7d. And what becomes of the rapidly increasing moneys invested? What are they for, and where do they go? Mark the reply. Each member has a separate account, and is furnished every year with a separate balance sheet. He is credited with the money he has paid during the year, which is added to his accumulations during all preceding years, also with the interest arising from his fund; then is deducted his moiety of the sick pay that has been incurred during the year—which last year did not amount to 6d., and the remainder is banked for him. For instance, we take as an example the account of one member. For this purpose the book was opened at random and the first account extracted: it is that of Mr. George Ingram of Balham, a comparatively young member.

	£	s.	d.
Deposit balance for 1882	9	2	2½
Interest added	0	5	3
Contributions for the year	1	6	0
	£10	13	5½
Deduct for share of sick pay	0	0	4¾
Total invested	£10	13	0¾

Mr Ingram thus increased his account during the year by £1 10s. 10d., and this was effected by a payment of 6d. per week, or £1 6s., and at the same time entitled him to sick pay during the year if he had needed it. It will be seen by this that 4s. 10¼d. more than he paid in was added to his account; and it will be perceived also that this gratifying result is provided by the interest that accrued on the sum invested. We now arrive at a very important circumstance that is worth remembering—namely, the probability, amounting almost to a certainty that, after a member has contributed to the funds for, say, seven years, that the interest alone of his money invested will meet his full share of liability for the sick fund, and every penny he pays in will go to increase the amount of his deposit. This, be it remembered, is his own money payable in full, with interest added, to whoever he appoints to receive it in the event of his decease. But if he lives he cannot draw it himself until he is seventy years of age, by which time the accumulations will amount to something substantial. The account cited is an actual one, and if the member referred to compares it with his balance sheet he will be able to point out any inaccuracy, if any has occurred, in the transcription of the figures. Every member's account is thus kept separately, only some being older are much larger; as for example, Mr. W. Heale has placed to his credit £38 5s. 0½d.; Mr. G. Wheeler, £37 14s.; Mr. F. Moulard, £37 14s.; Mr. J. George, £37 13s. 11½d.; and Mr. Heims, £27 17s. 6¼d. Should these members continue subscribing until they reach the age of seventy there is scarcely the remotest doubt that the aggregate sum to which they will then be entitled will amount to at least £500. It will be seen, therefore, that this Society, besides affording relief during sickness, acts as banker for its members, and practically becomes a life insurance company as well.

It is in the above important respect that it differs from the ordinary benefit societies, and the advantages cited of this Gardeners' Benefit and Provident Institution cannot be

over-estimated. The fundamental difference between the two was forcibly stated to us by Mr. George Baker, late gardener at Coombe Cottage, Kingston-on-Thames, and now of Membland Hall, Ivybridge, Devon, to whom the Society is much indebted for its success, and who was its Treasurer for many years. "I have paid," observed Mr. Baker, 7d. a week into the Odd Fellows (or Foresters, we forget which), since I was eighteen years of age, and I am now fifty. I have, fortunately, had nothing out in that time, and if I go on paying all my life there will be £12 at my death." And then he continued—"I have paid 1d. a week less into our Gardeners' Society for seventeen years, and now have nearly £40 to my credit, and if I continue paying as long as I paid into the other I shall have £100. This is £100 if alive at seventy, against £12 at death, and 1d. a week paid more for the latter privilege than the former!

It may be thought, however, that the past year was specially favourable, and that the balance sheet of that year is not a fair index of the state of the Society. We frankly state this was our opinion, hence we copied the income of the benefit fund for the past five years, and the disbursements to the sick fund during the same period. We found what we anticipated, that the year in question was a good one, but the one preceding was better as regards the bill of health. The average of the five years will, however, fairly represent the condition of the Society, and this would reduce the deposit account of the members by the full amount of nearly 2½d. The figures are as follows:—

		BENEFIT FUND.					Sick Disbursements.				
		Income.									
		£	s.	d.			£	s.	d.		
1878	...	107	5	0	1878	...	3	3	4		
1879	...	116	3	6	1879	...	4	10	0		
1880	...	129	16	6	1880	...	4	0	0		
1881	...	135	3	6	1881	...	1	11	6		
1882	...	144	2	3	1882	...	2	2	8		
Five years' average	}	...	126	10	1¾	Five years' average	}	...	3	3	5

This shows a balance in favour of income, of no less than £123 6s. 8¾d. What more can be needed to demonstrate the safety and stability of this excellent fund? But it may be thought we have omitted to deduct the expenses. This is not so, for the management fund is kept separate, and is supported by a special contribution from each member of 2s. 6d. per year.

The weekly sick pay to which members contributing 2s. a month is 10s. 6d. for twenty-six weeks, and half that amount for twenty-six weeks more; those subscribing 3s. a month have 16s. and 8s. respectively. If a member's illness is protracted beyond a year he is transferred to the benevolent fund, and the Committee do the best they can in each case. During this time no money is taken from his deposit, and when he is receiving pay no larger amount than two days' sick pay monthly may be received from him; but there is a slight reduction from his payment:—½d. from each 1s. if he joined under twenty-five years of age, 1d. if between twenty-five and thirty-five, and 1½d. if between thirty-five and forty-five. This goes to the benevolent fund, and it serves another purpose by reminding the member that he is contributing a little more to the sick fund than if he were well, so in a double sense the sooner he is well the better. There are other points worthy of attention, but they cannot be mentioned now.

Members are eligible to join the Society between the ages of eighteen and forty-five years, and there is no entrance fee. An unknown person desirous to join must send a medical certificate countersigned by either a clergyman of the Established Church or a well-known gardener or nurseryman, and must also furnish a copy of the register of his birth or his baptism, so that there may be no doubt of his eligibility.

We have yet to refer to the benevolent fund, and would especially commend it to the notice of the affluent employers of gardeners, also to nurserymen who may be disposed to contribute. Much good may be done and has been done by this fund, and it is most desirable that it be strengthened.

The before-mentioned benefit fund is quite self-supporting, and the members each contribute one month's contribution to the fund immediately under notice. The interest from the deposits of members who discontinue payment also goes to this fund, the "principal" standing to their credit, and is paid to them or their nominees according to the rules; but the fund is chiefly supported by the contributions of honorary members of £1 1s. a year, or a life payment of £10 10s. These unfortunately are few, and as the Society and its objects become known will, we trust, increase considerably. So few are they that we publish their names. Life members: William Marshall, Samuel Morley, and James Brand, Esqrs. Honorary members.—Amateurs: A. H. Lancaster and J. A. Lewis, Esqrs. Trade and Nurserymen: Messrs. Clay and Levesley, R. Dean, W. Paul (Waltham), Paul & Sons (Cheshunt), James Veitch & Sons, and B. S. Williams.

The rates of contributions and payments were prepared by Mr. A. Finlaison, Government Actuary, who certifies that they may be safely and fairly adopted by the members of the Association. Appended also is the certificate of the Official Registrar of the enrolment of this Society, which entitles it to the privileges of the Acts relating to Friendly Societies.

The Committee also state that "in drawing up these rules they have endeavoured to give every possible assistance to the 'Gardener' compatible with safety; the many benefits contained in them will, they trust, cause gardeners as a body to join the Society and extend its benefits."

They also make the following appeal:—

"To those engaged in horticultural pursuits, both as a means of subsistence and pleasure, we respectfully ask them to use their influence in adding additional members to our list, for in the present day lessons of thrift are being taught in every way by those engaged in promoting the welfare of the nation, and we believe the rules of this Society are framed entirely for the adoption of its principles, as they enforce the advantages of a savings bank with that of a life assurance. By enclosing a stamp the Secretary will reply by affording every information as to the Society's benefits."

His address is Mr. John F. M'Elroy, Moray Lodge, Campden Hill, Kensington, London, W. We shall also be glad to answer any questions relative to this Society, which ought to become a national one, unless there is already in existence an institution of the same nature better deserving the support of gardeners in all parts of the country.

It must be understood that this Society was not established in opposition to the Gardeners' Royal Benevolent Institution; so far from this being so, Mr. M'Elroy is a member of the "Royal" and not of the Society of which he is the Secretary, as he was too old to join. He discharges his duty most efficiently, and gratuitously except when there is a small margin in the management fund, which is given to him; but his chief reward is in feeling that he is doing good, and the members have presented him with a watch in recognition of his indefatigable zeal and valuable services.

THE PHYLLOXERA.

IN the summer of 1879 a friend and near neighbour having discovered, to his dismay, the gall as well as the radicle form of this minute, prolific, and destructive creature on his newly planted Vines, at once, with commendable candour and genuine friendship, communicated the unpleasant news to me. It was an act of friendship, because many would have endeavoured to conceal the fact from even their most intimate friends. In short at, and previous to that time, many private as well as public establishments in various parts of the kingdom were and had been for some time previous silent, and I regret to say not in all cases ignorant harbourers of this unwelcome visitor. From these sources it was being distributed by some means or other, and in one form or other, to every point of the compass, not wilfully, but through carelessness which merited censure.

In the autumn of 1878 I had observed with considerable disappointment and anxiety that the Grapes in a range of three vineries under my care, composed of Hamburgs, Madresfield Court, and

Muscat of Alexandria, failed to swell and colour so well as they had previously done. I could, however, scarcely conceive it possible that these defects were occasioned by an attack of phylloxera, having in the previous autumn not only thoroughly examined and increased the size of the borders, but I had also regularly watched with the keenest eye for any appearance of the peculiar gall formed by this insect on the leaf ever since its name had sounded so unpleasantly in British ears. When, however, in the summer of 1879 my neighbour paid me a visit and with his phylloxera eye fully open, expressed his suspicions that the arch enemy was near, I lost no time in again examining the borders, and to my horror discovered its presence to an alarming extent. I mention these details not only to show how subtle are its movements and how rapid is its increase, but more especially to show that the gall form of the insect was never present on these Vines. Had the roots been infested in 1877 I should most certainly have detected it; I am also equally certain that no galls had been formed on the foliage.

At last, after anxiously watching for nearly a quarter of a century, was I suddenly brought in close contact with the enemy, not merely a few scouts but an army. Those who have been similarly situated will clearly understand my feelings. The knowledge I then possessed of these creatures was somewhat imperfect, as I had imagined that so long as the insect and galls did not appear on the foliage I was safe from its attacks. Here it was, however, and the question was how to destroy it. Having obtained the permission of my employer to use my own discretion in dealing with it, I decided after mature consideration to destroy the Vines. Seeing a report, however, that submersion of the roots in a vineyard in the south of Europe had produced satisfactory results, I determined before making the new borders to construct concrete tanks in which to form them, allowing numerous outlets at the base to answer the purpose of drains, and which could be closed at will so as to allow of the borders being submerged at pleasure. Before finally adopting this method I selected pieces of root swarming with insects and placed them in numerous vessels filled with water, some mixed and others unmixed with earth; these were carefully examined nearly every day under a powerful microscope, and after the lapse of three weeks they were found to be still alive. These experiments, however much they may differ in their results from some similar experiments made by others, were at least quite sufficient to deter me from incurring the additional expense of forming tanks for the purpose of submersion. The effect of submerging the roots for even this length of time would, I thought, be quite as bad as the disease. Whether the time of year when the experiments were made (October and November) when the insects were in a partially dormant condition, and might possibly then be more difficult to destroy, or whether the particular form which infested these Vines (the root form) is more tenacious of life than some of the other forms, I cannot say, but I had unmitigable proof that they passed through the ordeal for twenty-one days apparently uninjured. I therefore decided to subject them, and all future visitors of a like nature, to the more potent element, fire. As quickly as possible root and branch, soil and rubble, were committed to a fire specially prepared for their reception, great care being taken that every particle was thoroughly reduced to ash or cinder. The walls and floors both inside and outside, were then thoroughly deluged and washed with a mixture of quicklime and water; the woodwork and glass was well washed with water and soft soap; the houses were then made as airtight as possible and thoroughly fumigated with sulphur; the wood and ironwork was then painted two coats, after which I felt that a fresh start might with a fair prospect of success reasonably be made.

In preparing the new borders the greater part of the old soil in the form of ashes and cinder was again used by mixing it with fresh loam. Everything being prepared the young Vines, struck from eyes well cleansed beforehand, were planted the following spring, and up to the present time I am thankful to say there is no sign of the reappearance of the pest. Experience has taught me, however, not to be too confident about this mysterious visitor, so every autumn I thoroughly examine the roots not only of these, but also of every Vine under my charge. It is sometimes said that only inside borders are affected, but in this case both inside and outside they were equally bad.

I have frequently tried to account for its sudden and mysterious appearance, but have never yet been able to do so satisfactorily. The most reasonable inference seems to be this: The potting shed, which is also used as the unpacking shed, adjoins this range and communicates with it by a doorway through the back wall. As the Vines immediately opposite this door first exhibited symptoms of weakness and were in much the worst condition when the insects were discovered, it is very probable that a small piece of affected Vine root may have been carried or blown on to the border from some package received. Whether this be so or not, I have since taken very great care that all packing material be kept quite clear from it and at once consigned to the fire. If Professor Riley's observations are correct,

however, we need no longer speculate on this head. I will leave the accuracy of his assertions for the consideration of wiser entomologists than I. He says, if I recollect rightly:—"On one occasion when I was visiting the vineyards in the south of Europe, the air suddenly assumed a yellow tinge, and appeared like a yellow cloud overhead, which suddenly descended on the Vines and everything else in the shape of winged phylloxera." If this be so it seems useless to speculate as to its introduction into any locality, for what guarantee have we that a similar cloud may not descend upon us any day in the summer season? The same authority also says, I think, "There are no less than half a dozen forms of this pest," and the winged one is, I think, the last. Such being the case, how necessary is it that we should immediately destroy it when found, so as, if possible, to prevent it assuming the winged form.

Since writing the above I have seen Mr. Ward's articles on the subject, and should like to make a few remarks in respect to the suggestion he makes regarding the inspection of Vine nurseries. The scheme although good appears to be fraught with many difficulties, and yet, if earnestly carried out on a sufficiently broad principle, it might tend greatly to check the increase and spread of phylloxera. To be of any practical use, however, the inspection must extend to private establishments also, in which places, I fear, the enemy often finds a more secure retreat than even in the nurseries. Why not organise a "National Phylloxera Assurance Society," whose province should be not only to provide the necessary men and means for judicious and efficient inspection, but also to guarantee a part or the whole loss sustained by the immediate destruction of phylloxera when found?

Every private person and every public body would unhesitatingly subscribe to such a purpose if properly organised and perfectly administered.—T. CHALLIS.

P.S.—Since posting the foregoing I regret to add that in making my periodical inspection of the borders I have again discovered the presence of this terrible Vine pest—not in the same houses as before, I am glad to say, but in an older range some little distance from them.

As the roots of these Vines have been annually inspected with the rest, and as no new Vines have been introduced, I cannot in any way account for the present attack; and it is not at all probable that they could have been on the older roots last autumn, while the fibrous roots near the surface were perfectly free from any signs of them.

The Vines and borders are now being consigned to the fire as quickly as possible. In the meantime I am endeavouring to make such experiments with some of the infested roots as will, I trust, be of some practical value. One result already obtained induces me in a slight degree to modify my former impression respecting the effects of submersion. This result may be partly due to the somewhat earlier period of the year in which I have now experimented with the insects, when they are more active and probably more sensitive to injury; but of this and the effects of other experiments I am attempting to make I will report at a future time.—T. C.

NOTES ON HERBACEOUS PLANTS.

Crassula alpestris.—In the corridor here is a large pan of this interesting plant. It somewhat resembles *Sedum sarmentosum* (*S. carneum* of gardens), but the leaves are more cylindrical and of a very lively green. Branches and flowering stems reddish brown, erect, or only slightly inclined, 4 to 5 inches in height. The flowers are pure white, and as freely produced as those of any common Stonecrop. Each cluster consists of twelve flowers, which stand erect, and are scarcely a quarter of an inch in diameter, and in miniature are very suggestive of the flowers of the common Bluebell or wild Hyacinth. The five stamens are furnished with chestnut-brown anthers, contrasting with the five pure white petals. It is a South African species, and occurs at higher altitudes than most of its congeners. Our plant has been in bloom over two months, and two small clumps in bloom are represented on the rockery. It is said to be quite hardy, and if such proves the case it is a welcome addition to our alpine. As we only received it at the beginning of the present year we have not been able to test its constitution. We had, however, very severe and destructive weather during March, which it withstood. It is well known that many of the so-called hardy succulents disappear during winter months as much from the influences of damp, caused often by insufficient drainage, as from frost. It is intended to make special preparation for this plant on the rockery by taking out the soil of one of the compartments to the depth of 12 inches and filling it with stones and broken bricks, on which to place some gritty or sandy soil.

Houstonia cærulea (Bluets of Americans).—This is one of the most desirable of all the low-growing rock plants, and was introduced into Britain long before any bold attempts at establishing rock gardens had been made. It is not an alpine in reality, but it is most fitted

to associate with such plants on account of its dwarf compact habit and floriferousness. It is partial to wet situations, and when planted in such places it grows freely and bears full exposure to the sun with impunity. If grown on the rockery a compost mainly of peat and grit suits it well, and its position should be only exposed to early morning's sun. If grown in pots it requires partial shade, or the pots should be plunged in very moist ground with small empty pots beneath. This insures good drainage and prevents worms getting in. It varies in the colour of its flowers, these being blue, lilac, also white with the faintest tint of purple with a yellowish eye. The flowers, which are scarcely half an inch in diameter, are solitary and borne on slender stems 3 inches in height, which are almost leafless and spring from the centre of the dense rosettes of its small and rather succulent leaves. None of the varieties has originated under cultivation, but all exist in a wild state in North America, where it occurs in moist grounds from Florida to Canada, abundant in some provinces, and either local or unknown in others. It belongs to the same family as the *Bouvardia*, and the flowers of the two genera in the cutting of the corolla bear a striking resemblance to each other.

Centaurea stricta.—The genus *Centaurea* is one of the largest of the Thistle-head Composites, and embraces upwards of 200 either critical or well-marked species, the great bulk of which on account of their wild and weedy appearance are of little or no regard as plants for general ornamental purposes, and this is doubtless the reason we rarely meet with more than a few under general cultivation. One that is most worthy of general appreciation is *C. stricta*. It is as yet rare, and belongs to the same section as the very familiar *C. montana*, both of which have their flower-heads made more showy than they otherwise would be by the presence of the conspicuous ray florets. It is these barren florets which tend most to make such *Centaureas* worthy of merit. Did the common wild *C. nigra*, or Hard-heads of our pastures, only possess ray florets it would be no longer a neglected plant. *C. stricta* is of dwarf habit, only attaining a height of 1 foot, and is remarkable for its pleasing silvery foliage, which adds much to the beauty of the plant, and for some time after it has commenced to make growth it is an object of admiration, but as the leaves become old this silveryness gradually lessens. The fertile or disk florets are violet and purple, those of the ray a pleasing blue. The heads are 2½ to 3 inches across. The leaves are all simple and uncut, except those near the base, which are lobed. It is a true alpine species, and is well adapted for the rockery. For the flower border it is better than *C. montana*, as its branches are not prostrate, but grow erect and support themselves without staking. The species comes from the Maritime Alps, where it grows at an altitude of 7000 feet; it also occurs on some of the other European Alps, as those of Austria. The flowers are produced in July, but our plant is in bloom now, being the second time this year. It was originally growing in a pot plunged in one of the spaces on the rockery, and showed flower buds before I lifted it to transfer to a warm greenhouse, with a view of getting it in bloom for the Manchester Whitsuntide Show. Several heads developed through the little stimulus afforded, and it was one of the thirty alpines exhibited. The growth ripened early and the plant rested early in July, commencing its second season of growth shortly afterwards. The specimen is now much more vigorous than before.—T. ENTWISTLE, *Wood Lawn, Didsbury*.

APPLES FOR PLANTING.

As some intending planters of Apples may be at a loss to know what varieties to select, I herewith give a few particulars of some of the sorts which succeed best here (Hereford). Three years since we formed a pyramid plantation comprising 180 varieties. The following are a few of those which have succeeded best, all of which are worthy of a place in every collection.

Early Julien.—A very heavy and constant bearer, invaluable on account of its earliness. Excellent for culinary purposes, and acceptable for dessert. The tree makes moderate but healthy growth.

Oslin, or *Summer Oslin*.—Early and an abundant bearer, of delicious flavour. The tree is healthy and a good grower.

Lord Grosvenor.—Early, a grand culinary variety, and a most abundant and constant bearer. The tree makes most healthy and vigorous growth, surpassing all other varieties in this respect. It bids fair to supersede *Lord Suffield*, which is much subject to canker in this neighbourhood.

Stirling Castle is, without doubt, one of the very best culinary Apples in cultivation. If it has a fault it is that it bears too freely, and in consequence does not make strong growth. At the same time, being a small grower, a great number of trees may be grown on a small space of ground. It will keep till Christmas, and the quality is excellent.

Ecklinville Seedling.—A grand Apple, in use during Sep-

tember and October. Young trees produce annually heavy crops of immense fruit of first quality for culinary purposes. The tree is very healthy, and a most robust grower, making handsome pyramids and splendid orchard standards.

Ringer.—A grand culinary variety, and a most abundant and very constant bearer. In use during September and October. Healthy moderate grower.

Manks Codlin.—Good, early, and most prolific.

Golden Spire.—Early, distinct, handsome. A most abundant cropper, of good quality. Tree healthy, hardy, and moderate in growth.

Duchess of Oldenburg.—An early sort, which should be more largely cultivated, being an Apple of first quality, very hardy, free grower, constant and an abundant bearer; fruit very handsome. Tree makes very fine pyramids or orchard standards.

Dumelow's Seedling (Wellington).—First class, and in every way suited to this soil and climate, very rarely failing to produce immense crops of fine sound fruit, which will keep till May. The tree forms grand pyramids and splendid orchard standards.

Old Hawthornden.—Succeeds well, and bears constantly heavy crops of fine fruit of excellent quality. Moderate in growth.

New Hawthornden.—Like Dumelow's Seedling, this is quite in its element in Herefordshire, producing fine crops of magnificent fruit, which will keep till spring. Tree strong, healthy, and very vigorous.

Frogmore Prolific.—A most desirable free-fruited sort, of first-rate quality. In use from September to Christmas.

Lane's Prince Albert.—This will shortly be looked upon throughout the country as "the" culinary Apple of the day. The tree is healthy, and for productiveness and quality cannot be surpassed, young trees two years after grafting bearing immense crops of fine fruit, which will keep till March.

Cox's Orange Pippin.—One of the late-keeping dessert sorts that should not be overlooked. To insure success with this variety here we find it necessary to plant the trees on high ground, and in soil of a much lighter texture than is required for many others.

Irish Peach.—A productive early dessert Apple of first-rate quality, as is also Yellow Ingestrie.

Worcester Pearmain.—This makes very handsome pyramids and orchard standards, producing good crops of handsome fruit.

Peasgood's Nonesuch.—Very large and exceedingly handsome, bears well here on young trees. Excellent in quality for either dessert or culinary use. Free grower, and very healthy.

Lady Henniker.—Very good, and a free bearer.

Lord Derby.—Very large, and a most constant bearer. The tree makes very robust growth.

Cellini.—A very abundant and constant bearer, but unfortunately subject to canker, especially when planted too deeply or on ground having a stiff clay subsoil.

Tom Patt.—Probably cultivated throughout this country in larger numbers than any other sort. It is a long-keeping culinary Apple of very good quality, and is without doubt a "never fail." Growth free, healthy, and vigorous.

King of the Pippins and its allies succeed admirably here, producing grand crops of handsome fruit, suitable for dessert and kitchen use. It also makes excellent cider.

Nelson Codlin and *Summer Queen* are both excellent cropping Apples of great merit.

Court of Wick and *Court-Pendû-Plat* are late dessert varieties of great excellence, succeeding well and bearing constantly good crops of handsome fruit.—H. R. ILLMAN, *Hereford*.

ROSES IN POTS.

HAVING read the directions respecting this method of Rose culture that have appeared in the Journal from time to time, I should like to give my experience, gained in a Rose nursery where some of the magnificent specimens that have been exhibited were grown. The trade Roses are grown in the manner I will describe, and which I believe few private growers are acquainted with, as the method so far as I know has never appeared in print. If you think this first attempt of mine worthy of publication I will send a list of the best Roses for pot culture.

Most of the instructions we read on this subject are somewhat as follows—"Pot before flowering in loam, a little decayed dung, and some bone dust; then after flowering plunge the plants in ashes out of doors to ripen the wood," to which I add, "and get red spider." My instructions are, Pot the Roses after flowering, carefully picking some of the old soil from the ball with a pointed stick. If they require a larger pot, let it be only one size larger. Roses do not like a big shift. The soil should consist of good fibry loam (not such as I used instead of better when a foreman, which was clay and leaf soil) one barrowful, decayed manure one harrowful, road or river sand half a barrowful, a 32-sized potful of Clay's fertiliser, and one of soot; if a

few small crocks or pieces of charcoal are added so much the better. Pot the Hybrid Perpetuals first, and for every harrowload of soil left add a third of a barrowful of chopped peat for the Teas.

Pot firmly, and stand the plants in a house or pit (mine is a pit), water them three or four times to thoroughly soak the soil, and be sure they are dry before they are watered again. Keep them close and shaded for a fortnight or three weeks, syringing them twice a day; then gradually discontinue the shade till they will bear the full sun, always increasing the air with the reduction of shade, but close the house or pit in the afternoon, and syringe the plants if the weather is fine. If green fly appears fumigate lightly.

From the latter part of September keep the soil rather dry, but not to let the young growth flag. About Christmas they may be pruned in the usual way—that is, if they are to flower in April and May. If wanted in March prune a fortnight earlier. Stop the ends with painters' knotting like Vines. Before starting, the top soil should be stirred and sprinkled with Clay's fertiliser or blood manure. As soon as active growth has commenced weak liquid manure may be given; the draining from a cowshed diluted to the colour of "husband's" tea is good, but that should be discontinued when the blooms show colour. The fire heat should be about 55° by day, 45° by night; the April and May Roses may have the fire heat turned off when the buds colour unless a severe frost occurs.

Mildew may generally be avoided by ventilating carefully and opposite the wind. For instance, mine is an ordinary lean-to pit facing south; well, with an east wind blowing I should put a small tilt under the west side of the lights, but if mildew should appear sprinkle the pipes with sulphur in the afternoon, start the fire, and damp the pipes with the syringe till the house or pit is filled with steam, then brush the loose sulphur off in the morning.

The May-flowering plants will have to be shaded with thin canvas when coming into bloom. Very dark Roses open better under a mat at any time, as they scorch and turn blue. The instructions given apply principally to amateurs and gardeners like myself, who can afford only a pit to grow them in and are content with Roses in May. I learnt what I know of Rose-growing where bushes are grown 6 feet through, but the remarks apply equally to smaller plants; and if cultivators with little conveniences will try the method next season they will perhaps thank me for the few hints I have given when they see the plants that will be the result of the practice described.

One more hint and I have done. Keep the plants open, and if any shoots as thick as your little finger start from the bottom of the stem, pinch the point out 6 inches above the plant and cut it level with the top at pruning time.

The following list of suitable varieties will be useful to those who have had no opportunity of seeing a collection. I name nearly forty varieties—quite enough for most people, though of course many more might be, and are successfully grown in pots.

Hybrid Perpetuals.—Alfred Colomb, Avocat Duvivier, Baronne de Rothschild, Beauty of Waltham, Capitaine Christy, Charles Darwin, Charles Lefebvre, Comtesse de Serenye, Comtesse d'Oxford, Countess of Rosebery, Dr. Andry, Duke of Connaught, Duke of Edinburgh, Edward Morren, Général Jacqueminot, La France, Madame Lacharme, Madame Victor Verdier, Marie Finger, Marie Rady, Prince Camille de Rohan, Prefet Limbourg, Paul Jamain, Sénateur Vaisse.

Teas.—Alha Rosea, Anna Ollivier, Catherine Mermet, Isabella Sprunt, Jean Ducher, Madame Berard, Madame Chedanne Guinnoiseau, Madame Falcot, Madame Lamhard, Marie Van Houtte, Niphotos, Perle des Jardins, President, Ruhens.

In addition to the above, if you have a lady to cater for who has a thought to spare for other things than single Dahlias and Sunflowers, grow two or three plants of that little gem Rosa polyantha Mignonette, and you will be rewarded by hearing her exclaim "Oh, how lovely!"

—A. L. G.

CELERY FLY—BRASSICA CATERPILLAR.

NEVER in my experience has the maggot of the Celery fly committed such havoc with the leaves of Celery as it has this season. The leaves of Parsnips have suffered from the same pest, and Parsley has not escaped. Now I should like to know if there is anything more potent than dusting the plants with soot on a dewy morning before the deposit of the eggs, and repeating occasionally to ward off the ravages of these pests. One thing is certain, that some six hundred early plants, not many yards away, are not infested, and these were supplied frequently with the stable drainings, but the skeletonised plants have had no such attention, and they may have lacked the salts of soda and potash which the earlier plants had from the urine of the stable cesspool. Some may think that effluvia from the watering with the stable drainage caused the fly to pass over the early to the late plants, but I consider that value of the ammonia, both of the drainings and of the soot, was due quite as much to the portion taken up by the roots and transmitted to the leaves of the Celery. Every plant, it may be contended, is a fitting feeding ground for insect pests of some kind. Once there they will increase and carry forward their work, and diseases of fungoid origin attack alike healthy as unhealthy plants; but either we must admit predisposing causes of parasite infection, or disregard some of the essentials of health, which, it is needless to state, are never ignored with impunity. Many cases in point might be adduced, as the freedom of Peach trees grown under glass from blister, the Tomato grown outdoors being attacked by disease whilst those in a genial temperature under glass are free from its ravages, and we must entirely set at nought the fact that a dry atmosphere encourages

thrips and red spider, and a close, moist, and cold one some of the forms of mildew.

But I have another calamity to record—viz., the prevalence this season of the Cabbage caterpillar. The white butterflies were assiduous in their attentions to the quarters of Broccoli, Savoy, and the different crops of Brassicas, not omitting Turnips. Soon after the butterflies had disappeared sparrows commenced an attack on the eggs, and many leaves of the Brassicas were soon cleared. When the caterpillars appear the sparrows quit the quarters, but then the thrush appeared and devoured the caterpillars with avidity.

Another point. I have a batch of Brussels Sprouts (about a thousand), and these were not infested with caterpillar. Was it due to their being manured with native guano, whilst those that suffered most had ordinary stable and farmyard manure?—G. ABBEY.

THE MADRESFIELD COURT BLACK MUSCAT GRAPE.

JUDGING from the numerous complaints which are still being made by many cultivators respecting the tendency of the berries of this Grape to crack during the ripening process, it is evident that the cause of this peculiarity is either imperfectly understood or ignored by those who fail to grow it free from this defect. Many years ago, soon after it was sent out, I chanced in company with a friend to visit the Horticultural Gardens at Chiswick, where in a small house hung some medium-sized bunches of this Grape perfect in shape, size, colour, and flavour, and without a blemish. The border was dry, the house was freely ventilated, and the atmosphere was cool and dry. A half-hour's walk from Chiswick brought us to another vinery in which were hanging some very fine Black Hamburgs and some Madresfield Court, marvellous in size, but alas! the contents of one-half the berries was on the stage and the floor underneath them. In colour they resembled Prunes, and the flavour was also very similar to that fruit. The border, an inside one and newly made, was wet, the temperature high, and the atmosphere moist. The gardener directed our attention to the Hamburgs with just and pardonable pride, but to the Madresfields he pointed with contempt. My friend smiled, and quietly remarked that the same conditions of treatment were evidently not suited to the two varieties. These two practical lessons learned in so short a time were neither ignored nor forgotten by either of us.

My practice has since been to withhold water almost entirely from the border after the berries attain that transparency which invariably precedes the colouring period. The house is also ventilated as freely as possible, without unduly lowering the temperature, and if the border be an outside one it is carefully protected from rain. Should the weather prove unusually bright at this time, and the foliage exhibits symptoms of exhaustion, sufficient water is given to prevent injury, care being taken if the border is inside not to saturate the whole surface, but to apply it at intervals of about 4 feet, wetting the surface as little as possible, and immediately covering the saturated part with dry mulch. If possible a fine day is chosen for the operation, free ventilation is allowed, and a brisk atmosphere maintained by a moderate artificial heat. Under these conditions this exquisite Grape may be cultivated to perfection, and seldom, unless the weather be unusually humid, does it show signs of cracking; should it do so, however, a brisker fire heat and somewhat freer ventilation will immediately arrest its progress. It matters not whether the border be rich or the soil heavy, provided it is neither cold nor wet; nor is there any necessity either to allow the laterals to grow unduly or to resort to the somewhat unnatural practice of nearly severing the shoots below the bunches. It is, however, of the utmost importance that the pruning at this period consist only in pinching out the terminal points, also to expose every leaf to the action of air and light.—C. W.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

LIKE many other gardeners I have held aloof from becoming a subscriber to the above Institution because I could not see my way clear enough to warrant me in taking such a step without knowing more about the working of the Society. I hope that Mr. Cutler will throw all the light he can on the subject. A few plain questions seem to me to require some explanation. Suppose a gardener is in a position to pay £10 10s. at once as a life subscriber; if disabled would he be entitled to any benefit from the Institution before the one who had been a subscriber of £1 1s. for ten years? For instance, if a gardener at the age of sixty becomes a life subscriber of £10 10s., and the one who has subscribed £1 1s. for ten years, and is of the same age as the life subscriber, which of the two would be considered the most eligible for the charity? Suppose A had been a spendthrift and had no nest egg, and B, who had been provident and had paid his life subscription of £10 10s., and who had also made some provision for declining years, and suppose the two were to be candidates for the charity at the same time, which of them would be considered the most eligible? Here seems to be the difficulty. I, with several other gardeners, have been led to believe it does not much matter how many years a gardener may have been a subscriber; and as regards age he would not be looked upon as eligible for the charity unless he was almost reduced to beggary. This idea is anything but cheering to those who would be subscribers. These are questions that require to be thoroughly ventilated. Suppose a gardener becomes an annual subscriber of £1 1s., say, at the age of fifty, and he is now seventy, and he feels that he is not able to follow his calling; he may have been a hard-working pro-

vident man, and saved a few pounds, and that he naturally feels that he is entitled to some help from the charity he has so long been a subscriber to. Suppose another gardener, No. 2, is the same age as No. 1, and has been a subscriber the same number of years, he may have been in better situations and received better pay than No. 1, but he may have been improvident, and has no little banking account to fall back on; which would be considered the most eligible of the two to be placed on the pension list? I send my name and address in proof of my sincerity to the Editor, and with the object of eliciting information that is required by hundreds besides myself, and if Mr. Cutler does not choose to reply because I do not choose to publish my name the Institution will suffer more than I shall.—A BEDFORDSHIRE GARDENER.

CONGRESS APPLES.

THE two Apples now figured have hitherto been considered identical by many growers, and there is little doubt that a large number of trees of both varieties are growing in many gardens under wrong names. It did not need, however, a very close examination of the numerous dishes of them staged at Chiswick to determine the undoubted distinctness of the two Apples. As will be seen by the engraving, Lord Grosvenor is decidedly the larger of the two, and totally dissimilar in

Fig. 65.—Apple Lord Grosvenor.

form, being distinctly angular; the fruit is 3 inches high and 3½ wide. Jolly Beggar, on the contrary, is only 2½ inches high and is 3 inches wide, being of symmetrical outline; in fact, the two Apples are alike in colour—yellow, but there the resemblance ends. Both, however, are useful varieties, and whoever possesses either will not be greatly disappointed. Lord Grosvenor has a general resemblance to Lord Suffield, but the fruit is more dense and heavy—no small advantage, and trees bear heavily in a small state; the fruit also keeps longer than that of Lord Suffield. Jolly Beggar is still firmer, also a better keeper, and is a very productive variety either as a bush tree on the Paradise stock or a standard on the Crab. What is the origin of Lord Grosvenor? Is it the good old Shepherd's Fame under a new name? Certainly the two varieties as seen at the Congress were identical.

NEW ROSES.

OCTOBER is the opening month of the rosarian's year. Then the catalogues arrive. "Then should the Rose-grower" (I quote a high authority) "examine stock to see if any plants of the past two years are, in his opinion, worth adding to his collection; if any, order those at once." I propose to take the first part of this advice. It is, on the whole, much easier to carry out than the second. Mr. Hinton has told us how to decide on a good Rose—"What I cannot be without!" The present suggestions may be taken as "What I have or should like to have." And first about the Bennett Roses. I may be pardoned a triumph in predictions come true. When Her Majesty is in commerce there are not many who saw her this year at South Kensington and elsewhere who

will be able to refrain from an instant ownership; also Earl of Pembroke, a very fine dark red Marquise de Castellane, and Princess of Wales, a Tea of novel excellence, are now admittedly Roses of position. Mr. Frettingham announces Lord F. Cavendish for next month, brighter than the Duke of Teck, "the petals pointed, a distinction which no Rose yet possesses." This Rose has obtained a first-class certificate. Helen Paul, as a white Rose of the second year, is gaining ground; though we have not yet got what we want, nor are the two white seedlings of Baronne de Rothschild—Merveille de Lyon or White Baroness—either of them likely quite to satisfy. A white A. K. Williams is still a hope of the future. Among Teas I have noted Etoile de Lyon of last year very highly spoken of, and Madame E. Verdier, a darker Gloire de Dijon, and the Hon. Edith Giffard, in the way of Devoniensis, as being of promise; while Souvenir de T. Levet, a red Niphetos, sounds exceedingly tempting.

Considering the fashion for single Dahlias, and the strides they are making in excellence and popularity, I am not surprised to see two single Roses announced this season amongst the novelties—Paul & Son's Single White and Single Crimson Perpetual. I have long thought that this most deserving and very beautiful class was becoming quite overlooked, and therefore hail this apparent return to them of public opinion. If single Dahlias are to be shown, why not single Roses? "D., Deal," please consider the point. A class allotted to them by the National Rose Society would at once reinstate them. What could be more beautiful than a box of Persian Yellow, for example, buds and blooms being judiciously mingled? The Austrian Briar—what a unique colour! Again, Fortune's Yellow: how beautiful as a climber! I see "D., Deal," gives Longworth Rambler a place in the garden Rose list; while Madame Plantier, though rather more than single, has an excellence in the mass not easily forgotten. I should like again to express the thanks of one (I am sure representing that of many) to Mr. Hinton for his two most interesting Rose-election tabulated papers.—A. C.

RIPENING VINE WOOD.

MANY amateurs, and indeed some professional Grape cultivators, err on the side of being too sparing with fire heat in the case of young Vines. In these comparatively sunless and cold seasons it is no easy matter to have wood well ripened, unless much assisted by abundance of artificial heat combined with free ventilation. I was lately called in to see a gentleman's Vines, which have lost a season through the neglect in supplying fire heat. The gentleman thought he would have the wood ripened without having recourse to artificial heat, but he now sees he has made a mistake. He is now trying by means of heat to have some portion of the wood ripened, but the prospect is not good for his success. Disappointment and delay is the result of this want of attention. It is a penny wise and pound foolish plan to think to save a few coals at the expense of the Vines.

If Vines are worth growing at all they are worth growing well, and the simple rule that fire heat is almost essential in our climate to ripen the young wood of Vines should not be forgotten by those who wish to begin well in Vine culture. On this depend the hopes of the ensuing year. Unless the wood be well ripened fruitfulness cannot be expected, and will assuredly not be found.

Nurserymen are sometimes hampered for room when growing young Vines for sale, and consequently crowd them too much, also failing to give them as much heat as they need. When such is done the young canes are not in such a ripe and fit state as they should be, and cannot be expected to do as well as otherwise they would have done.

When, however, a purchaser obtains a well-ripened stock of young canes he has the prospect of their breaking well, and showing and growing well, provided that other things are favourable. If these make strong growths let them be liberally treated to fire heat and air as the season advances, and the result will be wood well prepared for another season, when the expenditure of coals will be amply compensated for by abundant fruitfulness.—VINE-GROWER.

ECCREMOCARPUS SCABER.

A TRULY grand climber for a south wall, and well worthy of being more extensively known and grown than it is. Although introduced into this country from Chili very many years ago, yet it is but seldom met with, and why it is not more generally grown we know not, since it is handsome in foliage and flower, and with ordinary care easily grown. I recently saw a fine example of this grand climber growing most luxuriantly against the south side of the house occupied by Mr. Luckhurst at Oldlands. Here it was allowed to grow freely and interruptedly, twining itself round and amidst the shoots of a robust Maréchal Niel Rose, thus presenting a pretty effect with its bipinnate foliage and orange-scarlet flowers. Mr. Luckhurst tells me that he undertook experiments with some of the shoots with a view to ascertain the amount of growth made each day. He marked certain young shoots in the morning, and on measuring these in the evening found the rate of growth to be from 6 to 12 inches in about the same number of hours. It will thus be seen that this is a rapid grower and would quickly cover a large space.—T. W. S.

WHICH IS THE BEST WHITE ZONAL PELARGONIUM FOR BEDS?—Will some of your readers give the name of the best white-flowering variety

for bedding-out purposes, and the county where grown? In this district Madame Vaucher runs too much to leaf, and White Vesuvius, which is good under glass, comes too pinky outside to be satisfactory.—S. C., Norfolk.

DOUBLE-GRAFTING APPLES AND PEARS.

I AM glad to see that the problem of double-grafting Apples is attracting attention. The experiments of Mr. Harrison Weir noticed by you are most interesting and valuable, and I trust that other, and specially Scotch, pomologists will prosecute similar investigations. I have long advocated this method and personally experimented, but my efforts are yet too immature to publish. We shall see by-and-by.

Double-working Pears has long since been proved a great success. Some fifteen years ago I dismembered a large Pear of the old useless Honey sort that covered the gable of my house, and grafted thereon Comte de Lamy, Beurré d'Arenberg, and Easter Beurré, October, January, and March varieties. These far surpass in quantity and quality (and both are excellent) anything I have or see around me on the Quince. At the same time I treated similarly an old much-cankered Jargonelle, grafting it with Louise Bonne, Doyenné Gris, Beurré Diel, and with as

Fig. 66.—Apple Jolly Beggar.

great success, but not more than on the Quince. Another decaying Jargonelle I grafted with Swan's Egg and Muirfowl Egg—old common Scotch sorts as you know, which bear everywhere with us profusely on standards. Strange to say, although I had magnificent crops, neither I nor others who tried could ever ripen the fruit. Years ago I cut them also down and grafted triply with Croft Castle and Hacon's Incomparable. The former bears grandly but ripens badly. The latter has not yet fruited, but gives a good promise for next year. Once more only, not to weary you, I grafted on a Marie Louise (Quince), which is in our climate a shy bearer and with small fruit, such sorts as Passe Colmar and Beurré Diel. Both bear splendidly, but Passe Colmar is worthless in size.

We have much to learn yet, but we have made a noble and much-needed effort in the Apple Congress. Nothing has for years annoyed me more than the reckless disregard of some nurserymen alike of nomenclature and suitable sorts. I have seen a pyramid Cox's Orange Apple and pyramid Doyenné Comice Pear planted 700 feet above sea level.—M. H. N. GRAHAM.

ANEMONES FOR SPRING-FLOWERING IN POTS.

FEW can form any idea of the beauty of these plants when grown in pots for flowering during the spring months. *A. fulgens* is charming when well grown in 3-inch pots, and can be had in flower long before those planted in beds and borders outside. This variety is very effective with its bright scarlet flowers for the conservatory or greenhouse. It is very striking when a number of plants are staged together to form a front row to other plants; in fact, they are much more conspicuous in this position than when a few plants are employed amongst others. The roots should be potted at once in well-drained pots, as a good supply of water is needed while the plants are in active growth. If the tubers are strong one in each pot will be sufficient, but if larger specimens are

required three may be placed in 6-inch pots. The tubers should be well covered with soil, and the pots placed in a cool position. They can be covered with cocoa-nut fibre until the growths are visible, when it must be removed at once, and the plants kept afterwards as near to the glass as possible. No attempt must be made to force them, or failure will result. The double forms are undoubtedly the most valuable for cutting, and should be grown in 6-inch pots, three tubers in each. Any fairly rich soil will suit them, and a mixture of loam, sand, and a little manure will be found admirable. Frost should be excluded from them while they are in cold frames, and abundance of air must be given when the weather is favourable.—SCIENTIA.

WE learn that it is proposed to hold an EXHIBITION OF APPLES at Manchester. Mr. Bruce Findlay, the Curator of the Botanic Gardens, has issued invitations to growers, and it is stated that the Show will be opened to the public on November 1st.

— THE suite of apartments in Hampton Court Palace vacant by the death of the Right Hon. William Beresford have been offered to and accepted by Mr. A. GRAHAM, Superintendent of the Royal Gardens. Mr. Graham already occupies apartments in another part of the Palace.

— MR. CUTLER informs us that the simultaneous collection in aid of the Pension Augmentation Fund of the GARDENERS' ROYAL BENEVOLENT INSTITUTION for this year will finally close on November 30th. We are pleased to hear that the amount collected up to the 23rd inst. is £434 16s. 10d., as against £331 5s. 7d. at the same date last year.

— THE exhibition of CHRYSANTHEMUMS in the INNER TEMPLE GARDENS will, by the liberality of the Benchers, be opened to the public to-day (Thursday), and the display will well maintain the prestige that Mr. Newton has so deservedly earned as a cultivator of these popular plants. About 600 specimens are arranged in the glass house near the Thames Embankment, and they are all remarkable for their dwarf compact habit, vigorous foliage, and abundant buds. In a few days there will be a fine display of flowers; and already there are good blooms of Elaine, Chinaman, James Salter, Comte de Germany, Curiosity, M. Delaux, Chevalier Domage, Golden Beverley, Lady Selborne, Cry Kang, Ossian, and the pretty Pompon Rose Trevenna. A number of new varieties are included, and visitors will have a good opportunity of judging their respective merits.

— THE MIDDLE TEMPLE CHRYSANTHEMUMS are also unusually promising, the plants being in far better condition, more healthy, with finer foliage and larger buds than we have previously seen them. One thousand plants are grown, representing between 400 and 500 varieties, both old and new. They are arranged to form a sloping bank in the show house near the Fountain Court, and the effect that will be produced by a bank 100 feet long when the blooms are fully out may be readily imagined. Prominent amongst the earliest may be noted the indispensable Elaine, James Salter, La Charmeuse, Lady Selborne, Prince Alfred, Tendresse, and Catherine Talfourd. The exhibition will be opened on November 1st, and Mr. John Wright, under whose charge these gardens are now placed, deserves much credit for his first season's success.

— MESSRS. H. CANNELL & SONS, Swanley, send us flowers of some extremely pretty and distinct SINGLE DAHLIAS, amongst which two charming varieties are Midget (Cullingford), with very neat bright scarlet flowers 2 inches in diameter, and with florets of great substance. The other is named Chryso, and is exactly similar in size and shape, but of a rich clear yellow hue. These are two of the neatest varieties we have seen. Other notable forms are Gem of the Stripes, a small flower, the florets white in the centre and with broad dark scarlet margins. Virgo, also small, white. Curiosity is slightly larger, of a peculiar orange-buff hue. Mr. Moore is similar in form, but the florets are rich maroon, lighter at the base. Two varieties of still larger type are Mrs. Wright, with broad florets, white in the centre, margined with pale crimson, and Mrs. Goldring, a very large flower with broad petals of a soft rosy lilac tint.

— FLOWERS were also included of a distinct new Japanese CHRYSANTHEMUM GLOIRE RAYONNANTE, a superb variety of the Gloire de Toulouse style, with the florets quilled nearly to the point, much larger and of a warm lilac tint. It is a handsome and useful variety, the flowers being admirably adapted for vases, owing to their graceful appearance and soft colour.

— MR. JOSEPH WITHERSPOON writes respecting LORD DERBY APPLE as follows—"This Apple I have proved to be a most excellent variety for the north of England, it having borne heavily for the last three years. There it is not so large as Lord Suffield, but is of much the same nature and keeps longer."

— ROYAL METEOROLOGICAL SOCIETY.—The Home Secretary has acquainted the Meteorological Society that Her Majesty has been graciously pleased to grant it permission to adopt the prefix "Royal." The Society accordingly becomes the "Royal Meteorological Society."

— "T. W. S." writes—"I saw the other day a large quantity of the showy old plant AMARYLLIS BELLADONNA blooming in profusion in a narrow border in front of one of the conservatories at Buxted Park. These, I believe, were planted out many years ago, and, as they require but little attention and a limited amount of space, are worthy of a place in all gardens. It is, however, essential that the position be a dry one, and, as a rule, plenty of such similarly narrow borders occur in most gardens, which might be profitably occupied with masses of this showy old plant. I write profitably, since the large yield of flowers at this season will be found useful for cutting for decorative purposes."

— THE same correspondent finds that "IPOMÆA LEARNII succeeds remarkably well planted inside and trained up the roof of the winter garden. We allow it to grow unrestrictedly, and the majority of its shoots to hang gracefully down from the roof. It has borne an immense number of its beautiful blue flowers for months past, and will continue to do so for some time yet."

— THE forty-third ordinary meeting of THE ESSEX FIELD CLUB will be held at the head quarters, 3, St. John's Terrace, Buckhurst Hill (opposite the church), on Saturday, October 27th, at 7 o'clock P.M. The following papers will be read:—1, "Deneholes and their Relation to other Earthworks, &c.," by F. C. J. Spurrell, F.G.S. 2, "Miscellaneous Notes on Deneholes, 1883," by T. V. Holmes, F.G.S., M.A.I. The rooms will be open at 6 o'clock for the exchange of books and for the convenience of exhibitors at the meeting and conversation.

— "C. L." writes—"An enormous specimen of the fungus POLYPORUS SQUAMOSUS was recently found near the Welsh Harp, Hendon. Its greatest width was 3 feet, and the transverse diameter was 2 feet 8 inches, the stem being 7 inches across. Several others of slightly smaller dimensions have also been found in various districts this season."

— GARDENING APPOINTMENTS.—MR. George Newnham has succeeded Mr. H. King as gardener to Mrs. Carter at Ospringe House, Faversham, Mr. Newnham having previously been foreman in the same gardens. Mr. Thomas Hope, late gardener to the Hon. R. F. Boyle of Purley Lodge, near Reading, Berks, is now gardener to the Hon. Mrs. Eyre, Lindley Hall, Warwickshire.

A HORTICULTURAL RAMBLE.

THE ramble was not undertaken for that purpose. It had several objects in view. Clerical duty, the opportunity of visiting some kind and valued friends who had often wished me to do so, the seeing of some historic places, notably a pilgrimage to the "birthplace of the immortal bard," as the Yankees say; but as in all my "gurgling to and fro" horticulture has ever a charm for me, so I determined on this occasion to keep eyes and ears open, to gain information, to see what I could, and to tell afterwards what I thought might interest the readers of the Journal, especially as many of those whom I visited are not unknown to its columns as contributors to the general fund of information its pages give on all gardening subjects. Of the glories of Kenilworth and Guy's Cliff, as they have no horticultural interest I forbear to speak, but

WARWICK CASTLE

must not be left unnoticed. The situation of this splendid specimen of mediæval architecture is beyond expression beautiful. The beautiful stretch of the Avon, the magnificent view from the Laxtons, and the glorious Cedars which form the chief attraction of the grounds combine to form a feature of surpassing beauty which lingers on one's mind ever

afterwards. But if it is said that a brave man struggling with adversity is a sight fit for the gods, then must the position of Mr. Christie, the able and intelligent gardener, be one especially deserving of praise, for I do not know any place where it is carried out under greater difficulties. Take, for example, the rosery. Nothing can be more charming than the selection, nor have I seen one where better taste was displayed in the arrangement; but then it was so surrounded by lofty trees that the sun was to a great extent excluded, consequently the wood did not ripen and the blooming was very indifferent. I can sympathise with anyone who has not the Gladstonian mania of hewing down noble trees which have stood for centuries, but then if a rosery had to be made it would surely have been better to have selected some more open spot where the trees would not have interfered. But this is nothing compared to what has been done in the garden. Some few years a long range of houses for growing Grapes and Peaches, &c., was erected. Now when we consider the height of excellence to which all subjects connected with horticultural buildings has reached, it seems perfectly incredible that a range of buildings like these should have been placed facing east; and more than that, that Peach houses should have been placed behind other houses, with what results may be imagined. It certainly does great credit to Mr. Christie that with all this disadvantage he has been enabled to grow and ripen an excellent crop of Grapes; but this has been done by an expenditure of fire heat which would under ordinary circumstances have been totally unnecessary. But all his skill availed nothing with the Peach house. More luxuriant growth and clearer foliage it was impossible to see; but as the sun never reached the lower parts of the trees, consequently the wood could not ripen, and as a result no fruit could be produced, he had not had more than a dozen Peaches off the fine-looking trees. Who the planner of this marvellous fiasco was does not seem to be well known. Nobody seems inclined to acknowledge the authorship, but it is a remarkable instance of how things "ought not to be done." The garden is, as a good many places of the kind are now, underhanded, and the only marvel to me is how with such small resources Mr. Christie manages to effect what he does. The stove and greenhouse plants were well done, and along what is called the Earl's Terrace, which is not generally shown to visitors, overlooking the river, a good collection of herbaceous and other plants was arranged.

ALDERMINSTER,

from whence my friend the Rev. J. A. Williams has oftentimes sent contributions to the Journal, is about five miles from Stratford-on-Avon, and is pleasantly situated in the midst of quite a model village. There Mr. Williams has a good collection of his favourite flower the Rose. It is not really the vicarage house, which is at some little distance, but one that he has rented, and is quite close to a very beautiful old church which has been partially, and is about to be completely, restored. It is easy to be seen what the ruling passion of the vicar is with regard to flowers, for while other things have a place, *the* place is given to the Rose. It will be remembered that Mr. Williams was formerly at Yardley Wood near Birmingham, where he rendered good service to the cause of the Rose; consequently he has not as yet sufficiently established his collection, but the plants were in excellent health, and, like a good many other Rose-growers, the Teas have carried him captive. His selection of these is good, and he is about to increase his culture of them, and will root out, as I believe everyone ought to do when Roses are so easily procured, all weak-kneed Hybrid Perpetuals and replace them, but will increase his number of plants; and I shall be very much surprised if we do not see his flowers taking a good place at the exhibition table. In another part of the glebe he has planted an orchard, and the young trees were most promising, while in the old vicarage orchard were some of the most splendid trees of Blenheim Orange with the finest crops I have seen for many a day. After enjoying my short visit very much he drove me into Stratford, where one had the opportunity of seeing all the points of interest connected with our great poet, and from thence I went on to Malvern. There were many places of interest in and about the neighbourhood of this favourite resort, but as I had only one day I arranged to spend it at

HOPE END, NEAR LEDBURY,

where my friend Mr. W. J. Grant has his fine collection of Roses. Hope End, the residence of Mr. Hewitt (whose agent Mr. Grant is), is a most lovely spot. The house is a new one, in the midst of a beautifully wooded park, from whence fine views of the Bean and the distant mountains of Wales can be obtained. The place is somewhat famous as being the birthplace of Mrs. Barrett Browning, the poetess—her father, Mr. Barrett, having formerly been owner of the place—and it is said that many of her poems were composed on an islet in the piece of water which lies at the bottom of the valley. Like most places in these western counties Conifers seem to flourish well, and fine specimens of Wellingtonias, Araucarias, &c., are to be seen in the grounds. The garden is a thoroughly old-fashioned one, and does not call for any particular remark; indeed, I was more anxious to see Mr. Grant's garden than that at the big house. His house is situated in the lower part of the valley, while the garden occupies the side of a piece of rising terraced ground. Many good herbaceous plants are to be found here, *Bocconia cordata* I noticed as especially showy; but the Roses are the *pièce de résistance*. Here on the house are fine plants of Maréchal Niel, Rêve d'Or, and other climbing Roses; here, again, in a sheltered nook are good plants of Teas. Teas also occupy the wall at the top of the terrace, while a fine piece of Hybrid Perpetuals evidences that good flowers have been obtained, and are making vigorous growth for another season. But it is at some distance from his house, in a piece of ground which he

has purchased, that Mr. Grant has his chief stock. The soil is good and the ground lies well to the sun, and is not shaded although sheltered. Here on the seedling Briar, Briar cuttings, and Manetti (the two former being preferred), is a fine stock of about 2000 Roses of all the leading varieties. It is needless to particularise the varieties grown, for go where we may the same sorts always are cultivated. There may be a few places where a variety or two is pre-eminently good—as Thomas Mills is more of a favourite in Scotland than in more southern regions; but as a rule Marie Baumann, A. K. Williams, Charles Lefebvre, Duke of Edinburgh, Alfred Colomb, Madame G. Luizet, and such well-known varieties, are sure to form the bulk of the collection, especially where the grower is an exhibitor. He cannot dispense with them, nor can he afford to fill his ground with varieties that will not stand the exhibition test. One knows how very common it is to hear, "How many sorts of Roses do you grow?" and by the uninitiated public you will generally get credit for your powers as a rosarian in proportion to the number of varieties you possess. But an exhibitor knows better. He knows that if he wants Roses for the exhibition table it is no use his encumbering his garden with Roses which, however pretty, are useless for his purpose. One can understand now in going through the country how it is that competition is so great at our shows. The keenness with which the Rose is cultivated brings so many more into the field that, whereas in the earlier meetings of the National Rose Society it frequently happened that many classes were so little competed for that money was oftentimes saved, now such a thing rarely takes place. Members, too, who formerly exhibited in smaller classes increase their stock, and, as in duty bound, go up into higher ones.

My rambles extended from Herefordshire into South Wales, and I had intended to have noticed something of deep interest I had seen there, but must leave them for my next paper. One horticultural treat I missed owing to my not having time enough. Mr. Grant had arranged for me to go to Eastnor Castle, but time went on so rapidly in going through his interesting garden that we had to abandon it; but I should have been glad to have seen our champion fruit-grower at home. This must be reserved, if all be well, for another season.—D., Deal.

NOTES ON CELERY.

THERE may be little to add to what is already known in the cultivation of Celery. This year we have a good quantity of a variety quite new to us, and one of the best we have seen—viz., Harrison's Early Pink. Among half a dozen others it is the favourite. Major Clarke's Red is much like it, and is also a general favourite; not gross, but solid and crisp. Sandringham Dwarf and Turner's Incomparable are with me as unlike the original as can be. They are both about 4 feet high, pithy and loose, instead of short, stiff, and of great girth. I have had Turner's Incomparable stand in good condition to the end of May with very little earthing-up. Height is not a qualification which is claimed for Turner's and its synonyms; but for hardiness and being exempt from "holting," we know of none to surpass it. One evil too common is earthing-up too high, and long before growth is complete, forcing the soil too closely to the hearts of the plants.

The blanching process has always been a subject of varied opinion. Some maintain that the Celery should remain free of the soil till it has attained its full growth. Tie the stems evenly together, then earth-up all at once. From what we have observed in market gardens round London by the one-earthing system, we were induced to a large extent to follow up the practice of doing the work all at once a month before the Celery was required for use; and for more than twenty years we have (except for the earliest supply during August and onwards) earthed-up the whole crop at once. Sometimes this has amounted to over two thousand plants. This year, however, we have returned to the old practice so well known of earthing-up the crop as it advanced in growth, probably about four times. We at no time have been so well supplied with early well-blanching Celery. When each succession is planted a dressing of manure is placed over the surface and a good soaking of water is given. This season we placed mowings of grass over the surface of newly planted roots and thoroughly soaked the ground with weak guano water, and later, before earthing began, stimulants were again applied. The Wortley collars have been used to some extent, and, we believe, with much advantage.

After the experience of this season from a practice we have adopted for many years in a very limited form, we are inclined to fall back on the system which has been in practice long before the present generation of gardeners existed. We put much value on a judicious application of liquid manure. Thomson's Vine manure worked into the surface of the soil and washed down with clean water; or, what is better, heavy rains, which will tell its own tale by a vigorous and crisp growth. Lettuce, Tomatoes, Cucumbers, Melons, &c., are also greatly improved by applications of this manure.—M. T. C.

THE NATIONAL APPLE CONGRESS.

AMERICAN APPLES.

AN interesting addition was made last week to the Exhibition at Chiswick—namely, a collection of about fifty dishes of Apples grown by Mr. G. R. H. Starr at Port William, Nova Scotia, and exhibited by Messrs. Nothard & Lowe of London. They comprised some beautiful, clean, and highly coloured samples of the principal varieties grown in America for

exportation to England, together with others that are more rarely sent. In several cases the specimens were extremely fine, but it was notable that in more than one instance English exhibits of an American variety were even superior to the home productions. This was especially the case with King of Tomkins County, of which a dish of even handsomely coloured fruits was sent from Nova Scotia, and was perhaps the most beautiful in the collection, yet in Messrs. T. Rivers' contribution from Sawbridgeworth the same variety was represented by fruits considerably larger though less highly coloured. Again, good fruits of a variety named Holly were shown, which appears to be identical with the well-known Beauty of Kent, and in several English collections equally fine or finer specimens were notable. A particularly handsome Apple was Chebuct Beauty, a rival in size to Peasgood's Nonesuch, but of an intensely deep, rich, shining red colour; a variety in Mr. L. A. Killick's collection named Batchelor's Seedling was precisely similar to this in colour and form, equally handsome, but smaller. An extremely beautiful variety of American origin and a great favourite in some districts is Maiden's Blush; the fruits are of moderate size, of a delicate wax-like yellow tint with a soft rosy blush on one side—a most pleasing contrast of hues. In its native land it is valued as a culinary variety, and is much used for drying in the approved transatlantic method. De Rocas Seedling is another variety distinguished by its pretty colouring; it is also a medium-size Apple, creamy-white, streaked freely with rich rose. Munson Sweet was an attractive Apple, yellow, with rosy streaks on one side and scattered on the other. Nicnac is also a pretty variety, yellow with a rosy crimson side. Chenango Strawberry is a conical variety prettily streaked with red, and Hutching's Golden Ball is a fine yellow Apple of good size and even form. These are the most showy varieties, and the others are as follows—Sweet Russet, King of the Pippins, good in size and colour; Gravenstein of Waugh, Gloria Mundi, Peck's Pleasant, Dutch Codlin, Fallawater, Catashea, Yellow Belle Fleur, Emperor Alexander, Flushing Spitzbergen or Vandevere, Gravenstein, Reynard, a large yellow Apple, globular in form, and about 3 inches in diameter; Fall Jeannetting, Drap d'Or, red and yellow, pretty; Talman Sweet, Hubbardson's Nonesuch, Catshead, very large; Porter, a fine yellow Apple; Concord Pearmain, Blue Pearmain, Blenheim Pippin, Rhode Island Greening, Lyscom, Baldwin, Rambo, and Cooper's Russet.

CURIOUS OR LOCAL VARIETIES.

From some of the southern and western counties numbers of local varieties bearing homely or curious names were shown, and in Somersetshire these were particularly notable. The cider Apples were not, however, largely represented, or an interesting array of names would have been provided. Such titles as the Pawn Apple, Lopen Never Blight, Cup of Liberty, Golden Farmer, Sugar and Cream, and Honeycomb are of frequent occurrence. The last-named is a pretty Apple about 2½ inches high, yellow streaked with very bright crimson, but most of the others mentioned are not distinguished by any great external charms. The Ten Commandments in the Herefordshire collections is said to owe its name to the number of cells observable when the Apple is cut transversely. In other contributions we notice the Pursemouth, Fox Whelps, Dog's Nose, Sheep's Nose, Striped Pitcher, Egg Apple, Pigeon, Hall Door, in one case named the "Kitchen Door," Wax Apple, Fairy Apple, Summer Strawberry, and Lady's Finger, with many other characteristic or fanciful titles.

Amongst the Swedish Apples several names occur which sound strange to English ears, but with the exception of one variety they do not demand special notice; this one, however, the Akero, is said to be a great favourite in Sweden, and possesses a very distinct flavour. The Apple is about 2½ to 3 inches deep, and 2½ inches in diameter, with a deep eye and slender stalk, sometimes having a prominent fleshy projection on one side; it is dull yellowish in colour, tinged with rosy crimson and dotted thickly with a darker tint on one side. The flavour is slightly acid, but very distinct and rich.

The Blue Pearmain included in the Chiswick and Nova Scotia collections is a curious American Apple which, as the name implies, frequently comes with a bluish tint that is especially noticeable when the fruits are freshly gathered. This is due to a knot of "bloom" which forms upon the surface of the skin and bears some resemblance to the bloom of Grapes. The Apple is also of good flavour either for eating or cooking, but is preferable for the latter purpose.

The Lady's Finger is represented by two different forms, one in Mr. Killick's collection and the other from Herefordshire. The former, which is that known in Kent, is also said to be called Turkey's Egg in Yorkshire. It is cylindrical and conical, 3 to 4 inches deep, green streaked and spotted with crimson. The Herefordshire Lady's Finger is more conical, about 3 inches deep, yellow streaked and spotted with red, and deep red on one side, a projection at the side of the stalk being very prominent. Both are pretty Apples and of good cooking qualities.

One dish of Pigeon is noteworthy in the Essex collections, where it is said that scions were obtained from Baron Von Winterfeldt, near Hamburgh. It is of a strange dull ivory tint, darker on one side, and bearing a peculiar "bloom," somewhat after the style of the Blue Pearmain already mentioned. It has been fancifully named Pomme de Jerusalem, because the four cells are disposed in the form of a cross.

As another though widely different curiosity may be mentioned a box of fruits of the true Service Tree, *Pyrus domestica*, sent from the Oxford Botanic Gardens, in which is a very fine specimen of this tree, probably the largest in the kingdom. The fruits are small, egg-shaped, very austere when fresh gathered, but after "bletting" like Medlars, which they then somewhat resemble in flavour, it is much liked by some persons.

CONFUSION OF NAMES.

As might be expected, the Committee have had considerable work in determining the true names of the Apples shown, for much confusion has evidently prevailed in all districts, as not only have some old Apples gained fresh names in different districts, but some well-known varieties have been strangely confused. The following few examples will indicate this:—

Shown as	Determined to be
Counsellor	Yorkshire Beauty
Rymer de Caldwell	Yorkshire Greening
D. T. Fish and Poor Man's Friend	Warner's King
Cheshunt Pippin	Harrold's Pippin
Hamilton's	Hambledon Deux Ans
Newtown Pippin	Evagil
Cobham	Dutch Mignonne
Belle Dubois	Gloria Mundi
Emperor Napoleon	Small's Golden Pippin
Formosa	La Fameuse
Red Hawthornden	Yorkshire Beauty
Betty Geeson	Ringer
Lord Clyde	Golden Noble
Downton Pippin	Small's Golden Pippin
Old Nonpareil	Sturmer Pippin
Lord Nelson	Nelson's Glory
Flemish Beauty	Count Pendit Plat
Reinette Grise	Kentish Golden Knob
Flower of Kent	Tower of Glamis
Pott's Seedling	Tower of Glamis
Grenadier	Lord Derby
Warner's King	Stirling Castle
Golden Reinette	King of the Pippins
Broome Hall	Beauty of Kent
Barker's Seedling	Warner's King
Gadd's Seedling	Beauty of Kent
Cox's Pomona	Emperor Alexander
Calville	Cox's Pomona
Devonshire Queen	Red Autumn Calville
Spice Apple	Pitmaston Golden Pippin
Rendell's Pippin	Court of Wick
Gloucester Pippin	Blenheim Pippin
Reinette de Canada	Warner's King
Lord Exeter's Favourite	Hick's Faney

GLOXINIAS.

THESE are not so difficult to grow as is too generally, I think, supposed. The flowers are produced in great profusion, and for richness and variety of colour are not easily surpassed. The most that can be said against them is the flowers are too fragile and short-lived to be very serviceable in a cut state.

They are, however, very useful and telling in specimen glasses for dinner-table decoration. Another recommendation is, they may be had in flower at any time of the year; and where choice, easily grown, consequently cheap, flowers are in request, I would recommend their more extended cultivation. Having grown a batch of seedlings this year, and thinking a few cultural hints may be both serviceable and seasonable to those of your younger readers who may feel disposed to grow a few plants next year, I give my mode of procedure. The seed should be sown as early in the season as circumstances will permit. It may be sown either in a seed-pan or pot. Fill the pot three parts full of any rough material to act as drainage, on which place about an inch depth of finely sifted soil. Leaf soil and sand passed through a fine sieve is what we use. Make this perfectly level, and sow the seed evenly over the surface. Cover the seed very lightly with some of the same soil, give a gentle watering through a very fine rose, and place a piece of glass over the whole to prevent evaporation. On the top of this put a piece of paper, which will act as a shading as well as do away with the necessity of watering too often. The less watering the better. At the same time the surface soil must never be allowed to become dry. The seed will germinate freely in a temperature of about 60°. Keep a sharp look-out for the seedlings' appearance. When they show themselves remove the paper and shade only from the rays of the sun. Directly they are large enough to handle prick them out in pans or pots about 1½ inch asunder. When they begin to touch one another pot singly into thumb pots. Three parts peat to one of good loam, with a little silver sand and some charcoal broken small well mixed together, makes a very good compost to grow them in. In due time they will require another shift. Four-inch pots will be found quite large enough to grow them in the first season. They do not like overpotting. The drainage should be good, and they should be potted moderately firmly. Keep them close to the glass in a genial temperature, say 60° to 65° by day, and even higher with ventilation; water only when necessary, and shade from the direct rays of the sun. Water should be kept off the foliage as much as possible.

With the above treatment very creditable plants may be grown and flowered the same year. Indeed our batch of seedlings, which are now flowering profusely and will continue doing so for a month, were only sown on the 23rd of April. When the flowering period is over they may either have a rest given them or be grown on. That depends upon when they are wanted to be in flower. Any good sorts that the cultivator wishes to increase are readily propagated by the leaves. Insert the leaves into a pan of sand or leafsoil, and they will in due time produce bulbs that will ultimately make as good plants as the parent.—J. RICHARDSON, *Calverton Hall, Notts.*

MOSS ROSE—LITTLE GEM.

Moss Roses are favourites with everyone, the neat flowers, delicate or rich colours, distinct appearance, and pleasing fragrance, render

them unrivalled amongst the small-flowered types of Roses. A beautiful addition to the group is that shown in fig. 67, Little Gem or Crimson Moss de Meaux, which was raised by Messrs. W. Paul and Son, Waltham Cross, and sent out in 1880, when it speedily attracted general attention. Its popularity is growing every year, and we venture

arranged, that the flower in all its stages, from the bud to the fully expanded Rose, is a tiny gem. Those who are acquainted with the old Moss de Meaux, a lovely little Rose now almost extinct, may be told that the Little Gem is similar to that variety in size and shape, but the colour is deeper and fresher, and the plant grows freely, which

Fig. 67.—MOSS ROSE LITTLE GEM.

to predict that it will become one of the most favourite garden Roses in cultivation.

An excellent coloured plate of the variety was given in Mr. W. Paul's "Rose Annual" for 1879-80, accompanied by a good description, which we here reproduce.

"The flowers when expanded are not larger than a shilling; the petals are small in proportion, regularly shaped, and so beautifully

the former does not. It makes a beautiful compact-headed tree of small size when budded on short stems of the Dog Rose, the shoots formed after flowering rarely exceeding a foot in length. The form of the bud, flower, shoots, and leaves is well depicted by the artist, but the colour is usually of a much clearer tint, and the mossy envelope is equal, if not superior, to that of any variety in this group both as to style and quantity. Like all the Moss Roses of moderate growth, it delights in

a rich soil and close pruning, and thinning out the shoots where crowded is desirable. For freedom of flowering, when thus treated, we know of no Moss Rose to equal it."

If we recollect rightly this Rose has not been certificated, and if it has not it ought to have been, for both as a garden Rose and for affording charming flowers for cutting, it is a distinct and decided acquisition.

CONVOLVULUS CNEORUM.

THE Silvery Bindweed is a dwarf shrub from Greece with lanceolate leaves. It grows about 18 inches high, and is of semi-procumbent habit, which renders it very effective on the dry sunny aspect of rockwork, where it is hardy in all but the severest winters. The plant is evergreen, and bears a number of shining white flowers, which have the glitter of pearl, and, like it, are slightly tinged with red. Of free growth it soon forms a spreading low bush. Cuttings struck in late summer, wintered in a cold frame, and planted out in spring, form a bush nearly a yard across by September, during which it commences flowering and continues until frost. In order to guard against mishap from frost it is well to strike cuttings in August under a handlight, pot them when rooted, and winter in a cold frame or house. It may be mentioned that plants raised in this way, grown on in a cool house, and shifted into larger pots as required, are very showy for conservatory decoration. The flowers are borne like those of *C. mauritanicus* at the points of the growth, hence stopping must not be continued longer than is needed to lay the foundation of a compact plant. Although not nearly so trailing in habit as *C. mauritanicus* it makes a desirable basket plant, but is best seen as a rock plant. It does well in loam with a little leaf soil or decayed manure, and a little sand to keep it open. Good drainage is essential.—G. ABBEY.

SIX MONTHS IN A VINERY.

NEW YEAR'S DAY, 1883.—Other preliminaries having been attended to, we last week examined the border, or at least that part of it situated inside the house, as to its condition with regard to moisture. This was done by means of a small trowel, which was worked down a foot or 15 inches in several places. The soil was found to be so moist at that depth that when pressed it would cling together and show that water was not yet necessary, and, as it will be at least a month before the roots begin to move, watering may with advantage be withheld till that time. The outside part of the border we have no doubt is sufficiently wet, as it has had some 40 odd inches of rain on it within the past twelve months.

The winter so far having been a mild one, we have not thought it advisable to cover the outside border up to the present time, but were it to come very severe weather a little loose litter would be scattered over it, say 3 inches thick, to be removed in May, or as soon as the sun was sufficiently powerful to benefit the soil. Covering the border is at most a necessary evil, as the surface soil hardly becomes friable during the whole summer after having been covered for some time with moist dung; but still frost and melted ice are injurious to active roots and must be guarded against. I have known very serious checks to occur when this matter has been neglected.

The house is closed for the first time to-day, and a strip of paper is placed against the thermometer with instructions to the attendant to "keep to about 53° to 55°, night and day, by fire heat." These figures are not strictly enforced. Should very severe weather follow, there would be no complaint if the thermometer fell to 50° in the morning; and however much sunshine there may be we shall not for the present open the ventilators, but rather welcome the additional natural heat and house it to the utmost extent. It is a pity one single ray of the sun should be wasted at a time when it is so precious.

January 20th.—The weather during the past three weeks has been very mild for the time of year, the outside temperature seldom falling below 40° at night, and frequently not lower than 45° to 47°.

Two or three times we have had a little hoar frost in the morning, which was welcome so far that it was generally succeeded by a little sunshine. Most of the weather, however, has been dull and warm, and very often foggy. Little fire heat has been necessary to keep up the desired temperature in the vinery, and as there has been but little evaporation damping down has not been largely practised. A little water sprinkled under the pipes three or four times in the three weeks was all that was thought necessary, excepting on one occasion during this week, when the sun shone brightly all day (quite a red letter day this, worth more than a week of the other sort of weather); the thermometer, which was shaded, rose as high as 90° at noon and remained up to 70° till dark. We sprinkled the walls and path rather copiously. The ventilators were kept close, and we thought the following morning that visible progress had been made.

The instructions are still "53° to 55°, by fire heat; no ventilation;" but should the dull warm weather continue we shall deviate from the latter part of the programme, as it takes so little fire heat to keep up the desired maximum; and the outside temperature, owing to the

absence of sun and wind, being almost at a standstill, there will be a danger of the air in our vinery becoming too stagnant. Sunshine for an hour or two or a fall in the natural temperature will prevent this happening. But rather than allow the temperature of our house to remain stationary for a week, we would give a little air and make the pipes a little warmer for an hour occasionally.

Owing to the house having been forced gently for several years, the wood being thoroughly ripened and the natural temperature high, the buds were seen to be swelling a week ago. The day's sunshine I have mentioned came at a fortunate time to consolidate the little growth which had already been made, and it also gave an impetus to the Vine to make more growth. Some of the buds at the upper end of the house (for as I have said before, it is not built on level ground) are already nearly half an inch in length, with round brown-looking points which may soon be expected to unfold and show the shape of the tiny leaves.—WM. TAYLOR.

(To be continued.)

AUTUMN PROPAGATION OF ROSES.

ROSES with us are, as a rule, ripening slowly; neither is this to be regretted, as those dwarfs, especially which from some cause ripened early and lost much of their foliage, are now throwing up strong shoots, and must eventually be much damaged by frosts. At the present time, if pieces of long ripened growth are cut into 1 foot lengths and firmly bedded in the open ground, the chances are the majority of them will strike root. The nearly smooth or thornless sorts, such as Countess of Oxford, Capitaine Christy, John Hopper, Marie Finger, Mons. E. Y. Teas, François Michelin, J. S. Mill, Empereur de Maroc, Miss Hassard, Hippolyte Jamain, Madame Lacharme, Docteur St. Amand, Perle Blanche, Egeria, Dupuy Jamain, Senateur Vaisse, Paul de Malleray, and Madame Chirard are the most easy to propagate in this manner. Soil of a medium texture and to which road grit has been freely added appears the most favourable for the purpose, and it should be well broken up and made firm again, and the cuttings dibbled in to half their length, taking care they touch the bottom of the holes and be well fixed. It is a mistake to crowd the cuttings, as it is quite possible to have them in a flowering state during the following season. I recommend that the rows be made 18 inches apart and the cuttings from 10 to 12 inches asunder in the rows, and it is of great importance that they be inserted at once. By allowing this distance the young plants have room to properly develop, and when replanted the following autumn they lift without much injury to the roots. Heavy land, being generally liable to crack, is unsuitable for Rose cuttings. Neither will they lift well out of it. In any case it is advisable to mulch the cuttings with rough manure or other material, this serving to protect them, and also prevents loosening by the action of frosts.

There are three Roses we find particularly serviceable, as affording the greatest number of cut blooms when on their own roots, and these are Countess of Oxford, John Hopper, and Souvenir de la Malmaison. The latter also strikes readily, and continues to yield perfect though small blooms till frosts intervene. Another good "own root" Rose is Dupuy Jamain and La France. Mons. E. Y. Teas and Maurice Bernardin are very serviceable.—W. I. M.

GARDENS ABOUT BRISTOL.

THERE are few districts where gardening is better practised, nor where gardeners are more united or receive greater encouragement from their employers, than in the neighbourhood of Bristol. This is evidenced by the well-supported Society of Gardeners, which has Clifton for its head quarters, and which, thanks to the liberality of many gentlemen and nurserymen interested in horticulture, are enabled not only to hold two annual excellent horticultural exhibitions on their own ground, but also to successfully compete either individually or collectively at any exhibition where good prizes are offered. This, despite what some critics assert to the contrary, is to me proof positive of the capability of the gardeners, and a tour among them tends to strengthen that opinion. Every place visited gave evidence of the proprietor's love of horticulture as well as the intelligence and care of the gardeners in charge, and this, coupled with the fact of all being located in beautiful districts and commanding some of the finest views imaginable, rendered my rather hurried visit thoroughly enjoyable. Ashton Court is the most famous place near Bristol, both on account of its much superior dimensions and excellent management, as well as the success attending Mr. Austen wherever he exhibits either fruit or vegetables; but this exceptionally fine garden has already been described in these pages. There are also other well-managed gardens I was unable to visit, but trust to do so another season. May starting-point was

STOKE HOUSE.

This, the seat of W. H. Budgett, Esq., is a handsome Elizabethan structure, which has been built upwards of two hundred years, and is still in excellent preservation. It is charmingly situated, the scenery including a grand view of Avonmouth and the Bristol Channel. There is a good expanse of lawn, which is well furnished with deciduous and evergreen trees and shrubs, among these being fine old specimens of Malberries, *Pavia lutea*, *Cedrus Deodara*, Cedars of Lebanon, and *Cupressus macrocarpa*. One of the approaches also runs through a fine avenue of

Elms and Chestnuts. The flower garden is overlooked from the terrace, and at the time of my visit was in excellent order and still gay with the usual summer hedging plants. The conservatory adjoining the flower garden is a substantial structure, built principally of stone and metal, and is in every respect worthy of the place and its surroundings. The roof is festooned with *Taenias* and other climbers, with *Pelargoniums*, *Habrothamnus*, &c., for the pillars and walls. Included in the centre beds are fine specimen Orange and Citron trees, *Latanias* and other Palms, *Dracaena gracilis* and *Araucarias*. On the side stages among the flowering plants *Achimenes* were conspicuous, such good varieties as *Mauve Perfection*, *Garibaldi*, *Ambroise Verchaffelt*, *longiflora alba*, and *Diadem* being the best. Near the conservatory a good rosery has been formed, and among the many varieties grown, both as dwarfs and standards, the most noteworthy as being good autumn bloomers are *Madame Victor Verdier*, *Edouard Morren*, *A. K. Williams*, *Charles Lefebvre*, *Mons. Filion*, *Dupuy Jamain*, *Marquise de Castellane*, *Baronne de Rothschild*, *Countess of Oxford*, and *John Hopper*.

The fruit and plant houses are closely grouped at one end of the kitchen garden, and consequently are less expensively heated and are more under control than is the case in other places where they are scattered. In the latest vinery such good sorts as *Madresfield Court*, *Black Alicante*, *Lady Downe's*, and *Gros Colman* were carrying extra heavy crops, and were finishing well. Figs in pots were trained on the back wall of this house and prove profitable. The Peaches are being re-arranged, and the space will be considerably economised and the trees improved by the operation. Instead of having the trees on the roof only, the front trees are trained to a semicircular trellis, and this will admit of the high back walls being also utilised. *Pitmaston Orange* and *Etruge Nectarines* are preferred, and *Royal George* is still the favourite Peach. *Early Alfred Peach* is found to crop heavily, the fruit being of fair size, highly coloured, and of good quality.

Of the plant houses the most attractive is the stove. It is a long and narrow span-roof structure, with a central path, on each side of which are arranged banks of well-grown Ferns and fine-foliaged plants, and a canopy of flowering climbers completes a very pretty display. Among the Ferns I was much pleased with healthy free-growing specimens of *Microlepia hirta cristata*, and *Lastrea Richardsii multifida*, both being erect-growing crested varieties, and suitable alike for exhibition and decorative purposes. All the best *Adiantums* and *Gymnogrammas* are also well represented, and of fine-foliaged plants the most noteworthy are specimens of *Anthurium crystallinum*, *Croton Weismanii*, *Ananassa sativa variegata*, and *Dracenas* in variety. Orchids are being taken in hand, and a fairly good collection already formed. The end back wall is being covered with *Jasminum graecillimum*, planted in a box of peaty soil, and this free-blooming highly scented Jasmine seems well adapted for this purpose. Much of the roof is covered with a healthy floriferous plant of *Allamanda Hendersonii*, this being planted in a small raised heap of soil enclosed by ornamental stones, the remainder of the roof being occupied by *Stephanotis floribunda* and *Bougainvillea glabra* similarly treated, and *Dipladenias* in pots. In a very slightly heated pit a large batch of stout healthy *Poinsettias* in various heights were growing, and these, when introduced into heat early in November, are calculated to rapidly develop fine showy heads. In one of the cool plant houses thriving specimens of *Lapageria alba* and *L. rosea* are planted in substantial narrow tubs, which are made with divisions which can be taken out and more soil added on each side, the tubs in this manner being gradually filled with soil and roots to the obvious benefit of the plants. *Primulas*, *Cinerarias*, double zonal *Pelargoniums*, and other winter-flowering plants are all well and extensively grown.

In the frame ground a house with a sunken floor and roof formed with old lights is devoted to Tomato culture, and here, with a very little attention, abundance of fine Tomatoes are ripened during the summer and autumn, and the structure is afterwards serviceable for wintering Roses and other comparatively hardy plants in pots. The kitchen garden is not large, but is well cropped with vegetables and fairly well furnished with fruit trees. Such good Apples as *Cox's Orange Pippin*, *Lord Suffield*, *Nelson's Codlin*, *Margil*, and *King of the Pippins* were the most heavily cropped. Fine examples of the useful Anemone *Honorine Jobert* were observable in different parts of the garden, the whole resulting from a few roots cut to pieces and grown in pans during the winter previous. *Gladioli* in considerable quantities and all named were at their best, and *Asters*, *Stocks*, and other serviceable annuals were very gay and the strains good.

Mr. H. K. Ward has for some years had charge of these gardens, and it is worthy of note that his employer apparently fully appreciates his services, and does not neglect his personal comforts, nor that of the young men under him. All are well and comfortably housed, and in addition a good and constantly increasing library is provided for them. Would that more employers would imitate such an example, as by so doing they would at no very great expense materially contribute to the enjoyment, improvement, and steadiness of their employes.—
W. IGGULDEN.

DINNER OF THE APPLE CONGRESS.

On Thursday evening a party of about sixty gentlemen, members of the Apple Congress, assembled at Ashley's Hotel, Covent Garden, by invitation of the Horticultural Club, to celebrate the triumph at Chiswick in the usual way, with a little dinner. Dr. Robert Hogg, F.L.S., presided.

The usual loyal toasts having been duly honoured, Dr. Masters, F.R.S., proposed "Prosperity to the Royal Horticultural Society." He said the

promoters of the Apple Congress were under great obligations to the Council of the Royal Horticultural Society for the liberal provision made at Chiswick for the Exhibition, and for the staff of earnest workers who had contributed in so great a degree to its success. The best Codlin in the Show was the one named *Barron*, and he hoped the compliment intended would not be thought a barren one.

Mr. John Lee responded for the Society. He had been associated with it for fifty-eight years, and considered himself the oldest inhabitant. The influence of the Society had been continuous and powerful for good, and the plants it had secured for our gardens were of the utmost value, and the best testimony to its consistent purpose. He could remember when Douglas sent home from America the Red-flowering Currant, and reflecting on the many splendid acquisitions of Fortune and others for which we were indebted to the Society, he would say that the climax was attained in the present wonderful exhibition of Apples.

The Rev. H. D'Ombraïn proposed the toast of the evening, "The Health of the Committee of the Exhibition." Perhaps, as an outsider, he could the better propose this toast than any of the gentlemen who were mixed up with the Apples. To estimate the service rendered to society by this splendid affair was, perhaps, as yet impossible. In fact, the Committee had not yet finished their labours, and it might be said, perhaps, in the presence of the gigantic task, that it could never be completed.

Mr. L. Killick of Maidstone responded. He said they had indeed been compelled to work as perhaps some of them, though busy men, had never worked before. They were well rewarded, for such an Apple Show had never been seen hitherto. But there was a greater reward now consummated, for such a meeting at the festive board of truly representative men was no common event. The Show was intended for practical purposes, and its practical value was incalculable. The manner in which they were backed up by the cultivators, by the press, and by the public was a matter equally for astonishment and delight.

The Chairman (Dr. Hogg) said all parties were to be congratulated on the results of the endeavour. The Exhibition surpassed all previous undertakings of the kind. He remembered with some pleasure the fruit shows of years gone by, but there had been none such as this, and it must stand alone as an episode in the history of horticulture. It told them of the cohesion of horticulturists and of the horticultural power of the country. The whole of this great undertaking was accomplished in the space of three weeks, and they were indebted to Mr. Barron for its initiation. Perhaps even this success could not add to the esteem in which Mr. Barron was held, for he was always winning and keeping the golden opinions of all who knew him as a practical horticulturist.

Dr. Hogg then presented Mr. Barron with a gold watch and chain that the members of the Committee had provided for the occasion in testimony of their indebtedness to Mr. Barron for his enormous labours and the knowledge he had brought to bear upon the difficult subject of Apple nomenclature.*

Mr. Barron accepted the gift and returned thanks in his own quiet manner, saying that the Exhibition had far exceeded his own expectations, and that he was well rewarded therein. There were 182 exhibitors represented in the Show, and the dishes or lots numbered 10,080.

Mr. William Paul of Waltham Cross proposed "The Horticultural Press," for which Mr. Shirley Hibberd responded.

Mr. Bunyard of Maidstone proposed "Prosperity to the Horticultural Club," acknowledging the indebtedness of the Congress for the opportunity of the present pleasant meeting. The Rev. H. D'Ombraïn acknowledged the compliment.

Mr. Harry Veitch of Chelsea proposed "The Health of the Chairman, and the Chairman returned thanks, saying he believed the unparalleled exhibition of Apples at Chiswick would prove of immense advantage to the country.—(*Gardeners' Magazine*.)

GRAPES AT GILMERTON, EAST LOTHIAN.

THERE is a crop of Muscat Grapes at Gilmerton, East Lothian, worthy of recording, not only on account of the high quality of the fruit, but also because of the weight of crop and the simple conditions under which they are produced. It may be premised that a span-roofed greenhouse divides a short range into three compartments; a vinery at one end being filled with black Grapes, the Muscat house of which I write at the other end, and the greenhouse is between the two. All the Muscats are heavily cropped and fine, but a double-rod *Bowood* at one end is decidedly the finest. The length of rod will be about 16 feet, and on each of these two rods an aggregate of 60 lbs. weight at least is borne. The finest bunches are at the bottom of the house, some of them 4 lb. clusters, full, symmetrical, and large berries. I counted forty-two bunches on these two rods, one having been cut before I saw them.

The following details I obtained from Mr. Brunton while he described the past doings of these Muscats, of which he is justly proud. Their age is twenty-four years, the crop they are bearing this year being nothing unusual. The Vines have never been syringed. They are up to the present day innocent of all knowledge of red spider, thrips, and mealy bug. No plants have been allowed inside the vinery doors. The ventilators are rarely closed, but a piece of hexagon netting is kept nailed across the highest apertures, which open at the top of the vineries to the

* The watch bears the following inscription:—"Presented to Mr. A. F. Barron by a few pomological friends as a souvenir of the Apple Congress, held at the Royal Horticultural Gardens, Chiswick, October, 1883."

north. Mr. Brunton prunes so as to always have plenty of young wood, three and four shoots coming away from one "spur," if we may so term the growths annually left. The border is watered three weeks before the Vines are started, and receives no more till the time to start the Vines arrives the following year. A dressing of manure 1 foot thick is placed over the border when it has been watered, and which is not removed for twelve months. On the outside border a thick dressing of manure is placed at the beginning of each winter. The border is filled with a thick network of roots close up to the surface. The borders themselves were made in a manner rather different from the usual mode. Drainage a foot in thickness was first placed, then the top of the drainage was "grouted" with hot lime and water, and on this the soil was placed. One important item in the management remains to be noted—Mr. Brunton does everything required to the Vines himself.—B.

GARDEN CHEMISTRY.

SOILS.

AFTER the elements of which plants are composed, in importance we must rank the media in which they grow—the soil where the roots extend, and the air from which the leaves extract the bulk of vegetable substances.

Soils vary very much in physical, but even more so in chemical properties. There is a great difference between a sharp sand and a putty-like clay, while peat differs from either. As no garden operation is of so much importance, and as nothing else so much determines the failure or success of our efforts as the choice of soils, it must be of great advantage to have an intimate knowledge of what constitutes the difference among them. On this foundation all gardening practice is built, and success would be surer, while failure would oftener be avoided, if young men were taught what to avoid and what to choose in the matter of soils among their first lessons. Instead of groping their way, after long years of perhaps bitter experience, to the light, or indeed never really reaching it at all, it would then guide their footsteps from the first. As many of the ideas about soils are erroneous no apology will be offered for going rather minutely into this phase of garden chemistry.

All soils, with the exception of peat, are chiefly composed of fragments of rocks, and if even the softest of these be viewed through a good double lens this fact will be apparent. Sand then seems composed of boulders, limestone, or chalk of shells, and even clay looks gritty. For practical purposes an intimate knowledge of geology is not necessary to a good useful knowledge of soils, although the more knowledge one has in that direction as in every other the better. The nature of any given sample is of more importance than the particular formation in which it was found. It is very interesting to know that in the coal measures the soil generally is very poor, and in the old red sandstone generally very fertile; but a sample of good soil from over the coal deposits is for all that to be preferred to a poor one, though decidedly derived from the old red sandstone. In Fife some of the hungriest gravels occur in the district where the old red sandstone crops out, although very good also occurs; and over the coal measures—at the very spot, too, where the carboniferous strata are covered only by mould—good land occurs. In the long fertile tract known as the Carse of Falkirk and Stirling occurs land second to none in Scotland, yet the coal is underneath.

To the farmer the chemical composition of soils is perhaps of paramount importance; to the gardener physical properties come first. For both a good loam is best. To the farmer chiefly because it will often stand the continual drain to which it is too often subjected; to the gardener because such not only suits a majority of garden plants, but because it holds manurial matter better than light sandy soil, and is more easily worked and drained, being also warmer than clay. These are also advantages to the farmer.

The most common ingredients in soils are stones and sand in gravelly or sandy soil; these mixed with clay in loamy soils, clay in clay soils; sand, stones, clay, and lime in calcareous soils, and peat in bog earth. In addition humus is more or less present in all soils.

Sand is derived from the disintegration of rocks. Take a piece of trap and expose it to the air in our latitude. What after a time happens? It begins to decay, and we are all familiar with "rotten rock." The rain moistens it, for, compact though it may seem, it is porous, and water penetrates its structure. The frosts of winter expand this. Now the expansion of water as it becomes ice is quite irresistible. In this respect water differs from everything else. Mineral matters go on contracting the colder they get, and expanding the hotter they become. Water as it gets hot also expands from about 40° Fahr. upwards, but also from that downwards. But for this fact our ponds would in winter become solid ice. In freezing six pints of water become about seven of ice; hence ice is lighter than water, and floats, forming a protection to aquatic plants and animals instead of proving their destruction. But this expansive power proves destructive to the rocks, hence they crumble and fall; but the effect is chemical as well as physical. Mere mechanical force

grinds. The expansion of frost is merely mechanical. Now a piece of trap may be said to be composed of felspar and hornblende, and pieces of trap, no matter how small, are just composed of these minerals; but when triturated by the weather chemical decomposition comes into play. Felspar is a polybasic silicate of alumina, potash, soda, and traces of other bases; when chemical decomposition ensues the mineral breaks up into aluminic silicate, or clay and potassic and sodic silicates, &c. The aluminic silicate (clay) which forms from decaying felspar is very fine and soft. Hornblende, the other mineral in whinstone, as it is called in Scotland, contains much less alumina, but more silica, and as much as 10 per cent. of lime, 15 of magnesia, and 10½ of iron oxide. Sometimes felspar predominates in trap, sometimes hornblende. When the former is most plentiful a heavy clay soil is often formed from it very rich in potash. When hornblende predominates in addition to the potash, lime is also set free, but lime is apt to disappear. The Carse of Gowrie clay is a good example of a clay rich in potash, as much as 2½ per cent. being present in some spots—altogether a unique amount.

Granite does not contain hornblende, but contains a large amount of silica with a varying amount of felspar and mica. The silica appears in the polished monuments, with which most of us are familiar, like glass, and is in the form of quartz. The grey, greenish, or reddish matter mixed with the quartz is felspar. Soils formed from granite are often by no means poor in potash, but always deficient in lime and other necessary mineral matters. For this reason phosphates applied to Turnips in the far north often yield results which astonish those who are unaware of the cause. But most granite soils are very poor sands. Heavy rains wash away the fine clay, and with it everything else, that forms from the felspar, and leave the poor sand formed from the quartz. This fine matter is transported in the mountain streams when in flood; is carried down the brooks and rivers, and finally settles as silt in lakes or perhaps far out at sea. The further it is carried the finer will the matter be. The heavy particles settle first and form gravel; further on lighter sands form, then loams, and finally clays. A good example may be seen of the latter at present in process of formation off Grangemouth. Here the mud which comes from trap and granite hills, from the Ochils and Grampians, settles in the quiet of the Firth of Forth, causing no end of trouble and dredging to the harbour authorities of the upper parts on the estuary, and forming a large addition to the Carse of Falkirk, which is dry when the tide ebbs, and is, indeed, much higher than the cultivated lands within the dykes.

Few soils are so simply formed as these. They are, for the most part, made of rocks which have originally come from the igneous rocks (as those of the class to which trap belongs are called), but which have been degraded and remade times without number by such means as we have indicated.

By the means we have named, sandstones and clay slate and shale rocks have been formed. Another class exists—limestones. These form vast beds, and even hills and cliffs. They are familiar to us as chalk, marl, limestone, marble.

Doubtless in the far back past carbonic dioxide was much more plentiful in the air than now. This when dissolved in water—and it always is present in rain—becomes an acid possessing solvent powers on many minerals. It specially attacks lime. Hence the lime liberated by decaying rocks speedily becomes soluble, and is borne in every stream as bicarbonate of lime (calcic bicarbonate). Aquatic animals, many of them extremely small, separate this from the water and form their shells out of it, shells being carbonate of lime. Dying, their shells have been by ocean currents borne to sea valleys, and in course of long ages their accumulation has resulted in the immense beds with which we are familiar. In the case of corals the growth has been almost tree-like. Marls are just limestones which have been formed in the quiet of recent (geologically) fresh-water lakes. At the bottom of peat beds layers of shell are often found, and an occasional canoe. These have been formed in lakes which vegetation has since filled up. In some such way were the beds of limestone which lie under coal beds formed.

Burnt in the open air, limestones crumble, because they are chemically decomposed. Limestone is a carbonate of lime. The burning drives off the carbonic dioxide. Heated to a high temperature in a closed vessel the stone fuses—melts. Just in this way has marble been formed. Eruptions of trap or lava have fused the limestone, practically in closed vessels, because deep under air-excluding superincumbent layers, and the result is limestone fused—marble.

In all parts of the United Kingdom, but more especially in Ireland, great tracks of peat soils are formed. Peat beds are the remains mostly of mosses and bog grasses. They only form where water cannot get away, and being covered with spongy mosses on the surface, which not only love water but possess the power of holding it, and which have few soil requirements beyond water, keep dying at the base continually and as continually extending at the points, till in process of time beds of solid peat are formed, as much sometimes as 40 feet thick.

What we shall call moor earth is a kind of peat formed over thin poor soils, and often hard rock. It somewhat resembles mould, from which it, however, essentially differs. In this the Ericaceæ thrive. Bog earth is peat in an advanced stage of decomposition, also good for such of the grosser-growing Ericaceæ.—SINGLE-HANDED.

(To be continued.)

THE ROSE ELECTION.

MR. HINTON'S two lists of Roses in the Journals of October 11th and 18th are very interesting, and I venture to make a few remarks upon them. First, as to the new Roses sent out since 1877, or rather including 1877. As only six Roses were to be named as A1, and a great number apparently received a few first-class votes, while three—A. K. Williams, Madame G. Luizet, and Duchess of Bedford—receive thirty, twenty-six, and twenty-one respectively, there would naturally be a great falling-off afterwards in first-class votes. With regard to A. K. Williams, which is the only one which obtains full marks, Mr. Hinton contrasts it with Marie Baumann. With me it is decidedly a better grower; but as I happened to be judging at Manchester, where it was, I think, first shown, and being asked, after having gone through with my co-judges the portion of the schedule assigned to us, to adjudge the new Roses, and to decide with them which was the best stand, and also which was the best new Rose exhibited, we were unanimous in thinking it one of the finest sent out for a long time, and when I reached home I ordered two plants of it with a few other new ones. Next year, if I remember right, at the National Rose Show it received the premier reward as the best Rose in the Show. This caused it to be very much propagated, and I cannot help thinking that over-propagation, using every bud and forcing in heat, caused many weakly plants to be sent out. With me the first plants make very good upright growth, and it has the merit of opening nearly every bud perfectly, and it also forces well, and is a free bloomer.

Madame Gabriel Luizet is also, no doubt, a great acquisition, and I am not surprised that Lady Mary Fitzwilliam, though only sent out in 1882, obtained three first-class votes out of the four recorded, as there was a beautiful stand of twelve exhibited this year at the National Rose Show at South Kensington, and good as the Tea Roses were there this year, I thought it was one of the best stands shown. I quite agree with Mr. Hinton, though I have not grown many of the new Roses myself, but from what I have seen of them not many of the ninety-six will long remain in the catalogues. With regard to the Garden Rose Election I am glad to see our old friend Gloire de Dijon at the top of the tree, but I still doubt its being a Tea Rose, though it is called one; at all events it differs in habit from any other. We must not be surprised that many of what Mr. Hinton would call exhibition varieties come to the front in the list of garden Roses, for after all what we want are those which are free bloomers with well-shaped flowers. I am rather surprised with twenty-five voters that only one received full honours, and that so many different ones were named that the number of votes recorded fall off so rapidly.

Jules Margottin and Général Jacqueminot, though both good garden Roses, are much higher in the list than I should have expected, and I am surprised to find Charles Lawson, which is only a summer bloomer, named as No. 24. "D., Deal," puts Blairii No. 2 amongst his six, which also rather surprises me, as, though I have a good plant of it in a good situation, it rarely gives me a bloom. Céline Forestier, too, with me is also a shy bloomer, though a beautiful yellow, especially on the later shoots. "D.'s" list contains many which I fear would be found in very few gardens now, and it is certainly rather difficult to define what a garden Rose means, as distinct from any other kind of Rose. My idea is, Grow those which are good in habit and constitution, are free in blooming, and that are not too tender in their petals. There are some which like M. Noman, M. Lacharme, and others, will never open in wet weather, the petals being too thin they stick together with the damp. Even La France, beautiful and fragrant and free-blooming as it is, has this fault.—C. P. P.

By an accident I find I have classed Mr. E. Claxton of The Rosery, Allerton, near Liverpool, as a nurseryman. Taking the members of the National Rose Society and led by its list, the "Rosery," misled me. I wish to make the explanation in your columns, as it may cause Mr. Claxton annoyance in exhibiting. I should deeply regret this.—JOSEPH HINTON.

FRUIT-FORCING.

VINES.—*Early Houses.*—Vines from which ripe Grapes are to be cut by the middle to the close of April should now be closed, but fire heat need not be applied until the middle of November, except to prevent the temperature falling below 50°. It is advisable to have

in readiness a quantity of well-worked fermenting materials for introduction into the house when forcing is commenced; two parts Oak or Beech leaves to one part of stable litter, thrown into a heap and turned over a few times, will produce a genial atmosphere very favourable to the Vines before and after they start into growth. Old Vines that have been forced for a number of years will break freely at a lower temperature than young ones or those not previously subjected to early forcing. Especially does this apply when the canes have made a vigorous growth and had only a short season of rest. After the house has been closed for a fortnight a temperature of 50° to 55° at night, and 60° to 65° by day, will be suitable, and yet not too high to begin with at this season. Keep all young rods suspended in a horizontal position over the fermenting material, and syringe the rods and damp the walls and paths two or three times a day, but avoid keeping the rods constantly dripping with moisture, as it is prolific in inducing the emission of aerial roots from the rods. Apply water to the inside border, if necessary, at a temperature of 90°. The outside border must be protected from heavy rains or snow by a good thickness of dry fern or litter, if not already done.

Early Vines in Pots.—Those that have been started about the middle of the month will now be swelling the buds, and should be given the treatment in respect of temperature, syringing, and watering as advised for the early-planted Vines as above given, with a slight increase in temperature on mild nights, and in the daytime ventilating from 65°, and as far as possible effecting a change of atmosphere at least once in the twenty-four hours, as however essential a moist atmosphere is to a good break, a genial sweet atmosphere must not be lost sight of, as a close, stagnant, vitiated one is positively injurious. Keep the heat at the roots steady at 70° to 75°.

Young Vines in Pots.—Fruiting canes intended for fruiting next season and not to be started before December or later should be pruned at once, cutting all laterals close in and reduce the canes in length to 6 or 8 feet according to their vigour and the plumpness of the eyes; dress all the cuts with styptic. Keep in a cool dry house, and do not allow the soil to become dust-dry. Young Vines in pots not strong enough for fruiting should be cut back to a single bud, dressed with styptic, and kept in a dry place, and cool but safe from frost, until the time for starting into growth arrives.

Late Grapes.—Lady Downe's well ripened is unquestionably the finest for keeping up to May; and although the Grapes will now be fit for use, the quality is considerably improved by allowing them to hang on the Vines until the new year. The temperature should be maintained at a mean of 50°, 60° being the maximum and 40° minimum, allowing a free circulation of air when external conditions are favourable. Although damp is the greatest evil to be contended against, the soil of the border must not be allowed to become very dry, and if watering be needed it should be given in the early part of a fine day. To keep down dust the borders should be covered with dry bracken. If outside borders are still exposed cover them with a good thickness of dry material, and place over this lights or shutters to throw off the rain or snow.

Houses of Ripe Muscats.—Careful attention will be necessary where ripe Muscats are hanging, removing all leaves as they become ripe, and examine them frequently for the removal of decayed berries. Anything likely to cause damp must be avoided, and if there have been plants in the house remove them at once. The temperature for the present should be kept steady at about 60°, as a cold stagnant atmosphere is fatal to the Grapes keeping; and though the thick-skinned Grapes are not injured by moderate moisture, these soon decay when there is any excess either at the roots or atmosphere after they become ripe. Black Hamburgs should have a temperature of about 50° with free ventilation whenever the weather is favourable.

Renovating the Borders of Late Houses.—Where it is intended to make any alteration of the inside borders, preparation should now be made of material, so that the operation can be speedily performed as soon as the Grapes have been removed from the Vines. Turfy loam, old mortar rubbish, charred refuse or charcoal, and crushed bone got into a shed and mixed, will greatly facilitate matters. These materials may be used in the proportion of six parts turf, one lime rubbish, and one-twentieth each of charcoal refuse and crushed bones. For drainage nothing surpasses clean broken bricks, and these should be 9 to 12 inches thick. Provision should be made for the free passage of water from the drainage by suitable drains; but it will probably be expedient, as it is when the subsoil is wet or otherwise unfavourable, to concrete the bottom so as to prevent the roots striking into the subsoil, which should of course be done before the drains are laid. Thirty inches is sufficient depth of border, and if the whole of the soil be removed a 6-foot width of new border is quite ample for the first season, as this secures the filling of the border with roots, which properly fed is better than allowing them to ramble over a large space with few roots, and the danger of getting the whole into a sour state before it is needed for the Vines.

Cucumbers.—Brisk fire heat henceforward will be at times necessary, the temperature ranging from 70° to 75° with fire heat, advancing 5° to 10° from sun, and 60° to 65° at night, with a steady bottom heat of 80°. Ventilation must be moderate and careful, and given not to lower but to prevent too sudden and high temperature, admitting a little before 80° is reached, increasing it with the rising temperature, and so as to avoid cold draughts, and reducing it in good time, as a chill is injurious. Water the plants thoroughly when they require it with tepid liquid manure. The atmospheric moisture must be ruled by the weather, avoiding the extreme of too dry or too moist an atmosphere; damping available surfaces morning and afternoon will in most instances be

sufficient, and when sharp firing has to be resorted to it will be required more frequently.

HARDY FRUIT GARDEN.

FRUIT TREE PLANTING.—The Stations.—The preparation of the stations was explained in our last calendar. Let nothing induce you to plant in poor or shallow soil without such preparation. Our advice is not lightly given, and we have had full experience of soils—good, bad, and indifferent. Gardens wherein deep stations cannot be made advantageously are indeed few and far between. They are, however, occasionally to be met with, as for example at Newlands near Faversham, where there is only 14 inches of soil upon chalk, and upon the same formation beds of gravel upon chalk, with a poor thin surfacing of soil. Dwarf bushes and pyramids come into bearing quickly in such shallow soil, and yield excellent fruit for a few years; but the existence of trees under such trying conditions is a brief one, and it is best to resort to heavy surface dressings after planting.

The Time for Planting.—Under favourable conditions of soil and weather fruit trees may be planted from the beginning of November till the end of February; but experience has shown repeatedly that early planting in November answers best. The soil has time to settle and consolidate about the roots before spring; the healing of root wounds also makes considerable progress during winter; rootlets an inch or two long are frequently made before Christmas, and are rapidly spreading in the soil in spring by the time the stored-up sap is exhausted by new growth, which then sustains no check, for its demands upon the roots for food are promptly met and thoroughly sustained.

The Trees.—Plant no sickly or weakly trees. Avoid cheap offers of fruit trees; all hardy fruits of the best sorts may be obtained at most reasonable rates from our leading nurserymen, by whom due care is devoted to the production of healthy vigorous trees, named correctly, lifted and packed in the best manner, and despatched with promptitude. Unpack the trees immediately after they are received from the nursery, and if they cannot be planted, then bed them carefully in trenches, covering every root with soil, and if the weather is frosty shake a little litter over the soil. See that this is well done. We have in the pressure of a busy planting season had trees left in such trenches several weeks, which when taken out for planting had many roots dry and shrivelled, simply because due care was not taken to pack fine soil well about them. The trees lived, but none of them grew freely till the second year; a season's growth was lost—no light matter in fruit culture.

The Planting.—Before planting cut off all damaged roots, spread out the remainder at full length, work the soil thoroughly in among them, cover the top roots to a depth of 6 inches—not more, very deep planting often proves fatal, especially to Cherries—tread the soil firmly over the roots. Shorten the branches or stem to the bud from which new growth is required next spring, fasten the tree securely to wall, fence, or stake; attach a label to it bearing the name and date of planting, and spread a mulching of litter upon the surface. All this must be done at the time of planting and not afterwards, for every detail is to be regarded as indispensable. Enter also the position of each tree upon a plan of the garden, with its name and date of planting, and thus be prepared for any subsequent loss of labels.

Form of the Trees.—For walls: Peaches, Nectarines, Apricots, Figs, and Morello Cherries, all fan-trained, 15 to 20 feet apart, according to height of wall; Pears, Plums, and Cherries, single cordons 18 inches apart, or palmette verriers 15 to 20 feet apart. In all small gardens preference should be given to cordons for earliness and certainty of fruiting and variety of fruit. All large gardens should also have a considerable proportion of cordons. Espaliers: cordons or palmette verriers. Pyramids, 10 feet apart, are suitable either for garden or orchard. Bushes answer well when pruning is not understood; the only care required is to keep the centres open and the branches thinned—distance apart 20 feet. Standards should be 30 feet apart.

FRUIT LISTS FOR MARKET.—These lists contain all the most popular sorts of the Kentish fruit plantations, and the greater part of them are mentioned in Mr. Whitehead's "Hints on Vegetable and Fruit Farming," published last year under the auspices of the Royal Agricultural Society.

Dessert Apples.—Mr. Gladstone, Red Joanncting, Early Strawberry, Kerry Pippin, Worcester Pearmain, Red Astrachan, Devonshire Quarrenden, Ribston Pippin, Cox's Orange Pippin, Court of Wick, King of the Pippins, Claygate Pearmain, Adam's Pearmain, and Sturmer Pippin.

Kitchen Apples.—Early Julien, Duchess of Oldenburg, Keswick Codlin, Mank's Codlin, Lord Suffield, Stirling Castle, Cellini, Wormsley Pippin, Ecklinville Seedling, New Hawthornden, Loddington, Warner's King, Blenheim Pippin, Golden Noble, Lord Derby, Winter Queening, Grenadier, Dumelow's Seedling, Norfolk Beefing, Gooseberry.

Pears.—Summer Doyenné, Lammas, Windsor, Caillot Rosat, Bellissime d'Automne, Williams' Bon Chretien, Yat, Autumn Bergamot, Hesse, Marie Louise, Beurré Clairgeau, Eyewood, Louise Bonne of Jersey, Comte de Flandre, Beurré Bosc, Beurré de Capiaumont, Rondelet, Catillac, Bishop's Thumb, Broompark, Winter Nelis.

Plums.—Early Rivers, Diamond, Blue Prolific, Perdrigon Violet Hâtif, Early Orleans, Corse's Nota Bcne, Dauphine, Belgian Purple, Washington, Prince of Wales, Victoria, Prince Englebert, Pond's Seedling, Coe's Golden Drop, and Belle de Septembre.

Damsons.—Cluster and Prune.

Cherries.—Early Purple Gean, Early Rivers, Adam's Crown Heart, Elton, White Heart, Waterloo, Black Heart, May Duke, Black Eagle, Flemish, Kentish, and Bigarreau.

Nuts.—Pearson's Prolific, Kentish Cob.

Gooseberries.—Whitesmith, Early Sulphur, Crown Bob, Warrington, Lancashire Lad, Red Rifleman, Golden Drop, and Monarch. Preference is usually given to the first four for planting by the acre.

Currants.—Red Scotch, Red Dutch, Raby Castle, Black Naples, Baldwin's Black, and Lee's Prolific Black. In deep, cool, rich soil Black Currants are the most profitable of all market fruits.

Raspberries.—Prince of Wales, Fastolf, Red Antwerp, and Carter's Prolific.

Strawberries.—Keen's Scedling, Princess Alice Maud, Refresher, Dr. Hogg, La Grosse Suerée, Elton Pine, Eleanor, Comte de Paris, and Sir Joseph Paxton.

PLANT HOUSES.

Begonia semperflorens grandiflora.—Plants that are root-bound and have been flowering for some time should have a little artificial manure applied to the surface, which will assist them to make growth and continue flowering. Damp is the greatest enemy of these plants, and the flowers and foliage soon suffer if kept in a close moist atmosphere. A temperature of 60° at night will suit them, with an atmosphere as dry as it is possible. The last batch of plants raised from seed will now be well established in 3-inch pots, and should be dwarf and stiff if they have been kept near to the glass on a shelf, with ventilation when the weather is favourable. A portion may be at once transferred into 5-inch pots, and the others will be most useful for furnishing purposes in the size pots they now occupy. It is surprising what beautiful little plants can be grown in this size, and produce a large quantity of bloom if properly looked after and supplied with an artificial manure occasionally. This is one of the best Begonias that can be grown for winter.

Tydas and Gesneras.—If properly attended to these should be strong and giving every promise of a fine display of flowers shortly, especially the earlier-flowering varieties. The latter are attractive plants for table decoration; their beautiful foliage is very striking and effective, independent of their large spikes of flowers. Keep the plants as near to the glass as possible or they will become drawn, and then much of their beauty is lost. They delight at this season of the year in a rather warm dry atmosphere. Where much moisture is used when mixed with other plants they are liable to damp, or if the syringe is used near them their foliage becomes spotted and injured. Have these plants as much as possible by themselves, where water can be kept from their foliage. Their pots will be well filled with roots by this time, and weak stimulants should be given when they require water; that made from cow manure or clear soot water will be found very good, especially the latter.

Mignonette.—A few standards trained upon trellises may now be allowed to come into bloom, and another batch may be pinched over and tied down for the purpose of forming a succession. Later plants must have all flowers removed as soon as they can be seen, and encouraged in every way until the trellises are well filled with young growing shoots. These plants will now be growing rapidly, and must have the lightest position that can be accorded them. Our latest batches, all in 6-inch pots, are still in frames and as close to the glass as we can arrange them. They will remain in these positions until we are compelled to remove them to be safe from frost. Mignonette should never in any stage of growth suffer by the want of water; if allowed through carelessness to become dry once or twice the whole work of a season is thrown away, for when once the wood becomes hard and the foliage brown from this cause no after treatment can restore them.

Lily of the Valley.—These flowers are always appreciated, and where plants were assisted early to make their growth indoors under the influence of warmth, light, and air, they will now be thoroughly ripened and ready for starting. Plants prepared for early flowering soon produce their flower spikes if plunged into brisk bottom heat and the crowns shaded from light. To succeed home-grown plants single crowns are the best, and these for early flowering should be laid in pans or boxes amongst leaf soil or coeoa-nut fibre: for later flowering they can be placed thickly together in 5 and 6-inch pots. Early in the season they throw up their spikes rather irregularly; but when started in boxes and pans they can be drawn out as they come into flower, and vases filled or pots made up with them. The crowns of these should also be covered and plunged if possible in the propagating or any other close frame. Later in the season this close confinement is not necessary.

THE BEE-KEEPER.

HIVE-CONSTRUCTION, HONEY-PRODUCING, AND PRACTICAL MANAGEMENT OF BEES.—No. 6.

(Continued from page 345.)

Floorboard, &c.—This is 30 inches long and 19 wide, and is made of inch pine, with end pieces 2 inches wide running across the grain, tongued and grooved, and further secured by five 3½-inch nails at each end. Unless the wood is of good quality and well seasoned it has a tendency to sag a little in the centre owing to the length of the floorboard, so we set a loose leg resting on a brick on the ground under each, and this keeps all close up. It works on inclined runners,

and is wedged up in front only. The edge of the floorboard is rounded off flush with the front of the wedge when pushed home. This latter is made of two pieces of inch stuff with stay pieces at each end to give stability to the whole. It is difficult for one not conversant with the technical terms employed by joiners to make these details quite clear, but the accompanying diagram (fig. 68), which represents one end of the wedge and floorboard, will show how the parts are put together, and give an idea of the whole when complete. The rings at the side are to give a purchase just at the right place for withdrawing the wedge easily. No paint must be used where it will give trouble in parts which should work freely and easily, such as about the figure 2 in diagram. The front of the wedge, No. 3, has two pieces of wire bent in Vandyke shape along its whole length; these are useful as a foothold for the bees in windy weather. For about eight months of the year, say from March to October, a very large alighting board 26 inches long by 14 wide is used. It is made of light wood, and has a hinged leg to keep its outer edge about 5 or 6 inches from the ground. It is hooked on by a couple of eyes screwed into the front of the rounded part of the floorboard.

We do not find this alighting board any too large, and its uses are many and obvious—for hiving swarms, preventing crowds of returning bees from being dashed to the ground in windy weather, &c., while no toads or other vermin can creep up it, as they frequently do when the lower edge of the alighting board rests on the ground.

The porch extends along the whole front of the hive. It is

Fig. 68.

The dotted lines (A) indicate the leg of hive against which the stay piece rests. B, The hive front. 1, Floorboard; 2, Wedge; 3, Wedge front; 4, Stay piece; 5, Ring for withdrawing wedge.

4 inches wide, and is fixed close up under the plinth of the roof when the latter is closed. The level part of the floorboard is always dry in wet weather, as no drip can reach it. The roof is 8 inches high in the clear, rising to 10 inches at its highest point. It is made of light stuff, half inch for the sides and sloping portions of the top, and three-quarters of an inch for the ends and ridge piece, which latter is 6 inches wide, and has a groove along the under edges to carry off the rain. Three good-sized holes are cut in each end with a centre-bit, and covered with perforated zinc. The back plinth of the roof is made of stronger stuff than the others to give support for three hinges. A small chain at each end keeps the roof from opening too far back, and a hook and catch to secure it when closed complete the whole.

The hive stands on four stout legs, which are splayed outwards and raise it 14 inches above the ground.—W. B. C., *Higher Bebington, Cheshire.*

CURE FOR STINGS OF WASPS AND BEES— DESTROYING NESTS.

HAVING read the statement about the cure of wasp stings at page 283 of the Journal, I have tried the hollow tube of the key first, and then rubbed the place with a piece of Garlic, which seems to act like magic in removing the pain, and prevents any swelling, but, like all other remedies, it should be done as soon as possible after being stung. I have tried it with the stings from bees as well as wasps. I have also tried liquid ammonia and soda mixed, but not always with the same certainty as the Garlic. I first saw Onions recommended, but thinking Garlic would do better I have only tried Garlic, but I daresay Onions, Chinese Leeks, and Shallots would answer as well, whichever is the most convenient. I have taken over seventy wasps' nests this year, all within a circle of about a mile, so I have prevented them doing me much harm or damaging the fruit. I have taken some very large ones, some nests have been over 12 inches across. I found several in August with lots of young queens in quite as forward as in September other years. I have destroyed hundreds of young queens in the nests before they have had time to hatch out of the comb.

I take them by daylight, with a pair of the American bellows—the same as used for bees—and strong tobacco paper, and then dig the crown of the nest off and kill them with a rammer. I have sometimes

found the few left outside will begin to form another nest, but I have never seen any eggs or grubs in them, so I do not think they do much harm after. I have also found the nests not more than a yard apart, and one place I found three within 2 yards. Last year the wasps did a great deal of damage to the Peaches and Nectarines on the wall. I have gathered over a hundred at a time more or less damaged by them. This year the bees seem to have taken their place, but I find they only attack the damaged ones.

The wasps have been very busy on the Beech, Oak, and large Fir trees on account of the insects on them, and I have known the wasps to clear the Goosberry trees from caterpillars. I have often seen them fly away with the insects. So they do us a good turn sometimes as well as a bad one.—GEO. CLEMENTS.

BEE-FARMING.

I AM anxious to gain some information on the subject of keeping bees, as I have a very serious thought of establishing a bee farm in this neighbourhood, where I am surrounded with some 8000 acres of Heath. I wish to thoroughly acquaint myself with the following requisitions:—1, Is bee-keeping profitable? or is one liable to heavy losses in a bad season? 2, Is it such a thing as a person might take up with a fair chance of deriving a material income therefrom? 3, What would be the number of hives necessary to insure an income of say £400 per annum after all expenses are paid? 4, Is Heath alone without other feeding ground within a mile sufficient, in the event of a wet season during the flowering time, to insure a good crop? 5, What are the best hives to use and what are the best strains of bees to introduce? 6, What is the name of the best author on practical bee-keeping? 7, Does it require a very intimate knowledge of bees, their habits, and management to succeed? 8, Are there any bee farms in the neighbourhood of Surrey, and if so where? Having been a subscriber to your very interesting Journal for upwards of twenty years, I shall be glad for any assistance that can be rendered in this matter.—F. H. P.

[What do experienced apiarists say?]

SWARMS OF BEES IN SEPTEMBER.

THE reply given by "P. H. P." on page 325, in answer to my note on the above subject is not what I anticipated, being always under the impression that if the position which the bees occupy was favourable they would stop there and perish, as I have seen many do. Those it had been supposed were strong enough to stand through the winter, and being in straw skeps no attempt was made at feeding them, the bees probably knowing that by going further they might fare worse. I can understand bees turning out of their homes when altered circumstances compel them to do so, such as trees blowing down in which they are located, and an excess of rain finding its way into their abode, compelling them to seek fresh quarters. When discussing the matter with one who has watched and studied bees for many years, though not aiding his observations much by those of others, he was of opinion that in favourable autumns the bees would swarm as late as September, not from poverty but overcrowding. If this be true it would be supporting my fears—viz., that I had overcrowded my hives and fed them into the delusion that summer had come again. I must here state that the fears were only imaginary, as I had no reason to suppose that the bees were from our hives at all, but, knowing that I had made ours extra full and heavy, I was anxious to know if they were likely to thin themselves so late in the season.—C. WARDEN.

TRADE CATALOGUES RECEIVED.

- Bruant, Poitiers, France.—*Catalogue of Fruit Trees, Shrubs, &c.*
- F. W. & H. Stansfield, Sale, Manchester.—*Catalogues of Hardy Perennial and Alpine Plants, and British Hardy and Exotic Ferns.*
- Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Roses.*
- James Cocker & Sons, Aberdeen.—*Catalogue of Roses.*
- Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*
- Charles Turner, Slough.—*Catalogues of Roses, Fruit Trees, and Florists' Flowers.*
- André Leroy [successeurs], Angers.—*Catalogue of Fruit Trees, Roses, &c.*
- George Cooling & Son, Bath.—*Catalogue of Roses and Fruit Trees (Illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vine Roots.—We have received a package containing Vine roots and foliage, but no letter relative to them. Perhaps the sender will communicate with us if he desires any information on the subject of his specimens.

Pampas Grass (*Denne*).—We cut some spikes last year at this time and placed them in vases in a room, and they are as "feathery" and about as fresh as ever. They should be cut when quite dry, before they assume a brown hue, and they will keep well in any dry room.

Chrysanthemum segetum (*W. Rayner*).—This is the name of the plant you have sent, and is popularly known as the Corn Marigold. The flowers have been fashionable of late, and extensively grown in gardens. In all probability if some of the sturdy plants that are showing flower buds so freely were taken up carefully and potted they would expand their blooms freely in a greenhouse during the winter, and be very bright and acceptable.

Grenadier and Bramley's Seedling Apples (*W. B. Goslin*).—These come under the denomination of large Apples. The measurement and weight of one of the best fruits in each dish exhibited at Chiswick are as follows:—Grenadier, 3 inches high, 12 inches in circumference, 10 ozs. in weight; Bramley's Seedling, 3 inches high, 11 inches in circumference, and 12 ozs. in weight. Both are undoubtedly good varieties. Bramley's Seedling we have grown, and know it to be a good grower and bearer of fine fruit.

Crimson Clove Carnations (*J. S. F.*).—Our correspondent, Mr. Muir, raises his own plants from layers, but not for sale; besides, he resides some 300 or 400 miles from you, and you can get half a dozen plants much nearer than that. There is scarcely a nurseryman or florist of standing who cannot supply plants of this fine old border flower. Try some local dealer, and he will no doubt be able to send you what you want; if not, they can be had from York.

Seedling Apple (*S. L. S.*).—We consider your Apple a promising variety, and advise you to send fruits when in the best condition to the Fruit Committee of the Royal Horticultural Society; in the meantime we will keep those you have sent until they are quite ripe for examination and description, and shall be glad if you will favour us with your name and address in case we may require to write you for any further information. The habit of growth of the tree though not common is not altogether singular.

Plunging Bulbs (*J. J.*).—The pots may be placed anywhere in the open air on a layer of ashes or other base impervious to worms, and covered 5 or 6 inches deep with cocoa-nut fibre refuse. This is the best material, and is used by the most successful cultivators of Hyacinths for exhibition; but ashes, leaf soil, or old damp sawdust will answer the purpose very well. The pots should remain buried until they are filled with roots and the crowns have pushed to the length of from half to three-quarters of an inch. In withdrawing them they should not be at once exposed to the full light, but covered with moss or paper funnels for a time till the growths gradually assume a green hue; after this they cannot have too much light.

Heating Greenhouse (*Idem*).—The boiler you name will answer very well, and you can have pipes attached to it of any length desired. They ought at least to go the whole length of a lean-to house, and if across the ends all the better, while for heating a span-roof they should go all round the structure. The quantity of piping to use depends wholly on the temperature that is desired to maintain. Your former letter, to which you refer, has not reached us.

Gardeners' Benefit Society (*T. W. T.*).—You will perceive that the subject of your letter has been anticipated in the first article of our present issue. We are quite aware that a great number of persons obtain situations as gardeners that are no credit to the craft; but the fact remains that employers have the right of engaging them if they choose to do so, and no amount of writing would prevent them. Whether such persons as you allude to are eligible to join the Gardeners' Royal Benevolent Society we are unable to say; perhaps the Secretary might inform you if you were to write to him, but we doubt if they would find it easy to get a well-known nurseryman or gardener to recommend them to the United Horticultural Benefit and Provident Society previously referred to.

American Walnut (*A. M.*).—The name of the tree to which you refer is *Juglans nigra*, the Black Walnut or Black Hickory Nut. In Loudon's "Encyclopædia of Trees and Shrubs," it is stated that the growth of the tree is remarkably quick, more so than that of the European Walnut. At eight or ten years of age it begins to bear, and age increases its fertility. No tree will grow under its shade, and even grass is injured by it. In forty years, in good soil, it will attain the height of from 50 to 60 feet. The heartwood, which is black, remains sound for a long period, when exposed to heat and moisture; but the sap wood speedily decays. When properly seasoned the wood is strong, tough, and not liable to warp or split. It is never attacked by worms, and has a grain sufficiently fine and compact to admit of a beautiful polish. The tree is universally raised from the nut, which after being imported, ought to be sown immediately, as it seldom retains its vital power more than six months after it has ripened.

Insects on Melons (*H. Woolton*).—Your plants are attacked by an aphid similar to that which infests the Hop and other plants. If Melons are grown in a house and trained to a trellis overhead the insects may be prevented by frequent syringings and the occasional application of an insecticide such as quassia water, nicotine soap, or Gishurst compound; but they should never be allowed to increase to such an extent as is shown by the leaf you have sent to us, as then they can scarcely be destroyed without destroying plants that are half-killed already. If the plants are grown in frames and cannot be syringed on the under sides of the leaves the case is more difficult. In this event the leaves should be carefully sponged once a week with any of the above preparations; but the remedy must always be applied on the

appearance of the first insect. If this is done, and a moist genial atmosphere maintained, the plants may be kept clean. We have had experience with the same insect, but have grown healthy plants and good crops of Melons nevertheless. When we failed it was because we did not apply the remedy soon enough, and permitted the insects to cover the leaves thickly: they then, and only then, proved the victors.

Roses for Autumn (*Somerset*).—To your Hybrid Perpetuals you may add the following:—Bessie Johnson, La France, Jules Margottin, Mrs. Baker, Ferdinand de Lesseps, and Duke of Edinburgh. To the list of Teas add Catherine Mermet, Marie Van Houtte, Souvenir d'Elise, Perle des Jardins, Madame Bravy, Madame Lambard, Niphotos, and Anna Ollivier. The crimson Perpetual is a variety of the Damask Rose. The blush China is the Monthly Rose, and one of the latest of the free bloomers. If you need abundance of flowers for cutting at this season you should grow a number of plants of it, and an equal number of Souvenir de la Malmaison. The old Cabbage Rose is not an autumn bloomer, nor do the Hybrid Perpetuals flower with equal freedom every autumn. Much depends on the season; but usually with the aid of liquid manure and intelligent summer pruning most of them will flower freely in the autumn. The position is suitable for Tea Roses.

Insects in Mushroom Bed (*J. W., Leeds*).—The specimens simply enclosed in an envelope arrived in a crushed, dried, and shapeless mass, so that it is quite impossible to identify them. If no Mushrooms have yet appeared you may sprinkle the surface of the bed with ammoniacal liquor, which you can readily obtain from gasworks in your town, diluted with six times its volume of water. If Mushrooms have appeared, we think if you dissolve 2 ozs. of salt in a gallon of water and apply it at a temperature of 120° to 130° it will destroy the insects and not injure the bed. You do not say, however, that the insects have done any harm to the crop.

Galls on Pear Leaf (*Inquirer*).—These woolly excrescences appear to be the work of a species of Phytoptus, or gall mite, belonging to a family the transformations of which are imperfectly understood. It is considered that they are six-legged while young, eight-legged in their mature condition. A number of them of different ages may be observed living in the same gall upon the "happy family" principle. It has been noticed that they will infest one tree year after year, while others of the same kind standing close remain untouched. Their journeys, whenever they occur, are at night, it is believed. No one has suggested any method of checking their propagation, except the removal and destruction of infected leaves.

Commercial Gardening (*Yggdrasil*).—Your plan is not practicable. You cannot learn the business of florist and seedsman combined with market gardening, and gain experience in vineries in any "first-rate nursery," whatever premium you may be willing to pay. Your object, we perceive, is to make yourself competent to manage a small market garden and florist's business combined, and we know of no way in which you could gain the requisite information so quickly as in a well-conducted nobleman's or gentleman's garden. In such a garden vegetable culture and forcing, fruit culture and forcing, the propagation of all kinds of popular flowers for in and outdoor decoration, and the making of bouquets for various purposes are practised. By working two years in a garden where such work is well done (and such gardens are plentiful in every county) and observing closely the system of cropping and methods of procedure, entering in a book everything that is done, also the results whether favourable or otherwise of each operation, an earnest and intelligent man of business aptitude might in two years gain knowledge that might be turned to good account in a commercial undertaking in a favourable locality. By stating your requirements and objects to a good gardener he would no doubt, in consideration of a premium, undertake to afford you all the facilities in his power, and in the meantime allow you the usual weekly wages that are paid to assistants. This is the best advice we can give you, and you would not have had a less useful reply if you had sent us your proper name and address; and we may observe that your letter would not have been answered so fully if we had not known that our remarks are calculated to be useful to others who are desirous of obtaining information on this subject.

Primulas Dying (*J. A.*).—We have received the Primula, which is in a very unhealthy state, in fact irrecoverable, and you ask us to state "whether the plant or yourself are in fault." While recognising the fact that old plants of Primulas are very prone to decay, we are not able to commend your method of culture. The plant has not only been much overpotted, but the soil last used is too light, soft, and rich. Not a root has penetrated it, and, worse than this, those that came in contact with it have died. The plant would certainly have been better if it had been allowed to remain in the 5-inch pot. When once a Primula becomes decidedly root-bound shifting in nine cases out of ten is a mistake, and it is much better to let the plant remain in the small pot, supporting with weak stimulants. Repotting should always be done before the roots coil firmly round the sides of the pot, and the soil for the last shift especially should be of a more turfy character than that you have employed. At least half of it should be turfy loam, while yours appears quite destitute of that material, and resembles sifted leaves and decayed manure such as would be suitable for sowing seed in. Very fine healthy plants can be grown in 5-inch pots. You must not, however, expect old plants to thrive year after year, but raise young ones annually from healthy offsets or cuttings, and by exercising care in the selection of soil, also in potting and watering, you ought not to have any difficulty in growing the plants satisfactorily. You will find an article on double Primulas on page 326, vol. vi., our issue of April 19th of the present year. If you do not possess the number and require it, it can be had from the publisher in return for 3½d. in stamps, and quoting the date we have given.

Apple Trees not Bearing (*Lundy's Lane*).—Although you have given an excellent description of your Canadian orchard, you have omitted two items of information that have an important bearing on the case. Many Apple trees blossom freely yet bear no fruit, while others grow so luxuriantly that they produce no blossom. In the absence of information on these points we must found our reply on the circumstance you narrate of one tree bearing freely that had been split by ice. This indicates that the trees have grown robustly, and that a check is essential for the

production of blossom. Pruning such trees and leaving the roots untouched would make matters worse, as still stronger and more fruitless growths would follow. It is only when trees of this nature are much crowded that pruning is beneficial, and then it must be limited to removing some of the branches entirely, not shortening the whole of them, so that sun and air can have access to the foliage of the trees. But the chief remedy for rendering luxuriant trees fruitful is root-pruning. As soon as possible take out a trench half round the older and stronger growers at a distance of about 4 feet from the stem, and cut off every root, also all those penetrating downwards, undermining for that purpose 2 feet below the surface, quite to the centre, or immediately under the stem of the tree. In severing the roots do not leave any bruised or jagged ends, but cut each smoothly with a sharp knife. A tree thus operated on will then be exactly half dug up. Fill in the soil again, and if calcareous matter could be added so much the better, making it quite firm. This will check the growth of the tree materially and promote the formation of fruit spurs; yet if the growth next year is still too strong, shorten the roots on the other side of the tree similarly, and shorter, firmer, and more fruitful growths will follow. If they do not you may conclude the root-pruning has not been severe enough, and that possibly some strong roots striking straight down into the subsoil have been left uncut. There is no work on the Apple such as you appear to require, and information to meet each case can only be had through the press that is devoted to such matters. Our "Fruit Gardening for the Many" (4½d. post free) contains concise and sound information on the culture of hardy fruits, and may afford hints that may be of service to you. It must be remembered, however, that varieties recommended for this country are not necessarily the best for Canada. We do not know of a better work on Vines in the open air than De Breuil's "Vineyard Culture," as improved by John A. Warder, and published by Clarke & Co., Cincinnati. There is no work on the subject published in this country.

Arrangement of Pipes and Valves (T. A. O. F.).—You must have valves at the points marked F and G in the plan you have sent, then to all your other questions our answer is in the affirmative. You cannot, however, confine the heat to any one of the three houses at pleasure, for as you are, no doubt, quite aware, you cannot have heat in B without having it in A also, nor in C without having it in both A and B. The proposed arrangement with valves on the return as well as on the flow pipes will answer well, provided you do not want to force the Vines for very early Grapes. Your main point of perplexity is the valves at F and G. Suppose, for instance, the valve at D is closed and you have no valves on the return pipes, the cold water from the houses B and C would then by its greater density flow into A, the very thing that it is desirable to avoid. You must not only have a boiler guaranteed to heat the requisite length of piping, but to heat the water easily, and you will act wisely by not having the connecting pipes between the boiler and range of houses too small. We should prefer them as large again as shown in the plan, and the flow pipe should enter the boiler as near the top as possible. The cistern should be level with the highest point of the pipes in the vinery, where also an air pipe should be provided.

Selection of Fruit Trees (W. K., Langport).—Each of your walls, 50 yards long, will require ten trees 15 feet apart. For the south wall five Peaches—Early Beatrice, Dr. Hogg, Grosse Mignonne, Belle Bauce, and Walhurton Admirable; five Nectarines—Advance, Lord Napier, Stanwick Elruge, Balgowan, and Pine Apple. For the west wall two Apricots—Kaisha and Peach; four Plums—Green Gage, MacLaughlin's Gage, Reine Claude de Bavay; and for late fruit either Coe's Golden Drop or Blue Imperatrice: four Cherries—Early Purple Gean, Empress Eugénie, Black Tartarian, and Governor Wood. Other trees—Figs: Brown Turkey, and Brunswick; Medlars—Dutch for size, Nottingham for flavour, Damson-Cluster, and Prune; Raspberries—Prince of Wales, Yellow Antwerp, Carters' Prolific; Strawberries—Vicomtesse de Thury, Sir Joseph Paxton, Marguerite, Lucas, James Veitch, Dr. Hogg, Frogmore Late Pine, and Helena Glöede. Fifty Apples—Dessert: Red Joanetting, Mr. Gladstone, Kerry Pippin, Worcester Pearmain, Yellow Ingestrie, King of the Pippins, Margil, Pine Golden Pippin, Cox's Orange Pippin, Pine Apple Russet, Mannington's Pearmain, Cornish Gilliflower, Melon Apple, Lodgemore Nonpareil, Bess Pool, Lord Burghley, Summer Pippin, and Court Pendu Plat. Kitchen Apples: two each of Duchess of Oldenburgh, Keswick Codlin, Ecklinville Seedling, Warner's King, Stirling Castle, Loddington, Tower of Glamis, Golden Nohle, Northern Greening, and Gooseberry; one each of Lord Suffield, Small's Admirable, Cellini, New Hawthornden, Blenheim Pippin, Winter Queening, Alfriston, Striped Beefing, Hanwell Souring, and Dumelow's Seedling. Fifty Pears—two each of Williams' Bon Chrétien, Louise Bonne of Jersey, Comte de Flandre, Seckle, Doyenné du Comice, Fondante de Charneu, Comte de Lamy, Marie Louise, Marie Louise d'Uccle, Knight's Monarch, Fondante d'Automne, Dana's Hovey, Winter Nelis, Jewess, Huyshe's Victoria, and Easter Beurré; one each of Doyenné d'Été, Citron des Carmes, Jargonelle, Beurré Giffard, Summer Beurré d'Arenberg, Beurré d'Amanlis, Madame Treyve, Colmar d'Été, Souvenir du Congrès, Thompson's, Urhaniste, Durondeau, Beurré Clairgeau, Beurré d'Arenberg, Forelle, Zéphirin Grégoire, Beurré Bachelier, and Emile d'Heyst.

Names of Fruit (T. W. Sanders).—5, Lewis' Incomparable; 6, Beauty of Kent. The Pears are probably French or Belgian varieties not adapted to this climate; not one of them is worth growing, and we do not know their names. (W. A. M.).—1, Bedfordshire Foundling; 2, Striped Beefing; 3, Golden Winter Pearmain; 4, Braddick's Nonpareil; 5, Cox's Orange Pippin; 6, Hollandbury. Nelson's Glory is Warner's King, the other is Emperor Alexander. (J. F. W., Deal).—The Peach is no doubt the Salwey, but your situation evidently does not suit it. It requires to be grown in a warm sheltered spot. (J. L.).—1, Chaumontel; 2, Marie Louise; 3, Golden Noble; 4, Striped Beaufin; 5, Scarlet Pearmain; 6, Franklin's Golden Pippin. (Longcroft).—15, Goff; 17, Quince. Sorry we cannot recognise any of the others. It is a pity you had not taken the opportunity of the Apple Congress to have taken them to Chiswick and compared them. (Colville Browne).—1, Beurré Rance; 2, name not known; 6, Comte de Lamy. We do not recognise any of the others, and they are all inferior. See our reply to "Longcroft." (W. Thornton).—2, Braddick's Nonpareil; 3, Coe's Golden Drop; 4, Ten Shillings; 2, Pear Napoléon; 3, Nutmeg. (W. Graves).—The Apple is not known; it is probably a local variety.

Names of Plants (J. H.).—1, A dark-coloured variety of Dahlia glabrata; 2, Helianthus decapetalus. (J. W.).—Francoa appendiculata. (W. C. Preston).—Oncidium micropogon. (W. M.).—1, Vanda tricolor; 2 and 3, varieties of Odontoglossum Alexandrae.

COVENT GARDEN MARKET.—OCTOBER 24TH.

Good samples of Apples have well maintained the rise of last week, but common goods are heavy. Hothouse fruits in good supply with no alteration. A few St. Michael Pines to hand affecting home fruit.

IMPROVED DAIRY CATTLE.

ANY improvement which can be obtained in our breeds and the selection of dairy cattle still ranks high in the estimation of dairy farmers, for there never has been a period within the past fifty years when dairy farming was so profitable as at present. It is therefore extremely important to consider what can be done to improve those breeds which hitherto have been used for the production of milk and butter only. This has been the case especially for the past fifty years with the Channel Island cattle, whether Guernseys, Jerseys, or Alderneys. Previous to 1830, however, we had a breed of cattle commonly called Normans, in all probability deriving their name and nativity from Normandy, and it is said even at present many animals from Normandy are imported to this country and sold as Channel Island stock. These Normans were valuable as dairy stock, and in some respects were preferable to the ordinary Channel Island cattle of the present day. We found them in our own dairy and in numerous dairies in the southern counties. They were large roomy animals, capable of making heavy weights when fed for the butcher. They were not only large in outline, but were also very wide on the back and deep in the carcass, with short legs and strong bones, but remarkably kind and neat in the head and horn, with capacious udders and large teats. They were capital milkers as to quantity and the quality good, although the cream yielded was not so rich as our present Guernsey stock, but quite equal to the general run of Jerseys of the present day. With the Norman cows it was a general custom when they went dry or barren to feed them for beef, for which purpose they paid well, and they were particularly adapted for use as a suckling dairy, for we have obtained from them very heavy calves and of beautiful quality of veal, equal at weight for age to any calves produced by the Devons or Herefords of the present day. We have referred to this old breed because they were in some respects an illustration of improvements required at the present time, for it is well known that in the majority of cases where attempts have been made to feed for beef barren animals from a Channel Island dairy stock, that it has never been as a rule a profitable transaction even when they have been made fat enough for the shambles. They are, however, when out of profit for the dairy usually sold as useless for fattening at the present day.

The points we wish to prevail in the improved animal for dairy purposes next demand consideration. The points or requisites we

desire combined in one animal are milk, butter, and beef in the most abundant and profitable forms and conditions in which it is possible to obtain them. We have no race or breed of cattle which will furnish these three requirements at present in the greatest quantity, quality, and condition from one and the same stock. Shorthorns will yield us milk and beef in abundance under good and proper feeding, but the butter is absent more or less both as to quantity and quality feed as we will. The same remarks will apply in degree to nearly all our celebrated beef-producing stock, whether they are called Devons, Herefords, Sussex, or Longhorns, &c. Then we have the milking and butter-yielding stock, such as the Channel Island stock, including the Guernsey, Jersey, and Alderney cows, also the Ayrshire and the Dutch imported stock. All of these are good milkers, but varying in degree as butter-makers, yet they are one and all not calculated for feeding as beef-producing animals. The Guernsey stock is the best of those named, not only in quantity and quality of milk and butter, but also in their produce of beef of good quality, especially in those choice strains where the breeders have carefully looked to the production of animals of good outline and capacity for carrying flesh of good quality under judicious management and feeding.

The polled cattle or the Welsh breeds have in some instances a claim on our attention for both milk and beef-making, but they are unsuitable for the purpose of crossing when we are seeking to produce a race of cattle perfect in all the requirements we have named. Still a few observations upon the character and qualities of the Suffolk polled stock may not be amiss, for we shall not knowingly omit any animal and its capacity from our lists which may possess any of the requirements we are seeking. The Suffolk polled stock has been well described by a celebrated breeder, Mr. Gooderham, who says their milk and cream tests are very favourable and their beef-making character well known. There is, however, one special point as dairy stock of great consequence, that of never going dry, for it not only adds greatly to the annual product of milk, but it almost amounts to an insurance against puerperal fever at calving time. Undoubtedly this breed combines the points of good milkers and butter-makers, but not to the fullest extent, with also good beef-making capacity, but being also polled animals unfortunately excludes them from our list of animals we are seeking for having special points and purposes.

We must now refer more particularly to what we wish to produce as the best breed of dairy cattle for the future, for our aspirations lead us to endeavour and acquire in one race of animals the combined capacities which we cannot find in any single breed, to the extent at any rate which we desire. We shall therefore be obliged to fall back upon crossing to a certain extent to obtain what we seek. In fact, what we desire is an improved Guernsey breed, for in our experience we can surely obtain from the best pedigree stock at present the richest milk, yielding the choicest butter both in quantity and quality which can be produced from any variety of the Channel Island cattle. The Guernseys, too, at present are said to be the greatest milkers as to quantity of the Channel Island animals; but be this as it may, what we require is that they should yield as much milk as some of the best strains of milking Shorthorns, and yet retain the highest position as butter-makers which they now possess. As so many dairymen and amateurs take so much fancy to the Jerseys, and of late years so much pains have been taken to raise them in public estimation, still we must not be led away and believe that the Jerseys as improved possess all that is necessary in a perfect dairy cow. That it is not possible to cross the Jerseys so as to produce an animal capable of furnishing all that we require is at once seen in the fact that when she goes dry she cannot be made profitable by feeding for beef, nor could we mate the Jersey stock with any other known breed of cattle to furnish the beef in any appreciable quantity without deteriorating the milk and butter-making capacity. In the Guernsey stock the question of crossing at once assumes a different form, for these are large and roomy cattle and in various instances have been known when barren or gone dry to fatten freely and make a weight of beef of some profit to the feeders. Then arises the question, How can the point of beef-making be extended simultaneously with an increase of milk, and yet retain the excessive butter-making capacity which they now possess? This is a task which we have undertaken to explain, for we do not require what is usually termed a cross-bred animal only, a Guernsey in an improved state, by having taken what we require from some other breed, and that breed we pronounce to be the Shorthorn.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are at present chiefly engaged in the preparation of the land and seeding it with Wheat, winter Beans, and winter Vetches. Wheat-sowing and drilling especially must be done, the sooner the better; and we wish the home farmer to remember the result of delay in the seed time of last year, and which, in some instances, amounted to a serious disaster on various farms, particularly of cold, strong, flat-lying land. We, therefore, consider that in the event of the seed time being delayed in any future year, like last year, it would be far better not to

sow the land with Wheat at all, but wait until the spring for fair weather and sow Lent corn, the light lands with Barley, and the strong soils with Oats or drege, for we always reckon that as many quarters of Oats can be grown as sacks of Wheat per acre, unless the seed time for Wheat is favourable and at the early period. The fine weather which occurred the second week of the present month has enabled the farmers who now, for the most part, make their ricks near to where the corn is grown, to do a few days' thrashing, it being important for the condition of the straw as well as of the grain that it should be done in fine weather. The delivery after sale of the corn will take some horse labour in proportion to the distance of the farm from the mill or the railway station. Some of the Wheat is, however, in various districts much out of condition, owing, in various instances, to the ricks being partly made or not thatched when the rain came, and the consideration of this circumstance ought to induce the erection of Dutch barns by the owners of land, which may be erected in various parts of a farm or an estate. The home farmer could then secure his grain near to where it is grown, and also secure it under cover whether little or much has been carted, and thus be somewhat independent when storms occur, and not be subject to losses through ricks being partly built or unthatched. We note in some districts the water meadows, as well as other productive pastures, have been cut for hay the second time, and after a time has, in some cases, been ricked in fair condition. This is a matter requiring consideration where there is a large consumption on the farm, especially by dairy cows in the winter months. As to the benefit arising from ensilage, especially in late and moist climates, because all late aftermath, either Clover or meadow grass, can be preserved without risk of damage by the weather as ensilage, with a properly constructed silo, and properly filled, can be secured for use in the winter months. Upon some farms without any arable land capable of producing roots it is of the highest importance, and will frequently render unnecessary the large consumption of hay, and also diminish the amount of the feeding stuffs otherwise frequently required.

Hand Labour.—Men are now employed in spreading manures for Wheat on the Clover leas if not already done, also the winnowing of corn lately thrashed, unless the corn is cleaned and prepared for sale at one operation of threshing and winnowing at the same time by the same machine. Where the Turnip crop is being prepared for ploughing under before the Wheat is sown, this work may be partly done by women, who may assist the men in breaking down the roots, by carting them into the Gardner's cutter for men to grind in readiness for ploughing in, which cannot be done and the roots so effectually buried in any other way.

Live Stock.—The fashionable mode of feeding sheep by the use not only of hay and roots, but of cake and corn also in many instances, which not only incurs heavy costs but increases the labour bill in various ways; and as we note that so many farmers have been obliged to sell all their sheep to enable them to hold on their farms, and numbers of them have been obliged to quit their occupations, it is fast being found out that the large capital employed in sheep-farming and the consequent costs of labour and materials for feeding is a system only adapted for wealthy men, who if they lose by any particular transaction in farming are not thrown out of their farms. The fairs lately held for the sale of both cattle and sheep have again been higher in price than for a month previous. The dairy cows have now plenty of grass where it has been carefully preserved, so that each month should furnish for them some grass, although it may be supplemented further on by roots and hay or straw, and perhaps ensilage with the greatest benefit. The fattening and feeding bullocks for Christmas markets will now require the finishing touch of the feeder by an increase of all the best and most nutritious food and fodder, to give the animals the best and most glossy coat when shown for sale.

REMARKS.

14th.—Fine warm morning with gusty wind; almost continuous rain after 3.30 P.M.
15th.—Fine pleasant day, high wind and rain at night.
16th.—S.W. gale in early morning, squally day with heavy showers, fine and calm in evening.
17th.—Fine during the greater part of the day, sharp shower at 7 P.M., gale in evening.
18th.—Fine and bright, high wind in morning, calm evening.
19th.—Wet, calm, and dreary.
20th.—Fine pleasant day, cloudy in morning, but gradually getting brighter; glorious moonlight night.
Although the total amount of rain was large, more than half of it fell at night, and the week was pleasant for the time of year, as it was frequently fine and bright, and there was little mist or fog. Temperature remarkably similar to that of the preceding week, and about 3° above the average. There were several great and rapid changes of atmospheric pressure.—J. J. SYMONS.

2	F	Apple Show at Manchester.
3	S	
4	SUN	24TH SUNDAY AFTER TRINITY.
5	M	
6	TU	
7	W	Eastbourne Chrysanthemum Show.

THE PAST ROSE SEASON.

WHEN are you going to give us your *résumé* of the Rose season as you generally do?" is the burden of several letters that I have lately received. Circumstances have prevented my doing so before now, and for one reason I am not sorry, as it enables me to take in my review the autumnal-blooming as well as that of the Rose season proper, and thus to make it somewhat more complete.

I must preface my observations by saying what I have stated in former years, that I have exceptional advantages in taking my survey, the chief of these being that I am not an exhibitor. To some this might seem a disqualification, but I look upon it as just the reverse; for this reason—an exhibitor is so apt (it may be unconsciously to himself) to estimate the season by what his own success as an exhibitor may have been. If he have gained many prizes he is so apt to gauge the season by that, and think, that as it has been a good one for himself so it must have been for others. If he have failed he is very hard upon the badness of the year, because he has not come to the front; but a non-exhibitor, as he is uninfluenced by these feelings, can look upon matters more dispassionately. I have, besides, probably visited more Rose shows than anyone else, either in my capacity as Secretary of the National Rose Society or as judge; the only two of any importance that I have missed being the Crystal Palace and Bath, and these simply for the reason that I could not be in two places at once; for I have had in many cases to refuse earnest solicitations to act as judge because I have been otherwise engaged, and in many of these cases have been asked to nominate someone to take my place—a mark of confidence which I highly value. Besides this I have had the opportunity of visiting Rose gardens in all parts of the kingdom before and after the exhibition season, especially those of our chief amateur growers. I have seen the Rose gardens at that famous home of the queen of flowers Reigate, at Canterbury, at Darlington, Bath, Alderminster (the Rev. J. A. Williams'), Ledbury (Mr. Grant's), and have attended shows at Canterbury and Reigate, at Cardiff, Darlington, Sutton, Liverpool, &c.; so that, if with all these advantages I am not able to form a correct judgment of the season, I must be, as the lads say, "a duffer."

Before the Rose exhibitions had commenced I ventured to hazard the opinion that it would be a better Rose season than any we have had for some years past, and that if the weather in July were favourable we might expect such exhibitions as we have never before seen. Well, the weather in July was not favourable. In my own locality—not a rainy one—we had rain on one-half of the days of the month, and often these came most inopportunistly for exhibitions. Thunderstorms were prevalent. Thus the day before the Reigate Show a tremendous storm burst over the neighbourhood and diminished the exhibits by nearly one-half. The night before the "National" at South Kensington the same thing occurred in some localities, as, for instance, at Slough, where there was a division of opinion as to whether the Roses should be cut

at night or in the early morning. The latter carried it, but the result was disastrous, as a heavy fall of rain greatly damaged the flowers; but yet withal I believe the opinion I expressed has been generally coincided in. But how difficult it is to get a consensus of opinion may be instanced by your own pages. Several well-known growers expressed their opinion in the Journal about the National Show at Kensington and how widely apart they were, one declaring that it was the best this Society had ever held save that at St. James's Hall, another that it was the worst the Society had ever held! When doctors differ who is to decide? Let me say in passing that I believe the idea about the St. James's Hall Show is a sort of superstition that it would be well to get rid of. It was the first, and, like the first International Exhibition in Hyde Park, people never can think that another can be like it; but I have no hesitation in saying that one-half of the exhibits of South Kensington could not have been got into St. James's Hall, and this mainly owing to the vast increase amongst amateur exhibitors. The nurserymen are still about the same, but each year shows us new amateurs and exhibitors coming forward and taking up high positions.

The three Shows of the National were very decided successes. At the Metropolitan Show there were 441 entries made by 110 exhibitors, the largest of any Rose Show ever held; and although, as always is the case, a third of these failed to put in an entry, the number is very great. The value of the prizes offered was £230 independently of the two challenge cup trophies, £120 more; and my own opinion of it was, that although there may have been in previous years a few stands exhibited of superior excellence, yet that the general average of the Exhibition was above that of any previous year. There were no absolutely bad stands, and none, I think, of which the exhibitors need have been ashamed. The provincial Shows at Southampton and Sheffield were large, although, of course, not so large as the metropolitan; and in all other Rose shows that I have attended there was unquestionable progress. The best managed that I have attended was that at Darlington, illustrating the aphorism that of all governments a beneficent despotism is the best. My valued friend Mr. Whitwell took the matter entirely into his own hands. He had no committee to hamper him; he was treasurer, secretary, and committee all in one; he was able to command a staff of men thoroughly acquainted with business; everything was foreseen and everything provided for; the prizes were nearly all the gifts of individuals, and a most liberal schedule was arranged. The worst managed Show was—well, I will not pillory it, but societies ought to look to these matters. It is not fitting that when exhibitors come they should not know where their boxes are to be placed and that they should have to shift them half a dozen times, or that secretaries should lose their heads when the real work of arrangement takes place. At the same time exhibitors should look to it that they do not make the work heavier. They may comply with the rules in having their boxes in the place where the show is to be held; but if old and experienced exhibitors are rushing about to put their boxes in, or dawdling over them when everything ought to be cleared for the judges to commence their work, it is manifestly embarrassing, besides setting a bad example to novices, who think if the old hands do thus that surely they may do the same with more excuse.

If I had to chronicle last year the unexpected success of Mr. Whitwell, I have this year to record an equally remarkable success in that of Mr. A. Slaughter, who carried off the challenge trophy. When we remember that two years ago he obtained the prize for those who had never won a prize at the National, and yet this year carried off against such experienced growers as he had to contend with the premier prize, it shows that he must have unquestionably learned a good deal in those two years, and that as he did it with only a thousand Rose trees it is a great encouragement to those who have always been afraid of the big battalions. His has unquestionably been the most remarkable event of the year

in this line. Mr. Whitwell, who won it last year, was not able to put in even an appearance at South Kensington, the scene of his last year's triumphs.

I think the most remarkable feature in all the exhibitions has been the immense strides that the Tea Rose has made. Growers have learned that the Rose is not anything like so tender as it used to be represented. Many who only used to grow it by tens now grow it by hundreds, and I may safely affirm that there were dozens of stands this year which were not placed at all, that two or three years ago would have well taken a first prize. The wisdom of the rule excluding Hybrid Teas has been abundantly proved, and the extreme beauty of the stands has not been marred by flowers which, however beautiful in themselves, only detracted from the symmetry and refinement that ought always to be the chief characteristics of this most lovely tribe. That the favour which the Tea Rose has found is not likely to be evanescent I know, for wherever I have been there I have found that more space was being allotted to them; and that while many have said, "I shall not increase my Hybrid Perpetuals, I mean to go in for two or three hundred more Teas." I know one grower for sale who in one day received five orders for 1100 plants.

Of new Roses there is not much to be said. Etoile de Lyon has not been so extensively shown as I had hoped it would have been. Merveille de Lyon, of which so much has been said, has been shown several times, but it is not strictly speaking a new Rose, but a sport from Baronne de Rothschild, like Madame Moreau and White Baroness, but at present better than either of these. Of Roses which have not yet been in commerce Her Majesty, one of Mr. Bennett's seedlings, undoubtedly made the sensation of the year. It obtained the gold medal of the National Rose Society, and was greatly admired. It was described as a Hybrid Tea, but it was extremely difficult to trace any Tea blood in it. Whether Mr. Bennett is wise in holding it back is a matter of question. Already he has lost some of it, as his advertisement proves, and it would seem to me that it would be better for himself and for the Rose world in general if he had put it into commerce this year; but that is his business, and not mine. Another new English Rose is Lord Frederick Cavendish, raised by Mr. Frettingham of Beeston near Nottingham, to which the gold medal of the National Rose Society was awarded at the Wirral Rose Show. It is a very vigorous-growing Rose of the same type as Duke of Edinburgh and Duke of Teck, brilliant in colour but somewhat different in build: it is likely to prove a useful Rose to exhibitors. Lady Mary Fitzwilliam, a Hybrid Tea Rose of Mr. Bennett's, has been well shown, and is likely to be a popular Rose. Mr. House of Peterborough showed a promising Rose at Sheffield, but as he had not complied with the rules of the Society it could not be adjudicated upon. It is likely, however, that we may see more of it next season; but in truth the dearth of new Roses of value is very great, and although we still continue to have a number from France they fall into the background very quickly.

No event of the year was more welcome to the Rose-loving world than to see once more Mr. R. N. G. Baker of Exeter entering the lists; and although he did not exhibit in his usual form, yet the confident hope was expressed that he would another season resume his old place.

I have hitherto written of the Rose season from an exhibitor's point of view; but what a glorious season it has been for the Rose as a garden flower! All through August and September Roses have been gathered in all parts which would not have disgraced a stand in July, while the Teas have been something astonishing in their floriferous character and in the quality of the blooms. By-the-by, how very unlooked for (by me) is the position occupied this Rose season by that lovely and most variable Rose Madame Lambard. For whatever purpose required, exhibition or garden, it is ever good. The glory of Roses is, however, well nigh gone for the season, and the chief thought of the Rose-grower now is not to look out for blooms, but to be preparing for planting

for the ensuing year. This autumn has been a favourable one. Wood has well ripened in most places, and I trust that we look forward to another year with even more confidence than usual, and that old exhibitors will maintain their fame and new ones win honours in the cultivation of England's foremost flower—the Rose.—D., *Deal*.

ECONOMY IN STOKING.

ECONOMY of fuel in the heating of our horticultural buildings is a subject which may be discussed with advantage at this season, as with the present month begins the stoker's year. The introduction of and almost universal adoption of hot water, the powerful modern boilers, the general use of the one-boiler or double-boiler system, and a better class of stokeholes, has much lessened the labour and weary night-watchings of the stoker. In addition to the saving of labour there must also be a great saving of fuel where one fire is now doing the work of half a dozen. It is not my intention, however, to say anything on the actual saving effected by our modern appliances, but it would be interesting to have the subject discussed by some of your able correspondents who have facts and figures at their disposal. My present object in writing is to give a few plain directions to those of your readers who may have a fire to attend to during the coming winter months, and I hope they may be found useful to the amateur and simple enough to be understood by the youngest of the young gardeners.

In the first place let us consider what tools are necessary for our work. These are few and simple. A good stout poker; a similar piece of iron with end turned at right angles and flattened a little, so that it may be inserted between the bars in cleaning; a soot-rake, made by fixing a stout piece of sheet iron 5 inches by 3 inches (or larger, according to size of flues) at the end of an iron rod, fixing the rod in the centre of the plate. A similar article, but circular, is necessary where a boiler is perforated with smoke tubes. Each of these should be made of sufficient length to be worked with comfort, and be turned at the end to form a handle.

Before lighting a fire see that all the flues are clear and that the furnace is thoroughly cleared out, leaving neither clinkers, ashes, nor cinders. Let the wood get well ignited before placing any coals or coke on it. A few shovelfuls of the cinders just removed from the furnace are best to start with, allowing a full draught to play through the bars till a bright fire is produced. More fuel may then be added, and the draught modified to suit circumstances. Except in cases of hard forcing, and where a boiler has a great length of pipes to heat, fires should generally be a slow-combustion speed during fine days. Suppose, then, we commence our four-and-twenty hours' routine duties on the afternoon of a fine day when the fire has been banked up for the day. After the warmer houses have been closed and damped down in the afternoon, the fire is usually stirred to keep the temperature up after the sun is losing power. First draw the damper fixed in the chimney to regulate the draught out to its full length, and keep the ashpit door shut, so that any sulphur fumes may be drawn up the chimney and as little dust as possible escape from the ashpit. If the fire is burned low clear the bars of ashes and remove any clinkers, pull the fire together, and add a little fuel, leaving more or less draught according to the amount of heat likely to be required.

After a bright day we often have frost at night. If there are signs of frost it will be more economical to make a brisk fire at once than have to fire hard during the evening to raise the temperature when it is found to be getting too low. A kettleful of water may take some time to boil, but when it does boil it does not take a large fire to keep it boiling. So it is with a hothouse or a heating apparatus. Once heated it may be maintained for a considerable time with but little waste of heat. If there is no appearance of frost leave the damper out about an inch and the ashpit door open. This will keep the necessary heat in the pipes, and will be in a fit state for making up for the night any time from five to seven o'clock, as may be thought desirable. By a fit state for making up for the night I mean it should be bright but not burned too low. Draw the hot cinders together towards the front of the furnace, but do not stir them so as to knock the ashes out of the bars. Place what fuel may be thought necessary on the fire, but do not cram the furnace as is so often done. Let the greater part of the fuel be placed near the furnace door. Next draw some water from the sludge tap and pour it on the ashes below the bars, and place two or three shovelfuls of the wet ashes over the front of the fire, close both furnace and ashpit doors, and leave the damper out just so far as to let the smoke away and no more. Thus made up the fire will last for twelve or fourteen hours and retain a fair amount of heat.

As to the time fires are made up for the night, opinions may differ. I see no reason why 80 per cent. of our garden fires may

not be made up before six o'clock in the evening from the 1st of March till the 1st of November, except when frost or high winds prevail, when it may be necessary to keep them going to a later hour. In the morning the greater part of the fire will be found at the front enveloped in ashes. With the back of the shovel push this well back and carefully clear out any clinkers. These will sometimes be found in a cake all over the bars. Insert the clinker iron below, turn it over so that the hot ashes may be left, and lift the clinker out whole, if possible, and place it on one side to avoid the sulphur fumes arising from them. Clear the bars of ashes and bring the greater part of the fire towards the front again, place two or three shovelfuls of fuel on it, put the damper in to about 2 inches, open the ashpit door, and leave it to burn up bright. If the weather is cold and dull more fuel may be added in about half an hour and the damper pushed in a little, but leaving the ashpit door open. If the morning is a bright one, and with every appearance of a fine day, the fire may be banked up for the day, after having burned up for ten minutes or so, in the same way as we have recommended for nights, but with half the quantity of fuel.

In giving the directions it will of course be understood that they will only apply to those who have properly fitting furnace doors and a damper in the chimney. Sometimes I have seen the ashpit doors rusted and immovable on their hinges for want of use, and often missing altogether. Furnace doors are sometimes turned and twisted and anything but airtight. And, again, how often do we find boilers without anything in the shape of a damper in the flue to regulate the draught! Young gardeners are not responsible for these matters, and therefore cannot be expected to produce the greatest amount of heat from a given quantity of fuel. In the absence of both ashpit door and damper, in making up the fire use wet ashes and have the furnace door open a little way; but if there is a damper but no ashpit door the furnace door should be closed to exclude any cold air reaching the boiler surface. Leaving the furnace door open at night is a very common mistake. If the doors are so well fitted as to prevent the necessary air from reaching the fire, a little should be admitted by the small ventilator generally fitted into the ashpit door.

In conclusion allow me to urge upon your readers the great importance of having a damper in every chimney in the garden. Some have ignored the value of it, and would make you believe that true economy is to be found in a "roaring draught." I believe no boiler will give satisfaction without a good draught, but it will be equally unsatisfactory if the draught cannot be properly controlled. Some years ago in severe weather I found the little room I occupied rather draughty when high winds prevailed, the flames of fire going up the chimney with a "roaring draught." On these occasions I used to pull the flap or register (used for shutting the chimney up when not in use) forward till only a couple of inches space was left for the smoke to escape, and I have frequently observed a thermometer hung on the outer wall of the room rise 8° or 10° in an hour and a half. This anyone can try for themselves. If this result can be attained in an ordinary sitting-room, the economy of heat in a heating apparatus must be much greater by applying the same means. To get the greatest amount of heat out of a given quantity of fuel I should use a good draught till the boiler was quite hot, so that whatever fuel is added ignites almost immediately, and till that is nearly consumed allow only a limited draught up the chimney, but give unlimited air by the ashpit by keeping the bars free from ashes and clinkers, repeating the same process at intervals.—R. INGLIS.

SHARPE'S VICTOR POTATO.

HAVING grown the above new Potato this year a few notes in reference thereto may not be unacceptable to some of the numerous readers of the *Journal of Horticulture*, and more particularly to those who have not given it a trial. It is said to be a seedling, the result of a cross between the Alma Kidney and the old Early Short-top Round Potato. We purchased 1 lb. of seed, and to make the most of these when planting they were cut into single eyes. They received precisely the same treatment as our other Potatoes. The produce from the 1 lb. being as near as we could tell without measuring, nearly 4 pecks of good sound tubers. We took the trouble to have one of the largest tubers weighed; it weighed 21½ ozs. In shape and appearance it favours Magnum Bonum. It has very shallow eyes, which is a great recommendation in an economical point of view, and when cooked the flavour is excellent. Taking into consideration its prolific character, handsome appearance, fine flavour, and disease-resisting properties, I cannot speak too highly of it, and shall predict a very extensive cultivation when it becomes more known. Indeed, it is the best new early kidney Potato that has come under my notice for some time, and would recommend all who have not given it a trial to do so, as it is well worthy of one.—J. RICHARDSON, *Calverton Hall, Notts.*

SHALLOTS AND UNDERGROUND ONIONS DECAYING.—I grow a quantity of Shallots underground and other Onions, and I have them very large, as I thoroughly manure the beds. I generally plant my Shallots

and underground Onions during the first week in February, and when they commence growing I take care that they receive no check until they are taken up the first week in July. They are supplied liberally with liquid manure during hot weather, and I cease watering them the second week in June. For the last three years they have been subject to what is called the mould or gangrene, so much so this year that I have lost half of my Shallots, and rather more than half the underground Onions. I found in taking up these that the gangrene was growing inside in the very centre. I thoroughly dried them and kept them in a dry airy place, but it was of no use, as some decayed and others shrivelled. Can any of your able correspondents tell me the cause and state a remedy? The matter is a serious item to me, as I have to supply a house of seventy people.—R. R. S. H.

SCYPHANTHUS VOLUBILIS.

GRAMMATOCARPUS VOLUBILIS, better known under the name of *Scyphanthus elegans*, represented in the woodcut (fig. 69), is a native of Chili, from whence it was introduced to this country about the year 1824, but from inattention to the collecting of seeds was lost to cultivation, appearing again among more recent introductions. It is a hardy annual, having a very slender twining stem, which is

Fig 69.

hard and wiry, covered with small stiff hairs bent downwards, making it rough to the touch, but entirely devoid of the stinging properties of its near ally the *Loasa*. The leaves, which are opposite, are pinnatifid, with fringed margins.

The flowers are large, cup-shaped, and of a beautiful lively yellow tint, being sessile and terminal when the buds first appear, but the young shoots are generally produced on each side, so that when full expanded it is between two branches or forks. Planted against a south wall with a few twigs to cling to, it has a very pleasing effect, growing from 8 to 10 feet high, and is well adapted for covering old or unsightly walls.

It is also well adapted for covering trelliswork in the flower or pleasure garden, and is unequalled in the form of a screen, having also the advantage of giving variety to those generally grown.

Although perfectly hardy as an annual, I would advise its being raised in pots in a cold frame in spring, and planted where desired about the end of May.—D. D.

SIX MONTHS IN A VINERY.

JAN. 27TH.—The day following that on which my last note was made brought a welcome change in the weather. The temperature was lower, the sky clear at intervals, and the air a little fresh—a sort of model day for the middle of March. Owing to this we have now no doubt that the air of our vinery will be sufficiently changed through the laps of the glass, and that opening the ventilators may be deferred for a little time longer.

The 23rd was a most beautiful day, bright and cold, and we used it to the greatest possible extent by keeping our house close and by moving the fire rather earlier in the afternoon, so as to maintain as long as daylight lasts some of the extra heat which the sun has given us. The thermometer rose to nearly 80°, and kept as high as 70° till sunset. The maxim as regards forcing should always be “the more light, the more heat,” even though the latter may of necessity be principally artificial.

So far we have kept to a rather low maximum and minimum by fire heat, now after the hardening and consolidating action of the sun we decide on a little rise. Instead of 53° to 55° at night, we aim at 55° for the lowest. Still we do not insist on this, and one or two more mornings during the week when a little frost has come on with the daylight the mercury has for a short time been down nearly as low as 50°. The written directions now are—“About 55° at night, 60° day by fire heat, no air to be given.” The shoots have made considerable progress during the past week, a few of the forwardest having now unfolded a tiny leaf at the base. The growth appears stronger than it promised to be a week ago, and we are now able to make a partial selection. Where there are two or three shoots together, those which are certain not to be wanted are rubbed off with the finger, but we do not for the present disbud in doubtful cases.

There has been rather more damping this week owing to a greater amount of fire heat having been necessary, and the outside air being drier it also had its influence on the evaporation, although the house was kept as closely shut up as possible. But the damping was only applied to the floor and walls, none is applied directly to the Vine stems or foliage.

Feb. 10th.—During the past fortnight great progress has been made. The shoots are now from 3 to 7 inches long, with two to four fully expanded leaves, the largest of which measure 4½ or 5 inches across. Here and there in a few of the older ones are patches of dark colour, a sort of bluish green, only visible at present to the practised eye which is watching for its appearance. Yesterday it was only discernible on two or three leaves, now it shows slightly on a score or more, and indicates that the roots have commenced action, and that the leaves are no longer dependant on the stored-up food which was prepared last autumn and preserved in the stems for early use. The colour will spread rapidly now over the whole plant, and as we have taken care that there is no lack of food in the border, we may expect the progress to be still more marked than it has hitherto been. We commenced watering for the first time on the 2nd inst., the crust of the border having been previously broken an inch deep with a steel fork.

The lights are about 3 feet wide, and the border is 10 feet across. To this 30 square feet we allow 90 gallons for one watering; but as we do not want to have the water gone for a week or two, we endeavour to manage it so that the border may retain as much of it as possible in suspension. Bearing this in view it is not all given at once, but the border is gone over several times, giving a certain number of potfuls to each light according as it is found to soak in. Only the man who attends to the house is working at the watering, and he gives a part of the quantity now, and makes up half the total on the following day. Sunday now intervenes, and it is the 5th before watering is again proceeded with. A pound of Standen's manure is now spread over the border as far as the roots extend, which is about 30 square yards, and the watering is finished on the 6th. It will be understood that the attendant has had his multifarious duties to attend to as usual, and that the watering was done between times, and as it was the first watering and the border had become rather dry we preferred the operation to be spread over two or three days. The water was used at a temperature of about 60°. The 6th was a bright hot day, and but for the door being open to the adjoining compartment whence water had to be fetched we should have opened the ventilators for the first time; as it was the temperature did not rise above 85°, but as the sun had now become powerful I decided to give a little air on the next

bright day merely to prevent the temperature rising to a dangerous height. 95° from sun heat would not be dangerous, but at present I should not like to risk a temperature much above that.

The 7th was a dull day, so there was no question about giving air. The 8th was a warm morning, 50° in the shade outside. The sun rose brightly and the air was quite soft. A beautiful morning this to commence ventilating, and we did commence it by sliding three lights down a couple of inches at 8.45. They were closed again a little before 12; the sun still shining brightly, the temperature of the house rose to about 90°, and remained high all the afternoon.—W. M. TAYLOR.

(To be continued.)

THE OLD CRIMSON CLOVE CARNATION IN POTS.

YOUR correspondent's remarks (page 331) about this useful Carnation are by no means overdrawn, for it would be difficult to praise it too highly as a border plant. It may not be generally known that it is as useful as it is beautiful where grown in pots for the supply of its large fragrant blooms during the spring and early summer; in fact a supply of blooms can readily be kept from early in April until they commence flowering outside. To accomplish this young plants that have been layered and are now well rooted should be potted in 4 or 5-inch pots according to their size and strength. Moderately rich soil should be used for potting them in, and after the operation has been completed they should be placed in a cold frame and kept close until their roots reach the sides of the pots. The plants should then have a position where the temperature will range at night from 45° to 50° for a time, and then 5° more may be given for those intended to flower first, and the result will be fine blooms early in the month of April.

Although they will stand moderate forcing they must not be pushed on too rapidly or in too close an atmosphere, or they will draw up weakly and their flowers will be poor. Those for later flowering should be established in 3-inch pots, to be afterwards transferred into 6-inch pots, and if brought on gradually under cool treatment they will grow nearly as strongly as those planted in the outside borders, and prove very acceptable for cutting and conservatory decoration. We have established three good plants in 6-inch pots for late flowering for the conservatory, and they prove as useful as any plant that can be grown for flowering in such a position after the majority of spring-flowering bulbs are getting over. It is also an admirable plan to lift a few dwarf compact plants just before they are ready for layering, and pot them deeply in 8-inch pots for early forcing. After lifting if kept close for about fourteen days in a frame they become established, and can afterwards be placed outside until the approach of sharp weather, and then be housed either in a frame for a time or the greenhouse; but abundance of air must be given when favourable.

Those anxious to try a few good-sized specimens may still carry out with safety and success the lifting of a number of plants. At this season of the year it is best to select those that have been layered and have four or five strong young plants round the parent, all of which are well rooted. These should be lifted with a fair-sized ball, and then kept close in a frame the same as advised for the single plants in smaller pots. Those who attempt their cultivation in pots will, with ordinary care and attention, meet success that will amply repay for all labour.—W. B.

MEALY BUG IN VINERIES.

IN spite of knowing what a terrible pest mealy bug is when on Vines, there are a good many people who run much danger of getting it on their Vines through putting plants liable to bug in their vineries. Lately the writer was in two places where the Vines were badly infested with bug. Anything more disgusting than a bunch of Grapes infested with mealy bug can hardly be imagined, and great care should be taken by all who dread it to prevent its introduction to their vineries by means of plants temporarily placed in the houses devoted to Vine culture. When thoroughly established bug is by no means very easily eradicated. Many receipts are given, but most of them are very troublesome and even dangerous when applied. The bug may be destroyed at the expense of the Vine, which has several times been the case. Much better in this case is prevention than cure, and no one who places the least value on his Grapes should put plants liable to attacks of mealy bug in his houses. Rather grow fewer plants and have room for them elsewhere than run the risk of getting it on the Vines. Amateurs run particular risks in this matter, as they often have a few plants that they have not room for at particular seasons, and therefore put them in the vinery; in due course bug is reported on the Vines, and troubles begin.

A most rigid examination should be made of all plants that are going to stand in vineries, and should there be even one mealy bug seen rather consign them to the rubbish heap than place them in the vinery.—S.

ROSE SOUVENIR D'ELISE.—In ordering this Rose from one of our largest growers and most successful exhibitors I was told that it cannot be supplied from worked plants grown in the open air, and that it is not so grown in this country. I have had two dwarf plants in the open air since last November which have grown and flowered fairly well. Is the Rose so delicate that it will not endure an ordinary winter? We had no frost of any severity

here last winter, but such an excessive rainfall that I wonder on my cold soil any Teas survived.—NORTH HERTS.

LATE PEAS.

DOUBTLESS many will agree with "W. J. M.," on page 336, that now is the proper time to discuss the merits and demerits of late Peas, and not these only, but of varieties for the whole season's crop. Other enthusiasts in Pea culture must, like myself, feel gratified to notice the increased popularity of Peas amongst all classes. Returning, however, to the main subject, I readily join in the crowd of admirers in favour of Ne Plus Ultra as a late Pea; and although giving every reasonable encouragement to new comers, it is evident we must not as yet fail to make this old favourite our standard.

Having said so much for it I will endeavour as far as I am able to do other and newer kinds justice, taking first Mr. Laxton's new variety, Evolution, which, sown on May 24th, was ready August 20th, and has since October 18th yielded a plentiful supply of noble-sized pods of good colour and flavour. The seed was inserted 4 inches apart in deep well-prepared compost of loam, manure, charcoal, and half-inch bones. The height this Pea attained was about 5 feet, and the sticks were well covered with strong haulm. Telephone, like that grand second early variety Criterion, sown the first week in June came in very much all at once, bearing a heavy crop of good quality. Stratagem though a useful Pea is not specially valued here, and the pods did not fill well late in the season. G. F. Wilson sown May 25th is still (October 26th) giving us a few pods, and the variety is much appreciated. Omega bears well and the peas are of good flavour, but the haulm stops growing about the first week in September and the produce is soon over. Lastly, I regard Giant Marrow a valuable general crop and late Pea. Sown May 25th for the last crop, it is still bearing well, and the produce is of the best quality, but the pods filling rather slowly. I hope others have or will contribute their mite on the subject.—E. B., *Westmoreland*.

PLANTING ROSES WORKED ON THE CULTIVATED BRIAR.

IN view of the rapidly approaching season for Rose-planting it will be an assistance to many beginners in Rose culture if some authoritative expression of opinion can be given on the expediency of planting dwarfs worked on the seedling Briar and Briar cutting, with the junction of the stock and scion upon or below the surface of the ground.

It is, so far at least as can be gathered from published materials, an altogether undecided question. Canon Hole, in the 1877 edition of his book, appears to be in favour of burying the junction, but the largest growers now speak doubtfully on the point—*e.g.*, Mr. G. Paul "thinks that the union of the stock and the plant should be just on the surface;" while Mr. Prince (who should speak with authority upon the seedling Briar) says that "great care should be taken not to plant the Rose too deeply, but at the same depth at which it has been previously grown." This, in effect, coincides with Mr. Paul's opinion, as the bud appears generally to be worked near the surface of the ground, though the theory is that sufficient earth should be scraped away to allow the bud to be inserted on the root of the Briar, and thus when the plant is moved the junction can be buried without planting deeper than before, and the Rose given a chance of establishing itself.

Other nurserymen whose catalogues I have seen either ignore the subject or confine their remarks to the Manetti stock, and both Mr. Fisher in his "Art of Growing Roses," and the "Hints on Culture," by the National Rose Society, do the same. On the other hand, one who may be called our greatest amateur exhibitor (though he was unable this year to come out in his true form until the Wirral Show) treats both stocks in the same manner, and consequently buries the junction.

Such practice as his is worth any amount of precept, but it is at the same time a little surprising to find that Mr. Paul expresses a contrary view, unless, indeed, the question is so much affected by soil or other influences that each grower must form an opinion upon it for himself.

But if it should be established that, as a general rule, Manetti and Briar stocks should be differently treated, are there any distinguishing marks by which the different stocks can be recognised among a mixed lot of plants? If not, the name of the stock or some distinguishing mark should be added to the label accompanying each variety when plants are sent from a nursery. Worked cuttings might be identified, but if nothing but root is left of the stock it must require a very practised eye to distinguish the difference. The question may possibly not be of much importance, but as the cultivated Briar appears to be the favourite stock at present it seems desirable that definite directions should be laid down for its proper treatment.—NORTH HERTS.

CHRYSANTHEMUM SHOWS.

THE prospects of the Chrysanthemum season are very good, the plants generally are vigorous, the buds large and abundant, and that clean fresh appearance which adds so much to the beauty and success of Chrysanthemums is very notable in most cases. As usual the first fortnight of November will be a busy one with exhibitors, for a large number of shows are fixed for the same date, the early part of the second week seeming to be the favourite period, for from the 12th to the 14th no less than ten shows are announced. The competition for the second champion challenge vase at Kingston will be one of the chief events of the season. It will be

remembered that Mr. Molyneux, gardener to W. H. Myers, Esq., Bishop's Waltham, was successful in winning it last year, and should he be fortunate enough to again be allotted to him this season the competition will be terminated, but it is very likely that there will be a severe struggle for the honour.

At Liverpool the chief class is for eighteen incurved, and the same number of Japanese blooms, the leading prize being a ten-guinea silver vase given by a firm of artificial manure manufacturers, the competition to be "confined to the users of their fertiliser." The Birmingham Society offer good prizes throughout the principal classes, the highest being £10 for the best forty-eight blooms, twenty-four incurved and twenty-four Japanese; three other prizes are also offered in the same class of £7, £4, and £2, so that good competition may be expected. In the specimen Chrysanthemum classes a silver cup value £5, or the money to that amount, is offered for the best nine plants, other prizes in this section ranging £2 10s. to 5s.

The Stoke Newington Show, as one of the oldest in the kingdom, invariably attracts much notice from Chrysanthemum growers. The prizes are, as usual, very liberal, two silver cups, value respectively five and four guineas, being offered for a group of ten plants and for the best twenty-four incurved blooms in the Exhibition.

The Borough of Hackney Society's Exhibition at the Royal Aquarium, Westminster, prizes of good value are offered in a number of classes, both for Chrysanthemum plants and blooms, fruit, and vegetables. A £5 silver cup is offered for the best ten plants. For forty-eight blooms, twenty-four incurved and twenty-four Japanese, the prizes are £10, £3, and £1. Messrs. Dixon & Co. offer a silver cup for the best twelve Japanese blooms, and a silver cup value £5 is offered by the Royal Aquarium Company for the most effective group of Chrysanthemums; special prizes also by the Company, of £10, £3, and £1 10s., are offered for a collection of Grapes not less than twelve bunches. Special prizes for vegetables are contributed by Messrs. Webb & Sons, Stourbridge, and Hooper & Co., Covent Garden.

At Bristol the most important prize is a silver cup value £5 for six Chrysanthemum plants, large-flowered. Most of the other prizes are small, but a large number of specials are contributed by local supporters of the Society for plants, fruits, and flowers. Liberal prizes are also offered in a large number of classes at the Southampton, Winchester, Northampton, Croydon, and Tunbridge Wells Shows.

Of new Chrysanthemum Shows may be noticed Lincoln and Reading, at both of which fairly good encouragement is given to intending exhibitors, the schedules evidently having been carefully considered. A Show will also be held at Shrewsbury for the first time on the 22nd inst., the prizes being numerous but of moderate amount.

The following is a list of the principal shows with the dates on which they will be held:—

NOVEMBER.

7th.—Eastbourne (2 days).	15th.—Kingston (2 days); Staines.
8th.—Brixton (2 days).	19th.—Winchester (2 days).
12th.—Stoke Newington (2 days); Lambeth (3 days).	20th.—Hampstead (2 days); Lincoln; Chesterfield (2 days); Manchester; Twickenham (2 days).
13th.—Putney; Southampton (2 days); Brighton (2 days); Teddington (2 days).	21st.—Birmingham (2 days); Bristol (2 days); Northampton (2 days).
14th.—Bath (2 days); Royal Aquarium, Westminster (2 days); Bromley; Croydon (2 days); Tooting; Dartford.	22nd.—Reading; Aylesbury; Tunbridge Wells (2 days); Shrewsbury.
	27th.—Liverpool (2 days); Norton; Malton.

IMPORTED ORCHIDS.

SOME Orchids, at least imported plants, are evidently soon to be as cheap as bedding plants. Established plants are always likely to bring fairly remunerative prices. There is reason to complain of the endless varieties that are dignified with distinctive names, to the confusion of the buyer. There are so many Orchids that differ so little that it is absurd to honour them with a distinctive name—it only makes "confusion worse confounded," and often leads to much disappointment.

The rage for "something new" has no doubt been partly the cause of so many mere varieties, with little to distinguish them, being elevated into positions that in reality they have no just claim to. There are plenty of distinct Orchids being continually introduced to the country by collectors who are ranging every quarter of the globe. Why should mere varieties be heralded as something so different and vastly superior to anything as yet in commerce?

Though so many imported Orchids are disposed of for merely nominal prices, there are some that still fetch high figures, and these are undoubtedly rare and distinct. Semi-established and established Orchids yield more encouraging prices than the bulk of imported plants bring, and much trouble and anxiety on the part of the Orchid importer is often but poorly rewarded.

That splendid introduction Vanda Sanderiana is something to be proud of, and it is to be hoped its importers will be well repaid for their trouble. It is one of the Orchids that stand "head and shoulders" above the general crowd, and it has a grandeur which is peculiarly its own. Difficult to import and not easily established, it will most likely never be abundant, but all who can obtain a piece of it should do so.

Cypripedium Spicerianum is an Orchid that has gained for itself

a well-deserved popularity, and should it ever become very plentiful and cheap large quantities of it should be grown for cutting. It is most effective when interspersed with Maidenhair Fern.

Collectors would confer a boon on the public, and would only be doing what is right, if they would state when sending home the fruits of their labours that they cannot guarantee all their lots to be what they call them. Unless they see them in flower they cannot be sure that all they are gathering are the same. People would then not feel such disappointment as when they buy something minutely described as so-and-so, when time reveals the fact that it is something entirely different. The day when Orchids will "go to the wall" and other things take their place in the popular fancy is no doubt far distant, but the taste for them will be weakened rather than encouraged if high-sounding and seemingly accurate descriptions are given of plants that are really "dark horses," and may prove either very ordinary or extremely fine varieties.

In the race to be first in the Orchids it should not be forgotten that time, which slowly but surely reveals the truth, will disclose the merits or demerits of plants that have been much discussed, it may be overpraised, or too harshly condemned. "Take them and try them" should be the motto of Orchid salesmen. If you gain a grand prize happy are you; if not, try again. It is different with plants that have become established and have flowered, then accurate descriptions can be given and their value duly appraised. Many keen business men are taking up the growing-on of imported Orchids as a "spec." No doubt some will make it pay, and others will not. Those who grow for the love of them it must be confessed are more likely to appreciate their beauties than those who grow them as they would anything else that promised pecuniary reward, but one and all are interested in having only clearly defined varieties dignified with different names.—ORCHIDOPHILE.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

IN common with other readers of your Journal who have been anxiously looking for some public information from the Secretary of the Gardeners' Royal Benevolent Institution (who I am sure has not benefited the Institution by his reticence), I tender my thanks to Mr. Heale for his letter (page 339), so full of useful information, calling our attention to the Society above mentioned, but I think it hardly fair to say we are lukewarm in not supporting it. In my opinion the Society is to blame in not calling attention to the benefits offered, and placing the same before the gardening community oftener. I have never seen an advertisement or announcement about the Society before, although I have been a reader of the Journal for several years, much to my benefit. I believe there are numbers of gardeners who have never heard anything about the Society until this week. I have written for a copy of the rules, and if they are satisfactory I shall join it and endeavour to induce others to do the same.

It would be a good thing if country branches could be established, but the meetings not to be held at public houses, where I am sorry to see so many of the clubs are established at the present day. I should like to hear, Mr. Editor, your opinion on this question, as it is one of great importance to gardeners, which must be my apology for troubling you.—A SUSSEX GARDENER.

[In our opinion it is undesirable to have meetings of benefit societies in public houses whenever other suitable premises can be had for the transaction of business.]

PANSIES AND VIOLAS.

I FEEL sure that your correspondent, Mr. Wm. Plant, who asks me to define the difference between Pansies and Violas, could give the answer better than I can. Evidently it has occupied his mind, and as he comes fresh to the subject from the discussions of such thorough botanists and flower lovers as the Lancashire people are known to be, it stands to reason that he could, if he would, tell us much about the matter. It is rather amusing to read the rough-and-ready conclusion that some of the botanical societies have come to on the subject, that "all good flowers are Pansies and all poor ones Violas." This scarcely satisfies those who like a common-sense reason for all they talk about, and so we will go a little closer; though if we do go closer I must not be expected to be able to clear up everything.

The confusion and bewilderment with reference to the difference of Pansies and Violas comes very largely from the using of a generic name for a specific flower. Strictly speaking, they are all Violas, as Pansies are the offspring of *Viola tricolor* and its innumerable hybrids, and those commonly called Violas are more especially the offspring of *V. cornuta* and *V. lutea*. Gardeners understand them better by their eyes than by anything else, as any gardener would tell at a glance which was a Pansy or which was what is called a Viola. There is a great difference between the characters of the two flowers, and a practised eye would tell which was which at once with as much certainty as it would tell which was a *Pelargonium* as such, and a *Geranium*. The gardener who would detect at a glance the difference between the two flowers and say

positively which was a Pansy and which was commonly called a Viola, would no doubt be greatly perplexed to be compelled to define the difference between the two. No doubt it would be better to speak and write about these flowers according to strict rule, and so speak and write of Pansies as hybrid varieties of *Viola tricolor*, and of Violas so-called of *Viola cornuta*, *lutea*, and other hybrids; but if we did people would say we were pedantic. Our professional literature has a few curious things in it which confuse those in the outer circle of the garden, but which are as plain as the light to those who are to the manner born. May I suggest to Mr. William Plant that he and the botanical societies that he associates with should try to find a clear and easily understandable rule or law whereby the simple and unlearned may know the difference between Pansies and Violas, and also between *Pelargoniums* and *Geraniums*, as well as a few other families of plants that may be mentioned? This would help us much.—H., *Notts.*

To call all small Pansies Violas would certainly be leading the readers of the Journal to a wrong conclusion. We have the true *Viola cornuta* and also the largest Pansy. True, they are both of one family, but as widely different, particularly in size, as a cathedral to a hut side by side. What species our show Pansies were bred from would perhaps be difficult to say, as their improvement by selection and hybridising has been gradually going on for many years. I have often been told by my great grandfather that he had been growing them all his life, which must now be nearly a hundred years ago. *Viola cornuta* of course is nearly as old as the hills, but for garden decoration little or nothing was known of it until about twenty years ago, when Messrs. Wills and Bennett used it exclusively for bedding, and it was in great demand and cultivated extensively for edging. Soon afterwards *cornuta perfecta* was introduced, and in foliage, growth, and flower was as nearly half way between the ordinary Pansy and the *Viola cornuta* as it could well be. Since that time numerous crosses have been made and varieties sent out until we have got nearly back to the Pansy, and almost without a single exception they are inferior for a continuous blaze of colour for summer bedding. For instance, Blue Bell—this comes nearest to the Viola of all the present hybrids, and is a general favourite everywhere, and has driven Purple King Verbena nearly out of cultivation, although it stood upwards of twenty years and defied all previous purple-flowering bedding plants, and whereas if we had had no *Viola cornuta* we should have been obliged to use it now, even with its great fault, so subject to mildew, &c. The same with Yellow Boy, Viola, and Ardwell Gem. These with a few others of that colour have nearly vanquished the uncertain Yellow Calceolaria, and in a white variety Mrs. Gray even more clearly demonstrates the fact that the nearer we keep to the Viola the more value they are for summer bedding. This variety in foliage and growth is nearly identical with the Viola in its wiry habit, and it is by far the best white bedding plant in cultivation. Again, look at the horned Viola and a large show or fancy Pansy. The difference is very great, and those that have no pride for a continuous display of bloom in beds it would be easy enough to say the Viola is rubbish and not worth growing, and so far as an individual flower is concerned the meaning is quite correct; but plant a bed of Blue Bell and one of Thos. Grainger and many others side by side, and the difference between the cathedral and the hut would be more than manifest; and if Mr. Plant cannot decipher this, why not let the two classes be distinguished as they are now understood by all?—H. CANNELL, JUNR.

LILIUM AURATUM.

IN March last I bought 100 *Lilium auratum* bulbs. They were firm bulbs, about 3 or 4 inches in diameter. My desire was to grow them as well as possible and to extend their period of blooming, and so I decided to make the most of the bulbs in various situations and under different modes of culture. In following this resolution I potted a number of them. Some were placed singly into 6-inch pots, others were placed in threes and fours in 10-inch pots; some were planted in the bed of a conservatory, and a few were placed into the open borders. Although all the bulbs appeared alike their growths were not so. The little groups planted in the conservatory beds consisted mostly of fine bulbs. Certain bulbs in some of these made stems 5 feet high, while others did not grow more than 18 inches high. Some produced eight and ten fine blooms, and others only one and two. Some were rich yellow in colour, and others were nearly white. All were no doubt *L. auratum*, but the diversity was surprising. In the pots the same variation of growth was observable, but on the whole they did well and were very satisfactory.

The first blooms began to open in June, and the last were not over until the second week in October. Altogether the 100 bulbs kept up a constant succession of blooms for eighteen weeks or thereabouts. And what flowers! The plants in pots were the first to bloom, and those in the conservatory bed were not far behind them, while some of those in the open were out in July; but the wet spoiled the blooms so much in this position that I think it is a mistake to put them outside. They can be potted and be allowed to remain outdoors until the blooms are about to open, when they should be taken under cover, and they will soon expand. As to which of the bulbs will winter best, and grow and bloom most freely next year, I cannot yet say. It would, however, pay to buy in 100 or more bulbs annually, for such flowers are cheap at almost any price.—J. MUIR.

DESTROYING MICE.—I have had all my late Peas destroyed by field mice, and I have caught a lot of them in traps, but was unable to cope

with them they are so numerous here, the gardens being almost surrounded by woods. Could your readers inform me of any method of destroying them, or any way in which I could poison them in which there would be no danger to dogs? I have had one-third of my Strawberries destroyed by the same pest, cutting them off before they were ripe, and gathering them in heaps under the leaves. It will be a great boon to learn any plan by which I can destroy the worst of all garden pests.—B. S.

THE APPLE SHOW AT MANCHESTER which commences to-morrow (Friday), and will continue to the 9th inst., will doubtless be very interesting, as it will give growers in the north of England an opportunity of comparing the varieties chiefly cultivated there. We understand that the entries are fairly numerous.

— WE are informed that Mr. J. G. Baker of the Kew Herbarium, is preparing a FLORA OF THE ENGLISH LAKE DISTRICT for publication this winter. Mr. Baker is President of the Yorkshire Naturalists' Union, and has previously issued Floras of North Yorkshire, Durham, and Northumberland.

— MR. J. C. STEVENS announces that an importation of a NEW VANDA will be sold at his rooms, King Street, Covent Garden, to-day, and it will probably bring a good number of orchidists together. The plant is one of Mr. F. Stevens' introductions, and is from the island of Bali, one of the Javanese group, and is thus described:—"This splendid Vanda produces as many as twenty-four flowers on the spike, and is extraordinarily free-flowering. In habit it resembles *V. cœrulea*, but the flowers are near *V. insignis*. The colouring is chaste and striking, sepals and petals being carmine, spotted and striped on a white ground, and the lip violet." If the plant corresponds to the description it will be a most valuable acquisition, and will form a rival to the superb *V. Sanderiana*, which has attracted so much attention.

— RELATIVE to the late well-merited PRESENTATION TO MR. BARRON, a correspondent, Mr. Colville Browne, writes—"From this week's Journal I gather that a watch and chain have been presented to the prime mover of the Apple Congress. I for one feel rather aggrieved that, as far as I am aware, no opportunity was presented to us who have taxed the Committee so much to add our names to the list of subscribers. We are not all ungrateful." We are quite sure that our correspondent and many others fully appreciate what has been done at this Congress, and can quite understand their generous feelings, but anything like a public appeal for funds would not have been agreeable to a man of Mr. Barron's retiring disposition, and it was necessary to surprise him with the gift. Any spontaneous offerings that may be sent to us will be added to the presentation fund, if it is not yet closed.

— "How very lovely are the different species of *Pancreatium*, with their broad flat umbels of white, delicately cobwebbed and sweetly fragrant flowers. Of all these *Pancreatiums*, or *Hymenocallis*, as they are now called, we give the palm to *HYMENOCALLIS MACROSTEPHANA*. The great size of the corona or cup justifies the specific, and gives a character to the plant when in flower that is unmistakeable. The flowers are deliciously fragrant, and no collection of those plants should be without it, or, indeed, the other species of the genus. It may not be generally known that a flower in the embryo stage, and not thicker than a quill, if removed with a sharp knife, will expand in water, and, at least under a glass shade, will keep for ten days or so.—(*Irish Farmers' Gazette*.)

— MESSRS. COLLINS BROTHERS AND GABRIEL, 39, Waterloo Road, London, have submitted for our examination the finest HOME-GROWN BULBS of *LILIUM AURATUM* we have ever seen. One of them weighed 1 lbs. 6 ozs., and measured 1 foot 4 inches in circumference, and the others closely approached the same size and weight. We know that the largest of the imported bulbs of this plant do not as a rule answer so well as moderate-sized examples; but so solid and fresh are the fine specimens above referred to that it is difficult to imagine that they will not,

in good soil, produce wonderful plants. It is quite clear that the best of bulbs of this beautiful Lily can under favourable circumstances be raised "at home" just the same as Snowdrops can, and fine crowns of Lily of the Valley for forcing. Why not grow them well and more largely?

— WE have pleasure in directing the attention of our readers to a series of ten lectures on the DISEASES OF FIELD AND GARDEN CROPS that will be delivered by Mr. Worthington G. Smith, F.L.S., before the Institute of Agriculture at the British Museum, South Kensington, during the week November 12th to 17th. These lectures are sure to be most interesting and instructive, and embrace—1, Clover Sickness, Clover Mildew, *Peronospora trifoliorum*, *D.* 2, New Disease of Potatoes—*Peziza postuma*, *B. & Wils.*; and *Fusisporium Solani*, *Mart.* 3, New Disease of Onions—*Puccinia mixta*, *Uehl.*; *Peronospora Scheideniana*, *Ung.*; and *Mucor subtilissimus*, *B.* 4, New Disease of Grass—*Isaria fuciformis*, *B.*; Straw Blight. 5, Diseases of Turnips—*Oidium Balsami*, *Mont.*; *Peronospora parasitica*, *Pers.*; and Finger-and-Toe, *Plasmodiophora brassicæ*, *W.* 6, Ear-cockle, *Tylenchus tritici*, *Bart.*; and Dodder, *Cuscuta Trifolii*, *Bab.* 7, Grass Blight, *Erysiphe graminis*, *D.C.*; Corn Mildew, *Puccinia graminis*, *Pers.*; *Æcidium berberidis*, *Pers.* 8, New Diseases of Wheat, Barley, and Ryegrass—*Fusisporium* sp.; Ergot, *Claviceps purpurea*, *Tul.* 9, Potato Disease, *Peronospora infestans*, *Mont.*—its active state. 10, Do., do.—its passive state. The lectures will be illustrated with actual examples, and new drawings of all the diseases from Nature enlarged uniformly to 1000 and 5000 diameters. Tickets for the course are 10s. 6d., to be obtained at the Institute of Agriculture, South Kensington.

— AT the meeting of the LINNEAN SOCIETY to be held to-night (Thursday) at 8 P.M. the following papers will be read:—"Changes in the Fauna and Flora of New Zealand," by Dr. S. M. Curl; "On a Fossil Fruit from the London Clay," by J. Starkie Gardner; and "Origin of the Placentas in *Alsineæ*," by G. Lister.

— WE are reminded by a further sample of GISHURSTINE of the approach of winter, and we know by past experience how effectual it will be in keeping the leather of boots soft, and the feet encased in them dry during the period of slush that is sure to come, and when copse, farm, and garden have to be traversed. To all who are engaged in outdoor operations during the winter this excellent dubbing is highly commended.

— GARDENING APPOINTMENTS.—Mr. Denning, lately of the Royal Botanic Gardens, Regent's Park, succeeds Mr. Robert Abbey as gardener to the Earl of Chesterfield, Holme Lacy, Hereford. Mr. W. A. Walter, late gardener to Roger Eykyn, Esq., Gayton House, near Northampton, has been appointed gardener to Alfred B. Loder, Esq., Lillingstone Dayrell, near Buckingham. We are informed the following appointments have been made through Messrs. John Laing & Co., Forest Hill, S.E.—Mr. J. Slater, late foreman at Lord Foley's, Ruxley Lodge, Surrey, as gardener to Mrs. Hulse, Ewell House, Surrey; and Mr. Geo. Yoell, lately gardener to Mrs. Standring, Crystal Palace Park, S.E., as gardener to J. Lainson-Nash, Esq., Colley Lodge, Reigate.

— ON the 17th inst., in accordance with annual usage, the Master Wardens, and Court of THE FRUITERS' COMPANY waited by appointment on the Lord Mayor at the Mansion House, and presented to him their customary tribute of the finest and choicest fruits of the season. Formerly the present consisted of twelve bushels of Apples of various kinds, and of the best description which could be procured, and it was brought in white baskets, covered with napkins, by gaily-decked porters, who marched with it through the streets from Farringdon Market to the Mansion House, preceded by the Company's beadle. Then the Apples were presented, and according to the old ceremonial, the Lady Mayoress used to place a bottle of wine in the empty baskets for the use of the carriers. "The men were next regaled with a dinner (so the book of ceremonies stated), and, having satisfied themselves, retired, taking with them the fragments for their evening supper." Of late years the old usage has been varied, and instead of Apples only, the present of the company to the Lord Mayor has included all the choice fruit in season.

— "R. B., *Essex*," writes as follows on SPELLING PLANT NAMES:—"There appears to be plenty of room for improvement in the knowledge of plant-nomenclature amongst gardeners, as I recently saw in a public establishment some examples of misspelling of an extraordinary nature and a few of them will indicate how erroneous names are multiplied. *Silene aucaulis*, *Ramonda pyrendica* *Polygalachemæbuxa*, *Cortusa*

mathola, Calcolarie hysofolia, Asplenium reptonale (Asplenium septentrionale), Saxifraga neeros (S. nervosa), Erigeron elegontata (E. elongata), Liliun caladense (L. canadense), Androsace Lanugerosa (A. lanuginosa)."

— THE Hampton Court and other celebrated Grape Vines are, according to American accounts, completely distanced by a Vine in Pike County, Georgia, which, though only eighteen years old, is said to be "a quarter of a mile long, and to produce five waggonloads of Grapes annually." It must be grown on the "extension" system.

— THE "SCIENCE MONTHLY" (David Bogue, St. Martin's Place), is the title of a new illustrated monthly periodical devoted to popular science, and, judging by the first number now before us, it is likely to be a welcome addition to that class of literature. It contains several good special articles on various subjects, among them being two on "Insect Depredators" by Mr. J. H. Westwood Oliver, and on "Forestry at Home and Abroad," by Dr. J. C. Brown. Departments are devoted to The Library, Topics of the Time, The Observatory, The Laboratory, and The Museum; while a most interesting feature will be the articles on "Leaders of Science," which will be accompanied by portraits. With the present number a sketch of the life of Sir G. B. Airy, with an excellent portrait, is given. The work is well printed upon toned paper in double columns, contains thirty-two pages of closely printed matter, and is issued at 6d. per month.

— AN American paper states that a new industry has been started in Georgia. Two gardeners near Savannah have taken to raising ROSES. This year they sold 20,000 bushes to persons in the North, and had orders for 50,000 which they could not fill. They get from 10 dollars to 20 dollars per 100 for them. Over 500,000 Rose bushes are annually imported from Europe, but it is said that Georgia has a better climate for their production than even the South of France.

— "ACCOUNTS come to us from Italy," says Mr. H. M. Chichester in the "Journal of Forestry," "of a curious process for the 'METALLISATION' OF WOOD, the invention of Signor Giovanni Rubennick. The wood is first treated with caustic alkaline liquor (soda-lime), wherein it is left for the space of three to four days, the time depending on the degree of porosity of the wood, at a temperature of 75° to 90° Cent. (168° to 194° Fahr.). Thence the wood passes into a bath of calcic sulphohydrate, to which, at the end of twenty-four to thirty-six hours, is added a concentrated solution of sulphur in caustic soda. The duration of this bath is about forty-eight hours, and the temperature 30° to 50° Cent. (95° to 122° Fahr.). Lastly, for the space of thirty to fifty hours the wood is immersed in a solution of acetate of lead at the last named temperature. The process, it will be seen, is tedious; but the results are described as altogether surprising. Wood thus treated, when burnished with a piece of hardwood after a moderate amount of drying at a suitable temperature, takes a brilliant metallic polish. Particularly is this the case if the prepared wood is first rubbed with sheet zinc, lead, or tin, and then polished with a glass or porcelain disc. It then presents, we are told, all the characteristics of a very highly polished metallic speculum, combining therewith great strength and durability."

— A MADRAS visitor to COLOMBO, CEYLON, writes to the *Ceylon Observer* as follows:—"One of the earliest impressions of Madras visitors is the general tidiness which prevails both in and outside the town, and the superiority of the roads. In Madras the streets and roads are always either in bad order or under repair. In Colombo they equal the drives in an English park, and the trim rich greensward is very refreshing to the eye. The drives about Colombo are numerous and pleasant, but owing to the luxuriance of the vegetation the prospect is everywhere rather limited, except on the beach. A large proportion of the roads runs in various directions through the Cinnamon Gardens. These consist of plantations of the Cinnamon plant, which cover a large area of level sandy ground that stretches inland and to the south of the town. The soil in which the Cinnamon grows consists chiefly of fine white sand, and the plants are coppiced so as to make them send up a thicket of shoots. The Cinnamon Gardens are studded with villas, each standing in its own grounds, and often almost buried in rank vegetation. The wanderer from Madras is astonished to see here in great profusion the pretty purple-flowered *Melastoma malabathrica*, and the rampant Fern *Gleichenia dichotoma*, which are rarely seen much below the level of Coonoor with us on the east coast. Species of *Lygodium* also form a dense network of

vegetation in the hedges, and a Pitcher-plant grows in various places amongst the Cinnamon."

GARDEN CHEMISTRY.

LOAMS.

THE geology of soils we have but glanced at, for geology will not greatly help us. The best test of a soil is, not the rock on which it rests, but the vegetation which it carries. An accomplished gardener in choosing a soil will not turn his steps in the direction of stunted trees, poor crops of corn, and hedges filled with paling spars. If the turf should be ever so fibry he will not take it, if he has a choice, if its flora is largely composed of Juncuses, Carexes, and the species of Grass called "wire grass" by gardeners who well know how sharp a scythe must be to cut them, and how rapidly they take off the edge when they are largely present. We would much rather go where the grass is of that stout yet soft character which "cuts like cheese," and which is composed of Grasses and Clovers which feed cattle well, instead of half starving them, and perhaps a thick undersward here and there of Buttercups. The land that will not support good cattle without undue exercise on their part to find breakfast and dinner, though it may with help raise good crops, is inferior in many respects to that which supports heavy cattle in goodly numbers without other feeding.

Botany, then, will help us more in choosing a soil than will geology. But the botany of soils may be altered. In many parks the most luxuriant grass grows, which is the outcome, not so much perhaps of a fine soil, as of the cake and other foods supplied to the animals. The luxuriance is only artificial, and may be misleading.

Not long ago I knew a gardener who went many miles for turf to form Vine borders from off a gravel, simply because of the luxuriance presented by the grass and because of the very fibry nature of the turf. Such, men grown grey in the work of gardens, and who have observed closely, will tell us, as men such as Mr. Thomson of Drumlanrig have told us again and again, will produce only a mere "flash in the pan" while the organic matter lasts, and then failure will come. If the gardener in question has the teachings of chemistry to fall back on, failure, even with such a soil, may be indefinitely postponed; but the possession of that may be doubted, for if he had had such a knowledge he could have chosen a better within half a mile of his vineries, without much fibre, it is true, and with very little appearance of luxuriant verdure, because the fields had been badly done by. He was led astray by the will-o'-the-wisp of a fictitious fertility, because he could not properly value a much better soil just at hand because of an equally misleading poverty.

Another that I know with good loam, fibreless and turfless, but good loam still, within a hundred yards of his vineries, went over ten miles for turf from off the purest yellow clay, and not because of the permanent virtues of the soil, but of the age of the turf. No yellow clay, only soil and fibre and grass were apparent in the upper 3 inches of the soil. But ten years hence that fibre will be gone, and a putty-like mass in which Vine roots never thrive will be the result.

In choosing soil, then, it is not enough that plenty of fibre be present, not enough that the verdure be luxuriant. If the subsoil be gravel or sand such "loam" will soon become of itself the poorest of sand; if the subsoil be clay or even heavy loam it will become mere mud, and be fit for nothing in either case. Soils fit for making fruit borders may be of the very best quality and contain no fibre. If clay enough be present to form what gardeners call body, and if stones and sand be present in quantity sufficient to keep it open, and if it is known to produce good agricultural crops, it is far to be preferred before the most fibry turf that will soon become a blowing sand or an adhesive clay.

Experience has taught our most reliable authorities that for all fruits and most flowers and vegetables that a loam is the most proper. Farmers know that such is also best for them. But the word "loam" is with many a very indefinite term, generally applied to turf the vegetable fibre of which is decayed somewhat. When we use the word it must not be understood that we do so in the gardening, but in the agricultural sense, which is definite in its meaning and reliable. The young gardener who wishes to start with a correct notion of what constitutes the different varieties of soils cannot do better than make the following very simple mechanical analysis. Take 100 parts of soil, dry it thoroughly at a temperature of fully boiling point, and weigh it, and then thoroughly diffuse it in a tub of water. Allow it two or three minutes to settle, and then pour off the muddy liquid into another tub. After the

mud has settled in the second tub, run it off with an improvised syphon made out of gas pipe or other suitable tube. Then dry both deposits separately in an oven hot enough to dissipate all moisture, but not to bake the soil. What settles at once is sand, what does not settle for some time is agricultural clay. If no more of this clay be present than 10 per cent. the soil would be called sandy soil; if from 20 to 40 it would be sandy loam; if from 40 to 60 it would be loam; if from 60 to 80 clayey or heavy loam, and over 80 clay.

But soils are not wholly composed of sand and clay. Some contain much stony matter, and are called gravel; some contain hardly any mineral matter and are called peat. Besides, these soils contain a lesser amount of other matters, such as lime, potash, phosphates, ammonia, humus, &c. To illustrate this, perhaps a couple of tables will show my meaning better than any verbal description. Clay and sand are merely mechanical matters, lime and ammonia are plant-foods. Thus, though sand, clay, or peat may form over 90 per cent. of the whole, yet the mineral matters named as entering into the composition of plants are, relatively, of much more importance.

The substances usually found in fertile soils are—

This table shows that soils are composed of, first, mechanical constituents, and also plant-food prepared and in preparation.

I will now give an analysis of a fertile soil from the Carse of Gowrie by the late Professor Anderson of Glasgow, to show that even in a very fertile soil plant-food forms a small proportion of the whole.

	SOIL.	SUBSOIL.
Silica	61.1954	61.6358
Peroxide of iron	4.8700	6.2503
Alumina	14.0400	14.2470
Lime	0.8300	1.2756
Magnesia	1.0200	1.3938
Potash	2.8001	2.1761
Sulphuric acid	0.0911	0.0396
Phosphoric acid	0.2400	0.2680
Chlorine	0.0098	0.0200
Organic matter	8.5508	6.8270
Water	2.7000	4.5750
	96.5472	98.6882

The part played by the plant-food is elsewhere noticed, but this is the proper place to say something of the properties of the different mechanical constituents in soil.

In gardening language clay gives "body" to soil, and when it is absent soils are generally barren. In chemical language clay is an aluminic silicate, and, as we have seen, has its origin in the eruptive rocks, such as granite and whinstone. It is rarely that pure clay occurs, and in fertile soils it very generally contains potash, often in large quantities, as well as other mineral foods for plants.

If we take liquid manure, in which soluble phosphates, ammonia salts, &c., are dissolved, and filter the solution through a potful of loam, it will be found that the water leaves the phosphates, ammonia, potash, &c., behind. The clay in the loam has taken them out of the water, and will keep them in its grasp till used by the plants, at least in the case of the mineral matters; for, as we have seen, the ammonia becomes changed to nitrates, which clay cannot keep. Pure sand cannot do this. If such solutions be run through pure sand it will be found that very little of the manure is left behind. Besides fixing manurial matter, clay absorbs and retains water. Sand, from which what we call superfluous water is allowed to drip, will often contain no more than 5 per cent. of water. Clay, on the other hand, will hold as much as 50, and yet be apparently dry. Then clay, by reason of its superior attraction for water, will remain moist

because of the water which it attracts from the subsoil in dry weather when sands are parching dry. Again, of the moisture which sand really does retain when rain falls, most of it evaporates very readily. Clay soils do not thus lose theirs so readily. Then sand, of all soil ingredients, least possesses the power of absorbing moisture from the air. Clay has a great attraction for air-moisture. While sand will, if pure, hardly take in any of the moisture which condenses as dew on cool nights, which so often succeed hot drying days, clay will absorb a very sensible amount.

Sand, however, is not useless. Pure clay is so adhesive and retains so much water, especially in wet seasons, as to be unworkable. Sand opens them and allows the water to percolate. In very heavy soils, which become pasty mud in wet weather and compact masses in dry, roots cannot travel either to fix the plants or to find food. When sand is present, on the other hand, roots run easily, and find the food the clay holds. Because of their wetness clay soils are cold. When sand is present this wetness can be cured by draining, and so the soil is made warmer. While, then, sand on the one hand, and clay on the other, form neither of them desirable soils, a mixture of them—loam—without the objections of either, combines the virtues of both. But in choosing a loam for potting or border-making purposes, some care is necessary in order to avoid being deceived. It not uncommonly happens that in river bottoms, and even in hollows by the side of mountain streams, particularly when in flood, the flats are inundated, that what is apparently a medium loam, and is called by that name, is no loam, contains no clay, but is medium in texture because composed of very fine, what old experienced gardeners term "dead," sand. This is about the most objectionable soil that could be chosen, as it too frequently is. Poor and incapable of being enriched, it is also solid, impenetrable, and no sand, no grit can open it. The particles clog up everything, barring the way of either roots or air.

Sand when seen through the microscope is composed of round polished stone, mostly pure quartz. Gravel, as we wish to be understood in our use of the term, is only larger sand, and, though capable of trituration, resists weathering and chemical action with some obstinacy. But in addition to rounded quartz stones (small as sand, large as gravel), much gritty matter exists as sandy stony matter, not only capable of being easily disintegrated, but of yielding considerable quantities of plant-food. In the case of soils derived from such rocks as trap this is often very considerable. The acids generated by decaying vegetation, the salts, such as common salts so generally present in rain near the sea, and often applied in manure as sulphate of ammonia, nitrate of soda, &c., coupled with the digestive power of roots, have a wonderful effect in preparing for plant-food those potassic silicates, calcic carbonates, &c., which the disintegrating action of frosts and cultivation expose to their action. Not only, therefore, are stones mechanical agents in soils, retaining moisture as they do and keeping the soil open, but as we have named them in conjunction with vegetable remains, not plant-food, but capable of yielding it. Stones represent so much money value, even though not larger than what constitutes fine sand. They are partially disintegrated but not decomposed minerals.

Though iron must be regarded as plant-food, and its presence, therefore, a necessity in all soils, it frequently happens that as the red oxide it is too plentifully present. No better way of finding out whether this is the case or not exists than just examining the water. In clear water it imparts the well-known taste that the palate can detect. But such water will not run in a stream far, nor stand long exposed to the air without showing a red deposit. But springs of no great depth may show iron while the upper soil is healthily free from it. Sand that has long lain dry, even though the subsoil may be red or black with iron, is often first-class every way. It is when, in wet weather, the water stands on the surface where the land is low and undrained, or when apt to be flooded with iron-impregnated water, that too much iron is to be feared. But even such iron-impregnated soils might be of use for mixing with others singularly deficient in it. It is said that iron helps the colour of many flowers, Roses included. Possibly a little iron loam might be of use for such. In many cases iron causes the formation of impenetrable pans in the subsoil. How to deal with them will be noticed under another heading.—SINGLE-HANDED.

FORCING LILY OF THE VALLEY.

THE Lily of the Valley is one of the most generally esteemed flowers in cultivation, and on this account the supply of its beautiful and sweetly scented sprays of flowers cannot be obtained too soon, nor seldom in quantity sufficient to meet

the increasing demand. The best results are obtained from imported clumps, and these should be potted as soon as they can be had from the nursery in an admixture of light loam, leaf soil, and sand, in 6-inch and 7-inch pots, according to the size of the clumps. The pots should then be placed on coal ashes in a cold pit under glass, and covered with 4 inches thick of sifted leaf soil to exclude light and air. About the end of November a few pots should be removed to the Mushroom house and plunged as before. These, the soil being kept moderately moist, will produce their flower spikes by Christmas, when they should be gradually inured to light and air by placing an inverted flower pot over them at first, and finally arranging the pots on a shelf near the glass in an intermediate house to prevent the flower-spikes making a weakly growth. To those not in possession of a Mushroom house I would recommend the pots being plunged in deep boxes and placed under a stage in a stove, greenhouse, vinery, cellar, or any similar place, and when the flower-spikes have attained a height of 2 or 3 inches they should be treated as recommended above.

A fresh batch of plants—in quantity according to the number grown—should be taken from the cold pit to one of the structures already referred to, at intervals of a week or two, and covered with 3 or 4 inches depth of leaf soil, so as to maintain a good succession of flowers, and which, by retarding the flowering period of a small percentage of the crowns, may be kept up until they come into flower out of doors. However, as the season advances it will not be necessary to introduce the plants into heat at such short intervals, as they will, consequent upon their having had a longer period of rest, respond more readily to the influence of heat, and as spring approaches the crowns will produce their spikes of flower freely enough in the cold pit. The leaf soil should then be removed carefully from the surface of the pots, the latter washed and removed to a house. Home-grown crowns, selected and packed closely together in boxes of sandy loam and leaf soil, then watered to settle the soil about the roots, and treated in other respects the same as recommended for imported roots, would yield good supplies of flower for cutting, thereby leaving those in pots for embellishing the conservatory, &c. My experience of imported crowns of Lily of the Valley during the last few years is that in consequence of the wet autumns they have been inferior to those of previous years for early forcing, being small and immature, and crowns carefully prepared at home will equal if not excel them.—H. W. WARD.

PLEIONES.

THESE charming little Orchids are now at their best, and when they are well grown are invaluable where cut flowers are required. Considering they are so easy to grow it is surprising we do not see more of them. Anyone possessing a warm greenhouse or stove need not be afraid of disappointment. The pseudo-bulbs after flowering should be allowed to rest a short time, but never be quite dry. When the young growths are about 1½ inch long the pseudo-bulbs should be taken out of the pot and separated, carefully removing all the old compost from them, cutting the old roots to within about an inch of the pseudo-bulb; the portion left serves to keep them firm in the pot. They must be carefully washed to clear away any traces of scale, to which pest they are very subject, and which is very troublesome if allowed to run on the young leaves. The compost I employ, and better results cannot be desired, is good fibrous peat and chopped sphagnum with a liberal proportion of nodules of dried cowdung and charcoal, and a good sprinkling of sharp sand mixed well together. Six-inch pots half filled with potsherds are employed. The pseudo-bulbs, five or six according to the number of young growths, are potted firmly, raised above the rim of the pot. Afterwards keep them in a temperature of about 50°, and keep them damp but not wet until the new roots have reached the sides of the pot, then an increase of heat will be advantageous. We are always careful not to wet the leaves, or they will soon become spotted and will decay prematurely. As growth advances the pots are occasionally plunged in weak liquid manure up to the pseudo-bulbs. Continue this about twice a week until they have swelled; they will then require less water and may be placed in a cooler part of the house. In due course the leaves will ripen and fall, and the flower buds appear.

Pleione lagenaria, P. Wallichiana, and P. maculata have done well under the above treatment, the first-named hardly ever having less than four flowers on a pseudo-bulb, and in some cases five. P. Riechenbachiana I am growing for the first time, and am well satisfied with it. P. humilis does not do well with us. Will any of your correspondents who have been successful with it state their mode of treatment? The flowers should be pulled and not cut, as a much longer stalk is obtained by the former method.—WM. PLANT.

HEATING A SMALL GREENHOUSE.—Will you allow me to ask your readers what they have found the best method of heating a small greenhouse (mine is 18 feet by 8 feet) to keep out frost? I must not put up a chimney and make a smoke. I cannot use gas. I have used

so-called economic petroleum stove, but that is not economic, and the work in cleaning it is very unpleasant. I do not mind trouble, nor a little expense if it answers its purpose; but I shall be obliged for some experience and advice as to coke, charcoal, or anything else.—BRISTOL.

PROPAGATION OF TUBEROUS BEGONIAS.

IT is probable that Tuberous Begonias will be much more extensively grown next year than at any time hitherto, and in addition my experience justifies the assumption that they will become established favourites for outdoor flower garden bedding decoration, as Zonals are at present; Good varieties are still very scarce, and as people become acquainted with magnificent fleshy upright flowers 5 and 6 inches across they will not be satisfied with puny papery dwarfs only fit for the rubbish heap. Good varieties and their propagation, then, become a matter of importance, not only from a decorative but from a monetary standpoint. No better time than the present and onward can be found to think of this. A far-seeing gardener or amateur will be at once turning over in his mind how his beds are to be filled next year, and what combinations he shall have, the general details afterwards to vary with circumstances. I was looking over the invoice of a gardening friend yesterday, who had ordered a selection of Begonias with the view of growing them on during the winter and propagating the following spring as far as possible. None of the doubles were less than 5s. each, and they varied to 15s. The singles were as low as 3s. 6d. I admit the varieties were the newest and the best, and to be preferred to poor worthless seedlings at any price. As to seedlings I must explain. All seedlings are not necessarily to be rejected. By all means buy a packet of seed from some respectable firm that has a reputation to maintain. One word on fertilisation. The male and female organs are on different blooms. I have had Begonias with the latter wholly absent, and in a few cases the former. Under ordinary circumstances bees do not, as a rule, light on them; there is no fertilisation. It must be done by hand, and several firms enclose the thin pods in transparent oiled bags for the seed to ripen. As in every flower in the florist's list, the worthless varieties seed most profusely, so that a really good chance seedling is much less likely to be obtained than from an ordinary seedsman's packet of edged Auriculas, gold-laced Polyanthus, or flaked Carnation. From many years' experience I cannot say I have succeeded in getting anything worth naming in this way. However, it is by no means hopeless. For instance, Mr. Lonergan, gardener to George Gough, Esq., Birdhill, near this town, has raised some very fine doubles by hybridisation of semi-double seedlings raised in his garden. The process has an interest and zest that will always have an attraction; but the principle I contend for still remains—that really good varieties are "named," and must be obtained from those who make Begonia culture and propagation, including showing and growing, a speciality. I noticed a house 150 feet long of selected kinds with Mr. D. Saunders recently at Cork, not one of which was raised on the premises. Having some good varieties, then, which is the best method of increasing them? Increase by seedlings I have disposed of, except to say that, when tried, January is to be preferred to start them in a temperature as near as can be obtained to 65°, falling lower as they commence to grow, to prevent long-drawn plants. I have had some hundreds, and a neighbour thousands; all were consigned to the rubbish heap, except half a dozen of the more promising.

The most rapid system of propagation is by cuttings taken off below a joint, placed to dry for a few hours if succulent, inserted in thumb pots in cocoa-nut fibre in the stove or on a good hotbed. This process has the disadvantage that in many cases the tuber formed from the cutting does not start into growth the following spring, which an expert with whom I discussed the point attributed to having no eye or eyes, though otherwise sound. Probably others have noticed this.

The process I prefer as the most certain is division, just as you would a Potato, with this difference—you can see the eye in the latter but not the former; division, then, cannot take place until active growth has somewhat advanced. I prefer having the shoots an inch or two long. I have often then sliced a large tuber into six or eight pieces, and after allowing it to dry on a shelf for a few hours, or rubbing the cut with silver sand or charcoal, at once started it on its career, and in no instance, even in an ordinary frame, have they even flagged. There are other systems of propagation, such as by the leaves, as you would Gloxinias, but I cannot see any advantage they present over those named. One other point is material—the time to start them into growth. In an ordinary greenhouse (unheated, except to keep out frost), they will not start into growth before the end of March—that is, naturally. If put out they will not bloom until June or later. I beg to recommend starting in a hotbed in February, hardening off then until the time comes for bedding-out, when they commence to bloom right off, giving a clear gain of a month or more to the blooming period before housing for the winter—a matter of some consideration.—W. J. MURPHY, *Clonmel*.

FRUIT TREES IN POTS.

IN the Journal of September 27th and October 4th I find Souvenir du Congrès Pear very highly praised. I can do nothing with it outdoors in this locality, where few Pears succeed, but grown in pots in a cold house it does well, being a good cropper and producing very fine fruit. It is not unusual here to have fruits of the weight mentioned in the Journal—1 lb. to 1½ lb. Brockworth Park is also excellent for pot culture; I have

not noticed it mentioned before for this purpose, and would like to hear if anyone has tried it. We have many other varieties here that could not be left out of a good collection. I have gathered nearly eight dozen of Doyenné du Comice from one tree in a 15-inch pot. I send you a spray with five fruits on, and if you think it worthy I should like to see it illustrated. Some of the single Pears on the tree are very much finer than those.

The Gladstone Peach I have grown for two years, and it is excellent. Peaches and Nectarines were heavy crops in pots this year, averaging six

them? I had occasion the other day to visit a friend of mine, and knowing him to be a practical gardener was surprised to hear him so strongly condemn pot trees, saying "fruit grown on them was not fit for table." I am in hopes my friend will visit me, that our fruit may speak for itself. —GEO. HAWKINS, *Evenny Priory Gardens, Bridgend, South Wales.*

[The fruit referred to *has* spoken to our satisfaction. We have not tasted any more delicious than those gathered from the spray figured. The Pears shown are necessarily much reduced; each of them measured 9 inches in circumference. Eight dozen Pears of similar character

FIG. 70.—PEAR DOYENNÉ DU COMICE, FROM A POT TREE.

dozen per tree. One Nectarine had ninety-two good fruits, and well coloured.

I consider much more fruit may be gathered from trees in pots than grown in any other way on the same space of ground under glass. I admit the work is heavy, and the trees require much more attention than those do that are planted out. We have during very hot weather used 300 gallons of water per day. Is it not surprising, therefore, to hear gardeners say they do not like pot trees, knowing the labour attached to

gathered from a tree in a 15-inch pot represent one of the best examples of culture that has ever come to our notice, and we congratulate Mr. Hawkins on his success.]

AUTUMN PROPAGATION OF ROSES.

AT this season "W. J. M." again notices the chances of striking cuttings. I have not the slightest doubt that in favourable winters the plan he advocates will succeed, but the only autumn that I tried a large

quantity outside the frame every cutting died during the winter except two, and these both departed later. It is true we had a fearful winter, but a large proportion of the plants in the frame close to the exposed cuttings did very well, but then ours is a truly bleak country.

Our friend Mr. W. Taylor used to tell me that he inserted cuttings of Roses amongst the Cabbage plants and let them take their chance, and that most of them struck well; but then Longleaf is down in the valley. Not improbably the Cabbages or Broccoli are a great protection to the cuttings, and save them. Acting on this, I think I shall try again amongst the Broccoli, for the crowding in the frame is a serious disadvantage later on when removal is the order of the day; for the close quarters will make the roots intertwine and numbers will be broken off, for the union between the cutting and the root is singularly like a joint the first year, and a very slight twist brings about a separation.

When Mr. Taylor some years ago gave us his directions (the most certain I know) for striking Rose cuttings in small frames covered with sheets of glass, he laid special stress on making the hole for the cutting with a largish stick, the end being cut squarely off, so that each cutting (cut similarly square) might reach with certainty the soil on which it has to rest, and that the soil, well mixed with road grit, should be firmly pressed. I have adopted with much success making a small furrow, filling the bottom of it with the gritty soil, and then, making a shallow hole, place the cuttings side by side and fill up the furrow, pressing all firmly down.

Several years ago I ventured the idea that the smooth-wooded sorts struck more easily. This I see "W. J. M." also finds, but we may add to his list Charles Lefebvre, Alfred Colomb, Jules Finger, Madame Sophie Fropot, Madame J. Perrière, and Crown Prince. All of these I have proved as rooting easily, the latter especially. Madame Rothschild, Mabel Morrison, and Madame Gabriel Luizet I have also succeeded with, amongst the more thorny Marie Baumann, Baron de Bonstetten, Ferdinand de Lesseps have repaid the experiment, while amongst the Teas Marie Van Houtte, and Madame Lambert do very well in the frame; but would they succeed in the open? I fear not. My cuttings of last autumn have given me some beautiful blooms this season—quite repaying one for the trouble. One caution more. Prepare the ground, then prepare and plant the cutting without delay, the quicker the greater success.—Y. B. A. Z.

A FEW GOOD THINGS AT SWANLEY.

THERE are many "good things" in the establishment of Messrs. Cannell, as nearly all the world knows, for it is certain there are few civilised countries that have not had their floral collections enriched from this "home of flowers" in the pretty Kentish valley that has undergone such a remarkable transformation during the past few years. So great, indeed, is the variety of plants, notwithstanding the periodical weedings with the object of making the collection still more choice, that they almost bewilder by their numbers; and that such an assemblage is necessary proves the extraordinary diversity of taste that exists in cultivators of flowers. There appear to be not only local but national fancies. In one district a mania sets in for Pelargoniums, another for Fuchsias, another for Begonias, and so on; while in the continental, American, and Australian markets there are "runs" on plants that are not at the same time in such great demand at home. This, then, accounts for the multitudinous nature of the stock, for the clients of the establishment are scattered all round the globe.

Having had some small business connection with Mr. Cannell since his commencement as a trade florist in a small way at Woolwich, and each year had plants from his nursery, it is interesting to pay a visit now and then to head-quarters and to note the progress that is continually being made. I always take down a few names on these occasions of the plants that appear to me the most striking; and as such a list, however patchy it may be, may possibly be of some service to others I send it for what it is worth. When on a mission of the kind indicated I take no notice of the mere date of introduction of a plant; whether it is old and common, or new or rare, matters not. The chief question with me is, Is it meritorious? Passing the Dahlias, of which so much has been said lately, and that have been so grand and numerous represented in the several types, I pause, as everybody must pause, at the

PELARGONIUMS, commencing with a section that I fear is not sufficiently appreciated. I note as particularly attractive the following Ivy-leaved varieties:—Comte Horace de Choiseul, a free grower with deep salmon-coloured double flowers; very distinct. Eurydice, also a strong grower, with fine trusses of rosette-like purplish rose flowers. Gloire d'Orleans, compact, free, floriferous, with magenta-coloured flowers, and worthy of a place in every greenhouse and conservatory. Jeanne d'Arc, a free grower and bloomer, producing very large, double, nearly white flowers; an acquisition. Madame Crousse, also free and very fine, with pale rose-coloured flowers with dark-veined upper petals. To complete the half-dozen choice falls on M. Dubus, a dark and beautiful variety with fine flowers and trusses freely produced. There may be finer doubles than the above, but I have never seen them, and those named will give satisfaction to most persons who grow them well, while their cultivation might with advantage be greatly extended. These double varieties surpass the singles in my opinion, but those who think differently may try Beauté de Lyon, which is undoubtedly one of the finest, having large trusses and flowers of a bright magenta colour. Madeleine Reitterhart, very large and fine, glowing pink. Mrs. H. Cannell, purplish mauve, with striking trusses of well-formed flowers; and Masterpiece, a magenta variety of great merit, and a distinct acquisition. This is the best

quartette I can name, and with the doubles above mentioned we have a very choice collection of these charming plants.

Double Zonals.—As I only wanted a few, a few only were marked, these, so far as could be selected, being the best in their colours. F. V. Raspail, deep scarlet, with fine pips and truss, dwarf in habit and floriferous. Paul Charbonniere, orange-scarlet, with large trusses and fine flowers. Clara Pfitzer, rich glowing pink; free, sturdy, and fine. Madame François Dubois, purplish pink; compact, and floriferous. M. Gelein Lowagie, orange-scarlet, very bright, with noble trusses freely produced. Grand Chan. Faideherbe, deep crimson flowers of fine form and very striking. Charles Darwin, deep rosy purple; distinct and fine. Aglaia, very free, lighter purplish flowers, and highly attractive. General Farre, deep salmon, with flowers and trusses of the first quality. Lord Mayor, purplish pink; dwarf, and remarkably floriferous. And now we come to the whites, and not being able to determine the best, the two following had better be ordered:—Heroine and Madame Léon Dallay, the latter blush-tinted, but very charming. This is a very select dozen, exclusive of the liliputians Comtesse de Jannberg, Princess Stephanie, and Archduke Rudolph, which only grow a few inches high and cover themselves with flowers. The first is salmon shaded with purple, the second pinkish lilac, and the third rich magenta. They are distinct from all others in habit, foliage, and blooms.

Single Zonals.—To choose a dozen from 200 is not an easy task, and perhaps another examiner would select some others, yet he would scarcely exclude all that will be named. Mrs. Gordon, a splendid bright crimson flower with white eye; truss large, and habit good. Right Ahead, deeper than the preceding, having dark crimson flowers of the finest form, borne on large trusses. La France, this is of the Dr. Denny type, but finer in every way; upper petals purple with orange-crimson base. Dupont de l'Eure, a grand variety of the same type, with even deeper top petals, and a fiery orange base. Miss Hamilton, blush white with a dark eye, a charming Phlox-like flower that should be grown by everybody. Czarina, white with a pink centre, also one of the best in its class. Mrs. J. Gibson, bright clear salmon, with large pips and fine symmetrical truss; very effective. Eurydice, deep purplish pink, upper petals tinted with white, dwarf, free, and a fine trusser; very telling. Mrs. Strutt, paler in colour than the preceding, but scarcely less attractive, and altogether good. Constance, pure rose colour, very free and fine; the best of its colour. Paul Bauer, deep glowing pink, base of the top petals white, large pips and truss; distinct and attractive. Snowball, the best white variety; pure and fine. All the above have large round flowers. Two extra may be added of the semi-nosegay type, remarkable for their huge trusses and dazzling colour—namely, Bacchus, magenta-crimson, rich and glowing, and T. Schuler, brilliant scarlet, dwarf and free. This selection was made some time ago—that is to say, long enough since for the merits of the varieties to be proved, and is not the less reliable on that account. If there are any better, especially amongst the newer ones, as there probably is, perhaps some persons who have proved them will make their merits known.

Amongst the Show Decorative varieties two of the most effective were Edward Perkins, orange-scarlet with maroon blotch, and Madame Thibaut, round white flowers, veined and marbled with rose. These are very free and useful for the home stage and market purposes, and may safely be added to those collections that do not include them.

BEGONIAS.—Equal to the Pelargoniums in variety of colour and general effectiveness these commanded attention, double and single varieties being represented in great numbers. The finest half-dozen Tuberous varieties noted were Madame de Dumast, blush white, with flowers much larger and fuller than Gardenias, and very striking. Davisii hybrida flore-pleno, dwarf, floriferous, rich, and telling. Eugénie Lequin, orange-scarlet, very bright and full. Lucie Lemoine, one of the best whites, and admired by all. Edouard Morren, crimson-scarlet, full and fine; and Calypso, rosy pink, large and symmetrical. The double varieties, as a rule, are not so free as the singles, nor can they be so rapidly propagated, and hence it is difficult to maintain the supply, as they appear to be very popular, and the demand for them is consequently great.

Twelve superior single varieties, which admirers of these beautiful flowers cannot well do without, are François de Craen, crimson-scarlet, handsome and floriferous. Massange de Louvrex, bright orange-scarlet and dark foliage; very effective. Countess of Kingston, reddish crimson, flowers of great size and substance; extremely fine. Graham Bell, rich crimson, large, habit dwarf, and plants floriferous. General Roberts, deep velvety crimson; one of the richest and finest. Madame Valette, rosy carmine, round and smooth; plant dwarf and free. Annie Laing, soft rosy pink, large, well-formed, and free; the best of its colour. L'Abbé Froment, deep golden yellow, erect and fine; one of the best of its colour. Mrs. Highgate, rosy salmon, good form, free and pleasing. Lady Hume Campbell, white suffused with pink; large, free, and good.

John Laing, clear light scarlet, of the first quality, very attractive; and Madame Saladin, French white, free, with large flowers of great substance, and a general favourite.

Fine-foliage Begonias.—Varieties of the Rex type have been for a time under a cloud, but are again increasing in public favour. For growing in shady places, such as under the foliage of Vines, they have, when tastefully grouped with Ferns, a beautiful effect; while for planting on rockeries under glass few plants are more suitable. They are also admirably adapted for corridors, halls, staircases, and windows, as they thrive well in semi-dark positions, and colour better than in the full sun. From a very large collection the following twelve are chosen as distinct and good. To describe them is impossible, so beautifully are

they marbled and spotted:—Adrian Robine, Berthe Proutière, Charles Hovey, Duchess, Distinction, Fire King, Julia Serot, La Perle de Paris, Louise Chrétien, Mdle. Emma, Narga, and Van der Meulin. These plants are of the easiest culture, and most of those named are a great advance on the old varieties that are generally seen in cultivation.

Miscellaneous.—Having noted what I particularly went to see, houses full of Verbenas, Petunias, Fuchsias, Gloxinias, and other flowers were passed with an admiring glance, as also were some acres of Roses and Violas, with great squares of Delphiniums, Phloxes, Pyrethrums—in fact, apparent all kinds of flowers; but an edging of Lobelia Swanley Blue compelled a pause, so dwarf and dense was the growth and bright blue the flowers. It is a variety that will spread widely, and a good companion for it is Queen of the Whites, Scarlet Gem, Cloth of Gold, and King of the Roses Abutilons form a grand trio. The dwarf golden button-like Chrysanthemum coronarium Aurora was flowering freely, and is becoming popular; whilst amongst the stock of the florist's Chrysanthemums the great gun is Lord Wolseley, that every fancier will, sooner or later, have to add to his collection.

After seeing all that was to be seen, and much more than I can remember, I left Swanley with a feeling of astonishment at the widespread love for plants that now exists, and which must be growing yearly, or how else could such establishments as this have sprung up so quickly and be maintained so well? It is truly wonderful, and the more so since most, if not all, appear to be flourishing and extending. This is a healthy hopeful sign, as it is directly indicative of the public taste—a taste, no doubt, that has been, in a great measure, created by the enterprise of florists of the present generation, who have secured the best varieties that have been raised at home and abroad, and let the world know they possess them. This is the secret of success.—AN ANNUAL VISITOR.

CHRYSANTHEMUMS AT FINSBURY PARK.

THE popularity of the Chrysanthemum Show at this Park seems to be increasing annually, for in no previous season has it been visited by so many persons as this year, the structure devoted to them being almost constantly crowded, and particularly so on Sundays. The Superintendent, Mr. Cochrane, has earned a well-deserved success in instituting the Exhibition, and he has been ably assisted by his foreman, Mr. Mardlin, who has paid careful attention to the culture of the plants with good results. A substantial structure 100 feet long, with wooden sides about 6 feet high, and glass roof with abundant means of ventilation, was erected about a year ago, and is admirably adapted for the purpose. It has a flow and return pipe on each side, heated by two small independent coil boilers placed outside the house, and these are very useful in assisting to prevent damping, as all superfluous moisture can be quickly dissipated; by that means keeping the flowers fresh much longer, and the colours cleaner and brighter.

About 1300 plants are grown, comprising over 300 varieties, and they are arranged on each side of a central path, forming two sloping banks, which have a beautiful effect on entering the house, as the blooms can be readily seen, the numerous colours being carefully grouped to form a harmonious combination of tints. Several new varieties are represented, amongst them being George Gordon, a Japanese with very large deep rich red blooms, the florets broad. This is particularly deep in colour when young, and becomes lighter as it advances, some of the blooms exceeding Elaine in size. Some of Messrs. Veitch's novelties raised by Mr. Salter are notable, though few possess sufficient distinctness or merit to supplant other and older favourites. Tisiphone, the Goddess of Snakes, is a Japanese, with long ragged dark red florets, rather loose. Lucifer is another of the ragged Japanese type, yellow and red; Duchess of Albany, with broad white or creamy florets, is also a Japanese variety of Salter's raising, the blooms large and early. A new so-called Pompon is Ringleader, also one of Veitch's varieties. It is somewhat in the way of Lady Talfourd, nearly as large, but lighter in colour, and with the florets quilled nearly to the points.

Of the older varieties the following are especially remarkable for the size of their blooms:—Comte de Germany, extremely large; Elaine, White Globe, Abbé Passaglia, Cry Kang, Baronne de Prailly, Golden Beverley, Peter the Great, Refulgence, Tarantella, Triomphe du Nord, and many others. The banks are bordered with Pompons planted out, a number of varieties being represented; but Golden Circle, an early bright yellow variety, and Sœur Melanie, white and similarly early, are two excellent varieties, free, compact, and handsome.

Although the Show was opened early there are great numbers of buds to open yet, which will prolong the display for some weeks yet, and judging by the size and substance of the buds the later flowers will be fully equal, if not superior, to the earlier ones.

HISTORICAL JOTTINGS ON VEGETABLES.—No. 9.

THE CUCUMBER.

IN a household, so it is said, which happened to have amongst its inmates a number of word-critics, Cucumbers were not unfrequently placed upon the table. Some chance observation provoked a discussion, which led to the division of the assembled eaters into three parties respectively advocating Coweumber, Cucumber, and Cucumber. So warm became the disputes concerning the pronunciation of the oft-vexed word that the head of the family for the sake of peace

enacted that those who asked to be helped should henceforth simply call it "cumber." The English "Cucumber," the French "Concombre," and the Latin "Cucumis," indicate their nearness to each other. The root of the original appellation is thought to have been "curvus," from the tendency of the fruit to take a curve or twist. We, however, although the fruit is the part eaten, commonly place this on our list of vegetables, as it is not a fruit to be relished at dessert, as are some of its relatives.

Cucumis sativus, from which our many garden varieties of the Cucumber have been developed, is considered to be a native of northern Asia, but no wild examples belonging to this species have been discovered by travellers of modern times. In the order Cucurbitaceæ, where this is placed, the majority of the species are either bitter or purgative, and partial to warm climates; this bitterness resides in the rind of the cultivated Cucumber, for which reason it is attractive to some insects, perhaps, such as the detested cockroach or "black beetle," which eats, and is said to be poisoned by Cucumber. If so, it would be a fact worth knowing, since this insect occasionally proves troublesome in our houses, but I am assured by a gardener who has laid slices of Cucumber along the haunts of the cockroach that no diminution of numbers ensued. There have been, no doubt, from sundry accounts in old authors, instances of persons being poisoned by eating the fruit of other species of Cucumis, mistaking them for the edible kind, and possibly by that of the true Cucumber if grown under unfavourable circumstances.

Africa was evidently the early home of the cultivated Cucumber, and from those northern districts where large specimens were produced for the table thousands of years ago the cultivation of the plant spread to parts of Europe and Asia. It is one of the species over which the Israelites mournfully soliloquised during their desert wanderings, as they contrasted past luxuries with present limitations in food (Numb. xi. 5). And the Cucumber has long flourished, is still flourishing, in the rich soil lying near the Nile, we may safely date it at least 2000 years before the Christian era as a plant well known to the Egyptian races. Retaining their liking for Cucumbers, the Jews afterwards grew the plant freely in Palestine, hence that comparison would be forcible to them which is used by Isaiah, who likens Jerusalem to "a lodge in a garden of Cucumbers." It was exposed to as much risk as one of the temporary structures that were commonly thrown up in the Cucumber grounds to shelter a man employed to watch the ripe fruit. After such a shed had served its purpose, it would be neglected and allowed to fall into ruin until a farther need for it arose. The Greeks had the Cucumber from Egypt or Asia Minor, for it seems they had a high opinion of the plants that were produced about Antioch, and took the trouble to import them. One of the older Greek authors describes a peculiar plan followed by some of the Egyptian gardeners; they set Bramble bushes of tolerable size in a sheltered spot, and during the spring having cut these down almost to the earth, they inserted a seed of the Cucumber in the pith. A good quantity of manure was then placed round the Bramble stocks. This was done with the object of hastening the development of the plant, but he suggests as an improvement sowing the seeds indoors, rich earth being placed in baskets, which, at a proper time, could be moved to the garden and sunk. Pliny, writing in the reign of the Emperor Tiberius, describes forcing as he had seen it practised in Italy. Cucumbers were grown in boxes furnished with wheels, and these were shifted about according to the weather, the growth of the plants being encouraged even in the winter by exposing them to the light within buildings covered with a transparent material, now unknown, which would admit the sun's rays, but exclude cold.

It is most probable that the Romans, during their occupation of Britain, grew Cucumbers amongst the many vegetables which died out in the period of degeneracy that followed, with frequent conflicts between Briton, Saxon, and Dane. Nor does there exist any evidence that the plant was speedily reintroduced after the Norman Conquest, and not until the days of the Tudors do we get references to it as a plant grown in the gardens of the nobles. Gerard knew it well, and he doubtless had Cucumbers on the slopes of the garden near High Holborn, where he reared so many rarities, having a favourable situation and land well watered by the little brooks that flowed from the higher ground into the river Fleet. Parkinson may have gathered them from his garden in Long Acre, which appears to have been very flourishing in the reign of James I. Forcing was a novelty then, but Gerard mentions that as he had seen Cucumbers grown under frames, thin matting being stretched over hoops; also, he says, some gardeners in order to obtain Cucumbers of considerable length enclosed the young fruit in hollow canes or wooden cases, while they supplied the plant with abundance of manure. Then, he adds, the seed taken from these long and straight Cucumbers will generally on sowing yield fruits which are of superior quality, and resembling their parents in form. And, according to his wont, he discusses the medicinal value of the Cucumber, recommending it as an unfailing cure for skin

diseases. This was not, however, by its external use, lotions and salves containing Cucumber juice having obtained no fame then. Gerard recommends persons having "red pimples, coppery faces, and fiery noses," and wishing reasonably enough to improve their aspect, to eat some Cucumber every meal, mixed with oatmeal pottage. A ridiculous notion prevailed in the seventeenth century that if the seeds of the Cucumber were soaked in milk before they were sown the resulting plants would not draw up "the gross juices of the earth." Lord Chancellor Bacon, who did so much in his age as a pioneer of modern science, studied the cultivation of plants, and advised that the pits in which Cucumbers were planted should have a layer of chaff or woody fibre under the mould, because that would check any

and the fruit is now cheapened considerably as compared with its price at the beginning of this century, but "frame Cucumbers," like similar special articles, keep up their value. We think a great reduction has taken place in the quantity grown in the immediate neighbourhood of London, partly attributable to the disappearance of much of the garden ground, partly also to the circumstance that the crops have frequently yielded unsatisfactory results, which has arisen from various causes.

The poet Cowper had amongst other occupations to wile away his melancholy that of raising Cucumbers, and in one of his poems he versifies the details of the process. In a letter to a friend he remarks that although he grew them he was afraid to eat them, and when forwarding one of them to a friend he asked him to explain how it was he had grown this specimen and yet had not reared it. His friend was perplexed, and Cowper solved the riddle thus—"I raised the seed that produced the fruit that produced the seed that produced the fruit I sent you. The latter seed I gave to the gardener of Terningham, who brought me the Cucumber. So I virtually raised it by having raised its progenitor, and yet I did not raise it because the identical seed was sown at a distance." There is no small minority of our population afraid, like Cowper, to venture upon Cucumber, and medical authorities are very divided about its wholesomeness.—J. R. S. C.

Fig. 71.—GREEN ROSE.

tendency to a large absorption of moisture, which he regarded as undesirable for the fruit.

The very imperfect accounts we have of the oldest market gardens of London leave us in doubt where and when Cucumbers were first raised for sale in the metropolis. I suspect in the reign of William III., about Lambeth, Vauxhall, or Battersea being likely localities. Subsequently Cucumbers were extensively grown in the open suburbs of London on the Middlesex side of the river, hundreds of thousands being cut yearly for immediate eating or for pickling. An early forer of the plant was one Thomas Fowler of Stoke Newington, who was allowed to present a couple of Cucumbers to George I. on the 1st of January, 1721. Hertfordshire and Bedfordshire are two of the home counties that have produced quantities of Cucumbers in the open air,

THE GREEN ROSE.

"S. J. W." asks for particulars and a description of the green-flowered Rose, and desires to know whether it is worth growing as a novelty. The particulars at our disposal are the following, and they may possibly be of interest to others besides our correspondent:—

Mr. William Paul of Waltham Cross recorded in our columns in 1878 that this Green Rose (*Rosa viridiflora*) "was first seen in France in the possession of M. Verdier of Paris in 1855, who received it from an American nurseryman of Augustus, Georgia. I received it from M. Mieliez of Lille as a new Rose in 1857." Later in the same year Mr. Scargill wrote—"Respecting the origin of the Green Rose, the old man who collects the seed in the herbaceous ground at Kew tells me that the specimen there was brought by Sir H. Barkley from the West Indies (Demerara he thinks). He, however, added that it was taken to the West Indies by the French, and the specimen at Kew is labelled *Rose Verte*, which seems to indicate its French origin." The appearance of the Rose is represented in the annexed figure of a specimen that was sent to us by Mr. Smith of Romford. As to whether it is "worth growing as a novelty or not," that is a question of individual taste. We have grown it for years, and have often cut flowers twice the size of that shown in the figure. They are not beautiful, but are certainly novel.

NOTES FROM A SCOTCH GARDEN.

THERE are at this season few more useful flowers for filling vases than the Michaelmas Daisies. They may either be employed alone or for lightening heavier flowers. For the latter purpose *Aster simplex*, a pure white Daisy-like flower, is very lovely, and is only approached by the little *Vittadenia triloba*, a graceful plant with starry flowers which change from white to pink. *Aster Amellus*, purple; *A. versicolor*, white; *Erigeron grandiflorum*, light blue; and *Stenactis speciosa*, of a darker shade of blue, are all of great value just now. Other good Asters not yet open are *A. turbinellus*, *A. multiflorus*, *A. ericoides*, *A. novæ-angliæ*, and *A. novæ-belgiæ*.

One of our best out-of-door flowers at this season is *Alstroemeria peruviana*. It begins to flower in summer, and continues throwing up fresh flowering stems until stopped by the cold of approaching winter. I do not remember having seen this species specially noticed before. It is certainly one of the best hardy flowers we have. Another lovely flower

at present at its best is *Agapanthus umbellatus*. I do not know that it is hardy everywhere. Here it blooms well on a warm dry border.

Phygellus capensis is also one of our best border plants at this season. It likewise is said to be tender in some quarters. Here it succeeds perfectly. Cuttings strike if inserted now, and this is the best way to obtain a stock of plants. Those who are fond of single flowers should add the light blue *Scabiosa caucasica connata* to their collection. It keeps producing flowers for months, and is much appreciated by ladies. It is quite hardy. Judging by questions as to name, which are continually being asked, the soft rosy *Sedum spectabile* does not appear to be so well known as its merits entitle it to. We grow it by the hundred in border and bed, and can recommend it as one of the most taking of hardy flowers. A stock can be rapidly raised, as every little point strikes root freely in spring. Afterwards the rootstocks may be divided when replanting if more plants should be wanted.

What a fine Orchid is *Odontoglossum grande* when grown strongly! We have had several plants in bloom and more to follow, some of them with six blooms to a spike, and the individual flowers over 7 inches across. I find they do best grown close to the glass under a dense shade while growing. Our best variety is just showing its spikes; this I have known with seven flowers on a spike, and considered it very good. Of a different stamp is *Oncidium ornithorhynchum*, a quiet graceful beauty; it is quite the gardener's Orchid and worth growing by the dozen. Some varieties are hardly worth house room, so much do they vary.

Another Orchid of the greatest value at this season is *Phalænopsis amabilis*. It does in an ordinary stove, and, like *Odontoglossum grande*, should be kept pretty close to the glass and densely shaded. It is not difficult to manage, but I have found it necessary to change the sphagnum twice in a season in order to keep the roots in perfectly fresh material, an important point to be observed with *Phalænopsids*. It may be added that this species should be kept shorter of water during the winter than it would be safe to venture with *P. Schilleriana*, which, if allowed to get dry, will lose its flower buds.

While on the subject of watering it may be pointed out that it is not the best plan to dry up *Calanthes* too quickly; they ought to be watered until the foliage gives way. *Cœlogyne cristata* is another plant which at present should not be insufficiently supplied with water. Fresh roots are now formed, and the plants are all the better for being kept moist. The same remark applies to *Lycaste Skinneri*, which is now throwing up blooms and forming roots at the same time. I will only mention another species which every gardener should have, and which is now opening its first flowers, and that is *Cymbidium Mastersii*. This is certainly the most useful of the *Cymbidiums*. We have had spikes with a dozen and fourteen flowers, very lovely. Varieties differ considerably, however, in respect of length of spike.

I have considerable sympathy with "H." in the matter of new Potatoes. They are generally very disappointing. I think, however, as a rule gardeners continue to depend on old kinds for supply of ordinary wants. I do so, and so do others whom I am acquainted with. For instance, we have had Myatt's Ashleaf Kidney in use from June up to the end of August, and I do not know that it could be surpassed as a cropper, certainly not in the matter of flavour, by newer introductions. Of course White Elephants at 1½ lb. each may be brought as proof that I am wrong, but such examples are unrepresentable in any dish—with the exception of that of the family pig, and even in his case the smaller and more delicately flavoured Myatt's might be more profitable.

I am waiting for the first sharp frost to denude the Seakale crowns of the leaves which are now in the way in order to get the first batch lifted and placed in the forcing house. While so waiting I may be allowed to call the attention of others who may also be waiting, to this fact in the matter of forcing Seakale—that is, that you cannot give the roots too rich a rooting medium when planting them in their forcing quarters. Any poor worn-out rubbish is generally conceded to Seakale. But if you want it to grow quickly, to grow strong, and to grow brittle, employ instead of rubbish some dry horse droppings, and you will have a glad-some surprise. Rhubarb should be planted in the same material.

I have just one other note, and that is about a shrub—*Spiræa Van Houttei*. It is useful for forcing, but what I specially want to recommend it for is as a shrubby flowering plant. It ought to be grown extensively. It flowers early, wreathing its drooping shoots with little cymes of pure white.—X.

GREAT APPLE AND PEAR EXHIBITION—HEREFORD.

THIS annual Exhibition, kept in abeyance last year on account of the unproductive fruit season, was held in the Shire Hall on the 24th and 25th ult. To report with what amount of success, I need but state that some 2500 plates were staged, while for lack of room the cider and perry fruit had to be grouped in admired disorder throughout their respective classes. However, as the Judges did not seem to object to this perfunctory arrangement, the public certainly were gainers in the picturesque effect gained by the general effect. Not in extent only was the Exhibition pronounced to be the finest ever held in the provinces, but in the rare quality of the fruit; and, in a notable degree, in the marvellous dash of colour which pervaded the entire hall, an eloquent tribute was paid to our Herefordshire soil, which I feel sure our Kentish friends, so justly priding themselves on their superior climate and the consequent smoothness and symmetry of their fruits, will be the last to grudge us, roughly handicapped as we of the West Midlands are well nigh every year—even if we escape the spring frosts—before the early growths get a fair start. The size attained by the largest Apple among the collections of that noted exhibitor, Mr. Haycock, gardener to Mr. Roger Leigh, M.P., Barham Gardens, Maidstone, 1 lb. 4 ozs., was 2 ozs. in excess of the largest specimen in the Middlesex collection

at Chiswick, but not equal by several ounces to previous records attained at these exhibitions. The same exhibitor carried off the prize for the heaviest dessert Pear, Pitmaston Duchess, 1 lb. 8½ ozs. Indeed, it may be said that the clean and level as well as grand exhibits of this talented fruit-grower was the theme of general admiration, as I hear it also was at Chiswick.

I would venture here to guess at one great secret in Mr. Haycock's staging, conducing so signally to his success in gaining the Judges' fiat and popular favour. It is simply this, that, given the grand material he has to make the most of (of course, as Mrs. Glass says, you must first catch your hare), he always aims at levelling up throughout his entire collection, and thus never dwarfs a single specimen, or lets in a single weak corner, by introducing a disproportionate large plate or two. May it not be possible Mr. Haycock carries this principle too far in his magnificent collection of dessert Apples, for which he won first prize in an excellent class? Several noted fruit-growers, as Mr. Bunyard, pronounced it the finest ever staged. Still I venture humbly to suggest, first-rate as every plate was, that size throughout was too large for orthodox dessert Apples, where such all-round varieties as Queen Caroline and Blenheim Orange never (as here) should find a place. Perhaps the most interesting varieties were Melon Apple, Ross Nonpareil, perfect in colour; Mother Apple, Washington, superb specimen (from under glass I learn); Pine Golden Pippin, perfect; Margil, wonderful colour; and King of the Pippins, true type.

Mr. Thomas Griffiths, Tillington Nurseries, won the second prize with fine collection, including the refined Pomeroy, the fragrant Summer Queening, and juicy Astrachan, not to omit mentioning the local Phibury Pippin (called after one of Andrew Knight's many nurseries near Ludlow), a perfect model for a dessert Apple from its handsome neat looks, golden colour, and lasting properties. Third prize, Mr. John Watkins, Pomona Farm, Withington. Fourth, Mr. John Barnes, Hucclecote Gardens, Gloucester.

In culinary Apples, twenty-four varieties, Mr. Haycock was first with wonderfully bright and level specimens, specially including Royal Russet, Northern Spy, grand in colour and size; Bedfordshire Foundling, fine; Belle Duhois, immense; Lord Derby, splendid everywhere; Cox's Pomona, finest colour in the Hall; Lady Henniker, great acquisition; Annie Elizabeth, great size and density. Second prize, Mr. Ward, gardener to Lady Emily Foley. Third prize, Mr. J. Watkins.

The single plates, for which many private as well as committee prizes were offered, were very interesting and keenly contested, especially the Blenheim Pippin, Ribston Pippin, and Seek-no-Further, which appear to find a natural home in the orchards of Herefordshire from the number and excellence of the plates exhibited. Mr. H. Higgins, Thinghill, Hereford, took first prize for Blenheim Pippin and Seek-no-Further, and Mr. Haycock first prize for Ribston Pippin. The first Apple, I may mention in passing, is not being planted in such number as formerly, owing to the tree not coming into profitable bearing for many years. Mr. Haycock also took first prize for a high-coloured and fine Cox's Orange Pippin; and Mr. Haywood, Blakemere, first prize for the somewhat sensational culinary Apple of the district, Tom Putt, an everlasting bearer but no keeper.

Single plates of dessert Apples for present flavour were shown by Mr. Haycock, who was first with American Mother Apple, exquisite in flavour but too soft in flesh for most palates. Mr. C. Ross, gardener to Mr. C. Eyre, Welford Park, was second with Cox's Orange Pippin, of fine delicate flavour and crispness of flesh. Third, Mr. Walter, gardener to the Earl of Chesterfield, with the same variety; and fourth, Mr. H. J. Smith Brothers, Ledbury, with the Old Pomeroy. A grand class, twenty-eight plates.

Culinary Apples, for size, weight, and quality, any variety.—First prize, Mr. C. Haycock, 5 (plate of), with Belle Duhois, 6 lbs. 3 ozs. Second prize, Mr. Higgins, Thinghill, with Peasgood's Nonesuch, 6 lbs. 1 oz. This decision was not endorsed by the general public, the latter being of far greater diameter and more taking appearance, but the greater weight and density, and consequent longer keeping properties of the less popular variety perhaps rightly decided the Judges.

Dessert Pears for present flavour, any variety.—First prize, Mr. G. H. Piper, Ledbury, with small but exquisitely ripened specimens of Thomson's. Second prize, Mr. Wm. Woodhall, with small standard-grown Marie Louise, very sweet. Mr. Ross, Welford Park, Berks, unusually fine Seckle; and fourth, Mr. Haycock's Beurré Superfin.

Culinary Pears, for size, weight, and variety went as usual; first prize to Uvedale's St. Germain, Mr. C. Ross, 6 lbs. 4 ozs. Second prize, Mr. Trembling's Grosse Calabasse (under glass) 5 lbs. 7 ozs. Third prize, Rev. H. Tweed's Catillac.

In the class for any new variety of Apple or Pear there was no variety to call for special mention. Messrs. Saltmarsh sent a plate of their fine new Apple The Queen, lately certificated by the Royal Horticultural Society. Mr. George Bunyard brought also a plate of the promising new Apple Grenadier of large size and density. This well-known orchard nurseryman also brought a collection of twenty plates of the leading varieties of the day, not for competition, staged and named as one would expect from so high an authority. Messrs. Wheeler & Son of Gloucester also sent a collection of twenty varieties of Apples, not for competition, hardly up to the high reputation of this old-established firm. Messrs. Cranston & Co., King's Acre Nurseries, added considerably to the interest and success of the Exhibition, as well as to their increasing renown in fruit culture, by a really admirable collection of 150 varieties of most of the leading Apples in cultivation of a local and general character. The most noticeable perhaps were Chiffey Seedling, fine; Herefordshire Beefing, splendid colour, good bearer and keeper; Peasgood's Nonesuch, good everywhere; Stirling Castle useful; Sops-in-wine, curious, typically shown; Keswick Codlin (well kept), best early in Herefordshire as orchard tree; Lady Henniker, soon comes into bearing; Wiuter Queening, exquisite; Loddington, not its year.

Collection of dessert Pears, fifteen varieties.—First prize, Mr. Haycock. This exhibit was perhaps the greatest feature in the hall; certainly the finest I have ever seen staged as grown in England. They included—all nearly of same grand and level type—Triomphe de Jodoigne, General Todleben, Easter Beurré (enormous), Marie Benoist (grand), Conseiller de Cour, Pitmaston Duchess (almost as large as the Premier Pear), Doyenné du Comice, Beurré Diel, Doyenné Boussoch, Beurré Hardy (handsome), Passe Crassane, Duchesse d'Angoulême (immense), Durondeau (fine), Beurré Superfin, Nouveau Poiteau

Mr. Walters, gardener to the Earl of Chesterfield, was second with a smaller but clean bright collection, hardly up to the renown of the Holme Lacey cordon wall. Specially noticeable were Gen. Todtleben, Flemish Beauty (a real beauty), Marie Benoist, and Beurré Hardy (handsome). Third, Rev. E. Stacey, Wessington Court, Ledbury.

Suffice it to add that the cider and perry fruit classes were well filled, and as a useful result of these exhibitions, better filled than previously, with recognised varieties from which really good saleable cider and perry will be made. Sir Rupert Kettle sent a branch of the long willow-leaved Pear, and another full of fine fruit was also sent by Mr. Goodwin of Hampton Bishop. It is an interesting curiosity. Its botanical name is *Pyrus salicifolia pendula*, and it is being planted sparingly in the Herefordshire perry orchards to supply the tannin and acid which is apt to be deficient in perry Pears.

The gentlemen who kindly acted as Judges were Mr. Smith Carington, Worcester; Mr. George Bunyard, Maidstone; and Mr. Lewis Killick, Maidstone; the Rev. C. H. Bulmer, Credenhill Rectory, Hereford, and Mr. G. H. Piper, Ledbury, only taking the cider and perry fruit division.—THE HEREFORDSHIRE INCUMBENT.

BORDER CARNATIONS.

CARNATIONS are grown in nearly every garden, and I do not intend filling your space by making any remarks upon their popularity, usefulness, fragrance, or beauty, all of which are well known. These plants are perfectly hardy, and will, as far as I know, pass safely through our most severe winters. When this is the case why need we lift them at this season of the year or a little later, and establish them in pots and give them protection in cold frames until planting-out time in spring? Where two or three thousand plants are grown this practice necessitates considerable labour, besides occupying frame-room until they are planted out, and then, if the weather proves dry, good soakings of water until they are established. This potting system I have largely practised, and can say it has its advantages as well as its disadvantages. The latter, however, outweigh the former, and under these circumstances I do not see the utility of treating plants that are perfectly hardy as half-hardy.

If the plants were layered early they will now be thoroughly rooted, and can be lifted and placed at once in the positions they are to occupy for flowering next year. If they are well rooted and transplanted at once they will get fairly hold of the soil before winter, and do equally as well or better than if they had been potted, protected, and planted out in spring. When work of this description can be done in autumn it should be done, for in the spring so much needs attention. Perhaps the greatest disadvantage of autumn planting is the trouble slugs give, for they appear rather to appreciate the tender centres of these plants. These pests are very numerous in some gardens, but they can be destroyed. Before planting give a good dusting of fresh lime and soot to the beds and borders, and allow it to remain on for two or three days before digging. If this fails to remove the slugs and they attack the plants afterwards, select a dull moist morning, when the slugs will be out, and apply paraffin and water through a syringe to the whole bed on the same principle that has been recommended for miscellaneous plants in these pages. It is rare that autumn-planted Carnations do not start strongly and vigorously in the spring, and do even better than those that have been kept in pots and planted out in spring.

Carnations like a little fresh soil added annually to the beds in which they are planted, and for this purpose we use the soil which our Cucumbers and Melons have been grown, and in addition in this a little old Mushroom-bed refuse, but the former is preferable, and the plants thrive better in the beds to which the soil is applied than they do if only the manure is used. If fresh loam is used be careful that it does not contain wireworms, for they are the worst enemy the Carnation has to contend against. Whether wireworms like Vine roots or not, they are remarkably fond of making their way up the stems of Carnations, which, although they retain a fresh hue during the winter, turn yellow in spring and eventually die.—LANCASTRIAN.

KITCHEN GARDEN.

Asparagus.—The stems of this are now yellow and mostly withered, and as they serve no useful purpose afterwards they may be cut away a few inches above the soil, the ground being hoed, cleaned, and then given a good top-dressing. Where the roots are growing in beds and rather close together the whole of the surface of the soil may be dressed with manure, but when the plants are growing 3 feet asunder a little mound of manure need only be placed over each root. Roots which are intended to be lifted shortly for forcing need not be so treated. In lifting roots for forcing we do not take them all before us, but simply thin them by taking every alternate root, and as they are all young and annually developing, this practice suits them admirably. Before cutting down any of the stems we go over the whole of the quarters and put a short piece of stake in against each of the roots which it would be an advantage to lift for forcing, and by-and-by when nothing can be seen above ground these are good guides to lead to

taking the right ones. The roots should be lifted from the most crowded parts, and those which are strong and well developed will give the most satisfaction.

Storing Roots.—All roots of any value should now be under protection. Beetroot, if not already in, should be lifted and stored as directed some weeks ago. Carrots, which are a most important crop, as they must be kept sound and be plentiful for daily use until new Carrots are grown again in spring, should have every attention given them at this time. They are very hardy and will bear without injury a few degrees of frost, but they are better without this, and the best way of managing them is to take them all up now and store them in a cool shed or pit. In any case they must be kept in the dark quite dry. If allowed to lie exposed in a shed many of them will soon shrivel and become flavourless and colourless, but when packed in moderately dry soil, sand, or decayed leaf soil, or stored in a pit like Potatoes, they will keep excellently.

Stored Roots.—Potatoes and Onions which have been stored for some time should be examined now with the object of removing any that are decayed or wasting. Picking out one in time now may save nine in a case like this, and those which are quite sound will be likely to remain so for a long time to come, as any which are inclined to decay generally do so immediately after storing. Work of this kind should always be done on wet days.

Globe Artichokes.—In cold districts early frosts may injure these if not protected, and in all cases will now be benefited by being protected. They do not require very much, as it is sufficient to pack a quantity of decayed manure round the collar of each, and then put a little long litter or fresh-gathered leaves over this to protect the young leaves and crowns. The severe winters have sometimes injured them, but they always succeed best afterwards if a few of the leaves can be preserved throughout the winter.

Manure.—Wherever high-class vegetables are desired manure must always be the chief agent used in their production, and there are no kinds of artificial mixtures which can take the place of animal droppings. Cowshed manure is undoubtedly the best of all for the majority of gardens, and then comes that from stables and piggeries. Stable manure is not of much worth except for lightening heavy soils in a vegetable garden, especially when, as in our case, all the droppings are taken out for Mushroom-growing, the remainder being little better than straw. In all cases where at all available let a large quantity of cow manure be stored from now on during the winter, as it will be required from time to time onwards. We do not approve of having manure for growing vegetables stored for twelve months or more before using, as when only laid up for two or three months it may be used with the greatest advantage.

Vegetable Refuse.—In all gardens there is now plenty of various kinds of refuse, such as fallen leaves and tops, stems, and decayed leaves from many kinds of vegetables; every particle of this should be collected in a large heap, adding any old potting-shed soil and slops from the house as well as loose straw from the stable, and in fact everything capable of making manure, and as soon as a quantity has been gathered mix it well together by turning. In the spring this will be excellent for digging into Potato land or any portion of the kitchen garden.

Mushrooms.—Through the aid of Mr. J. Wright's excellent book the culture of these is rapidly extending, and many are induced to try Mushroom-growing now who considered themselves and their appliances quite incapable before. Let us ask those who do not succeed so well as they could wish with them in the open air to try a few small beds in any cool shed. We have a heated Mushroom house, but have ceased using it, and make up the whole of our beds in sheds. Any corner will do. They come freely in the potting shed, in the barrow shed, and in the tool shed, and being grown quite on the "cool system" they become fine in size and splendid in flavour. Sometimes we make a bed with one cartload of manure, and others have two or three in them. They are always spawned and covered before the heat becomes too low, and the surface is constantly protected with a thin coating of dry hay. When the bed has been soiled in the ordinary way it is a great benefit to the Mushrooms when they do appear to shake a little sand all over the bed and beat it gently in. This is one of the best means which can be employed to prevent the young Mushrooms from decaying prematurely. Beds made up now should be in full bearing by Christmas.

FRUIT-FORCING.

FIGS.—*Early Trees in Pots*.—Those from which the fruit is to be ripe by the close of April or early in May will need immediate attention in order to have everything ready for a start by the middle of this month. Potting or top-dressing having been performed in September, the house should be thoroughly cleansed, well washing the woodwork with soap and water, the walls being scalded with boiling water and afterwards limewashed, employing three parts quicklime to one of sulphur, and the house in other respects put into thorough going order. The Fig being much subject to attack from red spider and scale during the ripening process, the trees should be thoroughly cleansed, being careful not to injure the buds on the points of the shoots and spurs in first dressing them with a strong solution of softsoap (8 ozs. to a gallon of water) and afterwards with an insecticide. In washing, a hard brush may be used for the old wood, but the wood of the current year will need to be more carefully treated.

Succession Houses.—Houses in which the trees are planted out should be kept dry and cool for some time to come, but if these have been infested with red spider or other insects, pruning and dressing should

be followed up without loss of time. Root-pruning, lifting, and re-arranging the trees should be completed with as little delay as possible. In performing those operations it is well to bear in mind that Figs, when the roots are confined to a limited space, are most manageable and productive under restricted root space, hence it is better to err on the side of severe rather than light root-pruning. The fan is the best system of training, and branch-pruning is more a principle of thinning out the shoots that have reached the limit of the trellis than shortening back to make room for the young successional growths, which should be evenly disposed, with sufficient room for extension, over every part of the trellis.

Strawberries in Pots.—The plants intended for early forcing having been moved to quarters where they can be sheltered from heavy rains only, should have full exposure on all favourable occasions, and on no account must they be allowed to become dry at the roots. Standing the pots on Peach borders, where they must be exposed to piercing currents of dry air, is not suitable for Strawberries; indeed, the pots should be plunged in cocoa-nut fibre refuse or similar material, so as to insure uniform moisture at the roots, and when the drainage is perfect the roots will continue active until the plants are required for forcing. A slight covering of dry fern or litter in severe weather is all the protection required, removing it whenever the weather is mild. Although very little water will now be required the plants should be looked over, and any that require it should be given a thorough supply.

Early Fruiterers.—A batch of an early kind should be prepared for starting with the early vinery or early Peach house, and to which fire will not be applied until the early part of next month. See that the drainage is in thorough order, or make it so, and loosen the surface soil, removing a portion, but not injuring the roots, and add some fresh horse droppings rubbed through a fine sieve. Black Prince is still one of the best for very early forcing; Vicomtesse Hericart de Thury and La Grosse Suerée are good.

PLANT HOUSES.

Ericas.—The early-flowering varieties, such as *E. gracilis*, *E. caffra*, *E. melanthera*, and others, will now be coming into flower, and must have every care while in bloom if it is intended to retain them for flowering again next year. When used for conservatory decoration they are often crowded amongst other flowering plants, and in consequence much injured at the base. They should stand so that light and air can play freely about them, and should never while in such structures be allowed to suffer from an insufficient supply of water, or they will be useless for retaining for another year. Those in a more backward state that have only just formed their flower buds must have very careful attention, for if allowed to become very dry their flowers often will not come forward, but turn yellow; thus the work of a whole season is wasted. Light, air, and careful watering are the secrets of success at this season of the year. Keep a sharp look-out for mildew, which often attacks these plants during moist sunless weather.

Cyclamens.—Where these have been growing in cold frames they should now be housed without delay in a cool light airy structure. Frames are too moist for these plants at this season of the year, and if not removed where a somewhat drier atmosphere can be maintained their flowers and foliage are liable to damp. The earliest plants should now be strong in 4 and 6-inch pots, and some of them will have a good mass of flowers already above their foliage. These will be found most acceptable for the decoration of the conservatory and for room-decoration at the present time. Place a batch of the most forward plants on a shelf near to the glass in a temperature of 50° at night, which can be raised 5° more in a week or ten days. Admit air to these plants daily, so that their flowers and foliage will not draw up weakly. Give a little artificial manure on the surface of the pots, or water the plants every time they need it with clear soot water.

Primulas.—These should be removed from cold frames to shelves in vineries or Peach houses if better positions cannot be accorded them. These plants soon damp if kept in an atmosphere that is in any way confined; they should have abundance of air and light, and be placed near to the glass. Our earliest batch are now in flower, and have been removed to the conservatory. Remove flowers from all succession batches as they appear until they are wanted in bloom. The two latest batches will require potting, which should be done without delay. Those in 3-inch pots should be transferred to others 2 inches larger, except a few of the smallest plants, which will be found most valuable for many purposes of decoration in the size in which they are now in, and if liberally supplied with stimulants they will yield a large quantity of bloom when required. Where a very late batch is grown they will now be thoroughly established in 2-inch pots, these should have 4-inch. All that are repotted must be very carefully watered. The double forms we find do better if kept in a night temperature of about 50° where the air can be kept moderately dry. In this position they will continue to supply abundance of useful flowers in succession.

Cinerarias and Calceolarias.—These should still occupy cold frames, but must be in those with the most southern aspect. Attention is needed from the present time in ventilation. The ventilators must still be left open on the frames at night when the weather is mild. Watering must be done during the early part of the day, and no more water should be thrown about than is really necessary. Potting must still be continued as these plants require it, and the latest batch of both that are still in pans should be placed in 3-inch pots without delay if not already done. Give stimulants to the former when the pots are full of roots. Nothing

is better than clear soot water. Fumigate at the first appearance of aphides, but the foliage should be dry when doing so.

Carnations.—Tree and other varieties that have been grown for producing flowers during the winter and spring should occupy a light airy position in the greenhouse or other suitable structure where liberal ventilation can be given. Do not allow the plants to suffer by the want of water, and feed them moderately if the pots are full of roots. Do not attempt to force them, for a temperature of 50° at night, with ventilation daily, is ample, and in which the plants will for some time continue to unfold their valuable flowers.

Hybrid Roses in Pots.—Where these are required to be forced into flower early they should be placed under cover without further delay. The batch that has been prepared for this purpose can now be pruned. They should for early forcing be well cut back to one or two eyes, which is preferable to leaving them longer, for when forced early they do not break back so well as is the case later in the season. Where the stock of these has to be increased the plants should be lifted or obtained without delay and potted in 6 or 7-inch pots. If potted while the foliage is upon them they make a good quantity of roots and a better growth in consequence the following season. After potting, plunge them outside, entirely covering their pots with ashes or other material. Use for a compost good fibry loam, a seventh of manure, a little small bones, and sand according to the nature of the loam. If heavy, a good per-centage may be used.

Begonia Fraelii.—Another useful Begonia, with bright scarlet flowers, which are most freely produced during the autumn and winter, if purposely prepared for flowering at that season of the year. It is dwarf, and beautiful plants can be grown in 5 and 6-inch pots. This plant must be raised from seed, and useful specimens can be produced from seed sown now for next autumn. They can be better managed to flower at that season by using tubers that have been raised the year previous. Keep the young plants growing the first year as long as possible, so that they will rest until May, and then start them and grow them gradually, and by so doing they will be in the best condition for flowering at that season of the year for which they have been prepared.

THE FLOWER GARDEN AND PLEASURE GROUND.

Beds well planted with hardy flower and fine-foliaged plants are not unfrequently more gay, in April and May especially, than at any time when filled with summer bedding plants. Much depends upon the state of the plants at the present time. If strong and well rooted they transplant readily, are better able to stand the winter, and bloom more abundantly in the spring. Choose dry weather for preparing and replanting the beds, as it cannot well be done properly during showery weather. Where an early display is desired bulbs must be largely employed, and these may be either mixed in thinly with the flowering plants or be planted in masses, the surface of the beds being either carpeted with fine-foliaged plants such as *Festuca glauca*, *Dactylis glomerata*, *Cerastiums*, *Sedums*, *Pyrethrums*, or with sprays of Ivy, *Aucuba*, *Laurels*, and other evergreens dibbled in thickly. Mixtures are best avoided. The centre of the bed should be filled with one colour of Hyacinths or Tulips, another shade in a single row surrounding it, while either Snowdrops, white, yellow, or blue Crocuses, and *Scillas præcox*, *siberica*, and *amœna* can be used for an edging. The *Narcissus* being tall and very distinct, may well be banded with red or blue Hyacinths. Anemones, notably *A. coronaria*, form extremely pretty beds. Any of the above-mentioned carpeting plants divide freely, and may be dibbled in rapidly and neatly.

Plants suitable for edging the beds are blue Pansies, red Daisies, *Nemophila insignis*, *Aubrietias*, coloured Primroses, dwarf *Silenes*, with which may be mixed white and yellow Crocuses and Snowdrops, and yellow Pansies, common Primroses, *Cerastiums*, *Dactylis*, white Daisies, *Sedum glaucum*, with which may be mixed blue Crocuses and *Scillas*. Plants available for filling the centres of beds are blue, white, and yellow Pansies, *Alyssum saxatile*, *Myosotis* white and blue, and *Limnanthes Douglassii*, amongst which may be dotted any shade of red Hyacinths, and Tulips, and *Silenes*, *Saponaria* pink and white, white *Myosotis*, with which may be mixed blue Hyacinths. The dwarf Wall-flowers in masses are particularly effective, and with the dark-coloured sorts and *Saponaria calabrica* the *Narcissuses* may be associated.

Selections of Bedding Hyacinths and Tulips.—Hyacinths: *Alba maxima*, *Grand Vainqueur*, and *Baroness Van Tuyl*, whites; *Charles Dickens*, *Regulus*, *Marie*, and *De Candolle*, blues; *Robert Steiger*, *Von Schiller*, *Amy*, and *Fabiola*, reds; *William I.*, violet-black; *Victor Hugo* and *Anna Carolina*, yellows. Single Tulips: *Due Van Thol*, red and yellow; *Vermillon Brillant*, *Purple Crown*, rich crimson; *Cottage Maid*, white and rose; *Artist*, crimson; *Eleonore*, violet-purple; and *Canary*, yellow. Double Tulips: *Due Van Thol*, red and yellow; *La Candeur*, white; *Yellow Tournesol*; *Tournesol*, red and yellow; *Rex rubrorum*, red; *Etoile Cramoisie*, violet-crimson; and *Murillo*, blush rose.

Evergreen Shrubs and Coniferae for Bedding Purposes.—There are many kinds of these available for furnishing the beds during the winter months, and which can be transplanted from the reserve garden and back again at almost any time of the year. These, again, are not so effective when in mixture as when grouped in masses or to fill spaces in a design. Dwarf and neat they should be, and in this state can be purchased cheaply in large quantities, and the frequent removals check any strong growth. The list includes *Andromeda floribunda*, *Aucubas* in variety, *Buxus japonicus aurea* and *B. sempervirens aurea*, *Cotoneaster microphylla*, *Cupressus Lawsoniana* and its varieties, *Cryptomeria*

elegans, Erica herbacea carnea and vulgaris aurea, Euonymus japonicus and its silver and golden-variegated varieties, E. radicans variegatus, golden and silver-variegated Ivies, Juniperus tamariscifolia, Laurustinus, Japanese Privet, Mahonia aquifolia, Osmanthus in variety, Pernettya well berried and in variety, Retinosporas ericoides, obtusa, aurea nana, plumosa, argentea, aurea, and squarrosa, these being among the best of plants for the purpose; Skimmia japonica, Taxus baccata elegantissima, Veronicas decussata and Traversii, Vinca elegantissima, and Yucca recurva, this being well adapted for a central position both with spring and summer bedding plants.

Hardy Carpet Beds.—Those who employed hardy plants either for lining out or forming the groundwork of the designs may with but little trouble preserve a good appearance during the winter. The Alternantheras can be replaced by Ajuga reptans rubra, Iresines by the smallest Beetroot procurable from the kitchen garden; while the creamy variegated Arabis, golden-variegated Daisies, Golden Thyme, Stellaria graminea aurea, Golden Pyrethrum, Stachys lanata, Festuca glauca, and Dactylis glomerata can all be worked in. Large pieces had in most cases be better divided, and any long straggling leaves trimmed off. A well-established piece of Iris foetidissima variegata may be easily divided, and small pieces be used as dot plants. So also may be employed small plants of Yucca recurva and the variegated Retinosporas.

Dahlias.—There are thousands of seedling single Dahlias that are not worth preserving, and those, therefore, who have raised a lot should look them over at once and mark the best. The labels or other distinctive marks attached to the named doubles and singles should also be renewed in order to avoid confusion in the spring.

THE BEE-KEEPER.

ROBBING AND ITS REMEDY.

THE following letter has been forwarded, to which we append the reply of an experienced apiarian, the subject being of general interest.

"I have been feeding my bees from the middle of August to near the end of September, when, seeing that honey was stored near the windows, I wrapped up the hives for winter. About two weeks ago I noticed robbing going on, so closed alternately the hives of robbers and robbed, opening them on alternate days. Last week on a sunny day, not seeing any bees from the hive that had been robbed, I lifted it to examine and found it empty, only very few dead bees on floorboard. The combs are very dark, and mostly filled with what I take to be bee bread, and not room for much honey, of which there was none. The hive has been in use since 1880. It threw off two swarms in the spring, and I had only one glass super containing about 3 lbs. of honey. Can you give me any advice for future guidance, and the bees having once robbed will they be always robbers? I find I did very wrong in allowing them to clear some honey from a plate outside the hives. Wasps have been very troublesome. Could they have had anything to do with loss of bees?—E. S. W."

"E. S. W." acted wisely in feeding the bees during the latter part of August and through September, also in making the hives snug when October came and bees settle down into winter quarters. We do not gather how many hives of bees are kept by "E. S. W.," but whether only two or more, one hive was attacked and the stores carried off by the robbers. When examined, the pillaged stock was found to be without honey or bees; and since no mention is made of brood, we conclude that that was also entirely absent. The combs were dark—they naturally would be so after three seasons' use, and contained quantities of pollen. This hive had sent forth two swarms during the current season and had given a small glass super of honey. This super was doubtless filled during the time between the departure of the first and second swarms.

It will be remembered that, although the early spring was most promising, the weather became very wet and stormy towards midsummer. The usual consequence of such inclement weather in the height of summer is that many hives become either queenless, or young queens fail in bringing their matrimonial advances to a successful issue, and so remain drone-layers only. In either case the chances are that the hive dies out or becomes the prey of its stronger neighbours. Should the young queen be lost on her honeymoon excursion the bees may be able to raise another queen after the issue of the first swarm; but this is impossible should she be lost after the cast or second swarm goes forth, for by that time all the eggs left by the old mother queen, who led off the prime swarm, will either have hatched out or become grubs in a state too far advanced to be fed so as to develop the perfect queen.

We have entered fully on this explanation in order to support our opinion that the robbed hive was previously queenless and had been so for a long time, and this is most likely the correct

cause why it so easily succumbed to its enemies. We do not think that wasps destroyed it. We have often heard of wasps destroying stocks of bees, but have never yet met with any positive proof that such was the case. Certainly if a hive escape the searching inquiries made by robber bees it might so dwindle and dwindle that at length the few remaining bees might be destroyed by wasps. But our own experience is that weak hives invariably yield to the superior force of strong ones, and after making a poor and ineffectual resistance, generally join with the robbers in removing the spoil, and so survive with the fittest. "E. S. W." is quite right in supposing that the robbery may have been begun through honey having been set in a plate to be taken by the bee. We have had gallons of liquid honey standing in the open garden during a honey glut, and the bees have left it unnoticed, while we have continued extracting close to the hives. But in a bad season, and more especially towards the close of the season, the bees are thoroughly demoralised if once they get the scent of honey in proximity to their hives; and although robbing is so easily started, it is not so readily put an end to. We, however, still hold to our opinion that the attacked colony was queenless. A hive, even when weak, with a queen at its head, and with perhaps brood as well as stores to protect, will fight much more fiercely than the one in question seems to have done, since "very few dead bees" were to be seen on the floorboard.

We found on one occasion that carbolic acid was an excellent weapon to use against robber bees. Many years ago, when we kept a number of straw skeps, very large ones, we had an accident while overhauling a stock. It slipped from our hands, and the blow against the floorboard brought down several slabs of newly stored comb. There was a complete smash, and a thick stream of honey was soon running down the posts which supported the stand. It was late in the season, and before we could collect and clean up the honey a cloud of bees from some twenty hives was about us. We could only remove the stock to a distance and confine the bees left in it. Ultimately the colony was saved and did well another year; but we shall never forget the battle we had to fight with the other stocks, and but for the aid of the carbolic acid there would have been a civil war of extermination. The tumult was quieted thus. First we very much sprinkled the position first attacked with the dilute acid. It was applied pretty strong, however, for we found that out by the appearance of the skin on our hands wherever the solution had touched it. After several attempts the bees began to fight shy of the bedewed spot, and then we soon found that the neighbouring hives were being systematically attacked. With a feather a magic circle was drawn before the entrance of every hive that seemed weak, and, so far as we can now recall the event, nearly every hive had to be protected one after the other in the same manner. Entrances were reduced, and by the vigorous application of "the mixture" the enemy was repelled, while the inmates of the several hives ran the gauntlet as shades of evening fell, and at last all was quieted by the darkness. We renewed the application early next day, but the attack was feeble and the danger had passed. When any bee-keeper has a bad attack of the robbing mania among his bees let him try a solution of carbolic acid.

Because "E. S. W.'s" bees have once robbed there is no reason to suppose that they will always do so. We do not see how the theory of evolution will so act as to cause the next summer's occupants of a robbing hive to become more determined marauders. Neither the queen nor drones assist in the assault, and the bees which rob in late summer will have little chance of remaining long on the scene next season. The first hard work of the new year will soon remove them, and young bees will take their places which will know nothing of robbery, unless ill-gotten gains stored by their forerunners develop the piratical instinct in them as they consume them.—P. H. P.

BEE FARMING.—The publication of an interesting letter on this subject in answer to a series of questions on page 365 is unavoidably postponed.

TRADE CATALOGUES RECEIVED.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Select Fruit Trees.*

William Meadmore, Romford, Essex.—*Catalogue of Roses.*

Waite, Nash, Huggins, & Co., 79, Southwark St., London, S.E.—*List of Flower and Vegetable Seeds.*

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees, Shrubs, and Fruit Trees.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Garden Chemistry (S.).—We are obliged by your letter, and the subject which you bring before us shall have full consideration.

Selection of Fruit (W. R.).—In answer to your inquiry this week, last week on page 367 Sturmer Pippin was accidentally printed Summer Pippin.

Primulas (M. H.).—The flowers as regards size and form are of average merit. There are many larger and much richer in colour of which seed is sold by florists, nurserymen, and seedsmen who devote special attention to these plants.

Fungus (W. J. J.).—The fungus resembles a very small example of *Agaricus arvensis*, an edible species, but we should not advise you to eat it, as the specimen sent is very imperfect.

Burnt Clay for Vine Borders (G. T.).—The material you name, and which is known as ballast, is well adapted for mixing with soil for Vine borders for insuring porosity, and partially burnt clay is valuable for mixing with light soil for the growth of Vines. You may add lime rubbish as well if you can obtain it, and if the soil does not contain lime this also should be supplied. The ballast itself has little or no manurial value, but may be mechanically very useful in the border.

Insects (W. D. C.).—Insects so small usually arrive in such a shrivelled state as to render their identification impossible. This was the case with those you sent. We do not think they would attack Cyclamens either above ground or below if the plants were healthy, but they may possibly be found on decayed corms, in which case they are not the cause, but a result of the disease that may affect them.

Vine Roots (J. N., Swansea).—The roots we received a fortnight ago were examined at the time for signs of the attack of the phylloxera, concluding in the absence of any letter referring to them that they had been sent for that purpose. There were no symptoms of the presence of the pest either on the roots or leaves. Both are shrivelled now. You say nothing about the age of the Vines, but simply state they are in "bad condition." In all probability they will be improved by the fresh soil you propose supplying, and otherwise good treatment.

Isabella Sprunt and Madame Falcot Roses (S. J. W.).—As to "which is the best Rose for affording pretty buds for cutting, Isabella Sprunt or Madame Falcot?" that is a question of taste, and as we cannot recommend one without in effect condemning the other, we advise you to grow them both. This is the more desirable, too, as they do not succeed equally well in all places and under all circumstances.

Late Peaches and Nectarines (T. A., Wharfedale).—To your Peaches you may add Belle Bauce, Barrington, and Walburton Admirable; and to your Nectarines Pine Apple and Victoria. The sprays you have sent are of *Crataegus tanacetifolia*, a very distinct and ornamental species.

Bonemeal for Roses (North Herts).—You cannot have anything better than this for mixing with the soil for Roses. The quantity to use depends entirely on the fertility of the soil. If it is poor you may use a quarter of a peck to a bushel; if moderately fertile half that quantity will suffice. Roses like plenty of half-decayed manure incorporated with the soil, and a good layer of this spread on the surface over the roots.

Excluding Frost from a Conservatory (Amateur).—We scarcely understand your question. Do you not intend to have a boiler and hot-water pipes? For supporting it we should certainly prefer iron pillars, and a thick layer of prepared felt under the floor would be advantageous. As for the sides, "so far as the wood goes," they will exclude cold far better than the glass will. That is when the cold will chiefly enter, and you cannot keep the house pleasant for either yourself or the plants without artificial heat. You have left spaces for figures in your letter, as if you intended to fill in the blanks and forgot to do so.

Pears in Pots (H. S.).—You ought to have no difficulty in growing and ripening autumn and early winter Pears under glass in your cold locality; but you say your trees in pots do not bloom, and then ask us the reason. We cannot tell you the reason until you describe the condition of the trees. They are either underfed or overfed—that is, make too little growth or too much; if too much, the wood does not ripen. If you will state the age, size, and condition of the trees, with your method of growing, we will endeavour to aid you. We have not tasted better Pears this year than Doyenné du Comice that were gathered from a tree in a pot, and of which a reduced cluster is figured in our present issue. This variety, Williams' Bon Chrétien, Beurré de l'Assomption, Souvenir du Congrès, Louise Bonne

of Jersey, Marie Louise d'Uccle, Fondante d'Automne, Comte de Lamy, and other autumn Pears will ripen in your locality if well grown in pots and a suitable structure is provided for the trees.

Mignonette Failing (Idem).—It requires calcareous matter, and seldom fails to grow where plenty of lime rubbish is mixed with the soil. Try some in pots in which one-sixth part of the soil consists of lime rubbish, and the whole made firm. The plants will grow in this if they are properly watered and have abundance of light and air. Your question on Vines will be answered next week.

Apples not Bearing (Lundy Lane).—A general question of this kind cannot be answered satisfactorily, as it would involve our writing an essay on fruit. If from time to time you require information and will describe the condition of the trees that may not be satisfactory we will readily assist you if we can; and we think we shall be able to do so if you state your case plainly and clearly. The most profitable Strawberries grown for market in Kent are Vicomtesse Hericart de Thury and Sir Joseph Paxton, the latter being the larger, the former perhaps the most productive and hardy, both travelling fairly well when properly packed. We are not able to say whether they will succeed equally well in Canada. If you try them we shall be glad to hear from you on the subject.

Cotoneaster Simonsii (R. B.).—This is the name of the shrub of which you have sent us a spray, and it is very ornamental trained against walls. We have not seen a hedge of it, but hedges of *C. microphylla* are very handsome. The plants are propagated by layers and from seed. Half-ripened shoots pegged into the ground now, and the soil kept moist in summer, emit roots abundantly. The seed may either be sown now in drills in the open garden or be stored in moist sand and sown in the spring. In either case have the drills a foot apart, and cover the seed 2 inches deep with fine soil. It is long in germinating, and all the plants will not appear till the following spring. They grow rapidly, however, in good soil, and soon attain useful dimensions. The position of the drills should be marked with sticks at each end, and by stretching a string from one to the other over each drill the ground between can be kept free from weeds by running the hoe through it frequently.

Passion-flowers (H. S. P.).—Some Passion-flowers are hardy in favourable districts, others succeed in greenhouses, while several require hothouse treatment. If you will send us particulars of your plants and where they are growing we will endeavour to aid you; at present you do not enable us to give you a reply that will be of service. Are your plants unhealthy? If you will examine page 345 of our issue of October 18th, you will find a reply on *Calceolarias* in frames. We fear you do not read attentively.

Zonal Pelargoniums in Vinery (S. E.).—Fire heat with ventilation will be beneficial to your Vines now rather than otherwise, while a rather dry atmosphere will not be injurious to the plants. You had better not prune the Vines at present, but as the leaves turn decidedly yellow they may be safely removed instead of waiting for them to shrivel and fall. If your gardener has carried out your instructions and nipped off the growths immediately above the flower truss, and your plants do not flower continuously, do not blame him. That is a good method to adopt in summer for producing large trusses, but is the worst that can be indulged in now with plants that are desired to produce an unbroken succession of flowers throughout the winter.

Hybrid Perpetual Roses for Forcing (M. Taylor).—We find the six that force the most readily into flower early in the season are La France, Anna Alexieff, Abel Grand, Jules Margottin, Alfred Colomb, and Général Jacqueminot. For forcing, and to form a good succession later in the season, we consider the following twelve amongst the best:—Victor Verdier, Charles Verdier, Magna Charta, Marie Baumann, Fisher Holmes, Louis Van Houtte, Duke of Edinburgh, Madame Lacharme, Sénateur Vaisse, Coquette des Blanches, John Hopper, and François Michelin. In addition to these there are many varieties that are admirably adapted for cultivation in pots, and will flower well and give the greatest satisfaction if brought forward gradually under cooler treatment.

Determining Poisonous Fungi (Bodface).—Many rules have been given for determining poisonous fungi, but there are generally so many exceptions to them that they are unreliable and useless. They sometimes exclude a number of edible kinds, and at others include a few rare forms possessing injurious or doubtful properties. The only safe way is to study the species, and acquire a familiarity with their characters, when, as most of them are very distinct, they can be readily recognised. Several popular works are now published which would enable you to ascertain the names of the principal useful and obnoxious species, Dr. M. C. Cooke's "Handbook of the British Fungi," published by Mr. D. Bogue, St. Martin's Place, Trafalgar Square, price 6s., being one of the best. Carefully avoid all fungi that are in any degree doubtful; the majority that are highly coloured or which possess strong and offensive odours are poisonous, and some apparently very innocent species are similarly dangerous, but with a little application you will soon be able to recognise at a glance the most common kinds in each group. It must be also borne in mind that it is unwise to eat large quantities even of the most harmless, and careful cooking is most important, with a liberal use of condiments, such as pepper and salt. If you like to collect a few good examples of the principal fungi in your neighbourhood, numbering them, and keeping duplicates for yourself, we will endeavour to name them if you forward them carefully packed and carriage paid to this office.

Discharge of Gardeners (D. F.).—Your letter is far too inexplicit. It is necessary to know the allegation of the employer, whether it be ill or well founded. We can only say that if a gardener is paid weekly a week's notice to leave on either side is sufficient in the absence of any agreement to the contrary, and it is customary to give such notice at the end of a week (or before work is commenced on the following Monday), not in the middle, though circumstances may arise rendering this latter course legal. It is extremely doubtful if you would gain anything by taking legal proceedings, as even if you were to do so and win you would probably find your success costly, while to lose might be little short of ruinous. If an employer give a week's wages in lieu of notice, and the gardener has cottage, coals, vegetables, and milk as part of his wages, he must also be compensated for the loss of these during the week, according to the value at

which they are estimated. An employer is not compelled to give a character to a servant, but if he writes anything that is untrue about him, and thereby injures him by preventing him obtaining another situation, such employer renders himself actionable, and may be compelled to afford adequate compensation to the person whom he is proved to have injured unjustly.

Chamærops Out of doors (Sussex).—The well-known *Chamærops humilis* is the hardiest of Palms in cultivation, and is the only one found in Europe. This in the south of England succeeds well out of doors, and needs no protection; but in exposed cold or damp situations, even around London, it is frequently injured during winter if not protected. The same remarks apply to *C. Fortunei*, which is, however, generally less hardy than the other, though in some gardens it requires no protection. Two of the finest specimens we have seen are at Heckfield, Winchfield, Hants, the seat of Viscount Eversley. These were planted in 1869, and now have massive trunks and large heads. The plants or trees have had no protection afforded them since the first winter after they were planted, but they are supported with fresh soil annually, the turf being removed for that purpose and laid down again. It is to this care that must be attributed the large, handsome, glossy leaves. They are well matched in every respect, as they are not only of the same size but of different genders, and are the parents of many plants that have been raised from them since they were established in their positions. No doubt they would succeed equally well in your district if the soil is not too heavy. The *Cordyline* we do know under the name mentioned, but it is probable that it would have survived if it had been efficiently protected.

Liliums in Pots—Pipes for Heating (F. J.).—Some of the finest examples of *Lilium auratum* in pots are so grown by the cultivators year after year—that is to say, fresh bulbs are not obtained annually. There is no better time for potting than, as soon as the stems die down, shaking most of the old soil from the roots and removing the dead fibres, but retaining the strong fleshy roots that are usually attached to the bulbs. A compost of half loam and half turfy peat, with sand or gritty matter added liberally, is suitable, the bulbs to be covered an inch deep, but the pots not filled with soil, as it is desirable to leave space for subsequent top-dressings when stem roots are produced. The pots may be buried in ashes in a frame the same as Hyacinths, and there remain until growth appears from the crowns. If when the bulbs are examined they are small or decayed through any mistake in the management of the plants, they cannot of course be expected to give satisfaction another year. By all means use the ordinary metal pipes for heating your greenhouse. Although, as you suggest, thinner pipes "heat more quickly," they also cool more quickly, and this is certainly not an advantage when the fire gets low or goes out when you may be warm in bed on a cold frosty morning.

Cucumbers in Winter (Subscriber, Ireland).—We have not tried the two varieties you name, but should certainly do so if we had plants now in a forward state in pots. We have found the Cardiff Castle and Telegraph varieties answer our purpose well. But you will not find it easy to raise strong healthy plants so late in the season from seed; and if you have not had experience in growing Cucumbers in winter you must not be surprised if you find your first attempt disappointing. You are at least two months too late in starting, as plants for bearing well in winter require to be strong now and more than half covered the trellis. You will require a temperature of 70° without overheating the pipes, and a bed composed of fermenting materials will be useful, though Cucumbers can be well grown without it when sufficient bottom heat is in other ways provided. Instructions for raising plants for winter were given at the proper time in our "Work for the Week;" it is a pity you had not seen them and acted on the advice there published.

Nec Plus Meuris Pear (I. M.).—There is indeed a Pear of this name and a very good one it is when well ripened. It is described as follows in the "Fruit Manual":—"Fruit medium sized, 2½ inches wide and the same high; roundish turbinate, very uneven and bossed on its surface. Skin rough, dull yellow, very much covered with dark brown russet. Eye half open, generally prominent. Stalk very short, not at all depressed, frequently appearing as a mere knob on the apex of the fruit. Flesh yellowish white, buttery, and melting, with a rich, sugary, and vinous flavour. A first-rate Pear; ripe from January till March. It succeeds well as a pyramid, but is best from a wall. This is a seedling of Van Mons, raised in his Garden la Fidélité at Brussels, and named as a compliment to Pierre Meuris, his gardener, of whom Van Mons said, 'Meuris est né avec la genie de la Pomonomie.'" Thus the origin of the Pear accounts for its curious and fanciful name, out of which we are not surprised you could extract "no meaning." A tree ought to bear long before it is of the age of yours. If your tree grows luxuriantly and produces little or no blossom it needs root-pruning. Digging up and replanting it, making the soil firm about the roots, would no doubt induce it to blossom freely. If the growth is very strong try this plan, and the sooner the work is done the better, only let it be done carefully, reserving all the fibrous roots and keeping them moist, only cutting off at 4 feet distance from the stem the roots that are strong and fibreless. If the growth is only moderately strong, the tree may be dug half up this year by cutting the roots on one side and any that penetrate downwards, completing the operation another season.

Propagating Conifers (E. P. C. B.).—The following extract from the writings of Mr. Bardney on this subject, which are founded on practice, will answer your inquiry:—"At no period of the year is the propagation both of hardy flowering shrubs and Conifers carried on in nurseries with greater rapidity than from the present time onwards. The majority of Conifers are propagated by means of cuttings and grafting, many Pines excepted, and a few common varieties of Cupressus, which are readily raised from seed. The system adopted where the work is carried out on a large scale entails much labour. Narrow beds are formed about 2 feet wide, with a row of bricks placed edgewise on each side of the bed, leaving the tops of the bricks just above the soil. Handlights or small glazed boxes about the same width, and about 3 feet 6 inches in length, are in readiness before the cuttings are inserted. A heap of coarse river or red sand is placed at hand, and a good proportion is mixed in the soil, the surface being covered about half an inch in depth, after which it is ready for the cuttings. These, when the wood is fairly ripened, are frequently taken from the plants intended for

sale, and others from stock plants kept in borders for the purpose. Some care is necessary in taking them so that the plants be not disfigured. The portions intended for cuttings should be so taken that when dressed each will have a heel. It is necessary that the cut be cleanly done with a sharp knife. The cuttings should be made clean for about an inch of the stem near the base, and should be from 2 to 4 inches in length, but the length matters little provided a good heel is left and the wood is in a proper state of ripeness. This mode of making the cuttings applies with equal force to all the Cupressus, Thuias, Retinosporas, and many others, but such kinds as *Cryptomeria elegans*, *Retinospora ericoides*, and others equally free strike readily without a heel. The cuttings are inserted as thickly as possible under the handlights on the prepared border, making the soil firm around them. A good watering is then given and the handlights placed over them. These miniature frames are generally arranged in rows, leaving about 2 inches between each bed to allow room for the frames to be removed as occasion may require. Little trouble is necessary afterwards, only giving shade if the sun proves very hot for a time after the cuttings are inserted. It is scarcely necessary to again lift the lights before the early spring, as the cuttings seldom need water before then. Sufficient will soak in round the handlights during wet weather, and keep the soil moist during the winter. The cuttings should be kept as close as possible until they are well callused, which will be the case in spring, as if air is given in their early stages many of the cuttings may damp off. During winter the only attention that is needed is to cover the frames with mats or other protecting material in severe weather. It is better if they can be so covered as to exclude all frost, but this is not absolutely necessary. I have seen the soil frozen hard for a long time and little or no injury has resulted therefrom. Another course of propagation can be effected by placing the cuttings in pots in the Conifer house, which is generally kept at a temperature of 40° to 45° during the winter. This system is practised to a large extent because smaller cuttings can be employed, which is often convenient with new and choice varieties." We know of no work in which this subject is so fully treated as by the writer referred to in our issues of September 8th and 22nd, and October 6th, 1881, vol. iii., third series. If you do not possess these numbers they can be obtained from the publisher at the ordinary price of this Journal, plus the postage, in your case to France. There is no work published such as you desire to obtain.

Storing Potatoes (Idem).—The simplest method is to pile them when dry in heaps formed like the ridge of a house on a plot of hard smooth dry ground, covering them thickly with straight and dry straw, then digging a trench round the heaps and placing the soil on the straw of the desired thickness for excluding frost. The heaps may be 3 feet wide at the base and the sides made as steep as possible, as if flat the rain will not be excluded.

Naming Fruits (To Correspondents).—Despite the conditions that we are compelled to impose we have every week large boxes and hampers of fruit, also requests for replies by post, which it is absolutely impossible can be attended to; in fact, large consignments cannot even be examined. Fruit is sent in such quantities that space can scarcely be found for the packages, and the air of every room in our establishment is so saturated with the effluvia from the fruit that our employes have made serious complaints of its affecting their health. We are willing to name small quantities of fruit for a useful purpose, and do our best to do so; but we ask for some consideration under the circumstances. Miserable specimens of worthless varieties are frequently sent that are neither worthy of names nor culture. We are sorry to say that we have been imposed on by individuals who have made it their business to gather fruit from wherever they could and send it to us for names out of mere curiosity.

Names of Fruit (James Sheil).—Marie Louise. (*Chelto*).—Rambo, an American Apple. (*J. Mackenzie, M.D.*).—1, Winter Nelis (?); 2, not known; 3, Beurré Superfin. (*H. Wright*).—Hollandbury. (*R. J. L.*).—6, Dr. Harvey; 7, Cox's Orange; 8, Margil; 9, Sykehouse Russet; 10, Cockle's Pippin. (*Medicus*).—1, Winter Pearmain; 2, Hutton Square; 3, One of the fruits is Sturmer Pippin, the others are not; 4, not known. (*J. E. K.*).—1, Golden Winter Pearmain; 2, Cox's Pomona; 3, Cellini; 4, Reinette de Canada; 5, rotten; 6, Fondante d'Automne. (*T. Prothero*).—1, Cellini; 2, resembles Bramley's Seedling; 3, Minchull Crab; 4, Cox's Pomona; 5, Alfriston; 6, Ecklinville. (*Rev. W. Jenkins*).—1, Autumn Red Calville; 11, Yorkshire Greening; 2, Wyken Pippin; 5, Claygate Pearmain; 6, Longville's Kernel; 8, Norfolk Colman. (*J. E. Waiting*).—1, Marie Louise; 3, Ne plus Meuris; 4, Beurré Diel; 5, Beurré Clairgeau; 6, Napoleon. The Apples are rightly named, and the fruit is very good indeed. Your treatment was very skilful. (*G. R. A.*).—The seedling is a firm good Apple resembling Round Winter Nonesuch. No. 2 is Reinette de Canada. The small Pear is not the Warden, that being a large brown stewing Pear; the other Pear is Forelle. (*J. B.*).—Autumn Red Calville; 2, not known; 3 and 4, Golden Winter Pearmain. All the fruit has been attended to that we have received, except where it has been sent in very large quantities. Some small packages have arrived without any sender's name accompanying them, and we are quite unable to determine to which parcels the letters that have been received by post refer. One box contained Soldat d'Esperen and Dunmore Pears, which are correctly named, the other fruit in the same box being decayed.

Names of Plants (E. T. H.).—The plant is *Ampelopsis Veitchii*, which sometimes grows very large, particularly when loose from a wall, and in very rich soil. (*Pen and Ink*).—Your plant is *Vallota purpurea*, a Cape Amaryllid, and valuable for its property of flowering so freely in the autumn. It is grown in many gardens for decoration in the autumn. (*F. T., Reading*).—The Conifer is in all probability *Pinus cembra*. (*R. E.*).—1, *Anthoxanthum odoratum* var. *Puelli*; 2, *Panicum pinetorum*; 3, *Avena elatior* (*Arrhenatherum avenaceum*); 4, *Daucus Carota*. (*B. W.*).—1, *Adiantum hispidulum*; 2, *Gymnogramma calomelanos*; 3, *Asplenium viviparum*; 4, *Asplenium Belangeri*; 5, *Davallia elegans*; 6, *Davallia tenuifolia* var. *stricta*. (*Preston*).—*Maxillaria nigrescens*. (*J. J., Lancashire*).—1, The spray with four flowers is *Trichopilia albida*; 2, *Epidendrum nocturnum*; 3, *Odontoglossum Schlimii*; 4, *Odontoglossum hebraicum*. (*H. J.*).—1, *Odontoglossum grande*; 2, *Elæagnus argentea*; 4, *Abies Mertensiana*; 6, *Aspidium aculeatum*. The other specimens are insufficient for recognition without flowers or some information respecting the habit and character of the trees or shrubs. (*Aurora*).—The plant is *Tamarix gallica*, a native of European countries, and found growing near the seacoast. You will see abundance of it at nearly every watering place on the south coast of England.

IMPROVED DAIRY CATTLE.

(Continued from page 368.)

BEFORE giving our proposed mode of mating the animals to produce the type and character of stock desired, we propose to refer the best classes of cattle available for the purpose, and the stock will consist of two breeds only—viz., the Shorthorn and the Guernseys. We will first describe the style and character of the Shorthorns which appear best adapted for the objects in view—namely, the improvement of the Guernsey cattle. There are in the Shorthorn breed at least four distinct types:—the milking type; the long heavy fore-quartered type, such as graziers approve; the big up-standing, quick-growing stamp, which fills the eye at a market of store cattle; and the square lumpy bulls, which have done so much for Aberdeen and polled crosses. In making a selection for the purposes of a single cross with a Shorthorn cow and the Guernsey bull we must adopt as our type the milking type, but not pure and simple as above stated. What, then, is it we want? Why, deep milking animals or great milkers, would describe them more, exactly probably; but at the same time we require animals which yield good flesh points also to a certain extent. Then arises the question, How far can we trust an animal which is in the Herd-book of Shorthorns, or commonly called Pedigree Shorthorns? Practically it is impossible to obtain good milkers or deep milkers from full pedigree stock, but we have tribes to fall back on which give us the full advantages of a perfect beef-making animal in all points excepting one—that is, the shoulder top, which in full pedigree animal is covered with a heavy pad or roll of fat and flesh. No great milker can ever be obtained with such a characteristic in the formation of the shoulder top, and whenever it has been seen it was an exception to a rule which practical men as judges of deep milking Shorthorns assert that it is impossible to expect great milking qualities unless the udder is large and well formed, and the shoulder top is comparatively thin, also affecting the shape of the neck at its junction with the shoulder, and to some extent the chine for 6 or 8 inches behind the shoulder top point.

The next thing to be considered is, that if we cannot have the deep milking animals without making this concession to perfection of form, how much can we retain of the points remaining in an outline and conformation called perfection? The especial formation which we require to make the most valuable and perfect milking animal is a very slight loss to the butcher, because the meat upon the shoulder top and the base of the neck or portion of the spinal connection as above stated, only carries flesh of an inferior kind, and is sold by the butchers at almost as low a price as offal. In the selection of our deep milking animal we have or may have depending upon our own practical judgment in selection or breeding all the flesh points except those named; for although we have a bare narrow top to the shoulder points, yet there is no reason why the outline may not be all that can be desired, and also the length of carcass, which is frequently greater than in animals showing all the butcher's points. Again, we may have a deep wide chest and deep wide brisket, so essential to the constitutional development of cattle, and likewise all the width of frame which constitutes the general weight and character at weight for age of a perfect butcher's bullock; therefore the concession made to the milking animal of its points to assure it are small compared with the vast importance of the gain by animals of the best milking type.

It may be asked, Whence comes this bold assertion of ours and our practical brethren? We reply, From our own practical observation of the conformation of our best milking tribes, for in any breed of cattle it will be observed, and although we do not read of it much in various essays upon the breeding of cattle, yet we find it alluded to by Mr. Dixon in the Journal of the Royal Agricultural Society of England in his essay "On the Rise and Progress of Shorthorns," in 1865. He says—"Still, good milking pedigrees do not command an extra price, and in fact any allusion to them in a sale catalogue is rather regarded as an apology for doubtful or unfashionable blood. 'Something to give milk for the house,' is too often spoken of as a mere humble adjunct, and 'not worth dwelling upon' at the end of a row of high-bred cows and heifers, many of which are systematically

died off to keep them in bloom for shows or visitors, while their calves are provided with a nurse. A young heifer is selected with a view to well-covered flesh points, early maturity, and fine mellow handling: and there is none of that Ayrshire acumen at work which gives laws for the exact shape of the 'milking vessel,' which, like a peculiar feather extending from the 'vessel' up the twist and large veins from it under the belly. This test may have been carried to an extreme, and cows with badly formed 'vessels' may have sometimes turned out good milkers; but still it is this strict attention to milking-points (which among Shorthorned men generally stops short at a light neck and a big udder) which makes the Ayrshire cow such a perfect fill-pail for her size."

Here is quite enough evidence to admit the value of our version of the requisites whereby to designate a great milker as distinct from those animals bred for fattening purposes only.

As we wish to obtain the Shorthorn blood in females to mate with the Guernsey bulls, there are very strong reasons which should induce us to regard colour as of importance in taking even one cross between the Shorthorn and Guernsey breeds for the purposes before mentioned chiefly; but we must not forget how desirable it must be to preserve the prevailing colour of the Guernsey breed, which varies from a patched colour, the ground being white, varied in degree by patches of a light reddish brown to a pale lemon. It must in consequence be considered as the necessity of selecting the colour of the Shorthorns from which we obtain our heifers for crossing. In this matter our experience tells us, that notwithstanding the prevailing and fashionable colour is red or patchy deep red-and-white in some of the best herds of the kingdom, yet more value, as far as colour operates with the fancier, is set upon the red roan and the tendency to plain white. As these colours would not mix well with the prevailing Guernsey colours, we must look further and seek for the light or brownish red not unfrequently mixed with light speckled brown, and we well remember this colour prevailed throughout the valuable milking herd of Mr. Whittaker about the years 1827 to 1835. Many men valued these for their milking properties, but were rejected by others when required to form a pedigree herd, because of their light thin shoulders and splendid udders. Any animals which no doubt may be found which have descended from Mr. Whittaker's stock, will answer the best purpose as regards colour. Again, the late Mr. Riehd. Stratton had no doubt one of the finest strains of milking Shorthorns to be found in the kingdom about twenty years ago, although he raised some for milking and some for show, both at the Royal and also at the Smithfield Club meetings of full pedigree stock, both cows and bulls, but their prevailing colour, as we have often seen them at these exhibitions, were generally red-roan, sometimes nearly or quite white; but these, however suitable in some respects, would not nick in colour with the Guernseys.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are still daily employed in preparing for Wheat-sowing, and upon some strong flat-lying land we find it difficult immediately after the heavy rains which occurred before the 20th of October to work the horses as we wished; for our object is to plough and sow all the wettest land with a fallow surface daily, and keep the seeding and finishing work close up to the plough, so that if storms of rain should occur almost every furrow will have been seeded in fair condition. In fact we cannot and shall not easily forget the difficulties we encountered in the Wheat-seed time of last year, and the land which suffered from loss of plant was that which was ploughed one day to be seeded the following one: but that can never be done in any season as a rule, and never should be calculated upon, for when the days shorten the sun has little power to dry the surface if it once becomes sodden with rain. We have now ploughed nearly all the Clover lea ground, and some part has been sown in fair condition. In readiness for ploughing-in men are now mowing the greens off some very fine red round Turnips, also pulling and chopping the bulbs, which, when done, makes the land look as though covered with snow at a distance, the chopped Turnips looking so white. Now these together form a large bulk of vegetable matter, will yield a heavy weight of green manure for ploughing-in, and would prove too much for a corn crop if the land had not been badly treated by the last tenant. But as it is, the bulk of the Wheat we expect will be great, for there is vegetable manure enough to plough in, to throw down any kind of Wheat and injure it by lodging, except the dwarf rough Chaff and short-strawed Essex Wheat.

Hand Labour.—The men, and women too, should now be engaged in the work of pulling and preparing the Mangold crops for pitting and storing. We do not like cutting the greens off too close to the bulb, but we leave enough of the bud on the crown of the bulb to grow out a little in the store heap, for when they can do this most of the bruised roots will be preserved, whereas if the bulbs were crowned down too close they cannot then vegetate in the heap, and they would decay there instead of healing and coming out sound when required for use in the winter or spring. We find the best covering compared with straw is seaweed, or

otherwise the border-grass from round the fields and ditches, also in the plantations on the estate, which should be cut and used unless the game-keepers require it to remain as cover and layer for pheasants and hares.

Live Stock.—All the pregnant ewes should now be subject to constant changes of a moderate quantity of food daily: this will usually insure a strong and healthy fall of lambs from whatever sort of sheep we may be breeding. But on many estates the ewes are only just now being mated with the rams. This applies to most of the long-woolled ewes, as well as Shropshires, and hill stocks of Hampshire and Wiltshire Down breeds; whereas the Down breeds reared in some of the best districts in Dorset and Somerset are many of them forward enough to lamb in December and first half of January. Again, the horned ewes of the Dorset and Somerset breeds, especially the off-going stock, which have now been nearly all sold and have reached their new home, are now lambing fast, many flocks having at this time more than half yeaned, and produced a large number of twin lambs; as these ewes produce the largest per-centage of lambs of any known breed, some of the earliest of them are now strong enough to follow their dams into the Turnip or Cabbage crops for a night fold, but running upon the best Italian Rye Grass grown on the Wheat stubbles, or the Clovers, and Sainfoin, as grown in the Lent corn stubbles. The grass is now becoming short and stale for milch cows, and the worst of it should be left for the store cattle to look over, allowing the dairy cows to have the best grass on the farm, also with Cabbage and cake at the stalls at milking time. Unless severe frosts sets in they may lie out on dry pastures situate above the fog level for some time longer. Still the falling-off of milk should be a guide to some extent, for when that occurs, or if any of them are attacked with quarter-ill, they should immediately be housed or lie in well-littered yards and sheds at night time.

on experiments; and great as the outlay is in purchasing several tons of sulphate ammonia and applying it thus liberally, it is found the most profitable course to adopt in the cultivation of the crop. Its action is quick in producing strong tops, and without these the tubers are small and the crop light. In rich heavy soil they grow strong naturally, but in this light land they do not do so, hence the apparently costly yet really profitable practice that is adopted.

The yield of Potatoes had not been ascertained, but off one portion of land seven tons per acre of York Regents have been marketed. The crop of Magnum Bonum is very much larger—in fact, splendid; and there is without doubt one of the finest breadths in England of Reading Hero, the tubers of some acres being very large, sound, and clean. Both these Potatoes far surpass the Scotch Champion in this soil, and also Schoolmaster, some roots which had special treatment, grown on mounds, each producing 14 lbs. of splendid tubers.

The work of taking up several acres of Potatoes is no light one. Digging them by manual labour is a long and tedious process, and ploughing them up is at the best a rough mode of procedure, as they can only be secured by the pickers combing them out of the soil with their fingers, and this is both rough and tedious. But these old modes are fast becoming obsolete, for the crop was being lifted expeditiously with the implement under notice, which was, moreover, doing its work as well if not better than the most careful and competent men could effect with forks.

It was drawn by two horses. The wheels pass along each side of a row, a "sock," which is something like a turfing iron, being drawn along under the row, loosening and partially raising it, and at the same time, immediately behind this, a rapidly revolving cylinder with eight forks throws out the Potatoes, thoroughly desiccating the soil, clearing out the weeds, and spreading them on the land. The rake-like shield is to prevent the tubers being driven too far, the few that miss it often being cast 6 or 7 yards. Practically they were spread in a wide row convenient for picking, twenty persons following the machine for this purpose, and they were kept well employed. Not a tuber in a thousand or ten thousand was cut, and the "Digger" was saving the owner 14s. per day. There are three tines to the forks in Mr. Fisher's implement, the diggers now made by Messrs. Warburton of Preston containing some slight improvements on that represented in the engraving. Where Potatoes are grown extensively in fields an implement of this kind would appear indispensable.

Fig. 72. —WARBURTON'S POTATO DIGGER.

POTATOES IN LINCOLNSHIRE—WARBURTON'S POTATO DIGGER.

DURING a recent visit to Lincolnshire we observed this implement working so satisfactorily on the farm of Mr. Ismay Fisher of Scawby near Brigg, that we feel justified in directing attention to it for the benefit of those of our readers who grow Potatoes extensively in fields. In some parts of Lincolnshire and Yorkshire the Potato appears to be the staple crop for miles, and hundreds of acres of land are devoted to its culture. Much of this land is very low and has been subjected to the process of warping—that is, the admission of the tidal waters from tributaries of the Humber, the sediment of which on their recedence having rendered what was once a worthless tract one of the most fertile in the kingdom. Mr. Fisher, however, does not grow Potatoes on such soil as this; he is a high-land farmer, and one of the most competent, and has several acres of Potatoes this year on yellowish loam of medium texture which produces excellent crops, the tubers being of the best colour and quality. He has also a wonderful yield on soil that a few years ago was little better than blowing sand.

The best preparation of this light land for Potatoes is to first establish a crop of "seeds"—Clover and such herbage as will grow, and graze it for a season. This turf ploughed in gives "body" to the land, but something else is given by the cultivator for producing such excellent crops, as a casual observer would consider the land incapable of yielding. This "something" is eight or ten loads of farmyard manure, and 4 cwt. of kainit spread in the trenches before planting, supplemented by a top-dressing of 4 cwt. of sulphate of ammonia just before the plants are earthed. This heavy dressing of ammoniacal manures would frighten not a few cultivators, and those who rely on theoretical principles alone for growing Potatoes would consider it excessive. Mr. Fisher, however, is a close observer, studious, and practical, one of the last men to invest money either in manure or anything else without surety that it would return him fair interest. His method of manuring Potatoes is founded

of the Hymenopterous order, the giant sawfly, *Sirex gigas*. With the conspicuous borer or ovipositor at the tail, the female (your specimen being of that sex) cuts deeply into the wood of trees, chiefly Firs, depositing an egg in each incision. The larvæ feed upon the wood, and undergo pupation there, emerging as flies towards the end of summer usually.

OUR LETTER BOX.

Fly Infesting Cattle (A. K. C).—There are two species of fly which occasion much alarm amongst herds of cattle. One of these—*Tabanus bovinus*—simply wounds them with the keen lancets attached to the head; this is commonly called the breeze or gadfly. The other—*Æstrus bvis*—the botfly of popular phrase, forms the bumps or wurbles in the skin by depositing its eggs there, piercing the skin by an instrument attached to the abdomen. The specimen you enclose is neither of these, which are two-winged insects, but a four-winged species

REMARKS.

21st.—Fine bright day; misty evening.
 22nd.—Fair morning; fine bright afternoon.
 23rd.—Showery in early morning; fine bright afternoon.
 24th.—Fine and bright for a short time in early morning; dull drizzly day.
 25th.—Warm, dull, and drizzly all day; windy in the morning.
 26th.—Warm and fairly bright in morning, heavy shower at noon, fair afternoon.
 27th.—Fair morning, fine bright afternoon, foggy evening.
 There was a fair quantity of bright weather during the week, and not an unusual amount of fog. Temperature nearly 2° below that of the preceding week, but still about 2.5° above the average.—G. J. SYMONS.

COMING EVENTS

8	TH	Brixton Show (two days).
9	F	
10	S	
11	SUN	25TH SUNDAY AFTER TRINITY.
12	M	Stoke Newington (two days) and Lambeth (three days) Shows.
13	TU	Royal Horticultural Society, Fruit and Floral Committees at 11 A.M.
14	W	Bath, Royal Aquarium, Bromley, Croydon, Dartford, Tooting, and Walton [Shows]

ORCHIDS IN THE OPEN AIR.

WELL-ESTABLISHED notions die hard however erroneous they may be; and even now it is considered by many persons impracticable to cultivate Orchids successfully except in highly heated and specially erected structures that are more or less costly. This opinion is by no means so deep-rooted as it was—is, indeed, rapidly vanishing, and just in proportion is Orchid culture increasing. Year by year it is proved to demonstration by the best cultivators that there are numbers of Orchids that need no more than what may be termed a comfortable greenhouse temperature—that is to say, no artificial heat whatever from the end of May till October, and during the remainder of the year only sufficient to maintain, say, such plants as Cyclamens in a healthy state, and to keep Zonal Pelargoniums flowering through the winter. Yet Orchids will not grow everywhere. They do not succeed crowded among other plants on dry open stages and exposed to sharp currents of air such as Heaths will endure. Air they must have continually, but it must not be parchingly dry. It must be fresh, yet contain moisture; buoyant, yet not drifting through injudiciously opened ventilators. Mr. Williams spoke forcibly on this subject at Manchester a few years ago, and his words ought not to be forgotten—"The cool system, as it is called, has been a source of great annoyance to many, but if carried out in a proper manner it greatly enhances the value of this beautiful tribe. Many, however, have launched into extremes, and cruelly deceived young beginners especially, by assuring them that such and such species will grow in an ordinary greenhouse. These assertions being acted upon, the plants naturally enough drag out a miserable existence, and ultimately die. Now, an ordinary greenhouse is a house in which Pelargoniums, Ericas, and Fuchsias grow and flower, and I deny the possibility of any epiphytal Orchid continuing long in health under the same treatment and in the same atmosphere as these plants enjoy. That many kinds will succeed in as low a temperature I readily admit, but they require less of the blazing sun. They must also have a much moister air, and the sashes of the house must not stand open, as they do under ordinary circumstances, otherwise the leaves will soon shrivel and coil up, when, as a matter of course, death soon follows: therefore I contend it is wrong to assert that epiphytal Orchids will succeed in an ordinary greenhouse."

What are known as cool Orchids are systematically grown in what are practically cold frames in the summer, such as pits having a northerly rather than a southern aspect, and in which no fire heat is employed. This is the practice in many gardens, but it is a question if more healthy plants have ever been seen than a collection kept in an ordinary Cucumber frame which I have examined in a garden near London. In this case each plant was stood on a pot inverted in a saucer of water, and the frame lights were propped up more or less night and day for at the least three months, but always on the leeward side.

Mr. Smee of The Grange, Carshalton, near Croydon, has

gone a step in advance in Orchid culture, and it may prove an important one. This gentleman is an experimentalist, and his garden is an interesting experimental ground. It is the enclosure so vividly portrayed by his father in the handsome volume "My Garden." Of late Mr. Smee has given much attention to Orchids, having collected considerably more than 500 species and varieties, and a far greater number of plants. A great number of these are small, many recent arrivals not yet established; but there are several fine specimens which merit notice. Mr. B. S. Williams of Holloway is not a tyro in Orchid culture, and his opinion may be cited of a specimen he received from Mr. Smee, with his description of the house in which it was grown. In the beautiful "Orchid Album," March 20th, 1883, appears the following—"Lælia superbiens.—We received from A. H. Smee, Esq., The Grange, Carshalton, a fine spike of flowers of this noble Orchid, forming in itself a most beautiful bouquet. The sepals and petals were of a rosy pink; the lip dark rose colour, with the throat of a primrose-yellow veined with rosy purple, the upper part dark rose. It is altogether a charming winter-blooming species, but it is seldom seen. Mr. Smee is a great lover of Orchids, and is beginning to make a collection in which already some rare species appear. He is trying experiments in their cultivation, and we are inclined to think that many plants will succeed under his treatment. The house is a very peculiar one; we have not seen one like it before. It is a long house, and in it there are different temperatures kept up, so that the different Orchids can be grown in the same house. Many plants were in bloom when we saw the collection in January last. The place is a very interesting one, and in the summer must be very charming on account of the great variety of Ferns and other plants that are grown there, almost all kinds of plants being cultivated. The garden must be a source of great enjoyment to the owners, as both Mr. and Mrs. Smee take much interest in their Orchids and other plants."

The house referred to is a "home-made" span-roofed structure, the sides being of wood, also the roof on the sunny side is boarded, only the more shaded side being glazed. Under the boarded roof Ferns are at home, and on the opposite side Orchids flourish; and in this long house, with its temperature varying in winter from about 40° at one end to 60° at the other, experiments are constantly being made with different plants. But we will pass outside.

In the spring of the present year Mr. Smee, having several inferior varieties of Orchids that he did not wish to dispose of in a manner that has become customary—namely, sending them to the auction-rooms to be sold cheap (?) to some inexperienced purchaser, resolved to try them in the open air. If they had died the loss would have been small compared with the pleasure he would have if any of them really improved, and thus learning of what kinds he could safely entrust better varieties with advantage to similar treatment another season. Altogether 150 plants have been experimented on, and the result is very satisfactory, not one plant having died. In "my garden" are several small streams of water running from the Wandle. These are overshadowed by trees and shrubs, and dells and nooks are formed in which Ferns luxuriate. Here the Orchids were arranged, those in pots being placed on scaffold boards raised about 3 inches above the water; while plants in baskets, pans, or on blocks were suspended from the boughs of trees or on wires stretched from tree to tree, and during the summer the sight, as may be imagined, was quite a tropical one. The *Odontoglossums* have done well. *O. Alexandræ*, *O. gloriosum*, and *O. Rossi*; with its variety *majus*, have made much finer pseudo-bulbs, some producing two flower spikes from each. They are still out, and in a fortnight will be in full flower, weather permitting. *Dendrobium Wardianum* and *D. heterocarpum philippinense* were hung up in the trees on June 15th before one-third the growth was made. They were badly attacked with yellow thrips, which soon disappeared under the outdoor treatment. The plants gained strength, but made rather small growths.

They ripened early, were housed on October 5th, and are now in bloom. The remainder of this section made their growth in the houses and were put out to ripen. *Sophronitis grandiflora* made decidedly better growth outside than any of the plants did that were kept in the houses. *Phalænopses* (two only) were tried, and the ten weeks they were put out remained practically dormant; but Mr. Smee suspects that with the long period of rest they have had the plants will make more vigorous growth afterwards. It will be well, however, to give the exact dates when the different plants were placed outside, and when they were taken in, with the effect in each case as recorded by Mr. G. W. Cummins, the gardener. The plants I have examined, and can testify to the accuracy of the remarks appended.

RECORD OF EXPERIMENTS.

Date of putting out.	Names of Plants.	Date of Housing.	Remarks.
June 15	<i>Cœlogyne cristata</i>	Sept. 13	Made a quantity of small growths.
" "	<i>Cypripedium insigne</i>	Oct. 13	Fine strong growth.
" "	<i>Dendrobium Wardianum</i>	Oct. 5	Made growth and formed flower buds.
" "	<i>D. heterocarpum philippinense</i>	"	Made flower buds on old growths.
" "	<i>Odontoglossum Alexandræ</i> ...	Out still	Rich-coloured leaves, large bulbs, flowering.
" "	" <i>cirrhosum</i> ..	Sept. 20	Moderate growth.
" "	" <i>gloriosum</i> ..	Out still	Better growth than those indoors.
" "	" <i>Lindleyanum</i>	Oct. 13	Quite at home.
" 29	<i>Brassia verrucosa</i>	"	Improved; thicker bulbs.
" "	<i>Cattleya citrina</i>	"	Plenty of root, but little growth.
" "	" <i>Walkeriana</i>	"	Small, very healthy.
" "	<i>Cœlogyne ocellata</i>	Sept. 13	Made growth and flower spikes.
" "	<i>Cymbidium aloifolium</i>	"	Made some leaves.
" "	<i>Epidendrum ciliare</i>	"	Remained dormant.
" "	<i>Lycaste Deppei</i>	Still out	Equal to those in the house.
" "	" <i>Harrisonæ</i>	Sept. 21	Making healthy growth.
" "	" <i>Skinneri</i>	Out still	Imported pieces, established outdoors and flowering.
" "	<i>Masdevallia maculata</i>	Sept. 20	Flowered and made better growth.
" "	" <i>Veitchii</i>	"	Rather weak growth.
" "	<i>Odontoglossum nebulosum</i> ...	Oct. 13	Grand growth and roots.
" "	" <i>Erstedii</i>	"	Similar growth to those indoors.
" "	<i>Maxillaria grandiflora</i>	Oct. 21	Good growth; flowered outdoors.
" "	<i>Oncidium macranthum</i>	Out still	Quite at home.
" "	<i>Zygopetalum Mackayi</i>	Sept. 21	Completed growth.
July 18	<i>Cattleya Acklandiæ</i>	Oct. 13	Improved.
" "	<i>Chysis aurea</i>	Oct. 5	Made healthy growth.
" "	<i>Lælia albida</i>	Sept. 21	Made small bulb and flower spike.
" "	" <i>harpophylla</i>	Oct. 13	Made sheath.
" "	" <i>majalis</i>	Oct. 5	Finer growth than previous.
" 10	" <i>purpurata</i>	Sept. 21	Made roots; commenced growth.
" "	<i>Masdevallia coriacea</i>	Sept. 20	Strong growth.
" "	<i>Mesospidium vulcanicum</i> ..	Sept. 21	Healthy.
" 18	<i>Odontoglossum cordatum</i> ..	"	Better growth.
" 24	" <i>Rossi</i>	Out still	A number of growths.
" 10	" <i>majus</i>	"	Larger bulbs and flowering.
" 18	<i>Oncidium concolor</i>	Sept. 21	Making fine growth.
" 10	<i>Phalænopsis amabilis</i>	Sept. 15	Commenced a new leaf.
" "	" <i>Schilleriana</i> ..	"	At rest; leaves and roots healthy.
" "	<i>Pilumna fragrans</i>	Sept. 21	Good bulbs and leaves.
" "	<i>Pleione lagenaria</i>	"	Formed strong bulbs.
" "	" <i>maculata</i>	"	" "
" "	" <i>præcox</i>	"	" "
" 18	<i>Sobralia macrantha</i>	Oct. 13	Improved.
" "	<i>Sophronitis grandiflora</i>	"	Several growths; quite at home.
" "	<i>Vanda cœrulea</i>	Sept. 21	Healthy and growing.
Aug. 7	<i>Cypripedium barbatum</i>	Oct. 13	Improved in colour.
" "	" <i>venustum</i>	"	Made healthy growth.

All the following *Dendrobiums* were put out on August 10th, and were housed during the last week of September and early in October—namely, *D. Bensoniæ*, *D. chrysanthum*, *D. clavatum*, *D. crassinode*, *D. densiflorum*, *D. Farmeri*, *D. fimbriatum*, *D. Linawinianum*, *D. macrophyllum*, *D. lituiflorum*, *D. calceolus*, *D. moschatum*, *D. nobile*, *D. Parishii*, *D. Paxtoni*, *D. Pierardi*, *D. primulinum*, *D. suavissimum*, *D. Wardianum*, and *D. heterocarpum philippinense*. *Dendrobes* mostly made fair growth, went to rest early, and have every appearance of flowering early and freely. *D. nobile* is very strong and showing flowers; while *D. Wardianum* is in bloom, producing three flowers from a node.

Plants that showed signs of ill health were taken back to the houses as soon as noticed, but they were few, and some not mentioned in the record were too small to determine if

benefited or not. This trial is, we believe, unique of its kind in this country, and it has proved so interesting, satisfactory, and encouraging, that it is not improbable at the least a thousand plants will be subjected to outdoor treatment another year. It may be well here, however, to utter a word of caution. The same varieties of Orchids would not thrive equally well outdoors in all gardens, while in some they would be ruined. In the garden under notice it must be remembered the streams are canopied with foliage. There can be no dry air around the plants, and no driving winds can reach them. Given this shelter, shade, and moisture, there can be little doubt that many Orchids will succeed outdoors during the summer months; but when the air is dry and the wind blows fiercely the plants could not be expected to remain healthy. One thing, however, is clear, that the temperature outdoors in summer is quite sufficient for numbers of Orchids, and hence that of many houses is needlessly and injuriously high.

It may be observed that Mr. Smee's Orchids in the houses are in excellent condition and a credit to the owner and cultivator. With such a number of varieties the houses are never destitute of flowers, and on November 1st the following were in bloom.

IN THE LONG FERN HOUSE.

<i>Burlingtonia granadense</i>	<i>Maxillaria grandiflora</i>
<i>Cattleya Acklandiæ</i>	<i>Odontoglossum grande</i>
<i>Forbesi</i>	<i>Roezli</i>
<i>Eldorado</i>	<i>Rossi majus</i>
<i>Dendrobium Wardianum</i>	<i>Oncidium ornithorhynchum</i>
<i>bigibbum</i>	<i>Forbesi</i>
<i>Cyrtorchilum maculata</i>	<i>varicosum Rogersii</i>
<i>Cypripedium Harrisoni</i>	<i>Harrisonæ</i>
<i>insigne Maulei</i>	<i>Papilio</i>
<i>Spicerianum</i>	<i>Krameri</i>
<i>venustum</i>	<i>Phalænopsis amabilis</i>
<i>Houlletia chrysantha</i>	<i>Sanderiana</i>
<i>Lælia Dayana</i>	<i>Stanhopea insignis</i>
<i>Dormani</i>	<i>Trichocentrum albo-purpureum</i>
<i>marginata</i>	<i>Vanda cœrulea</i>
<i>præstans</i>	<i>Zygopetalum maxillare</i>
<i>Perrini</i>	
<i>Masdevallia tovarensis</i>	

IN THE COOL HOUSE.

<i>Masdevallia ignea</i>	<i>Odontoglossum membranaceum</i>
<i>maculata</i>	<i>Rossi majus</i>
<i>Normani</i>	<i>Lycaste Skinneri</i>
<i>Veitchii</i>	<i>Oncidium aurosum</i>
<i>Maxillaria grandiflora</i>	<i>incurvum</i>
<i>Odontoglossum Alexandræ</i>	<i>varicosum</i>
(good varieties)	<i>Sophronitis grandiflora</i>
<i>Odontoglossum cordatum</i>	<i>Trichosma suavis</i>
<i>maculatum</i>	

Among others showing bloom are *Cattleyas*, *Dendrobes*, *Lælia albida*, *L. anceps*, *L. autumnalis*, *L. purpurata*, and a fine specimen of *Lælia superbiens* with three very strong spikes. In one of the houses some now rare and extremely chaste *Anætochilus* are growing freely. Perhaps Mr. Cummins will oblige with a note detailing his method of culture—J. WRIGHT.

PEACHES AND NECTARINES IN COLD LOCALITIES.
